Next-Generation sequencing has revolutionized our understanding of human genetics and the genetics of human disease. Short read, high-throughput genetic sequencing has become the work horse of sequencing science and has proven to be an invaluable tool in our understanding of genetic variability. However, the detection of large rearrangements, identification variations in highly repetitive regions, phasing genomes to track inheritance blocks, and elucidating exon connectivity in long transcripts all remain exceedingly difficult in short read sequencing routines. Long read sequencing routines, such as those employed by Pacific Biosciences and Oxford Nanopore may prove to be essential to fully characterize structural variations, and to identify precise exon connectivity within the transcriptome. Because these technologies generate long, contiguous reads in excess of 10kb they are able to span very large structural elements and full length isoforms that would otherwise be unresolvable in short read sequencing. Over the last few years, significant advances have been made in the field of long read sequencing bringing their utility to the strength needed to address research into human variation. To highlight the utility of long reads and to investigate the handheld Oxford Nanopore MinIon device, we attempted cDNA sequencing of the human GM12878 cell line. From a single flowcell we were able to generate >40k consensus reads, of which > 10k were able to be annotated. From these 10k annotated transcripts we were able to identify more than 1000 novel transcripts including both novel extensions and splice isoforms. We were also able to show that the Oxford Nanopore reads are able to accurately identify transcription start and stop sites. We are currently undertaking additional experiments involving barcoding and other optimizations to increase the yield of annotated full length transcripts. These results can lead to greater insight into the underlying interaction of RNA and phenotype and the rapidly evolving Oxford Nanopore MinIon (predicted to generate more than 20Gb of data in a single run by 2016) is a potential tool for facilitating research of this nature.

1874T

Fast and computationally efficient joint genome calling using Spiral Encrypted Compression (SpEC). *J. Bruestle, B. Drees, A. Mangubat, S. N. Shekar.* Spiral Genetics, Seattle, WA.

The recent reduction in sequencing costs and increase in sequencing capacity indicates that the future of NGS analysis is moving rapidly toward large population-based studies. There are two important bottlenecks to the effective multi-sample analysis needed for these studies: ability to store the data and sufficient accuracy of variant calls to be able to compare across samples. Here we show that Spiral Encrypted Compression (SpEC) addresses the storage and accuracy issues in population-scale sequencing studies by storing read and alignment data with enhanced compression and allowing for information to be withdrawn at any genomic location on demand rapidly. SpEC is built to be lossless and compresses both the reads, as well as other fields, optimizing the compression of the data that are stored.

We compare the SpEC to CRAM by compressing a standard 50x NA12878 Illumina HiSeq data set (114GB) . SpEC compresses the file to 61GB (46. 5% reduction), compared to 76GB (33% reduction) with CRAM in lossless mode. When decompressing the SpEC file, the original BAM file is recreated bit for bit. When the CRAM is decompressed, all the data are restored. However, the fields are in a different order compared to the original BAM. Further, the compression time on a standard machine was approximately 2 hours for SpEC but 7 hours for CRAM.

SpEC allows for high accuracy variant calls. If a variant is not called in the VCF, but it is important to confirm whether it exists, SpEC can be used to quickly search for unique subsequences associated with the variant. The data can be searched even while compressed. This allows for backfilling of the variant calls in a sample with a greater level of certainty. This approach can also be used to quickly identify structural variants. We expect SpEC to be useful for joint variant calling offor SNPs, indels and structural variants in population-scale studies.

Overall, SpEC allows for a reduction in hardware costs, and the ability to accurately identify whether particular variants exist in the data. Both of these benefits are expected to be of considerable benefit to rigorous population based studies.

NGS Library Prep Methods to Achieve Comprehensive Coverage for WGS and WGBS from Low DNA Input. *L. Kurihara, J. Laliberte, C. Couture, C. Schumacher, S. Sandhu, R. Spurbeck, J. Irish, S. Chupreta, V. Makarov.* Swift Biosciences, Inc. , Ann Arbor, MI.

When performing whole genome sequencing (WGS) or whole genome bisulfite sequencing (WGBS), unbiased, even coverage of the genome is required in order to conduct comprehensive analysis from the lowest possible sequence read depth. Highly efficient conversion of DNA fragments into library molecules is also necessary when DNA input quantity or quality is limited. We have developed two library preparation methods to achieve these results for WGS, WGBS, or when targeted hybridization capture is performed. The WGS method uniquely repairs damage on both the 3' and 5' termini to enhance ligation efficiency to sheared DNA fragments. Combined with sequential ligation steps that optimize attachment to each terminus, this single tube 'with bead' method supports PCR-free sequencing from inputs as low as 10 ng circulating, cell-free DNA or 100 ng physically sheared DNA. Input quantities down to 10 pg can be used with PCR amplification. Efficiency of library conversion is ~50% for physically sheared DNA and up to 90% for circulating, cell-free DNA. Adapter titration is not required with reduced input quantities, which ensures efficient adapter ligation at all supported inputs and simplifies the workflow. Human WGS using this method demonstrates high complexity with exceptional coverage of GC-rich promoter regions compared to other methods. At inputs as low as 1 ng human DNA, PCR duplicates were present, however at 18X coverage, the genome was fully represented without loss of data or reduction in relative coverage of GC-rich promoter regions. For WGBS, our library preparation is performed post-conversion on denatured, bisulfite-converted fragments. This improves library recovery up to 100X compared to traditional library prep methods that ligate methylated adapters to double-stranded DNA prior to bisulfite conversion. Our efficient adapter attachment to single-stranded DNA supports inputs from 100 pg to 100 ng. Libraries made using this method require less PCR amplification than other methods, thus reducing the number of PCR duplicates. Human WGBS demonstrated comprehensive coverage of CpG islands when 10 ng input was used. Even at lower depth of sequencing to an average 11. 4X coverage from the 10 ng input library, 99. 7% of CpG islands were covered and showed an average depth of coverage of 7. 8X. This library preparation method enables single base resolution of methylation status throughout the genome, even from limiting DNA input quantities.

Performance comparison of four commercial human whole-exome capture platforms. *D. Shigemizu, Y. Momozawa, T. Abe, T. Morizono, KA. Boroevich, S. Takata, K. Ashikawa, M. Kubo, T. Tsunoda.* RIKEN Center for Integrative Medical Sciences, Yokohama, Japan.

Whole exome sequencing (WXS) is widely used to identify causative genetic mutations of diseases. However, not only have several commercial human exome capture platforms been developed, but substantial updates have been released in the past few years. We report a performance comparison for the latest release of four commercial platforms, Roche/NimbleGen's SeqCap EZ Human Exome Library v3. 0, Illumina's Nextera Rapid Capture Exome (v1. 2), Agilent's SureSelect XT Human All Exon v5 and Agilent's SureSelect QXT, using the same DNA samples. Agilent XT showed the highest target enrichment efficiency and the best SNV and short indel detection sensitivity in coding regions with the least amount of sequencing. Agilent QXT had slightly inferior target enrichment than Agilent XT. Illumina, with additional sequencing, detected SNVs and short indels at the same quality as Agilent XT, and showed the best performance in coverage of medically interesting mutations. NimbleGen detected more SNVs and indels in untranslated regions than the others. We also found that the platforms, which enzymatically fragment the genomic DNA (gDNA), detected more homozygous SNVs than those using sonicated gDNA. We believe that our analysis will help investigators when selecting a suitable exome capture platform for their particular research.

Evaluation of HiSeq X Ten Performance: Towards Clinical Applications. *K. Walker[1], C. Buhay[1], R. Sanghvi[1], Q. Wang[1], H. Doddapaneni[1], J. Hu[1], M. Wang[1], Y. Han[1], H. Dinh[1], E. Boerwinkle[1,2], R. A. Gibbs[1], D. M. Muzny[1].* 1) Baylor College of Medicine HGSC, Houston, TX; 2) University of Texas Health Science Center at Houston, Houston, TX.

High-throughput parallel nucleotide sequencing has revolutionized genomic research and reshaped applications in clinical health care. The HiSeq X Ten platform further expands these opportunities with unprecedented capacity. The Human Genome Sequencing Center (HGSC) at Baylor College of Medicine adopted the HiSeq X Ten system in the fall of 2014, with a view to eventual deployment in a CAP/CLIA environment. To evaluate the instruments we have analyzed more than 145 flowcells, representing 1,040 30X human genomes. These studies have included common disease cohorts, inherited cancers, mendelian disease cases as well as DNA from cell lines of lung and endometrial cancer. We assessed several metrics of performance, including genome coverage, coding region coverage and error rate relative to standards. We also measured the number of read cluster duplicates and examined variants (in duplicate samples) in order to assess the sensitivity and specificity of the platform. These evaluation efforts have provided valuable insight as to how sequencing depth and coverage uniformity impact the ability to accurately detect variants. Overall the platform has been consistent with its lane-to-lane performance. We have, however, observed unique modes of error due to the use of patterned flowcells including an increase in clustered optical duplicates, correlating with library loading concentration. We also have observed a periodic decrease in Q30 values in the last 50bp of the Read 2 sequence. Each of these issues are being addressed with local and vendor-driven solutions, and progressive improvements show that it is well on the way to being as robust as other Illumina platforms. Finally, we have recently evaluated DNA libraries prepared with Swift Biosciences Accel-NGS 2S DNA Library kits. These have exhibited excellent genome coverage in GC-rich regions for both PCR and PCR-free preparations even with FFPE sample inputs as low as 10 ng. These and other innovations illustrate that there remain many avenues for process improvement.

1878F

Accurate quantification and qualification of FFPE samples increases success rate of NGS library prep and sequencing. *B. Arezi, B. Rogers, K. Chen, B. Hsue, H. Hogrefe.* Agilent Technologies, La Jolla, CA.

FFPE tissue archiving is the most widely used method for clinical sample preservation, and provides a valuable source of diverse genetic information for cancer biomarker discovery. DNA recovered from FFPE tissues exhibits varying degrees of fragmentation, cross-linking, deamination, depurination and other lesions due to formalin fixation, paraffinization, and storage conditions; and as a result, NGS library preparation is often challenging. To increase success with FFPE-derived DNA, we developed a qPCR-based method to determine quantity of amplifiable DNA and extent of degradation. SureSelectXT libraries were prepared from multiple FFPE samples of varying integrity, and enriched using the ClearSeq Comprehensive Cancer Panel which targets 151 genes frequently mutated in solid and hematological cancers. As we will show, qPCR integrity scores are highly correlated with pre-capture PCR yield and sequencing metrics (library complexity and coverage), and can be used as a guide to determine appropriate sequencing depth for optimal coverage.

1879W

Repair of FFPE Extracted DNA Increases Next Generation Sequencing Library Yields and Quality. *F. Stewart[1], L. Chen[1], P. Liu[1], L. Ettwiller[1], R. Corbett[2], H. McDonald[2], P. Pandoh[2], C. Sumner[1], E. Dimalanta[1], T. Davis[1], Y. Zhao[2], M. Marra[2], T. Evans[1].* 1) New England Biolabs, Inc. , Ipswich, MA; 2) Genome Sciences Centre, BC Cancer Agency, Vancouver, Canada.

Clinical materials are commonly archived as Formalin-Fixed, Paraffin-Embedded (FFPE) samples. While these samples are an invaluable source of information about genetic alterations in human disease, especially cancer, unfortunately the methods used for fixation and storage significantly damage the nucleic acids contained within. As a result, it can be challenging to obtain useful information, including high-quality sequence data, especially when sample amounts are limited, as is frequently the case. In this work, we investigated the effects of DNA repair on library preparation and sequencing of FFPE samples. We evaluated a mix of repair enzymes that is designed to work on a broad range of DNA damage including modified bases, nicks, gaps, and blocked 3' ends. Results from FFPE DNA samples of varying quality show that DNA repair generally increases library yields, and improvements from 10% to 458% have been observed. Sequencing data analysis demonstrates that base calling qualities for all 4 bases are improved after DNA repair. Additionally, the G:C to A:T mutations that result from deamination of cytosine to uracil (a signature of FFPE DNA damage) are repaired by treatment with the DNA enzyme repair mix. Interestingly, sequencing miscalls for base pair changes not typically associated with fixation were also reduced. Importantly after DNA repair, a positive impact on read mapping and read pairing was observed, resulting in the generation of more useable data. Treatment of FFPE DNA by the repair enzyme mix is easily implemented upstream of library construction, enabling fast protocol times and easy automation. We anticipate that these improvements to the FFPE DNA sequencing workflow will enable the analysis of many FFPE samples that otherwisewould not be accessible.

1880T

iDASH: a secure cloud environment for biomedical data analysis, storage and sharing. *O. Harismendy[1,3], J. Kim[3], C. Farcas[3], A. Koures[2,3], L. Ohno-Machado[3].* 1) UC San Diego Moores Cancer Ctr, La Jolla, CA; 2) UC San Diego Clinical And Translational Research Institute, La Jolla CA; 3) Department of Biomedical Informatics, UC San Diego, La Jolla, CA.

Current analysis of biomedical data for research is confronted with a number of challenges: 1) a growing volume of data, 2) an increasing complexity and diversity of data and workflows, 3) a highly collaborative research environment and 4) growing concerns for data safety and privacy. Cloud computing and cloud storage have become major information technology solutions. While they are also becoming popular for the analysis of biomedical data, it is not always clear if and how they address these specific challenges. In particular the genome sequence of the participants in translational research studies is considered Protected Health Information and its storage and analysis must be performed in compliance with HIPAA regulation. Here, we present the iDASH private cloud, a HIPAA computing environment. Access to the resource uses RSA-based two-factor authentication behind redundant firewalls. Located in a Virtual Private Network within UC San Diego Supercomputer Center, iDASH benefits from point to point connection to major US academic centers, a security advantage over standard internet connections. The resource uses VMware virtualization technology to manage and instantiate virtual machines with up to 32 vCores, 256Gb of RAM and 1Tb disk under a 10G network, accessing both high capacity and high-speed storage. We have customized this environment for the analysis of human genetic data. Specifically, we provide a local copy of public resources such as 1000 Genomes, dbSNP or the human reference genome. We also have prepared and tested virtual machine images dedicated to genomic analysis that include popular analysis tools (BWA, BOWTIE, samtools, vcftools) and frameworks (bcbio-nextgen). Finally, we built FlightDeck, a web-based portal to prepare analysis manifests based on popular workflows and recipes, such as variant calling, and start the analysis with a seamless integration to the cloud in the background. We will present the results of testing standard workflows including sequencing read alignment and variants calling. The iDASH environment is a highly secure, academic computing resource geared towards the analysis of large biomedical data. IDASH is a member of the NIH/NHLBI National Centers for Biomedical Computing (U54HL108460).

1881F

Mutations on a DNase I Hypersensitive Sites in Human lead to Tumorgenesis. *W. Jin, K. Zhao.* Systems Biology Center, NHLBI,NIH, Bethesda, MD.

Cellar differentiation is dependent on gene transcription that is controlled by a large number of proximal and distal regulatory elements in the genome. These elements are focal points of various histone modifications and are located in accessible chromatin regions as indicated by the hypersensitivity to DNase I digestion. Recently, the combination of DNase I digestion with next generation sequencing (DNase-Seq) is becoming a very popular approach for accurate identification of DNase I hypersensitive sites (DHS) across the entire genome, which has significantly advanced our understanding of the dynamics of chromatin accessibilities and gene regulations during biological processes such as cell differentiation, proliferation, and response to the environment stimuli. However, these conventional DNase-Seq methods for genome-wide DHS profiling require millions of cells, which limits their utility. Here we report, an ultrasensitive and robust strategy, called Pico-Seq, for detection of genome-wide DHSs using only a small number of cells. Our analysis showed that Pico-Seq libraries made by 1 thousand cells could perform the same as that of conventional DNase-seq libraries using millions of cells. We apply Pico-Seq to the very small number of tumor and adjacent normal cells, dissected from formalin fixed paraffin embedded tissue slides from thyroid cancer patients, and detect thousands of tumor-specific DHSs, some of which seemed to have clinical relevance not previously appreciated. Analysis of the DHS sequences uncovers tens of mutations in tumor cells, one of them seems to be a drive mutation in the tumorgensis. The mutation disturbs a p53 binding motif and lead to significantly changes in the expression of genes critically involved in cancer development. In conclusion, Pico-seq can reliably detect DHSs in libraries using a few cells, which greatly extends the range of applications of DHS analysis for both basic and translational research and may provide critical information for personalized medicine.

1882W

Development of a Low Input FFPE workflow for Whole Exome Sequencing. *B. Marosy, B. Craig, K. Hetrick, P. D. Whitmer, H. Ling, S. Griffith, B. Myers, K. F. Doheny.* Center for Inherited Disease Research (CIDR), Johns Hopkins University, Baltimore, MD.

The Center for Inherited Disease Research (CIDR) provides high quality next-generation sequencing (NGS), genotyping and statistical genetics consultation to investigators working to discover genes that contribute to disease. CIDR is continually seeking new ways to improve its workflow and generate high quality data. Historically, sample requirements for a variety of targeted selection and NGS platforms have been a limiting factor for investigators. Regardless of input, not all samples are of high quality. Formalin Fixed Paraffin Embedded (FFPE) samples are a useful source of DNA for NGS studies but present additional challenges in the lab due to age of the sample, damage to the DNA from fixation resulting in changes to the nucleotide sequence and fragmentation of the DNA. Here we investigate different library prep kits (KAPA Hyper Prep (KHP) and Swift Accel-NGSTM 2S) designed for low input (50ng); DNA repair methods (USER, NEB PreCR, NEBNext FFPE DNA Repair); optimization for small fragment size (KHP and Swift Accel-NGSTM 1S); and quantitation methods (KAPA hgDNA Quantitation and QC kit) to develop a best practices workflow to generate libraries for whole exome sequencing from low input and FFPE derived samples. Both HapMap samples and FFPE samples of varying age and quality were used to generate libraries using these methods. Libraries were then enriched for whole exome sequencing using Agilent SureSelectTM XT and were sequenced on the Illumina HiSeq 2500 platform. Evaluation and optimization of a variety of conditions and commercial kits has enabled us to establish a workflow for low input and compromised samples for library prep using 50ng of DNA to generate high quality exome enriched sequencing data.

1883T

Massively parallel identification and annotation of causal 3'UTR regulatory variants. *A. Biton, O. Le Tonquèze, D. Torgerson, W. Zhao, N. Zaitlen, D. Erle, The CAAPA Consortium.* Department of Medicine, Lung Biology Center, University of California, San Francisco, San Francisco, California, USA.

Most genetic variants associated with diseases are found in non-coding regions, but our understanding of how these variants affect gene function remains very limited, as does our ability to determine which of the multiple linked associated variants in a region is causal. To address these issues, we recently developed a powerful massively parallel experimental method for functional analysis of sequences from 3'UTRs (fast-UTR, Zhao *et al. , Nat Biotechnol* 32:387, 2014). The 3' untranslated region (3'UTR) of genes contains binding sites for regulatory proteins and non-coding RNAs that regulate mRNA expression, stability, and translation. In our previous work, we demonstrated that fast-UTR accurately models difference in mRNA stability within a set of ~2000 selected 3'UTR sequences, identified binding motifs of known and novel 3' UTR cis-regulatory elements, and tested a small set of SNPs to demonstrate that fast-UTR could be used to detect effects of genetic variants. In this work, we are leveraging fast-UTR to survey the complete 3'UTR space of the human genome. We constructed a fast-UTR oligonucleotide library containing >200,000 3' UTR haplotypes encoded in 160-nt segments. These haplotypes include selected rare and common 3' UTR variants derived from whole genome sequences from the 1000 Genomes Project (>90,000 variants) and the Consortium on Asthma among African-ancestry Populations in the Americas (CAAPA) study (>12,000 variants). Rare variants were chosen based on their overlap with 1) regulatory motifs including AU-rich elements (ARE), constitutive decay elements (CDE), Pumilio, and miRNA binding sites, and 2) 3'UTRs of 400 asthma candidate genes identified from the Genetic Association Database (GAD) and the NHGRI GWAS catalog. We will report the activity of these sequences in three different cell types that are important for asthma pathogenesis: airway epithelial cells, CD4+ T cells, and airway smooth muscle cells. These data will provide an unprecedented framework to functionally annotate 3'UTR sequences as well as identify and predict functional consequences of individual genetic variants. These data will also help assess and interpret how SNPs discovered by eQTL and GWAS studies lead to variation in mRNA expression and thereby help understand the contributions of genetic variation to asthma and other diseases.

1884F

Towards a Standardized and Automated Workflow for Extracellular Vesicle Isolation and Characterization. *C. T. Schwartz, Z. Smith, B. Lee.* Beckman Coulter, Indianapolis, IN.

Introduction:Research involving extracellular vesicles (EVs) is rapidly expanding due to evidence suggesting a role in cancer metastasis and cell-to-cell communication. Improved and more efficient isolation and characterization processes for EVs are critical to advancing this exciting field and experts have recently called for the establishment of standardized methods. EV isolation is particularly difficult, requiring a labor-intensive density gradient centrifugation step to obtain highly pure vesicles. Downstream challenges involve a standardized sizing method and genetic profiling of encapsulated miRNA. Here, we describe a complete workflow from EV isolation to small RNA next-generation sequencing using Beckman's Vi-CELL Cell Viability Analyzer, DelsaMax Core, Biomek Automated Workstations, High-Performance and Ultracentrifuges, and SPRI-based reagents that improves the process and minimizes challenges. **Methods**:The Vi-CELL measured HCT 116 cell concentration and viability. Crude exosomes from the cell culture media were isolated by differential centrifugation. Gradient layering and fractionation for a discontinuous density gradient was achieved through a Biomek automated process, and following a centrifugation step, aliquoted fractions. Phenotypically-enriched populations of highly pure vesicles, assayed by Beckman's DelsaMax CORE, were separated, and total RNA was extracted utilizing Beckman's RNAdvance Cell v2 reagent kit with Biomek automation. Total RNA was analyzed using an Agilent BioAnalyzer 2100 for size and purity and subjected to a TaqMan® MicroRNA assay for quantification of relevant EV biomarkers. Finally, small RNA sequencing libraries were generated using the New England Biolabs NEBNext® Small RNA library kit, also automated on the Biomek platform. The libraries were subsequently sequenced on the Illumina MiSeq® platform and variant expression quantified for various EV fractions. **Summary**:The automated workflow provides a robust, high-throughput solution that can be translated to both basic and clinical research. The usual benefits of automation such as reduced processing time and user-to-user variability were achieved in the density gradient layering and fractionation, RNA extraction, and small RNA library prep processes. Lastly, next generation sequencing identified differentially-expressed genes among EV fractions with potentially clinical implications.

1885W

A Multi-Ethnic Genotyping Array for the Next Generation of Association Studies. *C. R. Gignoux[1], G. L. Wojcik[1], H. R. Johnston[2], C. Fuchsberger[3], S. Shringarpure[1], A. R. Martin[1], S. Rosse[4], N. Zubair[4], D. Taliun[3], R. Welch[3], C. Pethigoya[5], J. O'Connell[5], L. McAuliffe[5], C. Rosenow[5], N. S. Abdul-husn[6], G. Belbin[6], H. M. Kang[3], G. Abecasis[3], M. Boehnke[3], Z. S. Qin[2], J. M. Romm[7], C. A. Haiman[8], C. Kooperberg[4], R. J. Loos[6], T. C. Matise[9], K. E. North[10], C. Carlson[4], K. C. Barnes[11], C. D. Bustamante[1], E. E. Kenny[6], Population Architecture using Genomics and Epidemiology (PAGE) Study.* 1) Department of Genetics, Stanford University School of Medicine, Stanford, CA; 2) Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Atlanta, GA; 3) Department of Biostatistics, School of Public Health, University of Michigan, Ann Arbor, MI; 4) Fred Hutchinson Cancer Research Center, Seattle, WA; 5) Illumina Inc. , San Diego, CA; 6) Department of Genetic and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 7) Center for Inherited Disease Research, Johns Hopkins University, Baltimore, MD; 8) Department of Preventive Medicine, Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles, CA; 9) Department of Genetics, Rutgers University, Piscataway, NJ; 10) Department of Epidemiology, School of Public Health, University of North Carolina at Chapel Hill, Chapel Hill, NC; 11) Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD. In the past decade, genome-wide association studies (GWAS) have been extraordinarily successful in uncovering genetic factors underlying complex traits. However much of this work has only been performed in populations of European descent. To address this disparity, a collaboration between Illumina, PAGE, CAAPA (Consortium on Asthma among African-ancestry Populations in the Americas), and T2D Genes Consortium developed the 1. 9M SNP Multi-Ethnic Genotyping Array (MEGA). This array is designed to be a single platform to interrogate diverse variation from across the frequency spectrum and screen for prior genetic discoveries. The GWAS backbone is informed by whole genome sequences from the 1000 Genomes Project (TGP) and CAAPA, with additional compatibility from the Illumina HumanCore array. We developed a novel cross-population tag SNP strategy to maximize imputation accuracy for low frequency variants across six continental populations, with improved performance from previous generations of arrays. Importantly the performance of the array is high across all continental TGP superpopulations (>90% accuracy for MAF >=1%). We chose rare, functional candidates from >36,000 multi-ethnic exomes, prioritizing loss-of-function and predicted damaging sites. We also curated variants with domain experts, including boosting coverage in regions of interest (e. g. MHC), over 5,000 ancestry informative markers, uniparental markers, and over 25,000 variants of clinical, prior GWAS, pharmacogenetic, and eQTL importance. A reference panel of several thousand individuals, including HGDP and a large panel of Native Americans, is available on MEGA to aid in rare variant calling, ancestry characterization, and admixture analyses. We will present data on MEGA genotyping of >60,000 African-American, Hispanic/Latino, East Asian and Native Hawaiian individuals from PAGE and CAAPA. We will describe imputation performance in these populations and others, including the improvements to imputation accuracy derived from larger whole genome reference panels. Further details, summary statistics and other relevant information generated from the platform will be placed in a centralized community repository at *www. pagestudy. org/mega*. We intend MEGA to be a platform and an analytical resource for researchers interested in large-scale studies of diverse populations from across the globe.

1886T

Simplified adapter design for sequencing the Genome-scale CRISPR-Cas9 Knockout (GeCKO) libraries on the Illumina platform. *W. Wang[1], Q. Ding[2], L. Parsons[1], J. Wiggins[1], L. Guo[1], J. Miller[1], A. Ploss[2].* 1) Institute for Integrative Genomics, Princeton University, Princeton, NJ; 2) Dept of Molecular Biology, Princeton University, Princeton, NJ.

High throughput loss-of-function screening is a powerful strategy to functionally characterize large numbers of genes. The genome-scale CRISPR (clustered regularly interspaced short palindrome repeats)–associated nuclease Cas9 Knockout (GeCKO) system can effectively generate loss-of-function mutations in most human or mouse genes simultaneously for positive or negative screening (Sanjana, N. E. et al. Nature Methods 11, 783–784, 2014). However, the indexed staggered PCR primers for the final amplification are quite long, in the range of 91nt to 100nt. Recent improvements to the Illumina sequencing platform, both chemistry and software, lead to much better read data quality for low diversity samples. Therefore, we tried to shorten the Illumina adapter regions of GeCKO guide RNA libraries to increase the efficiency and specificity of the final PCR. In the forward PCR primer containing the Illumina P5 sequence, the stagger sequences of 1nt to 10nt were removed and the barcodes were shortened from 8nt to 6nt. For low levels of sample multiplexing, the reverse PCR primer was reduced to contain only the Illumina P7 sequence followed by the 24nt PCR priming site, while the reverse sequencing primer, indexes, and the stagger sequences were all eliminated. Using the simplified PCR primer design with up-front barcodes in Read-1, the original and E coli amplified GeCKOv2 human sgRNA libraries were successfully amplified by PCR and sequenced on Illumina HiSeq 2500. The read quality Q30 scores were over 95%, and the abundance of all sgRNA constructs was characterized. Further improvement is underway to develop custom sequencing primers to allow dual index reads and increase nucleotide diversity in the sequencing reaction.

1887F

Enabling population-scale PCR-free whole genome sequencing. *J. Abreu, R. Hegarty, M. Coole, D. Dionne, L. Holmes, M. Lee, S. McDonough, A. Tam, T. Desmet, B. Haas, Y. Farjoun, D. Perrin, N. Lennon, S. Fisher, S. Gabriel.* Genomics Platform, Broad Institute of MIT and Harvard, Cambridge, MA.

PCR-free human whole genome libraries sequenced on the Illumina HiSeq X are the current NGS gold standard for population-scale genomics, mendelian disease gene discovery, and understanding the genetic components of common diseases. However, input amount requirements and library production at scale represent challenges to implementation for this method. Here we present a scalable whole genome sequencing process which we have implemented to enable production of >100 whole genomes per day. By streamlining this workflow and optimizing library construction steps such as shearing and reaction cleanups, we have been able to reduce the amount of input gDNA while minimizing variability in insert size. Using this process, PCR-free libraries can be created using as little as 250ng of gDNA. Moreover, by applying only a few cycles of PCR to this process, PCR-plus libraries may also be created with only 25ng of gDNA. Completed libraries are combined to create pools of 24 samples or greater prior to sequencing. These pools are then assessed for evenness of sample representation using the Illumina MiSeq. Sample pools are spread across the number of lanes required to meet target coverage on the HiSeq X. This workflow, combined with enhancements made to our automated HiSeq X setup process, has minimized library seeding density variability on the Illumina HiSeq X flowcell while maximizing PF yield.

1888W

Sequencing the needle in the haystack: targeted capture for forensic DNA sequencing. *M. Carpenter[1], K. Elmer[1], J. Degenhardt[1], C. D. Bustamante[1,2], T. Dickinson[1].* 1) IdentifyGenomics, LLC, Menlo Park, CA; 2) Department of Genetics, Stanford University, Stanford, CA.

Many forensic DNA samples are heavily degraded and contaminated, making traditional PCR- and STR-based approaches unfeasible. Furthermore, conventional STR profiling can only be used for identification and does not provide phenotype information. More recently developed multiplex PCR-based resequencing approaches do provide targeted SNP coverage, but are limited by the number of targets that can be sequenced simultaneously and perform poorly on highly degraded DNA. We have developed a method for the targeted hybridization-based capture of DNA fragments containing SNPs relevant to numerous aspects of ancestry and phenotype. Our method, which we term PhenoCap, allows the prediction of phenotypic traits ranging from autosomal ancestry to facial morphology in a single workflow. PhenoCap targets over 3500 SNPs, as well as the full mitochondrial DNA sequence, Y chromosomal SNPs, and STR loci. In addition, we have extensively optimized our DNA extraction and PhenoCap protocols to enable analysis of even the most degraded, contaminated samples, including mixtures derived from multiple individuals. We aim to make PhenoCap analogous to a "forensic exome" that will provide a comprehensive individual profile for even the most challenging samples.

1889T

Producing 768 whole exomes per day with a highly optimized transposase-based library preparation protocol. *A. Cheney[1], C. Walsh[1], M. Costello[1], A. Kia[2], M. He[2], J. Walsh[1], J. Thompson[1], T. Desmet[1], C. Friedrich[1], N. Lennon[1], D. Perrin[1], J. Abreu[1], S. Dodge[1], S. Gabriel[1].* 1) Technology Development, Genomics Platform, Broad Institute, Cambridge, MA. , USA; 2) Illumina Inc, 5200 Illumina Way San Diego, CA 92122.

With over 50,000 samples to prepare for whole exome sequencing in 2015, the Genomics Platform at the Broad Institute needed a more efficient sample preparation process than current off-the-shelf products, featuring shearing followed by multiple enzymatic steps, enabled. In response, we have scaled up our process and achieved faster turnaround times by implementing a modified workflow using transposase-mediated library construction. Through a series of chemistry optimizations in collaboration with Illumina, and process optimizations within the Genomics Platform, we have incorporated an enhanced version of Illumina's Nextera Rapid Capture Exome into our fully automated workflow for efficient sample preparation that produces diverse libraries, enabling superior germline exome coverage equivalent to traditional sheared library construction. Chemistry optimizations include development and selection of a novel tagmentation transposase mutant with improved performance and implementation of a modified buffer that reduces oxidative DNA damage during capture, both of which will be included in Illumina's upcoming TruSeq Rapid Exome Library Prep Kit. Process optimizations include full, streamlined automation, design of custom indexed library adapters that enable higher plexing and better contamination detection, and 96-library pooling prior to hybridization. .

Evaluation of DNA sample fragmentation methods for input into library construction protocols. *B. D. Craig, B. A. Marosy, K. F. Doheny.* CIDR, Johns Hopkins University, Baltimore, MD.

The Center for Inherited Disease Research (CIDR) provides high quality next-generation sequencing (NGS), genotyping and statistical genetics consultation to investigators working to discover genes that contribute to disease. CIDR currently uses a mechanical method to fragment DNA with the Covaris E210 for input into library construction workflows. Samples undergo independent customizable fragmentation events in specialized sample tubes. When processing large sample numbers, serial fragmentation adds considerable time to the overall workflow (up to 10 hours for a 96 sample plate). To reduce workflow time and cost in the lab for library construction, we evaluated the KAPA enzymatic fragmentation kit that is controlled by varying time and temperatures within the reaction. This product does not require specialized equipment or consumables and all samples in a plate will be processed simultaneously with the same reaction conditions. We evaluated reproducibility of the fragmentation events, the impact of DNA amount on the profile and compared these profiles to current Covaris programs. Additionally, CIDR receives samples in a variety of EDTA concentrations which is an inhibitor of the KAPA reaction. In order to incorporate this product as a drop-in replacement to current CIDR best practice workflows, a bead cleanup must be performed to remove all EDTA. This extra cleanup resulted in an average of 45% sample loss prior to fragmentation. Depending DNA sample number and input amount required, the additional cleanup step could require more starting DNA and offset time saved over the Covaris protocol. Samples were run on the Agilent Bioanalyzer to evaluate the size profile and optimize the reaction time to fit the current Covaris protocols. Size distributions were not affected by DNA input amounts for experiments with the same reaction time and were somewhat consistent for the replicated time and input experiments. Our results show fragmentation profiles larger than the expected mode outlined in the default protocol suggesting more optimization to the reaction time will be required to better match the profiles of our current Covaris protocols and integrate with existing methods. Future experiments involve additional evaluation of the reproducibility of fragment size profiles generated under the same reaction conditions and the evaluation of sequencing data (insert size, library complexity, and target coverage) from libraries created with the KAPA fragmented samples.

Sequencing-based, Megabase-scale haplotypes resolve the complex genomic structure of germline and primary cancer genomes. *H. P. Ji[1], B. T. Lau[2], J. M. Bell[2], S. Greer[1], S. M. Grimes[2], E. Hopmans[2], C. Wood[2], R. W. Davis[2].* 1) Division of Oncology / Department of Medicine, Stanford University School of Medicine, Stanford, CA; 2) Stanford Genome Technology Center, Stanford University School of Medicine, Palo Alto CA.

Cancer genomes contain multiple types of genetic aberrations such as point mutations, genomic deletions, copy number variants and chromosomal rearrangements. Despite advances in next generation sequencing for cancer genome analysis, it remains a significant challenge to delineate the structure of cancer genomes given the intrinsic complexity and multiplicity of somatic genomic alterations. Contiguous phasing and haplotypes involves the assignment of genetic variations such as mutations and structural variants to specific haplotype blocks and homologous chromosomes. Thus, one can resolve complex structural variants such as somatic rearrangements, identify phased mutations and quantify aneuploidy composition. However, it has been impractical to generate contiguous phasing on a Megabase (Mb) scale with current whole genome sequencing approaches. For this study, we provide our results from a first time demonstration of Mb-scale whole genome analysis applied to primary colorectal cancer genomes directly from clinical samples. This approach is rapid, efficient and potentially scalable to large population studies. We used a novel and highly efficient DNA sequencing technology that enables phasing of whole human genomes. This high-throughput microfluidic platform prepares libraries with droplet-partitioned barcodes using as little as one nanogram. A diverse collection of barcodes is individually distributed over 100,000 different partitions. Individual DNA molecules, 10s of kb in size, are identified by barcode sequence reads specific to a given partition. Based on single nucleotide variants (SNVs) in combination with barcode sequence reads, we generate Megabase-scale haplotype blocks. Subsequently, we used a novel computational approach relying on unique barcoded sequences and haplotype assignment to resolve phased structural variants and other genetic aberrations covering Mb segments. We determined Mb-scale haplotype blocks from a series of primary colorectal cancer samples in comparison to matched normal diploid DNA. Using SNVs, we generated Mb-scale haplotype blocks, determined segmental haplotype blocks that cover allelic imbalances, identified copy number variations such as deletions and resolved the structure of complex cancer rearrangements. Overall, we successfully demonstrated the feasibility, highly scalable efficiency and potential advantages of using contiguous phased haplotypes in resolving cancer genome structure and other characteristics.

1892T

A Novel Topo-Based Ligation Technology for NGS Library Preparation. *J. Zheng, Y. Li, K. Sean, G. Roma, H. Pan, C. Shi.* Molecular Cloning Laboratories, South San Francisco, CA.

Next-Generation Sequencing (NGS), a revolution in genomic science requires three major workflow steps: 1) library preparation, 2) DNA sequencing and 3) bioinformatics data analysis. It is evident that a critical step for successful sequencing is to obtain high quality DNA libraries. To meet clinical researcher's demanding needs, an ideal library preparation method should have a streamline workflow with low hands-on time, require low DNA input and result in highly complex libraries with high yields in the least amount of time. Ligation of sequencing adaptors to both ends of end-repaired fragmented DNA is akey NGS library preparation. Most commercially available Illumina library preparation kits require dA-tailing of the DNA fragments followed by adaptor ligation to achieve sequencing ready libraries. Methods relying on the use of both dA-tailing and T4 DNA ligation may result in reduced library complexity and reduced library yields. Here we introduce a novel topoisomerase-based ligation workflow for DNA library preparation, which eliminates the need for dA-tailing for enhanced ease-of-use. This workflow also reduces DNA input requirements by selectively and efficiently ligating blunt-ended DNA fragments to sequencing adaptors while simultaneously preventing adaptor dimer formation from forming. This rapid method supports whole genome, amplicon, and RNA sequencing applications. Results show enhanced coverage and reduced GC bias for human genome DNA sequencing.

1893F

Massively parallel single nucleotide mutagenesis using reversibly-terminated inosine. *G. Haller[1], D. Alvarado[1], M. Dobbs[1,4], C. Gurnett[1,2,3].* 1) Department of Orthopaedic Surgery, Washington University School of Medicine, Saint Louis, MO; 2) Department of Neurology, Washington University School of Medicine, Saint Louis, MO; 3) Department of Pediatrics, Washington University School of Medicine, Saint Louis, MO; 4) Shriners Hospital for Children, St. Louis, MO.

Accurate, inexpensive and efficient methods of large scale mutagenesis of specific DNA sequences have the potential to alloware needed to rapidly assess the functional effects of genetic variation. for rapid assessment of the effects of single nucleotide changes on protein function. However, many currentThese methods to generate mutational libraries are remain limited by the need to synthesize oligonucleotides *en masse* to clone directly or to use as templates for mutagenesis. Here we demonstrate the construction of a systematic allelic series (SAS) with, an oligo-free method of massively parallel single nucleotide mutagenesis using that utilizes reversibly-terminated deoxyinosine triphosphates (dITP). We created mutational libraries containing every single nucleotide mutation within the N-propeptide of the type I (I) collagen gene *COL1A1* and within the full coding region of the *b-lactamase* gene (>1kb) which confers resistance to ampicillin, each in less than a day in a single reaction for <$30. Sequencinga 1kb SAS library revealed that, >90% of molecules harbored one and only one mutation, making library construction by this method extremely efficient and cost-effective. SAS-based mutational screening has the ability to greatly expedite interpretation of human disease genetic variantions, *in vitro* protein evolution, development of biopharmaceuticals and the determination of critical domains for proper protein function.

1894W

Pushing the Limits of Small RNA-Seq with Chemically Modified Adapters. *S. Shore, J. M. Henderson, A. P. McCaffrey, G. Zon, R. I. Hogrefe.* Research & Development, TriLink BioTechnologies, San Diego, CA.

Next-generation sequencing (NGS) is an evolving tool for nucleic acid sequence identification. NGS is widely used for basic research and discovery as well as clinical diagnostics. It is critical to develop the most accurate and reproducible library preparation techniques, especially when dealing with patient samples. Both DNA and long RNA-Seq have advanced, low input, PCR-free, and automatable library preparation techniques. In the continuously growing field of small RNA (including microRNA, piwiRNA, tRNA, and snoRNA) sequencing methods still have limitations including high input requirements and difficulties in automation. Separation of tagged library from adapter-adapter ligation products (adapter dimer) has been a persistent challenge due to the minimal size difference between products, which hinders a gel-free workflow. In order to resolve this problem we have screened several chemical modifications of adapter oligos to suppress adapter dimer formation. We introduce a novel method of small RNA library preparation that applies these modified CleanTag™ Adapters and creates the potential for automation without the need for a gel separation to exclude adapter dimer. We replace the gel purification step with a two-step magnetic bead purification for size selection since adapter dimer no longer dominates the reaction. This could be carried out by a liquid handling robot for a fully automated library preparation procedure. Current commercial library preparation kits recommend inputs of 100-1000 ngs. Reduction in adapter dimer has allowed for library preparation from much less starting material (as low as 1 ng). Using 10 ngs of total brain RNA input in conjunction with CleanTag™ Adapters, adapter dimers were reduced by over 3,000,000 reads compared to a commercial kit. Additionally, libraries using modified adapters resulted in 1,000,000 more miRNA reads than a commercial kit at this low RNA input. With increased library coverage and decreased side products the data generated from modified adapters brings us closer to analysis on a single cell level. Our method of small RNA library preparation results in high quality libraries from various tissues, cells, and low RNA input biofluids (*e. g.* plasma and urine). The ability to use very low inputs and to automate library preparation will allow high throughput sequencing and improved clinical assays.

1895T

Improving the information content of long fragment read technology by expansion to 5,000 compartments. *O. Wang[1,2], Y. Xie[1,3], W. Huang[1], C. Chang[1], J. Tang[1], X. Cheng[1], Y. Fu[1], W. Zhang[1], X. Liu[1], H. Jiang[1,2], B. A. Peters[1,4], R. Drmanac[4], X. Xu[1].* 1) BGI-Shenzhen, Shenzhen, Guangdong, China; 2) Department of Biology, University of Copenhagen, Copenhagen, Denmark; 3) School of Bioscience and Bioengineering, South China University of Technology, Guangzhou, China; 4) Complete Genomics Inc. , Mountain View, California, USA.

Individual humans genomes are diploid in nature, with half of the homologous chromosomes being derived from each parent and varying at millions of positions. How these variants act upon each other within each parental chromosome can have profound effects on gene expression and ultimately the health of an individual. As human genome sequencing moves towards clinical applications, determining which sets of variants are transferred in blocks from each parent (Haplotypes) is increasingly being recognized as critically important. Haplotype information can be generated either by computational approaches that rely on population based haplotype information, sequencing both parents or by laboratory-based experimental methods. Computational methods are cheap and easy, but have lower accuracy the farther apart variants are found and cannot place rare variants or de novo mutations into haplotypes; whereas experimental methods can potentially make up for all of these shortcomings. Almost all of them rely on dilution and compartmentalization of long DNA fragments such that individual compartments contain less than 20% of a haploid genome. This results in a statistically low probably of overlapping fragments from the maternal and paternal chromosomes in any given compartment. This strategy was first proposed by Drmanac and ultimately led to the development of long fragment read (LFR) technology; a process which can start from as little as 10 cells, provides excellent performance in phasing, and the highest level of accuracy in SNP calling. However, the current LFR is based on using 384 compartments and there would still be up to 20% of a haploid genome in each well. Increasing the number of compartments and thus lowering the fraction of a genome per well results in less overlap between parental fragments and fragments containing overlapping repeat sequences. In this study we sought to expand the current 384 compartments to 5184. This allows us to decrease the haploid genome content to about 0. 1% per well; significantly reducing the possibility of overlapping of long fragments. To achieve this number of compartments required the development of a novel combinatorial barcode ligation approach. With these modifications, we have generated a more informative library with a very low error rate and demonstrate how this type of data might be used in a clinical setting.

1896F

Single Tube, Whole Genome Phasing and Assembly using Bead-based Index Partitioning. *F. Zhang[1], L. Christiansen[1], R. Jackson[2], N. Morrell[2], N. Gormley[2], J. Shendure[3], K. L. Gunderson[1], F. J. Steemers[1].* 1) Advanced Research Group, Illumina, San Diego, CA, USA; 2) Technology Development Department, Illumina, Little Chesterford, Essex, UK; 3) Department of Genome Sciences, University of Washington, Seattle, WA, USA.

The ability to accurately phase and assemble genomes is dependent on long range sequence information. Here we show a sequencing library preparation method that effectively generates long indexed-linked reads of 30-50 kb in length in which each DNA molecule is converted to multiple short libraries with the same index. The libraries labeled with the same index share genomic proximity information and therefore infer the long haplotype structure. We show for the first time that index partitioning of DNA molecules (and parental copies) can be performed in a single tube without the need to use many physical compartments in order to separate, index and sequence the individual molecules. The key concept of the approach is based on the macroscopic transfer of indices attached to a single clonal indexed bead to a long DNA molecule. As a DNA molecule diffuses and binds to clonal indexed immobilized transposomes on a single bead, indices transfer through tagmentation to the DNA molecule. Because intra-tagmentation and /binding reactions on beads are significantly faster than intermolecular reactions between beads, individual DNA molecules are clonally labeled, while simultaneously labeling many long DNA molecules in the population with different i. e. , 96-100,000+ clonal indexed beads in a single tube. As such, we have greatly simplified the process of individual parallel indexed library preparations of fractions of the genome. As a proof-of-concept, we apply this method to phase over 99% of heterozygous SNPs from a HapMap sample into long, accurate haplotype blocks with N50 block sizes >1. 2 Mb using only 88 Gb of extra sequencing over the reference unphased VCF file. Additionally, we demonstrate utility of contiguity-preserving transposition (CPT-seq [1]) on beads in assembly applications greatly improving the N50's [2] and ability to detect structural variants, including gene-fusions, indels, (compound heterozygous) deletions, and paralogs. These technologies provide a simple, rapid, scalable and highly automatable route towards accurate haplotype-resolved sequencing and assembly of the genome[1] Amini, S. et al. Haplotype-resolved whole-genome sequencing by contiguity-preserving transposition and combinatorial indexing. Nat. Genet. 46, 1343–1349 (2014). [2] Adey, A. et al. In vitro, long-range sequence information for de novo genome assembly via transposase contiguity. Genome Res. 24, 2041 (2014).

Sequencing the B-cell and T-cell repertoire. *M. Karaca[1], J. N. H. Stern[2], G. Yaari[3,4], J. A. Vander Heiden[5], S. H. Kleinstein[3,5], D. A. Hafler[2,6], K. C. O'Connor[2], A. W. Briggs[7], T. Gilbert[7], C. Clouser[7], W. Donahue[7], L. M. Apone[1], F. J. Stewart[1], S. Russello[1], T. B. Davis[1], E. Dimalanta[1].* 1) New England Biolabs Inc. , Ipswich, MA; 2) Department of Neurology, Yale School of Medicine, New Haven, CT; 3) Department of Pathology, Yale School of Medicine, New Haven, CT; 4) Bioengineering Program, Faculty of Engineering, Bar-Ilan University, Ramat Gan, Israel; 5) Interdepartmental Program in Computational Biology and Bioinformatics, Yale University, New Haven, CT; 6) Department of Immunobiology, Yale School of Medicine, New Haven, CT; 7) AbVitro Inc, Boston, MA.

Immune sequencing, which allows for the study of complex immunological diseases by sequencing millions of V(D)J combinations from B-cell antibody and T-cell receptors, has gained popularity due to recent throughput and read length improvements in next-generation sequencing (NGS) technologies. However, structural and sequence complexities of antibody genes have made reliable targeting approaches challenging. We have developed and optimized a method for accurate sequencing of full-length immune gene repertoires of B-cells and T-cells. This allows for exhaustive somatic mutation profiling across complete V, D and J segments, full isotype information analysis (IgM, IgD, IgG, IgA and IgE), and the possibility for synthesis and expression of complete antibody chains for downstream immunological assays. The method uses a unique barcoding scheme specifically designed to tag every mRNA molecule so that all PCR copies of each mRNA fragment can be collapsed into a single consensus sequence, making the assay extremely accurate by resolving PCR bias and sequencing errors, as well as allowing quantitative digital molecule counting. One example of how our sequencing technology has been applied along with advanced bioinformatics to gain important biological insights is in a recent study exploring B cell traffic patterns in multiple sclerosis (MS), an inflammatory disease of the central nervous system (CNS)1. This work demonstrated that B cells traffic freely across the CNS tissue barrier, with a majority of B cell maturation occurring within secondary lymphoid tissue outside of the CNS. These findings identify a pathway required for B cell accumulation in the CNS and may aid in designing better therapeutics to combat this debilitating disease. 1J. N. H. Stern, G. Yaari, J. A. Vander Heiden, G. Church, W. F. Donahue, R. Q. Hintzen, A. J. Huttner, J. D. Laman, R. M. Nagra, A. Nylander, D. Pitt, S. Ramanan, B. A. Siddiqui, F. Vigneault, S. H. Kleinstein, D. A. Hafler, K. C. O'Connor, B cells populating the multiple sclerosis brain mature in the draining cervical lymph nodes. *Sci. Transl. Med.* **6**, 248ra107 (2014).

1898T

High quality library construction and reliable quantitation with NEBNext reagents. *E. Yigit, P. Liu, N. Tanner, J. Borgaro, L. Apone, V. Panchapakesa, D. Rodriguez, B. Langhorst, J. Menin, C. Sumner, C. Chater, F. Stewart, N. Nichols, E. Dimalanta, T. Davis.* New England Biolabs, Ipswich, MA.

The field of NGS has matured significantly over the past few years. While the use of NGS in the clinic was simply a possibility a few years ago, today it is routinely used in some areas of diagnostics. An expanded role for NGS in the clinic and research will depend on continued improvement of the upstream processes required to produce high quality NGS data. In particular, maximizing data output and minimizing instrument run failure are imperative. In this poster, we present data showing: 1) the improvements we've made in library preparation with the development of the NEBNext Ultra II Library Prep kit; and 2) the development of the NEBNext Library Quant Kit for Illumina, a simple and robust method for quantitation of Illumina libraries. In the first part, we show that libraries made with the Ultra II kit have low DNA input requirements; significantly improved library yields and reduced sequence bias. In addition, the workflow is simple and streamlined, greatly reducing the time required to produce high quality DNA libraries and the possibility of errors. In the second part, we demonstrate the effectiveness of the NEBNext Library Quant Kit for a broad range of library types and sizes as well as advantages offered by qPCR quantitation for obtaining optimal cluster density and user-to-user consistency. The NEBNext Quant Kit offers an efficient and cost-effective qPCR library quantitation workflow for users looking to optimize both sequencing yield and throughput.

1899F

A recombination-based technology in *Escherichia coli* for cloning large and specific human DNA sequences. *L. Brunelli, H. Shanmugam, G. T. Lyozin.* University of Utah School of Medicine, Salt Lake City, UT.

In addition to being driven by DNA sequencing and genome engineering, the Precision Medicine Initiative recently unveiled by the National Institutes of Health requires the complete functional analysis of the human genome. However, such comprehensive characterization remains a major challenge due to hundreds of thousands of poorly understood distal transcriptional regulatory elements in the human genome. To overcome this barrier, further advances in *in vivo* DNA cloning and engineering are urgently needed. We recently developed one of the few approaches for the precise, seamless engineering of bacterial artificial chromosomes (BACs) and P1 phage–derived artificial chromosomes (PACs), two cloning systems particularly suited for the analysis of mammalian genes (Lyozin G. T. et al. *Nat Methods* 2014). Nonetheless, current BAC and PAC library recombinants have on average <200 kb inserts with random boundaries. This limitation prevents their use in the analysis of specific regulatory variants distributed over large chromosomal regions and involved in human disease as is the case for *GATA4* in congenital diaphragmatic hernia (CDH), a severe structural birth defect (Arrington C. B. et al. *Am J Med Genet* 2012). Here we report the development of pP1RV2, a new high-capacity PAC-derived vector that can be used for seamless megabase-range gap repair DNA cloning and engineering. To show its applicability, we separately cloned two 190 kb BAC inserts with precise boundaries from overlapping BACs in the *GATA4* region. Cloning efficiency was ~30%, remarkably better than previously reported for high-copy number vectors such as pBR322 (~2% for an 80 kb insert, Lee E. C. et al. *Genomics* 2001; Copeland N. G. et al. *Nat Rev Genet* 2001). To our knowledge this is the first time that a high-capacity vector has been used in gap repair DNA cloning, allowing the precise manipulation of large and specific DNA segments in *E. coli*. Our long-term goal is to reconstruct a 1 Mb *GATA4* regulatory region relevant to CDH on pP1RV2. A technology for seamlessly engineering large, specific DNA sequences is essential to complete the functional resolution of the human genome and streamline the efforts of the Precision Medicine Initiative.

1900W

Unique molecular indexes to remove PCR bias in bisulfite sequencing. *I. lee[1], D. Wu[1], J. Lu[2], A. Lejeune[2], W. Timp[1].* 1) Biomedical Engineering, Johns Hopkins School of Medicine, Baltimore, MD; 2) Biomedical Engineering, Johns Hopkins University, Baltimore, MD.

Bisulfite sequencing is a high-throughput technique to measure 5mC DNA methylation, in which unmethylated cytosine residues are converted to uracil, affectively amplifying as thymine residues. This process exaggerates the variability in the DNA library's GC content, a known cause of bias in PCR amplification prior to next-generation sequencing. Such bias is a significant obstacle in sequencing analysis, precluding quantification of the observations and always requiring controls. We propose the addition of molecular barcodes into sequencing library preparation to remove the GC-content bias and increase the accuracy of methylation calls. Unmethylated *E. coli* DNA was treated with M. SssI CpG methyltransferase to produce a stock of DNA methylated at all C's in CpG contexts. Then, samples containing varying ratios of methylated and unmethylated DNA were prepared to assess the potential of molecular barcodes in decreasing GC-content bias. Standard bisulfite conversion and library preparation procedures (Pico Methyl-Seq™ or NEBNext® Ultra™) were used to prepare the libraries. Molecular barcodes were incorporated in the form of custom-made adaptors containing six to eight randomized nucleotide residues. The sequenced reads were analyzed with Bismark bisulfite mapping program. The reference location of each mapped read, its sequence, and/or its corresponding molecular barcode were used to identify PCR duplicates. For each set of duplicates, the best read, with corrections in methylation calls, was selected as the representative read. The methylation analysis resulted in universal but uncorrelated error in overall methylation, deviating up to 10 % from their original percentages. Removal of duplicates without molecular barcodes decreased the error to 7 %. Incorporation of molecular barcodes in the duplicate removal further decreased the error to as low as 2 %. Simulation of low-input condition by preparing the library with large number of amplification cycles showed increased resemblance of high-input results with molecular barcodes. These results indicate that molecular barcodes can be used to remove bias in sequencing introduced by PCR duplicates. In this study, molecular barcodes were used for bisulfite sequencing; however, this method can be applied in any NGS setting, especially when the input amount is low and the samples must undergo a large number of amplification cycles, as is the case in many clinical experiments.

1901T

Rapid extraction of high yield, high quality DNA from tissue samples. *D. O'Neil, S. Schroeer, M. Sprenger-Haussels.* QIAGEN GmbH, Hilden, NRW, Germany.

Genetic and genomic analysis from tissue samplesrequires the extraction ofhigh quality DNA. Mechanical disruption methods such as bead millingprovide high yield from tissue samples, but cause damage to thenucleic acids. Purely enyzmatic methods such as proteinase K digestion canextract nucleic acid without damage, but require long incubation times, often proceeding overnight, and without approaching theyields achieved by mechanical disruption techniques. Thus a method is needed which can provide a rapid extraction of high yield, high quality DNA from tissue samples. We have developed a method which combines mechanical, chemical, and enyzmatic disruption of tissue samples to provide rapid extraction of high yield DNA without causing significant damage to the nucleic acid. Mechanical disruption is achieved by vortexing the tissue in a container with a specially shaped milling bead. The lower power of a vortexer compared to a bead mill prevents shearing of the DNA. Low chaotropic conditions support a mild lysis of the sample and provide a synergistic effect for the simultaneous proteinase K digestion and mechanical shearing. DNA extracted from fresh-frozen and from stabilized tissue samples using the new method showed up to 10 fold increase in yield compared to a standard proteinase K digestion or a mechanical milling method alone. The entire disruption procedure was complete in 15 minutes for softer tissues such as liver or kidney, and within 30 minutes for tougher tissue such as stabilized lung or trachea samples. DNA from fatty tissues such as brain as well as fibrous tissues like muscle was extracted efficiently by this method. The new method provides extraction ofDNA from tissue samples superior to existing methods, on the criteria of DNA quality, yield, and time required for extraction. Technologies such as next-generation sequencing make the extraction and analysis of DNA from tissue samples more important, and a method which provide the most convenient and efficient extraction of DNA from tissue will support theroutine genomic analysis enabled by these technologies.

Pan-microbial detection using Axiom® Genotyping Solution from Affymetrix. *P. Rack[1], K. McLoughlin[2], S. Gardner[2], M. Mittmann[1], A. Pirani[1], C. Sheppy[1], C. Jaing[2], L. Bellon[1], T. Slezak[2], M. Shapero[1].* 1) Affymetrix, Inc. , 3420 Central Expressway Santa Clara, CA 95051; 2) Lawrence Livermore National Laboratories, Livermore, CA 94551.

BackgroundDifferent human body sites harbor distinct, diverse microbial populations, including eukaryotes, archaea, bacteria, and viruses, which define the human microbiome. Major efforts are underway to describe the establishment and flux of these dynamic microbial populations, with the goal of elucidating links to human health and disease. With the expansion of microbial genome sequence information, microarrays are well-positioned to capitalize on this evolving information content. Here we present an overview of Axiom® Genotyping Solution [mgb1]and a description of the design, development, and testing of a microbial detection array (MDA). **Experimental design** Axiom® Microbial Detection Array contains probe sequences targeted towards more than 12,000 organisms, using 133,500 target sequences. Probe sequences were designed with the guidance of data derived from proof-of-concept studies that informed probe parameters including length and tolerance to mismatches. This design enables species/strain-level resolution of the entities comprising a sample using a Composite Likelihood Maximization algorithm (CLiMax). To investigate models for relative quantitation, Langmuir adsorption curves were fitted using Latin-square data generated by target spikes of defined concentrations. Furthermore, defined samples of increasing complexity were used to interrogate and measure array sensitivity and specificity. Lastly, the Axiom® MDA was tested for the ability to identify and quantify microorganisms within complex biological samples, and results were compared to orthogonal approaches. **Conclusions**In summary, Axiom Microbial Detection Array offers a solution for the identification and enumeration of microbial entities comprising complex biological samples. The unbiased design of the Axiom MDA is agnostic of sample type, lending to its use and utility in the context of bioterrorism, environmental monitoring, food safety, and human and animal health. Furthermore, scalable sample throughput enabled by 24-, 96-, and 384-array layouts coupled with laboratory automation allows processing of tens to thousands of samples per week with minimal manual intervention and is consistent with the need for cost-effective detection and examination of microbiomes.

1903W

Automation of Micro RNA and Total RNA Purification from FFPE using the Beckman Coulter Agencourt FormaPure Kits and Biomek liquid handler. *B. Lee, J. Palys.* Beckman Coulter, Brea, CA.

Micro RNAs are small, naturally-occurring non-coding ribonucleic acids with sizes between 18 and 40 nucleotides (nts) that have been demonstrated to play a significant role in the regulation of gene expression. As a result, interest in smaller RNA species such as miRNA has increased. This poster describes the purification of miRNA and total RNA from challenged Formalin Fixed Paraffin Embedded (FFPE) samples using the Beckman Coulter SPRI (Solid Phase Reverse Immobilization) magnetic bead based chemistry and the Biomek automated extraction method. The FormaPure RNA 96 demonstrated method enables automated purification of total RNA, including miRNA and other small RNAs, from 1–96 samples on a Biomek Span 8 workstation. Total RNA and miRNA can be purified from very small amounts of FFPE samples using the LCM procedure. The Biomek automated SPRI method is an easy, high yielding and robust nucleic acid purification process that does not require centrifugation and vacuum filtration steps. Purified nucleic acids are easily eluted from the magnetic beads under aqueous conditions, which provide maximum flexibility for downstream applications. The data shows that the samples extracted using the FormaPure kit gave higher RNA yield, as compared to samples extracted from a column purification method.

1904T

Targeted SMRT® Sequencing and Alternative Splice Detection of cDNA using Roche NimbleGen SeqCap Enrichment. *D. Raterman[1], L. Feng[1], M. Brockman[1], Q. Meng[2], M. Wang[2], H. V. Doddapaneni[2], A. C. English[2], K. Walker[2], Y. Han[2], A. Roy[3,4], D. W. Parsons[2,4,5], D. M. Muzny[2], R. A. Gibbs[2,5], T. Hon[6], E. Tseng[6], T. Clark[6], T. Richmond[1], D. Burgess[1].* 1) Roche NimbleGen, Madison, WI; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX 77030; 3) Department of Pathology & Immunology, Baylor College of Medicine, Houston, TX 77030; 4) Department of Pediatrics, Baylor College of Medicine, Houston, TX 77030; 5) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030; 6) Pacific Biosciences, Menlo Park, CA.

It has been estimated that between 74% and 100% of human multi-exon genes are alternatively spliced. Alternative splicing gives cells the ability to create different protein isoforms with only a single gene and is a key factor contributing to increased cellular and functional complexity in higher eukaryotes. Current RNA sequencing protocols rely on high-throughput sequencing of short reads. However with an average transcript length in the range of 1. 5-2. 0 kb, advanced analysis tools are required to reconstruct full-length transcripts, making accurate annotation of each gene locus and transcript isoform quantitation challenging. Longer reads are expected to improve performance for transcript assembly, transcript quantification and gene fusion detection. With the current advances in sequencing technologies, it is now feasible to sequence full-length cDNAs. It is not efficient, however, to sequence whole RNA-seq libraries. Most tissues express between ~6,000-10,000 mRNA genes and the vast majority of transcripts are derived from a very small subset of genes. These highly expressed genes predominate most RNA-seq experiments and make detecting rare variants difficult. Our research details a novel method to target specific large fragment cDNAs using Roche NimbleGen capture probes for sequencing on the long-read sequencing platform from Pacific Biosciences. Only transcripts from genes of interest are captured and sequenced, greatly increasing the discovery power of a given experiment. cDNA was prepared from a brain sample and then hybridized using Roche NimbleGen's Neurology Panel Design. SMRTbell™ adapters were then ligated onto the captured products and sequenced on a PacBio® RS II machine. In addition, control samples that were not enriched were sequenced. Average on-target rates were 77% compared to the control samples where on-target rates were <7%. Further R&D efforts will focus on extending the utility of this novel method to the entire coding region, making it applicable to a broad spectrum of diseases. Full-length mRNA transcripts from patients with cancer will be enriched by HGSC VCRome exome probe set (~42 Mbp capture size) for transcriptome analysis. With unique advantages provided by long-read sequencing and target capture, we believe the new method will produce unprecedented comprehensive alternative transcript splicing, novel fusion structures, as well as mRNA nucleotide variants.

1905F

Improved sequencing and transcript detection utilizing an RNase H-mediated ribosomal RNA depletion method. *D. Sanjai[1], J. Pavlica[1], R. Wadsworth[2], M. Ranik[2], P. Jones[2], N. Hapshe[1], R. W. Kasinskas[1], E. van der Walt[2].* 1) Kapa Biosystems Inc, Wilmington, MA; 2) Kapa Biosystems (Pty) Ltd, Cape Town, South Africa.

As transcriptome sequencing becomes more ubiquitous, the development of new methods is needed to optimize library preparation, and thus achieve high-quality sequencing results. Ribosomal RNA (rRNA) accounts for the vast majority of total RNA, but contributes minimally to understanding gene expression. Therefore, efficient removal of rRNA is a critical step in RNA-Seq library preparation to maximize the yield of less abundant, biologically-informative, transcriptome-derived reads. In this study, we present an alternative method for rRNA depletion, which retains more precursor and long noncoding RNA species than a capture-mediated method, giving a more comprehensive view of the transcriptome. **Methods:** To address the needs of this growing field, we have developed the KAPA Stranded RNA-Seq Kit with RiboErase, which includes a highly effective workflow for the targeted enzymatic depletion of cytoplasmic and mitochondrial rRNA through the use of complementary oligonucleotide probes and RNase H. Our method is compatible with human, mouse, rat, and other related species, and is automation-friendly. In this study, we sequence Universal Human Reference RNA, comparing our RNase H-mediated method against a bead-based capture-mediated rRNA depletion technology. KAPA Stranded RNA-Seq Kit with RiboErase results show more efficient depletion of rRNA (up to 99. 9%), lower duplication rates, increased gene and transcript detection, and better coverage of GC-rich and low abundance transcripts. Moreover, our workflow demonstrates improved detection and coverage of precursor and long noncoding transcripts, which were better correlated to an undepleted total RNA control. By utilizing a targeted enzymatic method for depletion, our workflow enables superior reduction of rRNA and a more complete representation of the transcriptome, including precursor and long non-coding RNAs. Along with improved sequencing performance, the KAPA Stranded RNA-Seq Kit with RiboErase has been proven to be highly robust and reproducible across varying input amounts. Through the use of evolved enzymes, including the KAPA HiFi DNA polymerase, high-quality reagents, and an optimized “with bead” workflow, the kit has demonstrated improved coverage of difficult transcripts, including those that are GC rich and in low abundance.

1906W

Isolation and processing of 1000s of single cells for genomics applications using Nanowell Arrays. *M. Srinivasan, J. Dunne, R. Acob, S. Anandakrishnan, L. Chan, P. Espinoza, H. Hubschle, M. Ho, S. Husain, P. Lin, I. Mann, A. Mir, T. Schaal, H. Shapiro, M. Slater, K. Swaminathan.* WaferGen Biosystems, Fremont, CA.

Single Cell RNA Sequencing has quickly become an established method to understand cell specific differences and how those differences manifest both temporally and spatially in various tissues. Despite the immense progress, there is continued demand for new technologies that can miniaturize and automate the isolation of thousands of individual cells and process these individual cells for nucleic-acid sequencing or qPCR. A 5184-well nanoarray called the SmartChip and a dispenser that can dispense nanoliter volumes accurately into the nanowells are used to dispense cells into nanowells and process the cells for RNA-seq. In one variation, the Single Cell RNA Barcoding and Sequencing (SCRB-seq, Soumillion et. al. , http://dx. doi. org/10. 1101/003236 2014) method has been adapted to the SmartChip for 3’ tag counting applications. Furthermore, an image-analysis software called Cellector was designed, which enables the selective processing of individual wells based on a researcher’s needs - a feature that can minimize data analysis noise from multiple cell containing wells. Using Poisson dispense method where on average 1 cell is deposited into each well, Cellector routinely identifies about 1500 individual cells that are viable as judged by staining for DNA and dead cells using Hoechst 33342 dye and propidium iodide, respectively. The output from the image analysis software is uploaded to the dispenser and the dispenser adds reagents only to wells that are either manually and/or automatically selected. To maximize the utilization of the SmartChip real estate and decrease the cost/cell we have also developed a targeted deposition method to deposit cells at >75% occupancy rate. We present data to demonstrate the reproducible dispensing of individual cells in Poisson and targeted dispense methods. In both approaches, individual cells were barcoded with unique molecular identifiers, by adapting SCRB-Seq, to estimate differential gene expression. System simplicity, ease of use, number of sample addressable wells, system throughput, reagent flexibility and cell type compatibility make SmartChip an ideal candidate system for use in a wide variety of single cell genomic applications.

1907T

High-Throughput, High-Precision, Single-Cell Gene Expression Analysis Using a New BD FACS™ Cell Sorter. *X. Wang, J. Goglio, K. Dembski, T. Le, P. P. V. K. , S. Ghanekar.* R&D, BD Biosciences, San Jose, CA.

Gene expression studies performed on bulk samples may obscure the understanding of complex samples. Gene expression analyses performed on single cells, however, can offer a powerful method to resolve sample heterogeneity and reveal hidden biology. Previously, we demonstrated that BD's fluorescence activated cell sorting (FACS™) technology could accurately target and isolate single cells or a small number of cells for use in next generation sequencing (NGS) or transcriptome analyses. Gene expression data from the individual cells correlated strongly with the cell phenotypes used for isolating the cells. Here, we demonstrate applications of a new, entry level BD FACS cell sorter that rapidly selects and isolates single cells or cell populations, with high precision, for molecular analysis. The sorter employs innovative technologies recently developed by BD to automate many operating steps that are traditionally performed manually, making fast and easy cell selection and isolation possible for more researchers. The sorter has one laser for illumination and four parameters for detection (one composite scatter channel and three fluorescent channels), and collects cells into plates or tubes. In this study, we demonstrated the applications for: 1) elimination of dead cells from collection by positive propidium iodide (PI) staining; 2) isolation of single cells from different cell cycle phases (G0/G1, S, G2) with Hoechst dye staining; 3) accuracy of sorting cells by depositing different numbers of cells (1 cell, 5 cells, 10 cells, 20 cells, and 50 cells) per well in a 96-well plate; 4) isolation of single cells from a mixed cancer cell sample based on their specific cell surface marker staining. The gene expression of the sorted cells was analyzed, and gene expression profiles were generated. These studies demonstrate a simple, fast method using a new, easy-to-use sorter to select and isolate single cells for high-resolution genomic studies, including next generation sequencing, qPCR, and microarray analysis. It provides a powerful tool for studying complex samples at the individual cell level.

1908F

Integrated DNA and RNA sequencing of the same cell. *J. He.* Department of Biology, South University of Science and Technology of China, Shenzhen, Guangdong, China.

Interest in single-cell whole genome analysis is growing rapidly, especially for profiling rare or heterogeneous populations of cells. Various amplification protocols have been developed to sequence the genome or transcriptome of single cells. However, the current single-cell RNA-seq method or DNA sequencing method do not permit analysis of the transcriptome and genomic sequence of individual cells simultaneously. In this study, we developed a strategy that allows us to use next-generation sequencing to simultaneously obtain both full genome and transcriptome information from an individual cell. Using mouse oocytes as an example, we demonstrated that the integrated DNA and RNA sequencing of single oocytes can deliver both high coverage of genome and reproducible low-bias transcriptome. Our technology will help to fulfill the central goal of biology and medicine, which is to connect the genotype and phenotype of individual cells under physiological or pathological conditions.

1909W

Novel Luminex assay for Telomere Length measurement does not show Well Position Effects like qPCR. *M. G. Kibriya, F. Jasmine, S. Roy, H. Ahsan, B. L. Pierce.* Public Health Sciences, The University of Chicago, Chicago, IL.

Background: Telomere length (TL) is a potential biomarker of aging and short TL is associated with increased cancer risk. In large scale studies, qPCR is typically used for TL measurement, primarily due to its low cost and low DNA input requirements. Recent study showed that the well position of the sample in the qPCR plate impacts the TL measurement. Recently we have developed a novel non-PCR amplification, probe-based assay with signal amplification on Luminex platform for TL requiring ~50ng DNA. Here, we report for the first time a comparison of TL measures obtained from two single-plex (SP) qPCR, one multiplex (MP) qPCR, and our novel Luminex (LUM) assay for TL, with emphasis on sample positioning. **Material and Methods:** For qPCR, DNA from two individuals (A and B) were placed in 48 wells – DNA from person-A in the upper left (24 wells) and lower right quadrant (24 wells) and DNA from B in other two quadrants of BioRad CFX96. We conducted two types of SP-qPCR assays, using two different primer sets. For each SP-qPCR assay, two plates (one for Telomere and one for reference gene) were used. For the MP-qPCR and LUM assay, the telomere and the reference genes were assayed from the same well. In LUM, 24 wells were used for standards, and thus DNA from the same two individuals was replicated in 36 wells. **Results:** Coefficient of variation (CV) of TL for A-DNA was 8. 9%, 14. 9%, 24. 3% and 8. 4% for SP-qPCR set1, SP-qPCR set2, MP-qPCR and LUM respectively. Similarly CV for B-DNA was 11. 4%, 13. 8%, 19. 7% and 7. 2%. Irrespective of person, samples in the left and right most columns showed statistically lower TL (ANOVA, p=3. 4x10E-6, p=0. 012, and p=0. 02 for SP-qPCR set1, SP-qPCR set2, and the MP-qPCR assays respectively), but not in the novel LUM assay (p=0. 83). Similarly, samples in the rows of the upper and lower edges also showed slightly lower TL using SP-qPCR set1 and the MP-qPCR assays (ANOVA, p=0. 01, p=0. 001, respectively), but not in SP-qPCR set 2 (p=0. 42), or in the novel LUM assay (p=0. 96). For SP-qPCRset1, 28. 2% of the variation in TL was explained by column-to-column variation and 28. 9% was explained by person-to-person variation where as for the LUM assay only 2. 65% of the variation in TL was explained by column-to column variation and 52. 2% was explained by person to person variation. **Conclusion:** Our novel Luminex assay for TL had good precision and did not show positional effect of the sample that was seen with all the three qPCR assays tested.

Fusion Gene Detection and Gene Expression Analysis of Circulating RNA in Plasma. *J. Gu, K. Lea, X. Fang, H. Saunders, K. Bramlett.* Thermo Fisher Scientific, Austin, TX.

The presence of circulating (cell-free) nucleic acids in the bloodstream of individuals with cancer offers a potential non-invasive approach to monitor disease status and guide treatment options. In the past years, increasing interests have been shown on circulating RNA, especially circulating small RNAs for their application as biomarkers for potential toward more effective diagnosis and prognosis. However, widespread inconsistencies have been observed among the studies due to biases generated during sample collection, handling, RNA extraction and analysis. We developed a complete workflow that includes blood collection, plasma preparation, circulating RNA extraction, followed by expression analysis and gene fusion detection on Ion TorrentTM Next-Generation Sequencing platforms. Blood plasma samples from 2 healthy donors and 4 individuals diagnosed with Non-Small Cell Lung Cancer were utilized for circulating RNA isolation following a TRIzol® LS Reagent and mirVanaTM miRNA Isolation Kit-based method to maximize circulating RNA recovery. AmpliSeq library preparation was performed on purified circulating RNA using either AmpliSeqTM Transcriptome panel for expression profiling of 21K coding and non-coding genes, or an Ion AmpliSeq™ panel targeting fusion transcript detection from RNA. AmpliSeq transcriptome data was analyzed using ampliSeqRNA plugin in Torrent SuiteTM Software. ~3000 genes were detected in cfDNA from plasma samples with high correlation (r>0. 8) observed between healthy donors. Ion ReporterTM Software was used to analyze fusion transcript panel data. Detection of fusion gene transcripts was demonstrated by spiking trace amount of RNA from fusion positive cell line into circulating RNA from healthy donor, indicating high sensitivity of the detection system. In summary, this study demonstrated the feasibility of gene expression profiling and gene fusion detection from circulating RNA in plasma samples on Ion TorrentTM NGS platforms.

FlightDeck: a self-service web-portal for reproducible genomics research in the Cloud via Docker container. *J. Kim[1], T. Bath[1], C. Farcas[1], O. Harismendy[1], A. Koures[1,2], S. Ko[1], L. Ohno-Machado[1,2].* 1) Department of Biomedical Informatics, University of California San Diego, La Jolla, CA; 2) Clinical and Translational Research Institute, University of California San Diego, La Jolla, CA.

With increasing size of data and analysis complexity in genomics, the community relies heavily on robust software. Yet, there are several challenges for reproducible research: 1) missing or obsolete source code, 2) undocumented or unexpected dependencies to install and configure applications, 3) undisclosed values of the parameters used in published analyses, and 4) requirements for querying and pre-processing external reference datasets. To address these issues, we present FlightDeck, a self-service web-portal that encapsulates scientific software as Virtual Machines (VMs) and enables automated VM provisioning and configuration based on published workflows and recipes. With just a web-browser, users can upload experimental data, search a recipe of interest, provision a VM instance, start the analysis, and generate reproducible results. FlightDeck is different to existing projects such as Galaxy or GenePattern in that it allows users to run both prebuilt and user-defined custom workflow. A recipe includes a version of the source code, dependent libraries, and external reference data. Recipe authors also provide the VM specifications to ensure fully automated deployment. High demand VMs, such as alignment or variant calling are pre-provisioned via Docker and are available as VM images, reducing the total time to generate data. After uploading input experimental data to FlightDeck, users can run multiple recipes that apply different softwares/workflows and varied parameter values on the same data for a comparison. Software developers who want to focus on inventing a new algorithm, still have to go through a lengthy process of example data preparation, configuration and running existing softwares for an evaluation. FlightDeck makes all these steps as one-time-job by turning into a recipe and VM-snapshot, reducing the total software development time. FlightDeck is leveraging two virtualization technologies, VMware and Docker. Moreover it offers flexibility to run workflows on public (Amazon EC2) or private (iDASH – HIPAA compliant) clouds. FlightDeck offers a viable solution toward reproducible genomics research in a user-friendly manner. FlightDeck is developed as an iDASH resource, supported by NIH/NHLBI National Centers for Biomedical Computing (U54HL108460).

1912W

Web Tool to Guide Submission to ClinVar. *M. J. Landrum, J. M. Lee, G. R. Brown, S. Chitipiralla, B. Gu, J. Hart, D. Hoffman, J. Hoover, W. Jang, K. Katz, M. Ovetsky, G. Riley, A. Sethi, R. Villamarin, D. R. Maglott.* NCBI/NIH, Bethesda, MD.

ClinVar (www. ncbi. nlm. nih. gov/clinvar/) is an archive of interpretations of variants and their relationship to disease, along with the evidence that supports the interpretations. Records are submitted to the database from clinical testing and research laboratories, locus-specific databases, OMIM, GeneReviews, as well as expert curation panels and groups who provide practice guidelines. Submissions range from hundreds or thousands of variants submitted by clinical testing laboratories to single variant submissions by researchers publishing their investigation of a clinically relevant variant. The Variation Submission Portal at NCBI was developed to facilitate the submission process to ClinVar, dbSNP, and dbVar. Via the Submission Portal, information about individuals and their organizations is provided once, rather than with every submission, which saves time for all types of repeat submitters. The Submission Portal also integrates information about laboratories that submit to variation databases and the NIH Genetic Testing Registry, thus making it easier to submit data to more than one resource. Until recently, use of Submission Portal allowed registration of the submitter and uploading of data files. We now announce the addition of a guided interface for direct data entry, targeted to research laboratories that infrequently want to submit a small number of records. The wizard prompts the user through the steps of defining the variant, defining the condition about which the interpretation is being submitted, the interpretation itself, and the observations or experiments provided as evidence. The wizard ensures that data types required for submission are provided and encourages use of data standards like OMIM, Orphanet, and HPO identifiers. Submitters are guided through the possibilities for data types with multiple options; for example, a submitter may provide a disease as part of the assertion, or a set of clinical features or the indication for testing as part of the observations. The Submission Wizard is designed to support all types of submissions to ClinVar, including structural variants, pharmacogenomics variants, somatic variants, as well as interpretations based on functional rather than clinical significance.

1913T

Ingenuity Variant Analysis, leveraging the Knowledge Base and HGMD®, achieves over 30x enrichment in biologically relevant variants from whole genome and exome sequence data from patients with rare disease. *S. Shah[1], D. Bassett[1], K. Boycott[2], J. Devaney[3], G. Eley[4], R. Felciano[1], S. E. Hofherr[3], A. Joecker[1], K. Kernohan[2], A. Krämer[1], B. W. Meltzer[3], A. Muthiah[1], K. Patel[1], D. Richards[1], M. B. Seprish[3], B. Solomon[4], A. Subramanian[1], J. G. Vockley[4], R. Yip[1].* 1) QIAGEN Bioinformatics, 1700 Seaport Blvd, Third Floor, Redwood City, CA, 94063, USA; 2) Children's Hospital of Eastern Ontario (CHEO), 401 Smyth Road, Ottawa, Ontario K1H 8L1; 3) Children's National Medical Center, 111 Michigan Ave NW # 800, Washington, DC 20010; 4) Inova Translational Medicine Institute, 8110 Gatehouse Road, Falls Church, VA, 22042, USA.

Advances in next generation sequencing technology have enabled sequencing of the whole exome and genome to identify genetic variants underlying rare inherited diseases. QIAGEN's Ingenuity Variant Analysis™ (www. ingenuity. com/variants) is an application that enables users to extract valuable insights from the large amount of genetic variation data generated by next generation sequencing. The platform integrates advanced informatics tools with biological knowledge from the literature and databases to enable real-time interactive filtering and rapid prioritization of variants to interpret the biology accurately and in more detail. Ingenuity Variant Analysis leverages the Ingenuity Knowledge Base, a repository of expert-curated mutation findings, biological interactions and functional annotations created from millions of individually modeled relationships between proteins, genes, complexes, cells, tissues, drugs, and diseases. To support users focused on hereditary disease, QIAGEN now has fully integrated HGMD® Professional, a unique resource that provides comprehensive data on human inherited disease mutations, with Ingenuity Variant Analysis. This unique combination of analytical tools plus content allows researchers to access HGMD reports for variants present in their sequence data through the Ingenuity Variant Analysis interface. To further improve the platform and improve causal variant detection, we designed preset filter cascades, implementing best practices for rare Mendelian disease genetic data analysis. To assess case solve rate, we analyzed the sequence data from 48 patients, afflicted with severe congenital abnormalities, for which the causal variant was previously known. For each sample, we applied the predefined filters, along with the observed medical signs and symptoms in the patient. By leveraging the analytical tools and Ingenuity Knowledge Base and HGMD, we achieved over 30x enrichment in the biologically relevant variants. In 96% of cases (46 out of 48), the causal variant was identified from among the top 75 variants. Furthermore, the causal variant was among the top 20 and 5 variants, in 81% and 44% of cases, respectively. These findings showcase the robust state-of-the-art capabilities and biological knowledge underlying QIAGEN's Ingenuity Variant Analysis, enabling fast and accurate discovery of rare disease causing variants within exome or whole genome data.

1914F

Impact of Genetic Variation on Three Dimensional Structures and Functions of Proteins. *R. Bhattacharya[1], P. W Rose[2], S. K Burley[2,3,4,5], A. Prlić[1].* 1) Bioinformatics and Medical Informatics, San Diego State University, San Diego, CA; 2) UCSD San Diego Super Computer Centre, San Diego , CA; 3) RCSB Protein Data Bank, Center for Integrative Proteomics Research and Department of Chemistry and Chemical Biology, Rutgers, The State University of New Jersey, New Brunswick, New Jersey; 4) BioMaPS Institute for Quantitative Biology and Cancer Institute of New Jersey, Rutgers, The State University of New Jersey, New Brunswick, New Jersey; 5) Skaggs School of Pharmacological Sciences, University of California, San Diego, San Diego ,CA.

Statement of Purpose:

The Protein Data Bank (PDB) currently contains more than 100,000 experimentally-determined 3D structures of biological macromolecules. Of particular interest in the PDB archive are protein structures for genetic variants. These structures can be utilized to gain deeper insight into the molecular mechanisms that are changed by genetic variation. Here, we explore these proteins and manually annotate 375 SNVs for which atomic level resolution data are available. We present an overview of the observed effects of SNV on the structure and function of proteins.

Methods:

Our dataset consists of 375 unique SNVs from human that have PDB coordinates. We systematically review the available literature and performed searches in several databases (RCSB PDB, dbSNP, NHLBI Exome Variant Server, Pubmed) to identify the structural and functional effect of the SNV.

Summary ofResults:

We observe a wide range of possible changes caused by single point mutations, starting from changes in enzyme activity, protein aggregation, structural stability, binding and dissociation, finally a number of SNVs change the arrangement of large biological assemblies. To highlight two examples:

Arylsulfatase A (gene: *ARSA*, OMIM *607574) is a protein that that breaks down sulfatides. The mutation P426L causes defective oligomerisation (dimer instead of octamer) that increases the susceptibility to lysosomal cystein proteinases and results in a severe reduction in half-life.

Delta-aminolevulinic acid dehydratase (gene: *ALAD*, OMIM *125270) catalyzes an early step in the biosynthesis of tetrapyrroles. The mutation F12L causes ALAD Porphyria (OMIM #612740), a rare autosomal recessive disease. The variant changes the protein assembly from an octamer to a hexamer. The optimal pH for the enzyme is shifted from pH 7 (wild-type) to pH 9 in the mutant. As a consequence the enzyme is barely active under physiologic conditions.

Conclusion:

An increasing number of software methods attempt to predict the consequences of genetic variation. Our results show that the variety of consequences is much larger than assumed by many of these methods and that correct prediction remains a significant challenge. A comprehensive understanding of three-dimensional structure, dynamics, and biophysics will be required to write software tools that can make accurate predictions about the consequences of genetic changes manifested at the atomic level in protein and RNA gene products.

1915W

Simultaneous Quantification of HDR and NHEJ Alleles Induced by Genome Editing Using ddPCR. *J. Berman[1], Y. Miyaoka[2], S. Cooper[1], B. Zhang[1], A. Chan[2], S. Mayerl[2], G. Karlin-Neumann[1], B. Conklin[2].* 1) Digital Biology Center, Bio-Rad Laboratories, 5731 W. Las Positas Blvd, Pleasanton, CA 94588; 2) Gladstone Institute of Cardiovascular Disease, 1650 Owens St, San Francisco, CA 94158.

Genome editing tools such as TALENs and the CRISPR/Cas9 system have revolutionized our ability to edit genomes of any cell including human induced pluripotent stem cells (iPSCs). Sequence-specific nucleases induce double strand breaks or nicks at target sites, activating the DNA repair pathways of non-homologous end joining (NHEJ) or homology-directed repair (HDR). Through the production of small insertions or deletions, error-prone NHEJ is useful for disrupting gene function. However, for many applications, HDR is more desirable than NHEJ, since HDR utilizes homologous donor DNA to produce precise gene repair, while NHEJ causes unpredictable damage. Unfortunately, cell populations edited by HDR often contain alleles damaged by NHEJ. Since NHEJ and HDR involve different repair enzymes, it is conceivable that conditions could be achieved with high HDR and low NHEJ. To investigate conditions that favor HDR over NHEJ, we developed a rapid assay using droplet digital PCR (ddPCR) that sensitively quantifies both HDR and NHEJ at endogenous genomic loci. Combination of ddPCR and fluorescent oligonucleotide probes specific to wild-type, NHEJ, and HDR alleles allowed us to simultaneously detect NHEJ and HDR events induced by site-specific nucleases in a sensitive and quantitative manner. Using this method, we measured in human cells the relative contributions of HDR and NHEJ under multiple genome editing conditions including different types of sequence-specific nucleases and donor DNAs. We are currently optimizing mutagenesis conditions to activate HDR with minimum NHEJ in human iPSCs. Our system will result in significant improvements to genome editing technology.

1916T

Correcting a dysfunctional splicing site of the *HLA-DRB1* gene from CTD-2510D15 bacterial artificial chromosome (BAC) using the recombineering method. *K. C. Chen[1], P. L. Chen[1,2,3,4].* 1) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan; 2) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 3) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 4) Research Center for Developmental Biology and Regenerative Medicine, National Taiwan University, Taipei, Taiwan.

Site-directed mutagenesis is a common method used to change specific sequence of a gene in vectors. However, if the plasmids or bacterial artificial chromosomes (BACs) are too huge to be manipulated or ligated, it becomes challenging to accomplish site-directed mutagenesis. In 2005, Warming *et al*. (Nucleic Acids Res, 2005, 33(4): e36) reported a recombineering method, taking advantage of galK-base positive-negative selection system. Through, researchers can insert selectable or nonselectable maker and clone DNA fragments without using restriction enzymes. Here, we identified a dysfunctional splicing site at the beginning nucleotide of intron1 of *HLA-DRB1*08:03:02* derived from CTD-2510D15 BAC clone. We retrieved *HLA-DRB1*08:03:02* and flanking DNA fragments from CTD-2510D15 BAC and cloned the whole segment into a pL253 vector, resulting a 29 Kb plasmid. Through the galK-based positive-negative selection recombineering method, we successfully replace the critical single nucleotide. Our results showed that galK-base positive-negative selection method is a useful and efficient recombineering method to make a single nucleotide engineering.

1917F

Long range phasing of cardiac disease genes using new long read sequencing technologies. *A. Dainis[1], M. Wheeler[2], E. Tseng[3], J. Fu[3], A. Hendel[4], E. Ashley[1,2].* 1) Genetics, Stanford University, Stanford, CA; 2) Cardiovascular Medicine, Stanford University, Stanford, CA; 3) Pacific Biosciences, Menlo Park, CA; 4) Pediatrics, Stanford University, Stanford CA.

Phasing, the process of determining which variants are inherited together on the same allele, has traditionally required familial genetic information or multifaceted barcoding and computational strategies. With the advent of long read sequencing technologies, multiple SNPs can be captured in a single read from a single DNA molecule, permitting phasing with little bioinformatic intervention. We used long read technologies, including Pacific Biosciences SMRT Sequencing and Oxford Nanopore MinION Sequencing, to perform long range phasing of RNA transcripts and genomic loci of cardiac disease genes *MYH7* and *MYBPC3* from left ventricular human heart samples. We found that long read sequencing can be an efficient and effective method of haplotyping without additional family information. We present a streamlined analysis pipeline to turn sequencing data into VCF files for easy analysis and manipulation. We also found variability across sequencing strategies in phasing ability. Fast, efficient phasing of cardiac disease genes will provide information about disease haplotypes as well as uncover potential targets for allele-specific therapeutic strategies.

1918W

Development of a Target Capture-Based Multi-Gene Next Generation Sequencing Assay for Detection of Variants in Solid Tumors. *R. Kanchi Ravi, M. Panjikaran, T. Wang, I. Mitchell, Y. Xia, R. Tseng, A. Papoutsis, S. Gadient, C. Scott, G. Sims, J. Falk, A. Graber.* R&D Assay Development Commercial Ops Team, Genoptix, A Novartis Company, Carlsbad, CA.

Introduction: Next generation sequencing (NGS) is increasingly used in clinical laboratories as one of the most cost effective and robust methods to detect and identify single nucleotide variants (SNVs), insertions/deletions (InDels), copy number variations (CNVs) and translocations in cancer patient solid cancer samples. Amplicon-based NGS assays frequently only cover hotspot mutations and do not provide a lot of information on genomic alteration types such as CNVs and translocations. In this study we evaluate the development of a target capture-based multigene panel NGS assay in order to detect SNVs, InDels, CNVs, and translocations in clinical tissue samples. **Methods:** First we identified regions of interest for clinically relevant gene variants through comprehensive bioinformatic analysis and designed appropriate probe baits to capture actionable genomic alterations across 173 genes. The gene panel was validated with a target capture-based parallel NGS method developed at Genoptix, which used DNA/RNA isolated from characterized reference cell lines and formalin-fixed paraffin embedded (FFPE) tissue, and analyzed through custom built bioinformatic pipeline tools. Variants detected by the capture-based NGS assay were confirmed using the Ion AmpliSeq CHPV2 50 gene panel for SNVs, Nanostring nCounter® method for CNVs, and Oncomine Fusion Gene Panel® from Life Technologies for the structural variants/translocations. **Results:** Validation results support a minimum average sequencing depth of 500x coverage, a lower limit of detection (sensitivity) of 5% mutant alleles for SNVs and translocation fusions, 10% for insertions/deletions, and CNV detection (>6 copies for amplification and <0. 3 for gene deletions). The target capture-based NGS assay was tested using molecular standards, reference cell lines and FFPE tissue samples, achieving >95% accuracy for all variant calls. Variants detected by the NGS assay were successfully confirmed in independent confirmation tests for SNPs and InDels, CNVs and translocation fusions. **Conclusions:** Overall, this study provides thorough analytical validation of the 173-gene NGS panel and the analysis tools that can be used in a clinical laboratory for routine testing with the ability to sequence multiple patient samples including those with only small amounts of FFPE DNA. We also observed the assay to be specific and sensitive for SNV mutation analysis, InDels, CNVs, and translocations.

CancerDIRECT: Targeted enrichment of cancer-associated genes from FFPE samples. *K. Patel[1], B. Galvin[1], N. Henig[1], T. Davis[2], S. Russello[2], C. Hendrickson[2].* 1) Directed Genomics, Ipswich, MA; 2) New England Biolabs, Ipswich, MA.

Next generation sequencing is a robust platform for analysis of cancer genomes and an important tool for the diagnosis, prognosis and selection of therapeutics of this disease state. To further these applications, targeted enrichment of the most important cancer-related genes must be fast, simple and cost-effective for clinically relevant samples, such as FFPE, which are typically of low-input and extensively compromised. We have developed a novel target capture strategy that offers advantages over traditional in-solution hybridization and multiplex PCR protocols. Using our DIRECT target enrichment method, DNA fragments are rapidly hybridized to short probes that are captured by beads. The off-target sequence of the captured DNA, is removed via enzymatic digestion. The resulting targeted sequences are ligated to NGS platform specific adaptors and amplified by PCR. With the DIRECT method, genomic DNA can be converted into libraries ready for sequencing within 7 hours. To determine the efficacy of this methodology, we designed the CancerDIRECT panel to interrogate 50 genes commonly mutated in cancer, and tested it on FFPE samples. NGS analysis on libraries generated from these compromised samples, demonstrates that our approach captures targeted sequences with high specificity and uniformity, and detects variants with high accuracy and sensitivity.

1920F

Development of research genetics panel of 28 genes known to be associated with Primary Ciliary Dyskinesia (PCD) using Ion Torrent Technology. *M. A. Zariwala[1], M. W. Leigh[2], M. L. Daniels[3], W. E. Wolf[3], H. Dang[3], P. Mieczkowski[4], N. R. Schuch[4], A. Kraltcheva[5], D. Mazur[5], P. B. Vander Horn[5], M. R. Knowles[3].* 1) Marsico Lung Institute, Department of Pathology & Laboratory Medicine, University of North Carolina School of Medicine, Chapel Hill, NC 27599, USA; 2) Marsico Lung Institute, Department of Pediatrics, University of North Carolina School of Medicine, Chapel Hill, NC 27599, USA; 3) Marsico Lung Institute, Department of Medicine, University of North Carolina School of Medicine, Chapel Hill, NC 27599, USA; 4) High Throughput Sequencing Facility, Department of Genetics, University of North Carolina School of Medicine, Chapel Hill, NC 27599, USA; 5) Life Sciences Solutions, Thermo Fisher Scientific, Carlsbad, CA 92008, USA.

A defective ciliary structure, function or biogenesis leads to primary ciliary dyskinesia (PCD); a rare, recessive, genetically heterogeneous disorder. PCD diagnosis relies on identifying defective ciliary ultrastructure, and/or ciliary dysmotility/immotility, and/or clinical phenotype coupled to nasal nitric oxide measurements. Approximately, 30% of PCD cases do not have ultrastructural defects; thus, defining biallelic PCD-causing mutations is critical to aid diagnosis. Currently, mutations in 32 genes account for 2/3rds of all PCD cases. Development of a targeted gene panel with next generation sequencing assay for PCD may circumvent locus heterogeneity. A custom Ion AmpliSeq™ research panel was designed to sequence 28 (of the 32) PCD, plus 4 candidate genes using the Ion Torrent Personal Genome Machine (PGM™). A validation test-run included 15 cases with 28 known variants (7 base changes, 13 small indels, and a 220-kb deletion) across 14 genes. Twenty-four of 28 (86%) variants were called correctly, solving 12 of 15 (80%) cases by identifying biallelic mutations. Two (of 4) variants were missed due to amplification failure, 1 was missed due to its location (end of an amplicon), and 1 was 220-Kb deletion the panel was not designed to detect. The assay was refined as follows: Ion Library Equalizer™kit was used to normalize library input from different samples, 11 samples (instead of 20) were run on each 318™chip, and a list of 'hot spot' for known mutations was added to the Torrent Suite analysis pipeline to avoid missing known mutations. To discover mutations, 32 unrelated PCD cases with various ultrastructural defects were analyzed. The results revealed: 13 (41%) had two loss-of-function (LOF) mutations across 8 genes (*DNAI1*, *DNAH5*, *DNAH11*, *CCDC39*, *CCDC40*, *HYDIN*, *RSPH4A*, *SPAG1*); 6 (19%) had 1 LOF mutation and 1 rare missense variant across 4 genes (*DNAI1*, *DNAH5*, *DNAH11*, *DNAAF1*); 2 (6%) had two rare missense variants across 2 genes (*DNAH5*, *DNAAF3*); 4 (12%) had only 1 LOF mutation across 3 genes (*DNAH11*, *HYDIN*, *SPAG1*); and 7 (22%) cases were negative. In conclusions, biallelic variants in 21 (66%) of 32 PCD cases were identified using Ion AmpliSeq™ panel; thus, the panel is useful for the test translation into the lab. Additionally, the 11 (34%) negative cases will be useful for novel discoveries and large deletion/duplication analysis. This abstract was funded by 5U54HL096458-06 (NIH/ORDR/NHLBI), 5R01HL071798 (NIH/NHLBI), and UL1 TR000083 (NIH/NCATS).

Clinical Whole Exome Sequencing from Dried Blood Spot Identifies Novel Genetic Defect Underlying Asparagine Synthetase Deficiency. *A. Abhyankar[1], M. Lamendola-Essel[1], K. Brennan[2], C. Esteves[1], V. Felice[1], R. Wapner[2], V. Jobanputra[1].* 1) Molecular Diagnostics, New York Genome Center, New York, NY; 2) Department of Obstetrics & Gynecology, Columbia University, New York.

Purpose: Dried blood spots (DBS) are collected worldwide as part of neonatal screening programs and can prove invaluable in investigating etiologies underlying rare and common genetic disorders. We show that DNA isolated from archived DBS can be used to perform clinical-grade whole exome sequencing (WES) with accuracy comparable to similar assays performed using DNA extracted from whole blood. **Methods:** We received archived DBS for a premature baby delivered at 32 weeks of gestation, presenting with clonus tremors shortly after birth, microcephaly, blindness and seizures. The baby passed away at 15 months of age because of respiratory problems/seizures. DNA was isolated from DBS using Extract-N-Amp Blood PCR kit (Sigma). Whole genome amplification was performed in duplicate using the Repli-g Amplification kit (Qiagen). Peripheral blood drawn from both parents was used to isolate DNA. Library preparation was performed using SureSelectXT Human All Exon V5+UTR kit (Agilent). Paired-end WES was performed on the HiSeq 2500 (Illumina). Data was analyzed using in-house developed bioinformatics pipeline. **Results:** Exome sequencing performed on DNA obtained from DBS and parents identified Gly283Glu and Val160Ala compound heterozygous variants in *ASNS* gene. Parental studies demonstrated that the Gly238Glu variant was maternally inherited and the Val160Ala variant was paternally inherited. Computational tools predicted the amino acid changes Gly283Glu and Val160Ala to be damaging and deleterious (SIFT and Polyphen; CADD scores of 27. 1 and 20. 7 respectively). The Gly283Glu variant has not been reported in large public data sets (1000 Genomes Project and NHLBI GO Exome Sequencing Project). The Val160Ala is a rare variant, reported at frequency of 0. 0002 in the 1000 Genomes Project with no homozygous G/G genotype reported. Identified variants in the *ASNS* gene are considered likely pathogenic and explain the clinical phenotype. **Conclusion:** We report novel compound heterozygous variants underlying Asparagine Synthetase Deficiency and that DNA isolated from DBS stored for several years can be used to perform accurate clinical WES assays.

1922T

Sherloc: Evaluation of a Scalable Score-based Implementation of the ACMG 2015 Clinical Variant Interpretation Guidelines. *M. Anderson, K. Nykamp, S. Yang, Y. Kobayashi, M. Powers, S. Lincoln, S. Topper, Invitae Clinical Genomics Group.* Invitae, San Francisco, CA.

Recently, the American College of Medical Genetics (ACMG) published updated guidelines for the interpretation of sequence variants (ISV) with an evidence checklist and rules for combining evidence (Richards *et al.* , *Genet Med* 2015). While these guidelines represent a significant step forward in the standardization of variant classification across clinical laboratories, they are a general framework and require each laboratory to establish more specific procedures for their particular clinical setting. Moreover, the impact of these guidelines has not yet been thoroughly established in the literature. Using the draft ISV checklist (August 2013) as a starting point, we developed a weighted, score-based classification system designed to be scalable across a large clinical variant interpretation team. This system, called Sherloc, has been iteratively revised 4 times based on our experience interpreting more than 11,000 variants. These revisions increased the number of criteria from 22 to 87 in order to explicitly handle evidence details not directly addressed by the ISV guidelines. We also adjusted thresholds to improve classifications, created rules to properly account for redundant and conflicting evidence, and added extensive usage notes to increase consistency. To assess the concordance of Sherloc with current community standards, we compared Sherloc classifications of over 800 variants to a consensus classification derived from ClinVar entries with multiple submitters. We find that Sherloc interpretations are often (92. 2%) in the consensus majority, indeed more so than other ClinVar submissions when benchmarked equivalently (85. 7%). Most differences with ClinVar were not clinically impactful (e. g. , between likely benign and benign). We also find Sherloc to be highly reproducible across different team members when providing independent interpretations. By contrast, interpretations based on strict adherence to the ISV criteria have lower agreement with the community consensus (61%) and a higher VUS rate. We find Sherloc to be highly adaptable, efficient, and consistent across multiple disease areas and a large variant interpretation team. This score-based classification system adheres to the ISV guidelines, but also illustrates the specific application and evolution of the ACMG ISV criteria in a clinical molecular laboratory. We are in the process of publishing and releasing Sherloc for community feedback and in the hope that it may be useful to others.

1923F

Development of Next Generation Sequencing Based Genetic Diagnosis and Screening Panel for Hereditary Periodic Fever Syndromes. *T. Avsar[1,2], C. Holyavkin[1,2], N. Saygili[1,3], E. Yilmaz[1,3], M. Öztürk[1], E. Keleş[1], I. V. Bodur[1].* 1) R&D Department, Done Genetics and Bioinformatics, Istanbul, Turkey; 2) Istanbul Technical University, Molecular Biology, Genetics and Biotechnology Program, Istanbul, Turkey; 3) Istanbul Universty, Institute of Experimental Medicine, Istanbul, Turkey.

The hereditary periodic fever syndromes (HPFS) refer to a unique and complex disease group with hereditary genetic defects and periodic clinical symptoms. The prototypic and probably most common HPFS is Familial Mediterranean Fever (FMF) that is common in Turkey and other Mediterranean countries. Currently there are more than 20 HPFS diseases, some are rare and some are common in different populations. Diagnosis and prognosis of HPFS diseases differ based on the clinical manifestations and genetic mutations. An accurate genetic diagnosis will reduce the number of patients who having non specific treatments and living without a correct diagnosis. The aim of this study was to develop a next generation sequencing based genetic test for HPFS related 9 genes and validate them. To this aim, amplicons targeting 9 related genes were designed for all exons, some introns, exon-intron boundary and UTR regions. Primers were designed for long-PCR applications and, in silico analysis were performed in order to develop 7 multiplex PCR for 32 amplicons. Following library preperation, adapter and index tagmentation of PCR fragments were performed via in house designed oligos suitable for Illumina NGS systems. 120 previoulsy diagnosed HPFS samples were studied by using in house developed test. Results revealed common and shared genetic variants associated with HPFS (Table 1). Sensitivity, specificity, accuracy, positive/negative predictive values of the test were given in Table 2. The mean covarages of each genes were above 220X readings. The diagnostic yield of the tested samples were approximately 80%. Furthermore frequency of known SNPs were also compared in our Turkish sample cohort and it was shown that some rare phenotypes in different populations common in Turkish population and significantly associated with the disease phenotypes. Selected SNPs were confirmed by using Sanger sequencing. Additionaly, we developed a standardized bioinformatic analysis pipeline using Galaxy web server specific for HPFS panel. This strategy also facilitates the development of additional disorder-specific gene panels with the same standardized workflow. We evaluated the performance characteristics sequencing workflow, and found high reproducibility and accuracy, with 100% detection of HPFS genetic variants in our validation samples. We also explore the advantages and technical challenges of this strategy to further develop clinically relevant gene panels for genetically complex disorders.

1924W

A custom-designed next generation sequencing panel detecting extremely low-level mosaic mutations in overgrowth syndromes. *F. Chang[1], L. Liu[2], E. Fang[2], G. Zhang[2], T. Chen[2], M. M. Li[1].* 1) Pathology and Laboratory Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Overgrowth syndromes are genetically heterogeneous diseases caused by germline or postzygotic somatic mutations of different genes. Recent studies have shown that a group of mosaic overgrowth syndromes, such as congenital lipomatous overgrowth with vascular, epidermal, and skeletal anomalies (CLOVES), Proteus syndromes, and two overlapping disorders, megalencephaly-polymicrogyria-polydactyly-hydrocephalus (MPPH) and megalencephaly-capillary malformation (MCAP), are caused by somatic activating mutations in the genes involved in the PI3K-AKT signaling pathway. Due to the mosaic nature of these mutations, routine Sanger sequencing often yields negative results. We have developed a next generation sequencing (NGS) panel that covers all known mutations associated with these overgrowth syndromes in multiple genes involved in the PI3K-AKT pathway. Thirty three cases including two prenatal cases and thirty one postnatal cases suspected of overgrowth syndromes were tested using the NGS sequencing panel. Seventeen of the 33 cases showed activating mutations in PIK3CA with mutant allele frequencies ranging from 1. 5% to 49. 2%. The mutations were predominantly located in the kinase domain (10/17) followed by helical domain (4/17) similar to the mutation distribution reported in cancers. These PIK3CA mutations were only present in affected tissues in the majority of the cases demonstrating causal role of the mutation. In vitro cell culture showed significant enrichment of the cells harboring mutant alleles, suggesting that the activating mutation renders growth advantages to the mutant cells both in vivo and in vitro. Preliminary phenotype-genotype correlation analysis showed that mutations at residue 1047 are often associated with CLOVES syndrome while G914R mutation is preferentially seen in MPPH/MCAP. Our experience demonstrates that NGS technology is highly sensitive for the detection of low-level mosaic mutations and can be used for the diagnosis of these mosaic overgrowth syndromes in both prenatal and postnatal settings.

Analysis of sample multiplexing in massively parallel sequencing of the human clinical exome. *J. Devaney, B. Meltzer, K. Cusmano-Ozog, J. Campos, S. Hofherr.* Laboratory Medicine, Children's Natl Health System, Washington, DC.

The quality of data from massively parallel sequencing (MPS) can be affected by DNA quality. Another factor that can affect the quality of a MPS analyses is the number of samples that can be pooled in a sequencing run while achieving the desired coverage level. Our lab sought to optimize the number of samples that can be studied on a run an MPS system using the human clinical exome that consists of ~ 4800 genes. Genomic DNA was purified from peripheral blood using standard extraction conditions as recommended by the EZ1 DNA Kit (Qiagen) using an EZ1 Advanced XL. The MPS was completed using the TruSight One panel (4,813 genes) on a NextSeq 500 (Illumina). To find an optimized number of samples that can be multiplexed in each run, we examined the percent Qscore > 30, mean coverage depth, percent target coverage at 20X, confirmation of known variants determined by sequencing at reference labs, and the number of fragments under 20X coverage. We analyzed 48, 36, and 24 samples using a high output chip and 15, 12, and 9 samples using a mid-output chip on a NextSeq 500. The concentration of our library for all analysis was 0. 8 pm. The TruSight One (TSO) panel discovers around 8000 variants in the NA12878 (Genome in a Bottle) with over 99% present in the dbSNP141 database and typically discovers around 150 insertions with 88% in dbSNP and 210 deletions with about 78% appearing in dbSNP. We found that the Qscore > 30 was the same across all the runs. The mean coverage increased as the number of multiplexed samples decreased going form 80X to 151X on the high output chip while on the mid output chip went from 91X to 133X on the mid output chip. The percent target coverage at 20X went from 93. 6% (48 samples) to 97. 3% (24 samples) using the high output chip and from 94. 6% (15 samples) to 97. 3% (9 samples) with the mid output chip. For all the samples, we were able to confirm the known variants (SNVs and indels). Finally, we saw the number of fragments with coverage less than 20X drop from 2. 0% (1249 fragments; 48 samples) to 0. 8% (496 fragments; 24 samples). We were able to confirm all variants from reference labs in the samples regardless of the multiplexing level. Interestingly, the percent duplicate paired reads increased as the number of samples multiplexed decreased. In our lab, the optimal multiplexing of TSO panel samples is 24 for a high output chip and 9 for a mid output chip with analysis using a Nextseq 500.

1926F

Augmenting clinical exomes with low pass genome sequence to identify copy number variation. *M. O. Dorschner, M. A. Weaver, E. A. Phillips, M. B. Dauer, D. S. Hanna, C. J. Hale.* Center for Precision Diagnostics, Department of Pathology, University of Washington, Seattle, WA.

Clinical exome sequencing is rapidly being applied to the molecular diagnosis of human genetic disease. While exome sequencing has several advantages over small gene panels or even genome sequencing, it is not effective at identifying copy number variants (CNVs). Algorithms designed to detect CNVs from read depth or split read mapping do not provide adequate sensitivity or specificity for clinical testing. We recently launched an exome-based assay for the diagnosis of dementia, Parkinson's disease and amyotrophic lateral sclerosis. Several genes, including *PARK2* and *SNCA* frequently undergo genomic rearrangement. Rather than concurrently, or reflexively running a deletion/duplication array to detect potential rearrangements, we decided to evaluate the addition of low pass genome sequencing to exome data. We initially sequenced eight samples carrying known CNVs to a read depth of 8X. Six samples possessed CNVs in *PARK2* and two in *SNCA*. All CNVs, ranging from single- to multi-exon deletions, as well as whole gene duplication and triplication of *SNCA*were detected. To determine the lowest genome coverage that could be applied to the detection of these CNVs, we subsampled the 8X genome data down to 1X . At 1X, all CNVs were confirmed. We recently applied this approach to the molecular diagnosis of an early onset Parkinson's patient. This patient possessed a 40 base deletion in exon 3 of one *PARK2* allele, which appeared homozygous. Knowing that exons in this region of *PARK2* are commonly deleted or duplicated, we suspected an overlapping deletion of the remaining allele. Low pass sequence data of this patient's genome revealed a 175kb deletion, encompassing exons 3 and 4 of the other allele. Additional studies to investigate a broader range of CNV sizes, and sequence depths are under way to determine the sensitivity of combined low pass genome and exome sequencing. Low pass genome data represents a potential, cost effective method for expanding the sensitivity of exome sequencing and the scope of detectable disease-causing variants.

1927W

Multi-ethnic *APOL1* G1 and G2 allele frequencies and clinical validation of a personalized medicine *APOL1* genotyping assay for non-diabetic chronic kidney disease risk assessment. *A. M. Fedick[1], J. Zhang[1,2], G. Zhao[1], L. Edelmann[1], E. P. Bottinger[3], R. Kornreich[1], S. A. Scott[1].* 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.

The incidence of chronic kidney disease (CKD) significantly varies by ancestry and ethnicity, with African Americans (AAs) having a three to four-fold higher rate than European Americans (EAs). In addition to environmental causes, genetic studies have revealed that variant alleles in the apolipoprotein L1 (*APOL1*) gene, termed G1 (c. [1072A>G;1200T>G]) and G2 (c. 1212_1217del6), are strongly associated with increased risks for hypertensive end stage renal disease (ESRD), focal segmental glomerulosclerosis, HIV-associated nephropathy, and higher rates of non-diabetic CKD in the AA population. These data have prompted the implementation of *APOL1* genetic testing to identify at-risk AA patients for counseling to modify other risk factors (e. g. , hypertension) in an effort to reduce the progression of CKD to ESRD. To facilitate this personalized medicine program, a targeted *APOL1* genotyping assay was developed based on multiplex allele-specific primer extension using the Luminex platform. The *APOL1* genotyping assay was clinically validated using 58 positive and negative control samples, which resulted in complete concordance between genotyping and Sanger sequencing, suggesting a test sensitivity and specificity approaching 100%. The *APOL1* genotyping assay was found to be very robust, as both triplicate inter- and intra-run reproducibility testing results were completely concordant. To determine the *APOL1* G1 and G2 allele frequencies of the multi-ethnic population from the New York City metropolitan area, 7462 DNA samples (5463 AA, 1148 Hispanic, and 460 Asian) were subjected to genotyping. The *APOL1* G1 and G2 allele frequencies were 0. 22 and 0. 13, 0. 037 and 0. 025, and 0. 013 and 0. 004 for the AA, Hispanic, and Asian populations, respectively. Importantly, approximately 14%, 7%, and 3% of AA, Hispanic, and Asian individuals, respectively, carried two of the G1 and/or G2 alleles and are at elevated risk for developing CKD. Taken together, this novel *APOL1* G1 and G2 genotyping assay is robust and highly accurate, and represents one of the first personalized medicine clinical genetic tests beyond the currently available clinical pharmacogenetic assays.

1928T

To Confirm or Not Confirm, That is the Question: A Rigorous Approach to Evaluating the Importance of Sanger Confirmation of Clinical NGS Findings. *S. Lincoln[1], B. Funke[2,3], J. Zook[4], S. Yang[1], D. Watson[1], M. Bowser[3], S. Aradhya[1], S. Kulkarni[5], H. Rehm[2,3].* 1) InVitae, San Francisco, CA; 2) Department of Pathology, Harvard Medical School, Boston, MA; 3) Laboratory for Molecular Medicine, Cambridge, MA; 4) National Institute for Standards and Technology, Gaithersburg, MD; 5) Washington University, Saint Louis, MO.

Clinical next-generation sequencing (NGS) is becoming an established diagnostic tool. Because test results can influence significant medical decisions, many labs rule out false positive calls by confirming variants with an orthogonal method such as Sanger sequencing. The collective experience of many laboratories doing so is that the great majority of NGS calls indeed confirm, and therefore the need to broadly apply orthogonal confirmation has been questioned. However, identifying the highest confidence NGS calls and quantifying the degree of confidence in these calls can be challenging. Our cross-laboratory collaboration has developed a framework for addressing this challenge which can be used with different assay targets, NGS protocols, bioinformatics algorithms, and QC criteria. In brief, our framework involves: (1) assembling confirmation data from each laboratory across clinical and reference samples, (2) determining laboratory-specific QC thresholds for classes of variants [KT1]that each data set adequately describes, and (3) using proper statistical metrics to quantify the accuracy of variant calls that meet these thresholds. We use multiple thresholds: a strict tier, over which the likelihood of a false positive is exceedingly low, and a lower tier established to ensure sensitivity. Reported variants from the lower tier would need orthogonal confirmation while confirmation of the higher-tier variants may depend on clinical factors or operational criteria. To date, we have applied this framework to data from four laboratories. For example, in one dataset for 184genes in an NGS panel, 3082 variants were assembled as a complete and representative set of calls that (a) met that lab's top-tier QC criteria (e. g. , read depth and other factors), and (b) had high-quality orthogonal data available. All 3082 were confirmed as true positives. Further bioinformatic analysis identified a subset of 2394 with homogeneous properties in terms of genomic context, variant types and local sequence properties. The observed analytic false-discovery rate (FDR) for the 2394 remained 0. 0% and statistically these data demonstrate an FDR of at most ~0. 1% for such variant calls (at p=0. 05). Our framework is the first to combine data across labs to help evaluate the value of confirmation and determine the appropriate burden of proof needed potentially change practice. We believe these results and this framework can contribute to the ongoing community dialog on this subject.

1929F

Classification of truncating variants in the 3' end of genes requires a detailed analysis of C-terminal protein structure and function. *C. Perreault-Micale, K. Robinson, V. Greger.* Good Start Genetics, Cambridge, MA.

Truncating variants that introduce premature stop codons (nonsense variants and insertions/deletions causing a frameshift) or disrupt canonical splice sites (positions +/- 1 or 2) are generally considered to lead to loss of gene function. However, truncating variants that are near the 3' end of a gene may escape nonsense-mediated decay (NMD) and produce a protein that is at least partially functional. Genome-wide assessments typically use the last 5-10% of genes as a rough cut-off for pathogenicity due to NMD (i. e. , only truncating variants in the upstream 90-95% of the gene are considered pathogenic). However, a more detailed approach is required for the analysis of specific genes. Our goal was to assign gene-specific 3' cut-offs after which truncating variants should not be considered pathogenic for the purpose of genetic carrier screening. We performed an analysis of the C-terminal protein structure and function using information available, and also considered the last known truncating pathogenic variant reported in a patient, for 15 genes underlying severe autosomal recessive disorders in which loss of function is a known disease mechanism. Our results indicate that using a 3' cut-off of 5-10% for truncating variant pathogenicity is not the most accurate approach because it can lead both to pathogenic variants being missed, and to likely benign variants being mischaracterized as pathogenic. For example, in HEXA (Tay-Sachs disease) there is a crucial disulfide bond at p. Cys522 (7 amino acids from C-terminal end). Thus, biochemical and structural evidence, and the fact that this is a highly conserved residue, indicate variants affecting the extreme C-terminus of HEXA should be considered pathogenic. In BCKDHA (MSUD, type A) p. Tyr438 (7 amino acids from C-terminal end) is needed for proper complex assembly. In DLD (dihydrolipoamide dehydrogenase deficiency) regions up to p. Glu492 (17 amino acids from C-terminal end) correspond to important oxidoreductase and dimerization domains. Conversely, the high incidence of truncating variants in the cytoplasmic domain of PCDH15 (Usher syndrome, type 1F), which makes up nearly one-third of the gene, suggests they are unlikely to cause disease, possibly due to redundant isoforms. In *PCDH15*, many truncating variants are not necessarily loss of function variants. Thus, analysis of truncating variants in the 3' end of genes should be done in a gene-specific manner to improve variant classification.

1930W

Clinical validation of a NGS based in vitro diagnostic (CE-IVD) kit for targeted detection of actionable gene rearrangements in lung cancer specimens. *J. Schageman[1], J. Costa[2], O. Sheils[3], J. Glassco[4], D. Chi[4], J. Cooc[4], E. Ballesteros-Villagrana[1], R. Petraroli[1], J. Sherlock[1], J. Bishop[1], K. Bramlett[1].* 1) Thermo Fisher Scientific, , UK, Italy, Netherlands, USA; 2) Institute of Molecular Pathology and Immunology, University of Porto, Porto Portugal,; 3) Sir Patrick Dun Research Laboratory, St. James Hospital, Dublin, Ireland; 4) Life Technologies Clinical Services Lab, West Sacramento, CA USA.

In recent years, advances in next-generation sequencing (NGS) technologies have enabled faster and cheaper methods for uncovering the genetic basis of disease. For cancer, NGS based screening for known tumour subtypes can inform diagnosis and allow the clinician to tailor a specific therapy based on testing outcome. Here we present the validation of one such NGS based kit approved for CE-IVD* use to screen for specific chromosomal translocations in non-small cell lung cancer (NSCLC) samples by targeting specific breakpoints in known fusion transcripts.

The kit tested (Oncomine™ Solid Tumour Fusion Transcript Kit) included a single primer pool containing amplicon designs to simultaneously screen for over 75 specific rearrangements involving the receptor tyrosine kinase (RTK) genes ALK, RET and ROS1 as well as NTRK1. The panel was compatible with formalin-fixed paraffin-embedded (FFPE) lung tumour samples and achieved high-sensitivity down to 10 ng of RNA input. In addition, amplicon assays designed at the 5' and 3' ends the RTK genes provide non-specific evidence that a translocation exists in a sample by comparing expression imbalance between the two ends.

Validation testing was carried out at three external clinical laboratories (CLIA, CAP, INAB). In addition to positive and negative control samples, each site contributed FFPE lung tumour samples for which ALK fusion status was known prior to NGS library preparation carried out using the Ion AmpliSeq™ workflow. For site-specific samples (n=144, 16 samples per sequencing run), high concordance, sensitivity and specificity were measured at 97. 2%, 90. 5% and 98. 4%, respectively. Validation testing was carried out both in the United States and Europe and this kit isCE marked and registered in accordance with the European*in vitro* Diagnostic Medical Devices Directive (IVDD) (98/79/EC).

Non-ceruloplasmin-copper involvement in Alzheimer's disease and Mild Cognitive Impairment. *R. Squitti[1], M. C. Ventriglia[1], M. Cortesi[2], F. Papa[2], C. Vaccarella[2], M. B. Majolini[2], M. CA. Rongioletti[2].* 1) Department of Neuroscience -AFAR division, San Giovanni Calibita Hospital, Rome, Italy; 2) Clinical Patholgy Department, San Giovanni Calibita Hospital, Rome, Italy.

Numerous studies indicate a specific role of copper in aging and in Alzheimer's disease (AD) mechanisms. Specifically, it has been proposed that the hypermetallation of the Abeta peptide, which forms plaques in the AD brain, can be at the basis of redox cycles of oxidative stress, toxicity, Abeta oligomer formation and precipitation (reviewed in Squitti and Polimanti, 2013). We have contributed to this topic demonstrating in living AD patients that an increase in the serum copper fraction that does not bind to ceruloplasmin (Non-Cp-Cu) correlates with the AD typical deficits (Squitti, et al. , Neurol 2002, 2005), cerebrospinal fluid (CSF) markers of AD (Squitti et al. , Neurol 2006), and with a worse prognosis for of the disease (Squitti et al. , Neurol 2009). Furthermore, we have shown that loci of susceptibility for AD lie in genes pertinent to copper metabolism (Squitti et al. , 2013; Bucossi et al. , 2012; Squitti and Polimanti 2013, Bucossi etal J Alzh Dis 2013), in particular in the *ATP7B* gene, which codes for the ATP7B-pump controlling copper excretion through the bile and ceruloplasmin biosynthesis. Moreover, we have demonstrated that copper and non-Cp-cu levels are higher in AD patients vs. healthy controls by means of meta-analyses (Squitti et al. , J Alzh Dis 2014). Non-Cp-Cu helps in properly classifying subjects with Mild Cognitive Impairment (MCI) from healthy ones (Squitti et al. , J Alzh Dis 2011) and provides prognostic information about the conversion to full AD (Squitti et al. , Ann Neurol 2014). We have recently developed a patented devise to directly measure serum Non-Cp-Cu [Colabufo, N. and R. Squitti, P. E. European Patent Office (EPO) (RO/EP), 2012], highly reliable.

1932F

Whole Exome Sequencing for Molecular Diagnosis of Chinese Patients with Rare Genetic Disorders. *J. Wang[1], Z. Wang[1], L. Yin[1], X. Huang[1], T. Yu[1], R. Yao[1], J. Geng[1], N. Li[1], Y. Qing[1], X. Wang[2], Q. Fu[1], Y. Shen[1,3], Rare Diseases Collaboration in Shanghai Children's Medical Center.* 1) Molecular Diagnostic Center, Shanghai Children's Medical Center, Shanghai, Shanghai, China; 2) Guizhou Provincial People's Hospital, Guiyang, China; 3) Boston Children's Hospital, Boston, MA, USA.

Background: Over 7000 genetic disorders have been reported in Online Mendelian Inheritance in Man (OMIM). Most of them are rare and often difficult to be recognized and diagnosed at clinics in a timely manner. Whole exome sequencing (WES) has increasingly been utilized both as a disease gene discovery tool and a molecular diagnostic tool for rare genetic diseases. We set to evaluate the technical and clinical validity of WES as a diagnostic tool in a rare and complex disease clinic of a tertiary pediatric hospital in China. **Methods:** (1) We established the workflow of a WES test including SureSelect exome target capture and library construction, high-throughput sequencing with Illumina Hi-Seq or Mi-seq platforms, data analysis and variant processing with NextGENe® software and Ingenuity Variant Analysis online tool. (2) 72 children with various rare conditions of suspected genetic basis were selected for WES testing. We used Sanger sequencing for confirming candidate variants in proband. Additional family members were Sanger sequenced for the variants for co-segregation analysis. **Results:** (1) More than 99% of targeted regions were successfully captured and aligned to reference human genome. > 70% of total reads were within targeted regions using Agilent SureSelect V5 kit. >92% of targeted regions had >20X coverage when the medium coverage for the whole exome reached 100X. (2) We identified 47 pathogenic variations in 38 of the 72 patients, achieving a 52. 78% molecular diagnostic rate. Among the 38 patients, 24 had autosomal dominant disease, 9 had autosomal recessive disease, and 5 had X-linked disease. Of the 47 pathogenic variations, 22 were novel variants, 6 were *de novo*. 23 genes such as *ATP6V0A4, BMPR2, CPS1, CYP11B2, EDA, GORAB, KRT1, LGI1, MAP2K1, MYBPC3, MYH7, NR5A1, PDGFRB, PHEX, PLA2G6, PTHLH, SLC45A2, SMC1A, TRAPPC11, WT1* were involved with the diseases. **Conclusion:** We established a complete WES process from clinical ascertainment to variant confirmation and segregation analysis. We are able to achieve a high diagnostic yield (~53%) for the selected Chinese pediatric patients from the clinic. The time to reach a molecular diagnosis for patient is on average 28 days, with a material cost of $500 per case. The data support the utilization of WES as an effective diagnostic approach for patients with rare genetic disorders.

1933W

Strategies for calculating variant confidence by combining sequencing results. *N. Chennagiri, D. Lieber, T. Yu, J. Thompson.* Claritas Genomics, Cambridge, MA.

Based on the American College of Medical Genetics guidelines, clinical laboratories using High Throughput Sequencing Technology (HTS) should confirm all variants they report using an orthogonal technology, with many using Sanger sequencing. As whole exome sequencing becomes increasingly popular and reveals thousands of variants per run, clinical laboratories using whole genome technologies are faced with having to confirm a large number of variants which increases cost and turnaround time. At Claritas Genomics, we have developed an approach that uses an orthogonal technology and minimizes the need for Sanger sequencing. We sequence a sample using two HTSs – Illumina NextSeq and Ion Torrent Proton. We have developed methods to combine the two calls into a consensus call and assign confidence levels. We assign levels of confidence based on Positive Predictive Value (PPV) of the consensus calls calculated using NA12878 NIST reference dataset. About 85% of the total calls are concordant between the two technologies and are assigned the highest level of confidence - Orthogonally confirmed. The calculated PPV for such variants is 100%. These variants can be reported immediately without additional Sanger sequencing. Other variants are assigned lower confidence levels based on their PPV such as likely true positives or likely false positives and, if appropriate, can be Sanger confirmed or dropped from consideration if irrelevant to the phenotype being examined. The confidence levels provide a method for prioritizing variants to confirm and minimizing variants needing Sanger sequencing thereby significantly reducing turnaround time.

1934T

***CLIP-Cap*: *C*ombined *L*ong-*I*nsert *P*aired-End and *Cap*ture Sequencing for precise and comprehensive analysis of complex genomic rearrangements.** *C. Purmann[1,2], J. Hallmayer[1], J. Bernstein[3], A. E. Urban[1,2].* 1) Department of Psychiatry & Behavioral Sciences, Stanford University, Palo Alto, CA; 2) Department of Genetics, Stanford University, Palo Alto, CA; 3) Department of Pediatrics, Stanford University, Palo Alto, CA.

Currently, the study of complex genomic rearrangements requires several complementary yet disparate assays to characterize the exact nature of the rearrangement. Techniques that can reduce the number of experiments while achieving more accurate identification are highly sought after. Toward this aim, we have developed a method that combines Long-Insert Paired-End Sequencing and chromosome-wide targeted capture into one experimental workflow. This new genomic tool enables the resolution of complex genomic rearrangements in a single assay. For proof-of-principle, we analyzed a Phelan-McDermid patient with a complex and mosaic rearrangement on chromosome 22q13. A combination of four different assays – karyotyping, high-density microarray, fluorescence in situ hybridization (FISH), and digital droplet PCR from multiple subcloned cell lines - had revealed the presence of three different cell populations in the patient sample. Half of the patient cells carried a heterozygous terminal 22q13. 3 deletion. The other half of the cells was split into further two subgroups, both showing the presence of an isodicentric chromosome 22, but with two different breakpoints. CLIP-Cap, using an oligomer capture-design representing all of chromosome 22q, and a single sequencing run on an Illumina MiSeq instrument (2x300 nt and ~10M mappable PE-reads) allowed us to completely resolve this complex genotype with a single procedure, including determining the heterozygous terminal 22q13. 3 deletion and the different isodicentric breakpoints. We have been applying CLIP-Cap to additional cases from both patients with developmental abnormalities and cancer. Here, we present CLIP-Cap as a novel and widely applicable technology to resolve complex chromosomal abnormalities at highest resolution and with procedural and cost requirements that are comparable to, or an improvement on, current less highly resolving approaches.

1935F

Next-generation sequencing-based genetic testing of malignant hyperthermia. *H. Yeh[1], M. Liao[2], W. Yang[3,4], P. Chen[2,3,4].* 1) Department of Anesthesiology, National Taiwan University Hospital, Taipei, Select a Country; 2) Department of Medical Genetics, National Taiwan University Hospital, Taipei 100, Taiwan; 3) Graduate Institute of Medical Genomics and Proteomics, College of Medicine, National Taiwan University, Taipei 100, Taiwan; 4) Graduate Institute of Clinical Medicine, College of Medicine, National Taiwan University, Taipei 100, Taiwan.

Malignant hyperthermia (MH), also known as malignant hyperpyrexia, is a potentially fatal pharmacogenetic disorder triggered by certain drugs used for general anesthesia, such as inhalation anesthetics and/or succinylcholine. In susceptible individuals, these medications can induce skeletal muscle calcium regulation abnormality, and subsequent uncontrolled skeletal muscle hypermetabolism, which overwhelms the body's capacity to regulate body temperature and eventually leads to circulatory collapse and death if not treated quickly. Its unpredictability and high mortality make MH a disease urgently needing a predicting tool, such as a reliable, cost-effective genetic diagnostic test. Up to now, two known genes and at least 4 other loci can cause malignant hyperthermia, and as a whole only account for proximately 50-70% of cases. To make the situation more troublesome, the known causative genes, *RYR1* and *CACNA1S*, are both huge with numerous exons, which pose severe difficulties for genetic testing using traditional technology. Next-generation sequencing (NGS) for research and for clinical applications is revolutionizing genetics in recent years, and in this study we applied NGS to genetic testing of MH. We designed a capture-based targeted enrichment panel using the Roche NimbleGen SeqCap EZ Choice library covering the *RYR1* gene (chr19:38,924,340-39,078,204, hg19) and the *CACNA1S* gene (chr1:201,008,640-201,081,694, hg19). Data cleaning, filtering, analysis and verification were performed using BWA, SAMtools, Picard, GATK, ANNOVAR and IGV. Sanger sequencing was used for confirmation. Six clinically diagnosed MH patients were tested, and we identified the causative variants for four (66. 7%) of them. The identified causative *RYR1* variants were c. 7373G>A (p. R2458H) (two MH patients), c. 7304G>A (p. R2435H) and c. 6502G>A (p. V2168M), respectively. Four additional individuals (two with osteogenesis imperfecta and one with muscular dystrophy with complicated anesthesia courses, and one normal control) were also tested, and none of them carried potential causative variants at *RYR1* or *CACNA1S*. For those two MH cases without identifiable causative variants by the NGS-based test, we performed Sanger sequencing covering the coding regions of *RYR1* and *CACNA1S* to make sure that no variant was missed. In conclusion, the NGS-based method provides a sensitive, reliable, fast and inexpensive genetic diagnostic platform for MH genetic testing.

1936W

An integrated method for extraction of high-molecular-weight DNA and preparation of genomic sequencing libraries using agarose gels. *C. Boles, E. S. Abrams, D. Yun, T. Barbera.* Sage Science Inc. , Beverly, MA.

Purpose: Several new DNA sequencing methods can provide read lengths greater than 10,000 base pairs (bp). This trend has motivated researchers to reevaluate standard DNA sample prep methods which usually produce genomic DNA fragments of only up to 50,000 bp in length. To this end, we have developed a new workflow and equipment for rapid purification of high-molecular-weight (HMW) DNA (>50,000 bp) from whole blood and cell suspensions. The system can also be adapted to perform both DNA extraction and transposase-mediated sequencing library preparation in a fully integrated, automated process. **Methods:** Our method is loosely based on the original agarose-based sample preparation method of Schwartz and Cantor (1984). We embed cell suspensions in agarose, followed by lysis and enzymatic processing steps which are carried out in the sample-embedded gel. However, we dramatically accelerate the process by using electrophoresis to remove contaminants, and to exchange DNA processing reagents. Electrophoretic processing is enabled by the fact that the genomic DNA produced in our process is many megabases (mb) in size, and cannot be electrophoresed out of the sample gel. After purification and processing, the DNA is lightly and randomly cleaved with a non-specific nuclease, allowing the processed DNA sample to be electroeluted from the gel into a liquid-filled elution chamber. **Summary of Results:** Genomic DNA from whole mammalian blood can be electrophoretically purified in less than 30 minutes. Several random cleavases can be used to release the HMW DNA from the sample gel. Depending on the fragmentation conditions used, it is possible to recover purified HMW DNA fragments ranging from 50,000bp to 800,000bp in size. In addition, the post-fragmentation electroelution process can be used to perform size selection on the DNA products. Finally, we show that transposasome complexes carrying sequencing adapters can be used for the fragmentation step, thereby integrating DNA extraction, purification, and library construction into one automated workflow.

1937T

Accessing the Full Spectrum of Polymorphisms in HLA Class I & II Genes without Imputation for High Throughput Disease Association and Evolutionary Research. *S. Ranade[1], W. Lee[1], J. Harting[1], K. Eng[1], L. Hepler[1], B. Bowman[1], N. Westerink[2].* 1) Pacific Biosciences, Menlo Park, CA; 2) GenDx, Utrecht, The Netherlands.

The HLA system plays central role in the mechanisms governing the outcomes of disease, health and survival. Specifically the HLA class I genes HLA-A, -B, -C, and class II genes HLA-DR, -DQ, and -DP play critical role as factors responsible for organ transplant rejection and are important targets for clinical and drug sensitivity research. They have been associated with more than 100 diseases by direct or linkage-based association through extended LDs in the MHC region. However, due to their highly polymorphic diversity originating from exonic combinations as well as recombination events, HLA gene sequencing has always been a challenge. A large number of new alleles are expected to be encountered when HLA genes are sequenced in their entirety, emphasizing the need for allele-level resolution. Until now, technological challenges and lack of complete understanding about the impact of polymorphisms outside of peptide binding domains of HLA genes, most of the studies have remained exon centric and focused on these regions. To access the full spectrum of polymorphisms across the entire gene or complete length of the amplicon sequenced, without limitation from sequencing technology read length or availability of reference sequence, we have used, Single Molecule, Real-Time (SMRT®) technology from PacBio to interrogate the HLA system. In the present work, we employed DNA barcode tagged SMRTbell™ sample preparation approach to multiplex 96 samples for sequencing all of the HLA class I and II genes. Commercially available NGSgo® reagents (GenDx) for full-length HLA Class I and relevant exons of class II genes were amplified for high-resolution HLA sequencing. Sequence analysis was performed with PacBio® LAA software and the NGSengine® (GenDx) software package was used for HLA typing. In this study, PacBio sequencing was found to be a highly effective tool for generating accurate, fully phased, allele-specific sequences of full-length alleles of HLA genes without imputation. With long read lengths (average >10 kb) and concensus accuracy exceeding 99. 999% (Q50), we were able to confidently generate four field typing information and take a comprehensive snapshot of variants in exons as well as non-coding regions that may have impact on gene regulation and provide invaluable genomic insights to advance causality association research.

1938F

Comparison of third-generation sequencing with Sanger for HLA haplotyping in the context of a clinical study. *E. Palescandolo[1], C. Van Hove[1], W. Talloen[1], I. Lonjon-Domanec[2], J. Aerssens[1].* 1) Janssen R&D, Beerse, Belgium; 2) Janssen EMEA Medical Affairs, Paris, France.

HLA typing is routinely accomplished via Sequence-Based Typing (SBT, Sanger being the gold standard), but requires a high number of reactions to resolve uncommon types. The development of massively parallel sequencing combined with the recent improvements in read lengths holds promise to improve HLA typing efficiency and accuracy which might have impact in clinical settings. We compared the performance of SBT (Sanger) versus Pacific Biosciences' (PacBio) long-range single molecule sequencing method (SMRT) in the context of a clinical study that required assessing the correlation between rash reactions and HLA haplotype. The aims of our study were to 1) assess the feasibility of HLA typing with the SMRT sequencing technology, 2) determine its accuracy compared to SBT and 3) evaluate potential association between HLA and rash in the clinical study. In Telaprevir's HEP3002 early access program, patients chronically infected with HCV genotype 1 and with severe fibrosis or compensated cirrhosis were treated with Telaprevir in combination with peg-interferon and ribavirin (PR) for 12 weeks followed by 12 or 36 weeks of PR. We selected 33 patients suffering severe rash, grade 3 or 4 and 66 matched control patients without rash. Patients' DNA underwent Sanger and PacBio sequencing for HLA-A, -B, -C, -DRB1, -DQB1. For full haplotype sequencing we used published primers able to amplify a full locus in either one or two (overlapping) PCRs. Fisher's exact test was utilized to evaluate the association between HLA and rash occurrence. Compared to the current gold standard SBT, PacBio revealed correct alleles for 94% of the samples. The non-matching haplotypes were attributed as lack of typing in 2% (i. e. both alleles were not identified by PacBio), homozygous in 1% (i. e. PacBio found one allele whereas Sanger two) and actual mismatches 3%. Mismatches occurred because of SBT's inability to disambiguate alleles, lack of primer specificity or PCR allelic imbalance. In conclusion, 1) we demonstrated that PacBio can be used for HLA haplotyping and is superior to Sanger since it can resolve complex haplotypes mixtures and determine types up to the field four; 2) we found no association between rash susceptibility and Telaprevir based therapy.

1939W

Chromosomal microarray as a clinical diagnostic test for undiagnosed rare disease. *H. Kim[1,2,3], H. Lee[2], HJ. Kim[1], E. Cho[4].* 1) Dept. of Ped. Konyang Uninv. College of Med. Daejon, South Korea; 2) Medical Genetics, Ajou Univ Med Sch, Seoul, South Korea; 3) Dept. of Genetic Counseling, Gachon Univ. Gil Med. Center, Incheon, South Korea; 4) Green Cross Genome, South Korea.

PurposeGenomic imbalance is known as a major cause of rare diseases. This study is aimed to evaluate the clinical utility of chromosomal microarray (CMA) as a diagnostic test for undiagnosed rare diseases patients. Materials and MethodsCMA performed on 179 samples of 108 patients and 71 family members from 37 patients in a single clinical laboratory referred by a clinical geneticist during 2. 5 years period (Dec. 2012-May. 2015). The results of 179 CMA were analyzed for CNVs and classified into pathogenic CNVs, variant of uncertain significance (VOUS), benign CNVs and normal. The comparison between patients and family member was made for the significance of CNVs and phenotypes. ResultsCMA results of 108 patients were revealed pathogenic CNVs in 34 cases (31. 5%), VOUS 10 cases (9. 3%), benign CNVs 16 cases (14. 8%) and normal 48 cases (44. 4%). One case of pathogenic CNV coexisted with VOUS and three cases with benign CNVs. CMA results of 71 family members showed pathogenic CNVs in 6 cases (8. 5%), VOUS 7 cases (9. 8%), benign CNVs 13 cases (18. 3%) and normal 45 cases (63. 4%). One out of 6 pathogenic CNVs coexisted with VOUS. 19 out of 71 family members showed abnormal phenotype, and 19 abnormal phenotypes were associated with 6 pathogenic CNVs (31. 6%), 3 VOUS (15. 8%), 3 benign CNVs (15. 8%) and 7 normal (36. 8%). Pathogenic CNVs included deletion (8 cases, 23. 5%), long contiguous stretches of homozygosity (LCSH) >5Mb (11 cases, 32. 4%), duplication (6 cases, 17. 6%), del/dup (5 cases, 14. 7%), aneuploidy (3 cases, 8. 8%), uniparental disomy UPD (1 cases, 2. 9%). Sites of genomic alteration occurred in all chromosomes but chromosomes 19, 20 and Y. Most common changes found in chromosomes 2, X, 3, 10 and 21 in frequency in order. An identical pathologic CNVs were found in 20 family members from 37 patients, ten of them were found to have abnormal phenotypes as well. Conclusion-This study of CMA analysis detected high rate of pathogenic CNVs (31. 5%) in 108 patients. CMA is especially useful tool as a diagnostic test of patients with normal karyotypes, yet clinically chromosomal aberration suspected. Our comparison study of CNVs found among patients and family members indicated the importance of family study with phenotype examination and pediagree analysis to be included for the accurate interpretation of CNVs found by CMA test of proband and appropriate genetic counseling.

1940T

Analysis of genetic variation and haplotypes of CYP2D6 amplicons by long-read nanopore DNA sequencing. *M. A. Kennedy[1], S. Cree[1], A. L. Miller[1], E. W. Chua[1,2], S. Maggo[1].* 1) Dept Pathology, University of Otago, Christchurch, Christchurch, Canterbury, New Zealand; 2) Faculty of Pharmacy, Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia.

The liver enzyme cytochrome P450 2D6 metabolises many drugs including antidepressants, anticoagulants and chemotherapeutics. Its gene (*CYP2D6*) is amongst the most variable of human genes, but current assays detect only the most common variants. We are striving to develop methods that allow more comprehensive analysis of *CYP2D6* variation. One technology we are exploring is the MinIon (Oxford Nanopore Technologies, UK). This tiny DNA sequencer uses nanopore sensing, whereby the passage of a single DNA strand through each pore generates changes in ionic current, allowing potentially very long sequence reads on single molecules. These characteristics mean the MinIon has potential for rapid analysis of long PCR amplicons, and for direct phasing of genetic variants. A preliminary report demonstrates that the MinIon can read a long CYP2D6 amplicon and detect genetic variation (Ammar *et al*. 2015; F1000Res, 4:p17). For our analysis *CYP2D6* was PCR amplified on a 6. 6kb amplicon, in order to avoid potentially misleading pseudogene sequences. Sequences were extracted from the MinIon HDF5 files generated by Metrichor analytical software (ONT), then aligned using Lastz. As kit chemistry has improved (from R6 to R7. 3) we have seen corresponding increases in mean length of aligned segments (792bp – 6431bp), proportion of 2D reads (4-12%), and proportion of bases in aligned regions (62%-84%). In general we see blocks of good data interspersed with poor data, and known variants can be discerned. Errors appear to be randomly distributed within reads. On our most recent runs, we have successfully used oligonucleotide indexing to carry out simple multiplexing of samples. Our conclusions are that it is indeed possible to read *CYP2D6* amplicon sequences with the MinIon, and variants can be detected, although not yet called *de novo* with high confidence. We have demonstrated multiplexed analysis using oligonucleotide indexing. Remaining questions we are now addressing are simpler workflows, increasing confidence in variant calls, establishing the degree of sample multiplexing we can achieve, and quantifying the degree to which template switching during PCR may give rise to misleading haplotype determinations. Nanopore sequencing of CYP2D6 is a promising approach to rapid, simple and cost effective analysis of this important pharmacogene, although still in need of optimisation.

1941F

Newborn Screening for Spinal Muscular Atrophy. *W. Hwu, Y. Chien, S. Chiang, L. Hsu, N. Lee.* National Taiwan University Hospital, Taipei, Taiwan.

Background:Because of the needs for early diagnosis and early treatment of spinal muscular atrophy (SMA), newborn screening for SMA is attempted. Methods:Dried blood spot (DBS) samples were obtained from routine newborn metabolic screening samples taken at the age of day 3. DNA was extracted from a 3. 2mm punch from each DBS sample. A real-time quantitative PCR (qPCR) assay using primers and probes targeting IVS7+100 was conducted in 96-well plates. Newborns with a positive screening result, showing the absence of IVS7+100C, was requested for a confirmatory test, and at the same time, a second 3. 2mm punch from the original DBS was subjected to qPCR (with another set of primers and probes) and Droplet Digital PCR (ddPCR). The confirmatory process included clinical evaluation and a whole blood sampling for MLPA test. Results:From Nov. 17, 2014 to May 31, 2015, we have screened more than 46,000 newborns and have found 2 SMA patients. In addition, we experience 2 false-positive cases, one with borderline initial screening values, while the other suffered from a polymorphism at the targeted nucleotide (IVS7+100C>T). Therefore, the false-positive rate was low, and the positive-prediction rate was 50%. The theoretically false-negative rate of the current screening method was 5% because we will miss SMA patients caused by point mutations of the SMN1 gene. Conclusion:Newborn screening of SMA by qPCR method is feasible and can provide patients early diagnosis. Further screening on more newborns are necessary to provide the current incidence of SMA, and to explore the benefit of early treatment.

***CYP2D6* genotyping with the PacBio RSII using multiplex targeted long amplicon sequencing.** *S. J. White[1], H. Buermans[1], T. van der Straaten[2], R. Vossen[1], S. Y. Anvar[1], J. Swen[2], J. T. den Dunnen[1,3].* 1) LGTC and Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands; 2) Department of Clinical Pharmacy & Toxicology, Leiden University Medical Center, Leiden, Netherlands; 3) Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands.

CYP2D6 is among the most important enzymes involved in the metabolism of many routinely prescribed drugs. Specific variants in *CYP2D6* are associated with changes in the activity and amount of the CYP2D6 enzyme. *CYP2D6* genotyping is complicated because of homology with pseudogenes *CYP2D7/2D8,* and information on which variants are located on the separate alleles cannot easily be determined with standard assays. Targeted long amplicon sequencing using the PacBio RSII sequencing platform holds several advantages over second generation NGS systems, including the ability to sequence multi-kb amplicons without the need for fragmentation steps, obtain high accuracy consensus sequences, and deliver fully phased variant information for separate alleles. For optimal implementation of PacBio sequencing for variant profiling, efficient sample barcoding strategies are needed. Standard methods introduce sample barcodes either via ligation of barcoded SMRTbell adapters to amplicons, or via PCR, by using a set of fusion primers linking the barcode sequence directly to the locus specific primer. Downsides of these barcoding methods are that they are expensive and lack flexibility. We devised a PCR-based multiplexing strategy for long amplicon variant profiling using the PacBio RSII platform. A 6. 6 kb DNA fragment containing *CYP2D6* is first amplified with a pair of gene-specific primers containing forward and reverse M13 sequence tails. A sample barcode is subsequently introduced in a second PCR using a set of re-usable M13-tailed barcode primers. Barcoded samples are then pooled in equimolar amounts and processed for PacBio sequencing. Using this setup, we sequenced the complete *CYP2D6* gene for 12 individuals with previously established *CYP2D6* genotypes, called with the (now discontinued) AmpliChip CYP450 Test. Full length *CYP2D6* sequences were obtained for all individuals. Predicted genotypes from the PacBio RSII were in agreement with the previous calls. Two different allele sequences were evident in four individuals, providing the exact distribution of multiple heterozygous SNPs over the two separate *CYP2D6* alleles. In conclusion, we have developed a versatile and simple multiplexing method for obtaining fully phased allele sequences for *CYP2D6*. With minor modifications this method could be applied for targeted long amplicon sequencing of other loci.

Mutation screening of the SLC26A4 gene in Brazilian non-syndromic sensorineural prelingual deaf individuals. *S. C. S. Carvalho[1,2], C. H. P Grangeiro[1,4], C. G. P. Albuquerque[1,4], T. O. Anjos[2], J. R. Plaça[2,3], L. F. Araujo[1,2], B. R. Muys[1,2], E. M. Souza[1,2], G. A. Molfetta[1,2], W. A. Silva Jr[1,2,3], V. E. F. Ferraz[1,4].* 1) Department of Genetics, Ribeirão Preto Medical School, Ribeirão Preto, São Paulo, Brazil; 2) Center for Genomic Medicine - University Hospital of Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, São Paulo, Brazil; 3) Center for Cell-Based Therapy (CEPID/FAPESP); National Institute of Science and Technology in Stem Cell and Cell Therapy (INCTC/CNPq), Regional Blood Center of Ribeirão Preto, Ribeirão Preto, São Paulo, Brazil; 4) Department of Medical Genetics of University Hospital of Ribeirão Preto Medical School, São Paulo University, Ribeirão Preto, São Paulo.

Hearing is the main source for speech and language learning during childhood, and deafness or auditory deprivation can result in both emotional and social difficulties to those affected individuals. Approximately 360 million people in the world are affected by hearing loss, and hereditary deafness is the most common sensorineural disorder in humans with a prevalence of 1 per 1,000 live births. In most cases, inherited sensorineural hearing loss is heterogeneous and has a large number of genes involved. Studies have shown the important role of the SLC26A4 gene in the physiology of the inner ear, and mutations in this gene have been reported as a cause of hereditary hearing loss. Thus, the aim of this study was to investigate the prevalence of mutations in coding regions of SLC26A4 in non-syndromic prelingual sensorineural hearing loss (SNHL) patients assisted by the Department of Medical Genetics of University Hospital of Ribeirão Preto Medical School. To achieve this goal, were analyzed 79 DNA samples from unrelated deaf individuals, which were previously screened to GJB2/GJB6 mutations and had an inconclusive molecular diagnosis. Samples were analyzed by the High Resolution Melting (HRM) screening technique in order to detect alterations in melting curve patterns, which were validated by Sanger sequencing. The prevalence of mutations in SLC26A4 was 27. 8% (22/79) with 10 mutations found in this gene. Three of these mutations are previously undescribed mutations: p. Gly139Arg, p. Ile254Val, p. Asn382Lys. Among these 10 mutations, the most prevalent was chr7:g. 107301238C>G on exon 1 (the SLC26A4 promoter region), found in 11 deaf patients (13. 9%) in heterozygosity, as well as in compound and double heterozygosity (with GJB2) genotypes. The 1000 Genomes Project data suggests it as a polymorphism, but pathogenicity information on this mutation remains inconclusive. Four of these 10 mutations found in SLC26A4 have shown pathogenic scores by *in silico* analyses: p. Gly139Arg; p. Ile300Leu; p. Asn324Tyr and p. Asn. 382Lys; suggesting that these four mutations may constitute the cause of genetic deafness in 8. 9% of the patients. This data highlights the importance of the SLC26A4 gene for molecular diagnosis of hereditary hearing loss and gives strength to its potential contribution to the genetic counseling process. However, it is suggested that functional tests and segregation studies are needed in order to elucidate the role of SLC26A4 mutations to the phenotype.

Is Sanger Sequencing Still the Gold Standard? *T. F. Beck[1], N. Hansen[2], J. Mullikin[1,2], L. Biesecker[1].* 1) National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 2) NIH Intramural Sequencing Center, Rockville, MD.

Next-generation sequencing (NGS) costs are rapidly decreasing, and more clinical and research labs are using NGS for many types of evaluations. We focus on our experience in clinical translational genomics research. While some of these data are generated purely for research, it is often the case that medically relevant variants can be identified which we would like to return to the participant. Currently, the standard of care is to verify variants using Sanger sequencing before returning the results, which can be costly and time-consuming. We decided to evaluate the utility of Sanger validation given the current quality of NGS. In this study, we compare the variants found using exome sequencing on a set of five medically-relevant genes in over 250 participants against those found using Sanger sequencing data from the same cohort, namely the ClinSeq® cohort. Out of over 5,600 variants found in these participants using exome sequencing, only two variants were not validated by Sanger sequencing, and those two variants had exceedingly low most probable genotype (MPG) scores (4 and 10, respectively). Our findings indicate that Sanger validation may be unnecessary in a clinical setting, given the accuracy of current next-generation sequencing technologies.

1945W

A 4,500 Gene, Short-turn-around-time, NGS Neonatal Intensive Care Diagnostics Panel. *S. Dames[1, 3], D. Nix[1], C. Miller[1], S. Pew[1], C. VanSant Webb[1], J. Stocks[1], R. Mao[1, 2].* 1) ARUP Laboratories Institute for Clinical and Experimental Pathology, Salt Lake City, UT; 2) University of Utah Department of Pathology, Salt Lake City, UT; 3) University of Utah Department of Biomedical Informatics, Salt Lake City, UT.

Introduction: Rapid turnaround for NICU patients is critical for diagnosis and treatment, as well as reducing costs associated with NICU hospitalization. IDT has developed an inherited disease panel comprised of 4,500 genes—most of which have mutations described in HGMD. Using the Illumina NextSeq 500 platform 2x150 mid-throughput kit, we have developed a STAT, 4,500 gene panel. Proband and parents, when available, are sequenced, but only variants associated with the proband are reported. Our goal is a 7-10 day turnaround from receipt of specimen to preliminary report. **Methods:** Illumina libraries are prepared on a Beckman-Coulter SPRI-TE. Samples are hybridized between 4-16 hours. Post hybridization wash and PCR clean up are performed using an Agilent Bravo A. All other library prep and quantification steps are performed manually. Samples were sequenced using version 1 and 2 chemistries on the NextSeq 500. A UCSC bed. file (+/- 10 bp CDS) was derived using HGMD reference transcripts for each gene (when defined) or HUGO reference transcripts for genes. An intersect between the IDT and UCSC bed files was preformed since all exons are not captured in the IDT panel for a subset of genes. A total of 54,517 targeted regions are queried. The ARUP validated clinical pipeline was comprised of BWA, SAMtools, GATK, Freebayes, and snpSIFT/eff. Average processing time from sample to fastq is approximately 72 hours, with alignment and variant analysis an additional eight hours. **Results:** Samples NA12878 and ARUP's wild-type female/male controls were sequenced. Initial experiments using version 1 chemistry displayed greater than 99. 5% targeted coverage > 15-fold (Q-score >30 73%). NextSeq 500 background was higher compared to the HiSeq and MiSeq (up to 3% error in read 2) despite optimum cluster density. While this may adequate for germline mutations, it will be problematic for somatic or mtDNA assays. Subsequently the samples were run with version 2 chemistry and displayed greater than 99. 5% targeted coverage, Q-score >30 at 90%, with a flat error rate of <0. 5 percent. Concordance in raw vcf variant calls was > 99% for all three samples between versions 1 and 2. **Conclusions:** Preliminary experiments demonstrate that our proposed timeline for bench work can easily be met; however, a dedicated server is required for optimal turnaround for STAT tests. Despite the quality difference between versions 1 and 2 chemistries, raw vcf variants are greater than 99% concordant.

1946T

Clinical applicability of direct-to-consumer exome analysis. *J. Vengoechea[1], MP. Alfaro[1,2], J. Kelsay[1].* 1) Division of Genetics, University of Arkansas for Medical Sciences, Little Rock, AR; 2) Arkansas Chidlren's Hospital, Little Rock, AR.

A 30 year-old-man presented to the Adult Genetics clinic with results from a direct-to-consumer (DTC) next generation sequencing exome test. The patient pursued testing to explain his fatigue after taking medication for attention deficit/hyperactivity disorder. He had no other chronic conditions. The patient brought the results as VCF files. Cartagenia Bench Lab NGS 4. 0 was used for analysis. There were 55,645 variants from the whole exome; these were restricted to variants in genes with an OMIM phenotype leaving 15,795 variants. None met standard quality criteria used by our lab. After loosening the quality criteria to only include variants with ≥20X coverage, 14,125 variants remained. Next, variants with population frequency ≥ 3% in 1000 Genomes, dbSNP and/or ESP6500 were excluded. The remaining 1,631 variants were filtered to include only those that altered protein length, were reported in ClinVar or HGMD as pathogenic or were predicted to be pathogenic by 4 out of 5 *in-silico* prediction tools. The goal was a specific but not sensitive analysis. This left 58 variants for manual review. After excluding genes that caused syndromes that the patient clearly did not have, heterozygous variants for conditions with autosomal recessive inheritance and known benign variants, there were three variants of interest. The first was a frameshift variant in *MYF6*, a gene causative of centronuclear myopathy type 3. The variant was confirmed by a CLIA-certified lab. Only one affected family has been reported previously. The patient's CK level was normal. A muscle biopsy is possible, but the description of this syndrome is too limited to make formal recommendations. The second was a missense variant reported in HGMD and ClinVar in *PROS1,* the gene that encodes protein S. The patient had normal protein S activity. The third was a missense variant in *PKD1* predicted to be pathogenic by *in silico* tools. A renal ultrasound was ordered. This project showed that although it may be feasible to use DTC exome data to perform a clinical analysis, the great number of variants necessarily limits the analysis to known pathogenic mutations in autosomal dominant conditions while relying on clinical databases. Feasibility is further limited because there is no code to bill for the analysis of DTC results. The DTC test and our analysis did not answer our patient's chief complaint, and the low cost of DTC testing may be offset by the cost of confirmatory clinical studies.

1947F

Effect of Formalin Fixation on Targeted Sequencing and Genomic Analysis in Cancer. *R. K. Alla[1], E. Helman[1], M. J. Clark[1], S. M. Boyle[1], S. Luo[1], S. Kirk[1], P. Sripakdeevong[1], M. Karbelashvili[1], D. M. Church[1], M. Snyder[2], J. West[1], R. Chen[1].* 1) Personalis Inc, Menlo Park, CA; 2) Department of Genetics, Stanford University, Stanford, CA.

Tumor biopsies are often Formalin-Fixed and Paraffin-Embedded (FFPE) for histological staining, genetic testing and archival purposes. Formalin treatment preserves tissue by crosslinking proteins, but also leads to mutation of the nucleic acid bases and poses a challenge to identification of true variants in the tumor using next-generation sequencing (NGS) methods. Studies have shown that it is possible to isolate high quality nucleic acids from good FFPE samples and to profile small variants using NGS. These studies used tissue fixed with 10% neutral buffered formalin for 24 hours, a standard protocol in the pathology field. In our initial handling of FFPE samples we found that the quality of the isolated DNA and subsequent sequencing results vary widely. We hypothesized that this may be due to deviations from the standard protocol, such as inaccurate logging of the fixation protocol, variation in the fixation time, and varied storage conditions of the samples. To understand the role of formalin fixation on the quality of variants called, we performed an augmented target enrichment and sequencing assay on fresh frozen (FF) and FFPE samples from different sources. We assessed raw DNA quality, library quality, sequencing metrics (alignment rate, duplication rate, on-target efficiency, etc.) and variant concordance profiles between FF and FFPE. Preliminary results showed that formalin fixation causes an increase in global CG to TA mismatch rate from 0. 025% to 0. 04%. This led to additional variants detected at low (<5%) allele frequencies (AFs). We observed that about 45% of low AF mutations in FFPE samples were CG to TA transitions. We also noted that the severity of molecular damage across different tissue types correlated with the pathology lab preparing the FFPE sample. To directly test the effects of formalin, we subjected tissue to different FFPE protocols and compared their sequencing profiles to those of adjacent FF tissue. We varied fixation protocols to reflect the conditions from different pathology labs, adjusting formalin concentration, fixation time and storage conditions. Using the results of this study, we intend to develop fixation protocols optimized for sequence analysis to facilitate tumor clinical molecular profiling. We also demonstrate how a deeper understanding of the effects of formalin can improve sequencing analysis results from formalin-fixed tissues, especially at lower AFs where formalin-related errors have the greatest impact.

1948W

Defects in *TANGO2* cause episodic muscle weakness, rhabdomyolysis and cardiac arrhythmia. *J. A. Rosenfeld[1], S. R. Lalani[1], P. Liu[1], C. Miyake[2], M. Shinawi[3], L. Emrick[4], S. Schelley[5], M. K. Koenig[6], N. Memon[7], T. Chiang[1,8], T. Gambin[1], M. K. Eldomery[1], S. N. Jhangiani[1,8], N. Hanchard[1], J. S. Orange[9,10], L. B. Watkin[9,10], D. M. Muzny[1,8], H. Yang[1,14].* 1) Department of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Pediatric Cardiology, Texas Children's Hospital, Houston, TX; 3) Division of Genetics and Genomic Medicine, Washington University School of Medicine, St. Louis, MO; 4) Department of Neurology, Baylor College of Medicine, Houston, TX; 5) Division of Medical Genetics, Stanford School of Medicine, Stanford, CA; 6) Division of Child & Adolescent Neurology, Department of Pediatrics, The University of Texas Health Science Center at Houston, TX; 7) Division of Cardiology, DCH Regional Medical Center, Tuscaloosa, AL; 8) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 9) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 10) Texas Children's Hospital Center for Human Immuno-Biology, Houston, TX; 11) Division of Medical Genetics, Department of Pediatrics, The University of Texas Health Science Center at Houston, TX; 12) McKusick-Nathans Inst. of Genetic Medicine & Department of Pediatrics, The Johns Hopkins University School of Medicine, Baltimore, MD; 13) Department of Metabolic Medicine, Lady Cilento Children's Hospital, South Brisbane, Queensland, Australia; 14) Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, TX; 15) Department of Pediatrics, Texas Children's Hospital, Houston, TX.

Whole-exome sequencing (WES) is facilitating an increasing pace of human disease gene discovery. Leveraging the power of extensive genotype and phenotype data from a large cohort of individuals undergoing clinical WES (n>5500), we identified 12 individuals with bi-allelic defects in *TANGO2* [transport and golgi organization 2 homolog (*Drosophila*)] who shared clinical features including episodic muscle weakness with rhabdomyolysis, cardiac arrhythmia, intellectual disability, and seizures. Two individuals carried a homozygous loss-of-function variant, one nonsense and one affecting a splice site. Five individuals, all of Hispanic ancestry, were homozygous for the same missense variant and had evidence of a shared haplotype. Control data show this variant to be most common in the Latino population, with no homozygotes detected, and the frequency of homozygotes in our cases is enriched compared to simple population genetics predictions. The eighth individual carried the common missense variant on one allele and a large intragenic deletion on the other allele. The remaining four individuals were homozygous for large deletions affecting several *TANGO2* exons. The large deletions were identified by comparing normalized depth of coverage from clinical WES samples with that from individual patients. Following informed consent from a majority of these individuals, an in-depth phenotypic analysis showed a consistent phenotype among those with bi-allelic variants (sequence and copy number): recurrent metabolic crises frequently triggered by illness, progressive neurologic disease, and life-threatening cardiac arrhythmia. Two families had multiple affected siblings. Therefore, phenotype, segregation, and control data support bi-allelic pathogenic mutation of *TANGO2* as a cause of human disease. It has been reported that TANGO2 deficiency may cause morphology changes of golgi and ER membrane in *Drosophila* S2 cell lines, although specific functions of TANGO2 are poorly characterized. Preliminary cellular studies using tissue from a patient with the homozygous Hispanic missense variant suggested decreased TANGO2 expression, decreased golgi size, and increased ER stress. These results demonstrate the strength of large cohorts to facilitate rare disease discovery, particularly in minority populations, in addition to the importance of analyzing WES data for potentially pathogenic copy number variations.

1949T

Copy number variation detected by CMA- A review of 2000 cases. *Y. Hadid.* Genetics, Bnai Zion, Haifa, Israel.

Chromosomal microarray analysis is a method of measuring gains and losses of DNA (CNVs) throughout the human genome. It is considered to be a first-line test in the genetic evaluation of infants and children with unexplained intellectual disability, congenital anomalies, multiple birth defects, or autism spectrum disorder. The test is also recommended for further investigation of prenatal testing in pregnancies at risk: advanced age of mother, abnormal U. S finding, or pregnancy loss. Here we describe CNV results from 2000 diagnostic cases tested in the genomic lab (Bnai Zion medical center, Haifa, Israel). The samples are divided into three categories: Prenatal, Postnatal and tested parents for further investigation. The main conclusions from our experience about **postnatal** samples are that detection of pathogenic CNV by CMA method is relatively higher percentages more than normal karyotyping method. For **prenatal** testing, broader CMA testing will undergo a higher identification of chromosomal alterations clinically relevant, even at low-risk pregnancies. Our findings provide strong evidence for the entry of CMA diagnostic tests first line to all pregnant women undergoing invasive prenatal tests, regardless of risk factors.

1950F

Contributions of microarray data to the molecular diagnosis in 5700 consecutive clinical whole-exome sequencing (WES) cases. *W. Bi[1], P. Liu[1], J. Scull[1], H. Cui[1], T. Chiang[2], A. Hawes[2], Y. Ding[2], S. Matakis[3], D. Muzny[2], R. A. Gibbs[1,2], A. L. Beaudet[1], J. R. Lupski[1], A. Patel[1], C. M. Eng[1], Y. Yang[1].* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, 77030; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, 77030; 3) Baylor Miraca Genetics Laboratories, Baylor College of Medicine, Houston, TX 77021.

Whole-exome sequencing has been utilized in the molecular diagnosis of patients referred for evaluation of suspected genetic conditions. The disease causative variants reported in exome cases are usually single nucleotide variants (SNV) or small indels. The contribution of copy number variants (CNV) and uniparental disomy (UPD) to the molecular diagnosis in clinical WES cases is not well understood. Here, we analyzed microarray data for ~5700 consecutive primarily pediatric patients tested by WES in the Baylor clinical genetics laboratory between 2011 to 2015; a molecular diagnosis was found in 1539 cases (27%). HumanOmni1-Quad array or HumanExome-12 v1 array was performed on each patient as a quality control measure. In addition, concurrent chromosomal microarray analysis using a high resolution targeted clinical array with SNPs was requested for 307 patients. Disease-associated microarray findings were evaluated based on the clinical symptoms provided by the referring physicians to determine whether they are causative or not. Patients' phenotypes can be fully explained by microarray results in 42 cases, corresponding to 2. 7% (42/1539) of molecular diagnosed cases, which consist of microdeletion/duplication syndromes such as SMS and WBS or other disease-associated large >1 Mb deletions/duplications except for 3 UPD syndromes, 1 monosomy X, and 4 small <0. 5 Mb deletions involving disease genes. Phenotypes can be partially explained by array findings in 51 cases, of which in 32 cases, WES was pursued for potential additional molecular diagnoses beyond CNVs. Therefore, causative findings that can explain either part or the entire clinical findings were present in 93 cases (1. 6%, 93/5700; 6%, 93/1539). Disease-causing CNVs that are likely to be irrelevant to the phenotypes include 28 CNVs with reduced penetrance, a 15q11q13 duplication and a STS deletion. In addition, CNVs >1 Mb in non-disease associated regions were detected in 17 cases, with one CNV de novo, two CNVs inherited and the others without parental study. For autosomal recessive diseases, molecular diagnoses were obtainedfor five cases with a pathogenic SNV in one allele and a deletion involving the other allele of the disease genes. This study showed that microarray data contribute to 2. 7% to 6% of molecular diagnosis of whole exome sequencing and demonstrated that CNVs/UPD contribute to the diagnoses of autosomal dominant or X-linked diseases, as well as autosomal recessive diseases.

1951W

Next-generation sequencing and the molecular diagnosis of newborns in the neonatal intensive care unit. *H. Daoud[1], S. Luco[1], R. Li[2], O. Jarinova[1], N. Carson[1], SM. Nikkel[1,3], GE. Graham[1,3], J. Richer[1], C. Armour[1], SL. Sawyer[1,3], J. Majewski[2], KM. Boycott[1,3], DA. Dyment[1,3].* 1) Department of Genetics, Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 2) McGill University and Genome Quebec Innovation Centre, Montréal, Québec, Canada; 3) Children's Hospital of Eastern Ontario Research Institute, University of Ottawa, Ontario, Canada.

Genetic diseases often present in the first days of life and are associated with significant morbidity and mortality. Recent studies have emphasized the success of Next Generation Sequencing (NGS), notably Whole Exome Sequencing (WES), for the diagnosis of rare genetic disorders but its effectiveness in critically ill neonates has not been thoroughly investigated. Here, we report the application of NGS in a cohort of twenty newborns with congenital anomalies, ascertained prospectively and retrospectively, and admitted to the Neonatal Intensive Care Unit (NICU). NGS of a comprehensive panel of genes (Trusight One Sequencing panel, Illumina) with known associated clinical phenotypes was performed in the patients and their parents. We identified disease-causing mutations in seven of the twenty newborns, achieving a 35% molecular diagnostic rate. Diagnoses included bi-allelic mutations in *CHRND*, *FTO*, *WDR19*, *ACE*, an X-Linked mutation in *MTM1*, and *de novo* mutations in *SCN1A* and *DYRK1A*. The time to diagnosis varied considerably, though a return of results was possible within a 2-3 week timeframe. These results show the potential of NGS to deliver accurate and quick molecular diagnoses in the NICU, thereby eliminating the diagnostic odyssey that many of these patients historically underwent. A rapid accurate diagnosis in the newborn period may also significantly impact patient management, and in some cases alter treatment decisions, thereby improving care for patients with rare genetic disorders. The success of this project highlights the need to translating NGS in the NICU into routine clinical care.

1952T

Clinical exome sequencing: accelerating the pace of diagnosis and gene discovery for improved patient management. *C. Eng[1,2], D. Muzny[1,3], F. Xia[1,2], M. Walkiewicz[1,2], R. Person[1,2], Z. Niu[1,2], Y. Ding[2,3], P. Ward[1,2], A. Braxton[1,2], W. Bi[1,2], N. Veeraraghavan[3], T. Chiang[3], J. Posey[1], J. Rosenfeld[1], M. Leduc[1,2], R. Xiao[1], P. Liu[1], H. Cui[1,2], W. He[2], F. Vetrini[2], J. Zhang[2], C. Buhay[3], A. Hawes[3], W. Craigen[1], E. Boerwinkle[3], S. Plon[1,3,4], J. Lupski[1], A. Beaudet[1,2], R. Gibbs[2,3], Y. Yang[1,2].* 1) Dept Molec & Human Genetics, Baylor Col Medicine, Houston, TX; 2) Baylor Miraca Genetics laboratories, Houston, TX; 3) Human Genome Sequencing Center, Baylor Col Medicine, Houston, TX; 4) Dept Pediatrics, Baylor Col Medicine, Houston, TX.

We developed and optimized technical, bioinformatic and interpretive exome sequencing pipelines in a CAP/CLIA certified laboratory to identify causative mutations underlying disease phenotypes in undiagnosed patients being evaluated clinically for genetic disorders. Several variations of the exome testing approach have evolved for specific clinical scenarios including critical exome and prenatal exome sequencing with expedited technical and analytical reporting, trio and quad exome sequencing, and customized focused panel sequencing derived from the exome. Using these approaches, clinical exomes have been completed for 5700 cases, most of which are pediatric patients with neurological manifestations, and achieved a molecular diagnosis rate of approximately 27%- 31% for known disease genes using proband or trio approaches, respectively. The inheritance patterns of the contributing Mendelian diseases included about 53% AD, 34% AR, and 12% X-linked. About 5% of the positive patients were diagnosed with two genetic disorders resulting in blended phenotypes. Genetic events such as *de novo* variants, mosaicism in patients or parents, copy number variants (CNVs) and uniparental disomy were discovered, further documenting the frequency of these events in routine clinic populations of patients suspected to have genetic disorders. Patients without a molecular diagnosis after initial reporting have several avenues to an eventual diagnosis. Our clinical testing consent process allows the option of entering research studies for novel disease gene discoveries such as the Centers for Mendelian Genomics and more recently, the Undiagnosed Diseases Network. These research mechanisms as well as internal observations in the clinical lab have led to reports of new disease genes such as *ASXL3*, *MAGEL2*, *AHDC1* and *PURA* as well as candidate disease genes such as *MIPEP, GMNN, and TANGO2*. Moreover, we perform re-analyses of likely pathogenic changes in new disease genes for previously reported cases without a definitive molecular diagnosis. The combined efforts of data re-analyses and research activities resulted in additional molecular diagnoses and improved our exome diagnosis rate from 25% to approximately 30% over time. Our four year experience with optimizing clinical exome sequencing has demonstrated utility in different clinical settings as well as providing the basis for a multi-directional effort to continue to improve diagnostic rates through research and discovery.

1953F

Diagnostic Exome Sequencing (DES) provides a diagnosis for 23% of adult patients. *K. D. Farwell Hagman, S. Li, L. Shahmirzadi, D. El-Khechen, Z. Powis, C. Gund, K. Burk, S. Tang.* Ambry Genetics, Aliso Viejo, CA.

Diagnostic exome sequencing (DES) is successful in solving the diagnostic odyssey for roughly 30% of undiagnosed patients with a broad range of underlying Mendelian disorders. Pediatric neurologic manifestations are the most common DES referral indication. However, DES has also been successful in diagnosing adult patients undergoing the diagnostic odyssey. Among the first 1000 reported DES families, 175 (17. 5%) adult patients (>18 years old) were referred for testing. Significant family history was more common among adult patients (81. 1%) than children (65. 3%) (p=1. 826e-5). Among adults tested, 79 (45. 1%) were between 18-29 years old, 50 (28. 6%) were between 30-49 years old, and 46 (26. 3%) were between 50-79 years old. The most common referral indication among adult patients was cancer susceptibility (25, 14. 3%), followed by multiple congenital anomalies (23, 13. 1%), neurodevelopmental anomalies (15, 8. 6%), skeletal anomalies (14, 8. 0%), and ataxia/spasticity (10, 5. 7%). Positive findings were uncovered in 23. 4% of these families (41 of 175), compared to 29. 3% of children (242 of 825). A novel genetic etiology was proposed for 9 families (5. 1%). The diagnostic rate among patients <30 years old (29. 5%) is significantly higher than among patients greater than 30 years old (16. 7%) (p=4. 125e-3). Among the 41 adults with positive results, over half of the gene findings (23, 56. 1%) were autosomal dominant, 12 (29. 3%) were autosomal recessive, and 6 (14. 6%) were X-linked. Overall, the rate of *de novo* and likely *de novo* findings among adult patients (17. 5%) was much lower than among children (44. 4%) (p=5. 278e-5). The highest diagnostic yields were observed among patients with ocular anomalies (3/3, 100%), integumentary anomalies (2/3, 66. 7%), muscular dystrophy (3/5, 60%), intellectual disability (4/7, 57. 1%), renal anomalies (1/2, 50%), and cardiovascular anomalies (6/15, 40%). These data, including the high DES diagnostic rate of 23% among adult patients, highlight the potential medical-economics savings to patients as well as payers given that achieving a diagnosis abrogates the expensive, time-consuming, and often invasive diagnostic odyssey.

1954W

Clinical Diagnostic Yield for Autism and X-Linked Intellectual Disability Mutation Detection by Targeted Panels versus Whole Exome Sequencing: the GGC Experience. *J. Lee, M. Jones, S. McGee, K. Kubiak, F. Abidi, J. Jones, M. Basehore, M. Friez.* Molecular Diagnostic Lab, Greenwood Genetic Center, Greenwood, SC.

With the advent of Next Generation Sequencing (NGS), it is now possible to interrogate hundreds to thousands of genes at once for a given patient, increasing the potential diagnostic yield per assay. At the Greenwood Genetic Center, routine clinical diagnostic testing for syndromic autism and X-linked intellectual disability (XLID) is currently performed using targeted NGS panels that are specifically enriched for 83 and 114 genes, respectively. Here, we discuss our experience with diagnostic testing for autism and XLID by targeted panels versus by whole exome sequencing (WES). Since the inception of offering these targeted panels, our detection rate has been approximately 5-10% for each. This relatively low detection rate is likely due to the phenotypic diversity of patients and compounded by significant genetic heterogeneity. Therefore, WES has recently been pursued more frequently to diagnose these types of cases. Using this strategy we have begun to diagnose phenotypically diverse patients referred for autism, ID, or suspected XLID, that would not have been possible based on the content of our current targeted panels. Because targeted panels are limited in the genes that can be interrogated, WES offers the benefit of analyzing the entire exome, thus enabling mutation detection in newly associated disease-causing genes and potential new gene discovery. Overall, our diagnostic yield for WES is approximately 25%, much greater than the yield for our autism and XLID panels. However, certain limitations continue to exist for WES. Here, we review data from six randomly selected patients from independent WES runs, and focus on the autism and XLID genes that are covered on the targeted panels. We find that for the autism panel 99. 95%, and for the XLID panel 99. 99%, of exons are covered at a depth of 20X. However, for the respective exons by WES, the average coverage is 98. 57% and 97. 75%. Considering the span of coverage to ensure that all bases within the exons and 20 bases into the introns were covered in their entirety by at least 20X, greater than 99% of exons met these criteria for the panels, but it is closer to 90% by WES. We conclude that the diagnostic yield seems to be greater for these phenotypes by WES than by targeted panels, even though the coverage is not as complete for the most relevant genes. Our experience is consistent with others and supports the notion of using WES for patients with a broader clinical spectrum.

1955T

Clinical Exome Sequencing as a First-Line Molecular Diagnostic Test for Mendelian Disorders. *H. Lee[1], S. Strom[1], N. Dorrani[2], J. L. Deignan[1], N. Ghahramani[1], J. Jianling[1], R. Xian[1], S. Kantarci[1], F. Quintero-Rivera[1], K. Das[1], E. Vilain[2,3], W. W. Grody[1,2,3], S. F. Nelson[1,3].* 1) Pathology and Laboratory Medicine, Univ California, Los Angeles, Los Angeles, CA; 2) Pediatrics, Univ California, Los Angeles, Los Angeles, CA; 3) Human Genetics, Univ California, Los Angeles, CA.

The CLIA-certified and CAP-accredited UCLA Clinical Genomics Center launched the Clinical Exome Sequencing (CES) test in 2012. We routinely perform CES in pediatric and adult patients with a variety of clinical indications such as developmental delay presenting as part of a complex syndrome including co-morbid diagnosis of seizures, hypotonia or dysmorphic features, neuromuscular disorders, and ataxia. Causal variants have been identified across a variety of indications in both known and novel genes with a diagnostic rate of 27% (302/1100 cases). The conclusive molecular diagnostic rate was higher when CES was performed on a trio (32%, vs 23% for proband-only cases, p=0. 002), with de novo and phased compound heterozygous variants as the two additional categories of causal variants identified in trio cases. In addition to our routine CES practice with an average 8 week turnaround time from test ordering to reporting (TAT), we have also offered rapid turnaround CES testing (rapid-CES) at our center for 14 patients with critical conditions. The median TAT was 14 days, with a range from 11 to 25 days. Of the 14 cases, a conclusive molecular diagnosis was achieved in 5 cases (36%), which is statistically similar to the diagnostic rate of our routine CES cases. Single-gene and/or gene-panel testing was clinically available in all 5 cases; however, rapid-CES provided a much quicker TAT and was able to impact clinical management. TAT for the single-gene or gene-panel testing for the 5 genes varies widely depending on the reference laboratory, but would have required at least 4 weeks, and averages (6-10) weeks. Since CES can provide a broader search of the coding regions of the genome for causal variants, we expect CES to continue to be increasingly used as a first-line diagnostic test for many Mendelian disorders. Here, we have demonstrated that CES testing can be completed quickly while providing a high diagnostic rate in known or novel Mendelian disorders.

1956F

Establishing the next generation sequencing based genetic testing for pathological jaundice related diseases. *H. Li[1], H. Chen[2], M. Chang[2], Y. Ni[2].* 1) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 2) Departments of Pediatrics, National Taiwan University College of Medicine and Hospital, Taipei, Taiwan.

Jaundice is a medical condition with yellow skin, mucosa and eyes caused by the excess of bilirubin in the blood, reflecting impaired bile flow. In human body, any abnormalities related to hemolysis, failures in bilirubin conjugation, transport or bile secretion can result in the increase of bilirubin and lead to pathological jaundice. Many hereditary diseases can cause jaundice in this manner including: (1) hematological diseases with increased hemolysis such as G6PD deficiency, (2) diseases with no or lower UDP glucuronosyltransferase activities that affect bilirubin conjugation, (3) intrahepatic or extrahepatic cholestasis such as Dubin-Johnson syndrome, Alagille Syndrome and progressive family intrahepatic cholestasis, (4) inborn errors of bile acid synthesis also led to the failure of bile secretion. Since the causes of jaundice can be very complex despite the clinical symptoms are similar, it would be necessary and helpful to clarify which disease accounts the accumulation of bilirubin or impairment of bile flow by genetic test. However, the fact that more than 50 genes have been shown to relate to diseases with pathogenic jaundice leads the genetic testing by traditional Sanger sequencing a time and labor-consuming work. In this study, we tested the possibility of using next-generation sequencing (NGS) as the genetic test platform for jaundice related diseases. Target enrichment strategy was used and the whole genomic regions of target genes related with diseases mentioned above were captured with Roche NimbleGen customer designed probes. Libraries were paired-end sequenced by Illumina Miseq system. Variants calling and annotation were performed with Miseq Reporter Enrichment Workflow and Illumina VariantStudio software. SIFT and PolyPhen2 were used to predict the biological significance of the genetic variants. The average coverage depth of target regions is 202. 3 ± 23. 7 and the mean uniformity is 92. 9% ± 0. 3% indicate that the reads distribution is even across a targeted region. As a pilot study, patients with known genetic defects were tested for validations. All of the 20 previously identified disease causing variants were confirmed by this panel. There are 8 more variants newly identified by this method which can help to validate involvement of each genes in different diseases. The high throughput and high detection rate of NGS-based method shows the great potential to facilitate the clinical genetic testing for jaundice related diseases.

1957W

Data re-analyses lead to improved molecular diagnosis rate in clinical whole exome sequencing (WES): experience in 5,700 cases. *P. Liu[1], W. Bi[1], F. Xia[1], Z. Niu[1], R. Person[1], M. Walkiewicz[1], J. A. Rosenfeld[1], T. Chiang[2], M. Leduc[1], S. Pan[1], R. Xiao[1], J. Zhang[1], X. Wang[1], L. Meng[1], W. He[1], F. Vetrini[1], N. Veeraraghavan[2], P. Ward[1], A. Braxton[1], T. Vaughn[1], E. Boerwinkle[2,3], S. E. Plon[1], A. L. Beaudet[1], D. Muzny[2], J. R. Lupski[1], R. A. Gibbs[1,2], C. M. Eng[1], Y. Yang[1].* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 3) Human Genetics Center, University of Texas Health Science Center, Houston, TX.

The clinical application of WES generates a wealth of variant information for molecular diagnosis in patients with diverse clinical phenotypes. Follow-up reanalysis may lead to additional molecular diagnoses with potential clinical utility without repeating wet lab processes and incurring related costs. Here, we re-analyzed data from patients referred for diagnostic WES between 2011 and 2015. The initial diagnostic rate was 24% (1372/5700). Of the 4328 patients without a definitive molecular diagnosis in their first WES report, 3. 9% (N=167) received a new diagnosis after clinical WES re-interpretation 1 month to 3. 5 years after generation of the original report. Factors contributing to the growth of the molecular diagnostic rate include new disease gene discovery (59%), CNV analysis (19%), additional familial studies, mostly demonstrating *de novo* origin of a variant (15%), follow-up clinical correlation or updated variant interpretation (5. 5%), and interrogating specific regions with suboptimal WES coverage by Sanger (3. 0%). To illustrate the influence of the aforementioned factors on cases analyzed at different time intervals, we split our clinical WES cohort into two specific groups, NEJM2013 and JAMA2014, which correspond to two previous published studies. The overall rate of WES molecular diagnoses was ~25% at the time of each publication. After accumulating evidence for up to 3. 5 years, the enhanced diagnostic rates became 32. 8% for NEJM2013 and 28. 4% for JAMA2014. New diagnosis triggered by recent disease gene discovery predominates in the NEJM2013 group, accounting for 89% of the total growth compared to 58% in JAMA2014, signifying the importance of constantly updating disease gene databases when performing clinical WES analysis. The impact of CNV analysis and additional familial studies only emerged in the JAMA2014 group, representing 20% and 11% of the new molecular diagnoses, potentially reflecting physicians' evolving attitudes towards ordering WES prior to CNV analysis. Overall, our experience demonstrates the clinical and cost utility of WES reanalysis over time, and the impact of both new gene discovery and improved wet-bench experimental (capture design) and computational analyses (trio designs and CNV detection) that can yield significant increases in molecular diagnostic rates. Remaining challenges include evaluating the strength of evidence for new genes, CNV calling algorithms, and communicating updated results with referring physicians.

1958T

Genetic predisposition of human herpes virus associated lymphoproliferative disorders. *H. Liu[1], X. Chen[1], Y. Zhang[1], F. Wang[1], W. Teng[1], X. Han[1], F. Jin[1], C. Zhen[1], S. Song[1], Q. Yin[1], C. Tong[1], P. Zhu[2].* 1) Medical Laboratory Division, Hebei Yanda Ludaopei Hospital, Beijing, China; 2) Department of Hematology, Peking University First Hospital, Beijing, China.

PurposeLymphoproliferative disorders (LPD), which consist of infectious mononucleosis (IM), chronic active Epstein-Barr virus infection (CAEBV), hemophagocytic lymphohistiocytosis (HLH), X-linkage lymphoproliferative diseases (XLP), post-transplant lymphoproliferative disorders (PTLD) and lymphoma, are a series of diseases shared some common manifestations. Human herpes virus (HHV) is the most common pathogen related to LPD. HHV consists of 8 subtypes, including HSV-1, HSV-2, VZV, EBV, CMV, HHV-6, HHV-7 and HHV-8. HHV is conditional pathogenic, and HHV associated LPD occur mainly in East Asian countries. So we speculate that the pathogenesis of LPD is associated with genetic background of patients. The aim of the present study is to explore the genetic predisposition of HHV associated LPD. **Methods**608 HHV associated LPD cases were collected. All types of HHV were detected except VZV. EBV infection was the most common, which was detected in 82% cases. CMV infection was detected in 11% cases. Patients with different types of HHV infection did not show obvious differences in manifestations. 50 unrelated healthy donors who were HHV-negative were as normal controls. Coding exons and flanking intron sequences of six common HLH genes including PRF1, UNC13D, STXBP2, STX11, SH2D1A and XIAP were amplified and sequenced by Sanger sequencing. **Results**One quarter (157/608) of the patients harbored mutations in PRF1, UNC13D, STXBP2, STX11, SH2D1A or XIAP and 87 novel mutations were found. HLH cases showed the highest frequency of mutations (34. 8%). Monoallelic mutations were most common, accounting for 61% of the positive cases. Besides, 9% cases harbored synergistic mutations of two distinct genes. UNC13D was the most frequently mutated gene, followed by PRF1 and STXBP2. Deletion was often found in SH2D1A and XIAP. Synergistic mutations of two distinct genes could be found in some females with heterozygous SH2D1A or XIAP mutations. In silico analysis further suggested that the novel mutations found in the present study were associated with pathogenesis of LPD. **Conclusion**The present study investigates the molecular genetics of the largest cohort of HHV associated LPD in our country to date. We find that genetic immunodeficiency gene mutations play an important role in the pathogenesis of LPD and affects the clinical manifestations, prognosis and treatment options of LPD.

1959F

Sample ID Quality Control and Methodological Improvements for NGS Gene Panels. *J. M. Marqués, L. Repetto, L. Guggeri, V. Russo, E. García, A. Agorio, A. Torres, C. J. Azambuja.* GeniaGeo, Montevideo, Uruguay.

Many labs perform variant verifications by Sanger sequencing not only to check NGS results but also to check sample ID. In our lab we established the need for checking routinely the sample ID before the final report is generated. For this purpose we developed an internal control to perform systematically. We ordered custom Ampliseq™ primers for amplification of regions containing STRs commonly used in human identification and evaluated their performance in our Ion Torrent PGM. Then, we selected six informative STRs with good performance so we were able to differentiate one sample among over a million samples. We mixed the primers corresponding to STRs with pools from panels such as *BRCA1&2* and *CFTR* community panels, and Lynch and FAP custom panels. We have previously detected in these pools a certain degree of disequilibrium between amplicons so we performed modifications to the standard procedures by adding PCR cycles to some amplicons in order to achieve better equilibrium. Standard bioinformatics pipeline was modified with a different alignment argument to allow more accurate detection of small deletions next to the amplicon ends. In parallel, in a separate workflow, we performed the identification of each sample with 19 STRs markers by classic methods: PCR–CE with fluorescent primers, to establish the alleles markers for each sample. As the NGS yielded the results, before continuing with the pipeline for analysis of variants, we checked the identity of the sample comparing the results from both methods. Introducing the STRs in pools and performing the control quality mentioned above, allowed us to detect a problem with sample IDs in our lab. It has also been useful in cases where two samples had exactly the same variants because you could distinguish different individuals through STR NGS analysis. Finally, it allowed us to identify a problem with the consistency of an NGS result with its corresponding Sanger sequencing confirmation of a sample. Modifying alignment arguments in the bioinformatics pipeline enhances the detection of heterozygous and homozygous intronic polymorphic 4 bp deletion in *BRCA2* present at the end of an amplicon. Overall, improvements had been made regarding a more comprehensive protocol to diagnose germline mutations and to control sample IDs. Finally, we have developed an internal useful quality control for NGS that only needs a systematic PCR and Capillary Electrophoresis in parallel to NGS workflow.

1960W

A Quality Assurance Framework for Supporting a Clinical NGS Laboratory. *S. Marshall, B. Breton, A. Indap, T. Mullen.* Good Start Genetics Inc. , Cambridge, MA.

Integrated informatics and data science are essential components of a quality assurance framework to support the clinical next generation sequencing laboratory. NGS has changed how we do clinical molecular diagnostics, due in part to the significant increase in the complexity, volume, and automation of the underlying procedures. However, the paradigm of developing quality assurance tools and processes in the clinical operational setting remains unchanged. For example, monitoring assay health, tracking and trending instrument performance, identifying technical problems and reacting to them in rehearsed ways, are still the goals of a quality assurance program. By leveraging recent advances in the collection, analysis, and visualization of data, these important quality assurance goals can be met. These metrics and tools can help identify contamination and sample issues, automation errors, instrumentation malfunctions which could impact genotyping accuracy. Dynamic dashboards in Tableau enable lab personnel to quickly identify various quality issues. Integration with statistical methods implemented in R/python such as breakout/anomaly detection can enable more automated ways to identify these issues. In addition, integration with other 3rd party tools like UCSC Genome Browser provide orthogonal ways of viewing NGS quality and laboratory data in a clinical setting. To approach this challenge, we have developed an extensive suite of metrics that monitor run (batch) and sample quality. The metrics go beyond routine depth of coverage and Q30 scores; instead, these metrics interrogate clinical data on multiple additional dimensions. We have applied clinical informatics with robust data science to monitor the entire analytical laboratory process. Through interactive visualization of the data and analysis, we have integrated these tools into routine geneticist review.

1961T

Deciphering the best DNA extraction method for massively parallel sequencing of the human clinical exome. *B. Meltzer, J. Devaney, K. Cusmano-Ozog, J. Campos, S. Hofherr.* Childrens National Health System, Washington, DC 20010, DC.

The clinical exome contains 4813 genes based on information in the Human Gene Mutation Database, the Online Mendelian Inheritance in Man (OMIM) catalog, GeneTests. org, and the Genetic Testing Registry. The application of this test in the clinical lab requires quantities of genomic DNA that are pure, intact, double stranded, highly concentrated, and free from bacterial contamination. Therefore, we investigated four methods for DNA extraction from blood and cheek swabs for MPS anlysis. Genomic DNA was purified from peripheral blood using three different kits. In addition, we extracted check swabs using one kit. For all kits, we used the standard extraction conditions as recommended by the manufacturer. Three of the extraction kits use a robotic system for the extraction (EZ1 DSP Blood Kit, QIAsymphony DSP DNA Mini Kit, and ORAcollect-DNA) while the Gentra Puregene Blood kit is a manual extraction. All the extractions were quantitated using a Qubit 2. 0 Fluorometer (Life Technologies). The sequencing was performed using TruSight One (TSO) sequencing panel with analysis on a NextSeq 500 system. We performed alignment to the hg19 reference genome with the Burrows-Wheeler Aligner (BWA; 0. 7. 7). BaseSpace's version of BWA uses the Genome Analysis Toolkit (GATK; 1. 6) to call genetic variants (SNVs) and short indels. We examined the percent Qscore > 30, percent target coverage at 20X, and the number of fragments under 20X coverage for each type of extraction using three samples with duplicate extractions. In addition, we used the Kraken Metagenomics application to calculate the percent of bacterial DNA in the MPS data. Results: We analyzed 24 samples on the TruSight One panel and the four different extraction methods did not show significant differences in the Qscores, the total aligned reads (p=0. 29), coverage at 20X (p=0. 40), and number of fragments not covered at 20X (p=0. 47). In addition, we did not show significant differences between samples for the number of SNVs or indels called. Interestingly, the ORAcollect-DNA extraction (check swab) showed a higher percent of reads classified as bacteria (10. 1%) compared to the amount of bacterial DNA in the other blood-based extractions (4. 6%). The ORAcollect-DNA extractions (n = 6) all showed the bacteria *Streptococcus mitisas* as the most abundent (12% of baterial reads). We show that four different extraction methods can be used for DNA for MPS analysis using a TSO panel on a NextSeq 500.

1962F

Detection of small size CNVs (< 20 genes) in patients with epilepsy and related disorders. *L. Meng[1], T. Gambin[3], P. Liu[1], C. Shaw[1], W. Bi[1], A. Breman[1], J. Smith[1], A. Pursley[1], S. Lalani[1,2], C. Bacino[1,2], A. Beaudet[1], A. Patel[1], S. Cheung[1].* 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX. , USA; 2) Pediatrics, Baylor College of Medicine, Houston, TX. , USA; 3) Institute of Computer Science, Warsaw University of Technology, Warsaw, 00-665 Warsaw, Poland.

Epilepsy is a common medical problem with a complex clinical presentation and extreme genetic heterogeneity. So far, there are at least 100 single genes implicated in the etiology of epilepsy (26 definitive epilepsy genes, 62 OMIM genes, and 14 new genes identified by whole exome sequencing). Most of the clinical genetic tests for epilepsy focus either on large copy number variations (CNVs) or single nucleotide variations. Few studies have investigated CNVs affecting one or few genes, with even less known at the exonic level. This is partially due to the technological limits to reliably detect small size CNVs by most molecular assays. We designed a chromosomal microarray (BCM v8 CMA) to include coverage for 22 definitive epilepsy genes (84. 6%, 22/26), 46 OMIM genes (74. 2%, 46/62), and 8 new genes (57. 1%, 8/14). In order to evaluate the diagnostic yield of our CMA for epilepsy and related disorders, we retrospectively analyzed 23,630 cases studied at Baylor Medical Genetics Laboratory. Among 1714 cases with a clinical indication of an epilepsy-related presentation, 527 (31%) were found to have CNVs that are pathogenic or of uncertain clinical significance. Focusing on small CNVs with less than 20 genes, 26 cases had CNVs that include known epilepsy genes (27 CNVs, ranging from 1 to 18 genes per CNV). Noticeably, 12 of these cases involve only 1 gene, highlighting the clinical importance of exonic CNV detection in this cohort. Parental studies were performed on 8 cases with 4 confirmed to be *de novo*. We also analyzed cases with incomplete test indications and found 195 additional CNVs encompassing known epilepsy genes. The most common genes with CNVs in this patient cohort are *PLCB1* (20), *CNTNAP2* (19), *CDKL5* (15), *HCN1* (13) and *CLN8* (12). In total, we identified 22 cases carrying *de novo* CNVs of known epilepsy genes including *CDKL5* (4), *MEF2C* (3), *PLCB1* (2), *SCN1A* (2), *CLN8* (1), *ASAH1* (1), *BRAT1* (1), *CACNB4* (1), *CHD2* (1), *GRIN2B* (1), *GABRB3* (1), *GABRD* (1), *KCNT1* (1), *SCN2A* and *SCN9A* (1), and *STXBP* (1). With exon-by-exon coverage for disease and candidate genes, CMA has expanded its clinical utility from detecting recurrent microdeletion/microduplications to small CNVs at the exonic level. This not only increases the diagnostic yield for epilepsy and other genetic disorders, but also greatly expands our understanding about small size CNVs, which were usually not detected in routine clinical diagnostic testing.

1963W

Prenatal diagnosis of fetal akinesia deformation sequence caused by mutations in *KLHL40*. *X. Tian[1], PL. Kuo[2], TH. Chen[3], HP. Pan[4], Y. J. Jong[5], LJ. Wong[1,6].* 1) Baylor Miraca Genetics Laboratories, Houston, TX; 2) Departments of Obstetrics and Gynecology, National Cheng Kung University Hospital,Tainan, Taiwan; 3) Department of Emergency, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan; 4) Center for Medical Genetics, National Cheng Kung University Hospital,Tainan, Taiwan; 5) Departments of Pediatrics and Laboratory Medicine, Kaohsiung Medical University Hospital, and Graduate Institute of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung; and Department of Biological Science and Technology, National Chiao Tung University, Hsinchu, Taiwan; 6) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030, USA.

Background: Nemaline myopathy (NEM) is a common congenital myopathy. Mutations in at least 7 genes (NEM1-NEM7): *TPM3, NEB, ACTA1, TPM2, TNNT1, KBTBD13 and CFL2* are responsible. Recently, mutations in *KLHL40*, encoding the Kelch-like family member 40 protein, have been found to be associated with the severe form of NEM characterized by severe weakness, fetal akinesis and contractures, namely fetal akinesia deformation sequence (FADS). Most of NEMs are diagnosed by muscle biopsy followed by molecular confirmation. However, prenatal diagnosis by fetal muscle biopsy followed by sequencing of candidate genes one by one is costly and time consuming. The severe form of NEM is prenatally detectable. A comprehensive panel with quick turnaround time will be helpful for prenatal diagnosis. **Case report:** The proband is an 18 weeks fetus with akinesis and ultrasound detectable arthrogryposis. The mother had two previously similarly affected fetuses aborted at 21 and 28 weeks, respectively. Parents are unrelated Taiwanese. Clinical diagnosis of FADS possibly related to severe congenital myopathy was suspected. Molecular diagnosis was performed on the proband by target capture of genes causing a broad spectrum of neuromuscular disorders followed by next generation sequencing (NGS). **Methods:** All coding exons and at least 20 bp of flanking intronic sequences of 246 neuromuscular disease (NMD) related genes including KLHL40 gene are captured followed by NGS on Illumina HiSeq2000. Subsequent confirmation and phase study are performed by Sanger sequencing. **Results:** Our NGS analysis revealed two compound heterozygous mutations: c. 602G>A (p. p. W201*) and c. 1516A>C (p. T506P), in the *KLHL40* gene of the aborted fetus. The father carried the c. 1516A>C (p. T506P) mutation and the mother carried the c. 602G>A (p. p. W201*) mutation. The finding of *KLHL40* mutations is consistent with the congenital rapidly fatal form of NEM characterized clinically by in utero presentation of FADS. **Conclusion:** The comprehensive approach of target gene capture followed by NGS analysis effectively detects the mutations causing FADS. The inclusion of newly discovered *KLHL40* in the NMD panel increases the detection efficiency of the most common severe form of congenital NEM prenatally. The identification of the *KLHL40* mutations makes early prenatal diagnosis for this couple feasible.

1964T

Diagnosing skeletal disorders in the next generation sequencing era: lessons learned from skeletal disorder panels on 175 patients. *Y. Xue, W. R. Wilcox, M. Hegde.* Emory University, Atlanta, GA.

Making a correct diagnosis for the >450 highly genetically as well as clinically heterogeneous skeletal disorders is critical for management and accurate genetic counseling, but is often difficult due to overlapping clinical and radiographic features, especially at a young age, genetic locus heterogeneity and difficulty in choosing the appropriate molecular test. To expedite the molecular diagnosis of skeletal disorders, we designed proportionate short stature panels and skeletal disorder panels. The proportionate panels consist of sequencing of disease associated genes (45 genes), SNP array, Russell-Silver testing and UPD14. Skeletal disorder panels contain four subpanels (total 216 genes), namely, disproportionate short stature (85 genes), skeletal dysplasias with increased bone density (34 genes), skeletal dysplasias with decreased bone density or osteolysis (46 genes) and limb malformations and brachydactyly (51 genes). These four subpanels can also be ordered separately or together as a comprehensive panel. To compare the clinical diagnostic yields of the panels, we analyzed data from 175 clinical tests performed at the Emory Genetics Laboratory from January 2014 to April 2015. We found that the skeletal disorder panels had an overall 39% diagnostic yield in 75 cases while the proportionate panels had 5% in 100 cases. Among the distinct skeletal disorder panels, the disproportionate short stature had the highest yield of 75% (n=8) followed by skeletal comprehensive panel (51%; n=37). The lowest was the limb malformation panel at 0% (n=13). For proportionate cases identified with genetic causes, two cases had copy number changes, the two cases had sequencing pathogenic variants in single genes and one case had methylation abnormality consistent with Russel-Silver. Our results indicate that sequencing panel testing is an efficient approach for molecular diagnosis of disproportionate short stature. The reason for the low diagnostic yield of the proportionate panels might be disorders in this panel are relatively easily recognized and diagnosed by other means such as single gene sequencing; thus panel testing was not ordered. Limb malformations have many genetic causes remaining to be defined, which may explain the low yield.

1965F

When the Gold Standard is supplanted by Platinum: Analysis of the reliability of Sanger sequencing compared to that of Next-Generation Sequencing. *A. S. Zare, J. B. Warner, N. Gebremedhin, E. M. Zare, C. E. MacNally, V. R. Tadigotla, C. M. Stanley.* Courtagen Life Sciences, Woburn, MA.

Sanger sequencing, developed in 1977, has long been regarded as the gold standard of sequencing. Though the technology has seen many improvements and iterations in its long history, progress has slowed down significantly in the last decade. Efforts on developments in sequencing have been shifted to the fiercely competitive arms race in the Next-Gen Sequencing (NGS) space, causing this new technology to become more reliable and more robust than its predecessor. Yet, regulatory agencies still mandate the use of older technology to confirm all variants on outgoing reports, even when the preponderance of evidence points to the validity of variants detected via NGS. The question then arises, what is one to do when the outdated technology does not confirm the strong evidence present in the superior data? To address these concerns we describe the retrospective analysis of over 2,000 variants, which were initially identified by NGS and were subsequently Sanger sequenced for confirmation. Using an internally derived scoring method constructed on Phred base quality, mapping quality of reads, and coverage over a particular variant we define low quality reads as being reads with less than a score of 500. We analyzed 2,092 NGS variants that we've identified in 1,003 different samples, and only found 68 low quality variants that would require a secondary method of confirmation. In the total data set, we found only 28 variants that were not confirmed by Sanger sequencing. Of these 28 non-confirming variants, 23 were low quality variants with an internal quality score less than 500. The other 5 variants did not confirm by Sanger due to the existence of private SNPs existing under one of the PCR primers designed, resulting in allele dropout. The results of this study show the reliability of NGS when compared to Sanger sequencing, and illustrate the redundant effort needed by the diagnostic labs to create a secondary pipeline, which is now obsolete compared to the superior technology that exists today. Low quality variants likely need a method of confirmation. However, we propose the use of a sequencing technology that has quality and reliability comparable to the original detection technology.

1966W

Exon-level arrayCGH identifies novel multi-exon copy number variants in the TTN gene in patients with dilated cardiomyopathy. *O. D. Cano[1], A. P. Barnes[2], B. F. Birnbaum[2], I. Klein[3], T. de Marco[3], G. Li[1], D. J. Tan[1], A. Singleton[1], S. Aguilar[1], J. L. Jenkins[2], J. Wojciak[3], D. Dorsainville[1], D. Macaya[1], G. Richard[1], D. E. Pineda-Alvarez[1], J. Meck[1], C. Antolik[1].* 1) GeneDx, Gaithersburg, MD; 2) The Ward Family Heart Center and Division of Clinical Genetics Children's Mercy, Kansas City, MO; 3) University of California, San Francisco. CA.

TTN encodes for the protein titin, which is localized in the contractile apparatus in striated muscle. Titin, the largest protein in the human proteome, spans half the distance of the sarcomere and functions both as a scaffold for sarcomere assembly and as a molecular spring that provides passive tension in muscle fibers. Within the sarcomere structure, titin is anchored in the Z-line and spans through the I- and A-bands to the M-line. Pathogenic variants in titin are known to cause skeletal myopathies and/or cardiomyopathy. Loss of function mutations in TTN identifiable by gene sequencing account for ~25% of cases of familial dilated cardiomyopathy (DCM) and ~18% of sporadic DCM. These mutations occur predominantly in the A-band region of titin, and only rarely in the amino terminal I-band. To date, a single intragenic duplication of 28 kb involving exons 72-124 has been reported in a proband with DCM (Herman DS, et. al. , N Engl J Med. 2012:366:619). The duplication occurred in tandem and was predicted to be in-frame and encompassing the I-band. Using a multigene panel, which includes sequence analysis of 76 genes and exon-level deletion/duplication analysis of 60 genes associated with various forms of cardiomyopathy, we identified 3 patients with DCM from 2 unrelated families who were heterozygous for a multi-exon copy number variant in TTN. No other reportable sequence variants were identified in TTN or in any other gene of the panel. A 16 yo female with family history of cardiomyopathy and her 45 yo father had an 11 Kb intragenic deletion spanning exons 110-125. Based on *in-silico* analysis this deletion is predicted to be in-frame and would span the I-band of titin. Another 20 yo male with DCM who also had a family history of DCM carried a 27 Kb intragenic duplication of exons 193 through 245 of the TTN gene. This duplication is also expected to be in-frame if it occurred in tandem, and would alter the I- and A-band regions of titin. Further family studies are underway to determine if this event co-segregates with DCM in the family. Our findings suggest that intragenic, multi-exon deletions or duplications might be pathogenic and associated with DCM, and hence should be included in the diagnostic testing algorithm for cardiomyopathies.

1967T

Broadening the mutational spectrum of Cornelia de Lange syndrome: identification of four novel *HDAC8* deletions including the first report of a deletion in mosaic state. *M. Helgeson[1], J. A. Lee[2], G. Hoganson[3], J. Burton[3], C. Schaaf[4], R. Laframboise[5], S. Tremblay[5], I. Krantz[6], S. Noon[6], Y. Hu[1], K. Donato[1], Z. Li[1], L. Wysinger[1], S. Das[1], D. del Gaudio[1].* 1) Department of Human Genetics, University of Chicago, Chicago, IL; 2) Greenwood Genetics Center, Greenwood, SC; 3) Division of Genetics, University of Illinois College of Medicine, Peoria, IL; 4) Department of Pediatric Medicine, Genetics, Texas Children's Hospital, Houston, TX; 5) CHU de Québec, CHUL, Québec, QC, Canada; 6) Division of Human Genetics, The Children's Hospital of Philadelphia, PA.

Cornelia de Lange syndrome (CdLS) is a genetically heterogeneous disorder characterized by distinctive facial features, hirsutism, growth retardation, upper limb anomalies, developmental delays, and intellectual disabilities. Mutations in *NIPBL* [MIM 608667], encoding a cohesion regulatory protein, account for >80% of cases with typical facies. Mutations in the *SMC1A* [MIM 300040], *SMC3* [MIM 606062], and *RAD21* [MIM 614701] genes encoding for cohesin complex proteins, together account for ~5% of patients with atypical CdLS features. Recently, loss-of-function mutations in the X-linked *HDAC8* [MIM 300269] gene have been identified in a small number of patients with growth, cognitive and facial features consistent with those caused by mutations in *NIPBL*. We report the identification, by exon-targeted array-CGH, of four novel intragenic *HDAC8* deletions in female patients with features of CdLS. The deletions were confirmed by either Real-Time quantitative PCR or breakpoint sequencing. For one case the deletion was present in a mosaic state in the peripheral blood sample from the patient and was subsequently confirmed in buccal cells. For this patient, X-chromosome inactivation was random in peripheral blood sample, but was moderately skewed in buccal cells. For the other deletion patients, X-chromosome inactivation studies demonstrated a highly skewed pattern in the blood samples, presumably towards the normal allele, suggesting a strong selection against the mutations. Consistent with the molecular analyses, these patients displayed features of CdLS, including dysmorphic features such as synophrys, thin upper lip, and posteriorly rotated ears. Other features included significant speech and motor delays, growth retardation, myopia, and atrial septal defect. This study expands the spectrum of *HDAC8*-related CdLS mutations, highlights the importance of performing comprehensive molecular testing including copy-number analysis of *HDAC8*, and provides the first description of an *HDAC8* deletion in a mosaic state.

Success of next generation sequencing usage for adults and newborns affected with neuromuscular and skeletal disorders. *K. M. Rocha[1], M. Lazar[1], G. L. Yamamoto[1,2], M. Aguena[1], V. Takahashi[1], N. Lourenço[1], M. Varela[1], S. Ezquina[1], D. Bertola[1,2], R. C. Pavanello[1], M. Zatz[1], M. R. Passos-Bueno[1].* 1) HUG-CELL Dept of Genetics and Evolutionary Biology, Institute of Biosciences - University of Sao Paulo, Sao Paulo, Sao Paulo, Brazil; 2) Genetics Unit, Children's Institute, Clinics Hospital, Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil; 3) Faculty of Medicine, University of Sao Paulo, Sao Paulo, Brazil.

During the past two years our lab has been using the targeted next geneneration sequencing (NGS) as the primary method for genetic diagnostic of some groups of diseases. Since then, we have concluded the molecular testing of 406 patients that were referred to our service. Those patients were divided in four main groups: neuromuscular disorders (N=229), skeletal dysplasias (N=60), hereditary cancer (N=12) and other diseases, including neurodevelopmental and cystic fibrosis (N=105). We have detected mutations in 252 patients (62. 1%). The highest detection rate was found in patients grouped as neuromuscular disorders, 72. 9% (N=167), followed by skeletal dysplasias, 63. 3% (N=38), hereditary cancer, 41. 7% (N=5) and all other diseases, 40% (N=42). A significant improvement in the diagnosis rate was made through the use of a software (NextGene from Softgenetics) to detect gross deletions and duplications from NGS data. Although the majority of the cases had hemizygous deletion in *DMD* gene, we were also able to detect *DMD* duplications in females, heterozygous duplications of *PMP22* gene and heterozygous deletions of *MLH1*, *TWIST1* and *NSD1* genes. Apart from *MLH1* gene, which has not been tested by another method, all deletions and duplications were confirmed by MLPA. The use of this software has also simplified our routine, since now, we only do the MLPA as a confirmation test. Along with our routine diagnostic tests, we have also performed a pilot study with pregnant women in whom prenatal ultrasonography had showed a fetus presenting shortened or malformed limbs. These women were referred for clinical genetics prenatal consultation and received a letter of recommendation to collect blood and X-ray images from the newborn. After postnatal images evaluation, a diagnosis hypothesis was made and molecular testing performed accordingly. In the past few months, 10 cases were evaluated and 7 have completed molecular testing. Among these 7 cases, 5 newborns died in the perinatal period. Conclusive diagnostic was obtained in all 7 cases (lethal cases: otopalatodigital type II; thanatophoric type I, thanatophoric type II, achondrogenesis type II, osteogenesis imperfecta type II; non-lethal cases: achondroplasia, diastrophic dysplasia). Targeted NGS has been proved a valuable diagnostic tool in patients whose phenotype had been well characterized, mostly when the number of disease-causing genes is small and well known. Financial support: Fapesp/CEPID and CNPq/INCT.

1969W

Gross deletion of *TSPAN12* detected in patients with familial exudative vitreoretinopathy. *J. Song[1], S. Seo[1], Y. Yu[2], S. Cho[1], M. Seong[1], S. Park[1].* 1) Dept Laboratory Medicine, Seoul National Univ Hosp, Seoul, South Korea; 2) Dept Ophthalmology, Seoul National Univ Hosp, Seoul, South Korea.

Background: Familial exudative vitreoretinopathy (FEVR) is a rare hereditary disorder characterized by failure of peripheral retinal vascularization. FEVR is genetically heterogeneous, and found in various modes of inheritance. Autosomal dominant inheritance is the most common form in FEVR, with *FZD4*, *LRP5*, and *TSPAN12* known to be associated with the disease. These genes are essential components of wingless (Wnt) pathway and pathogenic mutations affecting the function of these genes result in abnormal retinal vascular formation. Until now, gross deletion of *TSPAN12* in FEVR patients had not been reported. Herein, we report cases of FEVR with *TSPAN12* deletion. **Methods:** In patients who were suspected to carry gross deletion of *TSPAN12*, gene dosage analysis of *TSPAN12* was performed. Diagnosis of FEVR was established by ophthalmic examinations. All patients had been previously screened for *NDP*, *FZD4*, *LRP5*, and *TSPAN12* mutation, which were all found to be negative. Gross deletions and duplications of NDP, FZD4 and LRP5 screened via Multiplex Ligation-dependent Probe Amplification (MLPA) were also negative. **Results:** Patient #1, who was found to carry chromosome del(7) (q31. 2q34), had peripheral retinal avascular area in both eyes. Considering the location of *TSPAN12* being 7q31. 31, it was suspected that whole gene deletion of *TSPAN12* was the pathogenic cause for patient's symptoms. Patient #2 was found to carry a rare *TSPAN12* variant of c. 484G>A as a homozygote by sequencing analysis. Her brother (Patient #3) who had the same diagnosis did not carry this variant. Since the variant did not segregate in this family, it was concluded as a less-likely pathogenic variant, but still there was a possibility of gross deletion in this exon regarding that this rare variant was detected as homozygote. Gene dosage analysis showed that all three patients carried half the amount of *TSPAN12* gene compared to normal control (ratio of 0. 45 to 0. 50), indicating that each patient carried gross deletion of *TSPAN12*. **Conclusions:** In this study, we have identified gross deletion of *TSPAN12* in patients with no mutation detected in NDP, FZD4 and LRP5. This is the first report of *TSPAN12* gross deletion detected in FEVR patients. Evaluating gross deletion or duplication of *TSPAN12* should also be considered in genetic workups for FEVR patients. ----------**Keywords**: Familial exudative vitreoretinopathy, *TSPAN12*, gross deletion.

1970T

Whole Exome Sequencing and Whole Mitochondrial Genome Sequencing for the Molecular Diagnosis of Mitochondrial Disorders. *R. Bai[1], A. Balog[1], J. Higgs[1], K. Retterer[1], D. Arjona[1], J. Juusola[1], Q. Abu Ali[1], S. F. Suchy[1], G. M. Enns[2], R. Haas[3], A. Goldstein[4], M. Tarnopolsky[5], S. Parikh[6], W. C. Copeland[7], D. Niyazov[8], M. J. Falk[9], S. J. Bale[1], W. K. Chung[10], G. Richard[1].* 1) GeneDx Inc, Gaithersburg, MD; 2) Stanford University, Palo Alto, CA; 3) Rady Children's Hospital-San Diego; 4) Childrens Hospital of Pittsburgh, Pittsburgh; 5) McMaster University Medical Center, Hamilton, Ontario; 6) Cleveland Cinic, Cleveland, Ohio; 7) NIEHS ,Research Triangle Park, NC; 8) Ochsner Health System, New Orleans, LA; 9) Children's Hospital of Philadelphia, Philadelphia, PA; 10) Columbia University Medical Center, New York, NY.

Molecular diagnosis of mitochondrial disorders (MtD) is challenging due to their clinical and genetic heterogeneity. Until now, it entailed consecutive testing for common mutations/ genes/disease-specific gene panels until a diagnosis was made or all these options were exhausted. Now whole exome sequencing (WES), which covers >96% of the gene coding regions in the nuclear genome, and whole mitochondrial genome sequencing (WMGS) are becoming widely applied to the molecular diagnosis of MtD. We performed WES on 865 patients clinically suspected of having a MtD, combined with WMGS in 673 of these cases. According to the MtD criteria (Neurology 2006, 67:1823), 86/163/616 had definite/ probable/possible MtD, respectively. In the majority of the cases (83%), WES was performed on proband-parent trios (WES-Trio), while the remaining 17% were singletons or non-trios. A positive diagnostic result was obtained in 254/865 (29%) cases tested by WES. The positive rate for trios (30. 5%) was appreciably higher than that of singletons and non-trios (23. 8%). Of the 254 positive cases, 97 (38%) had pathogenic/ likely pathogenic variants (PV) in known MtD genes, 15 (6%) had PV in genes encoding proteins involved in other mitochondrial pathways, and the remaining 142 (56%) had PV in well-known non-MtD genes with clinical features overlapping with MtD. Concurrent WMGS performed for 673 cases revealed PV in mtDNA at a clinically significant level of heteroplasmy in 26 (4%) cases, including 2 large-scale mtDNA deletions and 24 point mutations (8 homoplasmic, 16 heteroplasmic). Three of the PV were seemingly unrelated to the patient's reported phenotype, two of these cases as well as another six cases with PV in mtDNA also had a positive WES result, in a nuclear gene associated with either a MtD or a non-mitochondrial disorder. In summary, the combined positive rate of WES and WMGS in our cohort was approximately 32%, considerably higher than the positive rate (<20%) of our multi-gene panel for MtD, WHICH INCLUDES almost all the well-characterized mitochondrial disease genes. We provide evidence that PVs in mtDNA and nuclear genes may coexist in a patient, albeit this co-occurrence is rare. We suggest that WES-Trio/WMGS is effective as the first-line test for patients with a suspected mitochondrial disorder in order to achieve the best diagnostic yield.

1971F

Impact and implementation of benchmarking frequency thresholds for variant filtering in clinical diagnostics. *M. C. Dulik[1], L. K. Conlin[1,2], S. Biswas[1], J. L. Abrudan[1], V. Jayaraman[1], M. H. Li[1], I. D. Krantz[3], N. B. Spinner[1,2].* 1) Department of Pathology and Laboratory Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Pathology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Allele frequency is often a significant piece of information used in classifying the pathogenicity of a variant in clinical molecular genetics and cytogenetic laboratories. Many clinical laboratories performing exome and whole genome sequencing rely on allele frequency to filter variants to a manageable list for further interpretation. As the variant interpretation is the most time consuming and resource-heavy component of such tests, reduction of this variant list is desirable to include only the most important variants. This is especially critical for secondary finding analysis, which can identify numerous previously reported variants but is not the primary reason for the test. Secondary findings often require more effort than those for primary because in many cases multiple papers with additional evidence are considered for a reported variant. As part of the NHGRI-funded Clinical Sequencing Exploratory Research Program, the Pediatric Genetic Sequencing (PediSeq) Project at The Children's Hospital of Philadelphia and the University of Pennsylvania is identifying best practices for exome sequencing in a pediatric clinical diagnostics setting. To determine appropriate frequency thresholds for filtering secondary findings, over 130 genes implicated in causing autosomal recessive conditions were selected from our established PediSeq carrier status list. More than 200 prevalent, well-known pathogenic variants were identified through literature and databases searches. The overall contribution of each variant to causing disease was recorded if known, and allele frequencies for each variant were queried from publicly available databases. A set of 50 exomes were then filtered using a list of medically actionable genes, a commercially available database of reported mutations, and different allele frequency cutoffs to assess the impact of a benchmarked value as compared to the commonly applied value of 5%. On average, use of the benchmarked threshold reduces the list of variants by an average of 64%, resulting in 10 variants per exome versus 30 with the 5% cutoff. Interpretation of variants between the benchmark and 5% threshold in a subset of exomes resulted in the identification of no additional pathogenic variants. It is shown that by considering the composition of allele frequency databases and the frequency with which known pathogenic variants occur, one can reduce the overall burden of secondary findings for clinical exome sequencing.

1972W

The Genome Clinic in Geneva: development of an efficient and patient-friendly diagnostic application of NGS. *E. B. Hammar[1], S. Fokstuen[1], P. Makrythanasis[1,2], M. Guipponi[1,2], E. Ranza[1,2], K. Varvagiannis[1], F. A. Santoni[1,2], M. Albarca-Aguilera[1], M. Poleggi[1], A. Vannier[1], C. Brockmann[1], F. Couchepin[1], A. Mauron[4], S. A. Hurst[4], C. Moret[4], C. Gehrig[1], J. Bevillard[2], T. Araud[1], S. Gimelli[1], E. Stathaki[1], A. Paoloni-Giacobino[1], F. Sloan-Béna[1], L. D'Amato Sizonenko[1], M. Mostafavi[1], H. Hamamy[2], T. Nouspikel[1], J. -L. Blouin[1], S. E. Antonarakis[1,2,3].* 1) Genetic Medicine and Laboratory, University Hospitals of Geneva, 1211 Geneva 14, Geneva, Switzerland; 2) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 3) iGE3, Institute of Genetics and Genomics of Geneva, Geneva, Switzerland; 4) IEH2, Institute of Ethics, History and Humanities, University of Geneva, Geneva, Switzerland.

The advances of next generation sequencing (NGS) technologies enable their application in clinical care. However, there are several challenges for the implementation of NGS in clinical diagnostics including technical, financial, ethical, managerial, variant interpretation, genetic counseling and quality control issues. The aim of our work is to continuously improve the diagnostic use of NGS to be most efficient in terms of accuracy of variant interpretation, turn-around time of analysis and patient information. The reimbursement of diagnostic NGS tests has recently been accepted by the Swiss Federal Office of Public Health (SFOPH). The prices are described in the List of analysis (see link: http://www. bag. admin. ch). We use whole exome sequencing (WES) followed by targeted bioinformatics analysis of gene panels. In order to optimally integrate the implementation of NGS in clinical care, we have created a multidisciplinary working group, the Genome Clinic Task Force (GTCF), which meets once a week. During these meetings, clinical cases and results are presented, the degree of pathogenicity of variants is determined and the final laboratory reports are critically discussed. Reimbursement and ethical issues such as the content of the informed consent form, the disclosure of results as well as the management of incidental findings and variants of unknown significance (VUS) are also addressed. Since January 2013, a total of 116 cases have been included in the GCTF workflow, and 71 cases are finished. We found pathogenic variants (class 4 or 5) in 23% (6/26) of patients with developmental delay and in 57% (26/45) of patients suffering from various mendelian disorders, which gives us an average detection rate of (likely) causative variants of 46 % (33/71). Variants of unknown clinical significance (VUS, class 3) were found in 23 % (6/26) of the patients with developmental delay and in 7 % (3/45) of the patients with other phenotypes. VUS are disclosed only if they are closely related to the clinical phenotype. The mean duration of a complete analysis was 193 days. In order to render our diagnostic use of NGS even more efficient and patient-friendly, our main aims are 1) to improve different steps of the workflow in order to accelerate the analysis process 2) to integrate new and more reliable methods of variant interpretation (as described in S. Richards et al. 2015) and 3) to improve the genetic counseling.

1973T

Pre-clinical cancer: an example of how genomics could reshape the prognostic paradigm. *E. G. Seaby[1], R. D. Gilbert[2], G. Andreoletti[1], R. J. Pengelly[1], S. Ennis[1].* 1) Genomic Informatics, University of Southampton, Southampton, Hampshire, United Kingdom; 2) Wessex Regional Paediatric Nephro-Urology Service, Southampton Children's Hospital, Southampton, Hampshire, United Kingdom.

Whole exome sequencing (WES) has proven success in rare disease of unknown aetiology, yet one of its greatest strengths lies in the ability to return to and manipulate data for prognostic benefit. We present the case of a 4-year-old Caucasian male with atypical haemolytic uraemic syndrome (aHUS), moya moya and a non-specific dysmorphology. In 2013, this patient was referred for WES to elucidate a cause for his aHUS; no pathogenic variants were identified. In 2015, this case was revisited following clinical review. Phenotypic information concerning splenomegaly and persistent thrombocytopaenia informed a revised analysis. Filtering parameters reduced 51 variants to one heterozygous splicing variant in *CBL* (c. 1096-1G>T), later confirmed *de novo* by Sanger sequencing. Germline *CBL* mutations are associated with: Noonan-like syndrome; moya moya; vasculitis; and the progression to juvenile myelomonocytic leukaemia (JMML) following somatic loss of heterozygosity (LOH) on chromosome 11q. JMML is an aggressive, childhood myeloproliferative disease cured only by stem cell transplant, yet haematological heterogeneity is reported; some haematological abnormalities spontaneously resolve, while others progress aggressively. This considered, we scrutinised available data for LOH across chromosome 11 in the region of the *CBL* locus; facilitated by DNA extracted from peripheral blood. We retrospectively assessed LOH by plotting B-allele frequency ratios across the exome. Significant allelic imbalance across chromosome 11q strongly suggested a clonal expansion of peripheral lymphocytes consistent with myeloproliferation and a transformation to JMML. These results pose a difficult diagnostic dilemma; our patient is displaying evidence of myeloproliferation and progression to JMML despite not manifesting clinical leukaemia (a bone marrow aspirate and blood film were unremarkable). This pre-clinical finding hugely challenges the appropriate action(s) to take, especially since a decision to proceed to transplant is not without significant risk, yet may prove curative. This has necessitated a multidisciplinary convergence of genomic informaticians and clinicians into discussions concerning best practice. In the ever emerging genomics era, cases such as these will become ever prevalent and the interpretation and translation of genomic data within clinical medicine has the potential to force a paradigm shift in clinical diagnostics with substantial prognostic impact.

1974F

Prevalence of incidental findings of potentially actionable variants in exome chip in the CHARGE consortium. *M. K. Puurunen[1], Y. -P. Fu[2], C. J. O'Donnell[2] on behalf of the CHARGE Exome Chip Working Group.* 1) Framingham Heart Study, Boston University School of Medicine, Framingham, MA; 2) Division of Intramural Research, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD, USA.

BackgroundWith next-generation sequencing (NGS) methods, disease variants with potential clinical importance are increasingly detected (i. e. incidental findings). Knowledge of 'actionable variants' can lead to a clinical intervention or personal decisions. However, estimates in large general populations of the prevalence of incidental findings expected from contemporary genome analysis are lacking. AimIn a large consortium of community-based populations we aim to assess the burden and distribution of potentially actionable variants using Illumina Infinium HumanExome BeadChip. We focus on a panel of genes listed as disease-causing with possible adult onset by an expert panel (UW Clinical Sequencing and Exploratory Research "NEXT Medicine" Return of Results Committee). MethodsThe study includes 85,101 adults across 17 community-based cohorts within the Cohorts for Heart and Ageing Research in Genomic Epidemiology (CHARGE) Consortium [54. 5% female; 15. 9% non-European descent; mean age 57 years (range 18-101)]. In a preselected set of 112 'actionable' genes, we focused on 254 coding single nucleotide variants (SNVs) [251 nonsynonymous, 1 synonymous, 2 3'slice site] observed in the NHLBI Exome Sequencing Project (ESP) and classified by a trained annotation panel as pathogenic (n=6), likely pathogenic (n=10), variants of unknown significance (VUS, n=150), or likely benign (n=88) based on allele frequency and review of literature. ResultsThe overall burden of pathogenic or likely pathogenic SNVs was 0. 34%. The number of individuals with actionable genotypes of pathogenic variants, likely pathogenic variants, likely benign variants, and VUS were 41, 250, 16266, and 15107, respectively. Pathogenic or likely pathogenic genotypes (prevalence ranging from 0. 001% to 0. 096%) were noted in 10 genes that predict a range of diseases, including *SCN5A* (ventricular arrhythmia), *SERPINA1* (alpha-1 antitrypsin deficiency) and *BRCA1/2* (breast cancer). After accounting for cohorts, no age or sex differences were observed. Significant allele frequency differences between persons of European and African ancestry were noted for SNVs in *SERPINA1, SLC7A9* and *LDLR*. ConclusionsA significant number of participants with potentially actionable SNVs were observed in community-based studies genotyped by exome chip, some with important differences depending upon ancestry. Further research is warranted to determine the clinical importance of these variants.

1975W

Exome sequencing is an efficient method for the molecular characterization of rare Mendelian disorders. *A. E. Bale, D. J Dykas, A. E. Bailey, J. C. Sinson, S. Mane, R. P. Lifton, P. Tsipouras.* Genetics, Yale School of Medicine, New Haven, CT.

Whole Exome Sequencing (WES) is increasingly utilized in clinical diagnosis of genetic conditions due to its efficiency, comprehensiveness, and agnostic nature. Being one of the first to introduce WES in clinical practice we set to evaluate its utility by reviewing our first two years of use. Exonic sequences in DNA samples from blood or saliva were captured (Roche/Nimblegen SeqCap EZ Human Exome Library v2. 0) and sequenced on the Illumina HiSeq platform. Mean coverage of the human exome was 75-100X with 97% of bases covered at least 8 times. The resulting sequence was analyzed for genetic variants of likely relevance to human disease. We reviewed the clinical notes and lab reports from a total of 1,082 cases spanning a 24 month period (2013-2014). Major diagnostic categories of testing included acute metabolic disorders in newborns and infants, dysmorphic, metabolic, and neurologic conditions presenting in childhood, intellectual disability and autism, adult-onset cardiac, vascular, neurological, hepatic, hematological and connective tissue disorders, and hereditary cancer predisposition. The referrals were primarily through Yale faculty and affiliated community physicians. We detected a pathogenic variant in 242/1,082 (22%), a variant of uncertain significance (VUS) in 295/1,082 (27%), and incidental findings in 15/1,082 (1. 3%) of cases. These statistics are in agreement with other large scale studies. The greatest number of positive tests were detected in cardiomyopathies (pos 44%, VUS 39%, neg 17%), seizures (pos 25%, VUS 42%, neg 33%), and hematological disorders (pos 25%, VUS 25%, neg 50%). Samples submitted for connective tissue disorders showed the lowest rate (pos 3%, VUS 6%, neg 91%). During the two year period, the number of tests ordered per month increased three-fold, reflecting primarily an increase in the spectrum of clinicians ordering testing for large panels of genes. WES has disrupted molecular diagnostics. A single platform covering almost all hereditary conditions allows for cost-effective, comprehensive, phenotype-based diagnostics rather than an inefficient and lengthy gene-by-gene hunt for a diagnosis.

1976T

An integrated approach to genetic diagnosis: Genomic research and clinical care at the TGen Center for Rare Childhood Disorders. *A. M. Claasen[1,2], K. M. Ramsey[1,2], N. Belnap[1,2], S. Szelinger[1,2,3], A. L. Siniard[1,2], I. Schrauwen[1,2], J. J. Corneveaux[1,2], B. E. Hjelm[1,2], A. L. Courtwright[1,2], R. F. Richholt[1,2], M. De Both[1,2], S. Rangasamy[1,2], M. J. Huentelman[1,2], D. W. Craig[1,2], V. Narayanan[1,2].* 1) Neurogenomics Division, Translational Genomics Research Institute, Phoenix, AZ; 2) Center for Rare Childhood Disorders, Translational Genomics Research Institute, Phoenix AZ; 3) Molecular and Cellular Biology Interdisciplinary Graduate Program, School of Life Sciences, Arizona State University, Tempe, AZ.

Personalized genomic medicine is changing the landscape of diagnosis of rare diseases. At TGen's Center for Rare Childhood Disorders, our integration of a clinical diagnostic center and a genomics research laboratory provides a unique opportunity to significantly impact the lives of children with rare, undiagnosed genetic disorders, and their families. We have enrolled 914 individuals across 290 families into our study to date, and completed whole-genome or whole-exome sequencing of over 800 individuals. A further 42 families sequenced at external sites have been analyzed using our in-house bioinformatics pipeline and annotation. Our study takes a multi-omic approach to diagnosis, including sequencing whole-exomes of family trios, with complementary application of mRNA-seq, methylation arrays, and structural variant detection for difficult cases. Where appropriate, patients are consented for collection of fibroblasts for reprogramming and differentiation to appropriate tissue types to better understand the biology, particularly as new gene-disease associations are made. Currently, RNAseq has been completed for 102 individuals. We implement frequent re-analysis of genomic data using updated annotation and prioritization methods. Here we report a summary of the families currently in our study. Criteria for enrollment include a previously undiagnosed condition with childhood onset, ambiguous genetic origin, and negative or inconclusive genetic tests. The majority of patients present with some form of neurological phenotype, and suspected conditions include mitochondrial disease, Aicardi Syndrome, movement disorders, and epilepsy, among others. Identified variants are characterized by their likelihood, and in approximately 36% of cases a presumed causal or likely causal variant has been found, and in about 9% of cases we have identified candidate variants which require additional testing and functional validation. Following on from diagnosis, we have further supported families by facilitating enrollment of a number of diagnosed families into clinical trials, connected them with experts in the field, and provided alternative treatment options. Research initiatives include the development of animal models, and drug screens with FDA-approved compound libraries for selected causal genes. Our center provides a unique experience for families, through our personalized approach to diagnosis and follow-through care.

1977F

Lessons from Clinical Exome Sequencing in the Montana Genetics Program. *A. F. Elias, K. Berry, J. A. Camacho, M. Clark, J. Foster, C. Hudson, J. P. Johnson, T. Pitman, S. Wakefield, D. Xu.* Department of Medical Genetics, Shodair Children's Hospital, Helena, MT.

Shodair provides clinical and laboratory genetic services through an outreach model across Montana and bordering regions. Integration of genomic approaches into patient care faces particular challenges within the health care setting of Montana with its mostly rural communities and few urban centers separated by vast geographic spaces. At the same time, the state draws a growing number of specialists, allowing increasingly for local management of patients with complex health problems. NGS technologies including whole exome sequencing (WES) have led to a substantial increase in diagnostic yields. Here, we present our experience with WES over the past 3 years. From 1/2012 to 6/2015, samples from 39 patients were submitted to AmbryGenetics. Results of 27 patients were available at the time of this abstract. Fifteen samples were submitted between 2012 and 2014 compared to 24 in 2015 corresponding to a 10-fold increase. Initially, the majority of patients had undergone repeated unsuccessful evaluations. More recently our patients underwent WES earlier in the diagnostic process. Most patients had developmental delay, but the clinical presentations span a broad spectrum of phenotypes including autism, dysmorphism, congenital anomalies, metabolic disturbances and epilepsy. In 9 of 27 patients mutated alleles highly likely to be causative were identified (diagnostic rate of 33%). Inheritance patterns were AD (6), AR (2), XL (1). All 7 of the AD and XL mutant alleles occurred *de novo*. Eight of the 9 genes were associated with Mendelian disorders: *ANKRD11*;*BBS10*; *CASK*;*GLI3*; *KMT2A;MEF2C*;*SETD5*; *TCF4*. Compound heterozygous mutations detected in one patient in a gene without disease association were found in other patients with similar presentation using GeneMatcher. Variants in 334 genes not known to underlie a genetic condition and 51 variants of uncertain significance (VUS) without actionable information were reported. The large amount of variants can increase workload and complicate genetic counseling. As a result, we are implementing a NGS platform to sequence about 4,800 genes with known disease associations. This approach has the potential to maximize diagnostic yields while minimizing the number of VUS. In a setting like Montana, where timely specialist evaluations may be limited, a phenotype-genotype-guided evaluation early in the diagnostic process rather than diagnostic odysseys preceding genetic testing may be cost efficient and improve patient care.

1978W

Utility and limitations of exome sequencing as diagnostic tool for bilateral sensorineural hearing loss. *V. Jayaraman[1], J. Abrudan[1], M. Li[2], I. Slack[1], A. Sasson[1], M. Dulik[1], S. Biswas[1], E. DeChene[1], M. Luo[1], I. Scarano[1], R. Tilton[1], S. Noon[1], A. Wilkens[1], X. Ying[1], L. Conlin[1], J. Pennington[1], N. Spinner[1], I. Krantz[1].* 1) Children's Hospital of Philadelphia, Philadelphia, PA; 2) University of Pennsylvania, Philadelphia, PA.

Bilateral sensorineural hearing loss (BLSNHL) is one of the most genetically heterogeneous diagnoses with more than 200 associated genes. Current testing for BLSNHL is either done by Sanger sequencing or next generation sequencing (NGS) of gene panels. These tests can be cumbersome and are not comprehensive. We report the results of applying WES for the diagnosis of BLSNHL. This work was carried out through the CHOP/UPenn Pediatric Genetic Sequencing (PediSeq) project, an NHGRI funded (part of the Clinical Sequencing Exploratory Research (CSER) consortium), to study the application of exome and genome sequencing to clinical care. To evaluate coverage and clinical utility of the test we exome sequenced 269 samples (from a diverse pediatric cohort sequenced for various clinical indications) using exome capture (Agilent SureSelect V4), and sequencing (Illumina HiSeq 2000) at an average depth of 100X. Reads were mapped to the human genome GRCh37 using Novoalign; post processing and analysis was performed using a combination of Picard and GATK. A list of 247 BLSNHL genes was used as a filter for analysis. Our goals were to determine 1) the coverage for all 4,421 exons in the 247 genes; 2) the number of BLSHNL variants that could be potentially missed from randomly generated list of 454 variants from HGMD; 3) the diagnostic yield within our BLSHNL cohort. The average percentage of exons completely covered at 20X was 77. 71%. The average percentage of exons partially covered and not covered were 16. 09% and 6. 20% respectively. In order to determine the clinical utility of exome sequencing as a potential diagnostic test for BLSHNL, we had randomly selected 454 BLSHNL variants from HGMD within the 247 known hearing loss genes and calculated the percentage of capture at various read depth using this test. Out of the 454 variants, 318 (70%) were covered with a minimum read depth of 20X. 81 (17. 8%) of them had a read depth between 10X and 20X, 45 (9. 9%) had less than 10X and 10 (2. 2%) were not captured using this test. For our diagnostic yield rate with this test, we have successfully identified the genetic cause in 12 out of 47 probands. We have negative results on 14 probands and 21 probands have a variant of unknown significance in one of the 247 BLSHNL gene. We will present several interesting illustrative examples as part of this presentation highlighting the utility and limitations of exome sequencing for BLSHNL.

1979T

Clinical Exome Sequencing Experience in 4866 Consecutive Cases. *J. Juusola[1], K. Retterer[1], M. T. Cho[1], F. Millan[1], J. Neidich[1,2], K. G. Monaghan[1], G. Douglas[1], R. E. Schnur[1], L. B. Henderson[1], A. Begtrup[1], A. Lindy[1], D. Pineda-Alvarez[1], Q. Abu Ali[1], D. McKnight[1], R. Bai[1], S. Suchy[1], B. Friedman[1], A. Telegrafi[1], D. Copenheaver[1], J. Tahiliani[1,3], G. Richard[1], T. Brandt[1], W. K. Chung[4], E. Haverfield[1,3], S. Bale[1].* 1) GeneDx, Inc. , Gaithersburg, MD; 2) Pathway Genomics Corp. , San Diego, CA; 3) Invitae, San Francisco, CA; 4) Columbia University, Departments of Pediatrics and Medicine, New York, NY.

Since January 2012, we have analyzed 4866 unique WES cases with the goal of identifying a molecular diagnosis. Of those cases, 18% were submitted as proband-only, 6. 5% with one additional family member, 69% with two additional family members, most often parents, and 6. 5% with three or more additional family members. WES was performed in three family members to maximize sensitivity and specificity of variant calling and to enable identification of *de novo* variants and determination of phase. Mitochondrial genome sequencing was also performed in 39% of cases. Patients were referred for WES primarily for neurological indications (46%) or multiple congenital anomalies (22%). A definitive diagnosis was made in 29. 7% of cases, with 24. 5% of cases definitive when analyzing the proband only, increasing to 31. 7% when three family members were tested. With an increasing number of cases analyzed, the identification of recurrent *de novo* likely damaging variants in candidate genes has enabled us to identify new disease genes, suggesting that the yield of WES will continue to increase over time. Upon request, 179 cases were reanalyzed after one year and 11. 7% of these analyses yielded a positive diagnostic result, and another 9. 5% had variants in strong candidate genes identified by mining our internal database for individuals with similar phenotypes. When analyzing by mode of inheritance for cases with a definitive diagnosis, 36. 4% were autosomal dominant and *de novo*, 27. 5% autosomal recessive, 11. 6% X-linked, 8. 0% autosomal dominant and inherited, 9. 1% autosomal dominant of unknown origin, 3. 5% mitochondrial encoded, and 3. 9% unknown inheritance. Copy number variation detected directly from WES data accounted for 2. 7% of diagnoses. Uniparental disomy was identified in 13 cases, and a definitive diagnosis was established in 6 of these cases. Mosaicism for pathogenic variants was identified in 17 cases, 9 of which represented parental mosaicism. The overall diagnostic yield for patients whose symptoms included intellectual disability or developmental delay was 32. 4% (N=2650), 29. 9% (N=1403) for seizures, and 22. 9% (N=849) for autism spectrum disorder. Secondary findings for the 56 genes in the ACMG list were analyzed in 3815 cases, and 3. 7% were found to have reportable variants. The experience with our first 4866 WES cases suggests that analysis of trios improves the diagnostic yield and facilitates identification of novel candidate genes.

1980F

Exome sequencing as a diagnostic test to establish the molecular cause in renal disorders. *D. Lugtenberg[1], I. Rood[2], E. Cornelissen[3], J. Schoots[1], J. Wetzels[2], R. Roepman[1], EJ. Kamsteeg[1], H. IJntema[1], E. Bongers[1].* 1) Genetics, Radboudumc, Nijmegen, Netherlands; 2) Nephrology, Radboudumc, Nijmegen, Netherlands; 3) Pediatric nephrology, Radboudumc, Nijmegen, Netherlands.

Single gene disorders are estimated to account for ~30% of children and ~10% of adult patients attending renal outpatient services. In the Radboudumc diagnostic exome sequencing for a broad spectrum of isolated- and syndromic renaldisorders has been developed. The approach consists of a two-tier analysis in which the first step is to screen for pathogenic variants in genes that are known to be mutated in renal diseases (187 genes) or (renal) ciliopathies (125 genes). If causative mutations are not identified in the first step, the complete exome data set can be analyzed with informed consent. Here we present the results from exome seqeuncingusing arenal disease gene panel in74 unrelated patients with undiagnosed renal disease. This cohort includes patients with glomerular disease (34 cases), cystic renal disease (16 cases), electrolyte disorder (11 cases) and renal insufficiency with unknown etiology (13 cases). This analysisled to pathogenic mutations in 11 cases (15%), and in 12 other cases (16%) likely pathogenic variants needed follow-up studies. Further analysis of the complete exome data set in 19 patients, revealed novel candidate genes in six cases that are under investigation. In addition, copy number variation analysis of exome data revealed a pathogenic deletion of the *NPHP1* gene in two cases, confirming the clinical diagnosis. We conclude that diagnostic exome sequencing provides a powerful tool for detecting causative mutations in up to31 out of74 patients (40%) with a renal disease.

1981W

Improved Sensitivity and Rapid Confirmation of Variants via Orthogonal Sequencing of Exomes. *J. Thompson[1], N. Chennagiri[1], A. Frieden[1], D. Lieber[1], E. Lopez[1], T. Ross[1], T. Yu[1,2].* 1) Res & Development, Claritas Genomics, Cambridge, MA; 2) Boston Childrens Hospital, 300 Longwood Ave, Boston, MA.

Whole exome and genome sequencing studies have revolutionized the diagnosis of genetic disorders by providing information about pathogenic variants. However, each next-generation sequencing (NGS) platform has limitations in terms of coverage and error profiles. In addition, the large number of variants identified in each patient makes confirmation and interpretation of the data very challenging. ACMG practice guidelines recommend that “all disease-focused and/or diagnostic testing include confirmation of the final result using a companion technology”, a daunting task given the number of variants involved. Thus, the ability to confirm many variants quickly is critical. To maximize sensitivity and to minimize the time needed, Claritas Genomics has developed an approach using complementary and orthogonal sequencing technologies to analyze variants from whole exome sequences. Interpretation is restricted to phenotypically-defined, clinically relevant regions of interest (ROI). Each individual’s exome is sequenced using two separate DNA capture and sequencing methods. DNA is captured using a hybridization-based approach and sequenced using Illumina NGS. In parallel, DNA is captured using an amplification-based approach and sequenced using Ion Torrent NGS. Because independent and complementary technologies are used, the need for Sanger sequencing for confirmation is nearly eliminated. For a 2. 2 Mb neurologically-focused ROI, 91% of the variants are detected on both platforms and thus are orthogonally confirmed. When this analysis is carried out on DNA with an extensive truth set (NA12878), 100% of the orthogonally confirmed variants are true positives, supporting this approach. In addition, 8% of the true variants are found on only one platform and not called on the other due to insufficient coverage. The use of two capture methods and sequencing platforms extends the region over which variants can be detected so the region examined is more than either platform alone is capable. This improves sensitivity of detection, particularly with insertions and deletions because both platforms miss a significant number of such variants. Because the majority of variants are orthogonally confirmed and interpreted for pathogenicity promptly, there is no delay for Sanger confirmation and a rapid report can be provided to the physician. This provides the potential for physicians to act quickly on information with patients benefitting from timely feedback.

1982T

Experiences with the dissemination of secondary findings by diagnostic exome sequencing. *H. G. Yntema[1], M. Nelen[1], M. van Koolwijk[1], F. van Agt[2], N. Steinkamp[3], A. Mensenkamp[1], L. Haer-Wigman[1], L. E. L. M. Vissers[1], F. P. M. Cremers[1], A. van den Wijngaard[4], C. Marcelis[1], I. Feenstra[1].* 1) Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands; 2) Ethics Committee 'CMO regio, Arnhem-Nijmegen', Nijmegen, The Netherlands; 3) Department of Ethics, Philosophy and History of Philosophy, Radboud University Medical Center Nijmegen, Nijmegen, The Netherlands; 4) Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, The Netherlands.

In the Genome Diagnostics laboratory at the Radboudumc Nijmegen, whole exome sequencing (WES) has been performed for more than 4,000 patients. The WES diagnostic process is a two-tiered approach, in which tier 1 is limited to the analysis of genes known for the respective disease of the patient (*in silico* gene panel approach) and tier 2, performed if tier 1 is negative and informed consent is given, the analysis of the entire protein coding sequence. This second tier has the intrinsic risk of identifying secondary findings: mutations in disease genes not implicated in the aetiology of the disease the patient is tested for. As part of WES implementation as a diagnostic test, we set up a procedure on how to deal with secondary findings. Upon identification, a multidisciplinary committee of experts can be assembled on an *ad hoc* basis to discuss the dissemination a secondary finding. The committee consists of a clinical laboratory specialist, a clinical geneticist, a molecular geneticist, a social worker, a lawyer, and an ethicist. Other specialists with specific expertise are consulted upon indication. The committee checks informed consent, evaluates the molecular finding in the patient's clinical context, and discusses the potential medical and social impact of the finding. When it is decided (by majority vote) that the finding should be returned, a separate report is issued to the requesting clinician, not only reporting the mutation, but also the arguments for reporting the finding, as well as guidelines on how to further proceed. To date, WES beyond the gene panel of approximately 1,500 cases has been finished. Thirty-five (2. 3%) potential secondary findings have been discussed by the committee. For 21 (1. 4%) of these, mostly involving hereditary cancer and cardiac disease, it was (unanimously) decided to report the finding, based on the clear pathogenicity of the mutation and relevant medical actions that could be taken. The main reason not to report the remaining 14 findings was the unclear pathogenicity of the variant. In our hands, 1. 4% of patients receiving WES is confronted with a secondary finding. The expert committee judging these findings is considered beneficial for all laboratory specialists and clinical geneticists of our department. Furthermore, this committee is now also participating in most research projects within our hospital, suggesting that there is a wider need for discussing secondary findings than in a diagnostic setting alone.

1983F

Laboratorial diagnosis of the Fragile X syndrome: a fast, reliable and effective methodological approach supporting the Genetic Counseling services. *G. Molfetta[1,2,3], A. Marques[2,3], C. Furtado[4], E. Ramos[1], W. Silva Jr[1,2,3].* 1) Department of Genetics, Ribeirão Preto Medical School, University of São Paulo, Brazil; 2) Center for Genomic Medicine, University Hospital of Ribeirão Preto Medical School, University of São Paulo, Brazil; 3) National Institute of Science and Technology in Stem Cell and Cell Therapy, Regional Blood Center of Ribeirão Preto, Brazil; 4) Department of Obstetrics and Gynecology, Ribeirão Preto Medical School, University of São Paulo, Brazil.

Fragile X syndrome is the most common form of inherited intellectual disability characterized by loss-of-function of FMR1 caused by an increased number of CGG trinucleotides repeats accompanied by its aberrant methylation. It affects men and women with frequencies of 1:4000 and 1:6000, respectively. Mental disabilities in affected individuals ranges from learning disabilities to autism and severe mental retardation, and may be accompanied by a variety of other physical and behavioral characteristics, making the clinical diagnosis more difficult. Our goal was to offer a fast, reliable, effective and not expensive laboratorial diagnosis of Fragile X syndrome. During one year, we evaluated 186 patients under the clinical suspicion of Fragile X syndrome who have consented for the blood taken. Of these, 160 were male and 26 were female relatives of the probands. The methodological approach applied in the present study was 1) for the male diagnosis we evaluated the methylation pattern of the promoter region of the FMR1 gene by High Resolution Melting (MS-HRM) after DNA bisulfite conversion and 2) for the diagnosis of female carriers we employed the AmplideX FMR1 kit (Asuragen) allowing the exact determination of the number of CGG repeats. The MS-HRM method was able to confirm the suspicion of Fragile X in 10% (16/160) of the cases; twelve of them presented a mosaic pattern showing both methylated and non-methylated peaks. In order to confirm methylation mosaicism, the DNA genotyping was carried out in quantitative fluorescence polymerase chain biplex reactions (QF-PCR) using primers for AR and RP2 genes on X-chromosome. The QF-PCR results showed the presence of only one X-chromosome in the male patients. The AmplideX FMR1 kit enabled the diagnosis in 23% (6/26) of the female carrying more than 200 CGG repeats; five patients (19%) were premutation carries showing an allele characterized by more than 55 CGG repeats, and fifteen women (58%) had normal pattern of CGG repeats. Furthermore, one female patient presented the full-mutation allele in addition to the premutation allele characterizing this patient as an important subject to the Genetic Counseling. The molecular approach applied in the present study was informative to 15% of the cases under clinical suspicion of the Fragile X syndrome enforcing this as very reliable and fast methodology. Given the above results, we suggest the use of this approach for genetic counseling of the inherited mental disability.

1984W

Clinical implementation of *in silico* gene panel testing for clinically heterogeneous disorders using exome sequencing. *R. K. Basran, C. R. Marshall, A. Shlien, M. Eliou, J. Orr, L. Lau, D. J. Stavropoulos, P. N. Ray.* Molecular Genetics Laboratory, Genome Diagnostics, Department of Paediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, Canada.

The implementation of next generation sequencing technologies (NGS) in molecular diagnostics has resulted in a major transformation in service delivery. The ability to generate accurate sequence data from thousands of genes in a single experiment enables the development of comprehensive gene panel tests for genetically heterogeneous disorders that were previously not feasible by Sanger sequencing. At The Hospital for Sick Children (Toronto, Canada), we have developed and clinically validated expanded *in silico* gene panels using whole exome sequencing (WES) for several heterogeneous disorders including hereditary spastic paraplegia (HSP), connective tissue and bone disorders (CT), hereditary hearing loss (HL), and autoimmune disorders (AI). Previously for HL and HSP our laboratory offered a smaller subset of genes tested through Sanger sequencing. CT and AI disorders were not tested in our laboratory and were previously sent out of Canada for testing. NGS technologies have enabled our laboratory to expand our testing menu to include genes that comprise part of the differential diagnoses for these disorders in order to improve detection rates. Our laboratory's current strategy of using WES has several advantages including: (1) standardized workflows that facilitate the development of additional gene panels; (2) expansion of current gene panel as new disease associations are discovered; and (3) building of an internal database of allele frequencies to aid in interpretation of variants. Within the WES workflow, we have automated all informatics analysis, built both a database to store sequence data and a user friendly website for display and interpretation of variants. Through our validation studies we have shown high reproducibility and accuracy with >99% sensitivity for detection of single nucleotide variants (SNVs) and >95% for detection of small insertion/deletions (indels). The broadening of molecular testing for genetically heterogeneous disorders will lead to increased genetic diagnosis and ultimately better clinical care. .

1985T

Analytical validation of a saliva collection and DNA extraction protocol for a 25-gene hereditary cancer panel. *J. Cassiano, W. J. Landon, E. Goossen, D. Mancini-DiNardo, B. Leclair, B. B. Roa.* Myriad Genetics, Inc. , Salt Lake City, UT.

Background: Early identification of individuals carrying genetic mutations in cancer pre-disposing genes strongly impacts clinical management, significantly reducing morbidity and mortality from associated cancer syndromes. Analysis of DNA extracted from blood is the gold standard of germline molecular diagnostic testing. However, blood venipuncture can present challenges in some cases due to lack of on-site phlebotomy services, patient non-compliance, or inability for some patients to provide a sample due to poor venous access or needle-anxiety. DNA extracted from saliva can prove to be a viable alternative to venipuncture. We describe validation data for the collection and DNA extraction of saliva for use with our pan-cancer panel (PCP) test, an NGS-based sequence and large rearrangement (LR) detection platform for a panel of 25 genes associated with 8 cancer syndromes. **Methods:** 152 paired blood/saliva Population Control (PC) samples from healthy individuals and 29 saliva samples from previously tested patients who carry LRs in various genes (24 deletions, 3 duplications, 1 insertion, 1 triplication) were obtained from consented individuals. DNA was extracted and subjected to analysis for sequence variants and LRs. **Results:** NGS sequencing results based on analysis of 5,380 sequence variants in PCP genes found among 138 patients were 100% concordant between paired blood and saliva samples. 100% concordance was also observed between NGS and Sanger sequencing performed on a subset of paired samples. In combination with data from our NGS validation of blood DNA, the 9,303 total sequence variants found in PCP genes among 238 individuals yield an analytical sensitivity of 100% (99. 96%-100%, 95% C. I.) and specificity of 100% (99. 99%-100%, 95% C. I.) for the sequencing component of our test. NGS LR detection performed on 119 PC paired samples showed 100% result concordance between paired blood and saliva samples. The NGS results on 29 LR+ saliva samples showed 100% concordance with LR results previously reported based on testing blood samples. 100% concordance was also observed for saliva samples using orthogonal LR confirmation methods (aCGH, MLPA). **Conclusions:** There was 100% concordance in sequence variant and LR detection between blood and saliva samples. The development and validation of this saliva sample type protocol may lead to more accessible PCP testing, especially when blood venipuncture is a challenge.

1986F

Performance of ACMG variant classification guidelines within and across 9 CLIA labs in the Clinical Sequencing Exploratory Research (CSER) Consortium. *G. P. Jarvik[1], L. A. Amendola[1], H. McLaughlin[2], M. C. Leo[3], A. Milosavljevic[4], C. Horton[5], R. Ghosh[4], M. Dorschner[1], S. Punj[6], Y. Akkari[6], J. Salama[1], G. Cooper[7], L. Biesecker[8], L. K. Conlin[9], S. Biswas[9], M. Dulik[9], A. Ghazani[10], N. T. Strande[11], Y. Yang[4], E. Van Allen[12], N. Wagle[12], R. C. Green[13], A. Chinnaiyan[14], J. S. Berg[11], J. P. Evans[11], L. Garraway[12], N. Spinner[9], S. E. Plon[4], S. Richards[6], H. L. Rehm[2].* 1) University of Washington, Seattle WA; 2) Partners Laboratory of Molecular Medicine, Boston MA; 3) Kaiser Permanente, Portland OR; 4) Baylor College of Medicine, Houston TX; 5) Ambry Genetics, Aliso Viejo CA; 6) Oregon Health Sciences University, Portland OR; 7) HudsonAlpha Institute for Biotechnology, Huntsville AL; 8) National Human Genome Research Institute, Bethesda MD; 9) Children's Hospital of Philadelphia, Philadelphia PA; 10) Massachusetts General Hospital, Boston MA; 11) University of North Carolina, Chapel Hill NC; 12) Dana Farber Cancer Institute, Boston MA; 13) Brigham and Women's Hospital, Boston MA; 14) University of Michigan, Ann Arbor MI.

There is a need to standardize classification of genomic variants in medical sequencing. To date genomics laboratories have used non-standard classification systems. We have reported both inconsistency across labs in variant classification and a bias towards overcalling pathogenicity (PMID:25637381). The ACMG published guidelines for variant classification for Mendelian disorders (PMID:25741868) designed to increase consistency among labs. The Clinical Sequencing Exploratory Research (CSER) Consortium evaluated the use of these rules by 9 of the CLIA labs supporting CSER projects. 99 variants were considered, representing all categories (pathogenic, likely pathogenic, uncertain significance (VUS), likely benign and benign). 9 were classified by all 9 labs, using both the lab's own classification system and also the ACMG guidelines. 90 variants were classified by 2-3 labs (mean of 2. 85) again using both the lab and ACMG guidelines. The results were examined to evaluate intra-laboratory differences between variant classifications using the labs own criteria vs. adopting ACMG criteria and inter-laboratory differences using either the lab's own system or the ACMG guidelines. Of 335 paired variant calls, the intra-laboratory comparison of lab vs. ACMG criteria matched for 268 (80%). For those 67 discordant calls, the ACMG calls were closer to VUS in 45 (67%). Considering the inter-laboratory agreement for 98 variants, all reviewing labs (range 3-9) agreed for 36 (37%) using the ACMG and 38 (39%) using laboratory specific criteria. The Table summarizes the counts for the range of differences in classification by criteria, where "1 step" that the largest difference was 1 level of pathogenicity order, for example a range of pathogenic to likely pathogenic. Agreement among labs did not differ whether using the lab specific vs. ACMG criteria (p=0. 9); i. e. the ACMG criteria did not yield more consistent variant classification in this exercise. We further analyzed sources of disagreement in the use of the ACMG criteria and identified causes of variance in classifications that will be presented in more detail. In addition to providing useful analyses of how variant classifications approaches vary among labs, these data should allow clarification and refinement of the ACMG criteria that may increase consistency in variant classification.

Counts for inter-lab differences in classification by criteria					
Criteria	None	1 step	2 step	3 step	4 step
ACMG	36	42	19	1	0
Lab	38	41	17	1	1

1987W

Bias has no place in exome sequencing. *K. B. Pechter[1], A. I. Nesbitt[1], E. H. Denenberg[1], S. W. Baker[1], Z. Yu[1], E. T. Dechene[1], E. C. Bedoukian[2], M. Luo[1], L. K. Conlin[1,3], A. Wilkens[2], L. Medne[2], I. D. Krantz[2,3], M. A. Deardorff[2,3], A. B. Santani[1,3].* 1) Division of Genomic Diagnostics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA; 3) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Exome sequencing provides a 20-25% diagnostic rate in identifying the molecular basis for rare genetic disorders, however, there are challenges associated with the interpretation of such complex tests. In particular, we will discuss the importance of an unbiased whole exome sequencing (WES) analysis workflow that leverages detailed phenotypic capture, inheritance modeling, and comprehensive review of the literature. WES was performed on trios and data were analyzed by an in-house bioinformatics pipeline. Gene-associated variants were clinically correlated by both genetic scientists and clinicians, and variants were classified using ACMG guidelines. Case 1: An infant male proband presenting with seizures and complex brain malformations (including polymicrogyria, underdeveloped sylvian fissures, and hypoplastic pons) was analyzed by WES. We discovered a *de novo* missense mutation in the *GRIN2B* gene; *de novo* heterozygous variants in *GRIN2B* cause an autosomal dominant (AD) epileptic encephalopathy phenotype. However, this finding does not explain the complex brain malformations seen in this patient. Ultimately, it is unclear whether or not this case expands the phenotypic spectrum of *GRIN2B*-associated conditions or if the resolution power of WES was insufficient to identify a causative variant for brain malformations in this patient. This case highlights the importance of using an unbiased approach to analyze all data and explore the possibility of two molecular diagnoses. Case 2: A 7 year-old female proband presenting with microcephaly, spasticity, proportionate short stature, osteopenia with multiple fractures, and global developmental delay was analyzed by WES and a*de novo* variant in the *CTNNB1* gene was identified. Pathogenic variants in *CTNNB1* are associated with an AD mental retardation syndrome that overlaps with the majority of the patient's findings but does not explain the osteopenia and fractures. Investigation of the literature revealed heterozygous *CTNNB1* variants cause osteoporosis in mouse models, suggesting this was the molecular diagnosis for these features as well. This case emphasizes the importance of objective phenotype assessment followed by careful review of the literature to establish the full extent of the molecular diagnosis. Overall, these cases highlight some of the complexities that are inherent to the analysis and interpretation of WES data, and speak to the importance of an unbiased approach in executing this complex test.

1988T

Cytogenomic and molecular refinement of *STRC* and *CATSPER2* deafness-infertility syndrome deletion breakpoints. *L. Shi[1], Y. Kharbutli[1], J. Reiner[1], N. Cohen[1], A. M. Oza[2], S. Amr[2], L. Edelmann[1], L. Mehta[1], S. A. Scott[1].* 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Laboratory for Molecular Medicine, Partners HealthCare, Cambridge, MA.

Autosomal recessive deafness-16 (DFNB16) is caused by homozygous or compound heterozygous mutations in the *STRC* gene on chromosome 15q15; however, interrogating the gene is challenging due to a highly homologous ~100 kb segmental duplication distal to *STRC*. Larger homozygous deletions including *STRC* and the neighboring *CATSPER2* result in deafness-infertility syndrome, which is characterized by early-onset deafness in both males and females, and exclusive male infertility. Deletions of this region are typically detectable by clinical microarray-based comparative genomic hybridization (aCGH) testing; however, the lack of specific copy number probes throughout *STRC* can result in uncertainty of deletion size, affected genes, and predicted phenotypes. The need for higher resolution molecular methods for investigating this region was highlighted by our case of a 39 year-old female referred for prenatal genetic testing due to advanced maternal age and a previous pregnancy with trisomy 22. Chromosome analysis of the chorionic villus sample indicated a normal female karyotype; however, parental request for prenatal aCGH testing (180K) revealed a homozygous 33. 74 kb deletion of chromosome 15q15. 3 [arr 15q15. 3(43916972-43950720) x0; hg19] that included *CATSPER2*. The homozygous deletion was confirmed by a higher density array (244K) and droplet digital PCR targeting both *STRC* (introns 25 and 23) and *CATSPER2* (intron 7 and exon 7); however, it was not possible to determine if the homozygous deletion included the 5' region of the *STRC* gene. Parental aCGH testing revealed that *STRC* was deleted in the paternal allele, but loss of the 5' region of *STRC* could not be ruled out in the smaller maternal deletion. To better resolve the maternal deletion breakpoint, a two-tiered *STRC* allele specific-PCR assay was developed that narrowed the breakpoint to a 310 bp region located 440 bp upstream of the *STRC* transcription start site, indicating that the fetus carried one intact copy of *STRC*. The baby was born naturally at 39. 5 weeks and passed newborn hearing screening; however, childhood hearing monitoring is planned given the possibility of hemizygous *STRC* promoter dysregulation and the variable age of onset of DFNB16. Taken together, these data highlight the challenges in prenatal detection of homologous disease gene regions and underscore the need for higher resolution molecular methods for selected disease genes to better inform phenotype prediction and genetic counseling.

1989F

Novel compound heterozygous *LIAS* mutations cause glycine encephalopathy. *Y. Tsurusaki[1,2], M. Nakashima[2], H. Saitsu[2], N. Miyake[2], N. Matsumoto[2].* 1) Kanagawa Children's Medical Center, yokohama, JAPAN; 2) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, JAPAN.

Glycine encephalopathy (GCE) (MIM 605899), also known as nonketotic hyperglycinemia, is a rare autosomal recessive disorder of the glycine cleavage system that results in elevated glycine levels in body fluids. GCE is genetically caused by mutations in *AMT* (MIM 238310), *GLDC* (MIM 238300) or *GCSH* (MIM 238330), which encode T-, P- or H-protein, respectively, and together with L-protein constitute the glycine cleavage enzyme. Most GCE patients have *GLDC* mutations. Recently, *GLRX5* (MIM 609588), *BOLA3* (MIM 613183) and *LIAS* (MIM 607031) were identified as causative mutant genes for GCE. To date, three homozygous mutations have been reported in *LIAS*. All previously reported GCE patients showed elevated level of glycine in the serum. LIAS encodes lipoic acid synthetase, a [4Fe-4S]-type iron–sulfur cluster-dependent enzyme that acts as a prosthetic group on H-protein, which is localized within the mitochondria. *GLRX5* and *BOLA3* are iron–sulfur cluster biosynthesis genes. Here we report a patient with GCE and elevated level of glycine in both the serum and the cerebrospinal fluid. Trio-based whole-exome sequencing identified novel compound heterozygous mutations (c. 738-2A4G and c. 929T4C (p. Met310Thr)) in *LIAS*. Our data further supports *LIAS* mutations as a genetic cause for GCE. Aknowledgments: Drs. R. Tanaka, S. Shimada, K. Shimojima, M. Shiina, K. Ogata, T. Yamamoto are highly appreciated for contributing to this work.

1990W

Case series of colorectal cancer patients with BRCA1/2 mutations: Finding actionable genes in patients with atypical presentations. *K. Vikstrom, S. Yang, E. Esplin.* Invitae Corporation, 475 Brannan Street, San Francisco, CA.

Background: A new paradigm in genetic testing for hereditary colorectal cancer (CRC) risk has emerged. With next-generation sequencing (NGS), clinicians can choose to test 7 high-penetrance genes associated with CRC or more comprehensive panels of 30+ cancer genes for roughly the same cost. In this case series, we describe 6 patients who had unclear or overlapping features of different hereditary cancer syndromes and who did not meet NCCN testing guidelines for a specific syndrome. In each case, a gene panel detected a mutation in BRCA1 or BRCA2. Association of CRC with pathogenic variants in BRCA1/2 has been suggested (but not yet extensively demonstrated). Nevertheless, these findings in BRCA1/2 were actionable and would be missed by gene-specific tests under traditional criteria. **Methods:** Our study included 585 consecutive patients with an indication of CRC and/or gastrointestinal (GI) polyps, referred for panel testing at Invitae. Genomic DNA variants were identified using a 7- to 34-gene NGS-based hereditary cancer panel; the clinician's discretion determined panel size. Germline sequence variants and deletions/duplications were classified using a point-based system that closely adheres to ACMG guidelines. Patients' personal and family histories were obtained from test request forms and were de-identified for this analysis. **Results:** Hereditary cancer panel testing found a Likely Pathogenic (LP) or Pathogenic (P) variant in 92 of 585 (15%) patients. Of the 92 mutation carriers, 69 (75%) had a P/LP variant in a known CRC gene (APC, MUTYH, MLH1, MSH2, MSH6, EPCAM, or PMS2), while 6 (6%) had an P/LP variant in BRCA1/2. None of the patients with BRCA1/2 mutations, 2 females and 4 males, reported Ashkenazi Jewish ancestry. **Conclusions:** In this series of patients with an indication of CRC and/or GI polyps, 24 (25%) of LP/P variants identified were in non-canonical CRC genes and, of those, 6 cases (25%) had mutations in BRCA1/2 in the absence of other LP/P variants. The prevalence of BRCA1/2 findings is alone not strong evidence of causal association, however, it is greater than would be expected by random chance and these patients would have been found negative by traditional genetic tests. While more research is needed to understand the relationship between BRCA1/2 and colon cancer, physicians need to be prepared to deal with actionable BRCA1/2 results which are present in patients with CRC, particularly in those patients with atypical presentations.

Background: Whole genome sequencing (WGS) enables the analysis of genome-wide genetic variation that can range from single nucleotide alterations to large structural genomic variants. WGS has become more affordable and presents dramatic opportunities for a potential shift in diagnostic services for genetic disease. However, diagnostic WGS pipelines are yet to be validated as a clinical tool in the context of heterogeneous genetic disease.

Methods: We surveyed the diagnostic yield of an accredited, conventional next-generation sequencing (NGS) diagnostic testing method for 537 patients with genetically and clinically heterogeneous single gene disorders (specifically, inherited-retinal-disease). A stratified subset of 47 patients also underwent WGS, and we compare the diagnostic yield of a WGS pipeline to that achieved by the conventional NGS diagnostic test.

Findings: Over the clinical analysed region, the WGS pipeline achieved similar sensitivity and specificity rates to the targeted NGS diagnostic testing method. Importantly, the WGS pipeline detected pathogenic variants that were not identified by current NGS diagnostics and, amongst the 47 patients, facilitated an increase in diagnostic yield.

Interpretation: We demonstrate the capability of a WGS pipeline to detect pathogenic genetic variants missed by current methodologies,and to identify essential modifications for current and future molecular diagnostic practice. We establish the potential utility of diagnostic WGS pipelines for clinically and genetically heterogeneous Mendelian disorders.

1992F

Genome versus exome sequencing: Is WGS the better WES? *K. Oexle[1], J. Meienberg[1], K. Zerjavic[1], B. Roethlisberger[2], R. Bruggmann[3], G. Matyas[1].* 1) Center for Cardiovascular Genetics and Gene Diagnostics, Foundation for People with Rare Diseases, Schlieren-Zurich, Switzerland; 2) Division of Medical Genetics, Center for Laboratory Medicine, Aarau, Switzerland; 3) Interfaculty Bioinformatics Unit and Swiss Institute of Bioinformatics, University of Berne, Berne, Switzerland.

The use of next generation sequencing (NGS) in genetic diagnostics currently involves enrichment tools that capture fractions of the genome such as the set of all coding gene segments (exome). Recently, we compared the performance of several enrichment platforms for whole exome sequencing (WES) showing that all these platforms had problems in sufficiently (≥20×) representing the RefSeq coding region, especially GC-rich exons. We have now compared the performance of WES (Agilent SureSelect Human All Exon kit v5+UTR) with whole genome sequencing (WGS), especially WGS without amplification for library preparation (PCR-free WGS; Illumina HiSeq X Ten). PCR-free WGS turned out to be insensitive to GC content and to be more complete and homogenous in coverage of coding exons. Although the average read depth of PCR-free WGS (mean ± 95% confidence interval), 64 ± 7 reads) was roughly half of the average read dept of WES (146 ± 15 reads), the number of RefSeq genes whose coding parts were both completely and sufficiently covered (≥20×) was 6% higher in PCR-free WGS than in WES (99% versus 93%, p<0. 05). As such, WES did not seem to sufficiently serve its purpose. Additional data indicate that this shortcoming of WES cannot be amended by further increasing read depth since coverage distribution remains highly uneven. Hence, the advantage of WGS does not only include the potential of identifying non-coding pathogenic variation but, in view of its more homogenous and complete exomic coverage, WGS may simply be the better WES. Thus, as the costs of WGS decline steadily and the costs of sequence analysis can be curtailed by selecting *in silico* the WGS parts that are of diagnostic interest (virtual WES and gene panels), WES might soon be replaced by non-enriching and PCR-free WGS. Moreover, as genome-wideness and homogeneity of WGS makes it also suitable for the detection of copy number variation (CNV), we have assessed the potential of WGS to replace array techniques in CNV detection as well.

1993W

Diagnostic Exome Sequencing Identifies Alterations in the Newly Characterized Gene, *COQ4*, Expanding the Phenotypic Spectrum. *M. Tsang[1], D. Shinde[1], W. Alcaraz[1], D. El-Khechen[1], V. Bhambhani[2], N. Mendelsohn[2], B. Crabb[2].* 1) Ambry Genetics, Aliso Viejo, CA; 2) Childrens Hospitals and Clinics of Minnesota, MN.

Recently, biallelic mutations in *COQ4* have been reported in five individuals from four unrelated families with CoQ10 deficiency resulting in a wide phenotypic spectrum of mitochondrial disorders. Here we report an additional non-consanguineous family with two affected siblings with compound heterozygous mutations in *COQ4.* The proband is a 16 year old Caucasian girl with infantile onset seizures, severe intellectual disability, microcephaly, short stature, visual cortical dysfunction, neuromuscular scoliosis with restrictive lung disease, pancytopenia, recurrent infections, and epistaxis. She also has dysmorphic features including a prominent nose, extended nasal columella, small mouth, small hands and feet with significant contractures, and small limbs. Her 18 year old brother is similarly affected. A mitochondrial disorder due to autosomal recessive nuclear gene defect was suspected. Multiple genetic and metabolic tests were uninformative. Family centered diagnostic exome sequencing (DES) on the proband and her healthy parents revealed compound heterozygous c. 469C>A (p. Q157K) and c. 202G>C (p. D68H) missense alterations in *COQ4*. Both alterations are expected to be likely pathogenic, based on *in silico* and co-segregation data. Co-segregation analysis revealed that the affected brother was also compound heterozygous for both alterations and an unaffected brother was a heterozygous carrier of the p. D68H alteration. Consistent with a mitochondrial disorder, the patient's lactate and pyruvate normalized following CoQ10 supplementation. *COQ4* is a newly characterized gene that encodes a mitochondrial protein involved in the organization of a multienzyme complex for the biosynthesis of Coenzyme Q10 (CoQ10). CoQ10 is an essential mitochondrial inner membrane-associated lipid that acts as a carrier for electrons from respiratory complexes I and II to complex III. Previously reported patients with *COQ4* associated CoQ10 deficiency have varied clinical presentations ranging from early neonatal death due to acrocyanosis, bradycardia, hypotonia and respiratory insufficiency to hypertrophic cardiomyopathy, arthrogryposis, cerebellar hypoplasia, severe myoclonic epileptic encephalopathy, progressive ataxia, and scoliosis. Here we demonstrate the utility of family centered DES to diagnose a patient with a complex phenotype and expand the phenotypic spectrum of *COQ4* associated CoQ10 deficiency.

1994T

Exome sequencing of patients with primary immunodeficiencies; translational genomics with direct clinical implications. *P. Arts[1], A. Simons[1], A. R. Mensenkamp[1], W. A. van Zelst-Stams[1], J. A. Veltman[1], F. L. van de Veerdonk[2], A. Hoischen[1], M. G. Netea[2].* 1) Departement of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands; 2) Department of Internal Medicine, Radboud University Medical Center, Nijmegen, Netherlands.

Primary immunodeficiencies (PIDs) are a largely heterogeneous medical condition caused by defects in the innate immune response. The insufficient protection against pathogens leads to recurrent infections in patients suffering from PIDs. Severely affected patients are selected for diagnostic exome sequencing as we expect involvement of a genetic component besides the obvious environmental factors. In the diagnostic setting exome data are filtered for rare protein altering variants in the ~270 genes known to cause PIDs. Since May 2013 analysing this gene package resulted in genetic diagnosis for 10% of over 60 cases; an additional 15% of cases carry a single mutation in a recessive PID gene. 80% of all patients without a genetic diagnosis gave permission for exome-wide analysis in a research setting. Focusing on genes with a known role in immunological pathways led to identification of candidate variants in a large number of patients. The research setting allowed follow-up of the genetic variants on the genetic and functional level. Further genetic analyses included search for recurrently mutated genes in additional patients with similar phenotypes, and performing co-segregation analysis in families. In addition, *in vitro* stimulations of peripheral blood mononuclear cells obtained from patients and controls, and comparing specific cytokine production capacity provides additional functional evidence for the immunological defect. One example with direct clinical implication of this approach was characterization of the genetic, and functional defect in a patient with autoinflammatory symptoms and *SOCS4* mutation (Arts *et al.* 2015). In another example we identified recessive *BAG3* mutations in a patient with progressive multifocal leukoencephalopathy without apparent immunosuppression, and also identified an underlying interferon-gamma deficiency. For other cases the genetic or functional data provided sufficient evidence to change treatment, *e. g.* in two cases with recurrent viral infections interferon-gamma supplementation therapy led to a dramatic improvement in the respective patients' health. In summary, we believe that the combination of clinical and research exome analysis, together with functional immunophenotyping offers a great opportunity for improved diagnostics and ultimately treatment of patients with PIDs.

1995F

Expanding the phenotypic and mutational spectrum of *DYRK1A* – a rare cause of intellectual disability and microcephaly. *A. Knight Johnson[1], A. Blumenthal[2,3], E. Marsh[4], H. Dubbs[4], F. Kobiernicki[1], L. Ma[1], K. Arndt[1], L. Wysinger[1], G. Alkorta Aranburu[1], S. Das[1].* 1) Human Genetics, The University of Chicago, Chicago, IL; 2) Lakeridge Health Oshawa, Oshawa, ON; 3) University of Toronto, Toronto, ON; 4) Children's Hospital of Philadelphia, Philadelphia, PA.

The *DYRK1A* gene encodes a dual-specificity phosphorylation-regulated kinase, and is located within the Down syndrome critical region on chromosome 21. Mutations in this gene have been previously associated with autosomal dominant intellectual disability. All *DYRK1A* mutations described to date are null mutations, and typical features in affected individuals include congenital microcephaly, growth delay, severe intellectual disability, febrile seizures, and mild dysmorphic features including large ears and underdeveloped ear lobes. Out of 308 patients referred to our laboratory for panel testing for genes associated with either non-specific intellectual disability or microcephaly, we identified 2 patients with pathogenic variants in *DYRK1A* (0. 65%), indicating that pathogenic variants in this gene are a rare cause of intellectual disability and microcephaly. One of the pathogenic variants observed was identified in a patient with features typical of what has previously been described in patients with a mutation in *DYRK1A*, including congenital microcephaly, growth delay, intellectual disability, and a history of febrile seizures. The variant identified in this patient created a premature stop codon, p. Arg437*, consistent with the previously reported mutational spectrum for the *DYRK1A* gene. The second pathogenic variant identified was a missense variant, p. Phe308Val, which was observed in the *de novo* state in a 6 year old patient with relative microcephaly, developmental delays, and no history of growth delay or seizures. The p. Phe308Val variant affects a highly conserved amino acid within the tyrosine-kinase catalytic domain of the DYRK1A protein. This is the first report of a pathogenic missense variant in *DYRK1A*, and therefore expands the known mutational spectrum of this gene. The phenotypic features observed in this patient are less severe than what has been reported to date in patients with null mutations in the *DYRK1A* gene, suggesting a possible genotype-phenotype correlation.

1996W

A family with X-linked creatine transporter deficiency diagnosed by whole exome sequencing. *M. Mori, JL. Goldstein, SP. Young, DS. Millington, DD. Koeberl.* Division of Medical Genetics, Duke University Health System, Durham, NC.

X-linked creatine transporter deficiency (CRTR-D) is characterized by cerebral creatine deficiency, leading to intellectual disability, severe speech impairment, seizures, and behavioral issues. The diagnosis is suggested by marked elevation of urinary creatine/creatinine ratio or deficient cerebral creatine on magnetic resonance spectroscopy, and confirmed by identification of a pathogenic mutation in the *SLC6A8* gene. We report a male proband who was diagnosed with CRTR-D, and two younger affected brothers who were subsequently diagnosed. The proband presented to a Metabolic Clinic at five years of age with global developmental delay, absence of speech, epilepsy, recurrent vomiting and feeding difficulty requiring gastric tube feeding, delayed gastric emptying, and severe constipation. His prenatal and birth history were unremarkable. Previous biochemical and genetic testing including CGH microarray had revealed no cause for his symptoms. Urine creatine was not tested. Whole exome sequencing (WES) was performed on a research basis, and a maternally-inherited hemizygous mutation (c. 321_323delCTT; p. Phe107del) in the *SLC6A8* gene was identified. The diagnosis of CRTR-D was confirmed by a markedly elevated urine creatine/creatinine ratio. Both of his younger affected brothers had a mildly elevated creatine/creatinine ratio as newborns, which increased markedly at a few months to confirm the diagnosis. The older affected brother at 14 months of age has developmental delay, hypotonia, poor weight gain and growth requiring gastric tube feeding, myoclonus, and possible left ventricular compaction cardiomyopathy on echocardiogram. The mother's severe constipation may suggest her manifesting heterozygote status. CRTR-D was ruled out in three older brothers. The case illustrates a family with a complex clinical history in which CRTR-D in the proband was diagnosed by WES, and urine analysis of creatine allowed screening of at-risk male relatives. CRTR-D and other creatine synthesis disorders, including arginine:glycine amidinotransferase and guanidinoacetate methyltransferase deficiencies, can be detected by analysis of creatine and its precursor guanidinoacetate in urine, plasma or dried blood spots and therapy has been effective in a subset of affected patients. CRTR-D screening by analysis of urinary creatine in males with developmental delay is strongly recommended.

1997T

Application of multigene panel sequencing in prolonged QT interval patients with no mutation detected in *KCNQ1*, *KCNH2*, and *SCN5A*. *S. Seo, S. Cho, H. Park, S. Lee, M. W. Seong, S. Park.* Departments of Laboratory Medicine, Seoul National University Hospital, Seoul, Korea.

Introduction: Genetic testing for potentially heritable cardiac diseases has advanced from basic scientific discovery to clinical application. A positive genetic testing allows not only confirmation of diagnosis, but also has impact on risk stratification and, in some cases, genotype-based treatment. It is important that genetic testing to be requested with detailed phenotype provided, or it might easily result in a misdiagnosis. Methods: 36 patients with prolonged QT interval patients but no mutation detected in *KCNQ1*, *KCNH2*, and *SCN5A* were included in this study. Molecular genetic testing was performed by using a multigene panel consisted of in 20 genes (*AKAP9, ANK2, CACNA1C, CACNB2, CAV3, GPD1L, HCN4, KCNE1, KCNE2, KCNE3, KCNH2, KCNJ2, KCNJ5, KCNQ1, SCN1B, SCN3B, SCN4B, SCN5A, SLMAP, SNTA1*) known to be associated with inherited arrhythmia. This multigene panel also included around 80 more genes related to other cardiac diseases such as cardiomyopathies. Sequences were captured by TruSeq Custom Enrichment Kit (Illumina) and sequenced with MiSeq (Illumina). Results: Among the variants detected in 20 arrhythmia genes, there were one previously reported mutation of Brugada syndrome (*SLMAP* c. 805G>A), four likely-pathogenic mutations (*ANK2* c. 4259C>T and c. 7503A>C, *CACNA1*C c. 1552C>T and c. 2579G>A) and six variants with unknown significance. This allowed 5 out of 36 patients (13. 9%) to have positive genetic test results by routine interpretation. In addition, genes related to other cardiac disease were examined in patients who had cardiac manifestations other than prolonged QTc. One patient, who carried one of the *ANK2* variant with unknown significance, showed polymorphic ventricular tachyarrhythmia in his EKG. He also carried a novel variant of *RYR2* c. 11995A>G, indicating this variant may be the cause of catecholaminergic polymorphic ventricular tachycardia (CPVT). Another patient, who developed dilated cardiomyopathy with prolonged QTc, were found to carry *TAZ* c. 718G>A variant, a previously reported mutation known to be involved in X-linked infantile dilated cardiomyopathy. Conclusions: As panel sequencing for cardiac diseases became general, sharing of phenotypic information between the clinician and the laboratory is crucial for interpretation of the genetic analysis. Also, well-described mutations should always be taken into consideration, as this might lead to finding the other aspects of the patient.

1998F

A population-based genomic study of inherited metabolic diseases detected through newborn screening. *K. Park[1], S. Park[2], E. Lee[2], J. Park[1], J. Park[3], H. Park[4], S. Lee[4], J. Kim[4].* 1) Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea; 2) GreenCross Laboratories, Yongin, Korea; 3) Samsung Biomedical Research Institute, Samsung Medical Center, Seoul, Korea; 4) Department of Laboratory Medicine & Genetics, Samsung Medical Center, Seoul, Korea.

Purpose: We aimed to investigate the impact of next-generation sequencing (NGS) on the detection of inherited metabolic diseases (IMDs) in newborn screening (NBS) and to evaluate the genetic epidemiologic characteristics of IMD in the Korean population. **Methods:** A total of 269 dried blood spots with positive results on the current NBS tests were collected from 120,700 consecutive newborns. We screened 97 genes related to NBS using the Ion PGM platform and detected IMDs using the integrated screening model based on biochemical tests and NGS. Haplotype analysis was conducted to detect founder effects in recurrent mutations. **Results:** The overall positive rate of IMDs was 17%. We identified seven additional newborns with preventable IMDs, which would not have been detected prior to the implementation of NGS. The mutation incidence of IMDs was 1 in 2,568 births. Haplotype analysis demonstrated founder effects in p. Y138X in *DUOXA2*, p. R885Q in *DUOX2*, p. Y439C in *PCCB*, p. R285Pfs*2 in *SLC25A13,* and p. R224Q in *GALT*. **Conclusions:** Through a population-based study in the NBS environment, we highlight the diagnostic and epidemiological implications of NGS. We found that the integrated screening model provided better results compared to the current NBS tests because it detected additional cases of treatable IMDs.

1999W

Comprehensive analysis of genes associated with cobalamin deficiency, methylmalonic aciduria and homocystinuria by clinical next generation sequencing identifies novel mutations. *J. Zhang[1], J. Tang[2], Y. Wang[1], F. Li[1], H. Mei[1], J. Wang[1], W. Zhang[1], L. Wong[1].* 1) Molecular and Human Genetics, Baylor College of Medicine, Baylor Miraca Genetics Laboratories, Houston, TX, USA, 77030; 2) Department of Medical Genetics, Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China, 510080.

Introduction: Vitamin B12 (cobalamin, Cbl) which consists of a class of chemically related compounds with element cobalt in the center of a planar tetra-pyrrole ring is a co-factor for enzymes involved in chain fatty acids, cholesterol, and amino acids metabolism. Defects in Cbl dynamics including its absorption, transport, and metabolism result in methylmalonic aciduria with or without homocystinuria. A targeted Next Generation Sequencing (NGS) panel developed in a clinical setting was used to identify mutations in genetically heterogeneous methylmalonic aciduria with or without homocystinuria in a cost-efficient manner. **Methods**: 49 probands with clinical or biochemical findings suggesting Cbl deficiency or methylmalonic aciduria with or without homocystinuria were analyzed by a clinically validated Cbl NGS panel. In this panel, 21 genes involved in Cbl dynamics, methionine-homocysteine cycle, and methylmalonyl- and succinyl-CoA conversion were enriched by a customized capture library targeting mainly for coding exons and adjacent region. In addition, over 200 anonymized DNA samples with negative testing results for one or more of these 21 genes were re-analyzed by this Cbl NGS panel. **Results:** The overall detection rate for this Cbl NGS panel with the identification of two allelic (homozygous or compound heterozygous) pathogenic variant in all samples is 42. 8%. Importantly, we identified novel pathogenic variants including *CD320*: c. 386G>T (p. R129L), *GIF*: c. 67_68delCA (p. Q23Efs*86) and *MMACHC*: c. 182G>C (p. R61P) all of which were present in trans-configuration with another pathogenic allele in multiple patients with proper clinical and/or biochemical phenotypes. We also identified a homozygous pathogenic synonymous change in the *MTHFR* gene affecting its splicing resulting in classic severe MTHFR deficiency. This result highlights the importance to include this gene in the Cbl NGS panel to detect severe MTHFR deficiency despite the common and mild-deficiency variants. **Conclusions:** Comprehensive targeted NGS analysis of a panel of 21 genes provides a rapid and cost-efficient method to diagnose genetically heterogeneous methylmalonic aciduria with or without homocystinuria. This method prevails Sanger single gene sequencing as the first tier genetic testing with proper clinical and biochemical indications for Cbl deficiencies.

2000T

The usefulness of array as a clinical diagnostic tool in patients with congenital malformations and developmental delay: Brazilian experience in 162 children. *E. A. Zanardo[1], G. M. Novo-Filho[1], R. L. Dutra[1], M. M. Montenegro[1], A. T. Dias[1], A. M. Nascimento[1], F. A. R. Madia[1], T. V. M. M. Costa[1], F. B. Piazzon[1], A. F. de Carvalho[4], M. I. Melaragno[3], C. A. Kim[2], L. D. Kulikowski[1].* 1) Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina da USP, São Paulo - SP, Brasil; 2) Unidade de Genética Médica, Departamento de Pediatria, Instituto da Criança-HC/FMUSP, São Paulo - SP, Brasil; 3) Departamento de Morfologia e Genética, Universidade Federal de São Paulo, São Paulo - SP, Brasil; 4) Laboratório de Genética Humana e Mutagêneses, Departamento de Biologia Geral, Universidade Federal da Bahia, Salvador - BA, Brasil.

The genomic imbalances are the most common cause of congenital malformations (CM) and developmental delay (DD), however the etiology of these imbalances are not well understood, making difficult the counseling genetics and the treatment. Currently, the improvement of cytogenomics diagnostic techniques, such as the screening by arrays that allow total coverage of the genome, is fundamental to set an unequivocal clinical diagnosis and a more suitable genotype-phenotype correlation for patients with CM/DD, especially when the clinical suspicion is not well understood, and may improve the evaluation of these patients more efficiently. We report our experience with the implementation of several array platforms (Agilent, Affymetrix, and Illumina) and probe densities in clinical diagnostic and scientific research of patients without genetic conclusive diagnostic. The results were confirmed by MLPA and/or FISH techniques. Thus this study evaluated the genome of 162 children with CM/DD. All patients were previously assessed by conventional cytogenetic analysis. We identified several different genomic alterations in 137/162 (~84. 6%) patients, including deletion, duplication and loss of heterozygosity. Some patients 41/137 (~30%) showed only one copy number variation in the genome, others 41/137 (~30%) presented two abnormalities and 55/137 (~40%) revealed three or more alterations on different chromosomes, maybe due to a complex rearrangements. Our findings showed that the array is a powerful tool to identification and characterization of genomic changes and provides precise diagnosis of unidentified or unexplained diseases suspected to have a genetic cause, contributing to appropriate clinical management of the patients. The interpretation of genotype-phenotype correlations in patients with complex genomic rearrangements is a very difficult task but the results can directly contributes to the elucidation of new syndromes.

2001F

Improved methods for diagnosing mitochondrial disorders using whole exome sequencing. *I. A. Barbosa[1], K. Thompson[2], C. L. Alston[2], E. W. Sommerville[2], C. Fratter[3], J. Poulton[4], R. McFarland[2], R. W. Taylor[2], C. Deshpande[5], M. A. Simpson[1].* 1) Medical and Molecular Genetics, King's College London, London, United Kingdom; 2) Wellcome Trust Centre for Mitochondrial Research, Newcastle University, Newcastle upon Tyne, United Kingdom; 3) Oxford Medical Genetics Laboratories, Oxford University Hospitals NHS Trust, Oxford, United Kingdom; 4) Nuffield Department of Obstetrics and Gynaecology, Women's Centre, University of Oxford, Oxford, United Kingdom; 5) Clinical Genetics Unit, Guys and St Thomas' NHS Foundation Trust, London, United Kingdom.

Mitochondrial diseases are a highly complex group of multisystem disorders characterised by biochemical defects in oxidative phosphorylation. Mutations in the nuclear genome have been identified as the major cause of inherited mitochondrial disorders presenting early in infancy or childhood. We employed whole exome sequencing (WES) for the identification of disease-causing variants in sixty-two individuals with clinical and biochemical presentations of mitochondrial disease in whom mitochondrial DNA rearrangements and point mutations had previously been excluded. We established a pipeline to assist the interpretation of the patients' exome variant profile in the context of nuclear genes previously associated with mitochondrial disease. In addition we evaluated the exome variant profile using publically available databases of genes with known or predicted mitochondrial function and of genes previously associated with related clinical phenotypes. We evaluated rare (MAF < 0. 01) and previously unobserved alleles under both dominant and recessive models in each affected individual. A multidisciplinary team reviewed the identified putative pathogenic variants for each individual, prior to validation of the variant calls with Sanger sequencing. Overall, this approach yielded a diagnostic rate of 42%. This metric reflects both individuals harbouring pathogenic mutations in nuclear-encoded mitochondrial disease genes routinely tested within UK laboratories (18%) and a further 24% with pathogenic variation in genes that are not currently tested as part of a diagnostic work-up. We have identified a number of highly plausible candidate causal variants located in genes with described mitochondrial function and experiments to define the functional consequences of these alleles on mitochondrial function are ongoing. Our results illustrate the efficacy of whole exome sequencing and an appropriate analytical strategy to provide molecular diagnostics in this complex clinical phenotype.

2002W

Novel Mitochondrial Variant Identified in Leber Hereditary Optic Neuropathy Patients. *S. Lee[1], M. Seong[1], S. Seo[1], Y. Yu[2], J. Hwang[3], S. Cho[1], J. Kim[4], S. Park[1,4].* 1) Department of Laboratory Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea; 2) Department of Ophthalmology, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea; 3) Department of Ophthalmology, Seoul National University Bundang Hospital, Seongnam, Korea; 4) Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea.

Leber's hereditary optic neuropathy (LHON) is characterized by acute or subacute bilateral visual loss, primarily caused by mitochondrial gene mutation. The majority of LHON are accounted for four common primary mutations. Here we investigated other genetic cause for LHON cases without four primary mutations by mitochondrial genome sequencing. Twelve LHON patients were included in the study. The sequence analysis of the mitochondrial genome was done using Roche GS sequencing technology and NextGENe software. We selected sequence variants at a frequency ofgreater than 15% in read frequency. A total of 23 missense variants were identified and we selected five likely pathogenic or pathogenic variants through in-silico prediction and Sanger confirmation. Two ND1 variants, m. 3635G>A and m. 3472T>C were previously reported as pathogenic one. We identified one novel pathogenic variant, m. 13259G>A (ND5) in a patient along with two novel likely pathogenic variants, m. 14180A>G (ND6) and m. 8520A>G (ATP8) in two patients, respectively. Multiple sequence alignment and hydrophobicity analysis supports of the pathogenicity of this novel variant. The full mitochondrial genome sequencing may be beneficial to LHON patients without primary mutation.

2003T

Identification of known and novel mutations in Mitochondrial Disorders. *J. Sheth[1], D. Solanki[2], N. Pandya[3], H. Patel[1], M. Mistry[1], R. Bhavsar[1], F. Sheth*. 1) Foundation For Research in Genetics and Endocrinology, Institute of Human Genetics Biochem & Molec Bio, Inst Human Gen, Ahmedabad, Gujarat, India Email:jshethad1@gmail. com; 2) Mantra clinic, Vivekanand Multispeciality Hospital,, Bhavnagar, Gujarat, India; 3) Shelby Hospital, Shelby Hospital, Department of Infertility and IVF, Ahmedabad, Gujarat, India.

Purpose of study: Identification of mitochondrial disorders are a multi organ involvement occuring due to mitochondrial and nuclear gene mutation**Methods**: Present study represents three families having a child with suspected mitochondrial disorder at the age of 6 m to 3 yr. Based on clinical presentation two children were investigated initially for SURF1 and POLG1 gene mutation by Sanger sequencing and one case was investigated by a panel of genes involved in mitochondrial encephalopathy by NGS. **Result and Discussion**: 1: A female child born to non consanguineous parents at full term and at 6 months proband had reduced movement with encephalopathy. On investigation, three common mutations of Leigh Disease (T12706C, A13084T & G13513A) were ruled out. Further analysis of SURF1 gene identified homozygous splice site mutation in intron 8 (IVS+(+1)G-A). Case 2:2 years male child was born to a consanguineous parents presented with refractory epilepsy, motor developmental delay and failure to thrive with right upper limb lower limb paresis. MRI, CSF lactate, urine GCMS and enzymes for GM1, GM2 gangliosidosis, NCL were normal. He was investigated for POLG1 gene mutation and homozygous deleterious mutation c. 911T-G (p. L304R) in exon 4 was detected. Proband was confirmed to have Alper's syndrome. Case 3: A 3 years old female child born to a consanguineous parents. Had an episode of convulsion at 3 months. Proband expired at 3 years after sudden vomitting episode. Aminoacid study showed increased levels of plasma lactate, alanine & tyrosine and was suspected to have died of mitochondrial disease. Mother was investigated for the mitochondrial encephalopathy gene panel using Illumina NGS platform. Heterozygous mutation c. 2095G-A (p. V699M) in exon 15 of *PC* gene and c. 911T-C (p. I304T) mutation in exon 4 of *FASTKD2* gene was detected in the mother. Further investigation demonstrated heterozygous mutation c. 2095G-T (p. V699L) in exon 14 of *PC* gene in the father with no mutation in FASTKD2 gene. Prenatal studies were done for case 1 and 3 based on the mutation associated with mitochondrial disorder. Present study demonstrates the identification of a rare gene mutation and usefulness of gene panel study by NGS for mitochondrial encephalopathy. It also demonstrate nuclear DNA mutation seems to be more common in mitochondrial disorders.

Paternity Reclaimed: Ancestry Testing Reveals a Unique Case of Congenital Chimerism. *K. M. Sheets[1], B. Kirkpatrick[2], M. Baird[3], J. Heinig[3], D. Davis[3], D. B. Starr[4].* 1) Vibrant Gene Consulting, LLC, Cambridge, MA; 2) Genomic Medicine Institute, Geisinger Health System, Harrisonburg, VA; 3) DNA Diagnostics Center, Inc. , Fairfield OH; 4) Department of Genetics, Stanford University School of Medicine, Stanford, CA, United States of America.

DNA testing is utilized when a biological relationship between individuals requires confirmation such as child custody, child support, or immigration cases. In the US over 382,000 legal relationship tests are ordered annually1, using PCR assays that examine short tandem repeat (STR) regions. Limitations of these assays have been noted1,2. We report a case of congenital chimerism revealed as a result of incompatible blood types between parents and child, negative paternity test results, and an avuncular relationship revealed through ancestry testing. Tetragametic chimerism is a condition that occurs when embryonic cells from dizygotic twins fuse early in development, leading to the birth of a singleton with some or all cells containing alleles from both dizygotic twins2. This condition was suspected after a pregnancy conceived with intrauterine insemination revealed an exclusion of paternity while at-home ancestry testing indicated an uncle/nephew relationship between the father and child. Confirmatory testing was recently performed by a laboratory accredited for legal relationship testing. Gametic tissue from the father was tested and revealed the presence of a mixed DNA profile consistent with a major and minor contributor. Chimerism was confirmed when it was found that one son matched one set of alleles and the other son matched the second set. The STR test results from several different tissues of the father are provided. To our knowledge, this is the first reported case in which paternity was initially excluded by standard DNA testing methods (buccal swab), the results called into question because of ancestry/relationship testing, and later included as the result of alternate genetic (semen) analyses. Although this case is rare, with the increased use of assisted reproductive technology, this outcome could occur with increasing frequency2. Sources:(1) Annual Report Summary For Testing in 2010. AABB Annual Report, pp. 1-9. (2) Boklage, C. (2005). Embryogenesis of chimeras, twins and anterior midline asymmetries. Human Reproduction, 579-591.

2005W

Improved diagnostic yield of neuromuscular disorders applying whole exome sequencing for patients arising from consanguineous population. *Z. Fattahi[1,2], M. Fadaee[1,2], R. Vazehan[2], E. Parsimehr[2], A. Abolhassani[2], SH. Nafissi[3], MR. Akbari[1,4], A. Kariminejad[2], H. Najmabadi[1,2].* 1) Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran; 2) Kariminejad-Najmabadi pathology and Genetics Center, Tehran, Iran; 3) Department of Neurology, Tehran University of Medical Sciences, Tehran, Iran; 4) Women's College Research Institute, Women's College Hospital, Toronto, Canada.

Neuromuscular Diseases (NMDs) include a broad range of disorders affecting muscles, nerves and neuromuscular junctions. Approximately 761 different disorders fit in this group which is categorized into 16 different subgroups and 406 known genes. Diagnosis of these disorders is divided into three phases of clinic, pathology and molecular diagnostic laboratory. Today, molecular genetic studies are being considered as a strong laboratory tool in the neuromuscular disorders' workup. In general, overlapping phenotypes and heterogeneous genetic nature of NMDs have created diagnostic challenges in the field. So, there are still lots of undiagnosed patients despite the supportive clinical and pathological documents. Non-specific clinical features, large number and size of known genes, high number of unidentified genes, and multiple disorders associated with a same gene calls the implementation of next-generation sequencing as a new strategy to increase the diagnostic yield. In this study, whole exome sequencing was applied as a fast and accurate technique to investigate genetic causes of referred patients with inherited neuromuscular disorders to our laboratory. These patients were mostly offspring of consanguineous marriages, diagnosed with a kind of muscular dystrophy. During a year, total of 28 patients were referred and examined with the help of whole exome sequencing. Data analysis including alignment, variant calling and filtering redundant variants was performed to achieve a final list of the most probable pathogenic variants in known genes. Variant confirmation and co-segregation analysis as well as genotype-phenotype correlation was performed for detection of the causative variant. Eventually, in 20 out of 28 (71. 4%) patients with muscular symptoms, the pathogenic variant was identified in the following known genes; DMD, CAPN3, FHL1, RYR1, SYNE1, PLEC, TNNT1, SGCB, LMNA and twelve novel pathogenic variants were detected. Today, the advantage of whole exome sequencing in clinical diagnostic strategies of heterogeneous disorders is clarified. In our cohort of patients, the diagnostic yield of 71. 4% was achieved which is quite high compared to the overall diagnostic yield of 25 to 50% in other reports. This could be explained by the consanguineous background of these patients and is another strong indication for effectiveness of offering whole exome sequencing panels in diagnostic laboratories especially in populations with high rate of consanguinity.

2006T

Pitfalls of multiple ligation-dependent probe amplification in *DMD* gene mutation analysis. *M. Kim[1], S. Cho[1], J. Chae[2], B. Lim[2], J. Lee[1], S. Lee[1], S. Seo[1], H. Park[1], A. Cho[3], S. Kim[4], S. Park[1], M. Seong[1].* 1) Departments of Laboratory Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea; 2) Departments of Pediatrics, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, South Korea; 3) Department of Pediatrics, Ewha Womans University School of Medicine, Seoul, South Korea; 4) Department of Laboratory Medicine, National Medical Center, Seoul, South Korea.

Background: Multiple ligation-dependent probe amplification (MLPA) is important technology in molecular diagnosis of Duchenne/Becker muscular dystrophy (DMD/BMD. However, little about false positive rate of MLPA in this disease is known. Here, we retrospectively reviewed results of 591 alleged DMD/BMD patients who MLPA analysis had been performed in our laboratory between May 2006 and Dec 2012. **Methods:** Mutational analysis was performed as the following procedures: first, whole coding region was screened using MLPA; second, if normal on MLPA, subsequent direct sequencing was performed to search sequence variations for the clinically suspicious patients. In addition, direct sequencing was also done for single exon deletion or duplication, or indeterminate results on MLPA. **Results:** A total of 290 cases showed exon deletion or duplication results on MLPA. Among them, 75 cases (25. 9%) initially revealed deletion or duplication for single exon. Subsequent direct sequencing revealed that 11 single exon deletion cases (3. 8%) were false positive due to sequence variations involving probe hybridization or ligation site. Abnormal MLPA results were closely related with sequence change type and location within probe hybridization. The C to T change was most frequently observed single nucleotide change (55. 9%, N = 19). CA mismatch caused by C to T or A to G substitutions for forward probes binding sites or T to C, G to A nucleotide changes for reverse probes by C to T substitution and having lower melting point (Tm) than 75oC were significantly associated with abnormal MLPA results. **Conclusions:** Our study reveals that about one seventh of large gene rearrangements involving single exon in *DMD* might be false positive results by sequence variations within probe hybridization or ligation site. Therefore, single exon deletion or duplication has to be validated by other methods, and furthermore, careful design of MLPA probes is needed to avoid false positive results.

2007F

Informative results of exome sequencing in 10 out of 20 cases/sibships. *M. Smith[1], K. E. Singh[1, 2], N. M. Gallant[1,2], E. C. Chao[1], V. E. Kimonis[1].* 1) Dept Pediatrics, Univ California, Irvine, CA; 2) Memorial Care, Miller Children's Hospital, Long Beach CA.

We carried out clinical exome sequencing on 20 patients. In 10 cases/sibships pathogenic mutations were identified in genes that are known to impact phenotype and clinical findings in our patients were consistent with the clinical features described in the literature in cases with defects in those genes. A pathogenic mutation in the X-linked gene *SLC16A2* occurred in a male patient with developmental delay, hypotonia and delayed myelination. A pathogenic splice site mutation in the X-linked *CUL4B* gene occurred in a male patient with megalencephaly, developmental delay, and lack of speech development by 8 years. This mutation led to exome skipping and to intron inclusion. Two pathogenic mutations (phase unknown) were identified in the *POLR3B* gene in a patient with developmental delay and seizures. This gene encodes the second largest subunit of RNA polymerase III and mutations have previously been reported in cases with leukodystrophy. A pathogenic mutation in the *ARID1B* gene was found in a female patient with developmental delay, dysmorphology and congenital malformations; heterozygous deletions of *ARID1B* have been previously described in multiple individuals with developmental delay. Compound heterozygous mutations in the *NUBPL* gene were found in siblings with developmental delay, ataxia and seizures and cerebellar hypoplasia. An 18y old with hypovolemia, osteoporosis and spinal defects was found to be homozygous for a pathogenic mutation in the Barrter syndrome gene *SLC12A1*. Pathogenic homozygous splice-site mutation in the *SCARB2* gene was found in sibs with myoclonic epilepsy; *SCARB2* mutations are reported in action myoclonus and renal insufficiency. In a female with seizures developmental regression and deafness a pathogenic de novo mutation was found in the X-linked *MED12* gene and a known pathogenic mutation also occurred in *TCTN1*. *MED12* mutations have been found mainly in males with developmental delay however there are reports of females with intellectual disability and MED12 mutations. Heterozygous *TCTN1* gene mutations have previously been described in Joubert syndrome. Compound heterozygous mutations in *NGLY1* (N-glycanase 1) were found in siblings. We identified a *CACNA1S* mutation in a case with myopathy similar to a literature reported case. We continue to find exome sequencing to have a significant diagnostic yield for rare disorders leading in some individuals to specific therapies. Exome sequencing may be used as first or second line testing.

2008W

The Diagnostic Yield of a Multi-Gene Panel for Neuromuscular Disorders with Special Consideration to Variants of Unknown Significance. *A. S. Lindy, M. Bradbury, S. F. Suchy.* Neurogenetics, GeneDx, Gaithersburg, MD.

Neuromuscular disorders (NMD) encompass over 200 clinically and genetically heterogeneous disorders that primarily affect the peripheral nervous and musculoskeletal systems. Overlapping features can make a clinical diagnosis difficult, allowing potential health risks associated with the disorder to go unmonitored. Multi-gene panel testing is one tool available for providing an efficient genetic diagnosis. We evaluated the performance of an NMD panel of 73-76 genes. Testing was performed on 150 individuals with NMD using next generation sequencing (NGS) along with exon-level copy number analysis. A definitive positive result was identified in 33% of cases and defined as one or two pathogenic or likely pathogenic variants in a single gene, depending on inheritance. Negative results were reported in 18% of cases and inconclusive results were reported in 49% of cases, due to the identification of a variant of uncertain significance (VUS). Given the relatively recent association of some of these genes with NMD, and the lack of well-established criteria for variant classification within those genes, the likelihood of identifying a VUS is high. Although 33% of cases had no VUS, 52% of cases had 1-3 VUS. Of those cases with inconclusive results, 41% had a VUS in an autosomal dominant (AD) or X-linked (XL) disorder, while 15% had a single pathogenic variant in an autosomal recessive (AR) disorder, potentially representing carriers of AR conditions. Inconclusive results are difficult to relay to patients and create challenges in determining how to proceed with clinical management. However, interpretation of a VUS in the context of clinical information can guide additional testing that can further clarify the molecular results. In many cases, reclassification of the variant was possible based on segregation analysis (60 variants), biochemical studies (2 variants), or immunostaining of a muscle biopsy (26 variants). Muscle biopsies can be especially useful in the reclassification of VUS in disorders associated with both AR and AD inheritance (i. e. COL6A related disorders). Our results demonstrate the effectiveness of NMD multi-gene panels. Using these panels enables not only the identification of common causes of NMD, but also novel genetic variants in rare disorders that might otherwise be overlooked. Furthermore, our results indicated that even the finding of a VUS can lead to a positive diagnosis when molecular testing is combined with targeted follow-up testing.

2009T

Allele-specific digital PCR to differentiate CYP2D6 heterozygous duplication events. *P. A. Hegerich[1], S. Patel[1], J. Forcellini[2], M. P. Borgman[2], T. Hartshorne[1].* 1) Genetic Analysis, Thermo Fisher Scientific, South San Francisco, CA; 2) PGXL Laboratories, Louisville, KY.

The drug metabolizer phenotype of the major P450 enzyme, CYP2D6, can be predicted by genetic analysis. The combination of full, reduced, or no function alleles, in addition to gene copy number, is used to determine ultra-rapid, extensive, intermediate, or poor metabolizer status. Data from quantitative PCR (qPCR) experiments using TaqMan™ SNP Genotyping assays and TaqMan Copy Number assays can be translated to star allele diplotypes associated with metabolizer phenotypes. While qPCR can decipher most of the information necessary, phenotypes cannot be unequivocally assigned for samples that contain a CYP2D6 duplication or multiduplications and are heterozygous for alleles that are known to be duplicated and that have different functional levels. For these samples, allele-specific copy number analysis by digital PCR (dPCR) can be done in order to identify the duplicated allele. Digital PCR enables single sample analysis with high precision and sensitivity by partitioning target molecules into 20,000 individual reactions, thus elucidating the ratio of the heterozygous alleles. For the allele-specific copy number variation (ASCNV) application, TaqMan SNP assays to CYP2D6 variants that are associated with specific duplicated alleles were run in dPCR on samples of known SNP genotype and CNV status. Initial validation was conducted on Coriell cell line gDNA samples. Here we will describe work done on buccal swab samples collected from two different sites. Representative samples carrying CYP2D6 duplications that were heterozygous were selected to run with ASCNV dPCR. Samples were first digested with a restriction enzyme to separate tandem duplicated CYP2D6 alleles then run on the QuantStudio™ 3D Digital PCR system. Reactions positive for each allele, detected by allele-specific VIC™ or FAM™ dye-labeled probes, were visualized, and allele ratios determined using the QuantStudio 3D AnalysisSuite™ software on the Thermo Fisher Cloud. For samples heterozygous for target SNPs, 3-copy samples gave close to 1:2 ratios and the duplicated allele was readily identified. Interestingly, one *2/*4 sample with CN=4 and initial call of EM/IM returned a result of *2/*2/*2/*4 and thus a true phenotype of UM. We have thus shown that ASCNV dPCR and TaqMan SNP assays is a simple and effective method for identifying specific duplicated alleles in heterozygous samples. This method facilitates accurate CYP2D6 allele genotyping and better prediction of drug metabolizer phenotype.

2010F

Resolving false positive *CYP2D6* genotype results: *CYP2D7* variation is the culprit. *A. K. Riffel[1], M. Dehghani[2,3], T. Hartshorne[4], J. S. Leeder[1,5], K. Rosenblatt[2,3], A. Gaedigk[1,5].* 1) Division of Clinical Pharmacology, Toxicology & Therapeutic Innovation, Children's Mercy Kansas City, Kansas City, MO; 2) CompanionDx Reference Laboratory, Houston, TX; 3) Devision of Oncology, Department of Internal Medicine, University of Texas Health Science Center at Houston, TX; 4) Genetic Analysis, Thermo Fisher Scientific, South San Francisco, CA; 5) School of Medicine, University of Missouri-Kansas City, Kansas City.

Background: TaqMan™ genotyping assays are widely used to genotype *CYP2D6,* which encodes a major drug metabolizing enzyme to guide therapy. Assay design for *CYP2D6*, however, is arduous due to the presence of 2 pseudogenes, structural and copy number variation and numerous SNVs, some reflecting the wild-type sequence of the *CYP2D7* pseudogene. We have identified samples testing false-positive for the SNVs defining the *CYP2D6*15* (137Tins; frameshift) and **35* (31G>A, rs769258) allelic variants. The aim of this study was to identify the culprit causing false positives and remediate those by redesigning and validating alternative TaqMan genotype assays. **Methods:** DNA from 13,866 samples were genotyped by the CompanionDx® lab using TaqMan genotyping assays. Twelve samples had true positive calls and 54 samples had false positive calls for *CYP2D6*15* (confirmed by resequencing or the Luminex xTAG® CYP2D6 test). Nineteen samples were selected for follow-up. Long-range PCR was utilized to amplify the entire *CYP2D6* and *CYP2D7* genes for subsequent genotyping and/or Sanger sequencing. A high resolution melt assay was developed for a *CYP2D7* SNV. Alternate TaqMan assays were evaluated using *CYP2D6* and *CYP2D7*-gene specific XL-PCR and gDNA as templates. **Results:** The selected 19 samples were positive for *CYP2D6*15* when genotyped by CompanionDx. However, the 137Tins could not be confirmed for the majority of samples by Sanger resequencing. Genotype analysis of *CYP2D6* and *CYP2D7*-specific XL-PCR templates suggested that the false-positive mutation signal originated from *CYP2D7*. Sequencing of *CYP2D7* revealed a CC>TG SNV in exon 1 that reverts the sequence to *CYP2D6* and allows the TaqMan assay PCR primer to bind. Because *CYP2D7* also carries the Tins, a mutation signal is generated. This *CYP2D7* SNV was also responsible for generating a false-positive signal for the close-by *CYP2D6*35* rs769258 SNP. Alternate assays have been designed and evaluated. **Discussion:** Although TaqMan assays are carefully designed and evaluated before commercially marketed, rare or unknown SNVs underneath primer and/or probe regions can impact the performance of many PCR-based genotype assays, including TaqMan. In the presented case, a rare SNV in a highly similar pseudogene allowed primer binding to the variant site and thereby caused false-positive allele calls. Regardless of the test platform used, it is prudent to confirm rare allele calls by an independent method.

2011W

Characterizing CGG footprint at FMR1 gene by TP-PCR: Implication in diagnosis. *S. Agarwal, S. Muthuswamy, D. D. Dean.* Dept Genetics, Sanjay Gandhi Inst Med Sci, Lucknow, Uttar Pradesh, India.

Poor knowledge about role of CGG repeat at FMR1and lack of availability of proper and cheap molecular diagnostics may be a major barrier to early diagnosis that could improve quality of life and prognosis especially in the developing countries. As the treatment for Fragile X syndrome is not feasible, prevention of FXS by prenatal diagnosis of carrier women early during pregnancy is important. Therefore through present study, we used our in-house standardized TP-PCR method for screening CGG repeat expansion. The results were also reconfirmed with methylation sensitive PCR. We screened a total of 66 samples including 45 suspected FXS male children, 10 premature ovarian failure cases and 2 prenatal samples. TP-PCR method identified 5 (11%) out of 45 suspected FXS cases (intellectually disabled) to be positive for full mutation, 1 (10%) of 10 premature ovarian failure cases as permutation positive and 1 of 2 prenatal sample as permutation positive. Present study demonstrates that a significant number of FXS among intellectually disabled and identification of permutation in premature ovarian failure cases reinforces the need for family screening in early intervention and prenatal option. In prenatal cases it helped the parents to take decision for continuing pregnancy.

2012T

Increased identification of *CFTR* mutations using an expanded panel of validated pathogenic mutations. *W. Sun[1], D. Rabin[2], D. Goos-Root[1], T. Angeloni[1], S. Keiles[2], J. Radcliff[2], C. Strom[1].* 1) Molecular Genetics, Quest Diagnostics Nichols Institute, San Juan Capistrano, CA; 2) Quest Diagnostics, Madison, NJ.

Cystic fibrosis (CF) is caused by mutations in the *CFTR* gene. More than 1,900 CF mutations have been identified, most at frequencies <0. 1%. ACMG/ACOG guidelines recommend screening for 23 common *CFTR* mutations, which together account for the majority of mutant alleles in Ashkenazi Jewish and non-Hispanic Caucasian populations. Adding validated mutations may enhance detection. One obstacle to expanding the panel is the expense and time needed for sequence analysis of large numbers of mutations. Next-generation sequencing (NGS) allows rapid analysis of large numbers of mutations simultaneously, greatly expanding options for *CFTR* mutation screening. In 2014, we introduced an NGS-based expanded CF panel that detects up to 155 *CFTR* mutations. All additional mutations were deemed pathogenic: selection criteria for these mutations were a published association with a clinical diagnosis of CF; in vitro demonstration of disruption of the CFTR pathway or demonstration of a stop codon in the pathway; and an allele frequency ≥0. 01% in North America and Europe. Here we report the frequency of pathogenic mutations in the first series of clinical samples tested with this panel. Pathogenic *CFTR* mutations were detected in total of 340 samples. Of these, 61 (18%) were not part of the 23-gene ACMG/ACOG panel. Overall, 29 of the non-ACMG/ACOG panel mutations were detected in at least 1 sample. The most common was 3876delA (n=10), which was the 4th most frequent mutation overall (after deltaF508, R117H, and G542X). The next-most common non-ACMG/ACOG panel mutations were F311del, L206W, and R117C (detected in 4 samples each); and A559T, R352Q, and Y1092X (detected in 3 samples each). These mutations were detected at higher frequencies than more than half of the mutations in the ACMG/ACOG panel (data not shown). Of the remaining non-ACMG/ACOG panel mutations, 14 were detected in 1 sample each and 8 were detected in 2 each. Our findings indicate that the expanded panel detects pathogenic *CFTR* mutations in a substantial proportion of samples that would have been missed by testing with the 23-mutation panel alone. This analysis underscores the importance of continued evolution of *CFTR* mutation screening.

2013F

Hemoglobin Depletion Increases Sensitivity of Next Generation Sequencing-based Transcriptome Profiling. *D. Munafo, B. Langhorst, C. Sumner, C. Chater, L. Mazzola, J. Bybee, D. Rivizzigno, S. Russello, F. Stewart, E. Dimalanta, T. Davis.* New England Biolabs, Inc. , Ipswich, MA.

Peripheral blood can reflect molecular profile changes occurring in other tissues during pathological events even before clinical symptoms have appeared. Blood is also more accessible and easily collected than other tissues making it ideally suited for biomarker discovery. Whole blood transcriptome analysis by next generation sequencing allows for accurate detection of known as well as unknown transcripts with low- and high-abundance and it is beginning to demonstrate utility in early clinical diagnostics. One limitation of the whole blood RNA sequencing is that, the high content of hemoglobin transcripts (constituting up to 75% of total transcripts population) can mask detection of lower abundant biological meaningful transcripts. In this work, we demonstrate that globin depletion significantly increases sensitivity of transcript detection without altering transcript expression profile of the non-globin transcripts. Here, we present a method to deplete for hemoglobin transcripts. We applied this method to deplete multiple blood-derived samples (peripheral blood, leukocytes, bone marrow and umbilical cord blood) from adult, fetal and embryonic hemoglobin transcripts. Using next generation RNA sequencing, we assess depletion efficiency and we compare library complexity and transcript expression correlation before and after globin depletion. Whole blood RNA sequencing from single male donor reported to have 50% of total sequencing reads being hemoglobin transcripts. At 50 million paired-end read coverage, 23% hg19 annotated genes were detected. On the contrary, after globin depletion, only 0. 1% of sequencing reads mapped to globin transcripts increasing sensitivity of transcript detection by 30% (allowing for reliable detection of 2,787 additional transcripts). We achieved high depletion efficiency (up to 99. 9% globin depletion) with minimal off target effects (high FPKM correlation between depleted and non-depleted libraries; R2= 0. 87486). Globin depletion by this method is not altering the transcript expression levels. Globin reduction increases the coverage of less abundant transcript. This method can potentially be expanded to deplete for other highly express transcripts with minimal biological relevance. Moreover, it is amenable to high-throughput sample preparation and robotic automation to easy implement in a clinical setting.

2014W

Association analysis of genetic variants with type 2 diabetes in a Mongolian population in China. *H. Bai[1], W. Huo[1], H. Liu[1], S. Suyalatu[1], N. Narisu[2], Q. Wu[1].* 1) Inner Mongolia University for the Nationalities, tongliao, China; 2) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA.

T2D is a complex disease hallmarked by insulin resistance and pancreatic beta-cell dysfunction. In China, 9. 7% and 15. 5% of the entire population suffer from T2D and prediabetes, respectively. There are 4 million Mongolians currently living in various regions of China . With the help of recent advances in genotyping and sequencing technology, large scale genome wide association studies (GWAS) have identified approximately 70 single nucleotide polymorphisms (SNPs) conferring susceptibility to type 2 diabetes (T2D). However, most of these loci have not been replicated in a diverse populations and much genetic heterogeneity has been observed across ethnic groups with different genetic backgrounds. We tested 28 SNPs previously found to be associated with T2D by GWAS in a Mongolian sample of northern China (497 diagnosed with T2D and 469 controls) for association with T2D and diabetes related quantitative traits. We replicated a previous T2D association of rs2237897 near KCNQ1(OR=1. 48; P=0. 001)in a different Mongolian sample and replicated T2D association of ten other SNPs, namely,rs7578326 (IRS1), rs1531343 (HMGA2), rs8042680 (PRC1), rs7578597 (THADA), rs1333051 (CDKN2), rs6723108 (TMEM163), rs163182 (KCNQ1), rs1387153 (MTNR1B), rs243021 (BCL11A), and rs10229583 (PAX4) in our sample. Further, wetested four diabetes related lipids traits, namely,total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), triglyceride (TG), and showed that risk allele of the strongest T2D associated SNP in our sample, rs757832 (IRS1) to be associated with increased level of TG. We observed substantial difference of T2D risk allele frequency between the Mongolian sample and 1000G Caucasian sample. Further study of genetic architecture of these variants in susceptibility of T2D is needed to understand the role of these variants in heterogeneous populations. Keywords: SNPs, genetic association, Mongolian population, T2D. AcknowledgementsWe thank our study individuals for their generous participation in this study. This study was supported by the National Natural Science Foundation of China(81160101,81060098).

Identification and characterization of aberrant splicing variants using a generic approach. *A. J. Bergsma[1,2], M. Kroos[1], M. Hoogeveen-Westerveld[1], D. Halley[1], A. T. van der Ploeg[2], W. W. M. Pijnappel[1,2].* 1) Clinical Genetics, Erasmus Medical Center Rotterdam, Rotterdam, Zuid-Holland, Netherlands; 2) Pediatrics, Erasmus Medical Center Rotterdam, Rotterdam, Zuid-Holland, Netherlands.

Diagnosis of monogenic diseases often involves sequence analysis at the level of genomic DNA in which only the protein-coding exons are analyzed. This may result in failure to identify variants affecting pre-mRNA expression and splicing. Here, we present a generic assay that can be used to identify such variants without prior knowledge of the function of the gene product. Al coding exons are analyzed in an unbiased manner using a combination of flanking exon PCR, exon-internal quantitative PCR and sequence analysis. The approach was tested on Pompe disease, a devastating skeletal muscle disorder resulting from variants in the acid alpha glucosidase (GAA) gene. Patients with partial or uncharacterized GAA variants revealed several splicing defects including exon skipping, intron retention, cryptic splice site usage, and mRNA degradation. These events could not be predicted using splice prediction programs. mRNA degradation analysis could be used to determine Cross Reactive Immunological Material (CRIM) status with prognostic value for disease severity and response to Enzyme Replacement Therapy (ERT). The extent of leaky wild type splicing correlated with disease severity. We conclude that this approach is valuable for unbiased identification of pathogenic variants and that the quantitative information obtained can be used for clinical information.

2016F

A comprehensive analysis of ultrastructures of erythrocytes from patients with Glucose-6-Phosphate Dehydrogenase deficiency by atomic force microscopy. *F. Zishui, J. Chengrui, T. Jia, J. Weiying(Corresponding author).* Department of Medical Genetics, Zhongshan School of Medicine, Sun Yat-sen Univer, canton, China.

Acute hemolytic anemia will be triggered by oxidative stress in the patients with Glucose-6-phosphate dehydrogenase (G6PD) deficiency. However, the underlying hemolytic mechanism is unknown. To make clear the hemolysis mechanisms, a systematic study on membrane ultrastructures had been undertaken by atomic force microscopy (AFM) in G6PD deficient red blood cells (RBCs) after tert-butyl-hydroperoxide (t-BHP) oxidation. The RBCs architecture seem to be impaired causing the cells to lose its ability to maintain the typical discoid shape. Erythrocyte shrinkage and the increased membrane roughness were observed in the G6PD deficient cells. Compared with healthy control RBCs, as the concentration of t-BHP up to 0. 1mM, the membrane roughness of G6PD deficient RBCs showed significant difference (P<0. 05). Oxidative damage results in increased roughness of erythrocyte membrane, which may shorten the RBCs lifespan. The results in the present study will give an increased understanding for the hemolysis mechanism of G6PD deficiency.

2017W

Comprehensive Glycomics Analysis by MALDI TOF/MS in Human CSF. *X. Li[2], M. Davids[3,4], M. Kane[3,4], L. Wolfe[3,4], M. Raihan[2], C. Boerkoel[5], W. Gahl[3,4], M. He[1,2].* 1) Department of Pathology and Laboratory of Medicine, University of Pennsylvania, Philadelphia, PA; 2) The Michael J Palmieri Metabolic Laboratory, Children's Hospital of Philadelphia, Philadelphia, PA; 3) NIH Undiagnosed Diseases Program, Common Fund, Office of the Director, NIH, Bethesda, MD; 4) Office of the Clinical Director, NHGRI, National Institutes of Health, Bethesda, MD; 5) University of British Columbia, Vancouver, Canada.

The Congenital Disorders of Glycosylation (CDG) are a group of diseases with highly variable phenotypes and inconsistent clinical features. Over 100 CDG disorders have been identified and most of these are defects in protein glycosylation. Protein glycosylation is highly variable among different human tissues. For example, types of protein glycosylation of the human brain differ from those of peripheral organs and correspond to differing expression patterns for genes encoding glycosylation enzymes. To explore possible defects in protein glycosylation in the brain, we developed comprehensive glycomics analysis of N-glycome, O-glycome and free glycome by MALDI TOF/MS in cerebrospinal fluid (CSF). We used 0. 6 ml CSF that was frozen immediately after the collection for this analysis. The CSF was filtered through a size exclusion membrane to separate free oligosaccharides from glycoprotein. N-glycans were released from total CSF glycoprotein via PNGase F digestion and O-glycans were released separately by reductive beta-elimination reaction. After glycans were purified through SPE columns, they were permethylated and analyzed by MALDI TOF/MS. Thirty eight different N-glycan species, 85 free oligosaccharide and 25 O-glycan species were identified in 10 control CSF samples. The predicted structures for the majority of CSF glycans are found in online databases including UniCarbKB and CFG. Compared with plasma glycomics data, CSF hasmuch more O-glycan species including O-mannosylated glycans and polysialylated O-glycans. Comparing 166 CSF samples from patients with undiagnosed neurological disease from the NIH Undiagnosed Diseases Program (UDP) with 10 control CSF samples from different age groups that were collected by our clinical laboratory, about 20 UDP patients have CSF glycomics profiles significantly deviated from the profiles of control CSF samples. Four of the UDP patients have known genetic disorders that alter or are predicted to alter protein glycosylation in human brain, including one patient with putative CAD deficiency, a defect in uridine biosynthesis. Interestingly, one of the known patients has a completely normal plasma glycomics profile and urine oligosaccharide profile, while both his CSF N and O-glycomics profiles are abnormal. Our results suggest that CSF glycomics analysis could be a useful tool to discover new diseases or disease mechanism.

Detection of Large Rearrangements in a Pan-cancer Gene Panel using Next Generation Sequencing. *D. Mancini-DiNardo, T. Judkins, C. Daniels, J. Craft, J. Holladay, B. B. Roa.* Myriad Genetics, Inc. , Salt Lake City, UT.

Background: The advent of Next Generation Sequencing (NGS) has facilitated the detection of sequencing variants across multiple genes simultaneously. To date, however, large deletions and duplications are largely detected by alternative technologies such as MLPA and microarray CGH. Here we describe the detection of large rearrangements (LR) in a clinically validated pan cancer panel test using NGS. **Methods:** Dosage analysis was performed across gene coding exons and select promoters using NGS. All LRs were confirmed using one of three orthogonal approaches: targeted microarray CGH, MLPA or confirmatory PCR and sequencing of the mutant product. MLPA was initially used as the primary assay for dosage analysis in *PMS2* and *CHEK2*. *PMS2*-specific sequencing analysis and/or long range PCR were used where appropriate to confirm the presence of LRs in *PMS2*. **Results:** The proportion of clinically significant defects attributable to large genomic rearrangements across 25 genes was determined to be 9. 3% using the methods described above. Collectively, 86% of all LRs detected were deletions and 13% were duplications. We also detected five insertions, including the *BRCA2* Portuguese founder mutation (c. 156_157insAlu), and two triplications. Comprehensive coverage of exonic regions in this NGS assay also facilitated the detection of 9 partial deletions. Importantly, there were a large number of clinically significant LRs detected in *PMS2*, of which 36% occured in exons 11-15, a region that shares significant sequence homology to the pseudogene, PMS2CL. This finding stresses the importance of being able to accurately detect mutations in this region and distinguish between clinically significant LRs that occur in *PMS2*, and benign LRs in PMS2CL. **Conclusions:** NGS technology has been demonstrated as a reliable method to detect sequencing variants and has facilitated simultaneous, multi-gene analysis. The ability to interrogate for the presence of large deletions and duplications using the same technology has further streamlined the process of mutation detection, which increases the efficiency of testing and contributes to reduced turn-around-times. We have shown that dosage analysis by NGS can reliably detect the presence of genomic LRs in our pan cancer panel test. This study shows that LRs constitute a significant proportion of mutations found in individuals with a personal or family history of hereditary cancer, and should be part of a comprehensive genetic testing strategy.

2019F

Prognostic prediction of prostate cancer metastasis and biochemical recurrence. *A. Pearlman[1], K. Upadhyay[1], K. Cole[1], J. Loke[1], C. Campbell[1], S. Freedland[3], K. Sun[1], Y. Shao[2], H. Ostrer[1].* 1) Dept Pathology, Albert Einstein College of Medicine, Bronx, NY; 2) Division of Biostatistics, NYU School of Medicine, New York, NY; 3) Dept Urology, Cedars Sinai Medical Center, Los Angeles, CA.

Prostate cancer is the most commonly diagnosed male cancer and the second leading cause of cancer deaths among men in the United States. If left untreated, the majority of prostate cancers remain indolent for decades, but some progress to metastasis and death. If treated with surgery or radiation therapy, the risk of metastasis is reduced, but erectile dysfunction, urinary incontinence and rectal bleeding may occur in up to 50% of patients. The goal of this study was to validate a previously reported metastatic potential score (MPS) that could predict the likelihood of a prostate cancer to metastasize or recur biochemically (BCR) (Pearlman J Probab Stat 2012:873570). Using arrayCGH, genomic DNA copy number alterations were measured in radical prostatectomy specimens from 76 Duke University (DU - Affymetrix Oncoscan v3) or 104 Memorial Sloan Kettering (MSK - Agilent oligo array) men with prostate cancer. Multivariate logistic regression (logit) and Cox proportional hazards (Cox) models were used to assess the clinical validity of the MPS and other early pre-operative clinical predictors for outcomes of metastasis and BCR. A multivariate logit model comprised of the MPS and preoperative PSA levels resulted in a predictive accuracy of 80%, $p < 0.01$ for the outcome of metastasis in both DU and MSK cohorts. Accordingly, the outcome of metastasis-free survival in a multivariate Cox model of the MPS resulted in hazard ratios = 3. 7 and 7. 3, $p < 0.03$ along with a concordance index of 0. 70 and 0. 74 for the MSK and DU cohorts, respectively. Log rank test of the MPS plotted as Kaplan-Meier survival curves (cut at 50% of MPS range) resulted in a significant separation in both DU and MSK cohorts $p = 0.01$. Furthermore, for the outcome of BCR, the multivariate logit model of MPS/preoperative PSA resulted in a predictive accuracy of 0. 71, $p = 0.003$ (DU) and 0. 76, $p = 0.006$ (MSK). For the DU cohort MPS was the only predictor that achieved statistical significance when applied to a Cox model resulting in hazard ratio = 3. 6, $p = 0.002$ and concordance index of 0. 62, $p = 0.004$. In the MSK cohort the multivariate Cox model of MPS/preoperative PSA resulted in a hazard ratio of 5. 9, $p = 0.00008$ and concordance index = 0. 71, $p = 2.4E-07$. Thus, MPS is an accurate predictor of metastatic risk (and metastasis-free survival) for men with prostate cancer from different cohorts and tested on different arrayCGH platforms.

2020W

Identification of a novel homozygous COL18A1 mutation causing Knobloch syndrome using homozygosity mapping and whole exome sequencing. *A. Haghighi[1], A. Haghighi[2], A. Tiwari[3], N. Piri[4], G. Nurnberg[5], N. Saleh-Gohari[6], J. Neidhardt[7], P. Nurnberg[8], W. Berger[3].* 1) University of Toronto, Canada; 2) Department of Genetics, Harvard Medical School, Boston, MA; 3) Institute of Medical Molecular Genetics, University of Zurich Wagistrasse 12, CH-8952 Schlieren, Switzerland; 4) Kentucky Lions Eye Center, Department of Ophthalmology and Visual Sciences, University of Louisville, Louisville, KY; 5) Cologne Center for Genomics (CCG), University of Cologne, Weyertal 115b, 50931 Cologne, Germany; 6) Genetic Department, Kerman University of Medical Sciences, Kerman, Iran; 7) Toronto General Hospital, University of Toronto, Toronto, Canada; 8) University of Cologne, Joseph-Stelzmann-Str. 26, D-50931 Cologne, Germany.

In this study we investigated the genetic cause of a chorioretinal dystrophy with high myopia of unknown origin in a child. The proband was the result of a consanguineous marriage. Homozygosity mapping was performed using the Human SNP Array 6. 0. We also carried out whole exome sequencing (WES) using the patient's DNA. Results of homozygosity mapping and WES revealed a novel homozygous mutation in the *COL18A1* gene in the patient. This mutation causes a frameshift and premature stop codon in the last exon. The parents were both heterozygous for this variant. Mutations of *COL18A1* can cause Knobloch syndrome (KS). Retrospective analysis of clinical records of the patient revealed surgical removal of a meningocele present at birth. Our patient had all the main features of KS and a rare manifestation, chorioretinal degeneration. This is a first case of KS from Iranian population. Since this mutation is located in endostatin domain, a functional relevance of endostatin in KS is suggested. This study shows that linkage analysis in combination with whole exome sequencing is a proper approach for identifying the disease-causing mutations in conditions with unclear initial clinical diagnosis.

Screening for mutations and variants in FSHR gene in women with Premature ovarian failure in a South Indian cohort. *M. Sujatha, V. Madan Mohan, G. Jay Prakash, Ch. Sravanthi, A. Jyothy.* Institute of Genetics and Hospital for Genetic Diseases,Osmania Univeirsity, Begumpet,Hyderabad,Telangana State, India.

Purpose of the study : Premature ovarian failure (POF, MIM311360) is defined as a cessation of menses (amenorrhea) accompanied by elevated gonadotrophin levels before the age of 40 years. POF-I is considered as primary amenorrhoea(PA), POF-II is considered as secondary amenorrhoea (SA), and POF-III (POF,MIM311360). POF is an early ovarian malfunction with decreased production of follicles. Normal functioning of the FSHR receptor is crucial for follicular development. The Exon 1 encodes the N-termina part of the extracellular domain and exon 10 is large and encodes the C terminal part of the transmembrane domain and intracellular domain. Allelic variants (p. Thr307Ala and p. Asn680Ser) and mutations in the FSHR gene have been described as possible causes of premature ovarian failure. These findings led us to investigate the presence of mutations in all the exons and allelic variants in FSHR gene. Materials and Methods : A total of 100 patients and 50 controls from Institute of Genetics and Hospital for Genetic Diseases were considered for the present study . Clinical histories and endocrine profiles were obtained. FSH receptor gene exons 1,2,3,4,5,6,8,9,10A,10B were screened for unknown mutation by PCR, SSCP, DHLPC and DNA sequencing methods. Exons 8,10C,10A,Exon E-G for known mutations were screened by PCR, RFLP and DNA sequencing. Allelic Variants by PCR ,RFLP and DNA sequencing . Results :No mutations were detected in exons 1,2,3,4,5,6,8,9,10A, 10C, 10 D, 10E-G. But in exon 10B a novel mutation T1142G in a herozygote state was identified. The frequency of NN, NS and SS genotypes were 20. 8, 62. 5, and 16. 6% for POF-I and 26. 3, 42. 1, and 31. 5% for POF-II and 28. 57, 52. 38, and 19. 04% for POF-III. The control group showed 34. 2% (NN), 44. 7% (NS), and 21. 05% (SS). The frequency distribution of allelic variants TN, AS and, TS and AN were 48. 3, 41. 6, 6. 6, and 3. 3% for POF-I; 47. 5, 50, 2. 5, and 0% for POF-II; 39, 27, 17, and 17% for POF-III, and control group showed 54, 34, 6, and 6% respectively. The FSH levels of Ala307Ala/ Ser680Ser (SS) genotype for POF-I, POF-II, POF-III were 0. 92±0. 44, 10. 65±1. 34 and 150±28. 91 ($p<0.0001$) respectively. Conclusions:We conclude that mutations in all the exons of FSHR gene are rare in our population and allelic variant Ala307Ala/ Ser680Ser (SS) genotype is associated with clinical and endocrine profiles in patients with premature ovarian failure in South Indian population.

2022F

Development and clinical validation of a novel diagnostic test for Mucin1 kidney disease. *B. Blumenstiel[1], M. DeFelice[1], O. Birsoy[1,2], Q. Yu[1], Z. Leber[1], N. Lennon[1].* 1) Broad Institute of Harvard and MIT, Cambridge, MA; 2) Partners Healthcare, Laboratory for Molecular Medicine, Boston, MA.

Mucin -1 Kidney Disease (MKD), also known as medullary cystic kidney disease type 1, is a rare autosomal dominant inherited kidney disease which leads to progressive loss of kidney function and end stage renal disease. Progression of the disease most often requires dialysis or kidney transplantation in the later decades of life. Previous reporting has linked this progressive tubulo-interstitial disease to a difficult to detect mutation markedly underrepresented in massively parallel sequencing. The mutation is identified as a single base insertion in a single copy of a 60bp repeat unit comprising a long (~1. 5-5 kb), GC-rich (~85%) VNTR sequence in a coding region of the MUC1 gene. This single base cytosine duplication extends a 7C homopolymer to an 8C homopolymer, creating a frameshift which introduces an early stop codon and is expected to result in a truncated protein (Kirby *et al*. 2013). The inherent difficulty in detecting this specific mutation using standard commercial methods required the development of a novel assay for MKD diagnosis in a clinical setting. Here we describe the development, clinical validation and implementation of a mass-spectrometry based CLIA assay for accurately diagnosing patients with MKD. Validation of the MKD diagnostic assay tested across 48 samples in six replicate runs demonstrated a conclusive call rate of 95. 5% and accuracy of 100%. .

2023W

NGS-based Carrier Screen for Gaucher's Disease Calls Variants and Detects Large Rearrangements Between *GBA* and *GBAP1*. *K. M. D'Auria, M. R. Theilmann, K. Iori, C. S. Chu, I. S. Haque, E. A. Evans, H. P. Kang, J. R. Maguire, D. Muzzey.* Counsyl, South San Francisco, CA.

INTRODUCTION: With a carrier rate of 1 in 18 in the Ashkenazi Jewish population, Gaucher's Disease is included on most carrier-screening panels, yet 95% homology between the disease-associated gene (*GBA*) and its pseudogene (*GBAP1*) complicates genotyping by NGS alone. Variant L444P, which is present in 30% of the affected population, is particularly difficult to assess because the mutant base in *GBA* is the normal base in the pseudogene. As such, low-throughput and costly assays—including allele-specific qPCR or long-range PCR followed by Sanger sequencing—have been used to resolve this challenging variant and others, such as D409H, that are also pseudogene-derived. Here we present an entirely NGS-based method that detects ten of the most common deleterious *GBA* variants, giving a 97% carrier detection rate.

METHODS: Hybrid-capture probes were designed to enrich for DNA fragments spanning the variants of interest. To ensure that only *GBA*-derived reads contributed to variant calling in highly homologous regions, reads were discarded if they did not contain a sufficient number of *GBA*-derived bases for unambiguous mapping by the alignment software. Rearrangements in the locus were detected by combining a depth-based copy-number analysis and an assessment of allele balance at each variant position. NGS results for variants L444P and D409H were validated using a combination of long-range PCR and allele-specific TaqMan PCR on 60,000 samples.

RESULTS: Relative to the PCR assay, our NGS test correctly genotyped the L444P and D409H variants in all 60,000 samples. Remarkably, 26% of L444P carriers resulted from fusion genes and would have been false negatives using either a standard SNP caller on NGS data or a qPCR assay with *GBA*-derived primer sequences, underscoring the importance of our custom rearrangement-detection algorithm. Our assay additionally greatly improved the specificity of calling L444P, identifying 84% of heterozygous calls from a standard SNP caller as false positives. The allele frequencies of all other variants are in line with previous studies and sequencing projects.

CONCLUSIONS: NGS sequencing alone, with proper probe design and analysis, can accurately genotype all common *GBA* variants, even those that are pseudogene-derived and nested in highly homologous regions.

2024T

Rapid Capture Methods for Comprehensive Carrier Screening. *D. Muzny[1], J. Hu[1], C. Buhay[1], F. Xia[2], H. Doddapaneni[1], H. Cui[2], Y. Ding[1,3], A. Pourpak[3], M. Wang[1], E. Boerwinkle[1,4], P. Fang[2], N. Verraraghavan[1], Y. Yang[2], C. Eng[2], R. Gibbs[1], A. Beaudet[2].* 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX,; 3) Baylor Miraca Genetics Laboratories, 2450 Holcombe Blvd, Houston, TX; 4) Human Genetics Center, University of Texas Health Science Center at Houston, Houston, TX.

Advances in sequencing technologies and resulting improvements in gene discovery for Mendelian diseases now make accurate and rapid large scale carrier testing for recessive disease an imminent reality. We developed a novel 500kb carrier mutation gene capture panel that includes 168 complete genes that contain at least 850 known common genetic variants of clinical relevance. This capture based panel utilizes a '*lightning capture'* process to deliver variant calls in 5-7 days after sample intake. The '*lighting capture*' process includes: quick enrichment library preparation, (5-6 hours) and capture enrichment (approximately 8 hours); rapid sequencing (Illumina HiSeq2500) and data analysis via the HGSC-developed Mercury pipeline. We also employ the SNPTraceTm assay by Fluidigm in order to ensure reliable sample identification and to test for sample cross-contamination. These same loci form the SNPTrace test have been incorporated into the carrier capture design (500kb). Carrier testing for SMA, fragile X, deletions and duplications in DMD and recurrent clinically relevant CNVs in other genes is currently performed separately, using the Fluidigm platform. This method has been validated utilizing >1,100 control samples. Current methods employ a cost-effective 47plex co-capture format for hybridization with the regional capture reagent followed by sequencing of 94 samples (2 capture pools) per HiSeq 2500 lane for data generation. High enrichment efficiency was observed (72% reads on target and buffer) and superior coverage metrics (99. 1% of target bases ≥20x coverage, and 326x median coverage) across the design with ~400 Mb sequencing yield. A detailed analysis of the design performance using 140 de-identified samples found that known carrier mutations were correctly identified with high confidence (98. 5%), including large/complex indel mutations. Access to universal carrier testing for hundreds of medically relevant (severe) autosomal recessive and X-linked disorders with low cost and quick TAT will be highly impactful, particularly with the addition of conditions such as DMD and deletions and duplications of MECP2. Pre-conception or early post-conception testing of partners is the optimal form of screening to aid prediction of a couple's risk of offspring with an inherited genetic disorder.

2025F

Comparison between HPV Oncotect and Nuclisens EasyQ assay and its potential role in detecting preneoplastic lesions of the cervix. *F. Papa, C. Vaccarella, M. B. Majolini, M. Belli, A. Luciano, V. Mazzucchi, M. CA. Rongioletti.* Clinical Pathology Department, San Giovanni Calibita Hospital, Rome, Italy.

Objectives: This study compare the performance of NucliSENS EasyQ test (bioMerieux), a RT-PCR based method, or HPV OncoTect (InCellDx) a flow cytometry-FISH based method, in the detection of the E6/E7 mRNA expression of hrHPV**.** Moreover, we investigated the potential role, for the detection of high grade lesions, of the HPV OncoTect compared to pap smears to improve cervical cancer screening. **Methods:** We enrolled 173 patients positive for HR-HPV DNA and/or pap smear and referred for evaluation by means of the NucliSENS EasyQ. All patients were tested with HPV OncoTect and 87/173 underwent a colposcopy and histological evaluation according to clinical protocol. **Results:** HPV OncoTect displayed a reactivity of 25% in negative samples, 40% in atypical squamous cells of undetermined significance ASCUS, 48% in low-grade squamous intraepithelial lesion LSIL and 80% in high-grade squamous intraepithelial lesion HSIL. The corresponding results for NucliSENS EasyQ assay were 42, 60, 74, 90%, respectively. Histology analysis revealed that the sensitivity of HPV OncoTect compared to NucliSENS EasyQ was 20% versus 54% in normal specimens, 45% versus 69% in CIN1 and 87% versus 74% in CIN2+, respectively. Higher specificity was observed analysing CIN2+ samples with HPV OncoTect (69%) versus NucliSENS EasyQ (36%). **Conclusions:** HPV E6/E7 mRNA Oncotect test is more specific than NucliSENS EasyQ in identifying women with CIN2+ but has a lower sensitivity. HPV OncoTect is a promising tool for early prediction of persistent HPV infection and seems to be an interesting method to evaluate the preneoplastic lesions of the cervix and improve cancer screening.

2026W

Dried blood spot RNA sequencing (DBS-RNA-Seq): A novel approach for the identification of circulating biomarkers. *A. Wolfe, A. Siniard, I. Schrauwen, M. De Both, R. Richholt, M. Huentelman.* TGen, Neurogenomics Division, Phoenix, AZ.

Circulating RNA biomarkers can be used as indicators of the presence of disease, response to treatment, or potentially as a test of an individual's health status. A significant issue facing the field of biomarker discovery right now is the general lack of cohort size for study as well as longitudinal sampling of the recruited cohort. Much of this is likely due to the fact that most biospecimens are collected using relatively invasive approaches. We sought to optimize RNA biomarker assessment in an easy to collect biospecimen, the dried blood spot (DBS) To collect biospecimens with higher frequency and use them during longitudinal analysis, we developed a DBS-based next generation RNA sequencing approach (DBS-RNA-Seq). Drops of blood (~30ul) were collected onto RNA-stabilizing filter papers and allowed to dry. On average we isolated 10ng of total RNA from one DBS. This RNA was of sufficient quality and quantity to generate Illumina transcriptome and miRNA-Seq libraries, resulting in the detection of 7,000 genes and ~500 miRNAs when sequencing a sample to a depth of ~2 million or 650,000 counts, respectively. RNA-Seq analysis of DBS that were stored for 1, 7, 30, and 60 days demonstrated the presence of no significantly differentially expressed transcripts, suggesting that RNA species collected in this fashion are stable for long periods of time. This work therefore demonstrated the feasibility and appropriate performance of the DBS-RNA-Seq approach. Next, we attempted to utilize DBS-RNA-Seq to identify circulating RNAs associated with 1 hour of aerobic exercise. Each Monday for 4 consecutive weeks, DBS were collected from one study participant at the following time points: 5am (first wake), 9:30am, every 10 minutes during exercise for a total of 6 collections, and then 1, 2, 3, and 4 hours following exercise. The aerobic exercise consisted of a 17-mile road cycling ride of 165 Watts average power. After 24 hours of drying, total RNA was isolated from each DBS and utilized for transcriptome analysis. Several transcripts known to be induced by exercise, and many new transcripts, were identified during exercise as well as during the hours immediately following exercise. This work demonstrated the utility of DBS-RNA-Seq to identify biomarkers associated with a "condition", in this case, an aerobic exercise bout. Therefore, we propose that this approach could be utilized to characterize longitudinal RNA biomarkers in larger cohorts of disease cases and controls.

2027T

Using a new multiplex CNV analysis technology detecting *SLC26A4* deletions and duplication in 84 Chinese subjects with enlarged vestibular aqueduct. *H. Yuan[1,2], Y. Lu[1,2], J. Cheng[1,2], Z. Jiang[3], P. Dai[2].* 1) Medical Genetics Center, Southwest Hospital, Third Military Medical University, Chongqing, China; 2) Dept. of Otolaryngology, Chinese PLA General Hospital, Beijing, 100853, China; 3) 3. Center for Genetic and Genomic Analysis, Genesky Biotechnologies Inc. , Shanghai, 201315, China.

About 90%subjects with enlarged vestibular aqueduct (EVA) carry biallelic mutations in*SLC26A4*gene in clinic. However, only one allelic mutation or none mutation are detected in 10% EVA subjects by Sanger sequencing. We explore to detect possible copy number variations (CNV) in Chinese EVA subjects using multiplex CNVplex® technology. Fifty-one subjects with only one identified mutant and 33 lacked any detectable mutation in *SLC26A4* gene by Sanger sequencing were recruited in this study. We apply a new developed high-throughput multiplex CNV analysis technology to detect *SLC26A4* deletions and duplications in these Chinese EVA subjects. Sanger sequencing confirmed the breakpoints and segregation in these EVA families. Five different deletions and one duplication were identified in 23 of 84 Chinese EVA subjects. Three different exon 1 to 3 deletions were identified in 10cases, and exon 5 to 6 deletion was identified in 11 cases. Exon 7-10 deletion and exon 18-21 duplication were identified in one case. Our findings indicated that CNVs in *SLC26A4* play an important role in EVA etiology. Exon 1 to 3 deletion and exon 5 to 6 deletion are two pathogenic hotspots in Chinese EVA subjects. CNV detection with CNVplex® is necessary to increase diagnostic rate in genetic testing for hearing loss by identifying CNVs in *GJB2*and other genes underlying hearing loss other than *SLC26A4*.

TINA modified primers allow faster PCR. *S. M. Echwald, N. D. Mikkelsen.* Anapa Biotech A/S, Hvidovre, Denmark.

Rapid testing is important for the clinical relevance of many diagnostic assays. As PCR has become the leading technology for molecular diagnostics, increasing PCR speed has become important. Often, the efficiency of PCR-based clinical diagnostic assays is limited by the PCR primers. Here, we report the use of ortho-Twisted Intercalating Nucleic Acid (TINA) in PCR primers which results in increased efficiency and allows significantly shorter PCR cycling time without changing other PCR conditions. By incorporating TINA in the 5' region of PCR primers, assay time for routine assays for infectious agents such as MRSA, can be reduced significantly while retaining PCR specificity and efficiency, where DNA-based assays fail. TINA is a novel intercalator-type oligo modification which stabilize Watson-Crick based antiparallel DNA duplex helixes. A single oTINA molecule increased the annealing temperature (Tm) of an antiparallel DNA duplex by 3-4 °C. TINA is developed as a standard amidite and is available as a standard oligo addition from Eurofins Genomics and TriLink Biotechnologies.

2029W

Exome sequencing in children with life-threatening community-acquired *Pseudomonas aeruginosa* infection. *J. Fellay[1], S. Asgari[1], I. Bartha[1], LJ. Schlapbach[2].* 1) School of Life Science, École Polytechnique Fédérale de Lausanne (EPFL), Lausanne, VD, Switzerland; 2) Paediatric Critical Care Research Group (PCCRG), Mater Research, University of Queensland, Brisbane, Australia.

Background: *Pseudomonas aeruginosa (P. aeruginosa)* is a very rare cause of sepsis in children without comorbidities, but carries an extremely high mortality. Fatal *P. aeruginosa* sepsis in previously healthy children may be the first manifestation of a pathogen-specific primary immunodeficiency (PID). We used exome sequencing of carefully selected children and their parents to search for rare genetic variants that confer susceptibility to this infection. **Methods**: Seven family trios were included in the study. The probands were previously healthy children, age >1 month and <17 years, who developed sepsis due to community-acquired *Pseudomonas aeruginosa* bacteremia. Six of them died from the infection. The parents were apparently healthy individuals. We obtained high-coverage exome sequencing data for all study participants. After short-read alignment, we used GATK haplotypecaller to call single nucleotide variants (SNVs) and small insertions/deletions (indels), and SnpEff for variant annotation. We searched for rare loss-of-function (LoF) variants and assumed various inheritance models. **Results**: We found a novel frameshift indel in exon 7 of the BTK gene in one of the patients. BTK mutations are known to cause X-linked agammaglobulinemia, a PID that had already been associated with severe Pseudomonas sepsis. Using a taqman assay, we confirmed the presence of the variant in hemizygous form in the child and in heterozygous form in the mother. We also demonstrated the absence of immunoglobulins in a plasma sample of the affected child. We did not identify any obvious causal variants in the 6 other cases. **Conclusions**: Our results demonstrate that *P. aeruginosa* sepsis can be caused by rare, deleterious human genetic variants, and confirm that Mendelian susceptibility to common infections can have a dramatic impact in apparently healthy children.

2030T

Molecular inversion probe based re-sequencing in a clinical setting – highlighting *BRCA1* and *BRCA2*. *A. Hoischen[1], A. Mensenkamp[1], M. Kwint[1], R. Derks[1], B. van Lier[1], E. Bosgoed[1], A. Rikken[1], M. Tychon[1], H. Ouchene[1], E. Boyle[2], B. Martin[2], K. Neveling[1], J. Shendure[2], M. Nelen[1], M. Ligtenberg[1].* 1) Department of Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands; 2) Department of Genome Sciences, University of Washington, Seattle, Washington, USA.

Next generation sequencing (NGS) has revolutionized genome- or exome-wide sequencing, but there is still a need for improved NGS-based individual gene testing concerning reliability, accuracy, throughput and costs. Those values are largely determined by enrichment procedures. Molecular inversion probes (MIPs) have shown to be a cost-effective enrichment used in multiplex, particularly if used in large cohorts1. Here we present a workflow of re-sequencing *BRCA1* and *BRCA2* using single molecule molecular inversion probes (smMIP) in combination with NexSeq500 sequencing. The strategy involves the analysis of all coding exons and their flanking intronic sequences, deep intronic SNPs and a genome-wide backbone of 55 genotyping SNP markers. We designed 527 overlapping smMIPs on both strands avoiding known SNPs in probe binding sites2. Every base was targeted by at least two independent smMIPs. Next 152 *BRCA1* and *BRCA2* mutation positive cases were sequenced for both genes with an average coverage of >250-fold. This yielded 100% coverage of all targeted bases, with all coding bases to be covered at least 40x by at least one independent smMIP, and 97. 6% of coding bases covered at least 40x by at least two independent smMIPs. All diseases causing mutations and all known polymorphisms in both genes were detected, including one SNP that was missed using capillary sequencing due to allelic dropout. No false positives were reported. In addition we performed dilution series of known mutations. These provide evidence that smMIP based assays can also detect mosaic mutations with <1% mutation alleles. In conclusion, targeted *BRCA1* and *BRCA2* re-sequencing using smMIPs shows high sensitivity and specificity and can replace sequencing workflows in a clinical setting. In addition smMIPs allow low enrichment costs per sample and highly scalable workflows. References:1) O'Roak et al. Science 2012; Hiatt et al. Gen Res 20132) Boyle et al. Bioinformatics 2014.

2031F

Achieving high-sensitivity for clinical applications using augmented exome sequencing. *A. Patwardhan[1], J. Harris[1], N. Leng[1], G. Bartha[1], D. M. Church[1], S. Luo[1], C. Haudenschild[1], M. Pratt[1], J. Zook[2], M. Salit[2], J. Tirch[1], M. Morra[1], S. Chervitz[1], M. Clark[1], S. Garcia[1], G. Chandratillake[1], S. Kirk[1], E. Ashley[1,6], M. Snyder[1,5], R. Altman[1,4], C. Bustamante[5], A. J. Butte[1,3], J. West[1], R. Chen[1].* 1) Personalis, Inc. 1330 O'Brien Drive, Menlo Park, California 94025, USA; 2) Biosystems and Biomaterials Division, National Institute of Standards and Technology, Gaithersburg, Maryland, USA; 3) Institute for Computational Health Sciences, University of California, San Francisco, California 94158, USA; 4) Departments of Bioengineering & Genetics, Stanford University, Stanford, California 94305, USA; 5) Department of Genetics, Stanford University School of Medicine, Stanford, California 94305, USA; 6) Center for Inherited Cardiovascular Disease, Stanford University School of Medicine, Stanford, California 94305, USA.

Whole exome sequencing is increasingly used for the clinical evaluation of genetic disease, yet the variation of coverage and sensitivity over medically relevant parts of the genome remains poorly understood. Several sequencing-based assays have base-level coverage that is inadequate for clinical assessment. Using sequence data obtained from the NA12878 reference sample and pre-defined lists of medically-relevant protein-coding and noncoding sequences, we compared the breadth- and depth-of-coverage obtained among four commercial exome capture platforms and PCR-free whole genome sequencing. In addition, we evaluated the performance of an augmented exome strategy, ACE, that extends coverage in medically relevant regions and enhances coverage in high-GC rich regions that are challenging to sequence. Leveraging reference call-sets, we examined how improved coverage effects variant detection sensitivity. We observed insufficient coverage with each of the conventional exome-capture and whole-genome platforms across several medically interpretable regions. These gaps included known disease-associated loci and areas of the genome required for reporting secondary findings (ACMG). At clinically-relevant coverage levels (100% bases covered at >20x, with map Q20 reads), ACE improved coverage among genes in the medically interpretable genome (>90% covered compared to 10-78% with other platforms), the set of ACMG secondary finding genes (91% covered compared to 4-75% with other platforms) and a subset of variants known to be associated with human disease (99% covered compared to 52-95% with other platforms). Improved coverage translated into improved accuracy. ACE variant detection sensitivities exceeded those observed with conventional whole-exome and whole-genome platforms. Clinicians should consider analytical performance when making clinical assessments, given that even a few missed variants can lead to false negative results. We show that by comprehensively targeting medically interpretable areas, including those areas that are challenging to sequence, we improve sensitivity in regions of the genome relevant for clinical interpretation. In clinical applications where comprehensive coverage of medically interpretable areas of the genome requires higher localized sequencing depth, an augmented exome approach offers both cost and performance advantages over other sequencing-based tests.

2032W

Rapid screening of severely ill newborns and infants using whole genome sequencing. *R. J. Sinke[1], C. C. van Diemen[1], W. S. Kerstjens-Frederikse[1], T. J. de Koning[1,2], B. Sikkema-Raddatz[1], J. D. H. Jongbloed[1], K. M. Abbott[1], J. C. Herkert[1], P. B. T. Neerincx[1], G. de Vries[1], M. Meems-Veldhuis[1], M. Viel[1], A. J. Scheper[1], K. de Lange[1], J. Dijkhuis[1], J. van der Velde[1], M. de Haan[1], M. A. Swertz[1], K. A. Bergman[2], C. M. A. van Ravenswaaij-Arts[1], I. M. van Langen[1], R. H. Sijmons[1], C. Wijmenga[1].* 1) Dept. of Genetics, UMC Groningen, University of Groningen, Groningen, The Netherlands; 2) Beatrix Children's Hospital, University Medical Center Groningen, Groningen, The Netherlands.

For severely ill newborns quick molecular diagnoses are of utmost importance for clinical decision-making and can prevent unnecessary and sometimes invasive diagnostics. To date, immediate molecular testing is not a routine procedure for all patients since this is available only for few diseases. Here we describe a procedure and present the first results to analyze 2800 genetic disorders in severely ill newborns and infants by rapid whole-genome sequencing (WGS). WGS is carried out in parallel to standard diagnostic procedures (including imaging, SNP-arrays, biochemical testing, mutation analysis, etc.). The entire procedure from inclusion to reporting is completed in approximately 2 weeks. The final evaluation of the results is done by a multidisciplinary team of pediatricians, clinical geneticists, technicians, clinical genetic laboratory specialists, researchers and bio-informaticians. Thus far we have included 14 patients in the study and have provided a diagnosis of a monogenic disease for three patients. These patients presented with different clinical characteristics and that could be explained by mutations in the *EPG5, KLHL41* and *RMND1* genes. One patient was diagnosed with a 1p36 microdeletion upon routine diagnostic testing. We also tested 5 patients, who died within the first year of life, and their parents with rapid clinical exome sequencing, focusing on the same set of 2800 genes. We found compound heterozygous mutations in *BRAT1* in one child with an unexplained severe seizure and rigidity disorder. Currently we are evaluating the procedure, comparing our results with those from studies of the Kingsmore's group, who published diagnostic yields of 80% (in a prospective study, Saunders et al. Sci Transl Med. 2012;4:154ra135) and 57% (in a retrospective study, Willig et al. Lancet Respir Med. 2015 35:377-387). We will emphasize on phenotype selection, technical aspects of coverage and filtering methods. One preliminary conclusion explaining the lower yield in our studies, may be that our patient inclusion was biased towards patients with an unclear, complex phenotype.

2033T

Initial evaluation in constitutional cytogenomics of CNVkit, an algorithm for genome-wide copy number determination using on- and off-target reads in whole exome sequencing data. *A. Wiita[1], E. Talevich[2], L. Cheng[1], D. Wheeler[1], Z. Qi[1], J. Yu[1].* 1) Laboratory Medicine, University of California, San Francisco, CA; 2) Pathology, University of California, San Francisco, CA.

Background: Copy-number analysis is a routine clinical test for the diagnosis of autism, developmental delay, and congenital anomalies. The current gold standard methodology is cytogenomic microarray analysis. However, next generation sequencing, particularly whole exome sequencing, is becoming a routine clinical test for genomic analysis. There remains a need for improved bioinformatic strategies to extract copy number information from these datasets, potentially eliminating the need for separate microarray testing. **Methods:** We present the initial evaluation of a newly-described bioinformatic algorithm, CNVkit, in the setting of constitutional cytogenomics. CNVkit uses both on- and off-target reads as generated by targeted next generation sequencing data to determine genome-wide copy number variation. CNVkit accurately captures complex copy number variation in cancer samples (Talevich et al, submitted). However, its performance in constitutional genetics, with infrequent single-copy gains and losses, is unknown. In addition, the majority of CNV analysis software for exome sequencing is based on Illumina platform data. The Ion Proton technology holds promise for clinical laboratories based on shorter run times, though these data may present additional analytical challenges. Here, we compare CNVkit analysis on 11 DNA samples, analyzed by both whole exome capture chip (BGI custom design) on Ion Proton and SNP array (Illumina Infinium CytoSNP-850K). **Results:** We found high concordance between CNVkit analysis of exome data and SNP array for CNVs >400 kb (19/19 variants detected). This finding resulted in an analytical sensitivity of 100% compared to array. For variants below this size threshold, however, we found minimal concordance, with only 5 of 53 variants identified by array also called by CNVkit. These results suggest that CNVkit may be able to identify the majority of clinically significant copy number variants in a constitutional genetics setting. However, the non-exonic resolution of CNVkit, ~100 kb, may limit its ability to detect smaller variants. We will perform qPCR to confirm discordant CNV calls found by SNP array. We also aim to further refine the CNVkit algorithm for use with Ion Proton sequencing data. **Conclusion:** CNVkit shows initial promise in the analysis of copy number variants in a constitutional genetics setting and on Ion Proton data, though more refinement is required to equal SNP array for diagnostic testing.

2034F

Clinical whole exome sequencing reveals previously unreported likely pathogenic variants in the SCN8A gene in patients with early onset epileptic encephalopathy with intellectual disability. *F. Vetrini[1], J. Zhang[1], W. He[1], Z. Niu[1], M. Walkievicz[1], R. E. Person[1], A. L. Beaudet[1], D. M. Muzny[2], R. A. Gibbs[1,2], J. Lupski[1], C. M. Eng[1], Y. Yang[1].* 1) Department of Molecular And Human Genetics, Baylor College of Medicine, Houston, TX; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX.

Voltage-gated sodium channels (NaV) are essential for initiating and propagating neuronal cell action potentials in the brain. Pathogenic variantsin *SCN8A*, which encodes the sodium channel voltage-gated alpha8-subunit (Nav1. 6), one of the most abundant sodium channels in the brain, have recently been recognized as one of themechanisms leading to epilepsy and intellectual/developmental disabilities (IDDs). *SCN8A* related encephalopathy presents in infancy with multiple seizure types, in some cases associatedwith sudden unexpected death in epilepsy (SUDEP), motor manifestations including hypotonia, ataxia, dystonia, hyperreflexia, and psychiatric manifestation including behavioral disturbance and autism. We have used Whole Exome Sequencing (WES) to identify *SCN8A* pathogenic variants in seven patients with epilepsy and IDDs of unknown etiology. The patients presented with a variable clinical picture including early onset epileptic encephalopathy (n=7), structural brain abnormalities (n=3), ID (n=7), hypotonia (n=2), movement disorders (n=4), seizure–associated cardiac conduction defects (n=1). A total of five *SCN8A* novel missense mutation (p. D58V, p. 216G, p. A874S, p. Q1470E and p. G1475R) were found in this patient cohort and were predicted to be damaging to the structure of NaV1. 6 channel by Polyphen2 and SIFT *in silico* prediction programs. The mutations are scattered throughout the gene and potentially affect conserved domains of the channel: one in the cytoplasmic N-terminal domain (p. D58V), one in the linker region between S3 and S4 of domain I (p. V216G), one in the linker between S4 and S5 of domain II (p. A874S), and two in the inactivation gate between domains III and IV (p. Q1470E, p. G1475R). Sanger sequencing did not identify these variants in the biological parents, however, affected siblings from two different families carried the same variants, c. 2620G>T (p. 874S) and c. 4408C>G (p. Q1470E) respectively, strongly suggesting mosaicism in a parent in the two families. For the other three families, the variants appeared to arise *de novo* in the patients. However, the possibility of low level mosaicism should still be considered when counseling parentsand estimating recurrence risk for the family. In conclusion, the reporting of five novel *SCN8A* likely pathogenic variants may help further determine genotype-phenotype relationships for patients with early onset epileptic encephalopathy with IDDs due to defects in the voltage-gated Nav1. 6 channel.

2035W

Development of a high throughput workflow for CFTR mutation screening. *T. Hartshorne, J. Lang, E. Swartzman, P. Brzoska, D. de Castro, L. Tracy.* Genetic Analysis, Thermo Fisher Scientific, South San Francisco, CA.

Cystic fibrosis (CF) is an autosomal recessive genetic disease that is caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. It is the most common genetic disease of Caucasians, affecting 1 in 3000 newborns and having a carrier frequency of 1 in 25. CF impacts mucin production in lungs and other organs, and is a progressive incurable disease. To facilitate rapid, low cost, high throughput screening of individuals that carry CFTR mutations, we set out to develop a panel of over 200 TaqMan™ assays that detect specific CF-causing mutations. Target mutations were selected from the CFTR1 and CFTR2 databases, and prioritized based on frequency and consequence. CF-causing mutations occur primarily within coding and regulatory regions and include single nucleotide base substitutions, small insertion deletions, large deletions, repetitive sequences, and triallelic polymorphisms. The diverse nature of the mutations presented challenges to developing assays that used a single chemistry and that could be run together on one platform, but for the most part, these were overcome by using various design strategies. TaqMan SNP genotyping and endpoint assays were initially tested on both 384-well plates and OpenArray™ plates (= 3072-well), run on a real-time PCR system, with Coriell cell line gDNA samples that carry CFTR mutations. Given that most CFTR mutations are rare and control gDNAs are not available for them all, assays were also tested with synthetic DNA controls representing 3 genotypes for each CFTR variant, to ensure robust discrimination of alleles and genotypes. If an assay failed to perform well, the assay was redesigned and tested until a sufficiently robust assay was produced. The testing of DNA isolated from blood and buccal cell samples is underway, as are assay accuracy and concordance studies. We will present our progress towards development of a complete sample-to-data analysis workflow for high throughput CFTR mutation detection. Example assay data and analysis methods will be shown, in particular for difficult targets such as the 5T/7T/9T polymorphism. Our CFTR genotyping workflow will enable selection of assays based on CFTR mutation occurrence in populations of interest, screening of small or large numbers of samples using customizable panels of 60, 120 or 180 assays, and highly accurate and reproducible acquisition of CFTR genotypes from blood and buccal cell samples.

2036T

Validation of a high resolution NGS method for detecting spinal muscular atrophy carriers among phase 3 participants in the 1000 Genomes Project. *J. L. Larson[1], A. J. Silver[1], D. Chan[1], C. Borroto[2], B. Spurrier[2], L. M. Silver[2,3].* 1) GenePeeks, Inc. , Cambridge, MA; 2) GenePeeks, Inc. , New York, NY; 3) Department of Molecular Biology and the Woodrow Wilson School of Public and International Affairs, Princeton University, Princeton, NJ, USA.

Spinal muscular atrophy (SMA) is the most common pan-ethnic cause of early childhood death due to mutations in a single gene, *SMN1*. Most chromosome 5 homologs have a functional gene and dysfunctional copy, *SMN2*, with a single synonymous base substitution that results in faulty RNA splicing. However, the copy number of *SMN1* and *SMN2* is highly variable, and one in 60 adults worldwide are SMA carriers. Although population-wide screening is recommended, current SMA carrier tests have not been incorporated into targeted gene panels. Here we describe a novel computational protocol for determining SMA carrier status based solely on individual exome data. We find complete concordance with results obtained with the current qPCR-based testing standard. We applied our protocol to the phase 3 cohort of the 1,000 Genomes Project and found carrier frequencies in multiple populations consistent with the present literature. Our process is a convenient, robust alternative to qPCR, which can easily be integrated into the analysis of large multigene NGS carrier screens.

2037F

Standardizing the quality QC of any DNA isolation to safeguard the success of genetic testing. *T. Martens, T. Boonefaes, E. De Raeymaecker, T. Montoye.* Trinean, Dulle grietlaan 33, 9050 Gentbrugge, Belgium.

As genetic tests become more powerful yet also more complex and costly, it is prudent to include quality control steps throughout the entire workflow to ensure the quality of the downstream data obtained. To avoid financial and time costs due to analytical failures downstream, it is essential to include at the start an informed go/no go decision based on a good assessment of the DNA/RNA isolation yield and purity, preferably including the detection of carry-over constituents that may interfere with the tests. Here, we validate a simple approach for DNA quantification and purity QC, using a large DNA sample set derived from a variety of human tissues combined with a wide scale of extraction methods. This new QC tool combines the micro-volume spectrophotometry on the Xpose reader by Trinean with its spectral content profiling app for Mammalian gDNA to specifically quantify the isolated DNA as well as the amount of contaminating constituents in the sample contributing to the measured UV/Vis spectra. In this study, a large collection of DNA samples was used to compare the Xpose reader with recommended absorbance and fluorescence-based DNA quantification and purity analysis tools to verify its specificity for DNA quantification and impurity detection.

2038W

Genetic testing supply and demand: Tracking growth and competition in the genetic testing marketplace. *T. A. Murphy, J. D. Schneider, G. W. Hooker.* Bioinformatics, NextGxDx, Franklin, TN.

Introduction: The genetic testing landscape is growing and changing at a rapid pace, due in large part to innovations in sequencing capability. As the sequencing cost per base pair goes down, laboratories are able to expand their test offerings by introducing both new options for clinical use and, in many cases, options that compete with tests offered by other laboratories in the market. However, with broader scope testing comes the need for greater analytic infrastructure, which can be costly. Drawing from our data resource of more than 38,000 genetic tests we aimed to describe the growth in the market from June 1st, 2014 to June 1st, 2015. We also aimed to test the hypothesis that, corresponding to growth and increased competition in the market, average test price would decrease in this time period. **Methods:** We curate and maintain a database of clinically available genetic tests offered by US CLIA-certified laboratories. We collect information from laboratory websites on the tests they offer, and other available test attributes including methodologies, turn-around-times, test descriptions and test list prices. The mean time interval between updates of test information is 14 days. We tracked new tests entering the market on a monthly basis and compared average costs per test from June 2014 to June 2105. **Results:** Across this time period, we saw a net of 2,815 new tests introduced to the market, at a rate of about 8 new tests/day. 888 of these tests were multi-gene panel tests. As the market grew, the average price per test dropped by 14. 9% overall, with a 16. 8% decrease in the average price per single gene test and a 6. 5% decrease in the average price per multi-gene panel test. Of all tests in our database, clinical exome sequencing prices dropped the most, going from an average price of $8426 per exome test product to $6074 per exome test product. **Conclusions**: With expanding options for clinical genetic and genomic testing have come decreasing list price costs associated with these tests. The dynamic nature of the market suggests opportunities for utilization management and cost savings. which have the potential to increase patient access to genetic tests.

2039T

"Ion Ampliseq Custom Arrhythmia Panel" comprising 68 cardiac channelopathy genes is a gold standard for the rapid and sensitive detection of novel genes and variations in Long QT (LQT) syndrome.

B. Turkgenc[1,2], S. G. Temel[3,4], H. H. Aykan[5], A. Sulu[6], M. G. Ramoglu[7], F. Uysal[8], O. M. Bostan[8], T. Karagoz[5], F. Akalin[9], O. Baspinar[6], Y. Alanay[10,11], A. Celiker[12], S. A. Ozer[2], M. C. Yakicier[13]. 1) Acibadem Genetic Diagnostic Center, Istanbul, Turkey; 2) Marmara University, Department of Medical Biology and Genetic, Istanbul, Turkey; 3) Near East University, Faculty of Medicine, Department of Histology and Embryology, Lefkosa, North Cyprus; 4) Uludag University, Faculty of Medicine, Department of Histology and Embryology, Bursa, Turkey; 5) Hacettepe University, Faculty of Medicine, Department of Pediatric Cardiology, Ankara, Turkey; 6) Gaziantep University, Faculty of Medicine, Department of Pediatric Cardiology, Gaziantep, Turkey; 7) Ankara University, Faculty of Medicine, Department of Pediatric Cardiology, Ankara, Turkey; 8) Uludag University, Faculty of Medicine, Department of Pediatric Cardiology, Bursa, Turkey; 9) Marmara University, Faculty of Medicine, Department of Pediatric Cardiology, Istanbul, Turkey; 10) Acibadem Maslak Hospital, Department of Pediatric Genetic, Istanbul, Turkey; 11) Acibadem University, Faculty of Medicine, Department of Pediatric Genetic, Istanbul, Turkey; 12) VKV Amerikan Hastanesi, Istanbul, Turkey; 13) Acibadem University, Faculty of Science, Melocular Biology and Genetic, Istanbul, Turkey.

Background: Long QT (LQT) syndrome is a genetically heterogeneous disease with high frequence predicted between 1/2000 and 1/5000 and associated with a high risk of sudden death. It has been informed 14 different genes for LQTs until now. Approximately 25% of LQT families don't have detectable mutations in reported 14 LQT genes. The identification of the other genes responsible of LQT has a big importance on specification of molecular and diagnostic approaches. **Purpose:** Aim of our study is to investigate new cardiac channelopathy gene mutations underlying LQT's by using extremely sensitive and specific detection method "custom AmpliSeq™ panel". **Methods:** Whole blood was obtained from the proband and family members with informed consent. Genomic DNA was isolated by usingWizard® Genomic DNA Purification Kit, Promega. Targeted sequencing was performed on ion Personel Genome Machine using Custom Ion Ampliseq Panel comprising 68 genes known to be associated with cardiological arrhythmias. Data analysis was performed using Torrent Suite Software. The missense mutations were confirmed by GenomeLab™ GeXP Genetic Analysis System, Beckman Coulter. **Results:**We identified 28 different mutations (26 missense, 1 insertion and 1inframe deletion) among 12 unrelated Turkish families with LQTs. 8 of these were novel, 7 of these were reported as pathogenic alleles, the remaining 13 were reported as ''unknown" allele with MAF<0. 01%. We identified 1 novel and 3 reported KCNQ1 mutations, 1 ANK2 mutation and 2 AKAP9 variations as expected for LQTs. KCNQ1, ANK2 and AKAP9 variants were together with at least one other channelopathy variants (RYR1, CACNA1S, LDB3, SCN1B, CACNA2D1, CACNB2, BAG3, TRPM4, RBM20, MYH7, CASQ2, PKP2, DSG2 and RYR2). TRPM4, HCN4 and TNII3 variants were identified in other LQT families, separately. One case had a de-novo RYR2 and germline DSP mutation. Last patient had MYH6 and TCAP gene variations together. **Conclusion:** Our 68 gene panel for inherited *arrhythmia*sidentifies novel candidate genes responsible for LQTS and it's a gold standard on molecular diagnosis of the disease. Our study highlights that LQT panel should not be limited with only 14 gene, but also should be investigated other cardiac channelopathy genes. For future directions functional analysis of variations are under estimated. **Acknowledgements:** Inherited *arrhythmia panel is* supported by grant from SANTEZ Project (0253. STZ. 2013-2), Turkey.

2040F

Genetic and epigenetic analysis of amyotrophic lateral sclerosis (ALS) patients in the Slovenian population.

M. Ravnik-Glavac[1], K. Vrabec[1], D. Glavañ, B. Koritnik[2], L. Leonardis[2], L. Dolenc-Grošelj[2], J. Zidar[2], B. Rogelj[3]. 1) Department of Molecular Genetics, Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; 2) Institute of Clinical Neurophysiology, Division of Neurology, University Medical Centre Ljubljana, Ljubljana, Slovenia; 3) Department of Biotechnology, Jožef Štefan Institute, Ljubljana, Slovenia; Biomedical Research Institute, Ljubljana, Slovenia.

Amyotrophic lateral sclerosis (ALS) is the most common motor neuron disease. It is typically fatal within 2-5 years of symptom onset. A complex interaction between genes, environmental exposure and impaired molecular pathways contributes to pathology in patients with ALS. Epigenetic mechanisms control the hereditary and reversible regulation of gene expression without altering the basic genetic code. Although recent genetic studies have substantially improved our understanding of the causes of ALS, especially familial ALS, an important role of non-genetic factors in ALS is also recognized and needs further study. We first performed genetic analysis of *SOD1*, *TARDBP*, *FUS* in *C9ORF72* genes in 84 Slovenain patience with sporadic form of ALS and revealed mutations p. Val14Met and p. Gly93Cys in *SOD1* gene and 2 synonymous substitutions, p. Arg522Arg in *FUS* gene and a novel change p. Leu330Leu in *TARDBP*. Screening of *C9ORF72* revealed HREM in 5 patients. In concordance with other studies *C9ORF72* is the most common detected disease causing change. The research was continued in the field of methylation. Based on the results of the whole genome methylation profiling performed on 4 samples 14 genes were selected and the results were validated in 101 patients by MS-HRM. Methylated promoters were detected in 8 genes but the promoters of 6 genes were found unmethylated. Results of MS-HRM were confirmed by Sanger sequencing. In the field of miRNA, qPCR was used to examine the expression of 10 miRNA. Increased expression of let-7b, miR-132, miR-206 and miR-638 was detected. Reduced expression of miR-338 and its host gene *AATK* was found. MiR-9 was differently expressed in ALS patients, but its host gene *C1ORF61* was not expressed in blood. Two intergenic miRNAs, miR-663a which had variable expression across samples and miR-124a whose expression was reduced, were analyzed by MS-HRM. Results showed that methylation of their promoters are not the cause for reduced expression. MiR-143 and miR-451a both showed decreased expression but no CpG islands were found in their promoters. While some progress has been made in recent years, the majority of the genetic and epigenetic variations involved in the ALS are yet to be identified. .

2041W

The most variable region of the genome: The next generation of HLA-typing platforms. *J. Kaur[1], J. Sims[2], E. Earley[2], K. Robasky[2], E. Lai[1].* 1) Takeda Pharmaceuticals International, Inc, Deerfield, IL; 2) EA|Quintiles, Durham, NC.

The Human Leukocyte Antigen (HLA) region of the genome encodes self-recognition proteins, thereby blocking autoimmunity. For decades, data have been collected on this region in support of transplantation tissue-matching, but HLA-typing also has many other important applications. In addition to informing treatment for autoimmune dysfunction, recent advances in oncotherapy exploit HLA gene expression in cancer. Furthermore, HLA-typing has been used to predict adverse drug responses such as hepatotoxicity. However, these genes also represent the most variable region of the human genome, and typing them by traditional methods is both manual and time consuming. Fortunately, variants in the HLA genes display high linkage disequilibrium (LD) and the most common haplotypes are well documented and limited in number. Emerging HLA-typing technologies leverage these characteristics through multiplexed primer design and phasing of the HLA region to yield less costly, highly sensitive and specific HLA allele recognition. Here, we contrast and compare these nascent NGS-based and array-based platforms against the polymerase chain reaction (PCR) and sequence-specific oligonucleotide probes protocol from Luminex (PCR-SSOP-Luminex). We performed these assays on patient-derived samples which we population-stratified using hapmap data for controls. Using a reference panel consistent with the sample population, we found that HLA-types could be imputed on arrays with platform-agnostic phasing software at better than 90% concordance for 2-digit accuracy, and less concordance for 4-digit accuracy. When comparing the Omni5 to the Affymetrix Axiom (used for the UK Biobank), the Axiom array has significantly fewer probesets than the Omni5, and also fewer loci over-lapping with markers in the reference panel. This difference affects the concordance estimates, with the Omni showing 89. 33% concordance with the gold-standard on Class I alleles and the Axiom 83. 33% concordance. This is contrasted with the NGS-based assay which shows 99. 33% concordance. Notably, the price point for array technologies are an order of magnitude lower than NGS-based assays, which are more affordable still than the gold-standard. Informed by platform-specific cost data, we offer additional evidence-based guidance for contextual choice of HLA-typing technology.

2042T

DIRECT targeted library preparation for Illumina Sequencing. *C. Hendrickson[1], K. Patel[1], N. Henig[1], T. Davis[2], S. Russello[2], B. Galvin[1].* 1) Directed Genomics, Ipswich, MA; 2) New England Biolabs, Ipswich, MA.

Next-generation sequencing, coupled with targeted capture of disease-associated genes, has made the transition from research and translational studies to patient screening and diagnostic testing. However, current target enrichment methods, developed initially for research, lack the speed, simplicity, and specificity required for effective clinical execution. To meet these requirements, we have developed the DIRECT target capture method that offers significant advantages over traditional in-solution hybridization and multiplex PCR protocols. The DIRECT method for enrichment enables rapid capture of desired DNA fragments followed by conversion of these fragments into a highly specific, Illumina-compatible library within 7 hours, enabling sample-to-sequencing in one day. To validate the efficacy of this methodology with both intact DNA and fragmented circulating tumor DNA, we present data generated from our CancerDIRECT panel designed to capture genes commonly mutated in cancer. Our data demonstrates that this approach captures targeted sequence with high specificity and uniformity, and detects variants with great accuracy and sensitivity.

2043F

PCR based target enrichment for NGS panels and Sanger variant confirmation. *S. Lefever[1,2], J. Vandesompele[1,2], F. Coppieters[1,2].* 1) Ghent University, Center for Medical Genetics, Ghent, Oost-Vlaanderen, Belgium; 2) pxlence, Dendermonde, Oost-Vlaanderen, Belgium.

Targeted resequencing is an important application in clinical diagnostics. A wide range of target enrichment strategies have been developed, enabling the customer to focus on genomic regions of interest. Enrichment does not only significantly reduces sequencing costs per sample but also facilitates downstream data analysis considerably and imposes less ethical concerns. Due to its flexibility in design, high sensitivity and specificity, the polymerase chain reaction (PCR) is ideally suited as enrichment strategy. We developed and validated a primer design tool called primerXL and have generated almost one million assays for both fresh frozen and formalin-fixed paraffin-embedded (FFPE) samples, covering over 98. 7% of the human exome. Assays were designed to limit single nucleotide polymorphism (SNP) presence in primer annealing sites and minimize off-target amplification, thus generating assays achieving equimolar and maximal specificity under uniform PCR conditions. We have validated 2200 assays sampled from 200 disease causing genes. Wet-lab success-rate was determined to be over 96. 5 % upon testing by means of quantiative PCR without any optimization. Amplicons for two commercial reference DNA samples were pooled and sequenced on a MiSeq instrument. Sequencing results showed unprecedented equimolar coverage across the different amplicons with over 2/3rds of the amplicons having a coverage within 2-fold of the mean (and almost 90% within 5-fold of the mean). Specificity was very high with almost 95% of the assays having less than 2% of off-target mapping. Using our assays, NGS gene panels have already been developed for congenital blindness (16 genes), deafness (15 genes) and various cancer types (16 genes) achieving uniform sequencing coverage using different library preparation methods and sequencing instruments. To date, the Center for Medical Genetics in Ghent incorporates the primerXL assays in a high-throughput singleplex enrichment workflow to replace Sanger sequencing-based diagnostic tests with NGS (under ISO15189 accreditation). Due to the excellent performance the assays, a spin-off called “pxlence” was recently founded. Its short-term goal is to provide customers easy access to the predesigned assays, enabling them to enrich any exonic region or confirm any variant of interest through either NGS or Sanger sequencing. More information is available at www. pxlence. com.

2044W

Comprehensive Genetic Exploration of Skeletal Dysplasia Using Targeted Exome Sequencing. *J. Bae[1,2], N. Kim[1], W. Park[1,2,4], T. Cho[3].* 1) Samsung Genome Institute, Seoul, South Korea; 2) Department of Health Sciences and Technology, Samsung Advanced Institute for Health Sciences and Technology, Sungkyunkwan University, Seoul, Korea; 3) Division of Pediatric Orthopaedics, Seoul National University Children's Hospital, Seoul, Korea; 4) Department of Molecular Cell Biology, Sungkyunkwan University School of Medicine, Suwon, Korea.

Skeletal dysplasias are a group of genetic disorders of the skeletal system caused by mutations of genes involving bone and cartilage metabolism. A recent update of the nosology and classification of genetic skeletal diseases included 40 groups and 456 disease entities, listing 226 causative genes that have been discovered for 316 diseases. Clinical diagnosis of the specific disease entity causing skeletal dysplasia can be significantly difficult for several reasons. The purpose of this study was to evaluate the clinical utility of targeted exome sequencing (TES) as a molecular diagnosis tool for patients with skeletal dysplasias. A total of 186 patients diagnosed with or suspected to have skeletal dysplasia were recruited over a period of 3 years. TES for 255 genes associated with the pathogenesis of skeletal dysplasia was performed, and candidate variants were selected using bioinformatics analysis. All candidate variants were confirmed by Sanger sequencing, correlation with the phenotype and co-segregation study in the family. TES detected 'confirmed' or 'highly likely' pathogenic sequence variants in 74% (71 cases) of the assured clinical diagnosis group, as well as pathogenic sequence variants in 11 cases (16. 9%) of the uncertain clinical diagnosis group. TES successfully detected pathogenic variants in all 25 cases of previously known genotypes. TES data also suggested a copy number variation that led to a molecular diagnosis. TES data also suggested a copy number variation that leads to a molecular diagnosis. We demonstrated the feasibility of TES for molecular diagnosis of skeletal dysplasia. Further confirmation is needed for a final molecular diagnosis, including Sanger sequencing of candidate variants and suspected but poorly captured exons.

2045T

Discovery of small RNA biomarkers of hypertension through next-generation sequencing of urinary exosomes. *A. R. Davis[1], S. K. Sen[1], R. Quarells[2], C. Oguz[1], J. Vargas[1], S. Davis[1], G. H. Gibbons[1], MH-GRID.* 1) Cardiovascular Disease Section, National Human Genome Research Institute, 10 Center Drive, RM 7N321, Bethesda, MD. 20892; 2) Cardiovascular Research Institute, Morehouse School of Medicine, 720 Westview Drive Atlanta, GA 30310.

BackgroundGiven the fundamental role of the kidneys in the etiology of hypertension, biological signals of this disease may be found in urine. Discovery of urine biomarkers could improve diagnostics for essential hypertension. Exosomes are microscopic vesicles, 50-90 nm in diameter, excreted from renal tubular epithelial cells into urine. Recent advances in massively parallel sequencing allow for sub-nanogram amounts of nucleic acids (on the scale of regular exosomal miRNA content) to be analyzed using miRNA-Seq. However, no studies exist that have attempted this with small volumes of urine that are in the range of regular specimen collection in clinical studies. Hence, we set out to do a proof-of-principle study for the use of massively parallel sequencing on urinary exosome miRNA for discovery of hypertension biomarkers. ResultsSixteen 1ml frozen urine samples (eight each with and without Norgen preservative, respectively) were compared using the Norgen Urine Exosome RNA Isolation Kit to determine whether RNA yield would support massively parallel sequencing. We found substantially higher miRNA yields from urine with Norgen preservative (mean yield 62pg vs. 387pg). After determining the preferred biomaterial (urine with preservative), six low-value 1ml samples were chosen for a miRNA-Seq pilot project. Since the efficacy of miRNA-Seq library preparation with picogram amounts of RNA is not yet feasible, extracted RNA samples were amplified with the NCode™ miRNA Amplification System after adding a non-human synthetic spike-in miRNA control. Sequencing libraries were constructed using the Illumina TruSeq Small RNA kit, multiplexed and sequenced on a HiSeq2500 sequencer. Five of the six libraries passed QC and gave data close to the targeted 10M reads (average 9. 9M reads) while one library had lower yield and produced only 1. 6M reads. Average alignment rate across the six libraries was 60. 15 percent. Interestingly, along with the miRNAs, sequence data contained snoRNA, snRNAs, tRNAs and piRNAs, highlighting the diversity of exosomal small RNA content. ConclusionsWe demonstrate the feasibility of using limited amounts of urine from clinical subjects as substrates for biomarker discovery using massively parallel sequencing. To the best of our knowledge, our project represents the first examination of the urinary exosomal miRNome as it relates to hypertension and opens the door to exciting new discoveries of diagnostic biomarkers.

2046F

Maternal capillary blood: A new source of circulating cell-free fetal DNA for noninvasive prenatal testing. *R. Primacio, C. Jacob, D. Potter.* Gateway Genomics, San Diego, CA.

Noninvasive prenatal testing (NIPT) is currently limited to maternal venous blood collection by trained phlebotomists, which can restrict accessibility to prenatal screening. We aimed to identify a new source of circulating cell-free fetal DNA that would be convenient for broad population screening and reliable enough for noninvasive prenatal diagnosis. Maternal capillary blood samples were obtained from pregnant women (6-24 weeks gestation) by finger stick. Plasma was separated from whole blood by centrifugation, and circulating cell-free DNA was isolated using a commercial DNA extraction kit. Real-time quantitative PCR was performed to detect fetal DNA using a multi-copy sequence on the Y chromosome. An endogenous control gene was used to measure total cell-free DNA (maternal and fetal). We detected cell-free DNA in all maternal capillary blood samples. Y-chromosome specific sequences were detected in all pregnancies confirmed to have a male fetus. All gender results were in concordance with known fetal sex, without false-positive or false-negative results. The overall diagnostic accuracy was 100%, and provided 100% sensitivity and specificity. This new method for prenatal diagnosis of fetal gender from maternal capillary blood is simple, accurate, and reliable. The results of this study demonstrate that fetal DNA detection using maternal capillary blood is highly feasible and easily adaptable for population screening. This method simplifies collection of maternal blood and should increase the accessibility of NIPT.

Capturing phenotype data and standardising recruitment for rare diseases in the Genomics England 100,000 genome project. *A. D. Devereau[1,2], M. Ryten[1,3,4], E. Thomas[1,3], C. Turnbull[1,5], A. Milward[1], T. Fowler[1,6], M. J. Caulfield[1,7].* 1) Genomics England, Queen Mary University of London, Dawson Hall, Charterhouse Square, London, EC1M 6BQ, UK; 2) Manchester Centre for Genomic Medicine, 6th Floor, St Mary's Hospital, Oxford Road, Manchester, M13 9WL, UK; 3) Department of Medical & Molecular Genetics, King's College London, Guy's Hospital, London, UK; 4) Reta Lila Weston Research Laboratories, Department of Molecular Neuroscience, University College London (UCL) Institute of Neurology, London, UK; 5) Section of Cancer Genetics, Institute of Cancer Research, Sutton, UK; 6) UK Public Health, Epidemiology and Biostatistics, University of Birmingham, Edgbaston, Birmingham B15 2TT, UK; 7) William Harvey Research Institute and NIHR Biomedical Research Unit in Cardiovascular Disease at Barts, Queen Mary University of London, London, UK.

The Genomics England 100,000 genomes project will recruit and whole genome sequence (WGS) 50,000 English National Health Service (NHS) patients within its Rare Diseases Programme. It aims to transform diagnostic services and improve the understanding of rare human diseases. The reliable identification of genuine disease-associated genetic variants from the broader background of variants present in all human genomes is challenging. Successful implementation of WGS therefore depends on the selection of patients with a high probability of having a disease with an underlying monogenic cause. Equally, detailed and standardised phenotypic description of each patient is essential for the successful analysis of their genomic data. Therefore the implementation of the Rare Diseases Programme has required the development of clear guidelines regarding patient recruitment and detailed models for the collection of phenotypic information. Given the complexity of rare diseases (over 120 are included within the Programme) it has been necessary to provide guidance in a disease-specific manner. This has been achieved through the creation of disease-specific eligibility statements and phenotypic capture models. The eligibility statements provide clear inclusion and exclusion criteria and specify prior testing that should have been completed before recruitment. The data models encompass qualitative phenotypic description using the Human Phenotype Ontology (HPO) and capture of quantitative clinical and laboratory tests. These models have been built within an online catalogue which enables generation of disease-specific data collection forms within recruitment centers, generation of XML data models for data upload, and version control of the complex modelling process. We report on our experiences of developing these resources and of secure data within existing standards. We also report on the value of the process in itself as a means of defining best practice in the assessment and diagnosis of rare diseases, and clarifying relationships between independent diseases, as evidenced by the frequent re-use of models. The creation and publication of these resources will be one of the legacies of the Genomics England programme.

2048T

HLA variant identification techniques in African Populations. *M. O. Pollard[1], S. Peacock[3], N. Park[2], C. Pomila[1], D. Gurdasani[1], M. Quail[2], M. S. Sandhu[1].* 1) Genetic Epidemiology Group, Wellcome Trust Sanger Institute, Cambridge, United Kingdom; 2) Sequencing R&D, Wellcome Trust Sanger Institute, Cambridge, United Kingdom; 3) Histocompatibility and Immunogenetics Laboratory, Cambridge University Teaching Hospitals NHS Foundation Trust, Addenbrooke's Hospital, Hills Road, Cambridge, CB2 0QQ, UK.

The Human Leukocyte Antigen (HLA) genes located on chromosome 6 are responsible for regulating immune function via antigen presentation and are one of the determining factors for stem cell and organ transplantation compatibility. Additionally various alleles within this region have been implicated in autoimmune disorders, cancer, vaccine response and both non-infectious and infectious disease risk. The HLA region is highly variable; containing repetitive regions; and co-dominantly expressed genes. This complicates short read mapping and means that assessing the effect of variation within a gene requires full phase information to resolve haplotypes.

One solution to the problem of HLA identification is the use of statistical inference to suggest the most likely diploid alleles given the genotypes observed. The assumption of this approach is the availability of an extensive reference panel. Whilst there exists good population genetics data for imputing European populations, there remains a paucity of information about variation in African populations. Filling this gap is one of the aims of the Genome Diversity in Africa Project and as a first step we are performing a pilot study to identify the optimal method for determining HLA type information for large numbers of samples from African populations.

To that end we have obtained samples from 125 consented African participants selected from 5 populations across Africa (Morrocan, Ashanti, Igbo, Kalenjin, and Zulu). The methods included in our pilot study are Sanger sequencing (ABI), NGS on HiSeqX Ten platform (Illumina); long-range PCR combined with single molecule real-time (SMRT) sequencing (PacBio); and for a subset of samples library preparation on GemCode Platform (10x Genomics), which delivers valuable long range contextual information, combined with Illumina NGS sequencing.

Results from capillary sequencing suggests the presence of a minimumof twonovel alleles. Long Range PCR have been performed initially on a subset of samples using both primers sourced from GenDX and designed as described in Shiina et al (2012). Initial results from both primer sets were promising on Promega DNA test samples but only the GenDX primers proved effective on the African samples, producing consistently PCR products of the expected size in the Igbo, Ashanti, Morrocan and Zulu samples. We will present early results from our evaluation of the different sequencing technologies.

2049F

Impact of reasonable genetic testing in prevention of rare genetic disorders. *F. Hashemi-Gorji[1], V. R. Yassaee[1,2], A. Khojasteh[3], P. Toossi[4], Z. Ravesh[1].* 1) Genomic Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2) Dept. of Medical Genetics, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 3) Dept. of Oral and Maxillofacial Surgery, Dental School, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 4) Dept. of Dermatology, Skin Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Mandibuloacral dysplasia with type A lipodystrophy (MADA) is a rare genetic disorder inherited in an autosomal recessive fashion characterized by hypoplasia of the mandible and clavicles, acro-osteolysis and lipodystrophy due to mutations in the *LMNA* or *ZMPSTE24* genes. In the current study, we have investigated a consanguineous family clinically diagnosed with Mandibuloacral Dysplasia type A having an affected child for the *LMNA* gene alteration(s). Mother is now pregnant (12 weeks), seeking an advice for the fetus condition, ensuring to have a healthy baby. Peripheral blood was obtained from all family members after informed consent was achieved. Genomic DNA was isolated. The sequence of the *LMNA* gene, including all exons and exon-intron boundaries were analyzed by PCR and Sanger sequencing. Molecular analysis ascertained a homozygous mutation c. 1620G>A (p. M540I) in the affected child and heterozygous alteration in the rest of the family. Genomic DNA was isolated from CVS sample received, amplified using specific primers for identified deleterious mutation and analyzed by Sanger sequencing. Two pathogenic mutations c. 1620G>A and c. 1698C>T was identified in the fetus in heterozygous state. Genetic counseling as well as justified rapid and sensitive genetic testing can provide reassurance for the families to prevent the high burden of genetic disorders.

2050W

Application of Serum miRNA Signature for Minimization of Immunosuppression and Diagnosis ofRejection Following Liver Transplantation. *B. Keating[1], B. Chang[1], T. Guettouche[2], S. Asare[3], D. Phippard[3], M. DesMarais[4], A. Shaked[1].* 1) University of Pennsylvania, Philadelphia, PA; 2) Children's Hospital of Phialdelphia, PA; 3) Immune Tolerance Network, San Francisco, United States; 4) UCSF, San Francisco, CA.

Over 14,000 liver transplants are performed worldwide yearly. Even with advances in graft management, and immunosuppression therapy (IST), rates of acute cellular rejection (ACR) remain significant, and co-morbidities from ISTs such as nephrotoxicity and liver damage are still major clinical issues. The ability to sub clinically identify liver graft recipients on ACR trajectories, and those that can successfully withdraw from IST using minimally invasive, robust, reproducible biomarkers with high specificity and sensitivity would represent a major advancement in personalized patient care. We performed miRNA profiling of 752 transcripts on 318 serum samples from 90 liver recipients transplanted from the NIH Immune Tolerance Network immunosuppression withdrawal-030 and the NIH Clinical Trials in Transplantation03 studies. 48 recipients were randomized to supervised withdrawal of IST, prior to a clinically indicated biopsy event, and were analyzed for prediction of rejection and to identify those who may tolerate lower IST. Results: Serum miRNA profiles at time of biopsy from 104 samples with and without biopsy proven ACR were compared in a two-stage study. 15 miRNAs were observed to be significantly associated with ACR diagnosis after multiple testing corrections (FDR-adjusted p-value < 0. 05). A logistic regression model consisting of a 3 miRNA panel was identified that could differentiate ACR from non-ACR with an AUC of 0. 90 (95%CI=0. 84-0. 95), 92. 6% sensitivity & 84. 2% specificity [p=0. 0001]). This 3 miRNA ACR signature was tested in an independent validation set (sera from 19 ACR & 16 non-ACR patients), confirming the performance of the model to differentiate ACR vs non-ACR (AUC of 0. 89 [95%CI: 0. 83 - 0. 94], 84% sensitivity & 75% specificity, p = 0. 01). Statistically significant alterations in this three miRNA ACR panel preceded the rejection event by up to 40 days. The composite score of another distinct 3 miRNA panel early after initiation of IST minimization (at 75% pre-withdrawal dose) identified recipients able to withstand significant IST reduction (<25% of pre-withdrawal dose, AUC=0. 88 [95%CI: 0. 80 - 0. 95], sensitivity=0. 82, specificity=0. 90, p = 0. 02). Conclusion: The findings in these prospective clinical trials demonstrate that two distinct multi-marker miRNAs signatures from sera can be used to: diagnose ACR up to 40 days before the manifestation of clinical symptoms; predict rejection trajectories; and guide personalized minimization of IST.

2051T

A protein glycosylation screen to diagnose rare genetic disorders and unravel disease mechanisms. *M. Davids[1,2], M. Kane[1,2], X. Li[3,4], M. Mohd[3,4], M. He[3,4], W. Gahl[1,2], C. Boerkoel[5].* 1) NIH Undiagnosed Diseases Program, Common Fund, Office of the Director, National Institutes of Health, Bethesda, MD; 2) Office of the Clinical Director, NHGRI, National Institutes of Health, Bethesda, MD; 3) Department of Pathology and Laboratory of Medicine, University of Pennsylvania, Philadelphia, PA; 4) The Michael J Palmieri Metabolic Laboratory, Children's Hospital of Philadelphia, Philadelphia, PA; 5) University of British Columbia, Vancouver, Canada.

The NIH Undiagnosed Diseases Program(UDP) concentrates its efforts on the most puzzling medical cases, focusing on disease discovery and patient diagnosis using both genomic data and basic research. Some UDP patients could have Congenital Disorders of Glycosylation (CDGs), whose phenotypes lack consistent clinical features or biomarkers, and are difficult to diagnose. Therefore, we undertook an agnostic screen of plasma and urine to identify abnormalities of protein glycosylation in UDP patients. Plasma and urine screens were completed for 110 patients, and included profiling of plasma N-linked glycans by MALDI-TOF, plasma O-linked glycans by LC-MS/MS and MALDI-TOF, and urine free oligosaccharides by MALDI-TOF/TOF. Over 75% of UDP patients had a glycosylation profile that deviated from a healthy control population in at least one specimen. Additional evaluation of the N-linked and O-linked glycosylation profiles in primary dermal fibroblasts of 56 patients with glycome abnormalities resulted in a tractable glycome phenotype in ~50% of these cases. Using this approach, we identified different CDGs, lysosomal storage disorders (affecting glycoprotein degradation), and rare disorders in which glycosylation is affected indirectly. We also added abnormal glycosylation findings to the phenotypical spectrum of a known rare disease, shedding light on a potential factor of the underlying pathogenic mechanism. In summary, we described a comprehensive screening approach to identify primary protein glycosylation abnormalities and provide a useful tool for biochemically phenotyping patients with unknown diseases and unraveling the underlying mechanisms of diseases.

2052F

Identification of *SPINK* 5 mutations in consanguineous families confirms the diagnosis of Netherton syndrome. *A. Mirzaei[1], L. Youssefian[1,2], H. Vahidnezhad[1,2,3], S. Raftari[1], S. Sotoudeh[2], Q. Li[1], J. Uitto[1].* 1) Thomas Jefferson University, Philadelphia, PA; 2) Tehran University of Medical Sciences, Tehran, Iran; 3) Pasteur Institute of Iran, Tehran, Iran.

Netherton syndrome (MIM 256500) is a rare autosomal recessive genetic disease characterized by ichthyosiform erythroderma, ichthyosis linearis circumflexa, hair shaft abnormality ["bamboo hair"], atopy and increased risk of recurrent infections. This disease is caused by *SPINK5* gene mutations that lead to absent or decreased expression of the lymphoepithelial Kazal-type-related protease inhibitor (LEKTI) protein in all stratified epithelia. In this study, we have examined 3 patients from consanguineous families diagnosed by characteristic clinical features. Our patients were 2, 4 and 31 year old females who showed generalized skin lesions since birth. Microscopic analysis of the hair shaft revealed in all of our patients typical "bamboo hairs"of trichorrhexis invaginata. Mutation analysis by sequencing of all 34 exons of *SPINK5* in these patients revealed homozygous recurrent loss-of-function mutations, consisting of a nonsense mutation or a nucleotide insertion resulting in frameshift of translation: previously published g. 31358dupT (an insertion of T in exon 9) in one family, and recurrent c. 2368C>T (Arg790Ter) in exon25 in two families. Identification of these mutations in *SPINK5* confirms the clinical diagnosis of Netherton Syndrome and forms the basis for genetic counseling, prenatal testing and preimplantation genetic diagnosis.

2053W

The spectrum of pathogenic and likely pathogenic variants observed in individuals with melanoma undergoing inherited cancer testing. *D. Farengo-Clark, S. Hiraki, M. Marshall, L. Susswein, K. Hruska, R. T. Klein.* GeneDx, Gaithersburg, MD.

About 5-10% of malignant melanoma cases (MM) occur in familial clusters, and pathogenic and likely pathogenic variants (PV/LPV) in *CDKN2A* are identified in 35-40% of familial cases. PV in *CDKN2A* increase the risk of pancreatic (PC), breast, and brain cancer. Other MM susceptibility genes including *CDK4, PTEN, BRCA2* and *BAP1* have been reported. The aim of this study was to identify the spectrum of PV/LPV observed in individuals with a personal and/or family history of MM, multiple primary MM and/or PC. The clinical histories of all individuals reporting a personal history of MM who underwent multi-gene panel testing (not including *BAP1*), *CDKN2A*/*CDK4* or *BRCA1/2* sequencing and deletion duplication analysis at GeneDx were reviewed. Two-tailed Fisher's exact test was used to determine statistical significance. A total of 301individuals reported a personal history of MM, 9% (27/301) of whom were found to harbor a PV/LPV in one of the genes tested. PV/LPV were identified in *CHEK2* (7), *ATM* (6), *BRCA2* (4), *BRCA1* (2), *FANCC* (2), and one each in *CDKN2A, PMS2, PTEN, RAD51C, RAD51D* and *VHL*. Nine of 301(3%) individuals reported >3 primary MM, 3 of whom were found to carry a PV/LPV (*CHEK2, CDKN2A* and *BRCA2*). The presence of >3 MM was significantly associated with carrying a PV/LPV compared to those with <3 MM (p=0. 037). Seventy-seven patients (25%) reported a family history of MM, 7 of whom (9. 1%) carried a PV/LPV (ATM (3), CHEK2, CDKN2A, FANCC and PTEN). This yield was not significantly different from those without a family history of MM (p=0. 25). Nine individuals had a diagnosis of both MM and PC and 22% (2/9) carried a PV/LPV (ATM, VHL). The only carrier of a *CDKN2A* PV was diagnosed with three MM before age 40 and had a family history of both MM and PC. While familial MM is associated with PV in *CDKN2A*, we found that 81% of PV/LPV identified in patients with MM were in other genes, including a large proportion in *CHEK2* (26%) and *ATM* (22%). As MM is a multi-factorial disease, it will be important to further investigate whether these genes contribute to MM risk and the level of that risk. The overall frequency of PV/LPV was significantly higher in individuals with >3 primary MM and was not associated with a family history of MM. PV/LPV in CDKN2A were identified in a small fraction of patients with MM or familial MM, suggesting that other factors may account for the majority of MM.

2054T

Identification of pathogenic/likely pathogenic variants in individuals reporting a personal history of both breast and colorectal cancer. *M. Marshall, M. Roberts, L. Yackowski, S. Solomon, D. Farengo-Clark, Z. Xu, R. T. Klein, K. Hruska.* GeneDx, Gaithersburg, MD.

Breast (BC) and colorectal (CRC) cancers are both individually common in the general population, but knowledge about a single gene predisposing an individual to an increased risk for both cancers is limited. The focus of this analysis was to determine the yield of pathogenic/likely pathogenic variants (PV/LPV), in any gene offered as part of a multi-gene cancer panel, in individuals with a personal history of both BC and CRC. We searched our Inherited Cancer panel tests performed at GeneDx through February 2015 for individuals reporting a personal history of both BC and CRC. Clinical histories were reviewed to evaluate which patients met the National Comprehensive Cancer Network (NCCN) Hereditary Breast and Ovarian Cancer (HBOC) genetic testing criteria, Amsterdam II Criteria (ACII), and Bethesda Guidelines (BG). Two-tailed Fisher's exact test was used to determine statistical significance compared to those reporting a personal history of only BC or CRC. A total of 176 individuals with a personal history of both BC and CRC were identified; 23 PV/LPV were identified in 21 individuals (*ATM* (1), *BRCA1* (4), *CHEK2* (7)*, MLH1* (2)*, MSH2* (1)*, MSH6* (5), *PALB2* (1), *PMS2* (1), and *PTEN* (1)). *CHEK2* PV/LPV were observed in 5. 0% (7/139) of individuals undergoing testing with a panel that included this gene. This rate is higher than that observed in individuals reporting a personal history of BC (2. 7%, 218/8168, p =0. 10) or CRC (2. 0%, 20/991, p = <0. 05) alone. Of the 17 individuals for whom sufficient clinical information was available, 54. 7% (11/17) met NCCN HBOC criteria, 11. 8% (2/17) met ACII, 54. 7% (11/17) met BG, and 41. 2% (7/17) met both BG and NCCN HBOC criteria. If only BRCA testing was performed for those meeting NCCN HBOC criteria, 11/12 mutations would have been missed. Forty-six% (5/11) of mutations would have been missed if those meeting BG were only tested for Lynch syndrome-associated genes**.** PV/LPV were most common in *CHEK2* and were observed more frequently in individuals reporting both cancers as compared to those reporting a history of only one. Not only would the majority of these PV/LPV have been missed with single syndrome testing, but PV/LPV were predominantly identified in a gene associated with a lifetime risk for breast cancer satisfying the American Cancer Society recommendation for annual breast MRI, thus changing medical management recommendations based on the genetic test results and making an argument for multi-gene panels.

2055F

Massive analysis of cancer genes in high cancer risk patients by next generation sequencing. *J. Puig-Butille[1,3,4], L. Jimenez[1], P. Jimenez[3,4], M. Potrony[2,3], J. Malvehy[2,3,4], C. Introduction: Several germline alterations increase the susceptiblity to a wide spectrum of malignances, such as mutations in *CHEK2, STK11, MUTYH, BRCA1/2* or *CDKN2A* gene. Thus, in cancer patients with family history of different neoplasias the study of cancer related genes by a "naive" approach could be useful to identify high or medium penetrance cancer risk alleles. Aim of the study: To asses the utility to molecular screening of a cancer related gene panel in families with a wide range of neoplasias. Methods: The study includes 12 patients carrying high-penetrant mutations previously identifed (Validation Set) and 19 wild-type *CDKN2A* familial melanoma or multiple primary melanoma patients (MPM) (Analyses Set) from 19 families with affected individuals by other neoplasias (1st or 2nd relatives). Analyses was conducted using the TruSight Sequencing Cancer Panel Kit (Illumina, USA) and sequencing the library in a MySeq platfform (Illumina, USA). Raw sequecing data was analyzed by an standard pipeline using the DNAnexus cloud-based data analysis and management platform (https://www. dnanexus. com). Variants were filtering based on quality values and effect (synomimous variants and those non-synonimous variants predicted as bening by both SIFT and PolyPhen-2 tools were removed), and were classified into a five-tiered system based on multiple databases. Results: All mutations in patients from Validation Set were detected (mutations were located in BRCA1/2, XPC, MSH2, MLH1, APC, CDKN2A or MITF gene). Overall, 319 variants were detected among the high risk melanoma patients: 277 were classifed as benign/likely benign, 34 as variant of uncertain singificance (VUS) and 8 as pathogenic/likely pathogenic variant. A pathogenic variant was detected in 21% (4/19) of patients, likely pathogenic in 15,8% (3/19) and VUS in 31,5% (6/19). Pathogenic mutations were detected in BRCA1 (p. Lys654SerfsTer47), MUTYH (p. Gly396Asp, p. Asn335ThrfsTer) and ERCC3 (p. Gln586ArgfsTer25). Conclusion: In cancer patients reporting a familial history of a broad spectrum of malignances, a massive analysis of cancer related genes is a useful approach to detect high/medium penetrant mutations. However, co-segregation anaylses in the other cancer affected relatives within the family should be performed to clarify the role of these variants.

2056W

Association between single nucleotide polymorphism of BMP5 gene and risk of knee osteoarthritis. *RN. Srivastava[1], AC. Sharma[1], A. Mishra[1], SR. Srivastava[1], K. Baghel[1], S. Raj[2].* 1) Orthopaedic Surgery, King George's Medical University, Lucknow, Uttar Pradesh, India; 2) M S Ramaiah Medical College, Bangalore.

Introduction: Osteoarthritis (OA) is a chronic degenerative disorder of multifactorial etiology characterized by loss of articular cartilage, hypertrophy of bone at the margins, subchondral sclerosis and range of biochemical and morphological alterations of the synovial membrane and joint capsule. OA is probably affected by both genetics and environmental causes. Bone morphogenetic proteins (BMPs) are bone-derived factors that can induce new bone formation. Previous study identified few single nucleotide polymorphisms SNP's that altered transcriptional activity of the BMP5 promoter, which implies that polymorphism of BMP5 gene is involved in OA susceptibility. In this study, we investigated the possible correlation between the SNPs rs1470527 and rs9382564 in BMP5 gene and susceptibility to knee OA. **Material & Methods:** : This study was conducted in the department of Orthopaedic Surgery, King George's Medical University (KGMU), Lucknow. In this study cases consisted of men and women ≥40 years that fulfilled American College of Rheumatology (ACR) clinical and radiographic criteria for knee OA. Venous blood samples were obtained from all cases as well as controls for genetic analysis. Polymerase chain reactions were performed for SNP analysis using sequenced specific primer. **Results:** A total of 499 cases that confirmed radiographic knee OA and 458 age and sex matched healthy controls were enrolled. There was no significant difference in demographic characteristics between the cases and controls. The genotype distribution for rs1470527 and rs9382564 SNP was significantly different between the cases and controls ($p<0.0001$). Within both the SNPs of BMP5 gene, genotype CT and TT was found to be significantly ($p<0.0001$) associated with knee OA as compared with the CC genotype. In addition when alleles were compared, T allele of both the studied SNP was observed to be significantly associated with knee OA ($p<0.0001$). Further in relation with clinical symptom of OA, we observed signification association of TT genotype with both visual analogue scale (VAS) ($p<0.0001$) and WOMAC (Western Ontario and McMaster Universities) score ($p<0.05$). **Conclusion:** Our results indicate significant association of rs1470527 and rs9382564 polymorphisms of BMP5 with knee OA. If these data are supported and confirmed, it has major implications for the pathogenesis of OA and for identifying patients at risk for developing knee OA.

2057T

Are signs of obesity and hyperphagia still relevant for the clinical suspicion of Prader-Willi Syndrome? Evidence from a novel quantitative clinical diagnostic model. *L. Cordeiro[1], C. Rocha[2], C. Paiva[3].* 1) School of Medicine and Surgery, Federal University of Rio de Janeiro State, Rio de Janeiro, Brazil; 2) Neurology Graduate Program, Federal University of Rio de Janeiro State, Rio de Janeiro, Brazil; 3) Genetics and Molecular Biology Dept, Federal University of Rio de Janeiro State, Rio de Janeiro, Brazil.

Prader-Willi Syndrome (PWS) is a rare genetic disorder that results from the lack of paternal expression of the 15q11–q13 region. The definitive diagnosis is made by molecular testing, access to which may be limited by cost or geographical constraints. Though clinical diagnostic and screening criteria have been proposed, they were based on consensus of specialists without statistical validation. There are no clinical criteria developed with quantitative or statistical methods. This study bridges this gap by developing a clinical diagnostic/screening model for PWS with data mining and machine learning techniques. Evolutionary algorithms are a distinct class of optimization algorithms that try and mimic biological phenomena. They are typically employed when traditional methods fail, due to their ability of handling complex problems. We assessed the performance of several evolutionary algorithms in the maximization of the AUC of the ROC curve of a combination of 18 clinical signs and symptoms commonly observed in PWS patients. The modelscan be easily implemented in a mobile application, allowing them to be used by clinicians in the ambulatory setting. Our sample consisted of patients from the genetics clinic of a university hospital in Rio de Janeiro with clinical suspicion of PWS. All participants underwent proper molecular testing as per current ASHG guidelines. Confidence intervals for the AUC's were estimated by bootstrapping. The classification performance of all models derived from the evolutionary algorithms was statistically superior to the one from the current clinical model for PWS. The clinical diagnostic model achieved sensitivity of 87% and specificity of 93%, while our screening model reached 100% sensitivity with 71% specificity. Based on these results, we identified six clinical signs and symptoms – hypotonia, poor sucking, hypogonadism, global developmental delay, behavioral problems and typical facies – that seem to be key to the accurate clinical suspicion of PWS. Moreover, two major clinical signs and symptoms that were previously deemed important in the clinical diagnosis of PWS – rapid weight gain and hyperphagia – were not relevant in our models. Since PWS is frequently associated with childhood obesity, our results suggest that the increasing incidence of obesity in the pediatric population may be incorrectly inducing the suspicion of PWS.

2058F

Exon targeted array CGH for identification of clinically relevant small sized, intragenic CNVs. *A. Patel[1], T. Gambin[1], P. Liu[1], W. Bi[1], A. Breman[1], J. Smith[1], S. Lalani[1,2,3], C. Bacino[1,2,3], A. L. Beaudet[1,2,3], J. R. Lupski[1,2,3], C. A. Shaw[1], S. W. Cheung[1], P. Stankiewicz[1].* 1) Dept Molecular & Human Gen, Baylor Col Medicine, Houston, TX; 2) Dept. of Pediatrics, Baylor College of Medicine, Houston, TX; 3) Texas Children's Hospital, Houston, TX.

Copy-number variants (CNVs) smaller than 400 kb in size are often challenging for clinical interpretation and are usually not reported in routine chromosomal microarray analysis (CMA). Currently, CNVs involving single exons remain also beyond the detection limits of whole exome sequencing (WES). In 2008, we designed and clinically implemented array CGH with exonic coverage of over 1,700 disease and candidate genes and demonstrated its efficacy for detection of pathogenic losses or gains of at least one exon as small as a few hundred base pairs in size. Recently, we have expanded our custom-designed oligo array to include greater than 4800 genes with exon coverage and 60K SNP oligos to detect regions of AOH. Weanalyzed with single exon resolution the personal genomes of39,170 patients referred for CMA. To date, we have identified non-polymorphic CNVs in 17,367 (44%) subjects, 3,522 (9. 0%) of which were interpreted as abnormal. Among CNVs involving only a single gene reported in 5,861 patients (15%), we found 132 *de novo* (91 losses and 41 gains) and 1338 inherited (764 losses and 574 gains) events. In addition to 65 known disease genes (40 AD, 10 AR, and 15 X-linked), we have identified 36 non disease associated genes disrupted by 21 *de novo* single gene deletions or encompassed in 16 *de novo* single gene duplications. The most commonly affected single genes include *CHRNA7* (13 dels/277 dups), *IMMP2L* (135 dels/1 dup), *TMLHE* (118 dels/16 dups), *RBFOX1* (53 dels/54 dups), *DMD* (68 dels/31 dups), and *NRXN1* (79 dels/10 dups). By extending this analysis to CNVs harboring 5 or less genes, we identified *de novo* deletions affecting 335 distinct genes. Comparison with 137 autism genes from the SFARI database (categories S, 1, 2, and 3) revealed 59 (43%) genes disrupted by 537 single gene deletions. Out of 141 epilepsy related genes, we detected 26 (18%) genes interrupted by 85 single gene deletions. Additionally, our exon targeted array enabled detection of several pathogenic heterozygous and homozygous single exon CNVs missed in WES analyses. In aggregate, our data further demonstrateutility of an exon-targeted oligo array CGH for detection of small sized CNV, complementing WES in clinical diagnostics, as well as its potential for identification of novel diseasegenes.

2059W

Deficiency of Interleukin-1 Receptor Antagonist (DIRA): Report of the First Indian Patient and a Novel Deletion Affecting *IL1RN*. *A. Almeida de Jesus[1], L. Malle[1], L. Oliveira Mendonca[2], F. X. Donovan[3], S. C. Chandrasekharappa[3], G. Montealegre[1], D. Chapelle[1], D. Suri[4], R. Goldbach-Mansky[1].* 1) Translational Autoinflammatory Diseases Section, NIAMS, NIH, Bethesda, MD; 2) Hospital das Clínicas da Faculdade de Medicina da Universidade de Sao Paulo (HC-FMUSP), Sao Paulo, Brazil; 3) Genomics Core, NHGRI, NIH, Bethesda, MD; 4) Department of Pediatrics, Advanced Pediatric PGIMER, Chandigarh, India.

Statement of Purpose. Deficiency of interleukin-1-receptor antagonist (DIRA) is a rare autoinflammatory disease clinically characterized by early-onset generalized pustulosis, multifocal osteomyelitis and elevation of acute-phase reactants. DIRA is caused by autosomal recessive loss-of-function mutations in *IL1RN.* Seven DIRA causing mutations have been described. We report herein a novel disease-causing deletion affecting *IL1RN* gene and a PCR assay for the screening of Indian patients with a clinical suspicion of DIRA. *Methods.* Peripheral blood genomic DNA was obtained and patient was genotyped for the detection of copy number variations (CNVs) by a SNP array technique using the HumanOmniExpressExome-8v1. 2_A Illumina BeadChip, containing 964,193 SNPs. The detected aberrations were visually evaluated using Nexus Copy Number v7. 5. Primers flanking the deletion ends were designed using Primer3Plus and the breakpoint area was amplified by PCR and sequenced by Sanger technique. *Results.* **Clinical description:** A 5 month-old Indian girl, born to healthy non-consanguineous parents presented with pain on manipulation and irritability at the 3rd week of life and developed a mild pustular rash. Bone scintigraphy suggested osteomyelitis of multiple bones, and cultures from bone biopsy material were negative. Due to a clinical suspicion of DIRA, the patient was enrolled into a NIH protocol and started on recombinant interleukin-1 receptor antagonist (anakinra). Anakinra initiation resulted in marked and sustained clinical and laboratory improvement. **Genetic analysis:** SNP array analysis of patient's genomic DNA showed loss-of-heterozygosity for all SNPs in a region of approximately 21. 4 to 23. 7kb, indicating a homozygous deletion. PCR and sequencing of the breakpoint area allowed us to identify the breakpoints of the deletion, at chr2_hg19_113,865,011 and chr2_hg19_113,887,227, confirming a homozygous 22,216bp deletion that spans the first four exons of *IL1RN* (NM_173843. 2). This deletion has not been previously reported in patients with DIRA. Using a multiplex PCR with primers for wildtype *IL1RN*, the deletion breakpoint, and *GAPDH*, we confirmed that patient's parents are both heterozygous for this deletion. *Conclusion.* We describe the first Indian patient with DIRA and a novel homozygous 22Kb deletion spanning 2 coding exons of *IL1RN*. The primers designed to detect the novel deletion will be useful to screen Indian patients with a clinical suspicion of DIRA.

How to translate next generation sequencing (NGS) from research to clinical practice? *G. Barcia[1,2], S. Hanein[2], V. Morinière[1], C. Fourrage[1,2], C. Bole[2], P. Nitschke[2], G. Royer[1], Z. Assouline[1], I. Perrault[2], A. Elmorjani[2], R. Gesny[1], C. Haudry[1], M. Henry[1], S. Dos Santos[1], M. Bernardelli[1], S. Poisson[1], M. Rio[1,2], T. Attié-Bitach[1,2], C. Antignac[1,2], S. Saunier[2], V. Cormier-Daire[2], S. Rondeau[1,2], S. Monnot[1,2], J. Steffann[1,2], A. Rotig[1,2], L. Colleaux[1,2], JM. Rozet[1,2], S. Lyonnet[1,2], JP. Bonnefont[1,2], A. Munnich[1,2].* 1) Genetics Department, Necker Hospital, Paris, France, France; 2) Imagine Institute for Genetic Diseases, Paris, France.

Purpose: Whole exome and genome sequencing (WES, WGS) are powerful approaches to decipher the genetic bases of inherited genetic disorders, but they remains costly and time consuming, and are a source of uncertain and incidental findings. For these reasons WES/WGS are less relevant in the frame of diagnostic setting and genetic counselling. The *Imagine* Institute for Genetic Diseases and the Genetics Unit of the Necker Hospital, joined forced to translate a custom targeted next generation sequencing (TNGS) strategy into routine clinical practice. **Methods:** For each core disorder, custom TNGS panels were designed including genes i) whose mutations have already been associated to human diseases in at least2 patients, ii) belonging to cellular pathways specific for the studied disease. **Results:** So far 18 custom TNGS panels have been developed, dedicated to molecular diagnosis of ciliopathies (n=1221 genes, diagnostic yield: 63%), Leber congenital amaurosis (n=55; 57%), intellectual disability (n=253, 23%), mitochondrial diseases (n=215, 40%), Alport syndrome (n=3, 84%), chondrodysplasia and growth delay (n=70, 50%), osteogenesis imperfecta (n=20, 60%), genetic deafness (n=35, 15%), Cornelia de Lange syndrome (n=5, 40%), focal glomerular sclerosis (n=33, 15%), polycystic kidney (n=2, 50%), neural crest disorders (n=66), childhood epilepsy (n=151), cerebellar malformations and microcephaly (n=55), skin diseases (n=90), corpus callosum defects (n=423), Hirshprung disease (n=15), cortical brain malformations (n=55). An overall diagnostic yield (definitely- or likely-pathogenic variants) of 50% was achieved (range:15-85%). Owing to high horizontal and vertical coverage (depth coverage at 30X>99%), this NGS strategy enabled the detection of several disease-causing variants that initially escaped WES. No significant incidental finding was identified. Exonic copy-number analysis using TNGS data was validated. **Conclusions:** TNGS is a robust strategy for the first-step screening of genetic disorders in a diagnostic setting since it speeds up molecular diagnosis avoiding incidental findings and at a lower cost as compared to WES. A dynamic and reciprocal interaction between physicians and molecular biologists is necessary to develop TNGS panel, to select patients to screen, to interpret TNGS data and to draw genotype-phenotype correlations. TNGS offers a rational selection of patients available for the identification of novel genes by WES/WGS in the research setting.

2061F

Secondary Finding Preferences in Whole Genome Sequencing: experiences with a large developmental delay cohort. *K. East[1], K. Brothers[2], K. Bowling[1], M. Bebin[3,4], E. Lose[3,4], S. Simmons[3,4], W. Kelley[1], G. Barsh[1], R. Myers[1], G. Cooper[1].* 1) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 2) University of Louisville, Louisville, KY; 3) University of Alabama at Birmingham, Birmingham, AL; 4) North Alabama Childrens Specialists, Huntsville, AL.

Developmental delay, intellectual disability, and related congenital defects (DD/ID) affect 1-2% of children born and have a large impact on affected individuals and their families. Though many cases are attributed to an underlying genetic cause, identification of the specific variation often proves elusive. As part of the Clinical Sequencing Exploratory Research Consortium, we are conducting whole exome/genome sequencing in 450 affected probands and their parents to establish a genetic diagnosis for DD/ID and better understand the utility and impact of large scale sequencing in a pediatric neurology clinic. To date, we have enrolled 210 families, and have completed sequencing and analysis for 123. We have successfully identified DD/ID pathogenic or likely pathogenic variants in approximately 25% of our probands and have identified potentially pathogenic secondary findings in approximately 10% of parent participants. Participants are randomized to provide preferences for secondary finding disclosure either at time of study enrollment or at result return. Preferences are gathered through a novel instrument developed to illicit preferences on the types of risk information an individual would like to receive with categories defined by disease type (diabetes, cancer, alzheimer's disease). When pathogenic variants are identified, these preferences are used to determine whether a result is returned. Analysis of preferences solicited to date show that the overwhelming majority (>80%) of parents in this study elect to receive all types of secondary findings. However a minority of parents elects not to receive one or more categories of results. The categories declined vary with the most common category declined being risk of developing obesity. Reasons for decline include a lack of interest, perception of low risk status, or anxiety surrounding a specific category or type of disease. Reported secondary findings to date include genetic variation leading to an increased risk for malignant hyperthermia, cancer, and heart disease as well as carrier status for select recessive diseases.

ClinGen Actionability Working Group: Clinical Actionability in the context of Secondary Findings in Adults and Application to the ACMG 56. *J. E. Hunter[1], L. G. Biesecker[2], A. H. Buchanan[3], S. A. Irving[1], K. Lee[4], C. L. Martin[5], L. Milko[4], A. Niehaus[6], R. Nussbaum[7], J. O'Daniel[4], M. A. Piper[1], E. M. Ramos[6], S. Schully[8], A. F. Scott[9], A. Slavotinek[10], A. Sobreira[9], N. T. Strande[4], M. Weaver[11], E. M. Webber[1], M. S. Williams[3], J. S. Berg[4], J. P. Evans[4], K. A. B. Goddard[1], ClinGen Resource.* 1) Center for Health Research, Kaiser Permanente Northwest, Portland, Oregon; 2) Genetic Disease Research Branch, National Human Genome Research Institute (NHGRI), National Institutes of Health, Bethesda, Maryland; 3) Genomic Medicine Institute, Geisinger Health System, Danville, Pennsylvania; 4) Department of Genetics, University of North Carolina, Chapel Hill, North Carolina; 5) Autism & Developmental Medicine Institute, Geisinger Health System, Danville, Pennsylvania; 6) Division of Genomic Medicine, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland; 7) Department of Medicine and Division of Medical Genetics, University of California, San Francisco, California; 8) Epidemiology and Genomics Research Program, National Cancer Institute, National Institutes of Health, Bethesda, Maryland; 9) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland; 10) Department of Pediatrics, University of California, San Francisco, California; 11) American College of Medical Genetics and Genomics, Bethesda, Maryland.

Genome-scale sequencing provides the opportunity to discover "secondary findings", or variants unrelated to the primary indication for sequencing. Identification of pathogenic variants associated with an increased risk of a significant but preventable medical outcome allows the opportunity to intervene and potentially mitigate or prevent future clinical manifestations in patients and their family members. The Clinical Genome Resource (ClinGen) is a consortium working to build an open-access and centralized resource to assess the clinical relevance of genomic variants. The ClinGen Actionability Working Group (AWG) aims to identify genetic disorders with potential for clinical intervention when pathogenic variants are reported as secondary findings in previously undiagnosed adults. The AWG has developed a standardized protocol to identify and synthesize available evidence of clinical actionability for gene-disorder pairs. The AWG appliesa semi-quantitative scoring metric to the available evidenceto assess four domains of clinical actionability: 1) nature of the health threat; 2) likelihood the threat will materialize; 3) effectiveness of the intervention to prevent harm; and 4) nature of the intervention in terms of risk/burden to the individual. To date, the AWG has applied this protocol to the 56 genes and associated disorders recommended by the American College of Medical Genetics and Genomics (ACMG) to return as secondary findings. The clinical actionability scores for the ACMG 56 will be presented, along with relevant case examples illustrating the complexity of applying a standardized framework for evidence synthesis and scoring of actionability. The assessment of secondary findings in adults does not fully encompass the spectrum of actionable information from the human genome. Thus, future directions for the ClinGen AWG may include broadening the methods to address additional clinical scenarios such as variants actionable in childhood, somatic variation, pharmacogenomics applications, ending the diagnostic odyssey, and reproductive decision making. The ClinGen AWG framework will provide a structure to enable the research and clinical communities to make clear, streamlined, and consistent determinations of clinical actionability based upon transparent criteria to guide analysis and reporting of genomic variation. *ClinGen is funded by NHGRI, NICHD and NCI: 1U41HG006834-01A1, 1U01HG007437-01, 1U01HG007436-01, HHSN261200800001E.* .

2063T

Implementation of Genetic Sequencing into Clinical Practice: The Personalized Diabetes Medicine Program. *J. W. Kleinberger[1], T. J. Mathias[1], N. Ambulos[1], L. J. B. Jeng[1], D. Sewell[1], T. D. O'Connor[1], K. Tanner[1], C. M. Damcott[1], Y. Mohtasebi[1], K. A. Maloney[1], M. J. Nicholson[1], K. Palmer[1], S. A. Stein[1], K. D. Silver[1], R. B. Horenstein[1], E. A. Streeten[1], A. R. Shuldiner[1,2], T. I. Pollin[1].* 1) School of Medicine, University of Maryland, Baltimore, MD; 2) Regeneron Genetics Center, Regeneron, Tarrytown, NY.

Approximately 1-5% of diabetes mellitus, or at least 300,000 cases in the U. S. , is not polygenic but monogenic, most commonly maturity-onset diabetes of the young (MODY), but also neonatal diabetes mellitus (NDM) and syndromic forms. Monogenic diabetes is often misdiagnosed as type 1 or type 2 diabetes due to factors such as clinical overlap or lack of awareness by providers. Correct diagnosis is crucial because some forms of MODY and NDM are treated effectively with inexpensive oral sulfonylureas rather than insulin injections, while *GCK*-MODY does not usually require pharmacologic treatment. The Personalized Diabetes Medicine Program (PDMP) is a genomic medicine demonstration project funded through the NHGRI IGNITE (Implementing Genomics in Practice) Network to implement and evaluate a sustainable model for screening, diagnosis, and individualized treatment of patients with monogenic diabetes in diverse settings including an academic medical center (University of Maryland Center for Diabetes and Endocrinology), Baltimore Veterans Administration Medical Center, an integrated healthcare system (Geisinger), and a private practice (Bay West Endocrinology). Patients are identified by provider referral and by screening using a simple 7-item questionnaire followed by routine bloodwork and family/medical history collection. Eligible patients undergo next-generation sequencing of exonic/flanking regions of 40 genes. To date, 12 referred patients fulfilling eligibility criteria have undergone sequencing. Individuals carried a mean of 155±26 (SD) variants. Protein-altering variants with <5% population minor allele frequency (mean 3. 8±2. 9 per person) were assessed for pathogenicity using 2015 ACMG standards and guidelines. Pathogenic or likely pathogenic variants, including three mutations in two actionable MODY genes (*HNF1A* and *GCK*), are currently being confirmed through Sanger validation in our CAP/CLIA-certified Translational Genomics Laboratory before returning the results and interpretation to the clinician and patient through the electronic health record to guide diagnosis and therapy. An additional 11 samples (6 referrals and 5 identified by screening 272 patients) are being sequenced. This project, which includes engagement of a payer advisory panel, will generate an evidence base for the value of including an actionable highly penetrant genetic cause in the differential diagnosis that will inform standards of care and be applicable to a variety of diseases.

2064F

The diagnosis of neuronal ceroid lipofuscinosis by next generation sequencing eye and seizure panels. *E. C. Lisi[1], R. Sanchez[1], S. Richards[1], J. J. Alexander[2], L. Bean[2], C. Collins[2], M. J. Gambello[1], S. Shankar[1].* 1) Division of Medical Genetics, Dept of Human Genetics, Emory University, Atlanta, GA; 2) Emory Genetics Laboratory, Atlanta, GA.

Next-generation sequencing has revolutionized the practice of medical genetics. Multi-gene panels have provided diagnoses in patients with non-classical presentations for many disorders who would have otherwise likely gone undiagnosed. We report on a series of patients diagnosed with varying types of Neuronal Ceroid Lipofuscinosis (NCL) by identifying pathogenic variants via the Eye or Seizure Disorders Panels at Emory Genetics Lab. Patient 1 is a 5 year old female with a history of speech delay, apraxia and seizures with onset at 3. 5 years of age. A seizure panel revealed two pathogenic variants in *TPP1* (c. 509-1G>C and c. 1016G>A), and subsequent TPP1 activity in leukocytes was deficient, confirming the diagnosis of NCL2. Ophthalmology evaluation was normal. Patient 2 is a 15 year old female evaluated for a two year history of central vision loss, bilateral cystoid macular edema, and childhood onset seizures. The eye disorders panel identified a deletion encompassing the entire *CLN8* gene as well as a c. 200C>T (p. A67V) variant of uncertain significance (VOUS) in *CLN8*. Electron microscopy of lymphocytes showed inclusion bodies, supporting a diagnosis of late infantile NCL. Her brother, Patient 3, is a 22 year old with retinitis pigmentosa and seizures who was found to have the same genotype. Patient 4 is a 4. 5 year old male (consanguineous parents) with a history of refractory epilepsy, profound DD, global hypotonia, and microcephaly. The seizure panel revealed a homozygous c. 523C>T VOUS in *TPP1*. TPP1 enzyme activity in leukocytes was deficient, confirming the diagnosis of NCL2. NCL is a heterogeneous group of disorders; there are currently 13 disease loci. Given the phenotypic variability of NCL, we suggest that seizure or eye disorders gene panels should be considered for any patient with a combination of progressive vision loss, seizures, and/or regression.

2065W

Genetic Diagnosis for Deafness in a Large Clinical Cohort. *C. M. Sloan-Heggen[1,2], A. O. Bierer[1,], A. E. Shearer[1], H. Azaiez[1], E. A. Black-Ziegelbein[1], K. T. Booth[1], K. L. Frees[1], D. L. Kolbe[1,3], C. J. Nishimura[1,3], R. J. H. Smith[1,2,3,4].* 1) Molecular Otolaryngology & Renal Research Labs, Department of Otolaryngology-Head and Neck Surgery, University of Iowa, Iowa City, IA; 2) Department of Molecular Physiology & Biophysics, University of Iowa, Iowa City, IA; 3) Iowa Institute of Human Genetics, University of Iowa, Iowa City, IA; 4) Interdepartmental PhD Program in Genetics, University of Iowa, Iowa City, IA.

Deafness is the most common sensory deficit in humans, affecting 360 million people worldwide. Historically, the extreme heterogeneity of hereditary hearing loss made genetic diagnosis difficult and time consuming. With the advent of Targeted Genomic Enrichment (TGE) and Massively Parallel Sequencing, comprehensive testing for all hearing loss genes has become the most practical method of genetic diagnosing. However, with the rapidly changing knowledge of non-syndromic hearing loss and its mimics, platform maintenance is essential for sustaining the most comprehensive diagnostic testing available. Since January of 2012 over 1,500 unique probands have been sequenced through our clinical diagnostic services using a custom-designed TGE and analysis pipeline covering all known non-syndromic hearing loss genes and with the ability to cover both single nucleotide and copy number variations for a comprehensive hearing loss diagnosis resulting in an overall diagnostic rate of 40%. Each patient's clinical and genetic results were discussed at an interdisciplinary meeting to produce the most inclusive and integrated diagnosis possible. Evaluating such a cohort of all-comers allows several unique analyses. It shows that diagnostic rate is heavily impacted by inheritance, laterality, age of onset, syndromic features, and ethnicity of the patient. Individuals with bilateral, symmetric hearing loss have an increased diagnostic success of 44%, compared to only 1% of patients with unilateral hearing loss. Autosomal dominant hearing loss can be diagnosed 50% of the time, autosomal recessive—41%, and sporadic—37%. Non-syndromic hearing loss was diagnosed in 42% of cases, compared to 27% of syndromic hearing loss. Individuals of a Middle Eastern ethnicity have a high diagnostic success of 72%, versus only 25% in African Americans. Pre-evaluation of a patient's clinical characteristics can recommend use of such a panel for particular cohorts of individuals and allow for pretest counseling to guide patient expectations. Positive diagnosis can preclude additional unneeded testing which would otherwise be used to rule out additional syndromic features.

2066T

Detection of 3 novel mutations in the *GAA* gene in 3 iranian families with glycogen storage disease type II. *S. Tabei, S. Kohan Mozaffari, M. Fardaei.* Medical Genetics, Shiraz University of Medical Sciences, Shiraz, Fars, Iran.

Introduction: Glycogen storage disease type II or Pompe disease is the first recognized lysosomal storage disorder in which an extreme amount of glycogen accumulates in lysosomes of almost all types of tissues especially skeletal muscle and heart due to mutation in acid α glucosidase (*GAA*) gene. Pompe disease comes at different ages and with different degrees of severity. The severity of the clinical presentations, the tissue involvement, and the age of onset generally correlate with the nature of the mutation and the degree of residual enzyme activity. In this study, mutation analysis of the *GAA* gene in 7 families suspected to have Pompe disease was carried out. **Methods**: In order for mutation analysis in these 7 families PCR, Sanger sequencing, ARMS-PCR and RFLP-PCR techniques were used. **Results:** Among these 7 studied families, we determined 3 families with 4 mutations, in which 3 on them include NM_000152. 3:c. 1004G>A, NM_000152. 3:c. 2078dupA and NM_000152. 3:c. 896T>C didn't submit in any database and we successfully submit them in ClinVar with RCV000156939 ,RCV000156940, RCV000156941 ID and in SNPs databases with rs730880022, rs730880372 and rs121907940 ID respectively. In 1 family submitted mutation (NM_000152. 3:c. 1927G>A) with ClinVar and SNPs ID RCV000004238 and rs28937909 was found. **Conclusion:** Despite the importance of measuring glucose oligosaccharides or acid maltase enzyme concentration in urine, plasma, and blood spot as a diagnostic procedure mutation analysis is the best way to confirm the clinical suspicion for Pompe patients and provide valuable information for family screening and genetic counseling.

2067F

Pilot data from the Veritas Genetics myGenome Project. *J. V. Thakuria[1, 2, 3], D. Martinez[1], B. B. Simen[1], H. Fortin[1], M. Callahan[1], P. Estep[1], H. Russell[1], G. T. Berry[4], G. M. Church[1,3].* 1) Veritas Genetics, Somerville, MA; 2) Massachusetts General Hospital, Boston, MA 02115; 3) Harvard Medical School, Boston, MA 02115; 4) Boston Children's Hospital, Boston, MA 02115.

While the number of published reports demonstrating medical utility of exome sequencing in patients suspected of monogenic disease continues to grow, data are still limited on the medical utility of whole genome sequencing in healthy, asymptomatic individuals hindering broader access for the general population. Outdated ACMG recommendations limiting routine return of results to a panel of only 56 genes highlights the growing need for population-based data. Initial reports on the number needed to screen (NNS) in the general population before a suspected pathogenic mutation is identified varies widely from <1% to >20%, but is usually reported in the 1. 5%-5% range (excluding potential reproductive utility from knowledge of carrier status for recessive disorders) - and is highly dependent on variant filtering stringencies. Preliminary pilot phase data from over 50 whole genomes with >100X average coverage from the Veritas Genetics myGenome Project parsed against over 20,000 Mendelian genes, thousands of positive controls (including >350 deeply phenotyped Personal Genome Project (PGP) samples with whole genome data), and undergoing secondary individualized analyses based on voluntarily provided personal and family medical histories, is reported. The pilot cohort was recruited across 5 continents. Study consent, pre- and post-test genomic counseling, as well as return of results, are generally performed remotely via tele- or videoconferencing. All study participants are given the option to receive an easily portable, compressed copy of their whole genome data on thumbnail drive and may opt in for indefinite biobanking of their samples for ongoing research and clinically focused reanalysis of data on a yearly basis on average and guided by evolving medical genomics knowledge. Alternatively, participants may opt to have their samples discarded and backup data deleted after receiving their compressed data and initial medical interpretation of results. The Veritas Genetics myGenome Project represents a viable internationally executed workflow for high throughput, high quality, clinical grade delivery of whole genome sequence and interpretation at population-scale.

2068W

Diabetic Ketoacidosis in Vanishing White Matter. *H. Alamri[1], F. Mutairi[1], A. Alothaim[1], M. Alfadhel[1], A. Alfares[1,2].* 1) king Abdul Aziz Medical City for National Guard, Riyadh, Saudi Arabia; 2) Qassim University, Qassim, Saudi Arabia.

Introduction: Vanishing white matter disease (VWM) is an autosomal recessive chronic and progressive white matter disorder. The symptoms of the disease can begin shortly after birth or in adulthood, and the most common features include neurological deterioration, optic atrophy, seizures, coma, and death. However, hyperglycemia and diabetic ketoacidosis (DKA) have never been reported before in patients with VWM. Case presentation: A male infant, product of a full-term uncomplicated pregnancy with developmental delay, hypotonia, and seizures. MRI of the brain revealed features of white matter diseases. At the age of 8 months, he presented to the emergency department with irritability and was found to have a very high blood glucose (25 mmol/l; normal, 6-10 mmol), HbA1c (11. 4%; normal 4%-5. 6%) levels, as well as ketosis and metabolic acidosis (pH 7. 2). Consequently, he was diagnosed and treated as a case of DKA and discharged on insulin injections. However, further investigations for type 1 and 2 diabetes mellitus, genes associated with neonatal and infantile diabetic syndromes and muscle biopsy for mitochondrial disorders were all negative. Eventually the child died at the age of 2 years while he was on insulin injections due to sever hypotonia and recurrent chest infections. The patient is product of a double cousin marriage, two of his brothers had died at 1 year of age with similar neurological, diabetic and brain MRI manifestations. Whole Exome Sequencing (WES) revealed a homozygous pathogenic variant in *EIF2B1* c. 146T>G p. (Leu49Arg) in the proband and both parents were heterozygous. Discussion: The patient met the consensus statement from the International Society for Pediatric and Adolescent Diabetes (ISPAD) in 2014 for the biochemical diagnostic criteria for DKA. WES revealed the diagnosis of VWM, which is a heterogeneous disease with five genes involved. The eIF2B protein complex plays a critical role in the initiation of protein synthesis and the cellular response to stress by activating the initiation factor eIF2, which interacts with the glucose response stimulus. However, the relation between the eIF2B protein complex and glucose level is unclear and requires further research. Conclusion: We are reporting on a case with both VWM disease and DKA. To the best of our knowledge, this is the first case of a similar presentation, and yields additional observations regarding the role of *EIF2B1* in glucose regulation and expands the phenotype of VWM disease.

2069T

Clinical Rapid Whole Exome Sequencing Experience. *D. Copenheaver[1], J. Juusola[1], K. Retterer[1], P. Vitazka[1], F. Gibellini[1], A. Marth[1], E. Butler[1], M. Deardorff[2], E. Zackai[2], E. Bedoukian[2], A. Wilkens[2], L. Medne[2], A. Lehman[3], D. Niyazov[4], J. Graham[5], Z. Y. Kucuk[6], G. Nalepa[7], C. Griffin[7], M. Willing[8], J. Bernat[9], D. Vats[10], L. Massingham[11], A. Poduri[12], W. Chung[13], G. Richard[1], S. Bale[1].* 1) GeneDx, Gaithersburg, MD; 2) Children's Hospital of Philadelphia, Philadelphia, PA; 3) University of British Columbia, Vancouver, BC; 4) Ochsner Clinic, New Orleans, LA; 5) Cedars Sinai Medical Center, Los Angeles, CA; 6) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 7) Riley Hospital for Children, Indianapolis, Indiana; 8) Washington University in St. Louis, St. Louis, MO; 9) University of Michigan, Ann Arbor, MI; 10) Kaiser Permanente- Southern California, Los Angeles, CA; 11) Rhode Island Hospital, Providence, RI; 12) Boston Children's Hospital, Boston, MA; 13) Columbia, New York, NY.

Whole exome sequencing (WES) is increasingly being used to identify the underlying cause of genetic disease and has a reported diagnostic yield of 25-30%. Recently the use of WES has been reported for undiagnosed patients in the NICU or PICU in whom a rapid genetic diagnosis may significantly alter medical management. To determine the feasibility, yield, and usefulness of WES with a fast turn-around time, we report on results of the first 19 consecutive cases submitted to our clinical laboratory for exome sequencing providing results within 7 days or less. Express WES was performed on proband-parent trios. WES analysis was completed and in all cases a verbal result with presence or absence of diagnostic findings in known disease (HGMD) genes was provided within 3-7 days. Confirmation of all reportable variants and secondary findings was performed, and a written report was issued within 5-13 days from start of testing. A definitive diagnosis was made in 8 of the cases (42%). In one case, two distinct genetic diagnoses were made. Of the positive cases, four (44%) probands were diagnosed with an autosomal recessive disorder, three probands (33%) had de novo and two (22%) had inherited variants associated with autosomal dominant disorders, and one (11%) proband had an X-linked disorder. No reportable ACMG secondary findings were identified in this cohort. The probands' ages ranged from 5 days to 14 years. Eight were infants <11 months, and 13 were <2 years old. The majority of probands were referred for neurological indications (13/19) including seizures (7/19), two children had multiple congenital anomalies, and the remainder had other clinical indications. In three cases, express WES was chosen to aid with decision making regarding a stem cell transplant, lung transplant, or family planning of an on-going pregnancy. Other benefits of a rapid diagnosis were changes in medical management (n=7), the ability to make prognostic predictions and discuss palliative care with the family (n=4), to facilitate carrier testing and informed family planning, and to avoid further invasive or other diagnostic tests (n=9). Although our experience is still limited, our data demonstrate that express WES testing can be accomplished in a diagnostic laboratory setting, that this testing has good diagnostic yield of 42% and, if positive, provides value for determining prognosis, making management and family decisions much sooner than with traditional genetic testing.

2070F

Next-Generation Sequencing test within a neurologic region of interest leads to diagnosis of *RYR1*-related disorder for 36-year-old female after three decades. *P. Gerrol[1], N. Vena[1], A. Rutkowski[2, 3].* 1) Claritas Genomics, Inc, Cambridge, MA; 2) Cure Congenital Muscular Dystrophy, cureCMD. org; 3) Kaiser SCPMG, Los Angeles, CA.

We report on a 36yo female with a progressive neuromuscular disorder who has remained without a definitive molecular diagnosis, thus lacking the benefit of prognostic and familial risk information. She initially presented to Neurology at age 3 with motor delay and lumbar lordosis. Exam showed facial, neck flexor, and proximal weakness and use of a Gower maneuver. After a relatively stable disease course in childhood, there was gradual progression of muscle weakness, proximal greater than distal, in upper and lower extremities. She developed ophthalmoplegia (bilateral restricted upward gaze) and facial diplegia in the 2nd decade and is now wheelchair-dependent. Muscle biopsy showed type 1 fiber predominance and centronuclear myopathy but no cores/ultrastructural changes; however, *MTM1* (MIM 300415) sequencing and deletion/duplication studies were negative. We performed the Claritas Pediatric Neurology Exome, which employs two next-generation sequencing (NGS) technologies to detect and orthogonally confirm variants in 614 neurology-related genes. This approach focuses on genes with known clinical relevance and reduces the number of variants requiring confirmation, thus reducing turnaround time. NGS identified two variants in *RYR1* (MIM 180901): a novel frameshift variant and a previously reported missense variant. The maternally-inherited c. 14662_14663delAT (p. Met4888Valfs*20) frameshift variant predicted to result in a premature stop codon was interpreted as likely pathogenic. The c. 10622C>T (p. Ala3541Val) missense variant had been previously reported, but inconclusive evidence was provided to determine pathogenicity; it was classified as a variant of uncertain significance. The majority of pathogenic *RYR1* variants are private heterozygous missense changes leading to autosomal dominant central core disease and/or increased susceptibility to malignant hyperthermia. In contrast, individuals with congenital centronuclear myopathy tend to be compound heterozygotes for *RYR1* missense and truncating variants. Asymptomatic heterozygous carriers of the latter have been reported, supporting autosomal recessive inheritance. The molecular results identified, suggestive of autosomal recessive *RYR1*-centronuclear myopathy, are consistent with the patient's clinical phenotype, thus providing her with a molecular diagnosis after 30 years of uncertainty.

2071W

Clinical results from a pediatric neurological region of interest using an orthogonal NGS approach to identifying variants. *E. J. White, N. Bachman, S. Gruszka, S. Hansen, V. Lip, P. Milos, N. Napolitano, T. Restrepo, Y. Shen, N. Vena.* Claritas Genomics, Inc. , Cambridge, MA.

Statement of Purpose: There are many pediatric neurologic disorders that present with unique or overlapping phenotypes that often make identifying the underlying genetic variant a multi-year journey when using traditional molecular approaches to identify them. Through the use of next-generation sequencing (NGS) technologies, it is possible to sequence all the protein coding exons in the affected patient's genome simultaneously to quickly identify potential causative variants. In a clinical setting, it remains necessary to verify putative NGS results with additional molecular methods. In the case of whole exome sequencing, the number of variants needing confirmation may be in the hundreds. Methods: At Claritas Genomics, we have developed an approach to clinical testing which limits the number of potential variants needing Sanger confirmation. This approach both focuses on a neurological region of interest (ROI) encompassing 614 genes that have been implicated in causing seven pediatric disorder categories as well as employing two NGS technologies to orthogonally detect and confirm variants in the neurological genes. Any variants that are not confirmed using this approach can be resolved by Sanger sequencing. Results: We have compared results obtained using our assay with results from another provider's whole exome assay for 9 independent samples chosen for their pediatric neurological indications. These analyses were carried out in a blinded fashion. Of the nine samples, four samples produced clinically inconclusive findings in both assays. Three samples produced the same results in both assays. One sample produced a result that was interpreted as clinically relevant in the other provider's analysis but our analysis indicated this gene was not phenotypically relevant to the patient's disorder. The final sample produced a result that was clinically relevant based on our analysis but it was not identified in the other provider's whole exome. The use of orthogonal sequencing platforms provides immediate confirmation of most variants and also yields better sensitivity than either platform alone can generate, providing better results and more timely information for patients seeking answers to their diagnostic questions.

2072T

***De novo* mutations in prenatal trios with abnormal ultrasound findings detected by high coverage NGS panel analysis.** *H. Dai[1], H. H. C Lee[1], J. Zhang[1,2], H. Mei[1,2], S. Chen[1], Y. Feng[1], J. Wang[1,2], V. W. Zhang[1,2], LJ. Wong[1,2].* 1) Baylor Miraca Genetics Laboratories. Houston, TX; 2) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Introduction: *De novo* mutations are the major genetic cause for sporadic autosomal dominant inherited diseases. Trio analysis can provide prompt molecular diagnosis for diseases with fetal abnormalities. Overall *de novo* mutation rate has been evaluated at the genome/exome level in normal population. High coverage capture-based Next Generation Sequencing (NGS) panel trio analysis now is available to interrogate de novo mutations as one time and cost efficient method. **Methods**: Fifty trio samples submitted to us for molecular analysis of the abnormal fetus suspected of Noonan syndrome by target capture NGS using a custom designed capture library. Variants from 183 genes involved broadly in varies biological processes, including the Ras signaling pathway, were analyzed. The average depth of coverage is >600X, sufficient for the detection of low level mosaicism. *De novo* changes were further confirmed by Sanger sequencing in prenatal and parental samples. **Results:** A total of seven *de novo* changes were identified from 50 trios. Corrected with capture library size ~1Mbp, our data suggest an expected *de novo* mutation rate of 438/genome, 4/exome and 1 in 1255 protein coding genes, which is significantly higher than reported previously, presumably due to the biased patient population of abnormal fetal ultrasound suggesting Noonan spectrum disorder. Four missense changes are categorized as pathogenic/likely pathogenic for Noonan syndrome: *RIT1*:c. 170C>G (p. Ala57Gly); *RIT1:* c. 268A>G (p. Met90Val); *PTPN11*:c. 215C>T (p. Ala72Val); *SOS1:c. 508A*>G (p. Lys170Glu). Three *de novo* variants are novel intronic/UTR changes with unknown significance in genes not directly associated with fetal abnormalities (*HBD*: c. -61G>A; *GATA2*:c. *1574A>G; *FH*:c. 1236+28T>G). The allelic ratio of those changes range from 49% to 53%, suggesting pre-zygotic events, rather than somatic mosaicism. No low level mosaic changes in the blood samples of parents were detected with the deep NGS approach. **Conclusions:** Capture based trio NGS analysis provides accurate and prompt assessment for *de novo* mutations in cases with prenatal ultrasound abnormalities. High coverage NGS data also offers the ability power to detect possible mosaicism. Significantly higher *de novo* mutation rate might be expected due to the dominant phenotype and bias of sample selection. In addition to missense changes that are associated with pathogenesis, changes in introns or URT regions are of interest for further investigation.

2073F

Rare Genomics Institute research initiative provides non-profit patient services enabling deep insights into rare disease conditions through genome sequencing and cloud collaboration. *C. J. Lin, R. R. Haraksingh.* Rare Genomics Institute, Hanover, MD. , U. S. A.

The Rare Genomics Institute (RG) is an international non-profit which connects rare disease patients to cutting-edge genomic solutions for diagnosis and treatment. RG has partnered with 8 sequencing sites to provide our patients with whole exome sequencing (WES). An estimated 75% of patients who undergo WES do not receive a genetic diagnosis due to the rarity of their condition and our incomplete understanding of the functional significance of genomic variants. The RG research initiative addresses the need for combined in-depth analysis of the genetic and medical data for each patient which is not provided by physicians, genetic counselors, or sequencing services. Our research model involves crowd-sourcing ideas from our global network of scientists, cloud collaboration, adoption of state of the art computational systems, and utilizing the unique expertise of our in house scientific team to provide actionable insights into each case. Specifically, patient medical and genetic data is stored and shared via a partnership with online medical record system Patients Know Best. In-depth genetic analysis informed by comprehensive and well-defined medical phenotypes for each patient is carried out by our in house team of PhD-trained volunteer analysts using Omicia Opal variant filtering software. These analyses along with an extensive compilation of the literature relating to symptoms, genes of interest, treatments, or similar cases as well as opportunities to join relevant clinical trials and connect with external experts, are assimilated into scientific reports including recommended next steps. These reports are returned to the patients and published on our online forum for further research and collaboration. To date, we have enrolled ~20 families in our pilot program and completed analysis for 12. Of these patients, we found genetic diagnoses for 6, defined the syndrome for 2, connected several to external research experts for follow up studies, recommended clinical trials for a few, and a second family was found for one case. In all completed cases the families received satisfactory biological insight into their condition. Our research model is helping to meet a crucial need for rare disease patients and demonstrates that exome sequencing coupled with in depth analysis leveraging medical history and global collaboration can be deeply insightful. Initial results show that our approach can increase diagnostic yield for rare diseases from 25 to 50%.

2074W

Diagnosis of autosomal dominant polycystic kidney disease (ADPKD) by full gene sequencing and MLPA. *M. Procter[1], E. Paul[1], A. Morris[1], R. Mao[1,2].* 1) Res & Development, ARUP Lab, Salt Lake City, UT; 2) University of Utah Health Sciences Center, Salt Lake City, UT.

Autosomal Dominant Polycystic Kidney Disease (ADPKD) is usually an adult onset, multisystem disease. Fifty percent of individuals with ADPKD will develop end stage renal disease (ESRD) by age 60, however renal cysts may be present from birth. Clinical presentation of ADPKD can have a wide spectrum including the following symptoms: headache, high blood pressure, back or side pain, frequent urination, urinary tract or kidney infections, kidney stones, increase in the size of that abdomen as the kidneys become overgrown with cysts, end stage renal disease (ESRD), and kidney failure. Mutations in *PKD1* or *PKD2* cause abnormal or absent expression of the proteins Polycystin-1 (PKD1) and Polycystin-2 (PKD2). Altered/abnormal expression of the polycystins during development leads to dilation in the renal tubules, ultimately leading to the formation of fluid-filled cysts that are characteristic for this condition. These cysts are detected through renal imaging. Sequence variants in*PKD1* account for disease in 90% of individuals with ADPKD and variants in *PKD2* are causative in 10% of individuals with ADPKD. Individuals with *PKD2* mutations are less likely to develop ESRD than individuals with a *PKD1* mutation. *PKD1* is comprised of 46 exons on chromosome 16 and *PKD2* is comprised of 15 exons on chromosome 4. Chromosome 16 contains a region adjacent to the *PKD1* gene having 97% homology to exons 1 through 33 of *PKD1*. Sanger sequencing to avoid this pseudogene was achieved using a combination of long range PCR, nested PCR, and standard touchdown PCR for a total of 78 PCR amplifications. Deletion and duplication testing was done using MLPA with an extended denaturation time to accommodate the high G-C content of *PKD1*. Accuracy and precision of these assays were evaluated using samples from three normal individuals and two samples with known *PKD2* mutations. Samples with *PKD1* and *PKD2* deletions and duplications were unavailable so PCR amplicon was used as template for evaluation. These *PKD1* and *PKD2* mutation and deletion/duplication assays are robust, accurate, and reproducible. Genetic testing allows for diagnosis of affected individuals, testing of potential kidney donors, and testing of adult relatives of affected individuals. Early detection and treatment can reduce complications and disorders associated with ADPKD.

2075T

Review of *PRPH2 (RDS)* mutations found in patients enrolled in the National Ophthalmic Disease Genotyping and Phenotyping Network (eyeGENE®). *M. J. Reeves[1], K. E. Goetz[1], D. Blain[1], A. V. Garafalo[2], V. NDifor[2], R. S. Parrish[2], S. Vitez[2], X. Wang[1], S. J. Tumminia[3].* 1) Ophthalmic Genetics and Visual Function Branch, National Eye Institute/NIH, Bethesda, MD; 2) Astrix Technology Group, Bethesda MD; 3) Office of the Director, National Eye Institute/NIH, Bethesda, MD.

Purpose: The National Ophthalmic Disease Genotyping and Phenotyping Network, eyeGENE®, is a multicenter genomic medicine initiative that recruits individuals with inherited eye diseases from the United States and Canada for genetic testing and research into these diseases. *PRPH2*/*RDS* is a gene associated with various autosomal dominant conditions including retinitis pigmentosa, pattern dystrophy, macular dystrophy, and others. Seventy-one eyeGENE® participants of 52 familieswith a *PRPH2*/*RDS* mutation were reviewed to assess potential genotype-phenotype correlations. **Methods:** A blood sample was obtained from each participant, and genomic DNA was extracted. Clinical information submitted by the referring clinician was reviewed. A portion of the DNA was shipped to either the Laboratory for the Molecular Diagnosis of Inherited Eye Disease (LMDIED) at the University of Texas Health Science Center or GeneDx. *PRPH2*/*RDS* was screened by conventional Sanger or next generation sequencing, and the results were reported back to the eyeGENE® Coordinating Center and shared with the referring clinician and participant. **Results:** Mutations were distributed across exons 1, 2 and 3, with 39% of mutations in Exon 1, 40% in Exon 2, 4% in Exon 3, and the rest intronic. The most prevalent mutation type was an IVS2 mutation, c. 828+3A>T, which affected 9 of 52 families (17%). The c. 422A>G, p. Y141C mutation in Exon 1 was found at the second highest frequency of 4/52 (7. 7%). The c. 715C>T, p. Q239X mutation found in Exon 2 had a frequency of 3/52 (5. 8%). Patients were enrolled with a variety of diagnoses; e. g. , 20 patients as Stargardt disease, 26 as pattern dystrophy, 5 as cone rod dystrophy, 5 as retinitis pigmentosa, 3 as Best disease, 1 as choroideremia and 11 patients with 2 or 3 of these classifications. While the overall age of onset for this cohort was generally at around 40 years of age, it was difficult to determine whether or not there were true correlations between genotype and phenotype. **Conclusions:** The *PRPH2*/*RDS* gene has been shown to have high phenotypic variability, even within the same family. Because the disease presentation may be so variable and fit more than one diagnosis, it may be beneficial for eyeGENE® and others to develop algorithms and responsive diagnostic questionnaires so that the reported phenotype will be more standard between clinicians and a broader approach to genotype-phenotype correlations might be taken with larger patient datasets.

2076F

Development and implementation of a targeted next generation sequencing (TNGS) strategy for the molecular diagnosis of intellectual disability. *S. Hanein[2], C. Fourrage[1,2], G. Royer[1], A. Elmorjani[2], M. Rio[1,2], J. Amiel[1,2], V. Cormier-Daire[1,2], G. Baujat[1,2], C. Bole[2], P. Nitschke[2], J. Steffann[1,2], L. Colleaux[2], S. Lyonnet[1,2], JP. Bonnefont[1,2], A. Munnich[1,2], G. Barcia[1,2].* 1) Medical Genetics, Necker Hospital, Paris, France, France; 2) Imagine Institute for Genetic Diseases, Paris, France.

Purpose: Intellectual disability (ID) is a clinically and genetically heterogeneous disorder representing the leading cause for referral in the Genetics Department of the Necker Hospital with about 7000 patients every year. Trio whole exome sequencing (WES) is a powerful approach to gain insight into the genetic bases of ID, but it remains costly and time consuming as far as interpretation is concerned. Moreover, it can be a source of uncertain or incidental findings, and is therefore less relevant for the diagnostic setting. As a collaborative work of the *Imagine* Institute and the Clinical and Molecular Genetics Unit of the Necker Hospital, we developed a custom targeted next generation sequencing (TNGS) strategy for the molecular diagnosis of ID, including all genes whose mutations have already been reported in at least two unrelated patients. **Methods:** Genomic DNA libraries were performed using SureSelectXT Target Enrichment Reagent Kit according to the suppliers' recommendations, and were subjected to custom targeted DNA panel enrichment. 4615 regions of interest of 253 ID genes were captured with the 120-pb cRNA baits designed using the SureDesign software (Agilent). The targeted regions, encompassing 1,556 Mb of DNA, were sequenced by synthesis on an Illumina HiSeq2500, and data were analysed through the Imagine Bioinformatics core facilities. **Results:** We analysed 128 samples including 12 with known ID mutations, 14 patient-parents trios, and 74 index cases. We confirmed the presence of mutations in controls (including point mutations and indels). We identified pathogenic or probably damaging variants in 20/88 patients (23%), involving the *SATB2, STXBP1, CDKL5, MEF2C, SYN1, KATNAL2, PTPN1, SMC1A, SHANK3, NFIX, FLNA, BCOR* and *EHMT1* genes. **Conclusions:** With a diagnostic yield of 23%, TNGS is an efficient strategy for the first-step genetic screening of ID, avoiding incidental findings, and at a lower cost compared to WES. Even if targeted approaches are restricted to a few hundred genes, interpreting variants generated by TNGS is challenging. A dynamic interaction between physicians and molecular biologists is necessary to interpret TNGS results and to draw genotype-phenotype correlations. TNGS, enabling a comprehensive screening of all known genes involved in ID, offers a rapid, cost effective and relevant selection of patients available for the identification of novel genes by WES and WGS in the research setting.

2077W

Comprehensive genetic testing of 74 probands with Waardenburg syndrome using massively parallel sequencing. *j. Cheng[1], y. lu[2], h. j. yuan[1,2].* 1) medical genetics center, Southwest Hospital, Third Military Medical University, chongqing, China; 2) Dept. of Otolaryngology, Chinese PLA General Hospital, Beijing.

Waardenburg syndrome (WS) is heterogeneous and responsible for 1-3% of total congenital deafness. The combination of targeted exome capture and massive parallel sequencing (MPS) has become a promising method for detecting novel and known mutations involved in hereditary hearing loss in a rapid and cost-effective way. In this study, we tested 74 probands in China with representative Waardenburg syndrome, using the in-house platform including 438 genes associated with deafness. They were characterized by the association of congenital sensorineural hearing loss and pigmentary disturbances of the iris, hair, and skin, along with or without other features such as dystopia canthorum, musculoskeletal abnormalities of the limbs, Hirschsprung disease, or neurological defects. The results indicated that six known WS genes (*PAX3, MITF, SOX10, EDNRB, EDN3* and *SNAI2*) were responsible for about 57% (42/74) of WS cases. We identified 11 distinct *PAX3* mutations in 12 patients, of which 2 were novel; 8 distinct *MITF* mutations in 13 patients, of which 6 were novel; 13 distinct *SOX10* mutations in 13 patients, of which 11 were novel; 4 distinct novel *EDNRB* mutations in 3 patients. None of mutation was found in *EDN3* and *SNAI2*. In conclusion, 24 novel WS gene mutations were identified, which need to be confirmed; and 18 cases (about 24%) can be diagnosed surely. Further whole exome sequencing will be applied to identify the novel WS genes with the rest 43% undiagnosed WS cases.

2078T

Comprehensive molecular analysis of the *ABCA4* gene in Stargardt disease patients of the German population. *H. L. Schulz, F. Grassmann, R. Walker, H. Roth, M. Weber, H. Stöhr, B. H. F. Weber.* Institute of Human Genetics, University of Regensburg, Regensburg, Germany.

Autosomal recessive Stargardt disease (STGD1 [MIM 248200]) is the most prevalent juvenile-onset maculopathy and is caused by mutations in the ABCA4 gene. To date, more than 800 ABCA4-associated mutations have been reported to cause STGD1 and other retinal diseases. Several patients carry monoallelic ABCA4 variants in the coding or conserved intronic sequences some of which may belong to a subgroup of clinically distinct AMD/late-onset Stargardt disease patients. In addition, recent studies indicate the rare presence of deep intronic pathologic ABCA4 variants. To identify the ABCA4 mutation spectrum in German patients diagnosed with Stargardt disease, we analyzed the ABCA4 gene in 245 individuals by either Affymetrix-based custom-designed resequencing array (RetChip) analysis or NGS. A total of 142 different mutations found in this cohort were categorized as likely pathogenic or pathogenic based on allele frequency (MAF≤0. 5%), bioinformatical and functional analysis, or as variants of unknown clinical significance. This includes 39 novel mutations. In 45% of the patients, two causative mutations were identified, 24% of patients harbor only one ABCA4 mutation and no ABCA4 sequence alterations were identified in the remaining 31% of patients. To analyze the impact of deep intronic ABCA4 variants in our cohort, we sequenced selected regions of intron 30 and 36. Two different intronic variants that are predicted to strengthen cryptic donor splice sites were found in two patients with a second rare variant in the coding region of ABCA4. Finally, multivariate logistic regression of the patient cohort and ethnically-matched subjects was used to study the association of 18 polymorphic ABCA4 variants (MAF>0. 5%) with disease. This identified three statistically significant (Pval<0. 05/18) risk-increasing variants and two protective variants. From these, a genetic risk score (GRS) was computed as the sum of risk increasing and protective ABCA4 alleles weighted by the relative effect size of each SNP from the logistic regression model, revealed that patients have a significantly higher mean GRS (0. 606, 95% CI: 0. 497-0. 714) compared to controls (0. 0, 95% CI: -0. 054-0. 054). Patients that carry only one causative ABCA4 mutation have a statistically significant higher GRS than those with no or two ABCA4 mutations. This suggests that in patients with a single ABCA4 mutation, risk-increasing variants or associated changes may contribute to the disease.

2079F

First report of molecular genetics diagnosis of Niemann Pick disease in North-West of Iran. *E. Abedini[1], A. Khorrami[2], M. saeid nejhad[1], M. Ziadi[2], M. mohaddes[2].* 1) Azad university of Tabriz, Tabriz, Iran; 2) Tabriz University of Medical Science.

Niemann Pick disease (NPD) types A and B are rare autosomal recessive disorders occur by sphingomyelin phosphodiesterase1 (SMPD1) gene mutations that result in the deficiency or shortage of lysosomal acid sphingomyelinase (ASM) activity. The disease is characterized by the accumulation of sphingomyelin in the endolysosomal compartments and patients often present hepatosplenomegaly, respiratory complications, atherogenic lipid profiles and sometimes progressive neurodegeneration. In this study we report the molecular characterization of 7 unrelated Iranian Azeri Turk patients with type A and B NPD by sequencing of SMPD1 exones. For collecting more information in the case of frequency of the polymorphic hexanucleotide sequence. P. 37LA (3-8), reside within the signal peptide of ASM, we also design a control group including 50 healthy participants with the same ethnic background. L137P missense mutation, was observed in the 3 of 7 patients in homozygote status. 4 of 7 patients were homozygous for rs1050239 (c. 1522G>A; p. G508R). In the case of P. 37LA (3-8) the allele contained four hexanucleotide repeat units is the most frequent in both patients and healthy participents followed by 5, 6and 7repeats. whereas the number of repetition in ENSEMBLE and UCSC databases, both are five while in NCBI database seven repeats is considered as common allele. L137P is the only pathogenic mutation was found in this investigaton. The existence of allele with four repetations with high frequency for P. 37LA (3-8) in our population can be an example of founder effect.

2080W

***SPATA5* mutations identified by whole exome sequencing cause a novel autosomal recessive syndrome characterized by microcephaly, intellectual disability, seizures, and hearing loss.** *K. G. We describe a novel syndrome characterized by severe neurological impairment including intellectual disability (ID), epilepsy, microcephaly, abnormal muscle tone, and sensorineural hearing loss due to autosomal recessive mutations in the Spermatogenesis-Associated Protein 5 (*SPATA5*) gene. Clinical whole exome sequencing (WES) was performed on 3,359 patients with developmental delay, ID, or seizures. Ten affected children from 7 unrelated families were found to be homozygous or compound heterozygous for *SPATA5* variants, which were suspected to cause their phenotype. Through GeneMatcher we identified 4 additional probands from 3 families. All families were sequenced by WES either as a proband-parent trio or family analysis using affected or unaffected siblings for segregation studies, which supported autosomal recessive inheritance. *SPATA5* is a ubiquitously expressed member of the ATPase associated with diverse activities (AAA)-protein family located at 4q28.1. Involved in mitochondrial morphogenesis during early spermatogenesis, it may also play a role in post-translational modification during cell differentiation in neuronal development. Pathogenic variants in *SPATA5* may affect brain development and function, resulting in the neurological phenotype described here. All 15 *SPATA5* variants we detected were novel or rare (allele frequency <1/10,000), occurring in highly evolutionarily conserved regions. Variants included missense (9), frameshift, (3) in-frame deletion (1), nonsense (1) and canonical splice (1) mutations. The patients ranged in ages from 2-19 years and all have moderate-severe intellectual disability, with the majority of the children classified as non-verbal and non-ambulatory. Commonly reported features were developmental delay (14/14), microcephaly (12/14), abnormal EEG (14/14), seizures (13/14), abnormal muscle tone (14/14), sensorineural hearing loss (14/14), and visual impairment (13/14). Other features included brain MRI abnormalities, short stature, failure to thrive, and immunodeficiency. Two patients had muscle biopsies that revealed a possible mitochondrial disorder. Dysmorphic features were not noted. The findings presented in this case series may facilitate the identification of additional affected patients to further the knowledge regarding the phenotype associated with pathogenic variants in *SPATA5*.

The Emerging Need for Genetic Testing in Clinical Psychiatry. *C. G. Bouwkamp[1,2], J. A. Kievit[2], L. van Zutven[2], R. van Minkelen[2], I. Sterrenburg[3], V. Bonifati[2], S. A. Kushner[1].* 1) Department of Psychiatry, Erasmus MC, Rotterdam, The Netherlands; 2) Department of Clinical Genetics, Erasmus MC, Rotterdam, The Netherlands; 3) Delta Psychiatric Center, Poortugaal, The Netherlands.

Background: A family history of psychiatric illness is currently the single best predictor of disease risk, confirming the strong genetic basis for psychiatric disorders. However, patients with psychiatric disorders are seldom referred clinically for genetic testing. With the recent technological developments in genotyping rapidly adding to our knowledge of psychiatric genetics, we draw on the literature on psychiatric genetics and our experience of clinical genetic testing with the purpose to recommend a revision of the current standard of care in clinical psychiatry. **Methods & Findings:** Through our diagnostic service, we ascertained 31 probands with chronic severe mental illness and comorbid mild-to-moderate intellectual disability. Clinical examination included care dysmorphology screening, standard blood plasma and urine metabolic screening, Fragile X testing, and Illumina CytoSNP-12 300k DNA microarray genotyping. In 11 (35%) of 31 consecutively evaluated cases, we were able to provide an etiological molecular genetic diagnosis (n=4) or identify a potentially causative DNA copy number variant (n=7). In addition to these singleton cases, several families with a Mendelian pattern of psychiatric disease inheritance were ascertained, including one with a balanced translocation segregating with affective psychosis and recurrent spontaneous abortions. Whole genome sequencing and Sanger sequencing confirmation enabled us to identify the exact breakpoints of the translocation [t(6;15)(q26;q21)], which has intragenic breakpoints within *BCL2L10* and *PNLDC1* in all affected family members available for testing. **Conclusion:**On the basis of the existing literature and our experience with patients and families with chronic severe mental illness, we conclude that clinical genetic testing and counseling is warranted in patients with complex psychiatric syndromes, in particular those with clinically-relevant intellectual disability and/or congenital abnormalities.

2082F

Does this patient need to be tested for Lynch Syndrome? Assessing the reliability of family history for ascertainment. *H. C. Cox[1], E. Rosenthal[2], Y. Qian[1], B. Coffee[1], R. Wenstrup[2], B. B. Roa[1], K. R. Bowles[1].* 1) Myriad Genetics, Inc. , Salt Lake City, UT; 2) Myriad Genetic Laboratories, Inc. , Salt Lake City, UT.

Background: Lynch Syndrome (LS) is a dominantly inherited cancer syndrome caused by pathogenic germline variants in mismatch repair genes *MLH1*, *MSH2*, *MSH6*, and *PMS2*, as well as *EPCAM*. Mutation carriers are candidates for more aggressive clinical management such as increased surveillance and prophylactic surgery. Age and family history are key components in targeted genetic testing of individuals as outlined by Amsterdam criteria, Bethesda guidelines, and predictive algorithms. However, family history may be insufficient to identify individuals carrying pathogenic variants due to incomplete penetrance, phenotypic heterogeneity and limited generation sizes in contemporary families. **Methods:** We used pedigree simulation and statistical modelling to estimate the probability that a 40 year-old proband carrying a pathogenic germline variant in *MLH1*, *MSH2* or *EPCAM* would meet family history requirements for genetic testing. Simulated pedigrees spanned 3 generations with sibship sizes of 2 or 4. Sporadic cancer risks, birth age, and mortality were estimated from US population data. LS cancer risks were estimated from published values available at www. myriadpro. com. All analyses were performed using R version 3. 1. 3. **Results:** Preliminary results failed to identify >55% of appropriate patients using Amsterdam II criteria in sibships composed of 2 individuals. Relaxing this family history criteria as follows: 1) colorectal or endometrial cancer under age 50, 2) any LS cancer in an individual with a 1st or 2nd degree relative with a LS associated cancer at any age, 3) 2 primary LS cancers at any age, and 4) any unaffected individual who has a 1st degree relative that meets one or more of the criteria above, still failed to identify >12% of patients with pathogenic variants. Both family history analysis models failed to detect >25% of unaffected patients. **Discussion:** Genetic testing based on family history will identify a subset of Lynch Syndrome patients prior to cancer onset. However simulations demonstrate that the strength of family history declines significantly for families harboring a pathogenic variant with incomplete penetrance, particularly if the proband is unaffected and generation sizes are small. Whilst universal population testing is not yet a viable option, clinicians should consider broad pan-cancer testing rather than more limited cancer-specific testing for patients who are being assessed for inherited cancer risk.

Background: Spondylocostal dysostosis (SCDO) is radiographically defined as multiple segmentation defects of the vertebrae (SDV) affecting at least ten contiguous levels, with grossly symmetric abnormalities of the ribs. Clinical features of SCDO are a short trunk in proportion to height, a short neck and a non-progressive scoliosis. To date, 5 genes are known to cause SCDO : DLL3, MESP2, LFNG, HES7 and TBX6. Overall, the diagnostic yield associated with the sequencing of these genes approaches 25%. Objective: To identify relevant clinical and radiological findings that should orientate towards targeted gene sequencing with a relevant diagnostic yield. Methods: A national recruitment of patients with SDV was realized. For each patient, clinical data and X-ray were asked to the referring clinician. Genomic DNA was sequenced for the coding sequence of DLL3, MESP2, LFNG, HES7 and TBX6 using NexteraXT protocol on a MiSeq instrument (Illumina). Results: Overall, 53 patients were recruited in a two-years period. Clinical information was missing for nine cases. The global diagnostic yield was of 11%. Overall, 28/44 patients presented with visceral malformations and SDV. In this subgroup, no patient was found mutated for the tested genes. Among the 16 patients with isolated segmentation defect, eight had less than 10 contiguous SDV levels and were negative for gene testing. Among the eight cases with at least 10 contiguous SDV levels and no visceral malformation, six were positive for mutation screening, namely DLL3 mutations in two patients, LFNG mutations in 2 patients, MESP2 mutations in one patient and TBX6 mutation in 1 patient. In this specific subgroup, the diagnostic yield was of 75% (6/8). A radiological description of the positive cases was strongly consistent with classical description in the DLL3 and MESP2 cases. Discussion: In this cohort, the overall diagnostic yield was of 11%. A radiological selection for patients with at least 10 SDV levels and no visceral malformation would have lead to a 75% (6/8) diagnostic yield. Although DLL3 and MESP2 mutation may be anticipated based on published images, the radiological findings remained unpredictable for TBX6 and LFNG patients with one family reported in the literature for each. To conclude, our results suggest that targeted sequencing may be preferred in typical cases or in patients with extended SDV without visceral malformation.

2084T

Exome sequencing in intellectual disability and epilepsy. *J. Halvardson[1], J. Zhao[1], CS. Zander[1], E. Månsson[2], H. Edert Sävmarker[3], G. Brandberg[4], AC. Thuresson[1], L. Feuk[1].* 1) Department of Immunology, Genetics and Pathology and Science for Life Laboratory, Uppsala University, Uppsala, Sweden; 2) Örebro University hospital, Örebro, Sweden; 3) Gävle hospital, Gävle, Sweden; 4) Falun hospital, Falun, Sweden.

Intellectual disability (ID) has a prevalence of 1 – 3% and is defined by an IQ less than 70 with an onset before the age of 18. It has been estimated that at least 20 – 30% of ID patients are co-diagnosed with epilepsy. This gives strong over-representation of epilepsy in these patients compared to the general population prevalence of 0. 05 to 0. 1 %. In recent years exome sequencing has proved to be an effective method to identify causative disease genes in a great number of different syndromes, including syndromes with ID and epilepsy. Here we present the results of exome sequencing in 38 trio families where the index patient is diagnosed with both ID and epilepsy. The families have previously no known causative mutation or history of disease and have previously been screened for copy number variation using SNP arrays. We report 27 validated *de-novo* SNVs or INDELs in 20 of the 38 trio families (~53%). Among the validated *de-novo* mutations identified 22 were nonsense or missense mutations, while 5 were silent mutations. Nine of the *de-novo* mutations were found in genes where mutations previously have been reported to cause disease with ID and epilepsy. Several of the remaining mutations were found in genes highly expressed in the brain and predicted to be highly disruptive (CADD score > 20), opening for the possibility of identification of new genes associations to ID and epilepsy. In one patient we found a nonsense mutation in the *SETD5* gene, mutations in this gene are known to cause ID but not epilepsy. Interestingly in the same patient we also found a *de-novo* mutation in the *ERC2* gene, mouse knockouts of this gene have a disturbed inhibitory synaptic strength. Taken together this raises the possibility of the *SETD5* and *ERC2* mutations acting together to create both epilepsy and ID in the carrier. We also identify mutations in several genes not previously linked to ID or epilepsy, but that represent excellent candidates as causative genes based on their function in the brain or important metabolic pathways. For some of these genes mouse models show phenotypes with impairment of neurological function, adding evidence for mutations in these genes to be causative in neurological disease. Taken together the results of this study point out several new potentially causative genes in ID and epilepsy that are of great interest for further studies to understand their involvement indisease etiology.

UPD1 in a Newborn with Multiple Congenital Anomalies. *A. R. Seman[1], L. Rodan[2], A. C. Woerner[2].* 1) Claritas Genomics, Cambridge, MA; 2) Division of Genetics, Boston Children's Hospital, Boston, MA.

There have been reports in the literature of uniparental isodisomy of chromosome 1 (UPD), but none has revealed a unifying phenotype. In most cases, the UPD1 led to the unmasking of an autosomal recessive condition. A newborn girl with multiple congenital anomalies was referred for the Claritas Genomics custom SNP chromosomal microarray analysis (CMA), which identified uniparental isodisomy of the entire chromosome 1. The patient originally came to medical attention prenatally for concerns regarding small kidneys, dilated ureters, and oligohydramnios beginning at 26 weeks gestation. Additional ultrasounds and fetal MRI identified bilateral dysplastic kidneys and cardiomegaly. The patient was born at 38 weeks via spontaneous vaginal delivery with Apgars of 2, 5, and 5. Postnatal imaging identified aortic coarctation, right ventricular dysfunction, tricuspid regurgitation and confirmed renal dysplasia/hypoplasia. Physical exam was notable for dysmorphic features including deep set eyes, downslanting palpebral fissures, and 3,4 syndactyly of fingers. She later was noted to have bilateral clavicle fractures and bilateral hip dislocation. Mosaic chromosome analysis to assess for potential aneuploidy rescue was normal. None of the known autosomal recessive disorders related to chromosome 1 sufficiently explained the patient's entire phenotype, raising the possibility of more than one disorder, an atypical presentation of a known disorder, or a novel disorder. The patient's fractures raised the possibility of hypophosphatasia, associated with autosomal recessive mutations in the *ALPL* gene on chromosome 1; however, plasma ALP levels were not decreased and urine phosphoethanolamine was not increased. Exome sequencing of chromosome 1 is currently pending with the goal of identifying the responsible gene(s) for this patient's features. This case highlights the ability of SNP CMA to identify UPD that likely would not have been otherwise detected. This information helped to refine our search and will hopefully lead to an ultimate molecular diagnosis.

2086W

Genetic investigation of cystic fibrosis transmembrane regulator mutations in a cohort of consecutive patients candidate for assisted reproductive techniques. *C. Vaccarella, F. Papa, M. B. Majolini, V. Mazzucchi, A. Luciano, M. CA. Rongioletti.* Clinical Pathology Department, San Giovanni Calibita Hospital, Rome, Italy.

Introduction. The present study, investigated the frequency of mutations in the CFTR gene, in a group of consecutive patients candidate for assisted reproductive techniques with the aim of identify subjects carriers of the most severe ones. **Methods.** 22,416 alleles were screened for 56 CFTR gene mutations utilizing the CFTR INNO-LiPA**Results.** CFTR mutations were detected in 6. 2% of the screened alleles. In the large group of alleles analyzed 93. 4% were wt, 4. 4% were characterized by mild mutations, and 1. 7% by severe or severe/mild mutations. Indeed, the most common severe mutation was ΔF508/N observed in 192/22,416 (0. 86%) of all alleles analyzed, followed by the N1303K mutation with the frequency of 36/22,416 (0. 16%). Whereas regarding mild mutations, the most frequent was the 5T polymorphism present in 916/22,416 (4. 1%). **Conclusions.** Our results together with previous studies, reinforce the importance of an accurate determination of mutations in the CFTR gene, including the 5T polymorphism, in order to inform the couple of their carrier risk and the possibility on having affected child. Moreover, our findings highlight the potential of genetic screening as a tool to identify possible compound heterozygous subjects without CF-like symptoms.

Detection of Translocations in Clinical Cancer Samples using Targeted NGS Data. *S. Agrawal, R. Bettadapura, K. Sandhu, H. Adil, B. Singh, M. Sen, K. Kumari, D. Vishwanath, G. Deshpande, V. Gupta, S. Katragadda, R. Gupta, V. Veeramachaneni.* Strand Life Sciences, Bangalore, Karnataka, India.

Introduction: Chromosomal translocations are one of the primary genetic alterations behind various cancers and therefore detecting them is crucial for cancer therapeutics. Traditionally, oncologists have used single gene testing of hotspot mutations along with IHC (Immunohistochemistry) for copy number variants (CNVs) and FISH (Fluorescence In Situ Hybridization) for translocations to determine the course of therapy for patients. However, recently targeted sequencing of multiple genes is emerging as an attractive alternative in the clinical setting. Here, we demonstrate how a combination of a custom panel design and development of bioinformatics tools for structural variant (SV) detection has enabled the identification of known and novel translocations in somatic cancer samples along with point mutations, small indels and CNVs. **Methods:** A custom panel was designed to detect mutations including SNVs, small Indels and CNVs in regions of 152 genes known to be important for solid cancer therapeutics. Additionally, it was designed to detect gene fusion events that would occur as a consequence of translocations in the ALK, RET and ROS1 genes. Targeted sequencing was performed on >30 clinical samples, including lung, thyroid, breast and colon cancer samples, at an average depth of coverage of >300x. A new algorithm was developed to allow for split alignment of reads that don't align with a high score (>95) to the reference genome. Split alignment splits an input read into two segments, mapping each segment to a different location on the reference. Based on the split reads, a structural variant caller was developed to call out large deletion, insertion, inversion and translocation events. This method is now integrated into StrandNGS v2. 5, which was used to perform all analysis. **Results:** Using a threshold of 10 unique supporting reads, ~20% of the samples were found to have a translocation event involving at least 1 of the 3 genes mentioned above. These included known translocation events such as CCDC6-RET fusion in thyroid cancer as well as novel events involving the ALK gene in lung cancer. We have further confirmed a few of these translocations by RT-PCR. Thus, we have demonstrated that by using a targeted sequencing panel and a structural variant detection method based on split read alignment, we can successfully detect known and novel translocations in clinical cancer samples, thereby increasing the therapeutic yield of a single NGS-based test.

2088F

Report of a patient with cystic fibrosis and homozygosity for the Q1100P *CFTR* variant. *K. E. Singh[1,2], K. Lai[1], P. Do[1], E. Nussbaum[1,2].* 1) Miller Children's Hospital, Long Beach, CA; 2) University of California, Irvine, Irvine, CA.

Variants of uncertain significance (VUS) continue to evoke frustration among clinicians and families, even in well-characterized genes such as *CFTR.* In the absence of published clinical or functional information testing laboratories must rely largely on internal data in calling sequence variants as potentially disease causing, which can result in different laboratories making different decisions on sequence changes. Until functional studies become more easily attainable, as clinicians we desire clinical data on other patients with the same variants to aid in our own interpretation. We argue for more public reporting from clinicians and laboratories on patients with these suspected pathogenic variants. We present a Guatemalan infant of consanguineous parents with elevated immunoreactive trypsinogen (IRT) by California newborn screen, failure to thrive, pancreatic insufficiency, abnormal sweat chloride, and a homozygous VUS in *CFTR.* At five weeks he was admitted to the hospital for failure to thrive and diaphoresis with feeds. IRT on newborn screen was elevated but *CFTR* common mutation panel was normal. His sweat chloride was elevated at 90 mmol/L and fecal elastase was low at 85 and 45 µg/g on two separate occasions. *K. pneumonia* grew on respiratory culture. His weight gain improved with pancreatic enzyme supplementation but at five months he was only at the 5th centile. He was given a clinical diagnosis of cystic fibrosis (CF) (AHC [MIM 219700]). *CFTR* sequencing and deletion/duplication analysis identified a homozygous VUS, p. Q1100P (c. 3299A>C). Q1100P has been published in at least four individuals with a clinical diagnosis of CF; however, their second mutation was unknown. The testing laboratory for our patient does a high volume of *CFTR* testing and has seen this mutation in one individual with a clinical diagnosis of CF and a second mutation, but phase was unknown. Q1100P has not been reported in either dbSNP or 1,000 genomes. The amino acid position is highly conserved among vertebrates and *in silico* analyses were conflicting. Functional data is not available. Given the clear clinical diagnosis in our patient, the expectation for homozygosity given known consanguinity, and the available information on this variant we believe Q1100P is the molecular cause for our patient's CF diagnosis. Additional clinical information on other patients with this VUS as well as functional data can help clarify whether this VUS should be reclassified as disease causing.

2089W

Development and Implementation of a Bioinformatics Framework to Address Pseudogenes in Clinical Whole-Exome Test. *K. Cao[1], Z. Yu[1], KM. Gibson[1], BH. Funke[2], AB. Santani[1,3], M. Sarmady[1].* 1) Pathology, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Laboratory for Molecular Medicine at PCPGM, Boston MA; 3) Dept. of Pathology & Laboratory Medicine, University of Pennsylvania, Philadelphia PA.

Emerging applications of next-generation sequencing (NGS) in clinical settings have enabled genetic diagnostics labs to interrogate thousands of genes simultaneously (e. g. whole-exome). To ensure the quality of all aspects of the NGS test including sequencing, data analysis and interpretation, the College of American Pathologists (CAP) checklist requires clinical laboratories to perform stringent validation testing. A compounding factor that could significantly impact data quality is pseudogenes and highly repetitive regions. Alignment of sequence data in these regions poses significant challenge is inherently challenging, and result in false positive and false negative calls. We have developed and implemented a framework to identify and annotate "pseudo" exons for clinical whole exome-sequencing (WES) testing. For each coding exon, we assign a score between 0 and 1, named PseudoScore (PScore). PScore is calculated based on ENCODE mappability track of UCSC Genome Browser (GRch37). 100mer window size track was chosen to match the read length used for WES. We queried the mappability score for each base pair in the coding exon of all genes and generated the exon level PS by averaging the mappability scores in the region. The PScore correlates to mappability of the exon. As such, a PScore of 1 indicates the genomic sequence of the coding exon is uniquely mapped to the genome while a PScore of 0. 5 means there is another copy elsewhere in the genome and likewise 0. 33 suggests the presence of another two copies and so on. We found that 3,373 RefSeq genes (17. 5%) have at least one coding exon with various levels of sequence homology (PScore < 1) in the genome. Specifically, 1,078 genes have one or more sequence copies of whole coding exon(s) elsewhere (PScore $\leq$ 0. 5). PScores for all the coding exons were pre-calculated, and used as an annotation resource to specifically highlight variants located in an exon with PScore $\leq$ 0. 5. When a pathogenic variant is flagged, the laboratory confirms the origin of the variant by Sanger sequencing. In summary, we proposed a framework to identify pseudo-exons by assigning a PScore to each exon to quantify the level of homology of the exon. This framework can be used by clinical labs offering NGS-based diagnostics tests to fulfill CAP validation requirements and it further enhances reliability of their tests. This may help to flag potentially false variants caused by presence of pseudogenes or repetitive regions in the genome.

2090T

Comparing gene panel and augmented exome tests using a gold-standard dataset. *G. Chandratillake, G. Bartha, A. Patwardhan, D. Church, S. Garcia, R. Chen, J. West.* Personalis, Inc. , Menlo Park, CA.

Assessing the sensitivity and specificity of next-generation sequencing (NGS) based tests poses a challenge as it requires reference samples with known variants in all genomic regions that are included in the assay. Such gold-standard datasets have only recently been available for a subset of the genome. The Genetic Testing Reference Materials Coordination Program (GeT-RM) is a CDC initiative that aims to improve the availability of appropriate and characterized reference materials for genetic testing. These materials can be used by the genetic testing community for quality control, proficiency testing, test development and validation, as well as for research. In an effort to characterize the variants in reference samples, several clinical testing labs have run clinical gene panel tests on these samples and contributed their variant data to the GeT-RM. Together with data from the National Institutes of Science and Technology Genomes in a Bottle Consortium (GIAB), this data constitutes high-quality variant datasets that labs developing new NGS tests can use to assess analytical validity. We compared the gene panel test data submitted to the GeT-RM by clinical labs for reference sample NA12878, to the gold-standard data produced for this sample by GIAB. We also compared the results to those achieved with an augmented exome assay developed by our lab: the ACE Clinical Exome Test. Most of the panels are 100% covered by ACE capture regions and nearly all of the remaining panels are also covered. Taken together, we found that the sensitivity and specificity of the ACE Clinical Exome Test was comparable to most gene panel tests for those genes specifically targeted in the panels. In many instances, the number of false positives and false negatives obtained was lower with the ACE Clinical Exome Test than obtained with gene panel tests. Increased standardization and transparency in reporting accuracy data for NGS tests will facilitate test selection by healthcare providers and therefore ultimately benefit patients.

2091F

Microcephaly panel testing reveals an exon-level CASK deletion in a patient with a previously inconclusive whole exome sequencing result. *A. Shanmugham[1], G. Morley[2], G. Hoganson[2], D. Pineda[1], K. Wierenga[1], D. Tan[1], G. Richard[1], T. Brandt[1].* 1) GeneDx, Gaithersburg, MD; 2) Rockford Memorial Hospital, Rockford, IL.

The CASK gene encodes the calcium/calmodulin-dependent serine protein kinase, a member of the membrane-associated guanylate kinase (MAGUK) scaffolding protein family. Mutations in the CASK gene are inherited in an unusual X-linked manner, as heterozygous females develop mental retardation and microcephaly with pontine and cerebellar hypoplasia (MICPCH), while males may have isolated intellectual disability or FG syndrome (FGS, Opitz-Kaveggia syndrome). Here we present a 28 year old female with severe microcephaly, intellectual disability, seizures and cerebellar hypoplasia noted on brain MRI. Whole exome sequencing and mitochondrial genome testing was performed at GeneDx. Results revealed a heterozygous nonsense mutation in the CEP152 gene, which is associated with autosomal recessive Seckel syndrome and autosomal recessive primary microcephaly type 9 (MCPH9) without significant cognitive impairment, short stature or other dysmorphic features. It was noted that exon 22 of CEP152 lacked sufficient coverage in the proband by exome analysis. Subsequent exon-level copy number analysis of CEP152 was negative, thus excluding the presence of an intragenic deletion or duplication on the other allele. As the whole exome sequencing results were not diagnostic, a multigene panel, including sequencing and deletion/duplication analysis of the CEP152 gene and 27 additional genes associated with primary and secondary microcephaly was performed. This panel identified the nonsense mutation in CEP152; however, it also identified a partial deletion of 609 kb including exon 10 of the CASK gene, which is predicted to result in haploinsufficiency. Although this specific deletion has not been reported previously, other exon-level intragenic deletions and duplications as well as protein-truncating sequence variants are a common cause of CASK-related disorders. Therefore, the presence of this intragenic deletion is consistent with a diagnosis of MICPCH in the proband. This result highlights the utility of a multigene panel that includes both exon-targeted deletion/duplication and sequencing analysis as well as the limitations of whole exome sequencing in identifying small copy-number changes.

2092W

DFNB4 linkage analysis and *PDS* mutation detection in Iranian patients with deafness. *N. Yazdanpanahi[1], M. A. Tabatabaiefar[2], E. Farrokhi[3], M. Hashemzadeh Chaleshtori[3].* 1) Department of Biochemistry, Falavarjan Branch, Islamic Azad University, Iran, Isfahan, Iran; 2) Department of Medical Genetics, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran; 3) Cellular and Molecular Research Center, School of Medicine, Shahrekord University of Medical Sciences, Shahrekord, Iran.

Introduction: Mutations of *PDS* (SLC26A4) are associated with recessive non-syndromic deafness (DFNB4) and Pendred syndrome (PS). To date only a little is known about *PDS* mutations in Iran. In the present study the prevalence and types of *PDS* (*SLC26A4)* mutations and the relevant phenotypes in a series of Iranian patients with deafness were investigated **Methods**: Sixty patients and 61 unrelated families were included in the current study. In the 61 families, linkage was conducted for at least 4 informative short tandem repeats (STRs) of the DFNB4 locus. Selected individuals from the linked families and all of the 60 deaf individuals were subjected to sequencing of *SLC26A4*. Temporal bone CT-scan, thyroid ultrasonography and hormone assays were used to identify phenotypes of patients. **Results:** Seven out of 61 (11. 5%) families were shown linkage**.** Twelve mutations including: c. 2106delG, c. 65-66insT, c. 881-882delAC, c. 863-864insT, c. 1226G>A, c. 1238A>G, c. 1334T>G, c. 1790T>C, c. 1489G>A, c. 919-2A>G (IVS7-2A>G), c. 1412delT and c. 1197delT, were clarified in 9. 1% (12 families or patients) of total investigated alleles. Six out of 12 (50%) families with mutations had pendred syndrome (PS). **Conclusion**: The results probably suggest the high prevalence and specificity of *SLC26A4* mutations among Iranian deaf patients. It may lead to clarification of the population-specific mutation profile which is of importance in molecular diagnostics of deafness.

Clinical laboratories collaborate to resolve variant interpretation differences in ClinVar. *S. M. Harrison[1,2], J. S. Dolinsky[3], L. Vincent[4], A. Knight Johnson[5], E. C. Chao[3], D. M. Azzariti[1], S. Bale[4], H. L. Rehm[1,2].* 1) Laboratory for Molecular Medicine, Partners HealthCare Personalized Medicine, Cambridge, MA; 2) Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 3) Ambry Genetics, Aliso Viejo, CA; 4) GeneDx, Gaithersburg, MD; 5) Human Genetics, University of Chicago, Chicago, IL.

Recent efforts by the ClinGen Project (http://www. clinicalgenome. org/) to support widespread data sharing using the ClinVar database have allowed clinical laboratories to share variant interpretations that previously had been unpublished or unavailable to the larger community. In March, ACMG published guidelines for variant interpretation that provide a framework to classify variants; however, given the complexity of variant interpretation, application of guidelines still require subjective interpretation. In addition, many variants in the literature or reported in ClinVar, were assessed prior to the availability of these new guidelines. Four clinical laboratories have been working together to resolve these differences. As of June 1st 2015, Ambry Genetics, GeneDx, the Laboratory for Molecular Medicine (LMM), and University of Chicago's Genetic Services Laboratory, have shared 9822, 11706, 12092, and 7127 variant interpretations in ClinVar, respectively, resulting in 4879 unique variants interpreted by ≥2 of the four participating labs. Of these variants, 572 (12%) have one- or two-step differences between the three major categories: pathogenic/likely pathogenic, variant of uncertain significance, and likely benign/benign. To aid in understanding the basis for differences, non-identical interpretations were categorized as follows: Differences in Classification Algorithms (e. g. frequency thresholds), Difference in External Evidence (e. g. different data sources used), Differences in Internal Evidence (e. g. proband phenotype or segregation data), and Differences in Subjective Interpretation of Evidence. Identifying reasons for these differences enables the development of more specific guidance for variant interpretation and increases consistency amongst classifications. Preliminary data suggest the reasons for differences are variable and include all of the above. As the four participating clinical labs work through the 572 differences, trends are emerging to facilitate resolution of differences in bulk as opposed to evaluating variant-by-variant. Thus, data sharing through ClinVar offers a unique opportunity to identify classification differences between laboratories and to work together to resolve differences and strengthen the interpretation of variants that are used in patient care.

Beyond the ACMG 56: Parental choices and initial results from a comprehensive whole genome sequencing-based search for predictive genomic variants in children. *M. S. Meyn[1,2,3,4,5], N. Monfared[2], C. R. Marshall[6,7], D. Merico[1,6], D. J. Stavropoulos[7,8], R. Z. Hayeems[2,9,10], M. Szego[6,10,11], R. Jobling[4], M. Girdea[1,12], G. D. Bader[3,13], M. Brudno[1,12], R. D. Cohn[1,2,3,4,5], S. W. Scherer[1,2,3,6,14], R. Zlotnik Shaul[5,10,15], C. Shuman[3,4], P. N. Ray[1,2,3,6,7], S. C. Bowdin[2,4,5].* 1) Program in Genetics and Genome Biology, Hospital for Sick Children, Toronto, Ontario, Canada; 2) Centre for Genetic Medicine, The Hospital for Sick Children, Toronto, ON, Canada; 3) Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada; 4) Division of Clinical and Metabolic Genetics, Dept of Paediatrics, The Hospital for Sick Children, Toronto, ON, Canada; 5) Department of Paediatrics, University of Toronto, Toronto, ON, Canada; 6) The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, ON, Canada; 7) Department of Paediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada; 8) Department of Laboratory Medicine and Pathology, University of Toronto, Toronto, ON, Canada; 9) Program in Child Health Evaluative Sciences, Hospital for Sick Children, Toronto, ON, Canada; 10) Joint Centre for Bioethics, University of Toronto, Toronto, ON, Canada; 11) Centre for Clinical Ethics, St. Joseph's Health Centre, Toronto, ON, Canada; 12) Department of Computer Science, University of Toronto, Toronto, ON, Canada; 13) The Donnelly Centre, University of Toronto, Toronto, ON, Canada; 14) McLaughlin Centre, University of Toronto, Toronto, ON, Canada; 15) Department of Bioethics, The Hospital for Sick Children, Toronto, ON, Canada.

Paediatric genomic medicine presumes that knowledge of a child's genomic variants can be used to anticipate, diagnose and manage disease. A challenging aspect of this clinical paradigm is the identification of presymptomatic health risks in children through active searches for predictive (secondary) medically actionable genomic variants (MAVs). We are investigating this issue through the SickKids Genome Clinic, a multidisciplinary research project that carries out whole genome sequencing on 150+ children/year who are undergoing clinical genetic evaluations. With parents' permission, we search their child's genomes for predictive MAVs in 2800+ disease genes listed in the NIH Clinical Genomic Database. Of 373 families approached to date, 208 (56%) agreed to participate in the project and therefore receive their child's predictive childhood-onset MAVs. 131/208 (63%) participants also chose to learn their child's secondary adult-onset MAVs. Among these parents, 104/131 (79%) decided to learn their own status for the same risk variants. Consent involved multiple encounters with parents taking an average of ~9 days to reach a decision. Parents declining secondary variants were most concerned about psychological burdens and/or insurance discrimination. Bioinformatics analysis of the first 80 patient genomes yielded 2382 candidate variants in 1117 genes that were then manually assessed (~30 variants/genome.) While ~15% were novel, ~70% of candidate variants were listed in HGMD and/or ClinVar. However, most variants listed in HGMD as disease-causing failed manual assessment. E. g. , >90% of variants for dominant diseases listed in HGMD as disease causing were rejected due to inadequate evidence of pathogenicity. After manual assessment, 24/80 (30%) of children had at least one reportable predictive MAV. 7/80 (~8%) of children had a reportable predictive MAV in one of the 56 ACMG genes. Expanding our search 50 fold to include 2800+ disease genes yielded an additional 20 reportable predictive MAVs. 5/27 MAVs predicted adult-onset disease. Return of predictive MAVs and assessment of their penetrance is currently underway. We conclude that parental opinions vary widely regarding return of predictive MAVs; comprehensive genomic searching can yield predictive MAVs in ~30% of children; most predictive MAVs are associated with childhood-onset disorders; and the number of reportable predictive MAVs is constrained by disease prevalence and imperfect variant interpretation.

Clinical diagnostic pipelines at the Exome Laboratory in Baylor Miraca Genetics Laboratories. *Y. Ding[1], J. Chandarana[2], L. K. Dolores-Freiberg[3], W. Liu[1], J. Ma[3], S. Matakis[3], P. G. Otenyo[3], C. Qu[2], N. Saada[3], R. C. Glenn[1], N. Veeraraghavan[1], T. Chiang[1], A. C. Hawes[1], H. Doddapaneni[1], C. J. Buhay[1], J. Hu[1], M. Wang[1], V. Korchina[1], H. Cui[2], J. Scull[2], A. L. Beaudet[2], R. A. Gibbs[1], C. Eng[2], D. M. Muzny[1], Y. Yang[2].* 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX 77030, USA; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030, USA; 3) Baylor Miraca Genetics Laboratories, Houston, TX 77021, USA.

The Exome Laboratory at Baylor Miraca Genetics Laboratories (BMGL) has been providing clinical Whole Exome Sequencing (WES) services since October 2011. To date, approximately 6500 germline WES cases and 230 cancer/normal pair WES (CES) cases have been sequenced on the Illumina HiSeq2500 or HiSeq2000 with average of >11. 4 Gb data per WES, 17. 5 Gb per CES respectively and more than 97% of the targeted exome regions sequenced at a depth of 20X (average coverage >140X per WES and >212X per CES). In order to generate WES data with enhanced gene coverage and to improve our overall turnaround time (TAT), multiple process improvement measures have been implemented, including WES Version 3 capture reagent, which polishes the coverage of over 3600 known disease genes, a quick WES with overnight hybridization (QWES) for enabling five working days of TAT in the wet lab as well as automation using Biomek Beckman FXP (Laboratory Automation Workstation) dual arm robots in library construction for high throughput sample preparations. . In addition to regular proband only and trio exome testing, the lab also offers prenatal trio exome and critical trio exome with an overall TAT of 2-3 weeks for final clinical report. Gene panel tests include custom gene panel test BluePrint, for which referral physicians can order any genes of interest, as well as a panel of 168 autosomal recessive genes for universal carrier testing. The latter is a new test launched in our laboratory recently with quick TAT (14 days from sample intake to final clinical report) and high throughput by utilizing QWES and automation. In summary, the high capacity and short TAT for exome and panel tests has enabled the laboratory to provide exceptional service to patients and clinicians.

2096T

Interpreting Exome Data Using Selection-Based Prioritization. *J. T. Shieh[1,2], H. Gong[2], X. Ge[2].* 1) Institute for Human Genetics, University of California, San Francisco, CA; 2) Division of Medical Genetics, Pediatrics and Benioff Children's Hospital, University of California, San Francisco, CA.

Purpose: Exome sequencing is widely available, but significant challenges lie in data interpretation. To increase the yield from exome sequencing efforts, unbiased prioritization can be used for variants in sparsely annotated regions of the exome. **Methods**: Here we developed a strategy to evaluate any coding region in the genome for disease priority based on signature of purifying selection regardless of prior annotation. Thereby any variant from exome testing could be flagged if in critical coding regions. We performed exome-wide analyses using thousands of control adult exomes and determined coding regions that lack amino acid-altering variation. We tested for missense-depleted regions (MDRs) and corresponding protein characteristics to identify regions for potentially key conditions that limit reproductive fitness. We also apply these methods to inconclusive exome data from undiagnosed disease patients from our institution. **Summary of Results**: Genes with missense depletion demonstrated modest overall enrichment for disease genes (Orphanet/OMIM annotated). A greater difference in disease prioritization by missense depletion was identified in genes for x-linked conditions, suggesting optimized utility in that mode of analysis. Exome-wide scanning revealed MDRs in genes (n=239), including ones that align with conserved protein domains. By applying missense depletion analysis to undiagnosed pediatric disease exomes from patients with abnormal brain MRIs, we identify new candidates for disease. Further application of these methods will identify genes for severe conditions, including neonatal and childhood diseases that should be prioritized in clinical interpretation.

2097F

Successful linkage analysis in classical phenylketonuria families followed by direct sequencing and mutation detection. *S. Tabei, M. Silawi.* Shiraz Medical School, Shiraz university of Medical Sciences, Shiraz, Fars, Iran.

Introduction: Phenylketonuria (PKU) is the most common disorder of inborn errors of metabolism. Prevalence of PKU is about 1:10000 live births; however, due to high rate of consanguinity in Middle East and North of Africa prevalence of PKU is more than other areas. It is estimated between 1:4000 in Turkey and 1:3672 in Iran. **METHODS***:* Ten irrelated classical PKU families from Iran-Fars province were enrolled. Linkage analysis was performed through application of highly linked genetic markers to the *PAH* gene (VNTR, PAHSTR, and *Xmn*I marker) with new designed primers for polymerase chain reaction (PCR). Reliability of approach was assessed by Sanger sequencing, mutation detection and capillary electrophoresis (CE). **RESULTS***:* Through application of linkage analysis nine out of ten families were genotyped successfully. Heterozygosity of chromosome 12 was not detected in any of the enrolled PKU patients. Specificity of new designed primers for linkage analysis was confirmed by Sanger sequencing. Obtained results from linkage analysis were confirmed by direct sequencing and detecting causative mutations in half of the genotyped families. All the results were the same as the linkage analysis results. Labeled primers were capable and linkage analysis by CE was successful. **CONCLUSION***:* Linkage analysis is a powerful and reliable approach for detecting carriers in PKU families which are not screened for causative mutations before. We suggest studying the feasibility of the approach in preliminary diagnosis of PKU and confirming autozygosity of chromosome 12, prenatal diagnosis and preimplantation genetic testing. Also we recommend using labeled primers for constructing faithful local PKU associated haplotypes databases to provide fast, cheap and reliable detection of causative mutations in new cases of hyperphenylalaninemia.

Genetic variation in the *SMAD3* gene is associated with knee osteoarthritis in north Indian population. *A. ch. Sharma[1], R. N. Srivastava[1], A. Mishra[1], S. R. Srivastava[1], K. Baghel[1], S. Raj[2].* 1) orthopaedic surgery, king george medical university, Lucknow, Uttar Pradesh, India, India; 2) MS Ramaiah Medical College - Bangalore.

Introduction: Osteoarthritis (OA) is the most common degenerative arthritis, a type of arthritis that is caused by breakdown of articular cartilage with eventual loss of the cartilage of the joints. Smad3 is a key intracellular messenger in the transforming growth factor b signaling pathway. Previous study suggested Smad3 gene mutation is a possible predisposing factor for human OA and found gene mutation in OA, providing insight into the function of SMAD3 mediated TGF-b signals in the development of OA and also suggested that Smad3 gene mutation may be a risk factor for genetic susceptibilities to OA. In this case control study, we investigated the possible correlation between the SNPs SmaI (C/T; rs6494629), FokI (A/C; rs2289263) in Smad3 gene and susceptibility to knee OA. **Material & Methods**: This study was conducted in the department of Orthopaedic Surgery, King George's Medical University (KGMU), Lucknow. In this study cases consisted of men and women ≥40 years that fulfilled American College of Rheumatology (ACR) clinical and radiographic criteria for knee OA. Venous blood samples were obtained from all cases as well as controls for genetic analysis. Polymerase chain reactions were performed for SNP analysis using specific primer. **Results:** A total of 200 cases that confirmed radiographic knee OA and equal number of age and sex matched healthy controls were enrolled. There was no significant difference in demographic characteristics between the cases and controls. SNP (rs6494629 and rs2289263) mapping to intron 1 of SMAD3 was observed to be associated with knee OA. Within the SNP rs6494629 of Smad3 gene, genotype TT (p=0. 013) and CT (p=0. 009) was found to be significantly associated with knee OA as compared with the CC genotype; within SNP rs2289263, genotype CC (p=0. 04) and CA (p=0. 02) was found to be significantly associated with knee OA as compared with the AA genotype . **Conclusion:** Our data indicate that genetic variation in the SMAD3 gene may be involved in the risk of knee OA in North Indian populations, confirming the results from previous studies on the potential importance of this gene in the pathogenesis of OA.

2099T

Miniaturized next-generation sequencing (NGS) library preparation and quantification - ultra low sample input and ultra low cost libraries. *S. Vaezeslami[1], J. Jenkins[1], C. Frazer[2], B. Paeper[2], B. Yu[3], S. Quake[3], R. Morey[4], S. Mora-Castilla[4], L. Laurent[4], B. Peters[5].* 1) TTP Labtech Ltd, Melbourn Science Park, Melbourn, Rosyton, Hertfordshire, SG86EE, UK; 2) University of Washington, School of Medicine, Department of Genome Sciences, 3720 15th Ave NE, Seattle WA 98195, USA; 3) Stanford University, Lokey Stem Cell Building, Stanford, CA 94305; 4) University of California, San Diego, 9500 Gilman Drive, La Jolla, CA 92093, USA; 5) Complete Genomics, A BGI company, 2071 Stierlin Court, Mountain View, CA 94043, USA.

Miniaturized next-generation sequencing (NGS) library preparation and quantification - ultra low sample input and ultra low cost libraries Miniaturization of reaction volumes in different molecular biology applications such as next-generation sequencing (NGS), Gateway® cloning (Life Technologies), and quantitative PCR, has become of great interest in recent years. In the case of sequencing, this is due to a significant reduction in the cost per base pair allowing for high throughput applications, such as single cell nucleic acid sequencing, haplotyping and multiplexing. There are also a number of preparation steps in NGS that would benefit from a reduction in reaction volumes, such as reverse transcription of RNA. Almost all library preparation protocols recommend volumes that are within the volume range of manual pipettes, or that of larger volume liquid handlers. This is to ensure high accuracy and precision of these procedures. Our aim was to reduce the reaction volumes to sub-microlitre values without any changes in final results, thereby saving costs on reagents and sample input, and increasing the throughput. Pipetting of these reduced volumes was performed using an automated low volume liquid handler, mosquito HTS (TTP Labtech, Ltd). Specifically, we will discuss several examples of miniaturized library preparations, such as Nextera and Nextera XT (Illumina, Inc.), reverse transcription using SMARTer Ultra Low RNA Kit (Clontech Laboratories, Inc), and DNA quantification using Kapa SYBR® Fast qPCR kit (Kapa Biosystems, Inc). Here, for the first time, we demonstrated that by using an ultra-low volume liquid handling, we were able to reduce the input of RNA or DNA down to 20 pg, while the miniaturized processes produced high quality libraries and library quantifications comparable to larger volume libraries or reactions. This also provided dramatic cost saving benefits in sample preparation and quantification steps. Using a highly accurate and precise automated liquid handler allows for the miniaturization of a number of processes involved in cloning or next-generation sequencing without compromising the quality of the results. mosquito HTS provides contamination-free, positive displacement, accurate pipetting, which is highly reproducible without any operator error.

2100T

Fetal Jugular Lymph Sacs - What is the Significance? *D. Chitayat[1,2], K. Chong[1,2], M. Bedford[4], A. Toi[3], M. M. Nezarati[1,2,4].* 1) Prenatal Diagnosis and Medical Genetics, Mount Sinai Hosp, Toronto, ON, Canada; 2) Department of Obstetrics & Gynecology, Mount Sinai Hospital, Toronto, ON, Canada; 3) Department of Medical Imaging, Mount Sinai Hospital, Toronto, ON, Canada; 4) Genetics Program, North York General Hospital, Toronto, ON, Canada.

Fetal jugular lymph sacs are accumulations of lymphatic fluid in the anterolateral region of the fetal neck. They may be isolated or occur in association with other structural anomalies and in some cases are presenting with an increased nuchal translucency or cystic hygroma. . Their significance and the guidelines for the prenatal investigation when identified in the course of routine ultrasonography in pregnancy are still controversial. Our protocol for the investigation of these cases includes microarray analysis and DNA analysis for the Noonan syndrome panel. We report our experience with ten cases of prenatally diagnosed isolated fetal jugular neck cysts identified in the last 5 years (Table 1).

Case	GA at detection of Jugular Sacs(weeks)	NT(mm)	Cystic hygroma	DNA analysis for the Noonan Syndrome Panel [GeneDX]	QF-PCR/ Microarray	Outcome
1	13. 7	1. 7	No	N/A	Normal	Normal newborn
2	18. 9	3. 5	No	PTPN11c. 215C>G	Normal	Continued Pregnancy
3	19. 1	7. 4	Yes	PTPN11c. 1381G>A	Normal	TA
4	16. 5	8. 5	Yes	PTPN11c. 184T>G	Normal	Continued Pregnancy
5	15. 8	3. 2	No	N/A	Normal	Normal newborn
6	16. 0	17. 5	Yes	N/A	Normal	TA
7	13. 1	na	No	N/A	Normal	Normal newborn
8	14. 9	16	Yes	SOS1 c. 806T>C	Normal	Continued Pregnancy
9	14	10	Yes	RAF1 c. 776C>T	Normal	TA
10	12. 5	8. 0	Yes	N/A	T21	TA

TA – Therapeutic Abortion; na – not available; N/A – not applicableIn 10 cases identified by us in the last 5 years, 50% had a pathogenic mutation in a Noonan syndrome Panel, one had trisomy 21 and none had abnormality on microarray analysis (in the case with T21 we stopped the analysis following the QF-PCR results). However, all cases with abnormal results had NT > 3. 5 mm or cystic hygroma. This study suggests that the identification of fetal jugular lymph sacs with an increased NT/cystic hygroma is associated with an increased incidence of Noonan syndrome and its related disorders and should instigate mutation analysis of the Noonan syndrome panel.

2101F

Prenatally diagnosed aqueductal stenosis (triventricular dilation) and postnatal/autopsy findings. Report on 100 cases. *R. Jobling[1,2], N. Amir[2], A. Toi[3], P. Shannon[4], K. Chong[1,2], D. Chitayat[1,2].* 1) Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, Ontario, Canada; 2) Mount Sinai Hospital, Department of Obstetrics and Gynecology, The Prenatal Diagnosis and Medical Genetics Program; 3) Department of Diagnostic imaging; The University of Toronto, Toronto, Ontario, Canada; 4) Department of Laboratory Medicine and Pathobiology; The University of Toronto, Toronto, Ontario, Canada.

Hydrocephalus is etiologically a heterogenous condition. Up to 66% of the cases of childhood hydrocephalus are the result of stenosis of the aqueduct of Sylvius (Aqueductal stenosis)(AS). Most AS cases present at an early gestation with fetal ultrasound/MRI finding of dilation of the lateral and 3rd cerebral ventricles and the differential diagnosis includes infection, hemorrhage, chromosome abnormalities and a variety of single gene disorders including Dandy-Walker malformation and *L1CAM syndrome*. In many cases the underlying cause cannot be delineated making genetic counseling difficult. We report our experience with 100 cases presented prenatally with triventricular dilation on fetal ultrasound/ MRI. Of the 100 pregnancies 64 were terminated and 36 were continued. There were 12 cases which ended in still birth. In 49 of these cases pathological examination confirmed the diagnosis and in the rest the aqueduct was not found occluded or there was no pathological examination. Of the confirmed cases of AS 15 were isolated and 34 were associated with other congenital anomalies. In 5 cases intra-cerebral hemorrhage was identified and none of these were the result of maternal alloimmune antiplatelet antibodies. In one case fetal infection was identified as a cause. L1CAM gene mutation was found in four cases and in all of these cases the mother was a carrier. Chromosome abnormalities were present in 10 cases (3 cases of trisomy 21, one case of trisomy 18, one case of 45, X, one case of mosaic trisomy 22, one case of an unbalanced translocation of chromosomes 6 and 7, a duplication at 2q11. 2, a duplication of 15p13. 33 and a 110 kb deletion at 2p16. 3). In most cases an underlying etiology could not be identified. This large cohort of patients with AS provides insight into the maternal characteristics, presentation, associated anomalies, etiology and outcome of this rare and anomaly.

2102T

A study of X and Y chromosomal variations in a large fertile childbearing-age population. *P. Kezmarsky[1], E. Kirkizlar[1], Z. Demko[1], S. J. Gross[1], P. Lawson[2], C. Samango-Sprouse[3].* 1) Natera Inc. , San Carlos, CA; 2) Focus Foundation, Davidsonville, MD; 3) George Washington University School of Medicine and Health Sciences, Washington, D. C.

X and Y chromosomal variations are among the most common human whole-chromosomal copy-number variations, yet 75% of these disorders go undiagnosed during the affected individuals' lifetime. Various pre- and post-natal studies have generated incidence and prevalence estimates of these commonly occurring X and Y chromosomal disorders, but the population-based incidence and prevalence in the fertile adult population remains unclear. This study provides the first prevalence estimate for these disorders in the population of fertile individuals of child-bearing age. This retrospective analysis of prospectively collected data leveraged a routine noninvasive prenatal screening test that incorporates maternal and paternal genotypes to estimate the population-based prevalence of X and Y chromosome variations in the fertile adult population. From 141,918 fertile women and 29,581 fertile men, 119 X and Y chromosomal abnormalities (overall prevalence: 1 in 1,441) were identified (See Table 1). Among the females, fertility in 45,X/46,XX mosaic women was higher than previously reported, and demonstrated that pregnancy in non-mosaic 45,X women is possible. This is also the first documentation of incidence and fertility in 48,XXXX women, and provides important information for families with this prenatal diagnosis and individuals with tetra-X. For both cases of 48,XXXX observed in this study cohort, the duplication was observed on the q-arm only; the p-arm was disomic. Among males, reduced reproductive capabilities in those with 47,XYY has been described for the first time and supports greater variability in reproductive capacities in these disorders than previously appreciated. Together, this study expands the knowledge of X and Y chromosomal variations, and is critical to families who receive a prenatal diagnosis of one of these disorders as well as to individuals who may confront fertility issues as adults.

Table 1. Chromosomal abnormalities in the fertile adult population.

Females	n	Observed Incidence, 1 in:	Males	n	Observed Incidence, 1 in:
Total Aneuploid	103	1,378	Total Aneuploid	16	1,846
45,X	43	3,300	47,XXY	2	14,766
45,X	3	47,306	47,XXY	1	29,532
45,X/46,XX Mosaic	40	3,548	46,XY/47,XXY Mosaic	1	29,532
47,XXX	30	4,731	47,XYY	10	2,953
47,XXX	18	7,884	47,XYY	9	3,281
46,XX/47,XXX Mosaic	12	11,827	46,XY/47,XYY Mosaic	1	29,532
48,XXXX	2	70,959	Partial Y Deletion	4	7,383
46,XX Uniparental Disomy	3	47,306			
46,XY (sex reversion)	2	70,959			
Mosaicism of Unknown Type	23	6,170			

2103F

Maternal copy number variants are a significant reason for false positive noninvasive prenatal test results. *D. I. Chudova[1], K. J. Curnow[1], S. Bhatt[1], A. J. Sehnert[1], D. W. Bianchi[2].* 1) Illumina, San Francisco, CA; 2) Mother Infant Research Institute, Tufts Medical Center, Boston, MA.

Background: Noninvasive prenatal testing (NIPT) has been rapidly integrated into care for pregnant women at high risk for fetal aneuploidy. For low-risk women, a lower prevalence of aneuploidy results in lower positive predictive values (PPVs). Because PPVs are largely driven by specificity, we focused on reducing false positive NIPT results, including those that are due to the presence of maternal copy number variants (CNVs). Methods: Two primary modifications were made to the informatics algorithm in the clinical laboratory: additional sub-chromosomal coverage normalization steps and filtering. Normalization reduces variability in the sequencing data, whereas filtering over the chromosome ensures that outliers from sub-chromosomal maternal CNVs are excluded from the overall chromosome z-score. Here, we reanalyzed 11 false positive samples (5 trisomy 21, 2 trisomy 18, 3 trisomy 13, and 1 double trisomy 21/18) from the low-risk CARE study cohort (Bianchi *et al* NEJM 2014) using the updated analytic algorithm. Results: Reanalysis resulted in 6 cases that changed from aneuploidy detected to no aneuploidy detected. Of these, 3 were attributed to the improved normalization, and 3 were attributed to sub-chromosome filtering of outlier data from maternal CNVs. One maternal CNV was a duplication of ~3 Mb on chromosome 18p and two were duplications on chromosome 13q (one was ~5 Mb and the other ~8 Mb). These CNVs were identified in two independent blood samples from each individual. For the 5 cases that remained positive for aneuploidy, the sequencing results were consistent with a complete fetal chromosome gain on the previously identified affected chromosome. The corresponding newborns were all born at term, with no detectable physical abnormalities. Chromosome analyses were not performed on the infants or placentas. In the CARE study cohort, reanalysis with the refined algorithm increased the PPVs for trisomies 21 and 18 to 62. 5% (5/8) and 66. 7% (2/3), respectively. This compares with 45. 5% (5/11) and 40% (2/5) using the previous algorithm, and 4. 2% (3/72) and 8. 3% (1/12) using standard biochemical screening. Discussion: Maternal copy number variants are an increasingly recognized cause of false positive NIPT results. Continued informatics improvements in the analytic algorithm are of significant clinical value, particularly as the clinical population undergoing NIPT expands to include a greater proportion of lower-risk women.

Comprehensive Analysis of Clinical Performance of Harmony™ Prenatal Test. *R. Stokowski, A. Sparks, T. Musci, A. Batey, K. Song, A. Oliphant, E. Wang.* Ariosa Diagnostics, San Jose, CA.

Introduction: The core technology of the Harmony Prenatal Test is based on a targeted assay, Digital Analysis of Selected Regions (DANSR™) and a proprietary analysis algorithm, Fetal fraction Optimized Risk of Trisomy Evaluation (FORTE™). DANSR assays are targeted against chromosomes 21, 18, and 13 for fetal trisomy and other genomic regions to measure fetal fraction. FORTE analyzes DANSR products along with clinical information to provide a probabilistic assessment of fetal trisomy. Clinical performance of Harmony has been validated in multiple studies demonstrating high sensitivity and low false positive rates for Trisomy 21, 18 and 13 using various DANSR quantitation methods. (Sparks 2012, Ashoor 2013, Gil 2014, Nicolaides 2012, Norton 2012;2015, Verweij 2013, Juneau 2014) This study provides further clinical data using microarray for DANSR quantitation and a summary of overall performance of the Harmony test. **Methods:** Blood samples from 794 singleton, twin, natural and IVF pregnancies were collected for prenatal cfDNA testing in a prospective, multicenter, blinded study. Subjects either had invasive testing (amnio or CVS) for evaluation of fetal chromosome conditions or had karyotype at birth if aneuploidy was suspected at birth following newborn exam (twin samples only). Results of the Harmony test and karyotypes or birth outcomes were compared. Results from this study were combined with previously published studies on the performance of the Harmony test. **Results:** In the new study cohort, the mean maternal age was 35 years (range 18-48) and mean gestational age was 17 weeks (range 10-36). Using the Harmony test, T21 was identified in 106 out of 107 cases (99. 07%; 95% CI 95. 96-100. 00), T18 was identified in 28 out of 29 cases (96. 97%; 95% CI 86. 36-100. 00), and T13 was identified in 12 out of 12 cases. (100%; 95% CI 81. 60-100. 00). The specificity was 100% (95% CI 99. 58-100. 00) for trisomy 21, 18 and 13. Combining this dataset with previously published Harmony studies, the combined performance is:

Test	N	TP	FP	TN	FN	Sens	Spec	Sens 95% CI	Spec 95% CI
T21	23158	418	10	22727	3	99. 29	99. 96	98. 23-100	99. 93-100
T18	22402	147	5	22246	4	97. 35	99. 98	94. 23-100	99. 95-100
T13	14246	30	3	14211	2	93. 75	99. 98	82. 77-100	99. 95-100

Conclusion: Across multiple quantitation methods, the Harmony Prenatal Test with the core technologies of DANSR and FORTE demonstrates high sensitivity and extremely low false positive rates for the common autosomal trisomies in the general pregnancy population.

2105F

Population screening of 328,886 individuals reveals ethnic disparities in guidelines and cumulatively greater risk for severe recessive disease than for Down syndrome or neural tube defects. *I. S. Haque, G. A. Lazarin, M. Raia, H. Bellerose, D. Muzzey, K. D'Auria, H. P. Kang, E. A. Evans, J. Goldberg.* Counsyl, South San Francisco, CA.

Current US medical guidelines recommend universal ultrasound and serum screening in pregnancy for Down syndrome (T21, MIM 190685) and neural tube defects (NTDs, MIM 182940). Genetics guidelines recommend offering screening for cystic fibrosis (MIM 219700) and spinal muscular atrophy (MIM 253300) to all prospective parents and additional screenson an ethnicity-specific basis. The population risk for expanded panels of rare recessive diseases is an open question.

METHODS

We analyzed results of 328,886 tests for up to 110 Mendelian genes in a population reporting no family history, known carrier status, or infertility. Sample ethnicity was self-reported. 90% of tests used targeted genotyping of up to 417 known pathogenic sites; the remainder sequenced all exons and partial introns of the selected genes. We measured *SMN1* copy number by qPCR and *FMR1* 5'UTR CGG repeat count by PCR and capillary electrophoresis.

We interpreted novel variants using literature curation with ACMG guidelines and considered pathogenic those curated as known or likely deleterious [1]. We assigned diseases profound, severe, moderate, or mild severity by review of their symptoms [2].

From carrier frequencies, we computed the probability that a random birth would be affected by a disease (absolute risk). Fragile X syndrome absolute risk was weighted by allele size [3].

RESULTS

In all ethnicities the cumulative absolute risk of 89 severe/profound recessive diseases is larger than that of NTDs (1/1000) or of T21 in young mothers (1/1200, maternal age=20), conditions for which universal screening is recommended [4,5]. In African-Americans and the Ashkenazi Jewish, the cumulative risk of these 89 diseases is higher than that of T21 in the high-risk population (1/280, maternal age=35).

We also find ethnic disparities in care: current ACOG and ACMG guidelines have 1000x and 50x ratios respectively of absolute risk detected in Africans vs East Asians. Including 89 severe/profound diseases shrinks the maximum ratio to 4. 3x, indicating that low positive rates in current guidelines do not reflect the true distribution of disease risk.

We find no statistically significant difference between absolute risk computed from observed carrier-carrier couples and risk computed from carrier frequencies.

Next Generation Sequencing Assay Accurately Determines Carrier Status for Spinal Muscular Atrophy. *X. Wang, H. Y. Wan, C. B. Oyolu, K. R. Haas, D. Davison, K. Iori, C. S. Chu, I. S. Haque, E. A. Evans, H. P. Kang, D. Muzzey.* Counsyl, South San Francisco, CA.

INTRODUCTION: Spinal Muscular Atrophy (SMA) is a severe neuromuscular disease that is the second most common fatal autosomal recessive disorder. Nearly 95% of SMA-affected patients have *SMN1* genes that are rendered largely dysfunctional due to a splicing mutation that causes exon 7 to be preferentially omitted from the SMN protein. By convention, this single-base variant distinguishes *SMN1* from *SMN2*. Resolving SMA carrier status involves counting the number of *SMN1* genes and is traditionally determined through fluorescence-based readouts, such as allele-specific quantitative PCR or MLPA. However, these methods are relatively expensive, low throughput, and incapable of detecting novel variants. Here we report a high-throughput next-generation sequencing (NGS) method that naturally fits in the context of an NGS-based expanded carrier screen and accurately determines the *SMN1* and *SMN2* copy numbers in a sample.

METHODS: We designed hybrid-capture probes common to *SMN1* and *SMN2*. NGS reads were assigned to each gene according to the single base that distinguishes them in exon 7. Relative read depths were calculated by normalizing to the depth in regions elsewhere in the genome, where median copy number is expected to be two. Copy-number calls and associated confidence scores were calculated from a distance test that found the most likely integer copy number for each gene. Real-time quantitative PCR was used to confirm the NGS results.

RESULTS: On a set of more than 87,000 clinical samples including positive and negative controls, our NGS-based method correctly determines copy number of *SMN1* and *SMN2*, thereby resolving SMA carrier status with >95% detection rate. Since each of the tiled NGS probes individually contributes enough reads to call the copy number, the test avoids false positives that compromise the qPCR approach when a SNP is within a primer binding site. Finally, the NGS assay has higher accuracy across a broader dynamic range than qPCR, enabling confident copy-number calls in excess of two copies for *SMN1* and as many as six copies for *SMN2*.

CONCLUSIONS: We have developed an NGS-based assay for the most common cause of SMA that offers higher throughput, lower cost, and higher dynamic range than the current state-of-the-art standalone qPCR assays.

Establishing criteria for the return of results from genome sequencing for the purpose of carrier screening. *K. A. B. Goddard[1], P. Himes[2], L. Amendola[3], J. Berg[4], M. O. Dorschner[5], M. Gilmore[2], C. Harding[6], T. L. Kauffman[1], E. Morris[2], D. Nickerson[7], J. A. Reiss[2], C. S. Richards[6], A. F. Rope[2], D. K. Simpson[2], B. Wilfond[8], G. P. Jarvik[3].* 1) Ctr Hlth Res, Kaiser Permanente Northwest, Portland, OR; 2) Northwest Permanente, Kaiser Permanente Northwest, Portland, OR; 3) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 4) University of North Carolina Chapel Hill, Chapel Hill, NC; 5) Department of Pathology, University of Washington, Seattle, WA; 6) Oregon Health and Science University, Portland, OR; 7) Department of Genome Sciences, University of Washington, Seattle, WA; 8) Seattle Children's Research Institute, Trueman Katz Center for Pediatric Bioethics, Seattle, WA.

As part of the NHGRI Clinical Sequencing Exploratory Research (CSER) consortium, the NEXTGen study focuses on the use of genome sequencing in couples seeking preconception genetic screening. Although reporting carrier results from clinical sequencing is feasible and potentially relevant to individuals regardless of indication, these couples may have a greater near term interest in learning about and acting upon findings from carrier screening. We categorized the gene/condition pairs to facilitate patient autonomy in assuring that only requested information is returned. Secondary findings are also returned as part of this study. We established a Return of Results Committee (RORC) to develop criteria to select the genes/conditions to report in NEXTGen. The RORC includes expertise in clinical and molecular genetics, genetic counseling, bioethics, and epidemiology. We considered about 800 gene/condition pairs from commercial panels, publications, and contributions from RORC members. Gene/condition pairs were considered for 1) inclusion, and 2) categorization into one of five categories based on standardized criteria developed by the RORC. The RORC refined the criteria over time based on their experience, and a consensus was reached on each gene/condition pair. So far, 582 gene/condition pairs were determined appropriate for inclusion. Those that were excluded were primarily due to low evidence (e. g. , <2 people or <2 families). Based on participant feedback that they want to hear the worst case scenario, conditions with variable penetrance or expressivity were placed in the most serious category. The default category of serious encompassed the largest number (n=425) of conditions. To be categorized as lifespan limiting (n=186), more than 50% of known cases had to be deceased before the age of 10. Mild conditions (n=96) are typically not life threatening and there is only mild to moderate disruption of normal functions. Late onset (n=14) was defined as symptoms appearing for most people after the age of 20. Conditions with unpredictable outcomes (n=31) have a wide range of phenotypic expressivity that cannot be predicted based on genotype. Categorization is ongoing, but nearly complete. Placing conditions in non-overlapping categories required clear and precise category definitions, while accounting for wide variability in phenotypes. We are studying the utility of these categories for carrier screening.

Etiological Evaluation of Adverse Reproductive Outcome: A Large Study from South India. *A. Jyothy, A. Srilekha, K. Prasoona, T. Sunitha, A. Venkateshwari.* Institute of Genetics and Hospital for Genetic Diseases,Osmania University,Begumpet, Hyderabad, Telangana State, India.

Introduction: Adverse reproductive outcome (ARO) includes a wide variety of complications such as abnormal pregnancy, pregnancy loss, birth defects etc. The cause of reproductive abnormality could be the result of genetic, anatomic, endocrine, thrombotic, immunologic factors or physiological events that occur in mother, father and child. As there is a huge burden of these abnormalities in developing countries, we aimed to evaluate the causative factors in couples of South Indian origin with ARO. **Subjects and Methods:** The study included a total of 3927 couples with abnormal reproductive histories, referred to the Institute of Genetics and Hospital for Genetic Diseases and Modern Government Maternity Hospital, Hyderabad (March, 2010 to March, 2015). The pregnant women were organized into two groups: Group 1 included women carrying fetal congenital anomalies in present pregnancies (n=446) and Group 2 included women carrying normal fetuses with previous bad obstetric history and medical complications (n=3481). 3D/4D ultrasound scans and TORCH profiles were evaluated in all cases. Chromosome analysis in couples was done on peripheral blood lymphocytes using the standard protocols. Spectral karyotyping was performed to confirm the abnormal karyotypes. Prenatal diagnosis by amniocentesis has been carried out for evaluation of trisomies using FISH. **Results:** The study revealed 37% (n=165) of pregnancies carrying fetuses with central nervous system disorders as major congenital anomalies followed by 20% (n=88) renal anomalies. The seropositivity of Toxoplasmosis and Rubella were significantly higher in group 2 (p=0. 026) and group 1 (p<0. 01) respectively. Cytogenetic analysis in 1498 individuals revealed 5. 40% (n=81) chromosome abnormalities including 8. 64% (n=7) novel translocations. **Conclusion:** Adverse reproductive outcome continues to be a serious concern and cause of morbidity and mortality especially in developing countries and advanced screening methods have facilitated in early detection, appropriate management and counselling of these cases to reduce the burden.

Whole-genome amplified DNA from neonatal dried blood spot samples produces high-quality exome-sequence data. *M. V. Hollegaard[1], J. B. Maller[2,3], J. Grauholm[1], M. G. Pedersen[4,5], B. Neale[2,3], L. Olsen[6,5], C. Stevens[2], T. Hansen[6,5], P. B. Mortensen[4,5], T. M. Werge[6,7,5], D. M. Hougaard[1], M. J. Daly[2,3].* 1) Departnent Congenital Disorders, Statens Serum Institut, Copenhagen, Denmark; 2) Broad Institute of MIT and Harvard, Cambridge, MA, USA; 3) Analytical and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, USA; 4) National Centre for Register-based Research, Aarhus University, Aarhus, Denmark; 5) Lundbeck Initiative for Integrative Psychiatric Research (iPSYCH); 6) Mental Health Center Sankt Hans, Mental Health Services of Copenhagen, Roskilde, Denmark; 7) Institute of Clinical Sciences, University of Copenhagen, Copenhagen, Denmark.

Population based biobanks provide unique opportunities in the quest to understand the genetics of common and rare diseases. These repositories frequently contain millions of samples collected consistently over many years, and enable cost-effective and large scale studies while also minimizing bias. The Danish Neonatal Screening Biobank (DNSB) is the largest biobank in Denmark (by number of individuals), containing almost 2. 3 million neonatal dried blood spot (neoDBS) samples. This represents nearly the entire population of Denmark born since 1982. In addition Denmark have a unique system of very detailed health and social registries that are mutually connectable as well as linkable to existing biobanks. This allows researchers to study the etiology of numerous diseases in extraordinary detail. NeoDBS samples are precious and often very little material is available for research. To reach the recommended input amounts for NGS and array genotyping, the neoDBS DNA extract can be whole-genome amplified (wgaDNA). While this can be a robust process, it is critical to confirm technical consistency and accuracy for a particularly experimental design. Through exome sequencing and array genotyping of more than 1,000 samples we thoroughly evaluate the reliability and stability of neoDBS wgaDNA. First we addressed the reliability of wgaDNA by comparing genetic data from genomic DNA to wgaDNA from neoDBS. Second we use trios to quantify the de-novo mutation rate from wgaDNA. Third, we use a subset of samples with known 22q11 deletetions to evaluate if we can call large structural variations. Finally, we look at the robustness and usability of using wgaDNA from neoDBS by evaluating the exome-sequencing results of 600 case/control samples for Autism Spectrum Disorder. We demonstrate that neonatal DBS wgaDNA can be to produce high-quality genotype and sequence data. There are no signs of increased mutation rate, and the accuracy of genotype calls are comparable to standard genotyping approaches. That said few regions of the genome is not presented in the wgaDNA, suggesting a slightly sequence related bias of the amplification. Overall, this is overcome by the access to millions of samples, and the fact that the results produced are of high-quality.

2110T

An assessment of parental perspectives, understanding, and responses to fetal whole exome sequencing. *N. Vora[1], E. Hardisty[1], S. Robinson[1], C. Rini[2], D. Skinner[3]*. 1) Obstetrics and Gynecology, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Gillings School of Global Public Health; UNC Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) FPG Child Development Institute, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Statement of purpose: A fetal whole exome sequencing (WES) pilot study is ongoing at the University of North Carolina-Chapel Hill on non-viable fetuses. All have congenital anomalies suspected to have a genetic etiology not identified by standard prenatal genetic testing. One of the aims of this study is to assess parental perspectives, understandings, and responses to diagnostic WES information through semi-structured interviews. Methods used: Semi-structured interviews (approximately 45 minutes each) were conducted with both parents in in-person interviews to identify patient expectations, understandings, and perceptions after the genetic counseling and consent process. Mothers completed a pre-sequencing questionnaire and genetics literacy assessment following genetic counseling. Summary of results: Six parent-fetus triads were enrolled. Demographics were as follows: mean maternal age 30. 1 (range 25-38); 5/6 white, non-Hispanic; 6/6 had some college education; mean income $73. 7K (range $37. 5-135K); 4/6 had prior genetic testing; 3/6 planned future children; 6/6 legally married. The mean scores for a pre-sequencing genetics literacy assessment administered after genetic counseling was 92% (88-100%). The average perceived likelihood of the WES result to explain the loss was 6. 25/10; the average perceived likelihood of the WES result to provide information about parental health unrelated to the loss was 5. 2/10. From data obtained from the semi-structured interviews, 5/6 families verbalized that they hoped to obtain an answer to explain their fetal loss; 4/6 verbalized a desire to provide information that would help future families and research. Conclusions: In this pilot study, after being counseled about the ~30% chance of WES providing an answer, parents' perception of the likelihood that WES would provide an answer was higher. Most families verbalized their hope that WES would provide an explanation for their loss. This study suggests that families who have lost a baby with congenital abnormalities have high hopes and expectations about WES. More research needs to be performed to determine the diagnostic capability of WES in a prenatal setting and how family's expectations complicate pre-test counseling. .

2111F

All *FMR1* premutations are not equal: impact of frequency and repeat distribution on risk for fragile X syndrome. *G. A. Lazarin, K. Wong, I. S. Haque.* Counsyl, South San Francisco, CA.

Background:Instability in the *FMR1* gene can result in CGG repeat expansion, which in turn causes fragile X syndrome (FXS, OMIM 300624) when the repeat count exceeds 200. Premutations (55-200 repeats) have a greater risk of next-generation expansion to full mutation with increasing repeat size.

Previous studies have reported FXS prevalence of 1/4000-6000. There is evidence ofethnic predilection, but this is not well defined. Since the actualFXS risk in a population depends on both premutation frequency and allele sizes, we analyzed this data derived from our carrier screening.

Methods:Samples were considered only if no family history, known carrier status, or infertility history were reported. We also excluded those originating from ART clinics to avoid bias from premutation-inducedpremature ovarian insufficiency.

We report data from 134,840 individuals passing the above filters who were screened for FXS, including at least 2,789 in each of 10 self-reported ethnicities. *FMR1* 5'UTR CGG repeat count was assessed by PCR and capillary electrophoresis. Premutations were sub-divided according to previously described risk groups (Nolin 2003).

Results:Mean frequency of any premutationwas 1/383, with substantial ethnic variation:min 1/2857 in E Asians, max 1/182in Middle Easterners. The largest ethnic subgroup, NEuropeans, exhibited a frequency of 1/315.

Premutation repeat size distribution also differed by ethnicity. In all, 46. 1% of premutation alleles were in the lowest risk group (50-55 repeats), but by ethnicity, this ranged from 22. 6%-75. 0%.

We calculated the risk for fragile X syndrome in each ethnic population by weighting the allele frequencies and their associated full mutation expansion risks (Yrigollen 2012). This provides a more accurate indication of risk than reliance on simple carrier frequency. For example, though the premutation frequency was higher in N Europeans (1/315) than S Europeans (1/412), the latter's repeat distribution favored alleles with high transmission risk: 18. 2% of premutations were 90-200 repeats, compared with 4. 1%. The result of this phenomenon is actuallya higher risk for FXS in S Europeans, 1/2222, compared to 1/3846.

The highest risk identified was among Middle Easterners (1/1370) and the lowest was among SE Asians (1/100000).

Conclusion:Premutation frequency *and* repeat length must be considered in calculating risk for FXS. Our large screening database enables tabulation of accurate, ethnicity-specific, risk estimations.

2112T

High-efficiency biomarker extraction from dried blood samples using Adaptive Focused Acoustics (AFA™). *U. Geigenmuller, A. Purdy, W. Obendorf, G. Smejkal, A. Palmer, G. Durin, H. Khoja, J. Laugharn.* Covaris Inc, Woburn, MA.

Collecting and drying small amounts of blood on a solid support, such as filter paper, has several advantages over other forms of blood collection: It can be performed outside of a medical setting, requires only small amounts of blood, allows specimen transport at ambient temperature and as non-hazardous material, and facilitates storage for extended periods of time. Dried blood spots (DBS) are routinely used for newborn screening programs and are also finding use in adult screening programs such as HIV drug resistance testing. However, DBS also have a number of drawbacks. Specifically, variations in blood collection and blood spot drying techniques can easily render specimens unusable; insufficient drying or subsequent exposure to humidity leads to biomarker degradation; inefficient biomarker retrieval limits downstream analyses; and variation of spot size with spotted volume and haematocrit complicates quantitative analyses of blood biomarkers. Here, we present two innovations that together overcome many of the drawbacks of the current DBS technology: (1) a novel sampling device for collecting capillary blood (truCOLLECT) that simplifies the collection procedure, eliminates the need for a drying period before shipment, provides integrated sample barcoding, and increases biomarker yield; and (2) use of Adaptive Focused Acoustics (AFA™) for efficient release of biomarker from dried blood samples collected on truCOLLECT devices as well as from conventional DBS. The AFA™-based extraction process is highly automated and allows processing of up to 96 samples in 4 hours or less in a 96-well plate format, with less than 30 min hands-on-time. We determined yield of DNA, RNA, and protein extracted from truCOLLECT samples or DBS from six different donors using AFA™ or traditional chemical extraction methods. Biomarker quality was assessed by gel electrophoresis and qPCR for nucleic acids and by gel electrophoresis and ELISA for proteins.

2113F

Prostacyclin Synthase (PTGIS) interacts with nonsteroidal anti-inflammatory drugs (NSAIDs) to Protect from Miscarriage. *M. J. Bray[1], K. E. Hartmann[2,3,4], E. S. Torstenson[2], S. H. Jones[5], D. R. Velez Edwards[1,2,3,5].* 1) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, TN; 2) Vanderbilt Epidemiology Center, Vanderbilt University, Nashville, TN; 3) Department of Obstetrics and Gynecology, Vanderbilt University, Nashville, TN; 4) Department of Medicine, Vanderbilt. University, Nashville, Tn; 5) Institute of Medicine and Public Health, Vanderbilt University, Nashville, TN.

Nonsteroidal anti-inflammatory drugs (NSAIDs) are one of the most commonly used medications reported in pregnancy. NSAIDs directly impact prostaglandin pathways, and have been proposed as potential risk factors for spontaneous abortions (SAB, gestation <20 weeks). Prior studies have observed inconsistent associations between NSAID use and SAB risk, including racial differences. Given that response to medications may vary across individuals due to genetic differences, we conducted a genetic study evaluating NSAID by gene interactions for risk of SAB in a cohort of pregnant women. Women were enrolled in the *Right from the Start* (2004-2010) cohort. Periconceptional prescription and over-the-counter (OTC) NSAIDs reported up to the sixth week of pregnancy were obtained from study interviews. We evaluated ancestry using 100 ancestry informative markers and 201 haplotype tags; candidate SNPs were selected from NSAID metabolism pathways using 600 European American women. Interaction analyses between NSAID use and SNPs were conducted in logistic regression, adjusted for BMI, SAB history, and ancestry. NSAID exposure was reported by 63% of SAB cases and 62% controls. The strongest interactions were observed in multiple SNPs within the prostacyclin synthase (*PTGIS*) gene, the majority of which were in strong linkage disequilibrium (LD). The strongest interaction was at *PTGIS* rs5602 (OR 0. 34, 95% CI 0. 19 to 0. 60, p=2. 45x10-4) in fully adjusted models, and was statistically significant after a Bonferroni correction for multiple testing. NSAID stratified rs5602 single SNP additive association analyses that modeled A as the minor allele showed that NSAID users with the AA genotype were most protected from SAB (OR=0. 78, 95% CI 0. 56 to 1. 10), while non-NSAID users were at increased risk of SAB (OR=2. 11, 95% CI 1. 35 to 3. 29). Nominally significant associations were also observed at *PTGDR* and *CYP2A6* (p<5x10-3). Our findings suggest that risk for SAB due to NSAIDs in early pregnancy may be modified by *PTGIS*. However, further validation of our associations is necessary.

2114T

Association of G1733A polymorphism (rs6152) in androgen receptor gene with Idiopatic Recurrent Pregnancy Loss in Mexican women. *A. Porras[1, 2], A. LAZCANO[3], T. DA SILVA[1], J. JUÁREZ[1,2], J. García[2].* 1) Human Genetics, Universidad de Guadalajara, Guadalajara, Jalisco, Mexico, JALISCO, Mexico; 2) 2Division de Genetica, Centro de Investigacion Biomedica de Occidente, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; 3) Servicio de Ginecoobstetricia, Hospital General 180, Instituto Mexicano del Seguro Social, Tlajomulco de Zuñiga, Jalisco, Mexico.

AbstractBackground. Idiopatic Recurrent Pregnancy Loss (IRPL) is defined as two or more repeated pregnancy losses before the 20th week. Its etiology is multifactorial and some genetic polymorphisms have been associated to risk of IRPL. The G1733A polymorphism (rs6152, *Stu*I polymorphism) in the androgen receptor (AR) gene can influencein the regulation of the transcription of androgen responsive genes. **Objective.** To determine whether the G1733A polymorphism is associated with IRPL. **Methods.** We analyzed the G1733A polymorphism in the *AR* gene by polymerase chain reaction (PCR)-restriction fragment length polymorphism (PCR-RFLP) in 156 IRPL women, (≥ 2 miscarriages) without identifiable risk factors and 152 unrelated fertile women, controls (≥ 2 live births). The ages of individuals in both groups ranged from 18 to 42 years. **Results.** The genotypic frequencies of the G1733A polymorphism in controls were in accordance with Hardy-Weinberg equilibrium (HWE) (p=0. 496413). The observed frequencies of GG, GA and AA genotypes were 70. 51%, 26. 92% and 2. 56%, respectively, for the patients and 88. 82%, 10. 53% and 0. 66%, respectively, for the controls (OR=3. 321; C. I=[1. 803-6. 116]; chi2=15. 85; p=0. 00007). Allele frequencies of the G1733A polymorphism among patients and controls were 0. 840 and 0. 941, respectively, for the wild type allele (G) and 0. 160 and 0. 059, respectively, for the mutant type allele (A) (OR=3. 032; C. I=[1. 725-5. 331]; chi2=16. 01; p=0. 00006). **Conclusion.** This study suggests that G1733A polymorphism in the *AR* gene is strongly associated with IRPL in Mexican women (OR=3. 032). .

2115F

Pattern of cytogenetic aberrations in Tunisian couples with recurrent miscarriage. *R. Frikha, N. Bouayed Abdelmoula, T. Rebai.* Histology Laboratory, Univ Medicine, Sfax, Tunisia.

INTRODUCTION: Recurrent miscarriage (RM), as at least three or more consecutives miscarriages less than 24 weeks of gestations, is an heterogeneous condition with affect approximately 1% of couples who are trying to conceive. Chromosomal rearrangements are well recognized cause of miscarriage in couples with RM with an overall frequency varying from 2% to 8% of couples with RM. This study was conducted to assess the prevalence of chromosomes abnormalities and clinical characteristics of couples with history of RM from Tunisia. Further, to delineate strategies for genetic evaluation and clinical management in subsequent pregnancy. METHODS: We investigated the karyotype of 98 couples with more than 3 miscarriages, referred to our genetic counseling. Chromosomal analysis was performed using RGH banding in peripheral blood. In all the cases the detailed reproductive case histories were taken. RESULTS: Of a total of 98 couples, 4 men and 1woman had abnormal karyotype with an overall incidence of (5. 1%). The commonest abnormalities appear to be reciprocal translocation. Chromosome abnormalities seem to be more prevalent in younger couples. In addition; personal reproductive background have an impact on the risk of been carrier of structural abnormalities. CONCLUSION: These data strengthens the current guidelines for the cytogenetic evaluation of couples with RM after the third miscarriage. However, depending on the presence of other factors such as personal reproductive background, karyotype should be proposed after 2 miscarriages. For the couples with chromosomes abnormalities, a non invasive prenatal testing should be discussed.

Interleukin 1 Beta Gene Polymorphisms in Women with Early Onset Preeclampsia. *A. Venkateshwari[1], S. Sowmya[1], R. Aruna[2], N. Pratibha[3], A. Jyothy[1].* 1) Cell Biology, Institute of Genetics and Hospital for Genetic Dis, Hydrabad, Telangana, India; 2) Government Maternity Hospital, Petlaburz, Hyderabad,Telangana, India; 3) Department of Genetics, Osmania University, Hyderabad, Telangana, India.

Purpose of the study: Preeclampsia is a pregnancy-specific disorder characterized by hypertension and systemic endothelial dysfunction. Interleukin (IL)-1b is a possible mediator of maternal endothelial dysfunction in preeclampsia. Earlier studies reported increased levels of serum IL-1b as well as its natural inhibitor IL-1 receptor antagonist (IL-1Ra) in women with preeclampsia. In view of the above, the purpose of the present study is to evaluate the relationship between IL-1 beta polymorphisms +3954 C/T (rs 1143634), -31 T/C(rs1143627), receptor IL1Ra VNTR polymorphism and preeclampsia (PE), and analyze haplotype frequencies of the three polymorphic loci. **Methods:**A total of 140 patients and 135 women with normal pregnancy, from Government Maternity Hospital, Petlaburz, Hyderabad, India, were considered for the present study. PCR- RFLP was carried out for IL-1B +3954 and -31 genotyping and PCR for IL-1Ra, followed by agarose gel electrophoresis. Genotype and allele frequencies between case-control groups were compared by chi-square (χ^2) tests. Haplotype analyses was carried out with the help of Haploview software . **Results:**Significant statistical differences were found between PE and control groups regarding genotype and allele frequencies of the two polymorphisms of IL-1b and IL1Ra (For IL-1b -31C/T: χ^2= 21. 17, p=0. 000004; For IL-1b+3954: χ^2= 28. 24, p=0. 0001and IL 1Ra : χ^2= 13. 57 , p=0. 0002). Further, haplotype analysis of these SNPs revealed a significant association of STC, LTC and LTT haplotypes with patients compared to controls. **Conclusion:**The present study suggests that IL-1B cluster polymorphism could be a major genetic regulator in the pathogenesis of preelampsia.

Hypertension as a risk factor for uterine fibroids: a Mendelian randomization analysis. *K. S. Tsosie[1], D. R. Velez Edwards[1,3], T. L. Edwards[1,2].* 1) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, TN; 2) Division of Epidemiology, Department of Medicine, Vanderbilt University, Nashville, TN; 3) Department of Obstetrics and Gynecology, Vanderbilt University, Nashville, TN.

Uterine fibroids [OMIM: 150699] are common benign tumors that affect up to 77% of women by menopause and account for $34. 4 billion in annual U. S. healthcare costs. Fibroids are highly heritable with greater risk for women of African ancestry. Clinical and biological studies have reported a relationship between arterial hypertension and uterine fibroids but, to date, there has not been a published analysis associating causal genetic factors for hypertension with fibroids. Aggregate genetic risk scores (GRS) were calculated using 35 markers significantly associated (p>5x10-7) with hypertension (HTN) and high blood pressure (BP) from well-powered, independently replicated studies listed in the NHGRI GWAS Catalog. A Mendelian randomization analysis was conducted using imputed genome-wide data from 1,358 unrelated African American women with hypertension and image-confirmed fibroid status determined from electronic medical records. Logistic regression was used to evaluate whether HTN and BP are genetically associated with uterine fibroids. Women with greater numbers of hypertension and BP-increasing alleles had a higher uterine fibroids risk (OR=1. 03, 95% CI=1. 00-1. 06, p=0. 08). However, this association was not seen when only hypertension-associated alleles were included in the model. Hence, Mendelian randomization suggests a potential association between hypertension via blood pressure-increasing alleles and uterine fibroids in our defined study population of African American women.

Role of Kallmann Syndrome Gene *NELF* in the JAK-STAT Pathway. *E. Ko, L. Chorich, M. Sullivan, S. Quaynor, R. Cameron, L. Layman.* Department of Neuroscience &Regenerative medicine, Georgia Regents University, Augusta, GA.

Normosmic hypogonadotropic hypogonadism (nHH) and Kallmann syndrome (KS) represent two related disorders of human puberty, which share in common a deficiency of gonadotropin releasing hormone (GnRH). Proper migration of GnRH neurons from the olfactory placode to the hypothalamus is an important prerequisite for normal hypothalamic-pituitary–gonadal (H-P-G) axis function, which plays a critical role in pubertal development. Human mutations in nasal embryonic LHRH factor (*NELF*), which is also known as NMDA receptor synaptonuclear signaling and neuronal migration factor (*NSMF*), have been identified in nHH/KS patients. In addition, *Nelf* knockdown has been reported to disrupt GnRH neuron migration *in vivo* and *in vitro*. The mechanism by which NELF regulates GnRH neuron migration is unclear. We hypothesize that NELF could be involved in GnRH neuron migration either directly or indirectly through regulation of other genes or proteins. NELF has been reported predominantly localized in the nucleus and contains two atypical zinc finger domains. Jacob protein, the rat ortholog, is 98 % identical to NELF, and following NMDA receptor activation, it translocates to the nucleus and interacts with CREB, suggesting a role in transcription. In the present study, cDNA arrays were performed on RNA from migratory GnRH neuronal (NLT) cells following *Nelf* knockdown (KD) using Nelf shRNA lentiviral particles. Ingenuity pathway analysis (IPA) indicated the JAK-STAT pathway as one of the most relevant signaling pathways, since *Stat1, Stat2, Stat5a, Jak2*, and *Irf 9* were down regulated in the *Nelf* KD sample compared to a scrambled control. To validate these genes, RT-qPCR and immunoblot were performed. By RT-qPCR, all five genes were down-regulated by 48-82% following *Nelf* KD. Protein levels of STAT1 and JAK2 were decreased in immunoblots by 87% and 55 %, respectively. Our findings suggest that the nHH/KS gene product of NELF is involved in the JAK/STAT signaling pathway, which could be a potential mechanism whereby NELF regulates GnRH neuronal migration and function.

2119F

Immotile Short Tail Sperms (ISTS) defect: Genetic evaluation in-depth of alterations in essential candidate genes. *A. Mohseni Meybodi[1], M. Sabbaghian[2], H. Hosseinifar[2], H. Hosseini[2], T. Modarresi[2], H. Gourabi[1], M. A Sadighi Gilani[2].* 1) Department of Genetics at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran; 2) Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran.

ISTS defect in which sperm tail is short and fibrous sheath and axoneme are disorganized, is one of the syndromes that cause male infertility. Despite the studies have been made in this regard, its exact etiology in human is unclear yet. Four candidate genes causing ISTS are*SPEF2*, *RABL2B,* and A-kinas anchoring proteins genes (*AKAP3*and*AKAP4*). Proteins which coded by *SPEF2*and *RABL2B* are essential for correct sperm tail assembly and development, besides, AKAP3andAKAP4 are most abundant structural proteins in the fibrous sheath. In the present study, the variations of candidate genes were investigated in 35 infertile men with ISTS and 40 fertile men. In this purpose, DNA was extracted from peripheral blood of the patients (with more than 80% short tail sperms in at least two spermograms) and control group. Primers were designed for each target segment of candidate genes, and then PCR sequencing was carried out. Sequence analysis of*SPEF2*did not identify any mutation in exon three and 28. However, one polymorphism (363A>C) was identified in exon 3 in four of patients and three of controls (P>0. 05). Analysis of genetic data revealed that no mutations or single-nucleotide polymorphisms in exon four of *RABL2B*was identified, but an intronic variant [(C) nucleotide deletion (rs: 144944885)] was found in heterozygote form in five patients (P<0. 05). No alteration was identified in controls. Moreover, the 1499T>C polymorphism in*AKAP3*was just seen in five patients whereas none of the individuals in the control group had this alternation (P<0. 05). No genetic alteration but one was found in*AKAP4*gene which was a >1350 bp deletion in exon 5. Our results revealed that some specific gene alterations in*AKAP3*,*AKAP4*and*RABL2B*can take part an important role in sperm tail malformation, so it can be assumed as the etiology of ISTSalthough genetic alterations in*SPEF2*gene are not involved in this defect.

Genetic basis of obstructive azoospermia: Whole Exome Sequencing provides new insights into Congenital Absence of Vas Deferens. *O. Patat[1], A. Pagin[2], A. Siegfried[3], N. Chassaing[1], L. Monteil[1], V. Gaston[1], L. Bujan[4], M. Courtade-Saidi[3], F. Marcelli[5], G. Lalau[2], JM. Rigot[5], R. Mieusset[4], E. Bieth[1].* 1) Service de Génétique Médicale, Hôpital Purpan, TOULOUSE 31059, France; 2) UF Mucoviscidose, Service de Toxicologie et Génopathies, Centre de Biologie Pathologie Génétique, CHRU LILLE, Boul. du Prof. Jules Leclercq, 59037- LILLE, France; 3) Service d'Anatomopathologie, Institut Universitaire du Cancer (IUC), 1 avenue Irène Joliot Curie, 31059 TOULOUSE, France; 4) Service d'Andrologie, Hôpital Paule De Viguier, avenue de Grande-Bretagne, 31059 TOULOUSE, France; 5) Service d'Urologie et Andrologie, CHRU Lille, boulevard Professeur Leclercq, 59037 LILLE, France.

Introduction. Among the causes of male infertility, congenital bilateral absence of vas deferens (CBAVD) is a common cause of congenital obstructive azoospermia. Mutations in the gene *CFTR* are identified in nearly 80% of cases. For the remaining 20% the origin of the CBAVD is unknown and other genetics causes are strongly suspected. Thus, other genetic involvement is suggested, in a subset of these infertile men, by an increased frequency of unilateral renal agenesis. However, with the exception of *CFTR*, no other gene responsible for CBAVD has been identified to date. Due to the evident genetic consequence of infertility and as a result of psychological and sociocultural aspects, it is hard to obtain the multiplex pedigrees or complete trios which are required for family-based approaches of causal gene identification. To overcome this difficulty we compared the exomes of 23 unrelated CBAVD cases without any *CFTR* mutations detected after extensive gene screening. All the included cases were selected on the basis of a strict homogenous phenotype of CBAVD and were divided into 2 groups according to their renal status (agenesis or not). **Methods.** A total of 84 medical files of infertile men with CBAVD and a negative *CFTR* mutation screening result were reviewed by clinical experts in andrology. 23 unrelated patients who fulfilled the stringent phenotypic criteria underwent individual whole exome sequencing (WES). **Results.** After filtering, several hemizygous or heterozygous loss-of-function mutations were identified in at least two patients of the cohort. Some of these mutations affected compelling candidate genes, given their expression in the male genital tract, such as *MAGEC1, OTOG, CCDC168, ADGRG2* and *TP53TG5*. Moreover, immunohistochemical evidence was obtained for certain genes showing altered expression in the genital tract of mutated patients compared to normal subjects. **Conclusion.** The WES results strongly support genetic heterogeneity in CBAVD and offer new insights into the pathophysiology of obstructive azoospermia. Further investigations are in progress on larger cohorts of infertile men.

Molecular analysis of Y-chromosome micro-deletions and its relationship with male infertility in Zanjan, Yazd and East Azerbaijan province of Iran. *M. r Ranjouri[1], A. Biglari[1], P. Aob[1], M. Shekari Khaniani[2], M. h Sheikhha[3].* 1) Genetics and Molecular Medicine Department, Zanjan University of Medical Science, Zanjan, Iran; 2) Medical Genetic Department, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Iran; 3) Medical Genetic Department, Faculty of Medicine,Yazd University of Medical Sciences,Yazd,Iran.

Background:After Klinefelter's syndrome, microdeletion of Yq (YCMD) is the most common genetic cause of male infertility; Three regions in the long arm of the Y chromosome, known as AZFa, AZFb, and AZFc, are involved in the most frequent patterns of Y chromosome microdeletions. These regions contain a high density of genes that are thought to be responsible for impaired spermatogenesis. 15% of azoospermic or 5-10% of oligozoospermic males have Yq deletions. **Objective**: Our study aimed to determine the prevalence and type of Yq microdeletions and investigate and detect the Azoospermia Factor (AZF) region deletion, rearrangement and deleted azoospermia (DAZ) gene copy number variants in 3 province of Iran. **Materials and Methods:** A sample of 250 Iranian infertile males (118 with azoospermia and 132 with severe oligozoospermia) was screened for microdeletions and 250 fertile men were also studied as control group. DNA extraction and molecular analysis were done on blood samples. Multiplex-PCR (M-PCR) method was done with 14 STS primers were selected to determine Y-chromosome microdeletions to identify the presence of microdeletion in AZFa, AZFb or AZFc region and also sY587/DraI PCR-RFLP assay were used for determine DAZ copy number variants. **Results:** The Multiplex PCR method identified 21 (8. 4%) infertile males with Y chromosome microdeletions, while none was found in the controls. Amongst the AZF subregions, three cases had deletions in AZFa (1. 2%), seven in AZFb (2. 8%) and eleven in AZFc (4. 4%). the ratio of Y chromosome microdeletion in azoospermic men was higher than this ratio in oligospermic men [11% (13/118) among azoospermic men and 6% (8/132) among severe oligospermics] and also results revealed a significant prevalence of AZFc subtypes deletion and reduced DAZ gene dosage in Iranian azoospermic cases affecting Y chromosome deletion. **Conclusion:** Based on the present study, the frequency of microdeletion in Iranian population is 8. 4% and This study is the first one to investigate AZFc subtypes deletion and DAZ genes dosage in Iranian infertile men and also we concluded that DAZ gene deletion is a risk factor for spermatogenic failure.

2122T

Evaluation of the expression of *AR* and *SOX3* genes in sertoli cells of azoospermic patient. *M. Sabbaghian[1], A. Mohseni Meybodi[2], F. Sangsefidi[1], T. Modaressi[1], M. A. Sadighi Gilani[1].* 1) Department of Andrology at Reproductive Biomedicine Research Center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran; 2) Department of Genetics at Reproductive Biomedicine Research center, Royan Institute for Reproductive Biomedicine, ACECR, Tehran, Iran.

Sertoli cells located in seminiferous tubular basement membrane and surrounds different types of germ cells. Androgen Receptor (AR) is one of the most important transcription factors in sertoli cells, which binds to DNA and influences expression of genes involved in spermatogenesis. The final distinction and separation of spermatids from seminiferous epithelium is dependent and maximally sensitive to AR depletion within the testis. Moreover, during spermatogenesis, expression of *SOX3*, a transcription factor, expressed in sertoli cells, is necessary for differentiation of spermatogonia type A. The purpose of this study was to separate and purificate sertoli cells from human testis and to investigate the expression of *AR* and *SOX3* genes in sertoli cells of azoospermic patients with different spermatogenesis status. Biopsies were obtained from 10 men who referred to the Royan institution and underwent testicular sperm extraction (TESE). Tissue samples were transferred to lectin coated petri dishes after enzymatic dissociation and isolation. After few passages, all the cells were harvested and the cell type was confirmed by immunocytochemistry. *AR* and *SOX3* gene expression level was determined by real time RT-PCR. Isolation, purification and culture of the human sertoli cells were performed successfully. It was shown that *AR* and *SOX3* genes are expressed in these cells and there is significant difference in the expression of these genes in sertoli cells derived from tissues with successful sperm extraction (TESE+) compared to samples without sperm (TESE-). The results showed that the expression of *AR* gene in human sertoli cells could play an important role in spermatogenesis and its expression level could be related to the outcome of sperm extraction. Also, the expression of *SOX3* gene in (TESE-) is more than (TESE+), that indicate negative effect over expression of *SOX3* gene in spermatogenesis.

2123F

Low levels of PAPP-A as a sole parameter predicting high risk of aneuploidy in the fetus in pregnant women younger than 35 and NT <3mm. *A. Singer[1], V. Nadler[2], V. Katalan[2], M. Shohat[2], R. Berger[2], C. Vinkler[3].* 1) Dept Clinical Gen Unit, Barzilai Med Ctr, Tel Aviv, Israel; 2) Maccabi Health Services Rechovot Israel; 3) Institute of Medical Genetics,Wolfson Medical Center, Holon. Israel.

First trimester Down syndrome screening test is widely used in Israel and is part of the national screening program during pregnancy. The tests include measurement of nuchal translucency (NT), plasma free-B-hCG and plasma level of pregnancy- associated protein-A (PAPP-A). Low level of PAPP-A has been previously shown as predictor of adverse outcome of pregnancy and increased risk for aneuploidy. The aim of this work is to assess the incidence of pregnancies with aneuploidies in a group of women younger than 35y with NT measuring below 3 mm and low levels of PAPP-A as a sole parameter predicting high risk of aneuploidy in the fetus. PAPP-A levels of 0. 2 MoM or less are infrequently encountered in clinical practice, being seen in no greater than 0. 5% of the population. This level has been considered as a cut off value considering the need for both further evaluation and close monitoring of the pregnancy. Data on consecutive patients attending a first trimester screening program were collected. Of those with PAPP-A levels ≤ 0. 2 MoM only women under 35y of age with NT< 3mm were considered. First trimester screening was performed on 100,483 women with a live singleton pregnancy between 2006 and 2013. The PAPP-A level was 0. 2 MoM or less, in 360 pregnancies (0. 36%). Of these we were able to obtain information regarding karyotype for 93 women so far (25. 8%). The incidence of karyotype abnormality in this group was 11 cases (11. 8%), including trisomy 21(7/11), trisomy 18 (2/11), 47,XXY (1/11) and one case of triploidy. We are currently analyzing further information and more accurate results will be presented in our final report. Non-invasive prenatal testing (NIPT) is currently recommended in some countries to women at a high risk for aneuploidy (>1:200). Based on initially partial result, it is suggested that this high risk group should include women with low PAPP-A levels (<0. 2MOM) as a single abnormal parameter.

2124T

Noninvasive prenatal diagnosis of Huntington disease: detection of the paternally inherited expanded CAG repeat in maternal plasma. *M. J. van Belzen[1], J. M. E. van den Oever[1], E. K. Bijlsma[1], I. Feenstra[2], N. Muntjewerff[3], I. B. Mathijssen[4], E. Bakker[1], E. M. J. Boon[1].* 1) Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands; 2) Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands; 3) Clinical Genetics, Maastricht University Medical Center, Maastricht, The Netherlands; 4) Clinical Genetics, Academic Medical Center, Amsterdam, The Netherlands.

Huntington disease is an autosomal dominant progressive neurodegenerative disorder, characterized by irrepressible motor symptoms, cognitive impairment, and psychiatric disturbances. It is caused by a CAG repeat expansion in exon 1 of the HTT gene. There is currently no cure for the disease. Prenatal testing is available for couples who do not wish to transmit the disease to their offspring. With a shift towards noninvasive testing, we have explored and validated the use of noninvasive prenatal diagnosis (NIPD) for HD. Fifteen couples have been included, assessing a total of n = 20 pregnancies. Fetal paternally inherited CAG repeat length was determined in total cell-free DNA from maternal plasma using a direct approach by PCR and subsequent fragment analysis. All fetal HD (n = 7) and intermediate (n = 3) CAG repeats could be detected in maternal plasma. Detection of repeats in the normal range (n = 10) was successful in n = 5 cases where the paternal repeat size could be distinguished from maternal repeat patterns after fragment analysis. In all other cases (n = 5), the paternal peaks coincided with the maternal peak pattern. All NIPD results were concordant with results from routine diagnostics on fetal genomic DNA from chorionic villi. In conclusion, we demonstrated that all fetuses at risk for HD could be identified noninvasively in maternal plasma. Additionally, we have confirmed results from previously described case reports that NIPD for HD can be performed using a direct approach by PCR. For future diagnostics, parental CAG profiles can be used to predict the success rate for NIPD prior to testing.

2125F

Analytical Validation of a Novel Next-Generation Sequencing Based Pre-implantation Genetic Screening Technology. *M. Umbarger[1], J. Gole[1], A. Gore[1], E. Boyden[1], M. Slevin[1], B. Milette[2], M. Henein[2], P. Saunders[1], D. Maganzini[1], G. Celia[2], G. Porreca[1].* 1) Good Start Genetics, Cambridge, MA; 2) Dominion Fertility, Arlington, VA.

Current data indicate that pre-implantation genetic screening (PGS) increases pregnancy and decreases miscarriage rates. However, high cost has limited its adoption. This may be overcome by utilizing more efficient and streamlined workflows employing next-generation DNA sequencing (NGS). We have developed a novel method for PGS that couples NGS with a technology termed FAST-SeqS which utilizes a PCR reaction to amplify repetitive elements from all chromosomes while simultaneously attaching sequencing adapters and sample specific molecular barcodes. To evaluate the analytical accuracy of our new NGS-based PGS approach we used cells derived from both previously karyotyped primary fibroblasts and trophectoderm (TE) biopsies of blastocyst stage embryos. In the cell-line studies, five-cell samples from two euploid (46,XY; 46,XX) and six aneuploid (47,XY,+9; 47,XY+13; 47,XX,+18; 47,XY,+21; 47,XXY; 47,XYY) lines were run through the developed assay and the resulting molecular karyotype calls were compared to the reported karyotypes. 168 aneuploid and 55 euploid samples were correctly called, yielding 100% sensitivity and specificity. In the embryo-based studies, paired TE biopsies were obtained from previously cryopreserved blastocysts. One biopsy was tested using FAST-SeqS and the other was tested using the Illumina 24sure array comparative genomic hybridization (aCGH) approach, one of the most commonly utilized PGS technologies. 24 aneuploid and 30 euploid samples were correctly called, and one euploid sample was incorrectly called, yielding sensitivity and specificity estimates of 100% (95% CI 86. 2 - 100%) and 96. 8% (95% CI 83. 9 - 99. 8%), respectively. One false positive and two false negative chromosome calls were made; the latter two occurred in a sample correctly classified as aneuploid, and the associated raw copy number calls were close to our calling threshold, suggesting that the embryo may have been mosaic aneuploid. Together, our cell-line and TE-biopsy-based data indicate that our NGS-based PGS approach yields molecular karyotype calls that are both highly accurate and consistent with traditional aCGH calls.

2126T

Characterization of the mtDNA bottleneck in human preimplantation embryos and zebrafish germline and non-germline cells. *A. Otten[1], S. Sallevelt[1], J. Dreesen[1], C. de Die[1], A. Paulussen[1], T. Theunissen[1], M. Winandy[2], E. Lambrichs[1], I. Eijkenboom[1], M. Gerards[1], J. Vanoevelen[1], K. Tarbashevich[3], E. Raz[3], D. Samuels[4], B. Van den Bosch[1], M. Muller[2], H. Smeets[1].* 1) Clinical Genetics, GROW, MUMC , Maastricht, Netherlands; 2) GIGA, Université de Liège, Liège, Belgium; 3) Institute of Cell Biology, Münster University, Germany; 4) Vanderbilt University School of Medicine, Nashville, USA.

In most animals, the mitochondrial DNA (mtDNA) inherits through a segregational bottleneck, during which a limited number of mtDNA molecules is passed from oocytes to the offspring. However, size, timing and possible differences between germline and non-germline cells of this bottleneck are still debated. To get more insight in this, we collected data of individual human PGD embryos from carriers of the m. 3243A>G or m. 8993T>G mtDNA mutation, as well as of zebrafish embryos. In the human oocytes/embryos, the m. 3243A>G mutation load showed in most cases a Gaussian distribution for individual carriers, whereas the m. 8993T>G was fundamentally different. In one m. 3243A>G carrier two populations with regard to the heteroplasmy level were observed. From this data we estimated the bottleneck sizes, based on the Kimura distribution, which ranged from 48-93 (m. 3243A>G) and 11 (m. 8993T>G, one carrier). This is somewhat lower than the minimum mtDNA counts in embryogenesis in mice (about 200) and selection mechanisms cannot be excluded. Oocytes and PGCs were collected from zebrafish embryosduring development. We measured, on average, 21. 0x106 mtDNA molecules (range: 5. 1x106 – 42. 2x106) in zebrafish oocytes, which is higher than in mammals, probably due to the absence of implantation during teleost development. Oocytes from different females had similar mean mtDNA copy number values with high intra-individual variation (CVs: 28-49%). During development, the mtDNA copy number per cell decreased until the segmentation period, suggesting the onset of mtDNA replication. The mtDNA copy number in FACS-sorted primordial germ cells (PGCs) from different embryonic stages was, at lowest, on average, ~170 (range: 65-287) mtDNA molecules in PGCs, similar to the mice germline bottleneck. For FACS-sorted non-PGCs, the lowest value was ~50 (range: 18-88) mtDNA molecules. Our data suggest that the lowest mtDNA copy number is reached after a fixed developmental stage, implying that considerable variation will exist among PGC and non-PGCs of the same female fish. If similar in humans, this could provide an explanation for theoccurrence of (*de novo*) mutations that reach high mutation loads within a single generation. Early differentiation of PGCs during the developing embryo most likely causes the observed differences in bottleneck size, which would suggest different segregation of familial mtDNA mutations in germline and non-germline cells.

2127F

Preimplantation genetic diagnosis for male infertility with chromosomal rearrangement. *C. C. Huang, S. U. Chen, Y. S. Yang.* National Taiwan University Hospital, Taipei, Taiwan.

Infertile men with chromosomal rearrangement (CR) are highly vulnerable to produce unbalanced gametes which result in recurrent miscarriage, affected offspring or infertility. Preimplantation genetic diagnosis (PGD) with blastomere biopsy and fluorescent in-situ hybridization (FISH) had been used to select normal/balanced embryos for transfer. However, FISH is inherent with some technical difficulties such as cell fixation and signal overlapping. Here weapplied a strategy of PGD using blastocyst biopsy and array comparative genomic hybridization (aCGH) for male reproductive problems with CR. A total of eight men diagnosed as CR were included. Blastocyst biopsy was performed and biopsied blastocysts were cryopreserved individually. Testing was performed with aCGH and the euploid embryos were transferred in the following thawing cycles. The overall diagnostic efficiency is 88. 7% (47/53) and the euploidy rate was 34% (16/47). Six cycles of embryo transfer (ET) were carried out, resulting inthree live births with a pregnancy rate of 50% per transfer cycle. Two couples had no euploid embryos for transfer. Blastocyst biopsy retrieved more genetic material and may provide more reliable results. Meanwhile, aCGH offered not only detection of chromosomal translocation but also more comprehensive 24 chromosomal analyses than traditional FISH. Our study demonstrates an effective PGD strategy of blastocyst biopsy, aCGH and thawed ET for male reproductive problems with CR.

Prenatal Caffey Disease: A Tale of Two Siblings. *M. S. Saleh[1,2], P. S. Shannon[3], A. T. Toi[4], R. S. Silver[2], R. T. Teitelbaum[2], S. K. Keating[3], O. N. Nevo[5], D. C. Chitayat[1,2].* 1) The Hospital for Sickkids, Department of Pediatrics; 2) Division of Clinical and Metabolic Genetics; Mount Sinai Hospital, Department of Obstetrics and Gynecology; 3) The Prenatal Diagnosis and Medical Genetics Program; 4) Department of Laboratory Medicine and Pathobiology; 5) Department of Diagnostic imaging; Sunnybrook Health Science Center.

Caffey disease or cortical hyperostosis is a condition characterized by massive subperiosteal new bone formation usually involving the diaphyses of the long bones. Two forms of Caffey disease have been identified 1) The classical mild, transient infantile form typically associated with fever, joint swelling and pain with onset around age two months and 2) the Lethal prenatal form which typically presents before 35 weeks' gestation, characterized by cortical hyperostosis, short, thick and angulated long bones associated with polyhydramnios and pulmonary hypoplasia. We report two cases of prenatal Caffey disease born to healthy and non-consanguineous parents of Indian-Sikh descent. **Case 1**: The mother was 26 years old G2P1L1 and the father was 28 years old. The couple was healthy and had a son who was well. The pregnancy was initially uncomplicated. Detailed fetal ultrasound at 20 weeks gestation was normal and there was no exposures to teratogens. At 30 weeks gestation an ultrasound revealed polyhydramnios, all long bones were below the 5th centile in length, angulated and thick and there was scalp edema. Echocardiography was normal. No hydrops fetalis was detected. The couple decided to terminate the pregnancy and the autopsy showed cortical hyperostosis of all long bones. The fetal autopsy showed a female fetus with X-rays and histopathology consistent with cortical hyperostosis. **Case 2**: The couple embarked on their 3rd pregnancy and this was initially uncomplicated. A fetal ultrasound at 29 weeks gestation showed polyhydramnios, all long bones were thick, bowed and measured below the 5th centile, the chest was narrow, there was frontal bossing with forehead edema, echogenic gut, absent stomach bubble, large IVC and a large and bulky placenta. The couple was counseled regarding the recurrence of cortical hyperostosis and decided to terminate the pregnancy. The fetal autopsy showed a male fetus with X-rays and histopathology consistent with cortical hyperostosis. DNA analysis of the*COL1A1* gene and a whole exome sequencing (WES) showed no detectable abnormalities. The occurrence of the same condition in sibs of both sexes born to unaffected parents is consistent with an autosomal recessive mode of inheritance. However, the negative WES raises the possibility that this prenatal and lethal condition is the result of an autoimmune condition caused by maternal antibodies directed towards a component of the fetal skeleton.

2129F

Prenatal presentation of an inherited chromosome 6p22. 3 microdeletion, encompassing the JARID2 gene. *M. Biderman Waberski[1], H. Al-Kouatly[2], MH. Fries[2].* 1) National Human Genome Research Institute, National Institute of Health, Bethesda, MD; 2) Maternal Fetal Medicine & Genetics, MedStar Washington Hospital Center, Washington, DC.

Microdeletions in the short arm of chromosome 6 are relatively rare and patients demonstrate varying degrees of intellectual disability and facial dysmorphism. The gene *JARID2* resides on chromosome 6p22. 3 and has been proposed as the most likely gene contributing to this phenotype. We describe an affected mother, daughter and fetal presentation of a 393kb microdeletion in chromosome 6p22. 3 encompassing *JARID2*. This is the first report of inheritance of a microdeletion in this region, displaying variable expressivity. The mother is a 28 year old woman G4P1021. Her personal medical history includes bilateral club feet, meningitis as an infant, blepharophimosis, and a madelung deformity as well as a learning disability. Her 6 year old daughter also had bilateral club feet, an ASD and VSD requiring surgical repair, a madelung deformity, ptosis of her left eyelid, and significant developmental delay including motor and speech delays. Genetic evaluation for this daughter revealed the microdeletion in chromosome 6p22. 3 (15,340,206-15,740,872) via SNP microarray analysis. This mutation was assumed to be de novo in the daughter until fetal anomalies were detected in a subsequent pregnancy, including a large omphalocele, a mildly enlarged nuchal translucency at 2. 5 mm and a short nasal bone. Amniocentesis revealed the presence of the same microdeletion, which was confirmed to be inherited from the mother. Additional prenatal imaging showed IUGR, bilateral clubbing of the feet, VSD, small lens cataract, scoliosis, and kyphosis. A fetal MRI showed that the omphalocele contained the entire liver, stomach and small bowel, measuring up to 10. 4cm x12. 8cm. He was delivered via scheduled c-section at 38 weeks, with a normal APGAR score and a birth weight of 2557g (5th %ile). In addition to prenatal findings he was hypotonic, however no major dysmorphic features were appreciated. This is the first description of a child with a major abdominal wall defect and a microdeletion in chromosome 6p22. 3. The microdeletion overlaps *JARID2.* Haploinsuffiency of this gene has been associated with features present in this family including impaired cognitive function and variable dysmorphic facial features. This case further reveals the phenotypic variability of this deletion syndrome and expands the phenotype to include major organ defects, including abdominal wall defects and heart defects.

2130T

Prenatal whole genome SNP array: frequency and relevance of incidental diagnoses in parental samples. *L. Govaerts[1], D. Van Opstal[1], K. Diderich[1], M. Joosten[1], S. Riedijk[1], A. Prinsen[2], F. de Vries[1], R. Galjaard[1], M. Srebniak[1].* 1) Dept Clinical Gen, Erasmus Med Ctr, Rotterdam, Netherlands; 2) Dept Obstetrics and Gynaecology, Erasmus Med Crt, Rotterdam, Netherlands.

Background: We routinely perform SNP array analysis as a first-tier test for all prenatal indications. In cases with ultrasound abnormalities, fetal and parental samples are simultaneously tested, facilitating the interpretation of fetal array results, in order to ensure short reporting times and avoid parental anxiety. However, by doing so there is a chance to detect a chromosomal aberration in parental DNA samples. These so-called incidental diagnoses are abnormalities found by chance, unintentionally, in parents of probands (Srebniak et al. , Eur J Hum Genet 2014). The aim of this study is to investigate the frequency and nature of these incidental diagnoses in order to judge whether our current protocol needs to be changed. **Methods:** In 2010-2014, 1,682 pregnant women were referred for prenatal SNP array testing because of ultrasound anomalies. Only CNVs present in the fetus were investigated in the parental samples. For quality assessment, the whole genome plots (LogR ratio and BAF) were viewed and eventually the presence of large chromosomal imbalances was noticed. **Results:** An incidental diagnosis was found in 0. 36% (6/1682) cases:In three pregnant women, mosaic Turner syndrome was found. Their phenotype was apparently normal withoutfertility problems. They were referred to our Turner expertise clinic, for evaluation of health issues such as increased risk of cardiovascular symptoms, endocrinological pathology and premature ovarian failure. In one pregnant woman the array demonstrated a mosaic interstitial deletion in 2q37. 1. She had a history of recurrent miscarriages and this deletion could explain the miscarriages. In two partners an aberration associated with an increased risk for a hematological malignancy was found. One of these men was diagnosed with constitutional mosaic trisomy 8. He had neither dysmorphic features nor structural anomalies. The other partner had a mosaic partial trisomy of the long arm of chromosome 1, without any dysmorphic features. Both were referred for extensive hematological evaluation. No malignancy was found, but both will stay under hematological surveillance. **Conclusion**: Because the frequency of incidental findings in parental samples is low and all incidental diagnoses found in our cohort were relevant for health surveillance of the parent. In our opinion, there is no reason to change our protocol with regards to the quality check of the parental samples.

2131F

Thrombocytopenia Absent Radius (TAR) Syndrome due to compound heterozygosity for 1q21. 1 microdeletion and an hypomorpic mutation in *RBM8A* gene. *D. Barel[1], A. Orr-Urtreger[1, 2], A. Bar Shira[1], S. Bak[1], M. Busilov[1], Y. Yaron[1, 2], A. Reches[1, 2].* 1) Tel Aviv Medical Center, Tel Aviv, Israel; 2) Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

IntroductionCongenital anomalies of the limbs can be diagnosed on early second trimester ultrasound. It is often challenging to reach a diagnosis in such cases. We describe a case of prenatally detected limb malformations in a fetus confirmed as TAR syndrome by molecular analysis. **Case presentation**A 26 old primipara was referred for genetic counseling due to bilateral agenesis of the radii and hypoplasia of the humeri and a small left hand detected by transvaginal sonography at 17 weeks of gestation. No joint movement was observed. The parents are of non-consanguineous Iranian and Ashkenazi Jewish origin, with no family history of genetic diseases. After a multidisciplinary consultation the couple opted to terminate pregnancy. Pathologic examination demonstrated a female fetus with bilateral abnormal development of the bones in both upper limbs including: short humeri, very short radii, curvature of the ulnae, small left hand. In addition, ear deformities and clitoromegaly were also noted. Molecular studies demonstrated compound hetrozygosity for a 1q21. 1 microdeletion including the *RBM8A* gene and a *RBM8A* hypomorphic mutation (c. -21G>A). This is a common variant located in the 5' UTR of the gene leading to reduced protein expression. Parental analysis demonstrated that the 1q21. 1 deletion was inherited from the father. The hypomorphic mutation is being tested in the mother. **Discussion**TAR syndrome is a rare autosomal recessive disorder characterized by upper limb defects including agenesis of the radius and humeral hypoplasia and thrombocytopenia, which is usually transient. Other skeletal manifestations include abnormalities of the lower limbs, ribs, and vertebrae. In some cases, additional malformations are found in the heart and genitourinary system (renal anomalies and agenesis of uterus, cervix, and upper part of the vagina). Most patients demonstrate submicroscopic deletion in chromosome 1q21. 1 including the *RBM8A* gene on one chromosome and a hypomorpic mutation in the *RBM8A* gene on the other copy. Some patients have bi-allelic intragenic mutations of *RBM8A* gene. The majority (50-75%) of the 1q21. 1 deletions are inherited from an unaffected parent. The second mutation in the *RBM8A* gene may be inherited from an unaffected parent or occur *de novo*. If the mother is found to be a carrier, the parents will opt for preimplantation genetic diagnosis (PGD) for subsequent unaffected pregnancies.

2132T

"It was the last thing on my mind": couples' experiences and needs for support following the diagnosis of a fetal abnormality in pregnancy. *S. A. Metcalfe[1, 2], B. J. McClaren[1], P. Pitt[1], C. Hickerton[1], M. Menezes[1,3], J. Halliday[2,4], J. Fisher[5], K. Petersen[6], J. Hodgson[1,2].* 1) Genetics Education and Health Research, Murdoch Childrens Research Institute, Parkville, Melbourne, Victoria, Australia; 2) Dept Paediatrics, The University of Melbourne, Royal Children's Hospital, Parkville, Melbourne, Victoria, Australia; 3) Monash Ultrasound for Women, Melbourne, Victoria, Australia; 4) Public Health Genetics, Murdoch Childrens Research Institute, Parkville, Melbourne, Victoria, Australia; 5) Monash University, Clayton, Melbourne, Victoria, Australia; 6) La Trobe University, Bundoora, Melbourne, Victoria, Australia.

Background: The identification of a fetal abnormality in pregnancy can arise following screening and/or diagnostic testing. Despite this being a clinically common situation there are little empirical data about couples' experiences, especially following the diagnosis. This study aims to explore the psychosocial impact of receiving a prenatal diagnosis of a fetal abnormality and identify professional and social supports that are used and needed by couples. **Method**: A longitudinal case study approach with women and their partners from 3 clinical sites in Victoria, Australia. Quantitative (using depression, anxiety, stress scales and intimate bonds measure) and qualitative data collected via individual interviews with women and men at 3 time-points: 6 weeks, 6-9 months, and 2 years post definitive diagnosis. Initially women only were interviewed, and later this was expanded to include their male partners. **Results**: A total of 102 individuals have been interviewed at the first time-point (75 women, 27 men), regarding their experience of receiving a prenatal diagnosis. Conditions identified included chromosomal abnormalities, complex cardiac, structural/organ malformation and neural tube defects. Of the 75 pregnancies, 59 were terminated and 16 were continued. Participants commonly experienced significant grief and overwhelming sadness and many women described intense feelings of isolation. Stress levels were higher than normative controls (p<0. 0001) but women and men showed higher partner support and less control compared with normative controls (p=0. 0001). Those choosing to have an abortion frequently described feeling negatively 'judged'. Access to abortion, levels of support and the perceived quality of support varied both within and across the sites, and couples, whether terminating or not, identified a need for greater access to information and support. Later timepoint interviews indicated that women continued to focus on the need for support when trying to become pregnant or when actually pregnant again. **Conclusions**: Following prenatal diagnosis, couples describe variable and sometimes inadequate levels of follow-up bereavement care and support. The expanding scope of prenatal testing, including non-invasive prenatal screening and chromosomal microarrays, means couples are increasingly faced with complex choices. Providing prenatal testing in the absence of a full range of supportive options may be considered unethical.

2133F

Methionine Synthase (MTR) and maternal risk factor for Down syndrome child-A case-control study. *A. Kaur, A. Kaur.* Human Genetics, Guru Nanak Dev University, Amritsar, India.

Introduction: Methionine Synthase (MTR) is essential for the conversion of homocysteine (hcy) to methionine using cobalamin as a cofactor. Presence of SNPs in *MTR* gene alters homocystein/folate levels by decreasing enzyme activities. These changes influence the DNA stability and methylation pattern which may be one of the factors that plays role in the development of a Down syndrome (DS) child. A case-control study was performed to assess the role of polymorphism (MTR 2756 A-G) in *MTR* gene as a maternal risk factor for DS child in Punjab. **Methodology:** We investigated 110 mothers having DS children with mean age of 27. 5 years and 70 controls with mean age of 28. 5 years having at least one normal child and no miscarriages. Genotyping was done using PCR-RFLP method followed by restriction digestion by *Hae III* enzyme. **Results:** A total of 110 cases and 70 controls were analyzed. Out of 110 cases, 53 (48. 2%) and 52 (47. 3%) showed homozygous wild and heterozygous mutant genotype, respectively. Only 5 (4. 5%) cases exhibited homozygous mutant genotype and among controls, 5 (7. 14%) display homozygous mutant genotype, 27 (38. 6%) revealed homozygous wild and 38 (54. 3%) heterozygous mutant genotype. Higher percentage of homozygous mutant genotype was observed among controls. The chi square value (χ^2=1. 829, p= 0. 400) and genetic models [dominant-0. 68 (0. 37-1. 24), codominant-0. 70 (0. 42-1. 17), recessive-0. 62(0. 17-2. 22)] suggested non-significant association between cases and controls. On the other hand, minor allele frequency in controls (G=34. 29%) was observed to be higher as compared to cases (A=28. 18%), however, there was evidence of no significant difference (p=0. 267). Both cases and controls were found to be in Hardy Weinberg equilibrium (χ^2=6. 032, p=0. 049). **Conclusion:** No association of the studied polymorphism with birth of DS was observed. Present data do not support a role for MTR 2756 A-G as maternal risk factor for a DS birth. Future studies are needed to investigate the potential function of this polymorphism as maternal risk factor for DS.

2134T

Prenatally initiated workup for Desbuquois dysplasia type 1: The utility of SNP-microarray in identifying a candidate gene. *K. Rock[1], J. Hoover-Fong[2], J. E. Hooper[3], K. J. Blakemore[4], A. A. Baschat[1].* 1) The Johns Hopkins Center for Fetal Therapy, Department of Gynecology and Obstetrics, The Johns Hopkins University School of Medicine, Baltimore, MD, USA; 2) Greenberg Center for Skeletal Dysplasias, McKusick-Nathans Institute of Genetic Medicine, Department of Pediatrics, Johns Hopkins University, Baltimore, MD, USA; 3) Department of Pathology, The Johns Hopkins University School of Medicine, Baltimore, MD, USA; 4) Maternal Fetal Medicine, Department of Gynecology and Obstetrics, McKusick-Nathans Institute of Genetic Medicine, The Johns Hopkins University School of Medicine, Baltimore, MD, USA.

Desbuquois dysplasia (DBQD1 [MIM 251450]) is an autosomal recessive chondrodysplasia marked by micromelia, severe joint laxity and dislocations, a characteristic radiographic 'monkey wrench' appearance at the proximal femur due to femoral neck shortening and a medial metaphyseal 'notch'. Type 1 Desbuquois dysplasia is caused by *CANT1* mutations and is distinct from type 2 which is caused by mutations in *XYLT1,* in that the former has unique hand anomalies including accessory phalangeal ossification centers, advanced carpal bone maturation, and/or axial phalangeal deviation. Severe prenatal presentations have been rarely reported. A 27 year old, G2P0010, Pakistani woman from a consanguineous relationship presented at 17 weeks gestation with multiple fetal anomalies including bilaterally short ulna, radius, tibia and fibula (<5th%ile), bilateral severe knee abduction and clubfeet, suspected bilateral hand syndactyly with unusual thumb positioning, and kyphosis. Findings were almost identical to a 16 week ultrasound in her first pregnancy. That pregnancy was terminated without postmortem examination, but SNP-microarray revealed loss of heterozygosity (LOH) of 330. 9 Mb (~10. 3%). No specific genetic diagnosis was made. The parents requested termination of this 2nd pregnancy at 18 weeks given concerns of recurrence. Autopsy revealed severe, bilateral, symmetric genu recurvatum; broad, short neck; micrognathia; cleft palate; wide spacing between the 3rd and 4th fingers bilaterally (prenatally interpreted as syndactyly of adjacent fingers) with bilateral bony fusion of the first two phalanges; clubbed proximal ulnae; and short, superiorly displaced first toes. SNP-microarray showed LOH of 177 Mb (~6. 16%). Considering the common physical features of the fetuses, examination of all genes within overlapping regions of LOH revealed *CANT1* as a candidate gene. With limited fetal DNA available, sequencing of *CANT1* revealed a c. 643G>T (Glu215Term) heterozygous mutation in both parents, thereby establishing a diagnosis of Desbuquois dysplasia type 1 in the fetuses. In this case, independent SNP-microarray results did not provide a diagnosis, but knowledge of the specific areas of LOH with consideration of the phenotype targeted one gene of interest. In clinical situations in which ample DNA is not available, utilization of SNP-microarray in consanguineous families at risk for rare autosomal recessive disorders may dramatically narrow the list of candidate genes.

2135F

Successful array CGH analysis of fetal cells derived from maternal blood: A step towards cell-based NIPT. *A. Breman[1], E. Normand[1], S. Qdaisat[1], I. Van den Veyver[1], R. Singh[2], N. Uldbjerg[4], L. Hatt[2], P. Schelde[2], S. Kolvaa[2], J. Chow[3], L. U'Ren[3], J. Stilwell[3], R. Seubert[3], E. Kaldjian[3], A. Beaudet[1].* 1) Baylor College of Medicine, Houston, TX, USA; 2) ARCEDI Biotech ApS, Aarhus, Denmark; 3) RareCyte Inc. Seattle, WA, USA; 4) Aarhus University Hospital, Aarhus, Denmark.

Detection of genomic copy number abnormalities from one or a few a single cells using array CGH offers a promising non-invasive alternative for prenatal diagnosis. Towards this goal, wehave established a collaborative method for performing fetal cell-based, noninvasive prenatal testing (NIPT) during the first trimester. The long-term goal is to develop a test that would allow the use of array CGH and next generation sequencing to detect clinically important copy number variants (CNVs) and point mutations to accomplish all of the diagnostic testing that is possible at present using amniocentesis or chorionic villus sampling. Through multiple collaborations, we have performed successful array CGH on fetal cells isolated from the maternal circulation. ARCEDI Biotech ApS has developed methods for paraformaldehyde fixation of whole blood followed by immunomagnetic bead enrichment, immunostaining on glass slides, custom scanning for positive cells, and picking using commercially available laser capture or cell picking equipment. RareCyte, Inc has focused on developing methods for preservation, density based enrichment, immunostaining, custom high-resolution scanning and analysis, and integrated single-cell picking. Baylor College of Medicine has focused on clinical use of the RareCyte picker, whole genome amplification, array CGH, and interpretation of clinically relevant copy number abnormalities. Using various combinations of these strategies, the group has successfully recovered and analyzed fetal cells from maternal blood samples using short tandem repeat (STR) analysis for confirmation. Array CGH was successfully performed on whole genome-amplified DNA from fetal cells in cases where the fetus was male. Our data suggests between 6 and 12 fetal cells, likely trophoblasts, can be recovered from 30 ml of maternal blood. The immediate goal is to implement a research version of cell-based noninvasive array CGH that would detect all aneuploidy andclinically significant copy number variations (CNVs) down to 3 Mb resolution or less. The longer term goal is to validate the test for commercial use by comparing array CGH from concurrent invasive and noninvasive samples obtained during the first trimester. Cell-based NIPT has dramatic potential advantages over cell-free testing primarily because of the ability to analyze fetal DNA free of contamination by maternal DNA. We conclude that cell-based NIPT can be developed as a routine clinical test in the near future.

2136T

Women in Western Australia; knowledge, understanding and attitudes towards the potential for population Non-Invasive Prenatal Testing (NIPT) for de novo single gene disorders. *S. M. Long.* Genetic Services of Western Australia, King Edward Memorial Hospital, Perth, Western Australia, Australia.

Background: The diagnostic options available through the public health system are chorionic villus sampling (CVS) and amniocentesis, both of which carry a small risk of pregnancy loss. Non-invasive prenatal testing using cell free fetal DNA (cffDNA) in maternal blood (NIPT) has been eagerly anticipated by both consumers and health care providers and from November 2012 has been offered in Western Australia. With the widespread uptake of NIPT and expanded panelof conditions tested for, such as Prader-Willi/ Angelman syndrome, Cru-di-chat, 22q11 deletion and 1p36 deletions the question of how far away population screening for single gene disorders is arises. A proof of concept study at King Edward Memorial Hospital has already commenced to investigate the feasibility of single gene disorder testing through cff DNA in maternal blood as have other studies. However prenatal testing in the presence of a family history of a condition and genetic counselling pre-test is an extremely different situation to population screening in a prenatal testing with no family history. **Statement of purpose**: The proposed research aims to investigate current knowledge and attitudes surrounding NIPT for single gene disorders in the general population, by both qualitative and quantitative research methods. **Methods:** The initial study consists of qualitative interviews with three cohorts of women to assess what is already known about prenatal testing, what attitudes are towards disability and termination of pregnancy and what they think of the potential for new screening options. The transcripts are analysed by NVivo and checked for thematic saturation. This qualitative study will then inform the design of a much larger online survey. **Results:** The women interviewed have a basic knowledge of prenatal screening and diagnostic tests, with most women aware of screening for Down syndrome and the diagnostic test called amniocentesis. Women have little knowledge about other conditions screened for and unless they have a child with a genetic condition they have little knowledge of genetic conditions in general. While most women are supportive of a woman's right to choose termination of pregnancy in the setting of fetal abnormality they are unsure about decision making in the context of uncertain results. The option of potentially prenatally testing for hundreds of different de novo genetic conditions at once has perceived benefits and drawbacks.

2137F

Demonstration of a Subchromosomal Noninvasive Prenatal Testing Method Using Genome-Wide Sequencing. *R. C. Tim[1], A. R. Mazloom[1], J. Tynan[1], T. Liu[1], Y. Wu[1], C. O'Neal[1], Z. Qazi[1], M. Ehrich[2], P. Oeth[1].* 1) Sequenom Laboratories, San Diego, CA; 2) Sequenom, Inc. , San Diego, CA.

Noninvasive prenatal testing (NIPT) has gained widespread acceptance for the detection of fetal whole chromosome abnormalities such as trisomies 21, 18 and 13. However, a broad range of clinically relevant subchromosomal aberrations can also be identified with high accuracy when using genome-wide sequencing of circulating cell free fetal DNA (ccffDNA), especially events ≥ 7 Mb in size. This study demonstrates a methodology for the identification of such microdeletions and microduplications (MDs) using low coverage sequencing data (0. 4 - 0. 5X genome coverage). Assay sensitivity was tested using a model system composed of fragmented and size selected genomic DNA (gDNA), representing a range of subchromosomal abnormalities, mixed into ccfDNA from non-pregnant female donors to mimic ccffDNA at various fetal fractions. Sixty-three independent mixture model samples with events ≥ 7 Mb and a median mixture ratio corresponding to 5. 8% fetal fraction were interrogated. The measured analytical sensitivity was found to be slightly higher than the in-silico predicted sensitivity, therefore validating the simulations. The expected sensitivity of microdeletions > 7 Mb is greater than 95%. It should be noted that the observable event sizes based on sequencing were smaller than the clinically reported sizes (often by 15% or more) due to poorly mappable regions within the genome. Assay specificity was assessed using ccfDNA extracted from presumably unaffected (euploid) maternal plasma samples. The 395 samples tested were not known *a priori* to possess subchromosomal events ≥ 7 Mb based on previous low coverage sequencing results. After filtering for the typical quality control criteria, no subchromosomal events > 7 Mb were detected. Consequently the data in this study suggests high sensitivity and specificity for the detection of subchromosomal events > 7 Mb can be achieved.

2138T

Contribution of NIPT in case of ultrasonc malformations: more than 2 years of French experience. *G. Viot, L. LHOMANN, C. BERNABE-DUPONT, C. LACAM, P. BOUHANNA, I. THUILLIER, F. JACQUEMARD.* prenatal diagnosis unit, Neuilly sur Seine, France.

Detection of fetal DNA in maternal blood allows non-invasive prenatal testing (NIPT) of aneuploidy with very high sensitivity and specificity. The implementation of NIPT increases in lot of countries with time with a recognized indication of all for the diagnosis of trisomy. In our unit, we asked ourselves the question whether this test could be proposed in other indication, especially after discovery of ultrasonic malformations. From January 2013 to April 2015, we carried out 3 000 tests mainly because of advanced maternal age or abnormal first trimester screening (FTS). For 117 women (3. 9%), fetal DNA was proposed while scan detected fetal malformations (28. 5%: thick nuchal translucency; 21. 4%: soft signs of trisomy 21; 12. 85%: intrauterine growth retardation; other: 37. 27%). For 2 cases, the result was positive for trisomy 21. Classically, fetal DNA testing is not a good option in case of ultrasonic anomalies. For all these women, we granted the request for specific reasons: refusal of patients to perform an invasive procedure due to the risk of induced miscarriages, risk of premature delivery or history of premature labor, decision to continue the pregnancy whatever the outcome, assisted procreation history. Genetic counseling is mandatory before testing. Test limitations were explained. An ultrasound control was always performed in our unit. Clinical evaluation of newborns and follow-up were always practiced after birth. After ultrasound discovery of anomalies and in very specific situations, NIPT can be performed after genetic counseling and explanation of its limitations. In the near future, it appears important to evaluate the help of this non-invasive approach, mainly after discovery of soft signs in favor of Down syndrome.

2139F

First Report of Prenatal Diagnosis for Severe Genodermatoses in Egypt. *K. Amr[1], K. Gaber[2], G. Kamah[3], M. Farag[2], H. Naser[1].* 1) Medical Molecular Genetics, National Research Centre, Cairo, Egypt; 2) Prenatal Diagnosis Unit , National Research Centre, Cairo, Egypt; 3) Clinical Genetics, National Research Centre, Cairo, Egypt.

Background: Genodermatoses are mostly severe inherited disorders. A great success in identifying responsible genes & characterizing mutations within such genes paved the road for DNA-based prenatal diagnosis. Examples of severe genodermatoses candidate for prenatal diagnosis include autosomal recessive congenital ichthyosis (ARCI), Xerodemapigmentosa (XPA), Sjögren–Larsson syndrome (SLS) and papillonlefeuvre syndrome (PLS)where clinical severity affects span &/or quality of life hence urging prenatal diagnosis. **Materials and metho**ds: The study included five amniotic samples (AF) from carrier mothers descending from five pedigrees with history of affected sibs with severe genodermatoses including; two mothers of previous ARCI cases, one XPA, one SLS and one PLS. DNA was extracted from AF samples by QIA gene extraction kit followed by mutational screening for XPA, TGM1, ALDH3A2 and CTSC genes. **Results**: prenatal diagnosis was successfully performed in all cases. For the family with history of XPA, the fetus was found to be heterozygous carrier for E111X mutation; For ALDH3A2 gene the fetus was affected for E331X nonsense mutation; for TGM1 gene the two fetuses were heterozygous carriers for R264W,R143Hmissense mutations. The fifth AF sample PLS showed homozygous wild type genotype. **Conclusion**: The high incidence of consanguinity & consequently AR rare disorders combined with the lack of curative therapy, points to the importance of implementing preventive programs. Prenatal diagnosis and genetic counseling represent an important step in prevention & alleviating the burden of severe genodermatoses on the family & community.

2140T

5-tiered Scheme for Classification of High-Resolution Oligo-SNP Array Results in Invasive Prenatal Diagnosis: Findings from 3,091 Clinical Cases. *A. Anguiano, J. C. Kelly, L. P. Ross, L. W. Mahon, R. Owen, F. Z. Boyar, C. M. Strom, J. C. Wang.* Cytogenetics, Quest Diagnostics Nichols Institute, San Juan Capistrano, CA.

Precise classification of copy number variants identified by high-resolution (HR) oligo-SNP array in prenatal diagnosis delivers key genetic information that is often a significant factor for families making decisions about their pregnancies. Our laboratory reports HR oligo-SNP results using a standardized 5-tiered scheme: 1) abnormal/pathogenic, 2) likely pathogenic, 3) uncertain clinical significance, 4) likely benign, or 5) normal. We assessed the findings of HR oligo-SNP array testing of chorionic villus and amniocentesis samples in clinical practice. The HR whole-genome CytoScan™ HD oligo-SNP array was implemented among a cohort of 3,091 high-risk pregnancies with a threshold set at 50 kb for chromosomal loss, 200 kb for gain, and 5 Mb for regions of allelic homozygosity (ROH). The major indications for invasive testing were abnormal ultrasound (64%), abnormal maternal serum screen (16%), and advanced maternal age (15%). Benign gains or losses, gains or losses < 1 Mb not encompassing genes, and gains < 0. 5 Mb of unknown clinical significance were not reported. Presence of ROH was reported for samples with either ≥2 ROH with a total size >10 Mb or a single ROH >10 Mb. Pathogenic findings were identified in 290 (9. 4%) cases, and variants of uncertain clinical significance (VOUS) were found in another 272 (8. 8%). ROH was found in 88 (2. 8%) cases (range, 11-515 Mb; median, 51 Mb). The most frequent pathogenic findings were trisomies (103 cases; 35. 5%), microdeletions/microduplications <10 Mb (95; 32. 8%), and large deletions/duplications and unbalanced translocations >10 Mb (53; 18. 3%); DiGeorge syndromes, STS deletion, and 17q12 and 16p13. 11 deletions and duplications were the most prevalent. Among the 272 VOUS cases, 45% were likely benign and 53% were of uncertain clinical significance (most due to partial duplications affecting genes implicated in autosomal dominant disorders). Only 4 (1. 5%) cases were classified as likely pathogenic. The overall detection rate was about 9. 5% for predicting a phenotypically abnormal pregnancy, and close to 5% for copy number variants requiring detailed clinical assessment for genotype-phenotype correlation. The results from this cohort provide further support of HR oligo-SNP array as a first-tier genetic test for prenatal diagnosis in high-risk pregnancies. The 5-tiered standardized interpretation scheme provides valuable information to inform pregnancy decisions.

2141F

Prenatal diagnosis in Huntington disease and reproductive choices. *H. Bouchghoul[1], S. Clement[2], M. Gargiulo[3,4], C. Cazeneuve[5], S. Noel[5], E. Schaerer[5], M. Dommergues[1], D. Vauthier[1], J. Nizard[1], A. Durr[2,5].* 1) Service de Gynécologie Obstétrique, Groupe Hospitalier Pitié-Salpêtrière, APHP, Sorbonne Universités, UPMC Univ Paris 06, CNRS UMR 7222, INSERM U1150-, Paris, France; 2) 2-Institut du Cerveau et de la Moelle, INSERM U1127, CNRS UMR7225, Sorbonne Universités - UPMC Université Paris VI UMR_S1127, Paris, France; 3) 3-Laboratoire de Psychologie Clinique et Psychopathologie, EA 4056, Université Paris Descartes, Sorbonne Paris Cité, Institut de Psychologie, Paris, France; 4) Institut de Myologie, Groupe Hospitalier Pitié-Salpêtrière, Assistance Publique-Hôpitaux de Paris, Paris, France; 5) APHP Department of Genetics, Groupe Hospitalier Pitié-Salpêtrière, Paris France.

In France, persons carrying the mutation responsible for Huntington disease (HD), an expanded CAG repeat in the HTT gene, who wish to prevent transmission of the mutation to their offspring can request a prenatal diagnosis (PND) and, eventually, terminate the pregnancy. Our goal was to determine the impact of PND on subsequent reproductive decisions, as well as to investigate how the information was disclosed to children born after a PND. Between April 1, 1996, and January 29, 2015, 62 couples requested 102 PND for HD in our center. This represents only 18% of the 346 carriers aged <45 years who requested presymptomatic testing during this period. There were 31 carriers and 31 spouses of male carriers; 74% and 87% were nulliparous, respectively (p= 0. 20). Women were contacted by phone between March and May 2015 and invited to participate in a survey; 55 responded positively (89%), 1 declined and 6 could not be reached. The median delay between the last PND and phone contact was 6. 5 years [4. 5-9. 9]. Multiple PND were sometimes requested: 1 (n=33), 2 (n=24), 3 (n=2), 4 (n=2) and 6 (n=1). Those who requested more than one PND were carriers as well spouses (p= 0. 78). Spouses and female carriers were aged 27. 1 [24. 9-31. 3] and 30. 5 years [26. 9-32. 6] (p= 0. 15). Pregnancies were terminated after an unfavorable result (52/102), except for one carried to term and one miscarriage. Repeated PND were significantly more frequent after an unfavorable initial result (21/36) than after a favorable result (8/26) p= 0. 03. During follow-up, there were 16 pregnancies after a PND, 33% (10/30) in carriers versus 24% (6/25) in spouses (p= 0. 46). Twelve out of 45 children born after a PND (27%) were informed of their status by both spouses (8/21, 38%) and female carriers (4/24, 17%, p= 0. 11). In conclusion, PND is rarely requested after presymptomatic testing for HD, and is comparable in female carriers and spouses of male carriers. The hypothesis that future reproductive choices in women are impeded after direct testing of the fetus is supported by our data; a second PND is requested more often after an unfavorable first result. Only 16 children were born without a PND during follow-up. The traumatic dimension of the PND procedure was well reported by the women in general. The fact that the parents disclosed their status to 27% of the children born after a PND, despite their youth, was unexpected and may reveal a long-lasting suffering of the parents due to their own risk.

Needs and views of Quebec pregnant women on personalized reproductive medicine. *G. Lapointe[1], R. Drouin[1,2], C. Bouffard[1].* 1) Université de Sherbrooke, Sherbrooke, Québec, Canada; 2) Université Laval, Québec, Québec, Canada.

INTRODUCTION: Whole-genome sequencing tools are entering the field of human reproduction and gradually replacing conventional diagnostic techniques. These techniques produce a large quantity of genomic data and medical information about the fetus, thereby giving rise to personalized reproductive medicine (PRM). Thus PRM engages parents to take unprecedented responsibility on unborn children's health. This new responsibility, combined with the explosion of genetic information, the advent of non-invasive prenatal tests and direct-to-consumer genetic testing, exposes PRM to several pitfalls. Our research objective was therefore to develop empirical knowledge on the quantity and type of information that pregnant women would like to have about their fetus. **METHODOLOGY**: Descriptive-interpretive qualitative design and general inductive analysis of 15 semi-structured interviews with pregnant women who did not have a known risk of genetic disease, and whom had previously been briefed on available and forthcoming prenatal tests. **RESULTS**: Preliminary results show that women refer to the lack of information provided by physicians in the context of trisomy 21 prenatal screening to express their concerns about more complicated tests. They talked about the types of information, medical or not, that they would like to receive, or not, concerning their fetus' health. They also emphasized the importance of being informed on the medical and psychosocial consequences of their prenatal genetic testing choices. The quality of this information seems highly important to them, in order to evaluate the burden of their responsibility in line with their choices and the impact of these latter on the future of the pregnancy. This new «active participation» and responsibility of parents that PRM implies seems excessive to them and some women fear that it will be harmful for themselves and their child. **CONCLUSION**: At last, the pregnant women we interviewed want to have the choice, but not without complete information about genetic, medical and social issues. In addition, participants are open to learn more about the genome of their fetus, but propose that it should be done in a regulated framework with proper medical assistance.

Frequency of Total Uniparental Isodisomy and Triploidy in a Series of Oligo-SNP array analyses of Products of Conception and Prenatal Diagnosis. *B. T. Wang[1], R. Owen[1], F. Z. Boyar[1], L. Ross[2], L. Mahon[2], J. C. Wang[1], M. El Naggar[1], J. Kelly[1], M. Hemmat[1], A. Anguiano[1].* 1) Cytogenetics Dept, Quest Diagnostics,Nichols Inst, San Juan Capistrano, CA; 2) Genetic Counseling Dept, Quest Diagnostics, San Juan Capistrano, CA.

Molar pregnancy occurs in 0. 1% of all pregnancies. A molar pregnancy occurs when tissue that normally becomes a fetus, instead becomes an abnormal growth in the uterus. Two types of molar pregnancies have been observed. The first is complete hydatidiform mole (1 in 1500 pregnancies) due to a diploid conception that is essentially a total uniparental disomy (TUPD); this type of molar pregnancy carries a significant risk for developing persistent gestational trophoblastic disease. The second type is partial hydatidiform mole (1 in 700 pregnancies), seen in most cases with triploidy. Products of conception (POC) are often evaluated with routine chromosome analysis, which has a failure rate of up to 25% due to degradation of tissue after fetal demise and cannot detect TUPD. Oligo-SNP array analysis, on the other hand, has a much lower failure rate (<10%), a shorter turnaround time and can detect cases of TUPD, as well as triploidy. In this study, we determined the frequency of TUPD and triploidy in 1,471 consecutive POC samples and 3230 amniotic fluid specimens analyzed using the CytoScan HD Oligo-SNP array (AffymetrixTM). Oligo-SNP analysis identified TUPD in 6 (0. 4%) and triploidy in 56 (5%) of the 1,471 POC cases. Among the 3,230 amniotic fluid specimens, oligo-SNP detected TUPD in 1 case (0. 03%) and triploidy in 9 (0. 3%). The number of cases with TUPD do not include cases with total uniparental heterodisomy. In conclusion, this study demonstrates the clinical usefulness of the oligo-SNP array for identifying chromosome complements associated with complete and partial molar pregnancies. Oligo-SNP provides additional value over the non-SNP based array platforms. Choice of a SNP-based array is beneficial for patient care after spontaneous abortion, including the detection of abnormal chromosome complements that could lead to persistent gestational trophoblastic disorders, thus enabling proper monitoring and clinical management. Thus, oligo-SNP array should be considered as a first-tier analysis for pregnancies ending in spontaneous abortions.

2144T

Integrated Analysis of a Longitudinal Preterm Birth Cohort Reveals Significant Inflammatory Candidate Genes. *M. K. Veerapen[1,2], E. Rampersaud[3], N. Morris[4], J. E. Potter[5], M. M. Rodriguez[6], W. Shu[7], Z. Stowe[4], O. A. Bodamer[1,2].* 1) Division of Genetics and Genomics, Boston Children's Hospital, Boston, MA; 2) Department of Biochemistry and Molecular Biology, University of Miami, Miami, FL; 3) Department of Computational Biology, St Jude's Hospital, Memphis, TN; 4) Department of Psychiatry, University of Arkansas, Little Rock, AR; 5) Department of Obstetrics and Gynecology, University of Miami, Miami, FL; 6) Department of Pathology, University of Miami, Miami, FL; 7) Department of Neonatology, University of Miami, Miami, FL.

Introduction: Although affecting up to 13% of total deliveries, and the largest cause of perinatal morbidity and mortality, the longitudinal aspect of preterm births (PTB) during pregnancy is relatively unknown. *Objective:* We proposed to identify temporal differences in the transcriptome and DNA methylation in PTB and term births: during pregnancy, delivery and post-partum. All maternal samples were controlled for age, gravida and gestational weeks; and selected for complication free pregnancies and vaginal deliveries, to eliminate potential confounding factors. *Method*: Total RNA and DNA from peripheral blood were extracted using MagMAX Tempus Blood RNA extraction kit and QIAamp DNA Blood Midi kit, respectively. Ribosome reduced RNA was used to evaluate the transcriptome for known genes. Bisulphite-treated DNA was genotyped for methylation using Infinium Human Methylation 450K BeadChip arrays (Illumina). RNA was library prepared according to TruSeq RNA library prep protocol and run at 2 samples per lane on the Illumina HiSeq2000 generating 25-35 million reads per library. We aligned and assembled raw reads to UCSC Known Genes (hg19). Differential expression (DE) was evaluated using generalized linear regression and Wald test for significance. Pathway analysis using MetaCore was performed to evaluate biological clustering of transcripts. DNA methylation was evaluated using F-tests and linear regressions for differentially methylated positions (DMP). The transcriptome and DNA methylation results were integrated using Spearman correlation. *Results and Discussion*: The established regression model resulted in 3408 DE genes (q<0. 05). These genes were overrepresented for infection and inflammation networks, supporting current physiological causes of PTB. However, only 232 genes were highly upregulated (fold change (FC)>1. 0). Most of the 20,448 DMPs (q<0. 05) were overrepresented in open seas CpG island type. We identified 6 candidate genes (FC>2. 0) with DMPs in upstream genomic regions, which were moderately negatively correlated (Spearman's χ=0. 61). Potentially, these genes have biological significance in PTB etiology through their involvement in neutrophil activity, oxidation, innate immunity and macrophage activation. *Conclusion*: To the best of our knowledge, this is the first longitudinal and integrated analysis of a PTB cohort. The 6 genes identified in this study may be relevant for the identification of biomarkers during pregnancy in the prevention of PTB.

Association of fetal genotypes with cytokine protein expression levels and preterm birth. *R. F. Clark[1], N. C. Gaddis[1], S. W. Erickson[1], G. P. Page[1], C. M. Cotten[2], D. J. Zaccaro[1].* 1) RTI International, Research Triangle Park, NC; 2) Dept. of Pediatrics, Duke University School of Medicine, Durham, NC.

Preterm birth (PTB)-related disorders are the leading cause of neonatal morbidity and mortality. Inflammation is strongly associated with PTB, and cytokines are markers for inflammation. Several studies have suggested that fetal genotypes may play a role in determining the magnitude of the inflammatory response at the fetomaternal interface. Although associations have been found between maternal genotypes and PTB-related disorders, few studies have examined and identified fetal genotypes that are associated with the morbidities and mortality associated with PTB-related disorders, and those that have demonstrated modest association require validation/replication. We investigated which fetal cytokine levels in whole blood (and their specific regulatory genotypes) are associated with specific neonatal outcomes. We analyzed the Neonatal Research Network candidate gene and genome-wide association datasets to investigate associations between single nucleotide polymorphisms (SNPs) and cytokine levels. We also used quantitative trait loci (QTL) analysis to: 1) test if genetic markers act in cis to regulate cytokine protein levels, 2) test genetic association to identify variants in genes affecting cytokine protein levels, and 3) identify QTLs that are associated with cytokine protein levels. We found highly significant (all p<10-8) associations for cis-SNPs with the *CRP*, *IL6*, and *IL18* protein amounts. We also revealed highly significant associations for trans-SNPs of *IL6* and *NTF4* for CXCL8; of *NTF4*, *IL17C*, and *IL6R* for CCL3; and of *IL12A* and *TREM1* for IL6R blood protein concentrations. Further analysis examined whether any of the cytokines measured over 5 time points were associated with altered risk of adverse outcomes in PTB infants. Survival analysis using Cox Proportional Hazards Models with time-dependent covariates was employed to relate outcomes to cytokines in a longitudinal framework. CXCL8 and IL6 were both positively associated with death as an outcome, and CXCL8 was positively associated with intraventricular hemorrhage (IVH) (all p<0. 001). Combined, these analyses have related SNPs that alter IL6 and CXCL8 protein levels to death and IVH. More complex analyses have been undertaken to further delineate the influences of inflammatory pathway genes and cytokines to PTB-related disorders. Identifying these genetic contributions may lead to more effective prevention strategies, attenuating the individual and societal burdens of premature births.

Molecular genetic study to elucidate complex molar pregnancy: differential diagnosis of an unusual case of hydatidiform mole with fetus. *A. C. M. Malinverni[1,2], M. I. Melaragno[1], L. Pola[1], M. E. S. Colovati[1], E. Iwamura[2], L. D. Kulikowski[3], A. F. Moron[4], S. Y. Sun[5], M. M. S. Ishigai[2].* 1) Genetic Division, Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, São Paulo, Brazil; 2) Department of Pathology, Universidade Federal de São Paulo, São Paulo, Brazil; 3) Pathology Division,Cytogenomics Lab, LIM 03, Universidade de São Paulo, São Paulo, Brazil; 4) Department of Obstetríc, Division of Fetal Medicine, Universidade Federal de São Paulo, São Paulo, Brazil; 5) Department of Obstetric, Universidade Federal de São Paulo, São Paulo, Brazil.

Hydatidiform mole (HM) is a complication of pregnancy, characterized by several degrees of trophoblastic hydropic degeneration and proliferation of chorionic villi with potential risk of malignancy. There are two types of HM: complete hydatidiform mole (CHM) and partial hydatidiform mole (PHM). The more difficult differential diagnosis is between PHM and dysmorphic, non-molar spontaneous abortions. While PHMs are triploid, non-molar abortion can be diploid or triploid. We report on a primigest patient, with bhCG 201,039 mIU/Ml at 27 weeks gestation. Ultrasound showed several cystic areas. Fetus of 27 weeks gestation passed away within 15 minutes. Fetal blood karyotype showed 69,XXY, suggesting PHM. Histological examination showed two villous populations: trophoblastic hyperplasia and atypia, villous dysmorphism with epithelial pseudoinclusions, terminal and stem villi edema and cistern formation with stem vessels thrombosis, suggesting PHM/placental mesenchymal dysplasia (PMD). Immunohistochemistry study showed Ki67+ in trophoblastic atypia spots. P57 showed a discrepant pattern with lack of expression in cytotrophoblast and stromal cells and positive expression in others, but with diffuse expression in stromal cells with focal positivity in cytotrophoblast cells. The positive p57was less expressed in villi cells and the syncytiotrophoblasts were uniformly negative leading to suspicion of cellular mosaicism/placental mesenchymal dysplasia. Fluorescence *in situ* hybridization (FISH) using paraffin material with centromeric X, Y and 18 probes in 100 nuclei showed 51% of diploid cells (XX) and 48% triploid (XXX). The trio Genotyping by AmpFLSTR® MiniFiler™ PCR Amplification Kit with parent´s whole blood and patient´s placental tissue revealed only pattern alleles. While cytogenetic analysis and the clinical findings were suggestive of PHM, FISH corroborated with the pathological findings of placental mosaicism associated with molar behavior. Molecular genetic testing for the diagnosis of HM showed only a paternal contribution to the genome, but with a mosaic cell line, which indicated the diagnosis of twin molar pregnancy and mosaic conception or non-molar fetus and hydatidiform mole mosaic. These data showed the importance of molecular techniques in the differential diagnosis of HM, and should be considered when the morphological screening does not allow definitive diagnosis, and also to better understand the mechanisms of HM formation. Several common fetal genetic variants have been associated with birth weight, but little is known about how maternal genetic variation influences fetal growth through the intra-uterine environment. To identify maternal genetic variants associated with birth weight, we performed a meta-analysis of 11 genome-wide association studies (GWAS; n = 19,626 women of European descent). We selected 18 single nucleotide polymorphisms (SNPs) for replication analysis in up to 13 further studies (n = 18,319 women of European descent). One SNP reached genome-wide significance (rs10830963, *P* = 2. 0 x 10-11) in a combined analysis of discovery and replication results. Rs10830963 is intronic in *MTNR1B* and is known from previous GWAS to be associated with fasting glucose levels, type 2 diabetes and gestational diabetes. Each copy of rs10830963-G (the allele associated with higher fasting glucose) corresponded to a 31g [95%CI: 22, 41g] higher offspring birth weight. The association between maternal rs10830963 and birth weight was unaltered by adjustment for fetal genotype in 8716 maternal-fetal pairs. We also found evidence of a collective effect of known maternal fasting glucose-associated variants on offspring birth weight: more low *P*-values than expected were observed among 13 variants selected, with the glucose-raising allele corresponding to higher offspring birth weight for the 5 most significantly associated SNPs. In conclusion, our study demonstrates that maternal genetic variation at *MTNR1B* influences offspring birth weight and supports a broader role of genetic variation affecting maternal glucose levels in fetal growth. Our study also highlights that the effect sizes of associations between other maternal genetic variants and birth weight are unlikely to exceed 20g per allele, and therefore much larger sample sizes will be required to detect them.

2148T

Low folate levels and MTHFR polymorphism C 677T in case mothers of chuldren with neural tube defects and control mothers of Pakistani origin. *N. Nauman[1], S. Jalali[2], S. Shami[2], S. Rafiq[1], G. Grobe[3], A. Hilger[3], M. Draakan[3], M. M. Nöthen[3], M. Ludwig[4], H. Reutter[5].* 1) Department of Pathology, Rawalpindi medical college, Rawalpindi, Holy Family Hospital, Pakistan; 2) Department of Animal Sciences,Quaid-i-Azam University, Islamabad;Pakistan; 3) Institute of Human Genetics, Bonn, Germany) (Department of Genomics Life &Brain Center, Bonn, Germany; 4) Department of Clinical Chemistry and Clinical Pharmacology, Bonn, Germany; 5) Institute of Human Genetics, Bonn, Germany) (Department of Neonatology,Bonn, Germany.

Introduction: Neural tube defects (NTDs) are congenital malformations of the central nervous system which result from a failure of the neural tube to close during the fourth week of embryogenesis. Low folate levels are associated with increased risk of neural tube defects. Genetic studies, examining the gene coding for the folate metabolizing methylenetetrahydrofolate reductase (MTHFR) enzyme suggest, that the functional677C/T thermolabile polymorphism contributes a genetic risk to NTDs. Previousstudies suggest that not only the fetal genotype but also the maternal genotype mighthave an impact on fetal development. The deleterious effects of this variantmutationcan be overcome if folate levels are adequate. Here we carried out a case control studyof case and control mothers of Pakistani origin. **Patients and Methods:** We examined 109 case mothers of children born with NTDTs and of100 control mothers without history of NTDs in their offspring. Case mothers and control mothers were of Pakistani origin. Red blood cell folate and serum folate levels were determined using Abbot Axym ion capture protocol. The C677T MTHFR polymorphism was genotyped by polymerase chain reaction followed by restriction digestion (PCRRFLP). Genotype and folate level comparisons were carried out using chisquare analysis. **Results:** Mean RBC folate and serum folate levels were significantly lower in case when compared to control mothers (p<0. 0001). Genotype analysis of case mothers and controlmothers revealed 11(10. 09%) and2(2%), respectively, to be homozygous for the MTHFR 677T allele. 32(29. 35%) case and 26(26%) control mothers were heterozygous. Genotype comparison by chisquare analysis of case and controlmothers was significant (p=<0. 0393). **Conclusion:** We found the homozygous MTHFR 677TT genotype to be more frequent among case when compared to control mothers. Mean RBC and serum folate levels were significantly lower in case when as compared to control mothers. Combined analysis of these results with the information of folate supplementation during the periconceptional period of case and control mothers is warranted to further elucidate the role of the MTHFR genotype and folate supplementation per se in the risk of NTDs in pregnancies of women of Pakistani origin.

***MED12* mutations in uterine leiomyomas: clinical implications.** *HR. Heinonen[1], A. Pasanen[2], R. Bützow[2], M. Mehine[1], P. Vahteristo[1], J. Sjöberg[3], O. Heikinheimo[3], N. Mäkinen[1], LA. Aaltonen[1].* 1) Department of Medical and Clinical Genetics, Genome-Scale Biology Research Program, University of Helsinki, Helsinki, Finland; 2) Department of Pathology, Haartman Institute, University of Helsinki and HUSLAB, Helsinki, Finland; 3) Department of Obstetrics and Gynecology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Uterine leiomyomas are hormone-dependent smooth muscle neoplasms that affect nearly 70% of females during their reproductive lifespan. Approximately 25% of these women suffer from symptoms such as abnormal menstrual bleeding, pelvic pain and discomfort, pregnancy complications, and even infertility. Various drug therapies are available, but commonly serve as a temporary relief of symptoms or a preoperative measure. Consequently, leiomyomas are the primary indication for hysterectomy. Risk factors for leiomyomas include early age-at-menarche, nulliparity, high body mass index (BMI), and African origin. Furthermore, certain genetic variations increase the risk of leiomyomas. In 2011, we discovered that *MED12* is frequently mutated in uterine leiomyomas. Subsequently, we showed that up to 86% of leiomyomas harbor a *MED12* mutation and the mutations associate with a smaller tumor size and a larger number of tumors within the uterus. The analysis included also other clinical variables, such as BMI, but no statistically significant associations were observed. These results were derived, however, from a relatively small sample set, thus further studies with larger sample sizes are needed to confirm the observed trends. In this study, we have collected all feasible leiomyomas ≥ 1 cm in diameter, a total of 540 tumors, and the respective normal myometrium tissue samples from 180 patients undergoing hysterectomy at Helsinki University Central Hospital. Location, size, histopathological characteristics have been recorded and *MED12* mutation status determined for each lesion. In addition, we will collect comprehensive clinical data from patients' medical records including symptoms, known leiomyoma risk factors, and responses to different treatments. We will compare the association of *MED12* mutation status with these clinical and tumor-specific variables. This study aims to identify the clinical characteristics unique for *MED12* mutation-positive leiomyomas that should be relevant when targeted treatments become available, and could provide new knowledge on the tumorigenic mechanism underlying these extremely common tumors.

Transcriptional profiling analyses of cell free RNA in the amniotic fluid with pregnancy of intrauterine growth retardation. *D. H. Cha[1,2], S. H. Shim[2], Y. J. Shin[2], J. E. Park[2], S. H. Kim[1], Y. W. Jung[1].* 1) Dept OB/GYN, Kangnam CHA Hosp, Seoul, South Korea; 2) Genetic Laboratory of Fetility Center, Kangnam CHA Hospital, South Korea.

The intrauterine growth restriction (IUGR) is commonly defined as slow growth of fetus with low weight. Fetal growth restriction leads to the risks of fetal death or morbidity. Because the earlier IUGR leads to the greater risks to the unborn baby, it is important to the serial monitoring of fetus with IUGR. Amniotic fluid (AF) includes nutrients and growth factors for fetal development and provides an important source for the study of multiple functions in fetal development. Because the supernatant of AF has abundant cell-free nucleic acids originated from the fetus, the studies of AF cell-free fetal RNA are valuable for understanding of fetal maturation during each stage of pregnancy. In our study, we performed a comparative analysis based on Affymetrix microarray using cell-free fetal RNA isolated from amniotic fluid of fetuses with IUGR and controls to understand the prenatal development of fetuses with IUGR. We found 448 differentially expressed genes, in which, there are 204 up-regulated genes and 244 down- regulated genes with > 1. 5 fold-change in expression by IUGR (p-value < 0. 05). And we analyzed these DEGs using the both tools such as DAVID and IPA database etc. In analysis by DAVID, the results showed that many of up-regulated genes are involved in various organs while most of down-regulated genes are involved in brain in fetus with IUGR. In functional analysis by IPA, it revealed that up-regulated genes mainly belong to pathways related with protein synthesis. On the other hand, down-regulated genes belong to several pathways including protein degradation. Therefore, the results suggest the retardation of brain development in fetus with IUGR comparison with normal.

Pathway-based analysis of preeclampsia genome-wide association data suggests hematologic and immune pathways are integral to disease pathogenesis. *K. J. Gray[1], V. P. Kovacheva[2], H. Mirzakhani[3], A. Bjonnes[4,5], B. Keating[6], B. T. Bateman[3], R. Saxena[3,4,5].* 1) Maternal-Fetal Medicine, Brigham & Women's Hospital, Boston, MA. , US; 2) Department of Anesthesiology, Brigham and Women's Hospital, Boston, MA, US; 3) Department of Anesthesia, Critical Care and Pain Medicine, Massachusetts General Hospital, Boston MA, US; 4) Center for Human Genetic Research, Massachusetts General Hospital, Boston MA, US; 5) Program in Medical and Population Genetics, Broad Institute, Cambridge, MA, US; 6) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA, US.

Preeclampsia is a severe disorder of pregnancy characterized by new-onset hypertension and proteinuria. While genetic background is known to influence risk, the genetic loci contributing to risk are not well understood. To better understand preeclampsia genetics, we conducted a large-scale gene-centric association analysis of women of European ancestry with 516 preeclampsia cases and 1097 normotensive controls using a cardiovascular gene-centric 50K SNP array. None of the loci genotyped were independently associated with preeclampsia based on a p-value of $< 5x10^{-8}$for genome-wide significance. The Data-driven Expression Prioritized Integration for Complex Traits (DEPICT) tool was then used to prioritize genes, pathways, and tissue/cell types involved in preeclampsia based on association signals with $p < 10^{-3}$. DEPICT identified 40 prioritized genes (false discovery rate < 5%) present in 172 overlapping pathways (see Table for top genes). Potentially relevant biologic processes identified include: abnormal immune system physiology, abnormal immune serum protein physiology, abnormal physiological neovascularization, hemorrhage, decreased glycogen level, abnormal blood vessel physiology, increased leukocyte cell number, abnormal innate immunity, abnormal respiratory system physiology, and increased neutrophil cell number. The prioritized genes were significantly enriched in the hematologic and immune systems and specifically included monocytes, phagocytes, neutrophils, and hematopoietic cells. Taken together, these data strongly suggest that genetic loci central to immune and hematologic processes are integral to preeclampsia pathogenesis. Ongoing work aims to replicate and extend this analysis in a GWAS from 3000 preeclampsia cases and matched controls.

Table. Top genes prioritized in DEPICT analysis in women with preeclampsia.

Natural Conception in a Patient with 46,XX/46,XY Chimerism: A Case Report. *L. N. Parsons[1,2], B. Szlendakova[3], P. M. Lemen[3], P. vanTuinen[1,2], J. F. Peterson[1,2].* 1) Department of Pathology, Medical College of Wisconsin, Milwaukee, WI; 2) Wisconsin Diagnostic Laboratories, Medical College of Wisconsin, Milwaukee, WI; 3) Department of Obstetrics & Gynecology, Medical College of Wisconsin, Milwaukee, WI.

Disorders of gender differentiation are a heterogenous group of conditions resulting in a wide range of chromosomal, anatomical, or gonadal features; 46,XX/46,XY chimerism is a rare finding within this category of atypical sexual development. Because of the associated phenotypic characteristics in internal and external sexual organ development in these individuals, fertility and successful pregnancy without the assistance of reproductive medical intervention is exceedingly rare. Herein, we report a case of unassisted conception in a 31-year-old patient with 46,XX/46,XY chimerism. Classical cytogenetic analysis of 77 PHA-stimulated lymphocytes (peripheral blood) revealed a 46,XY karyotype in 75 cells, and a 46,XX karyotype in two cells. Upon further review of the patient's history, it was noted that the patient was born with ambiguous genitalia and had undergone multiple corrective surgeries including perineoplasty, corporal resection, and clitoral resection at 18 months of age, followed by introitoplasty and vaginoplasty at 13 years of age. Abdominal and pelvic ultrasounds in childhood revealed a cervix, unicornate uterus, bilateral fallopian tubes, left ovotestis with epididymis, and right ultrasonographically normal ovary. The patient subsequently underwent removal of the left ovotestis/epididymis, and a biopsy of the right ovary revealed histologically unremarkable ovarian tissue. To date, the patient's pregnancy is at 22 4/7 weeks gestation and of female gender; however, due to the prior surgical interventions described above the patient is not a candidate for vaginal delivery. Thus, we describe an exceedingly rare case of fertility and unassisted conception in a 46,XX/46,XY chimeric patient. It is unclear whether the presence of male cells in this pregnant woman, in proportions and distribution of which is yet not fully known, will influence fetal development.

2153F

Delineating Epigenetic Dynmaics in Spermatogonial Stem Cell during Neonatal Development at Single-Base Resolution. *TL. Lee[1], J. Liao[1], SH. Ng[1], K. Yip[2], Q. Cao[2], WY. Chan[1].* 1) School of Biomedical Sciences, The Chinese University of Hong Kong, Shatin, Hong Kong, China; 2) Department of Computer Science and Engineering, The Chinese University of Hong Kong, Shatin, Hong Kong, China.

Spermatogonial stem cells (SSCs) are male germline stem cells that either self-renew or differentiate to produce progenitor spermatogonia to initiate spermatogenesis. Similar to other stem cells, it is believed that these processes are tightly regulated through precise epigenetic and transcriptional dynamics, and its aberrant alterations could lead to significant developmental and reproductive impact. Although the gene expression and epigenetic profile shift dramatically when SSCs are committing differentiation in adult testis, the interplay between epigenetic and transcriptional regulations in SSCs remains largely unknown in neonatal mice. Here we reveal the genome-wide dynamics of DNA methylation modifications and gene expression in undifferentiated (Kit negative) and differentiating (Kit postive)neonatal SSCs . Epigenetic modifications on DNA methylation and demethylation marks in form of 5-methylcytosine (5mC) and 5-Hydroxymethylcytosine (5hmC) were revealed by whole genome 5mC/5hmC profiling at single-base resolution, whereas the transcriptomes were profiled by RNA-Seq. First, transcriptome analysis suggests striking signaling and transcriptional differences during kit transition, which are characterized by key self-renewal and proliferation pathways. Second, we have unraveled the baseline epigenetic status of SSC in the first wave of spermatogenesis for the first time. To our surprise, in contrast to other stem cell differentiation models, there are no significant global changes in 5mC or 5hmC levels during neonatal SSCs differentiation. Instead, we identified substantial differences on 5mC/5hmC distribution in Kit+ and Kit- SSCs. Third, analysis of the relationship between 5mC/5hmC marks and gene expression suggests that both 5mC and 5hmC at promoter regions repress the expression of the corresponding genes, while 5mC and 5hmC at gene bodies positively correlate with gene expression in neonatal SSCs. Taken together, our results provide comprehensive information of the transcriptional and epigenetic landscapes in neonatal SSC development and highlight the unique 5mC/5hmC signatures associated with Kit+/- SSCs, which may contribute to gene expression regulation. These epigenetic marks and gene targets will allow identification of novel molecular mechanisms in neonatal SSCs development.

2154T

Sexual dimorphism in placental telomere length over gestational age. *SL. Wilson[1,2], Y. Liu[1,2], WP. Robinson[1,2].* 1) Department of Medical Genetics, Child and Family Research Institute, Vancouver, BC, Canada; 2) Medical Genetics Dept. University of British Columbia, Vancouver, BC, CA.

Telomeres are repetitive sequences at the end of the chromosomes that protect chromosome ends from degradation and end fusion. Reduced telomere length (TL) is associated with biological and social stresses, age, and disease state. TL has been reported to be significantly shorter in placentas from pregnancies complicated by preeclampsia (PE) and/or intrauterine growth restriction (IUGR). This has been attributed to oxidative stress and hypoxic conditions that occur in PE/IUGR. However, such effects could alternatively be due to normal variation in telomere length related to gestational age or fetal sex. To further clarify these relationships we assessed whether placental TL was associated with i) gestational age or fetal sex within a control cohort; ii) PE/IUGR after taking into account confounding variables; iii) genome wide changes in DNA methylation (DNAm); and iv) targeted changes in DNAm (such as DNAm changes in *TERT, TERC,* or stress response genes). Average TL was measured by qPCR in 94 control placentas from first trimester to term, as well as 22 early-onset PE (EOPE, <34weeks), 19 late-onset PE (LOPE,>34weeks), and 9 normotensive IUGR placentas. We observed a slight trend towards shorter TL with increasing gestational age, (r=-0. 02, p=0. 09). TL was on average longer in female compared to male placentas (t-stat=-3. 37, p=0. 01). Adjusting for sex, we found no difference in TL when comparing EOPE (p=0. 17), LOPE (p=0. 22), and IUGR (p=0. 27) to control placentas. Of our samples, 18 EOPE, 18 LOPE, 9 IUGR, and 13 controls were also run on the Illumina Infinium HumanMethylation450 array, measuring >480,000 CpG sites across the genome. A p-value distribution comparing the association between DNAm measures at all the probes and TL showed a minimal skew to significance, indicating that some CpG sites may be associated with TL. However, no individual CpG sites were found to be associated with TL once corrected for multiple comparisons using a FDR<0. 05. Nor were any specifically associated with DNAm changes at *TERT, TERC,* or other candidate genes. Our data do not confirm TL as a marker of placental stress in PE or IUGR. Longer TL in female placentas may be attributable to increased estrogen exposure during pregnancy, as estrogen has been found to activate telomerase in a number of tissues, due to the estrogen response element upstream of the *hTERT* promoter. We did not find evidence that genome wide DNAm can explain any of the variance in TL in placental tissue.

2155T

High-security DNA bank accounts to protect and share your genetic identity. *J. Den Dunnen.* Leiden University Medical Center (LUMC), Leiden, Netherlands.

With the cost of genome sequencing decreasing every day, DNA information has the potential of affecting the lives of everyone. In general, an individual has little knowledge about his own DNA information, can rarely access it and has hardly any control over its use. This may result in preventable health-related situations and significantly inhibits its use and scientific progress. What we urgently need is a “DNA bank”, a resource providing a secure personal account where, similar to a financial institution, you store your DNA sequence. For any genetic study performed the data generated must be transferred (paid) to your DNA account, including the report showing what has been tested, what was concluded, and based on what evidence. This demand will stimulate trusted public repositories to emerge where consensus opinions on variants and their predicted consequences are available. To ensure independence and a focus on the individual’s interest, the bank should be run by independent trusted mediator. Regulations could be established and oversight arranged by global governing bodies such as the WHO, UNESCO or others. Using their private and secure DNA bank account individuals govern their sequence-related business, regulate access, knowing for what purpose (informed consent) it will be used and only to the genetic data they are willing to share. Depending on the individual’s wishes, the bank may get the right to share data in summary statistics (e. g. variant and phenotype frequencies). The bank serves as an intermediate between parties that have questions or information in relation to specific variants without revealing a person’s identity. The bank may ask individuals to participate in a genetic study by completing a phenotype questionnaire and share this information anonymously. The DNA account ensures the individual is in the driver’s seat, knows what’s known and controls what’s happening.

2156F

Illumina Methylation Array Information in Public Databases May Be Used to Impute Alcohol and Tobacco Consumption Histories on Potentially Identifiable Individuals. *R. A. Philibert[1, 2], N. Terry[3], C. Erwin[4], W. Philibert[1], S. R. H. Beach[5], G. H. Brody[5].* 1) Psychiatry, University of Iowa, Iowa City, IA; 2) Behavioral Diagnostics Inc. , Iowa City, IA; 3) McKinney School of Law, Indiana University, Indianopolis, IN; 4) Department of Medical Education, Texas Tech University Health Sciences Center, Lubbock, TX; 5) Center for Family Research, University of Georgia, Athens, GA.

Illumina methylation arrays are increasingly used as tools in studies of complex medical disorders. Current policy dictates that data from these arrays, like those from genome wide genotyping arrays, be deposited in publicly available databases. Unlike the genotyping information, access to the methylation data is often not restricted. An underlying supposition in the current non-restricted access to methylation data is the belief is that protected health and personal identifying information cannot be simultaneously extracted from these arrays. This assumption appears to be incorrect. For example, in a recent publication we have shown that smoking status can be inferred with a high degree of certainty from methylation data (Receiver Operator Characteristic (ROC) area under the curve (AUC) =0. 99). Here, we demonstrate the potential likelihood for a similarly powerful imputation (AUC >0. 95) for heavy alcohol consumption using Illumina data. In addition, we show how highly informative genotype fingerprints can be extracted using a simple algorithm. Taken together with recent events demonstrating that personally identifying genetic data can be surreptitiously obtained, these findings suggest that protected health information can be obtained about potentially identifiable individuals from public databases. Furthermore, this risk will grow more pronounced as researchers identify additional manners through which methylation arrays record illness and health behavior. As a consequence, currently accepted practices for handling methylation array data do not sufficiently protect the potentially individually identifiable protected health information contained in public databases. Given the stigma as well as potential social/legal consequences of such de-identification, we suggest that more attention needs to be paid to whether access to genome wide epigenetic data should be restricted to investigators who follow generally agreed practices and accede to data use agreements prohibiting re-identification. .

2157T

Consent, confidentiality, and information-sharing in genetic medicine: ways forward for the UK and beyond. *S. Dheensa[1], A. Lucassen[1,2], A. Fenwick[1].* 1) Clinical Ethics and Law, University of Southampton, Southampton, United Kingdom; 2) Wessex Clinical Genetics Service, University Hospitals Southampton Trust, Southampton.

When patients do not notify their family about relevant genetic risks, healthcare professionals (HCPs) can, according to UK guidelines, disclose information without patient consent when the benefit of doing so outweighs the public and patient's interest in maintaining confidence. US guidelines say the risk must be serious, imminent, foreseeable and likely. These guidelines take an individual, rather than familial, view of confidentiality, and take maintaining confidence as default over disclosure. But should we question these norms? US and UK court cases (e. g. ABC v St George's NHS Trust 2015) have not determined a legal duty to warn, but this does not preclude an ethical responsibility. Several interventional studies show that direct action by HCPs (inviting relatives to counselling/education sessions, or confirming disclosure by checking family files, etc.) increases testing uptake for hereditary cancers among relatives. Genomic medicine will make such issues more important, since HCPs will need to engage family to clarify VOUSs, or test them for IFs. We thus aimed to explore views about consent, confidentiality, and information-sharing. METHOD: Interviews with patients (n=33) and focus groups with 80 genetic HCPs. RESULTS: Patients and HCPs had contrary views. While both considered genetic information to be familial, HCPs in practice fell back on an individual definition of confidentiality, and thought their duty to relatives was discharged by giving patients 'relative letters'. We will outline several reasons for this view. (1) They worried professional involvement could exacerbate poor family relationships. By contrast, patients thought family secrets made family dynamics worse, and favoured HCP intervention. (2) HCPs assumed familial communication would happen eventually without their intervention (e. g. , via word-of-mouth). Yet HCPs gave many examples of where this had not occurred and people developed preventable disease. (3) HCPs assumed they could convince patients to disclose at follow-up appointments. However, patients did not always know they could have such appointments, which were dwindling anyway, due to resource limitations. (4) Resources alone would not lead HCPs to take action: they worried about liability and would want a 'cultural shift', involving all HCPs, towards taking action. CONCLUSION: HCPs must develop a consensus about their responsibility to family members. We will outline practical ways for HCPs to enact this responsibility.

2158F

Patients' attitudes towards collecting and sharing genetic information for clinical care versus research in an integrated healthcare system from participants and nonparticipants of the Kaiser Permanente Research Program on Genes, Environment, and Health. *J. Harris[1], C. G. Tai[2], B. A. Koenig[3], C. Somkin[1].* 1) Kaiser Permanente Division of Research, Oakland, CA; 2) Department of Epidemiology & Biostatistics, UCSF, San Francisco, CA; 3) Social & Behavioral Sci/Inst Hlth & Agning, UCSF, San Francisco, CA.

Historically, many have argued that the objectives of research and clinical care are fundamentally different and to make this distinction clear for research participants, a boundary line is drawn between activities conducted for research purposes and for clinical care. However, especially in the realm of genetics, several activities often cross this boundary. The return of individual results and incidental findings to research participants has the potential to take research activities into a clinical care context. Concurrently, rapid adoption of whole genome or whole exome sequencing in clinical genetics often outpaces current efforts to determine the clinical utility of genetic variants, especially rare variants, and thus many care decisions based on sequencing results can cross into the realm of research. The purpose of this study is to explore patients' understandings about the boundary between clinical care and research in the context of an integrated healthcare delivery system such as Kaiser Permanente (KP). We conducted two focus groups, one comprised of KP members who are participants in the Kaiser Permanente Research Program on Genes, Environment, and Health (RPGEH) and a second comprised of KP members who did not participate in the RPGEH. We developed a moderator's guide with examples from clinical genetics and addressed the following questions: How do patients define clinical care and research? What are patients' expectations about research and data sharing within an integrated healthcare system with a comprehensive electronic medical record? How do patients balance tradeoffs between benefits and concerns (i. e. medical progress versus data security and privacy) in blurring or maintaining the boundary between research and clinical care? Does previous participation in a research biobank influence these views? Recordings of focus group discussions were transcribed and qualitatively coded to identify themes and supporting quotations. Findings from this study provide important insight useful for updating research practices to address current challenges in genomic research. Understanding the perspectives of patients and research participants can help improve informed consent procedures, attend to concerns around the therapeutic misconception, and develop appropriate governance policies for data sharing.

2159T

Attitudes about data sharing in the age of personal genome sequencing: Preliminary findings from the PeopleSeq Study. *M. H. Helm[1], S. C. Sanderson[2,3], K. D. Christensen[1,4], T. M. Hambuch[5], M. P. Ball[6], M. D. Linderman[2], N. M. Pearson[7], J. S. Roberts[8], G. M. Church[4], E. E. Schadt[2], R. C. Green[1,4].* 1) Department of Medicine, Division of Genetics, Brigham and Women's Hospital, Boston, MA; 2) Icahn School of Medicine at Mount Sinai, New York, NY; 3) Health Behaviour Research Centre, University College London, London, UK; 4) Harvard Medical School, Boston, MA; 5) Illumina, Inc. , San Diego, CA; 6) PersonalGenomes. org, Boston, MA; 7) New York Genome Center, New York, NY; 8) University of Michigan School of Public Health, Ann Arbor, MI.

Background: As personal genome sequencing (PGS) becomes more common, it is important to evaluate participants' comfort and interest in sharing their genome data (GD). Several programs currently offer PGS to healthy adults for education, research, wellness, and prognostic purposes. Most programs return reports with interpreted results to participants. Additionally programs may provide participants with their GD, which some programs also make available publicly. This issue became even more pertinent as the NIH Genomic Data Sharing Policy took effect in 2015. The PeopleSeq Study surveys ostensibly healthy adults who have undergone PGS to assess their attitudes towards data sharing. Methods: PeopleSeq Study participants that have been surveyed to date are all individuals who paid for PGS through Illumina's Understand Your Genome program, which returns a clinically focused report to participants through their ordering physicians, followed by a chance to explore their results at a 1-2 day symposium. Our survey included questions on participants' comfort with GD sharing. Results: Respondents (n=87) were on average 53 years old, white (86%), with high income (89% annual household income ≥$100,000), educated (90% doctorate or professional degree), married (85%), male (71%), and had biological children older than 18 years (29%). When asked how comfortable they were with the idea of sharing their GD with others, 56% of respondents reported being 'very comfortable,' 29% 'somewhat comfortable,' 7% 'somewhat uncomfortable,' and 5% 'very uncomfortable. ' Three percent of respondents reported that they would not consider sharing their GD; 33% reported they would share it with select individuals if it remained confidential; 56% would share it publicly, but anonymously; and 30% would share it publicly even with their identity attached. Most respondents thought it would be 'difficult' (25%), 'very difficult' (30%), or 'impossible' (13%), for someone to identify them via only their GD, while others thought it would be 'not very difficult' (23%), or 'easy' (6%). Conclusion: Overall, PeopleSeq Study respondents were comfortable with GD sharing, depending on how the data would be shared. Most thought it would be challenging to be identified by GD alone, but almost 1/3 recognized that GD could be linked to identity. Future goals of this study include comparing other PGS cohorts to explore how attitudes towards GD sharing vary between different models of results disclosures.

Harmonizing Privacy Laws to Enable International Biobank Research. *M. Rothstein[1], B. Knoppers[2].* 1) Inst Bioethics, Univ Louisville, Louisville, KY; 2) Centre of Genomics and Policy, McGill University, Montreal, CA.

Large-scale genomic research increasingly relies on international collaboration in compiling and analyzing biological specimens and associated medical information. In some countries, however, laws directed at biobanking, research, or privacy present obstacles to the cross-border sharing of human specimens or health data. Pursuant to an NIH-funded grant, we identified 25 countries engaging in substantial biobank-enabled genomic research. For each country, we invited a leading authority (or authorities) on the biobanking, research, and privacy laws of the country to research and analyze the applicable laws. Using a standard template, they considered the state of biobanking in the country, the privacy framework, the governance of the biobank, and the barriers to access and use of the specimens and data for research. Then, they drafted an interdisciplinary article to be published in the *Journal of Law, Medicine & Ethics* in 2016. The lead investigators distilled the information and prepared a series of recommendations to facilitate the use of biobank resources for genomic research while maintaining essential privacy protections. This presentation will be the first public discussion of the preliminary findings and recommendations of the study.

2161T

Can an online decision-aid help parents of children with treatment-resistant epilepsy make whole exome sequencing decisions? *S. Adam[1], N. Bansback[2], P. H. Birch[1], R. Coe[1], M. B. Connolly[3], E. Toyota[3], M. J. Farrer[4], M. K. Demos[3], J. M. Friedman[1].* 1) Dept Medical Genetics, Univ British Columbia, Vancouver, BC, Canada; 2) School of Population and Public Health, Univ British Columbia, Vancouver, BC, Canada; 3) Div Neurology, Dept. Pediatrics, Univ British Columbia, Vancouver, BC, Canada; 4) Centre for Applied Neurogenetics, Djavad Mowafhagian Centre for Brain Health, Univ British Columbia, Vancouver, BC, Canada.

As clinical genome-wide sequencing becomes more widely utilized by non-genetics specialists, alternatives to conventional genetic counselling, which is often available only through clinical genetics services, are necessary to optimize decisional support and informed consent for families. We have developed an interactive online educational tool and decision aid called "DECIDE" to help families make choices about whole exome sequencing (WES) for diagnosis of serious mendelian diseases. To determine the efficacy of this tool, we are testing it with parents who are considering research WES for a child with treatment-resistant epilepsy through the Neurology Department of a tertiary children's hospital. Prior to testing, families are randomly assigned to receive either DECIDE first or counselling by an experienced genetic counsellor (GC) first, followed by the other intervention. Outcome measures assessed before, between and after the interventions include patient knowledge, empowerment, and decisional quality and certainty. Results on the first 30 families studied show that mean (SD) knowledge score at baseline was 9. 0 (5. 1) out of 20, increasing to 13. 8 (3. 1) after the first intervention ($p< 0. 0001$). There was no significant difference in knowledge improvement between the two study arms, and there was little additional gain in knowledge between the first and second interventions. Empowerment scores also increased after each intervention, but the change was not statistically significant, and there was no significant difference in empowerment between the groups. Most parents in both groups reported that they were confident about their decisions, had sufficient support and advice, understood the pros and cons of testing, and knew which risks/benefits mattered most to them. Almost all parents chose WES for their child. Issues identified as most important in making this decision were: "getting an answer", the possibility of better management, better access to resources, and helping others/advancing science, each of which was mentioned by over 2/3 of participants. Impact on insurability and future reproductive planning were each important for about 1/3 of families. Follow-up analysis is ongoing, and 70 more families are currently being enrolled in the study. As WES use by non-genetics specialists becomes widespread, use of tools such as DECIDE may improve pre-test decision-making and consent processes.

2162F

DECIDE: Development of an interactive tool to guide parents' choices regarding genomic incidental findings results. *J. M. Friedman[1], S. Adam[1], P. H. Birch[1], R. Coe[1], J. Hicklin[1,2], N. Bansback[2].* 1) Dept Medical Genetics, Univ British Columbia, Vancouver, BC, Canada; 2) School of Population and Public Health, Univ British Columbia, Vancouver, BC, Canada.

We have developed DECIDE, an online educational tool and decision aid, to support genetic counselling and decision-making in individuals considering trio diagnostic genome-wide sequencing (GWS). The content was determined through interviews and focus groups with parents who had undergone research GWS, from discussions with genetic health professionals, and from the literature, and was modified after usability testing of pilot versions. DECIDE presents multi-media information about the genetics of disease, the testing process and return of results, including variants of unknown significance, at varying user-selected levels of detail and complexity. Users' decisions are guided by facilitating consideration of consequences in the context of their own priorities and values. Users first consider whether or not to have diagnostic GWS on the basis of issues such as the effect of GWS results on availability of resources for their child and family, the possibility of management options, and implications for insurance or reproductive decisions. A second component of DECIDE informs and guides users' choices regarding receipt of incidental findings (IF). To simplify choices, IF are binned into conditions that are typically of childhood onset or typically present after childhood, and, in each case, those with and those without effective treatments. DECIDE suggests choices based on values assigned by the software to each issue, weighted according to users' responses, but the user can accept or decline these suggestions. Decisions about whether or not to have diagnostic GWS and about return of IF for each of the four bins are made separately, and each parent makes choices for her- or himself and separate choices for the affected child. Assessments of users' knowledge and understanding of the consequences of having GWS and of the quality and certainty of each decision are integrated into DECIDE. The decisions of record are made during subsequent genetic counselling and consent sessions. DECIDE offers a number of advantages, including accessibility at times and locations convenient to users, participation by multiple family members, choice of multiple levels of complexity and learning formats, and the opportunity to review information at a later date. The utility and cost-effectiveness of DECIDE with respect to improving genetic counselling and consent for diagnostic GWS is currently being tested through randomized controlled trials.

2163T

***e-consultative* informed consent for a social research in health among teenagers with Neurofibromatosis type 1.** *F. Duplain-Laferrière[1], G. Bouffard[1], D. Drouin[1,2], C. Bouffard[1].* 1) Laboratory of Transdisciplinary Research in Genetics, Medicines and Social Sciences, Div Genetics, Dept Pediatrics, Fac Med Health Sciences, Université de Sherbrooke, Sherbrooke, QC, Canada; 2) Dept Pediatrics, Fac Med, Laval University, Quebec City, QC, Canada.

Following an ethnographic study conducted among adolescents with Neurofibromatosis type 1 (NF1), aged 15 to 19 years, we were interested to know their concerns regarding the impact of this genetic condition on their social life (*school, work, society*), their love-life and intimate relationship, their reproductive expectations, the quality of family and social interactions (peers, teachers, friends, etc.) and intergenerational dialogue. During the preparatory phase of the study, we realized that face-to-face interviews would not work with adolescents. They agreed to participate, but responded in an evasive manner. This attitude was in stark contrast with the enthusiasm they had demonstrated for the study. To better understanding the situation, we consulted a group of late adolescents affected by NF1. They identified three sources of problems due to the intimate nature of the questions. They were uncomfortable with 1) the idea of their parents consenting for them as they are underage, 2) discussing these topics with an adult face-to-face, and 3) the possibility that the researchers were likely to meet their parents in NF associations activities. Eventually, they advised us to opt for an anonymous online questionnaire. While this approach allowed them to exercise their decision-making autonomy and to freely express themselves anonymously by using a familiar mode of communication, it required more care about the ethical issues raised by online consents and the consent of a teenager. In this context, we developed an *e-consultative* informed consent. The consultative part consists to ask them to give their opinions on the ethical dimensions of the study and the relevance of the research questions and objectives. They had to answer all the questions to get access to the research questionnaire. This presentation shares our results on the effectiveness of this new form of consent. In addition to informing the teenagers, it increases the probability that it will be read and understood. Despite some improvements, the *e-consultative* informed consent form increases the chances that the participants will read and understand the issues of the research, while having their intelligence and taking their needs into consideration.

2164F

Incidental findings; figures and hurdles of informed consent in a diagnostic setting. *M. Kriek[1,2], M. J. V. Hoffer[1], R. E. van Hellemondt[3], S. G. Kant[1], E. K. Bijlsma[1], M. Koopmans[1], M. E. Y. Laurense-Bik[1], A. C. J. Gijsbers[1], C. J. van Asperen[1], G. W. E. Santen[1], A. Tibben[1], C. A. L. Ruivenkamp[1].* 1) Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands; 2) Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands; 3) Department of Ethics and Law, Leiden University Medical Center, Leiden, Netherlands.

The purpose of whole exome sequencing in diagnostics is to increase the number of persons with a molecularly verified diagnosis. In accordance with European guidelines, variants will initially be sought in genes with a known relationship to the patient's disease (targeted analysis). If targeted analysis fails to yield pathogenic variant(s), the next step is exome-wide trio analysis. During this step, findings may emerge that are related to a disease other than that for which DNA testing was initiated. In our clinical diagnostic setting, these incidental finding (IF) are divided into two categories:a) Findings suggestive of a condition for which prevention or treatment is available. b) Findings suggestive of a condition for which no treatment/prevention program is available at present but knowledge of the condition may be important to the patient or family members. Due to the health implications, IF under category a) are always reported to the patient/ parents. IFs in category b) are only reported if one has agreed to be informed of such findings. Should patient/parents decide not to be informed of IFs at all, exome analysis will remain restricted to relevant disease genes. These choices are discussed in a pretest counselling by a clinical geneticist and before exome-wide analysis is initiated, a signed informed consent (IC) form is mandatory. From January 2014 till June 2015, exome sequencing was requested 331 times of which 69 comprised targeted analysis and 262 included exome-wide analysis. The main reason for a targeted approach included the inability to obtain DNA from both parent (62/69: 90%), in two cases no IC form was returned and the remaining 5 cases wanted to avoid the chance of identifying IFs. Fifteen of the 262 exome-wide cases initially forgot to indicate an IF category on the IC form. In 16 cases only one parent gave consent for a minor. From the remaining 231, 50 cases chose category a) (22%) and181 chose category b) (78%). This survey shows that the vast majority of patients wants to be informed about all IFs. However, there is a small but non-negligible subset of patients (5 out of 331: 1. 5%) who doesn't want to be informed about any IF. By offering patients/ parents the opportunity to choose their most appropriate way of reporting IFs, they can play an active role in this complex but important decision process.

2165T

High participation and engagement rate in a systematic hospital-based genomic medicine research project with broad consent. *V. Mooser[1], C. Currat[1], L. Chapatte[1], C. Roth[1], M. Bochud[2].* 1) Biomedicine Service, Lab Department, CHUV University Hospital, Lausanne, Switzerland; 2) Institute for Social and Preventive Medicine, Lausanne, Switzerland.

BACKGROUND AND STATEMENT OF PURPOSE :Little is known about hospitalized patients willingness to engage into genomic research project. This type of knowledge is critical for the planning of precision medicine initiatives. The purpose of the present study was to evaluate the participation rate of hospitalized patients to engage in a systematic hospital-based genomic medicine project based in Switzerland, and to identify factors associated with this engagement. METHODS :Within the framework of the Lausanne, Switzerland, University Hospital Institutional Biobank (BIL), inpatients and selected outpatients are systematically invited to grant researchers broad access to their biomedical data and to donate blood for future whole genome sequencing. Additionally participants are offered the options to be re-contacted in case of incidental findings and to receive an electronic newsletter. Multivariable logistic regression analysis was used to identify personal factors associated with willingness to participate in BIL and with interest in these options. Analyses were restricted to the initial 11099 invited patients for whom full dataset was available, and were stratified by age groups. RESULTS :Overall participation rate was 82. 4% (9141/11099) and was higher in the < 64-year old group (odds ratio [OR] 1. 70; 95% confidence interval [CI] 1. 53 to 1. 90). In the ≥ 64-year old group, participation was lower among women (OR 0. 77; 95% CI 0. 68 to 0. 89), among non-Swiss citizens (OR 0. 66; 95% CI 0. 55 to 0. 79) and those with emergency admissions (OR 0. 59; 95% CI 0. 51 to 0. 69). A total of 8576 (93. 8%) and 3020 (33. 0%) participants were willing to be re-contacted for incidental findings and to receive the newsletter, respectively. CONCLUSIONS :A large proportion of patients are willing to actively participate in this particular systematic hospital-based genomic research program. Hospitals adopting broad consent represent an efficient setting to recruit participants into precision medicine initiatives.

2166F

Family tree and ancestry inference: is there a need for a 'generational consent'? *S. Wallace, E. G. Gourna, V. Nikolova, N. A. Sheehan.* Health Sciences, University of Leicester, Leicester, United Kingdom.

Purpose: Genealogical research and ancestry testing, long used in scientific and demographic research, are now a popular recreational activity. Clients provide their self-reported and/or DNA to ancestry or direct-to-consumer companies and can receive information including ethnic origins, possible relatives, and health status. But little research has gone into the impact of the use of these services on biological and social families. The ASHG has noted the need to investigate these issues because of questions around the privacy and security of ancestry-related databases. We examined consent materials, which are designed to inform individuals about the implications of participation, for language on the implications for third parties. Method: We used content analysis to examine web pages, consent materials, privacy statements, terms of condition and other applicable documents provided to potential clients of ancestry and direct-to-consumer genetic testing companies to determine what consent is required, what risks associated with participation were mentioned, and whether the consent or notification of third parties was required. Results: We identified four categories of companies: 1) those providing services based only on self-reported data, such as personal or family history; 2) services based only on DNA provided by the client; 3) services using both; and 4) services using both that also have a research component. Language varied across the companies. Category 1 companies generally stated that clients should obtain consent from, or notify, third parties when using their services. Category 2 companies made no mention of third parties. Category 3/4 companies make some reference to the implications for third parties but do not specifically call for them to be informed about a client's participation. While in some cases such language was prominently placed, more often it was in text within terms and conditions or privacy statements that may not be read by potential clients. Discussion: Because both family history and DNA can provide information on more than just the individual providing them, companies should make it clear that clients should inform third parties about plans to participate and possible implications. More generally, ways that third parties can be involved in consent need to be explored. Can there be a 'generational consent' that would include more than just the individual in decisions about participating in genetic investigations?

Consenting in the time of genomic sequencing: Experiences from the BabySeq Project. *C. M. Weipert[1], M. C. Towne[2], S. Pereira[3], J. O. Robinson[3], P. B. Agrawal[2,4,5], R. B. Parad[4,5,6], I. A. Holm[2,4], A. L. McGuire[3], A. H. Beggs[2,4], R. C. Green[1,7].* 1) Department of Medicine, Division of Genetics, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 2) Division of Genetics and Genomics, Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA; 3) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 4) Department of Pediatrics, Harvard Medical School, Boston, MA; 5) Division of Newborn Medicine, Boston Children's Hospital, Boston, MA; 6) Department of Pediatric Newborn Medicine, Brigham and Women's Hospital, Boston, MA; 7) Partners Center for Personalized Genetic Medicine, Boston, MA.

Background: Genomic newborn sequencing (gNBS) has the potential to provide comprehensive and clinically useful information on a wide range of conditions. The BabySeq Project is a randomized, controlled trial exploring the utility of gNBS for parents and healthcare providers. Two cohorts incorporating 240 infants and their parents at Brigham and Women's Hospital (BWH) and 240 from the Neonatal Intensive Care Unit at Boston Children's Hospital (BCH), are being randomized to standard newborn screening (NBS) alone or gNBS plus NBS. Genomic results related to childhood conditions are being returned to the gNBS arm. Given the breadth and complexity of potential results, and uncertainties surrounding the downstream impact of genomic information, the development of the informed consent process was complex, compounded by the logistics of obtaining consent and samples in the short, post-partum period when the infant is in the hospital. Our goal was to address these challenges by creating a multi-step, in-depth consenting process. Methods: Utilizing feedback from our IRBs at BWH and BCH, we designed a consent process that includes educational tools and a series of 'Consent Understanding Questions' for parents, intended to be minimally invasive but maximally informative. In light of potential future ethical implications, eligibility criteria include requiring consent from both biological parents (if known) and excluding multiples. Only parents who clinical staff feel are capable of making decisions in the post-partum period are approached. Results: Enrollment began in May 2015. Four out of the 9 initial families approached have agreed to participate (2/5 at BCH and 2/4 at BWH). Reasons for declining participation include feeling overwhelmed, the time commitment required, concerns about genetic discrimination and declining health status of the infant. The average time for the consent process was 65 minutes, and the average score for the 'Consent Understanding Questions' was 17. 3/18 (n=4). We will be actively enrolling more participants in the upcoming months and will plan to present our most up-to-date numbers. Conclusion: The development and use of a comprehensive informed consent process has allowed us to explore gNBS in both healthy and sick newborn populations. This study will provide important insights into the thoughts and feelings of parents regarding gNBS, while also providing essential data on the feasibility of implementing gNBS on a population-based level.

Context Matters. Attitudes, Experiences and Meanings of Consent to Stakeholders within Newborn Screening. *K. W. Miller[1], S. G. Nicholls[1,2], H. Etchegary[3], L. Tessier[2,4], C. Simmonds[3], B. K. Potter[1], J. C. Brehaut[5], D. Pullman[3], R. Z. Hayeems[6], S. Zelenietz[4], M. Lamoureux[4], J. Milburn[4], I. Turner[7], P. Chakraborty[4], B. J. Wilson[1].* 1) University of Ottawa, Ottawa, Ontario, Canada; 2) Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 3) Memorial University, St. John's, Newfoundland and Labrador, Canada; 4) Newborn Screening Ontario, Canada; 5) Ottawa Hospital Research Institute, Ottawa, Ontario, Canada; 6) Hospital for Sick Children Research Institute, Toronto, Ontario, Canada; 7) Provincial Medical Genetics Program Eastern Health, St. John's, Newfoundland and Labrador, Canada.

Background: Newborn bloodspot screening (NBS) is the program through which babies are screened for a variety of conditions shortly after birth. In Canada, NBS generally proceeds on an implied consent basis, potentially generating an ethical tension between the goals of promoting high uptake and of promoting fully informed consent. **Objectives:** Examine how current consent practices are described and experienced by different stakeholders, and how discussions of participation in NBS map across different definitions of consent practices. **Methods:**Aligned with qualitative methodology, semi-structured interviews were conducted with parents, healthcare professionals, and policy decision-makers. The study was undertaken in two Canadian provinces (Ontario and Newfoundland & Labrador). Interviews were audio recorded, transcribed, and analyzed for key themes. **Results:**Participant responses were context dependent: in addition to individual experiences, participant conceptions of key terms appeared to influence attitudes. Major themes related to varied responsibilities and requirements of parents and professionals and the level of expectation for parental involvement. A minor theme related to a perceived overemphasis on individual consent as an ethical panacea, at the expense of alternate governance structures. **Conclusions:**Findings highlight variability in experiences of the process of obtaining informed consent as well as how consent approaches are perceived by different stakeholders in NBS. The results further our understanding of attitudes toward consent and how these affect the process in practice, illustrating that the context and language of consent plays a key role in attitudes to consent-related issues for newborn screening. These results have informed the next stage of research: a self-completion survey involving a larger, more representative sample of the same stakeholder groups will differentiate attitude categories and assess whether attitudes are associated with stakeholder grouping or other important participant characteristics.

2169T

Ethical, Legal, and Social Implications of Personalized Genomic Medicine Research: Current Literature and Suggestions for the Future. *S. Callier[1], R. Abudu[1], M. Mehlman[3], M. Singer[4], D. Neuhauser[4], G. Wiesner[2].* 1) George Washington University School of Medicine and Health Sciences, Washington, DC; 2) Vanderbilt-Ingram Cancer Center, Vanderbilt University School of Medicine, Nashville, Tennessee; 3) The Law-Medicine Center, Case Western Reserve University School of Law, Cleveland, Ohio; 4) Case Western Reserve University School of Medicine, Cleveland, Ohio.

Purpose: The goal of this systematic review was to assess the ethical, legal, and social implications (ELSI) literature on personalized genomic medicine (PGM) research. **Methods:** The abstracts of 2,029 articles extracted from scholarly databases and published during a 5-year period (2008-2012) were systematically reviewed. A total of 402 articles met our research criteria and were organized thematically to assess the representation of ELSI issues, stakeholders, health specialties, journals, and empirical studies. **Results:** Empirical and normative ELSI analyses were published in both scientific and ethics journals. Investigational research comprised 34 percent of the literature reviewed (136 articles) and the remaining articles (266 or 66 percent) comprised normative analyses, commentaries, and news stories. Traditional ELSI concerns dominated the discourse including discussions about disclosure of research results. In fact, there was a dramatic increase in the number of articles focused on disclosure and the implications of discussing incidental findings with research participants. Few ELSI papers focused on particular health disorders, the use of racial categories in research, low and middle income countries, or special populations, such as adolescents, elderly patients, or ethnic groups. **Conclusion:** Considering that personalized medicine will become more tailored to individuals, groups and populations in the future, further analysis is needed on how ELSI scholarship can better serve the growing global, multidisciplinary, and translational goals of PGM research.

Direct to Consumer Genetic Testing – exploring the ethical and legal dilemmas and considering regulation in Europe. *A. C. de Paor.* School of Law and Government, Dublin City University, Dublin 9, Ireland.

With rapid scientific and technological advances, the past few years has witnessed the emergence of a new genetic era and a growing understanding of the genetic make up of human beings. These advances have propelled the introduction of companies offering direct to consumer (DTC) genetic testing, which facilitates the direct provision of such tests to consumers, (for example via the internet). Although DTC genetic testing offers benefits by argaubly enhancing consumer accessibility to such technology, promoting proactive healthcare and increasing genetic awareness, it presents a myriad of challenges, from an ethical, legal and regulatory perspective. As DTC genetic testing usually eliminates the need for a medical professional in accessing genetic tests, this lack of professional guidance and counselling may result in misinterpretation and confusion regarding results. In addition, an evident concern relates to the scientific validity and quality of these tests. A further problem arising is the lack or inadequacy of regulation in this field, which may result in privacy violations as well as other unauthorised use of genetic information, and potentially discrimination. This legislative vacuum is apparent at European Union (EU) level, where there is no concrete legislation, as well as amongst EU Member States, few of which have introduced regulatory frameworks specifically addressing this area. In light of the increasing accessibility of DTC genetic testing, and the lack of a comprehensive regulatory regime in Europe (and indeed elsewhere), a need arises to highlight the emerging ethical and legal dilemmas and consider an up to date regulatory framework. Further, with inevitable advances in science, as well as increasing internet accessibility, the challenges presented are likely to become more amplified. In consideration of the ethical and legal challenges arising, this paper highlights the regulation of DTC genetic testing as a key concern of the EU, recognising its importance to both the scientific community as well as in respect of enhancing consumer confidence in such technologies.

2171T

Regulating Genome Editing Technologies: Towards a Proportional Approach. *R. Isasi, E. Kleiderman, B. M. Knoppers.* Centre of Genomics and Policy, McGill University, Montreal, PQ, Canada.

Human genome editing represents an innovative and powerful tool offering great scientific and therapeutic promise. Yet, it has rejuvenated old socio-ethical and legal (ELSI) debates and society is faced, once again, with assessing the implications of intentional human germline modification. Professional organizations and regulatory and funding agencies are calling for the scientific community to proceed with caution by establishing robust frameworks so as to assess the safety and efficacy of this technology, while also considering its socio-ethical dimensions. For some, a cautious approach represents adopting tiered policy measures, for example, by means of self-imposed moratoria limited to research and/or clinical activities directed at germline modification. For others, it means maintaining a vigilant attitude while allowing the gathering of evidence on the benefits and risks of the technology. Still, for some, a precautionary approach entails adopting outright legal restrictions that could go as far as limiting somatic genome modification. To contextualize and assess the strengths and weaknesses of current proposals, and to help inform ELSI and scientific debates, this presentation will focus on the results of an international comparative study of policy frameworks regulating somatic and germline modification in 16 jurisdictions (e. g. Australia, Belgium, Brazil, Canada, China, France, Germany, India, Israel, Japan, Mexico, Singapore, South Korea, the Netherlands, the United Kingdom and the United States). We will address convergence and divergence of positions on issues related to the permissibility of germline and somatic technologies in research and clinical applications, the effectiveness of current policy restrictions and the adequacy of existing oversight mechanisms. Finally, we will identify strategies to aid in the development of a coherent approach to consensual policy and promote proportional oversight of genomic technologies.

2172F

Ethical and Legal Issues Associated with the Use of Genomic Information in the Context of Pandemic Influenza. *M. Lewis, T. Bailey.* Johns Hopkins University, Baltimore, MD.

Advances in genomics are contributing to the growing body of evidence about genetic determinants of infectious disease in humans. President Obama's Precision Medicine Initiative likely will further drive scientific inquiry to deepen our understanding of how genetic factors can impact the human body's response to infectious agents, their treatments, and vaccines developed to prevent disease. In the scientific community, there is general consensus that a significant influenza pandemic is inevitable. In the near future, it may be possible to classify individuals as having increased or decreased susceptibility to influenza based upon the individual's genetic profile. Specific genetic variants have been shown to be associated with development of severe disease. In contrast, other variants have been shown to limit the mortality and morbidity associated with influenza infection. If an influenza pandemic (or other type of outbreak) with significant morbidity and mortality were to occur, this type of genetic information could be used to facilitate decision-making in policies related to quarantines, workforce availability, the allocation of scarce resources, and other issues. This presentation will examine the important ethical and legal issues that could be raised if genetic information is used in this way and will explore the extent to which state and federal laws, including genetic privacy laws, could potentially impact the use of genetic information in this context. The presentation will develop a framework to consider the legal and ethical issues raised by the use of genetic information in this setting. This type of framework could be used to consider in real time the ethical, legal and social challenges that could arise.

2173T

What are the clinical and socioethical recommendations of researchers and physicians about inherited chromosomally integrated human herpesvirus 6? *V. Noel[1], R. Drouin[1,2], L. Flamand[3], C. Bouffard[1].* 1) Laboratory of Transdisciplinary Research in Genetics, Medicines and Social Sciences, Div Genetics, Dep. Pediatrics, Fac. Medicine & Health Sciences, Univ Sherbrooke, Sherbrooke, QC, Canada; 2) Dep. Pediatrics, Faculty Medicine, Laval Univ. , Quebec City, QC, Canada; 3) Dep. microbiology, infectious disease and immunology, Faculty of Medicine, Laval Univ. , Quebec City, QC, Canada.

The human herpesvirus 6 (HHV-6) has the unique capacity to integrate telomeres of the chromosomes (ciHHV-6) of nucleated cells after infection. ciHHV-6 can therefore be found in gametes and be transmitted from one generation to the next and through organ and tissue donation. This worrisome situation affects between 40 and 70 million people around the world and may be associated with illnesses (encephalitis, infertility, cancers, etc.), of which some are fatal. Despite its consequences, this phenomenon has attracted little interest in scientific and public health milieus. To highlight the importance of this issue, several researchers and physicians go so far as to publish warnings in basic research articles in purely scientific journals. This uncommon phenomenon, prompted us to investigate these concerns. Thus, our objectives are to know: 1) the positions of these researchers and physicians about the current situation, and 2) the solutions they propose in order to identify their clinical and socio-ethical concerns. **METHOD**: Qualitative design used asynchronous online text-based interviews (combine questionnaire and chat box) with 24 researchers and physicians working on HHV-6. Qualitative generale inductive analysis with the use of NVivo10 software. **RESULTS**: The participants suggested four types of interventions: 1) the establishment of a screening program in the context of grafts and transplants; 2) medical information on the integrative capacity of HHV-6 and pathogenicity of ciHHV-6; 3) reevaluation of types of antiviral drugs and doses to counteract the adverse effects of pharmacological treatments and standardize the therapeutic treatment plan; 4) standardization of diagnostic tests to prevent false positives or negatives. Participants reflect on the clinical and ethical scopes of a screening program in the contexts of clinical practices and grafts or transplants. **CONCLUSION**: It was very interesting to note the convergence of opinions and the recommendations of the participants. The concerns are numerous and justified considering the lack of knowledge about the ciHHV-6's clinical and ethical consequences. These first data on the topic respond to needs expressed by researchers and physicians concerned by the ciHHV-6 in their practices. In this sense, the results of this research can guide the thinking and decision-making process to improve and harmonize practices and the wellbeing of affected individuals and populations.

Attitudes of genetics professionals and anthropologists toward race, ancestry, and genetics: results of a national survey. *J. Yu[1], S. C. Nelson[2], T. M. Harrell[1], J. K. Wagner[3], C. D. M. Royal[4], M. J. Bamshad[1,5].* 1) Department of Pediatrics, University of Washington, Seattle, WA; 2) Institute for Public Health Genetics, University of Washington, Seattle, WA; 3) Department of Anthropology, Pennsylvania State University, State College, PA; 4) Department of African and African American Studies, Duke University, Durham, NC; 5) Department of Genome Sciences, University of Washington, Seattle, WA.

Genetics professionals (GPs) influence public opinion about race and ancestry. Claims about population genetics research and GPs' attitudes toward these topics are pervasive in the public domain and contribute to ongoing debates about the role of race and genetic ancestry in research, medicine, and society. Indeed, some of the most vocal concerns about GPs' use of race and genetic ancestry have come from anthropologists. We assessed GPs' and anthropologists' perspectives on the relationships between race, ancestry, and genetics to identify concerns and inform the development of relevant policies. We conducted a 49 item online survey with GPs (n=1513) and anthropologists (n=3286) about race, ancestry, and genetics and their relevance to science, health, and society. Notably, responses to common statements about race differed between GPs and anthropologists. For example, a majority of GPs disagreed with common statements such as "races don't exist" (61%) and "race has no genetic basis" (67%) whereas most anthropologists agreed with such statements. The majority of respondents (52%) agreed that genetic ancestry testing should be subject to federal regulation and rejected its use in adoption (80%), university admissions (88%), and by law enforcement (57%). More than 70% of respondents agreed that the term "race" should be replaced by a more appropriate and precise term, but fewer GPs (51%) than anthropologists (71%) agreed that the use of the term "race" to describe human groups should be discontinued. Nearly 80% of respondents agreed that genetic ancestry—inferred from genetic markers—rather than race, is a better proxy for genetic relationships among sub-Saharan Africans, Asians, Europeans, Pacific Islanders, and Native Americans; yet fewer anthropologists (37%) than GPs (61%) agreed that continental populations – Africans, Asians, Europeans – are useful for examining genetic relationships (i. e. relatedness) among people. Qualitative analysis of 515 GPs' survey comments revealed that GPs recognize many different definitions of race that they use selectively depending on context. Overall, GPs and anthropologists appear to disagree about the biological relevance of race yet mainly agree in many other respects about the use of race and genetic ancestry. We suggest that recommendations about the use of race and genetic ancestry should move beyond debate over definitions and instead focus on specific contexts such as in scientific research, medicine, and society.

2175T

An Unreasonable Lack of Accommodation? GINA and the Legal Issues of Using Human Genetic Information in Workplace Infectious Disease Control. *T. C. Bailey, M. H. Lewis.* Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD.

The 2008 Genetic Information Nondiscrimination Act (GINA) broadly prohibits uses of genetic information in employment-related decisions concerning hiring, firing, and the terms and conditions of employment. In this, it proceeds from the flawed assumption that there are no scenarios in which genetically differentiated employment decisions are on balance preferable and justifiable in comparison to GINA-compliant genetically neutral employment policies. In this paper, we challenge this assumption in the context of workplace infectious disease control policies like mandatory employee vaccination, infectious disease screening and treatment requirements, and work assignments that under GINA must be applied in a genetically neutral fashion without consideration of individual human genetic factors that affect the acquisition, clinical course, transmission, testing, treatment, or prevention of infectious diseases. We contend that GINA unreasonably precludes employers from taking cognizance of and accommodating the genetically heightened risks (as opposed to phenotype based risks) that some employees may face compared to others from genetically neutral workplace infectious disease control policies. We defend this contention with a focused analysis of GINA's application to three hypothetical health care employment scenarios involving genetically neutral workplace infectious disease control policies applied to employees with genetic factors that adversely affect the course or control of infectious diseases:1) A genetically neutral workplace vaccine mandate applied to employees with information of personal genetic factors associated with heightened propensity to develop serious adverse reactions to the required vaccine or reduced propensity to develop protective immunological responses to the vaccine. 2) A genetically neutral work assignment of employees to care for patients with infectious diseases despite their having information of personal genetic factors associated with heightened propensity to acquire those diseases or, if infected, develop clinically severe forms of the diseases. 3) A genetically neutral annual screening of employees for particular infectious diseases with subsequent requirement of treatment applied to employees with information of personal genetic factors associated with reduced propensity to develop transmissible disease or with heightened propensity to develop serious adverse effects to the required treatment.

Crafting Tools to Engage the Public in Newborn Screening Policy. *R. Ryan[1], B. Koenig[1], H. Longstaff[2, 3], J. Harris-Wai[1, 4].* 1) Institute for Health and Aging, University of California, San Francisco, San Francisco, CA, CA; 2) Engage Associates, Vancouver, BC Canada; 3) Office of Research Ethics, Simon Fraser University, Burnaby, BC Canada; 4) Kaiser Permanente Northern California, Division of Research, Oakland, CA.

Nearly every child born in the U. S. is screened for multiple lethal or debilitating inherited disorders at birth through state-run newborn screening programs (NBS). Recently, two NBS programs were sued following high profile media coverage, resulting in the destruction of over 5 million bloodspots. In the face of growing public concern and pressure for expansion based on technological innovation, it is critical to seek authentic community guidance of NBS programs. While there are several promising models of community engagement for genomics policy development, few of these models have been systematically evaluated. The purpose of this analysis is to describe: 1) the development and implementation of a deliberative community engagement (DCE) convened to inform policy decisions in the California NBS program and 2) the creation of novel evaluation tools to examine whether and how our DCE model was effective at obtaining informed, legitimate, and representative input for the CA NBS program. We use a deliberative democracy framework to inform our four-day DCE. The first phase utilizes various communication formats to educate 30 deliberants about the NBS program from a diverse range of perspectives. Afterwards, deliberants participate in large and small group discussions to generate a set of policy recommendations on several decisions facing the NBS program. These include how stored bloodspots can be shared with researchers in a way that maintains public trust, how and when permission should be obtained from families for research use of bloodspots, and ongoing community involvement in the newborn screening program. The four key variables used to evaluate the DCE are: 1) quality of recommendations; 2) legitimacy of process and recommendations; 3) capacity for future recommendations; and 4) impact of the DCE on participant knowledge and attitudes about NBS and the DCE process. We use a mixed-methods approach to assess and evaluate each of these key constructs, including pre/post-test surveys, transcript analysis of selected group discussions, post-DCE survey, and expert review of the DCE and final recommendations by an external evaluator using a structured checklist. Few deliberative engagements conduct systematic evaluations, and selecting evaluation criteria has been noted as a distinct challenge to the field. Our evaluation tools are useful in evaluating the quality, process, and legitimacy of the DCE and its impact on deliberants and policy outcomes.

2177T

Advanced cancer patients' attitudes regarding incidental findings arising from tumor genomic profiling. *J. G. Hamilton[1], E. Shuk[1], M. Genoff[1], P. Gaissert[2], V. M. Rodríguez[1], J. L. Hay[1], K. Offit[2], M. E. Robson[2].* 1) Department of Psychiatry & Behavioral Sciences, Memorial Sloan Kettering Cancer Center, New York, NY; 2) Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY.

Background: Tumor genomic profiling is used in patients with advanced cancers to guide targeted treatments and clinical trial participation. This process involves sequencing a patient's germline DNA to aid in the interpretation of somatic variants, and can thus reveal complex incidental findings regarding a patient's inherited disease risks. As the medical genetics community debates the management of incidental findings, it is critical to understand how cancer patients view the implications of this information for themselves and their families. Method: We interviewed 40 patients with advanced breast, bladder, colorectal, or lung cancer who had tumor genomic profiling at our institution (10 patients for each cancer; 63% female, 85% white, ages 30-82). Patients were not offered their incidental findings, but were asked to discuss anticipated benefits and harms of these results. Transcribed interviews were evaluated using a thematic content analysis approach consisting of coding and interpretation of the data by team consensus. Results: Most participants were interested in learning their incidental findings due to perceived benefits including the inherent value of information, and the ability to inform future disease prevention, detection, or treatment efforts; altruistically help others; provide health benefits to family; and explain their cancer diagnosis. Yet, some expressed disinterest due to concerns about the limited clinical utility of these results given their terminal disease status and/or age, and psychological effects. Many could not identify harms of learning incidental findings, whereas others noted adverse psychological effects and concerns about the complexity or uncertainty of information, privacy and insurance implications, and family communication challenges. A majority also believed that their immediate family would be interested in learning their incidental findings. Nearly all participants believed that doctors should offer to return actionable incidental findings, but most thought that patients should have a choice of whether or not to receive this information. Conclusion: Advanced cancer patients are interested in learning incidental findings, although concerns exist about the clinical and emotional implications of this information for patients and their families. Such concerns must be addressed to ensure that patients make informed decisions about learning incidental findings, and to derive maximal health benefits from this information.

2178F

Interest in and outcomes with return of individual genetic research results for inherited susceptibility to breast cancer. *A. R Bradbury[1], L. Patrick-Miller[2], B. E. Egleston[3], A. Brandt[1], J. Brower[1], L. DiGiovanni[1], J. M. Long[1], J. Powers[1], J. Stopfer[1], K. L. Nathanson[1], K. N. Maxwell[1], S. M. Domchek[1].* 1) Medicine, Division of Hematology-Oncology, University of Pennsylvania, Philadelphia, PA; 2) Center for Clinical Cancer Genetics. The University of Chicago Medical Center, Chicago, IL; 3) Biostatistics and Bioinformatics Facility, Fox Chase Cancer Center, Temple University Health System, Philadelphia, PA.

Background: Interest in, optimal communication models and patient reported outcomes (PROs) of returning individual genetic research results (IRR) are unknown. **Methods:** Breast cancer patients who provided a biosample for research were offered the opportunity to receive IRR for 25 cancer susceptibility genes. Participants completed pre- (V1) and post-test (V2) counseling and surveys evaluating PROs. We used linear regressions with estimation by GEE where appropriate. **Results:** Of 854 IRR available, 64 participants were deceased; 81 did not have contact information. 400 participants have been contacted. 90 (23%) consented to study, 9 (2%) declined, 107 (27%) did not respond to repeated contacts, and 40 (10%) are considering participation. 142 (36%) have not had a follow-up contact. To date, 72 have completed V1 and 65 (90%) chose to receive IRR (V2). 11 (17%) participants received a positive IRR including 3 deleterious/likely deleterious (D/LD) results in high-penetrance genes (*MSH2, MSH6, TP53*) and 8 in moderate-penetrance genes *(ATM, CHEK2, MYH Het, RAD51D*). 14 (22%) participants learned of a VUS. Confirmatory testing was recommended for all D/LD IRR and VUS in high-penetrance genes. To date, 13/14 (93%) were confirmed clinically; confirmatory testing was covered by insurance in all cases. Anxiety, depression, and uncertainty decreased after receipt of IRR (Table 1). Those with a positive result had greater decreases in uncertainty (p=0. 03 compared to negatives but not VUS, p=0. 20) and increases in satisfaction (p=0. 01 compared to negatives but not VUS, p=0. 07).

Table 1	Baseline**N=55^N=43^^	After V1**N=55^N=43^^	After V2**N=43^^

Conclusions: A minority of research participants are interested in receiving IRR. Most chose to receive IRR after genetic counseling and do not experience increases in distress or uncertainty. Confirmatory testing is important and to date has been covered by insurance.

2179T

Assessment of Current Practice and Athletic Trainers' Knowledge of the NCAA Sickle Cell Trait Screening Mandate. *M. Crandall[1], J. Scott[1], S. Dixon[1], R. Macatangay[1], M. Blitzer[1], J. Boughman[2].* 1) University of Maryland, School of Medicine, Baltimore, MD; 2) University System of Maryland, Alephi, MD.

Purpose: Keeping student athletes safe is an ongoing goal among all schools and sports, yet unfortunately, there are still exercise-induced sudden deaths occurring each year. One suspectedcause is sickle cell trait (SCT). SCT is a typically asymptomatic genetic condition yet evidence shows under extreme physiological conditions (including intense exercise or dehydration) SCT can cause significant problems and potentially sudden death. Following a lawsuit, the National Collegiate Athletic Association (NCAA) is now mandating universal SCT screening for all student athletes within their conferences but not much is yet understood about the implementation of the mandated screening. This study was designed to assess the current practice of this mandate as well as the overall awareness and comfort of athletic trainers working within this capacity, to identify inconsistencies where additional resources may be useful. **Methods**: An online survey was administered to all certified athletic trainers in the mid-Atlantic region, recruiting 330 responses, an 8% response rate. **Results**: Approximately 52% of trainers working in the collegiate setting reported athletic trainers are responsible for disclosing and discussing SCT screening results with student athletes. Trainers reported less comfort discussing these results than solely disclosing a positive or negative result. Comfort level was significantly correlated with type of previous experience or education in genetics. Trainers that reported formal experiences expressed greater comfort discussing SCT results (p=0. 006). Trainers also reported a wide variety of additional healthcare professionals that they would contact for information on this topic; collegiate trainers reported seeking a general practitioner most often. Most (71%) trainers reported their institution does not provide them access to healthcare professionals trained in genetics. Those provided such access, did not report consistent procedures for consultation. **Conclusion**: This study has identified significant variability in the current practice of implementation of the NCAA SCT screening mandate that may impact achievement of its intended goal. Additional resources should become more routinely accessible, and more involvement of genetics professionals, including genetic counselors, in the follow-up education and dissemination of this genetic material should be considered.

2180F

Is there an ethical and/or legal obligation for healthcare providers to re-contact former patients in light of new genetic findings? *D. Carrieri[1], S. Dheensa[2], A. M. Lucassen[2], P. D. Turnpenny[3], A. J. Clarke[4], S. E. Kelly[1].* 1) University of Exeter, UK; 2) University of Southampton, UK; 3) Royal Devon and Exeter Hospital, UK; 4) University of Cardiff, UK.

Advances in genetics and genomics have the potential to allow more accurate diagnoses, improve knowledge of disease aetiology and risk, and inform therapeutic decisions. For health benefits of genomics to be achieved, a number of issues in clinical implementation need to be addressed, including ethical and practice issues that have yet to be examined empirically and conceptually in any depth. Key among these is the clarification of professional responsibilities and obligations, as well as patient expectations, for recontacting patients in light of new genetic findings and the reinterpretations of earlier findings. These issues are becoming more urgent with the arrival of Genomics England and related endeavors. Our current three year (2014-2017) ESRC funded project 'Mainstreaming Genetics: Re-contacting patients in a dynamic healthcare environment' http://ex. ac. uk/mgc addresses these questions. In particular it aims to: 1. Survey current clinical practices regarding re-contacting in the NHS and other European healthcare systems 2. Analyse the ethical and legal issues surrounding a potential responsibility or obligation to re-contact patients 3. Investigate patient and healthcare professional perspectives concerning re-contacting in different medical specialties using semi-structured interviews, vignettes, and questionnaires 4. Engage with stakeholders to integrate the above findings and analyses in the drafting of professional guidance or to develop a professional framework for making decisions about re-contacting patients We will present and discuss the framing and initial findings of this project.

Whole genome sequencing (WGS) in paediatrics promises to provide a transformative set of tools for gene discovery and clinical care, but evidentiary, ethical, and implementation challenges remain. While reporting adult onset medically actionable secondary variants (SVs) in children is the subject of vigorous ethical debate and emerging best practice guidelines, there is a paucity of research examining the perceived benefits and risks of WGS from the perspective of parents of children enrolled in WGS protocols. To this end, we explored parental experiences with WGS, as well as their preferences and reasoning related to pursuing or declining SVs for themselves and their children. The Hospital for Sick Children's Genome Clinic analyzes genomic data from children with developmental delay and/or congenital anomalies for both primary and secondary variants. A choice-based model, grounded in a relational best interests rationale, is used for managing the return of SVs to parents of index children. Parents of children enrolled in the Genome Clinic were invited to participate in semi-structured interviews following completion of an informed consent discussion and pre-test counseling. Interviews were transcribed verbatim and analyzed thematically, using a mixed coding strategy whereby pre-determined codes from the interview guide and emergent codes from the data were combined. We report the perspectives of 23 parents of 18 Genome Clinic participants. The majority of parents were supportive of WGS; they valued its role in providing diagnostic 'answers' to potentially guide treatment and family planning, and in advancing science. However, many parents expressed ambivalence about the receipt of SVs and importantly, some chose to learn SVs for their child but not for themselves. In part, ambivalence stemmed from the struggle to weigh and balance perceived benefits and risks to their child and to themselves. But ambivalence also stemmed from the perception that parents have a moral obligation to learn about their child's SVs regardless of any personal stress associated with this knowledge. Our findings align with previous reports indicating that parents endorse genome-based diagnostic testing. However, our findings expose a degree of moral pressure on parents to know what WGS makes knowable and, inidentifyingparents' interests inSVs fortheirchildren but not for themselves, challenge arelationalbest interests rationale for disclosing adult-onset SVs. .

My46 usability and preferences for results among African Americans. *S. M. Jamal[1], J. Yu[1], J. Crouch[2], A. Shankar[1], M. J. Bamshad[1,3], H. K. Tabor[1,2,3].* 1) UW Department of Pediatrics, Seattle, WA; 2) Seattle Children's Hospital and Research Institute, Seattle, WA; 3) UW Department of Genome Sciences, Seattle, WA.

The majority of translational research on return of genome sequencing results has focused on European Americans affected by rare genetic conditions. In this context, web-based digital tools have been developed and used to provide education during informed consent, solicit preferences, and return results. As genome sequencing is increasingly used in racially and ethnically diverse populations, testing novel approaches to soliciting preferences and returning results will be critical to ensuring parity in genomic healthcare and research. We conducted interviews with 24 African Americans (AA) to assess the usability of My46, a web-based tool, to solicit preferences for genome sequencing results. In pre-preference setting interviews, a third of participants expressed interest in learning ancestry inference results, followed by results for cancer, diabetes and sickle cell disease/trait often motivated by family history and interest in conditions that disproportionately impact AAs. When presented with options for results classified by trait categories, the majority (58%) sought all available results. Everyone wanted carrier results; 96% wanted results about medication response, genetic ancestry, and risk of heart disease; and 79% wanted results about digestive and muscle conditions. Half thought they might or would likely change their preferences for results return in the future, especially if their health changed. My46 usability scores (ranging 1-5) were consistently high: overall mean score was 4. 47; subscale scores for system use (4. 52), information quality (4. 44), and interface quality (4. 46). Almost all participants indicated high satisfaction using My46 to choose results, felt that My46 provided information to select preferences, and would recommend My46 to others. Despite high satisfaction, 25% would have rather chosen preferences with a person than a website. By comparing participants' initial expectations for results with their My46-solicited preferences, we highlight the importance of offering specific categories of results. These results also suggest that soliciting preferences may be a dynamic process rather than a one-time event, and that a fraction of research participants will prefer face-to-face interaction despite expressed satisfaction with a web-based tool. These findings support the use of web-based approaches to solicit preferences for sequencing results from AA research participants and characterize the usability of one such tool, My46. org.

2183T

Content and delivery preferences for genome sequencing results among young breast cancer patients. *K. Kaphingst[1,2], A. Elrick[1,2], J. Ivanovich[3], B. Biesecker[4], S. Lyons[3], M. Goodman[3].* 1) Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; 2) Department of Communication, University of Utah, Salt Lake City, UT; 3) Division of Public Health Sciences, Washington University School of Medicine, St. Louis, MO; 4) Social and Behavioral Research Branch, National Human Genome Research Institute, Bethesda, MD.

Introduction. Genome sequencing raises the challenge of returning secondary findings. To inform policies for return of results, we examined what genome sequencing results young breast cancer patients would want returned, from whom, and when, since various results could be relevant at different life stages. **Methods.** 1080 women diagnosed with breast cancer age 40 or younger completed an online survey. We examined level of interest, preferred source, and preferred timing for return of seven types of possible genome sequencing results: risk of preventable/treatable disease or unpreventable/untreatable disease; treatment response; unknown meaning; health of children/other relatives; and non-health (ancestry/physical traits). We built seven multivariable logistic regression models to assess whether prior genetic testing, family history of breast cancer, BRCA mutation status, genome sequencing knowledge, and importance of health information were associated with preferred timing for return of each result type. **Results.** The proportion very interested in each result type ranged from 77% (risk of preventable/treatable disease) to 16% (unknown meaning). The majority of participants (64% to 81%) preferred that each type of result be returned by a genetic counselor or clinical geneticist, except for variants affecting treatment response for which the most common preference was an oncologist (37%). The proportion that wanted a result type returned before or at breast cancer diagnosis ranged from 96% (treatment response) to 31% (ancestry/physical traits). In multivariable models, no variable predicted preferred timing of return for all result types. Three factors were significantly associated with preference for results return before/at diagnosis in at least four models: knowledge of genome sequencing limitations (odds ratios [ORs]: 0. 89-0. 93); importance of health information (ORs: 1. 1-1. 5); and prior genetic testing (ORs: 0. 49-0. 65). **Discussion.** Participants were most interested in actionable findings delivered by a genetics professional. Preferred timing varied across types of results; participants with less knowledge of genome sequencing limitations, no prior genetic testing, and greater reported importance of health information were more likely to want return of results before or at diagnosis. A one-size-fits-all policy for return will likely not meet these patients' needs or preferences, and options to return results at different times may be warranted.

2184F

Genomic Sequencing of Newborns: Exploring Psychosocial Risks to Families. *S. Pereira[1], L. Frankel[1,2], J. O. Robinson[1], C. M. Weipert[3], M. C. Towne[4], A. Gutierrez[1], K. Lee[1], I. A. Holm[4,5], D. Dukhovny[6], A. H. Beggs[4,5], R. C. Green[3,7], A. L. McGuire[1].* 1) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 2) Department of Psychological, Health, and Learning Sciences, University of Houston, Houston, TX; 3) Division of Genetics, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 4) Division of Genetics and Genomics, Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA; 5) Department of Pediatrics, Harvard Medical School, Boston, MA; 6) Department of Pediatrics, Oregon Health & Science University, Portland, OR; 7) Partners Center for Personalized Genetic Medicine, Boston, MA.

The integration of genomic sequencing into the clinical care of newborns has been met with both enthusiasm and trepidation. While genomic sequencing has the potential to provide clinical and personal utility to physicians and families, there are also concerns about the psychosocial risks of disclosing genomic information. Empirical studies exploring the psychosocial risks of returning genomic information to individuals have found no measureable changes to participants' psychological health, though these studies have primarily focused on symptoms of depression and anxiety in adults in response to receiving their own results. There is little data on how returning genomic information to parents about their children impacts family relationships. Furthermore, despite growing interest around exploring how genomic sequencing can be integrated into newborn screening, there is almost no data examining the impact on families of returning genomic information on newborns. Thus, research to fully understand the benefits and harms of genomic sequencing of newborns is vitally needed. The BabySeq Project is a randomized, controlled trial evaluating the benefits and potential harms of providing genomic sequencing to families of newborns and their physicians. Two cohorts of newborns and their parents are being enrolled: 240 newborns from the Well Baby Nursery at the Brigham and Women's Hospital in Boston, and 240 from the Neonatal Intensive Care Unit (NICU) at Boston Children's Hospital (480 total); their health care providers are also being enrolled. Newborns are randomized to receive standard newborn screening (NBS) only, or NBS plus genomic sequencing. Parents complete longitudinal surveys at 4 time points over the course of their baby's first year of life assessing psychosocial response, family impact, and attitudes toward and perceived utility of NBS and genomic sequencing. Impact on family relationships is assessed in three specific domains: perceived child vulnerability, parent-child bonding, and self and partner blame. Drawing from psychology and genetic counseling literature, this presentation will examine the relevance and implications of these family dynamic phenomena to the use of genomic sequencing in the clinical care of newborns.

"We all get dealt our cards": Participant Responses to Return of Secondary Results from Exome Sequencing. *H. K. Tabor[1,2,3], J. Crouch[2], S. Nelson[1], K. B. Shutske[2], S. M. Jamal[1], A. Shankar[1], J. Yu[1], M. J. Bamshad[1,3].* 1) Dept. of Pediatrics, University of Washington, Seattle, WA; 2) Treuman Katz Center for Pediatric Bioethics, Seattle Children's Research Institute, Seattle, WA; 3) Dept. of Genome Sciences, University of Washington, Seattle, WA.

Exome sequencing (ES) is being used increasingly in a broad range of research and clinical settings. Consequently, much debate continues about whether and how secondary results (SR) should be offered for return, which SR should be offered, and the potential benefits and harms of SR to both pediatric and adult patients. Yet, there are little empirical data about responses to and impact of SR return, and no empirical data about the impact of SR that may have clinical utility but may not be considered "actionable. " Studying such responses is important to guide policy development on return of SR. We recruited 131 people, who had previously undergone ES as a part of research studies, to select preferences for SR return. The study population included 52 parents receiving SR for their children and 79 adults receiving their own SR. Primary diagnoses of participants included: autism; brain, limb and craniofacial malformation disorders; cystic fibrosis; thoracic aortic aneurysm/dissection; and dilated cardiomyopathy. Participants were told that no results related to their primary condition would be identified or returned. On average, 4 results were returned (range of 0-7), and included results for risk of type 2 diabetes and age-related macular degeneration, a range of carrier status results, and medication response. We interviewed 48 participants one month after they received SRs and conducted qualitative content analysis of interview transcripts. We identified several key themes in responses to SR. First, most participants were not upset by SR and did not view them as upsetting or as "a crisis. " Second, they described the impact of SR being mitigated in context of other life events, such as health or personal issues. Third, they planned to apply health information management approaches that they used for their primary condition to their SR. Fourth, they planned to use SR to plan for the future, especially among parents of children with cognitive delays. Fifth, they planned to use SR as a motivator for health-promoting behavior. Sixth, they viewed SR as explaining family history or confirming diagnoses/risks they were already aware of. Seventh, they expressed disappointment that they had not received more genetic results and a desire for additional information. In conclusion, empirical data about SR-specific responses can provide important guidance for the offer, receipt and translation of SR as a part of clinical ES and its application to precision medicine.

2186F

Public Attitude Toward Disclosure of Incidental Findings in Genomics Research. *Z. Yamagata[1], I. Ishiyama[2], K. Muto[3], J. Minari[4], G. Yoshizawa[4], K. Kato[4].* 1) Dept Health Sciences, University of Yamanashi, Chuo, Yamanashi, Japan; 2) Tokoha University, Shizuoka, Japan; 3) The University of Tokyo, Tokyo, Japan; 4) Osaka University, Osaka, Japan.

[Objectives] The return of the findings to the participants, in particular incidental findings, is a controversial issue. This study aims to determine the public attitude toward the return of incidental findings obtained from genomics research. [Methods] From the general Japanese population, 2,400 people were selected using a random sampling and a mail survey administered in February 2014. The questions that were used in this study were as follows: (1) Do want to know the incidental findings?; (2) When do you want to declare your intention whether or not you want to know the incidental findings?; (3) What kind of incidental findings do you want to know?. A multiple logistic regression analysis to determine the factors related to whether they want to know the incidental findings was also conducted. [Results] The response rate was 56. 4%. The response that indicates they want to know incidental findings was 72. 0%; the response that indicates they do not want to know was 6. 4%; the response that indicates they were undecided was 21. 6%. There were no differences according to gender. For the timing of declaration of intention whether or not they want to know incidental findings, the response that indicates they want to declare it when they participated in a study was 22. 1%; the response that indicates they want to declare it when incidental findings are known was 38. 9%; the response that indicates they want to declare it both when they participated in a study and when incidental findings are known was 37. 4%. For the type of incidental findings they want to know, the response that indicates findings related to diseases of which prevention and treatment methods are available was 62. 2%; the response that indicates findings related to diseases of which prevention and treatment methods are unavailable was 44. 0%; the response that indicates findings related to effect of drugs and the presence or absence of side effects was 70. 0%. For the results of the multiple logistic regression analysis, the odds ratio of the response that indicates they want to know the findings was as follows: genomic literacy score, 1. 38 (95% confidence interval [CI] 1. 09 - 1. 74); age, 0. 96 (CI 0. 94 - 0. 98); no child, 0. 46 (CI 0. 23 - 0. 90); highly educated, 0. 88 (CI 0. 73 - 1. 07). [Conclusions] Of the study subjects, 70% responded that they wanted to know the findings. The response indicating they want to know the findings was associated with genomic literacy score, age and the presence of children.

2187T

Clinical Annotation of Sequence Variants in a Population-based Study of African Americans: Implications for report of incidental findings. *A. A. Adeyemo, F. Tekola-Ayele, A. Bentley, A. P. Doumatey, J. Zhou, G. Chen, D. Shriner, The. MH-GRID Consortium, CN. Rotimi.* NHGRI/CRGGH, National Institutes of Health, Bethesda, MD.

The widespread adoption of whole genome and whole exome sequencing (WES) in population genetic association studies has spurred great interest in how to handle incidental findings that could be of medical significance. In contrast to clinic based sequencing which is motivated by clinical indications, genetic association studies are implemented to identify variants that may not necessarily be the causal variant for the disease or trait. . We present our findings from WES of 555 unrelated African Americans from the Washington DC metropolitan area. The subjects were enrolled as part of the Howard University Family Study, a population based genetic epidemiology study with participants that were not ascertained for any specific phenotype. After appropriate technical filters, variants that had a call rate >= 95% (n=12,449) were annotated for clinical significance using the NCBI *ClinVar* database (20150504 version, n=111332 entries). Based on g the *ClinVar* classification of clinical significance, 471 (3. 8%) of the variants were classified as “pathogenic”, of which 56 were nonsense mutations leading to a stop codon. These represented a wide range of complex or monogenic disorders including: breast cancer susceptibility (e. g. *BRCA2*), drug toxicity (e. g. *TPMT* deficiency) and hematologic disorders (e. g. *G6PD* deficiency). Over 90% have entries in OMIM. While most of the disorders associated with the mutations are recessive or complex, eight of the mutations were for autosomal dominant disorders. There were 132 singleton and 1 doubleton individuals carrying pathogenic variants (in contrast to 1926 and 14, respectively for the other variants). Genes harboring these pathogenic mutations showed enrichment for the PANTHER pathways: blood coagulation (5. 87 X 10-6) and *TGF*-Beta Signaling pathway (8. 54X10-3). These findings illustrate how population based association studies have the potential to generate incidental findings of potential clinical significance. It also highlights the urgent need for sequencing studies to have in place at the onset a plan for handling incidental findings especially in study populations that lack adequate access to genetic counseling and medical genetics services.

2188F

Intentions to receive individual genetic research results and incidental findings from genomic studies among research participants in a familial cancer research program. *J. T. Loud, R. Bremer, P. Mai, M. H. Greene, B. P. Alter, S. A. Savage.* Clinical Genetics Branch, National Cancer Institute, Rockville, MD.

Purpose: To describe the frequency with which adult clinical research participants from high-risk families enrolled in a familial cancer research program give consent to receive their personal, clinically-validated research genetic test results (RR) and incidental findings (IF). **Methods:** Consents from 629 adult (≥18 years old) participants enrolled in three longitudinal studies within NCI's Clinical Genetics Branch's Family Cancer Research Program (Inherited Bone Marrow Failure Syndromes, Li Fraumeni Study and Familial Testicular Cancer Study) were obtained between January 2012 and June 2014. Genetically affected and unaffected individuals, including those with and without cancer were enrolled. Separate consents were obtained for the longitudinal study and for specific clinical genetic testing. A cross-sectional analysis was performed on the choices indicated on their most recent longitudinal study consent regarding receipt of RR and IF. **Results:** Nearly all research participants (97. 2%) indicated their preference to receive RR and IF. The participants who intended to decline either RR, IF, or both included: 3 cancer survivors (1=RR, 1=IF and 1=both), 9 who knew their primary mutation status (4=RR; 4=IF; 1= both), 3 were non-bloodline (1=RR; 2= both), 1 was untested but with the phenotype of interest (1=IF), and 2 were parents of an affected child (2=both). We speculate that the individuals who knew their mutation status (mutation positive=8; mutation negative=1) and declined RR, IF or both already had sufficient information or were not prepared to learn more. Both parents who refused both RR and IF had a child affected with a dominantly inherited syndrome, yet they chose not to learn which lineage harbored the mutation. The three cancer survivors were >50 years old, two were childless, and perhaps felt that the information wouldn't be useful for their personal healthcare decision-making. **Conclusions:** In this well-defined, highly-motivated population of individuals from families at high genetic risk of cancer, adult research participants overwhelmingly indicated their preference to receive both their RR and IF. Future research will seek to identify the underlying reasons for declining RR and IF in the small numbers of those who did so, and to study the impact of receipt of RR and IF on personal medical decision-making in individuals from families at high genetic risk of cancer.

2189T

Whole Genome Sequencing Analysis and Reporting for Ostensibly Healthy Individuals in a Research Study. *M. D. Linderman[1,2], G. A. Diaz[2], S. A. Suckiel[1,2], R. E. Zinberg[2], N. S. Abul-Husn[2,3], S. C. Sanderson[1], M. Wasserstein[2], E. Sarapata[4], A. Kasarskis[1,2], E. E. Schadt[1,2].* 1) Icahn Institute for Genomics and Multiscale Biology, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Genetics and Genomics Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 3) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; 4) Harvey Mudd College, Claremont, CA.

Personal genome sequencing (PGS) is increasingly employed for pre-dispositional screening for disease risk in ostensibly healthy individuals. The shrinking cost of whole genome sequencing (WGS) makes it possible to apply this technology to increase both the scope and precision of pre-dispositional PGS. However, the increased scope and complexity of this data creates corresponding challenges for the implementing laboratory and reporting provider. As part of the HealthSeq project, a longitudinal cohort study in which unselected ostensibly healthy participants received a variety of genetic results from WGS performed on the Illumina HiSeq platform, we developed a comprehensive sequencing analysis and interpretation protocol and report. We concurrently reported both health and non-health-related genetic findings to 40 individuals (5 in a pilot , 35 in the HealthSeq study), including monogenic disease variants, polygenic disease risk, pharmacogenomic phenotypes, physical traits and ancestry. A mean (SD) of 48. 9 (15. 9) potential monogenic disease variants per participant were extracted for review by genetics professionals, with 1. 65 (1. 5) and 0. 63 (1) ultimately determined to be pathogenic and likely pathogenic respectively, according to the then draft ACMG variant interpretation guidelines. Predicted absolute genetically informed risk for Type 2 Diabetes, Coronary Artery Disease and Age-related Macular Degeneration were in the ranges [35%, 84%], [43%, 63%] and [9%, 72%], respectively. No correlation was observed between predicted risk and participant-reported family or health history. Metabolizer phenotypes for clopidogrel and simvastatin, genotypes used for warfarin dosing, ancestry information, and genotype-based predictions for lactose intolerance and other non-health-related traits were also reported. We expect the breadth of the pre-dispositional PGS result return to grow over time to satisfy recipient interests and maximize test utility. Our experience concurrently reporting a broad spectrum of health and non-health-related PGS results will provide valuable data to inform the future development of much needed standards and procedures for predispositional WGS.

2190F

What is the psychological impact of personal genome sequencing on ostensibly healthy individuals? The HealthSeq project at six-month follow-up. *S. C. Sanderson[1,2], M. D. Linderman[1], S. A. Suckiel[1], R. Zinberg[1], G. A. Diaz[1], M. Wasserstein[1], A. Kasarskis[1], E. E. Schadt[1].* 1) Icahn School of Medicine at Mount Sinai, New York, NY; 2) University College London, London, UK.

There is growing interest in the potential value of whole genome sequencing (WGS) for seemingly healthy individuals. WGS in this context could potentially lead to improved health and wellbeing, advances in disease prediction and prevention, and even diagnoses of previously unsuspected disorders. The HealthSeq project is a longitudinal cohort study in which ostensibly healthy individuals were offered personal WGS results. Qualitative and quantitative interviews were conducted at multiple timepoints including 1 week ("T3") and 6 months ("T4") after personal results were returned. Psychological measures included an adapted version of the Multidimensional Impact of Cancer Risk Assessment (MICRA) questionnaire. Participants were asked how often they had experienced a range of positive and negative feelings about their personal genome sequencing (PGS) results over the past week (never/rarely/sometimes/often). Twenty-nine (82. 9%) of the 35 participants completed the T3 and T4 follow-up interviews. Scores on the 6-item MICRA Distress Subscale (0=no distress, 40=high distress) decreased from T3 to T4, although most participants' scores were low at both timepoints (mean 1. 69 vs. 0. 48 respectively: Z=-2. 68, p=0. 007). At T3, most participants reported they had never "regretted" having their genomes sequenced (27/29, 93. 1%); most that they had sometimes or often felt "relieved" (27/29, 93. 1%) and "happy" (28/29, 96. 6%) about their results; and one fifth (6/29, 20. 7%) that they had sometimes or often felt "concerned about insurance. " One participant reported having sometimes regretted having PGS. In the qualitative portion of the interview, this participant discussed their feelings about their PGS results which included a rare 'pathogenic' Brugada syndrome variant, and increased risk of Alzheimer's disease (APOE e4/e4). At T4, the majority of participants again reported never having regretted having PGS (28/29, 96. 6%); two thirds reported having felt relieved (18/29, 62. 1%) and happy (20/29, 68. 9%) about their results; and a quarter (7/29, 24. 1%) that they had felt "concerned about insurance". The majority, but not all, of HealthSeq participants reported positive experiences, and little distress or regret, about having PGS. Insights from the HealthSeq project regarding the psychological impact of PGS on healthy people will be useful for clinicians, researchers and policy-makers concerned with maximizing the potential benefits and minimizing the potential harms of PGS.

2191T

Developing a provider facing genome sequencing report: Results of key informant interviews. *J. L. Williams[1], A. K. Rahm[1], A. L. Fan[1], H. Stuckey[2], D. T. Zallen[3], J. Green[1], M. Bonhag[1], L. Feldman[4], M. Segal[4], M. S. Williams[1].* 1) Genomic Medicine Institute, Geisinger Health System, Danville, PA; 2) Department of Medicine, Penn State Hershey College of Medicine, Hershey, PA; 3) Department of Science and Technology in Society, Virgina Tech, Blacksburg, VA; 4) SimulConsult, Inc. , Chestnut Hill, MA.

Background: Genome sequencing is rapidly entering into clinical practice often without adequate education for clinicians to understand implications of the results that are returned. Rapid detection of new genes and mechanisms leave even seasoned geneticists scrambling to synthesize the resulting information into meaningful communication for patients. We propose to develop genomic results reports with advanced functionality including point of care education and clinical decision support. Providers associated with a whole genome sequencing research study were invited to participate in semi-structured interviews aimed at soliciting their feedback on a draft genome results report. **Methods:** A draft provider report was developed by the research team based on the CDC recommended genetic test report format. In addition to clinicians, the team includes a patient investigator and several experts in patient engagement and communication. The draft report was then presented to participants in a clinical research project exploring the use of genome sequencing for undiagnosed cognitive disability and autism. Semi-structured interviews were used to elicit prior experience with genetic test result communication and feedback about the draft report. Interviews were transcribed and analyzed using interpretative phenomenological review. **Results:** Participants endorse the importance of having a report created for providers and a report designed for patients. Analysis of provider comments resulted in recognition of three constructs around communication of genome sequencing results. Universally, the providers found genetic results complex and expressed concern about their ability to adequately understand the genomic finding and implications. Second, providers expressed relief at having diagnosis-specific information readily available within the context of the patient visit that guided clinical care for the patient. Finally, providers accepted and appreciated a resource that could support communication of genome results with families. **Conclusion:** Participants value a report that will offer explanation of genome findings in a way that increases communication of the result with their patients. The final genome results reports will be used in the comparative effectiveness portion of this PCORI project.

2192F

Parental Views of Newborn Screening Using Next Generation Sequencing Technologies: Implications for Policy. *G. Joseph[1], F. H. Chen[2, 3], J. Harris-Wai[3, 4], J. M. Puck[3, 5], C. F. Young[6], B. A. Koenig[2, 3].* 1) Anthropology, UCSF, San Francisco, CA; 2) Institute for Human Genetics, UCSF, San Francisco, CA; 3) Institute for Health and Aging, UCSF, San Francisco, CA; 4) Division of Research, Kaiser Permanente, Oakland, CA; 5) Pediatrics, UCSF, San Francisco, CA; 6) Genetics, CSU Stanislaus, Turlock, CA.

Parental views about the translation of next-generation sequencing (NGS) into the public health newborn screening (NBS) setting are not well elucidated. One goal of NSIGHT, a NICHD/NHGRI funded program exploring the use of NGS in newborns, is to examine stakeholder views, perspectives and values about the possible future expansion of NBS to include NGS. To address this goal, we conducted five 2. 5-hour-long focus groups between November 2014 and February 2015 with: parents of children with primary immune disorders recruited from an academic immunodeficiency clinic (1 group; n=5); and women 18-30 weeks pregnant recruited from prenatal clinics at two urban California hospitals, an academic medical center and a public hospital (3 English; n=22 and 1 Spanish; n=5). Participants represented a socio-economically and ethnically diverse sample. To elicit preferences about the incorporation of NGS into state-mandated public health screening, we provided information about case examples of pharmacogenomics (PGx) and adult onset disorders such as hereditary breast cancer, and explored issues of parental consent, return of results, and data privacy. Focus group recordings were fully transcribed in English. Transcripts were coded by multiple team members and analyzed using qualitative methods: thematic analysis of coded segments of text and constant comparison across demographic and disease categories. Several policy-relevant findings emerged: 1) a clear preference for more comprehensive NBS education in the prenatal period; 2) mixed views on whether a formal informed consent process was needed for current NBS or NBS expanded by NGS, but with expressed desire to be informed of downstream research using blood spots as a matter of respect and trust; 3) a preference for return of PGx results but no consensus on return of variants for adult onset disorders; and 4) expressions of both hope and concern about the medical system's capacity to safely store and make available NGS results when they are needed across the lifespan. Taken together, these results indicate that parents and prospective parents desire greater inclusion in the NBS process, suggesting the need for iterative review and revision of existing policies as technology evolves.

2193T

Ethical, legal and social implications of the application of genomics to infectious disease prevention, treatment and outbreak control. *R. Dvoskin[1], T. Bailey[1], P. Duggal[2], M. H. Lewis[1], D. Salmon[2], A. Sutherland[2], C. L. Thio[2,3], J. P. Kahn[1], G. Geller[1,2,3].* 1) Johns Hopkins Berman Institute of Bioethics, Baltimore, MD; 2) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3) Johns Hopkins Medicine, Baltimore, MD.

Advances in genomics are contributing to the development of more effective, personalized approaches to the prevention and treatment of infectious diseases. Sequencing technologies are furthering our understanding of how genomic signatures in humans, pathogens and vectors—and their interactions—contribute to individual differences in immunologic responses to infections, vaccines, and drug therapies. With the potential for tailored interventions for individuals or subpopulations, ethical, legal and social implications may arise for clinical and public health practice. We conducted 12 key informant interviews with international experts in genetic epidemiology, immunology, infectious disease surveillance, vaccine development, public health ethics, law and policy. We also conducted four two-hour focus groups on this topic, two with a diversity of Johns Hopkins faculty in relevant fields, and two with graduate students in the schools of medicine and public health. Themes identified included: host genomics will be important for developing better and safer treatments and vaccines; among the most important infectious disease applications of genomics are immunogenomics, vaccinomics, and pathogen genomics; and genomic information is already used in clinical decisions for infectious disease—without much regard for downstream (ethical) implications. We will present examples of genomic discoveries with current or potential implications for infectious disease management along with ELSI issues that could arise as a result. For example, given known associations between human gene variants and susceptibility to influenza infection or response to vaccination, might individuals' genetic information be used to influence workforce restrictions on healthcare personnel during a flu pandemic? Or, given associations between gene variants and non-response to hepatitis B vaccine, might genotype inform decisions about prioritizing access to therapy, particularly in resource-limited settings?We will highlight the importance of anticipating such ELSI issues in advance of new scientific discoveries. Additionally, we will ask attendees how they see genomics figuring in to infectious disease research and management in the next five to ten years; what ethical, legal, or societal concerns they might foresee; and how they would want these issues to be addressed and analyzed.

2194F

RWANDAN PATIENTS WITH DISORDERS OF SEX DEVELOPMENT: DIAGNOSTIC CHALLENGES AND BEHAVIOR PROBLEMS IN AFRICAN CONTEXT. *L. Mutesa[1], J. Hitayezu[1], A. Uwineza[1,2], S. Murorunkwere[1], J. Ndinkabandi[1], A. Ndatinya[3], F. Rutagarama[3], O. R. Karangwa[3], A. Gasana[4], J. H. Caberg[2].* 1) Center for Medical Genetics, University of Rwanda, KIGALI, Kigali, Rwanda; 2) Center for Human Genetics, University of Liege, Belgium; 3) Department of Pediatrics, Rwanda Military Hospital, Rwanda; 4) Department of Urology, Rwanda Military Hospital, Rwanda.

BackgroundDisorders of sex development (DSD) comprise a variety of congenital diseases with anomalies of the sex chromosome, the gonads, the reproductive ducts and genitalia. The most common DSDs result from disruption of androgen levels and activity that affect later embryonal development, such as congenital adrenal hyperplasia and androgen insensitivity syndrome (AIS). DSDs are always challenging and very difficult to manage. Socio-economic and cultural aspects have a great impact on decision making regarding the management of these conditions. The situation is more complicated in resource-poor settings like in Africa, where access to education and medical care is limited in both quantity and quality of infrastructure, diagnostic tools and medical professionals. In addition, traditional values and beliefs are also very strong in various cultures and sexual issues are taboo subjects. MethodsThe present study is a 5-year prospective descriptive cohort of patients with suspicion of DSDs referred to our genetic clinic between January 2010 and December 2014 for genetic investigations and counseling. All patients underwent abdominal ultrasound or MRI and hormonal analysis before genetic testing including karyotype and molecular tests. ResultsIn total,A series of 49 patients aged between 1 and 39 years were clinicaly and geneticaly diagnosed with DSDs associated with behavior problems in most of cases. The majority were diagnosed either with sexual ambiguity and hypospadias, or micropenis, or primary amenorrhea, or poor development of secondary sexual characteristics, or primary infertility. In most of female cases, the ultrasound and MRI revealed absence of uterus and ovaries. The FSH, LH or testosterone hormons revealed major abnormal values in more than 60% of patients. The AIS and Rokitansky syndrome were observed in the majority of these patients. The choice of gender identity after karyotyping raised several psychological and ethical issues in the majority of adults patients. The outcome of surgery was successful for the social integration of some of these patients. ConclusionThe present study showed that patients with DSDs have major behavior problems in African context. They suffer from extreme anxiety and very high psychological behavior disorders related to their gender identity. Our data suggest that gender assignment has to be avoided before expert and multidisciplinary evaluation especially in young patients.

Incidental pathology findings in the Genotype Tissue Expression (GTEx) program. *L. Carithers[1], S. Koester[2], R. Little[2], N. Lockhart[3], A. Rao[1], J. Struewing[3], S. Volpi[3], C. Weil[1], H. Moore[1].* 1) National Cancer Institute, Rockville, MD; 2) National Institute of Mental Health, Rockville, MD; 3) National Human Genome Research Institute, Rockville, MD.

GTEx is a National Institutes of Health (NIH) program that collects tissues from over 30 different tissues from hundreds of deceased donors and performs molecular analysis to evaluate the relationship between genetic variation and gene expression in normal human tissues. These deceased donors may have also donated organs and tissues for transplant purposes. Pathology review is conducted on all GTEx tissues to ensure that the correct target is sampled and to evaluate autolysis, however there have been rare observations which may have potential medical significance to either organ transplant recipients or to recipients of banked tissues (skin, bone, tendon, etc). The GTEx Executive Committee, made up of lead Program Directors from the National Human Genome Research Institute, the National Institute of Mental Health, and the National Cancer Institute, requested consultations with representatives of the NIH Department of Bioethics, relevant clinical experts and policy experts from the Organ Procurement and Transplantation Network (OPTN) to determine if an ethical obligation exists to return these incidental findings to the biospecimen source sites in order to allow notification using the proper medical and regulatory channels. They also examined the literature related to the risk of disease transmission to organ and transplant recipients. It was determined that there may be an ethical obligation to inform biospecimen source sites when incidental pathology findings could have potential medical significance to transplant recipients. A formal group of experts, the GTEx Incidental Findings Evaluation Group, composed of experts in oncology, pathology, and bioethics was established to evaluate incidental findings identified by GTEx pathologists. When the Evaluation Group determines that a pathology incidental finding may have potential medical significance to a transplant recipient, a pathology evaluation is requested from a CLIA certified pathology laboratory. The Evaluation Group then reviews the surgical pathology report from the CLIA lab and makes a recommendation to return or not return a finding to the corresponding biospecimen source site. Over 850 GTEx cases have been reviewed and only a select few cases have had incidental findings that were determined to be of potential medical significance to transplant recipients. Those findings have been returned to the biospecimen source sites for transmission to treating physicians and tissue banks.

2196F

Next-generation counseling: increased efficiency and high patient satisfaction utilizing web technology and telephone for post-test counseling and education in carrier and inherited cancer screening.
M. Gilats, G. A. Lazarin, K. Ready, E. W. Denne, I. S. Haque. Counsyl, South San Francisco, CA.

Post-test patient followup is integral to genetic screening programs. In cancer screening, an increasing number of patients is being tested outside traditional genetics clinics; in reproductive genetics,increasing use of expanded carrier screening (ECS) and its high test-positive rate also poses a challenge. The efficient allocation of genetic counselors' (GCs) time is a necessary step to large-scale implementation of genetic testing in these novel contexts.

To address this need, our laboratory has offered three models of an online results delivery system with access to post-test telephone genetic counseling. Here we compare the models' effects on GCs' time spent: V1 (every patient speaks to a GC), V2 (results are systematically triaged, and most patients are given results online, with web education and immediate GC consultation option), and a "traditional" model (the clinic delivers results and GC consultation is available when initiated by the patient).

We analyzed consultation uptake, duration, and satisfaction for 410,668 carrier screening results and 1,232 inherited cancer screening results issued by our laboratory, identifying the following trends:

1. In all versions, more serious results were associated with longer consultation times.
2. In V2 and the traditional model, more serious results were also associated with higher consultation uptake rates.
3. Consults were longer on average for V1 results than for V2. E. g. , an individual carrier consult was 12 min (9 - 17 min, interquartile range) for V1 and 10 min (7 - 15 min) for V2. The shorter consult times may derive from pre-consult web education issued through V2.
4. Illustrating optimal GC allocation, the V2 model increased consultation rates up to 5. 7x versus the traditional model for positive inherited cancer screen results and the V2 website education provided for negative results enabled lower consultation rates compared with V1.
5. Patient satisfaction was high (4. 9 / 5. 0 rating) in all models.

We demonstrate time utilization benefits by a results-delivery model that combines web education and counseling. Time saved by efficient delivery of simpler results offsets time used due to increased positives. In one example, 2 min per consult were saved. As a laboratory issuing multiple thousand results per week, with concomitant GC availability, this translates to hours saved enabling feasibility of post-test follow up for widespread gene-panel screening in both the reproductive and oncology contexts.

Design, implementation and outcomes of a "Psychiatric Genetics for Genetic Counsellors (PG4GC)" workshop in the UK and creation of the International Society for Psychiatric Genetic Counselling (ISPGC).
K. McGhee[1], A. Inglis[2], J. C. Austin[1,2]. 1) Translational Genetics Group, Dept. of Life & Environmental Sciences, Bournemouth University, Poole, Dorset, United Kingdom; 2) University of British Columbia, Departments of Psychiatry and Medical Genetics & British Columbia Mental Health and Addictions Research Institute, Vancouver, BC, Canada.

Knowledge about the roles of genetic and non-genetic contributors to the development of psychiatric disorders is rapidly accumulating. Concurrently, the importance and urgency of translating this knowledge into better health provision is increasing. The first specialist psychiatric genetic counselling (PGC) service of its kind opened in Vancouver in 2012, generating interest from healthcare professionals from around the world who wished to develop similar services. In responding to this interest, we noticed that for many of these individuals, the barriers to their provision of high quality specialist services for individuals with psychiatric disorders and their families related to four core issues: lack of familiarity with specialist (psychiatric and/or genetic) terminology, feeling out of touch with the state of the art research used in psychiatric genetics, lack of confidence in discussing psychiatric disorders – both in general and their aetiology (in lay language) specifically, and uncertainty regarding how to discuss the risks for illness recurrence amongst family members of affected individuals. Therefore, with a target audience of genetic counsellors in mind, we developed an intensive two-day workshop (PG4GC) that aimed to address these four core issues and form the foundation for the development of a strategy for delivering PGC both within the UK and globally. The workshop, which was delivered in the UK in Feb 2015, incorporated didactic content, small and large group discussion, a problem based learning case, and individual reflective work. In total, 23 participants from seven countries attended and completed pre- and post- workshop surveys, which revealed that participants were more confident with respect to all four core issues after the workshop. At the conclusion of the workshop, participants founded the International Society for Psychiatric Genetic Counselling (ISPGC, which interested individuals are welcome to join). Members of this fledgling organization met at the 2015 World Congress of Psychiatric Genetics and will facilitate an ASHG workshop based upon our earlier model. Plans are underway for a second PG4GC workshop in 2016 and for expansion of the ISPGC.

The Individualized Medical Genetics Center: Facilitating Systematic Integration of Genetic Testing into Patient Care. *L. Medne[1], E. Bedoukian[1], A. Wilkens[1], M. Deardorff[1,2], I. Krantz[1,2].* 1) Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

The implementation of genetic testing is becoming progressively more complex yet it is being used in individual patient care at an increasingly rapid rate. Challenges encountered by those ordering genetic testing include: comprehension of diagnostic options, selection of the appropriate genetic test, authorization by insurance, communication with patients and families, promotion of patient autonomy, interpretation of genomic variants, assessment of variants with diagnostic utility and their potential phenotypic correlation, as well as many others. There is thus an overwhelming need for collaborative integration of genetics professionals within any medical specialty that orders complex genetic testing. This recognition led to the development of the Individualized Medical Genetics Center (IMGC) at The Children's Hospital of Philadelphia (CHOP). The IMGC is currently composed of two medical geneticists and three genetic counselors whose mission is to facilitate access to state-of-the-art appropriate genetic testing and targeted medical management for children, families, and clinicians across CHOP. Since July 2014, the IMGC has been involved with over 450 patients. IMGC team has done 56 inpatient consults and 313 outpatient evaluations. Referrals to the IMGC have included requests for test selection, obtaining insurance authorizations, evaluation with pre- and post-test counseling. Specialties utilizing IMGC services have included: rheumatology, endocrinology, immunology, neurology, and hematology. Perhaps surprisingly, geneticists have also referred patients to the IMGC for the primary indication of insufficient time in clinic to facilitate complex testing like exome sequencing. IMGC facilitated tests have included single gene testing, panel testing, targeted familial testing, and exome sequencing. There has been positive feedback from both families and clinicians. IMGC has tracked several metrics: insurance approvals and denials, confirmed molecular diagnoses, variants of uncertain significance, secondary findings, and additional testing needed for result interpretation. The IMGC team provides clinical expertise towards exome analysis offered by CHOP's Division of Genomic Diagnostics. The IMGC is an unprecedented and valuable initiative that facilitates complex genetic care for patients across the hospital. The success of its unique model for the facilitation of genetic testing may benefit similar endeavors at other hospitals in the US and abroad.

Examining Preparedness Among Hispanic Women Undergoing Genetic Cancer Risk Assessment. *B. Nehoray[1], C. Ricker[2], K. Yang[1], J. Weitzel[1], K. Blazer[1].* 1) City of Hope, Duarte, CA; 2) USC Norris Comprehensive Cancer Center, Los Angeles, CA.

Background: Despite recognition of Genetic Cancer Risk Assessment (GCRA) as a standard-of-care service, there are significant disparities in access to GCRA among at-risk underserved Hispanics. This study examines the preparedness of patients participating in a randomized controlled study examining the effect of a culturally-appropriate pre-GCRA telephone intervention on attendance, preparedness, knowledge, and satisfaction with *pro-bono* GCRA services. **Methods**: Participant eligibility was adult Hispanic women who met NCCN criteria for *BRCA* referral. Participants were randomized to a motivational interview intervention (MI), time and attention control (TAC), or usual care (UC). A 10-item preparedness survey was administered verbally immediately pre-GCRA. Items included understanding about GCRA, information sought about cancer genetics, communication with and engagement of family. **Results:** Of 281 participants, 88, 105, and 88 were in the MI, TAC, and UC arms, respectively. Most (77%) had a history of breast or ovarian cancer. Most understood the purpose of GCRA, describing it as: to learn if cancer in the family is hereditary (43%), for gene testing (23. 5%), and to learn about family risk (17%). Over half (52%) came with questions, including risk to family members (13. 5%), cancer etiology (8. 5%), and how genetic testing is performed (4. 5%). Of 19% who sought information before GCRA, the Internet was the most frequently cited source (9%); <2% sought information from a clinician. Overall, 46% were accompanied to the appointment; stated reasons were for emotional support (27%), to understand information (22%), or for transportation (12%). Participants were often accompanied by a partner (17%), daughter (12%), or sister (5%). Fifty-two percent did not contact family members for history, 15% stating that they already had family history information. Participants often contacted female relatives: mothers (20%), sisters (17%), and aunts (7. 5%). **Conclusions:** No significant differences in responses were noted between study arms; however, 90% knew the purpose of GCRA. This contrasts with the literature, which reports limited understanding of cancer genetics among Hispanics. Moreover, many came to the session accompanied by a family member, and with questions about GCRA. Further analysis of the other components of the study will better elucidate the potential value of culturally-appropriate pre-GCRA communication to enhance uptake and experiences with GCRA.

2200F

Exploring the process of decision-making about participation in genetic research on mental illness. *J. Austin[1,2], H. Andrighetti[1], A. Semaka[1].* 1) Dept of Psychiatry, UBC, Vancouver, BC, Canada; 2) Dept of Medical Genetics, UBC, Vancouver, BC, Canada.

Introduction: There is a range of barriers to recruitment for research on mental illness (MI), including distrust of researchers and social stigma. Among individuals who do participate in MI research, little is known about how and why they decide to participate. This study explored the process of decision-making around participation in genetic research on MI, including motivating factors and perceived benefits of participation, and expectations regarding return of genetic research results. **Methods:** This qualitative study utilized grounded theory methodology. Open-ended interviews were conducted with 16 individuals who had either completed participation or had recently made a decision about participation in a genetic research study on MI, led by genetic counselors. Interviews were transcribed and analyzed using the constant comparative method and open, axial, and theoretical coding procedures. **Results:** Illness acceptance and establishment of trust with the research team and institution were foundational elements required for individuals to consider participating in genetic research on MI. Main motivators for participation included perceived personal relevance, anticipated benefits, a desire to "give back", and accessible study procedures. Perceived benefits of research participation included access to support and resources via the research team, the opportunity to learn, and improved self-worth. Return of personal genetic research results did not appear to be a major factor in the decision-making process regarding participation. **Conclusion**: Our data suggest that participation in genetic research on MI helps make meaning of individuals' illness experience and empowers them to adopt positive health management strategies. Our results support the value of genetic counselors in research. Genetic counselors possess a unique skill set that enables them to build trusting relationships that facilitate recruitment and retention of participants. These findings may inform strategies that improve participation rates, decrease attrition, and maximize participant benefits.

2201F

Genetic counselling in a wound care unit: Unexpected contribution to conventional diagnosis strategies by drawing a pedigree to diagnose hereditary sensory and autonomic neuropathy type 2 (HSAN2) in female patient. *M. O Cevik[1], F. DOGAN[2].* 1) MEDICAL GENETICS, ADIYAMAN UNIVERSITY SCHOOL OF MEDICINE, ADIYAMAN, TURKEY; 2) DEPARTMENT OF PLASTIC and RECONSTRUCTIVE SURGERY ADIYAMAN UNIVERSITY SCHOOL OF MEDICINE, ADIYAMAN, TURKEY.

Here,we report a 30 year old woman who had never obtained a genetic counselling service in her previous life and whose disease could not be diagnosed with classical analytical approach previously for 20 years. Our collaboration enabled clinicians to recognize the hereditary nature of the disease and changed the course of therapy. According to her previous medical documentation available, patient's very first symptoms had started as early as she was 6 years old. She had started feeling tingling and nubness on her both feet the gradual loss of pain feeling. Then, in time, she started having skin injuries-ulcerations that would never heal again and frequently got infected. At the age of ten, to stop these ulcerations, amputation had been applied to her left big toe. Amputation almost stimulated a rapid osteolysis response in her left foot to proximale to the knee and she lost her left tibia and fibulae. Soon after amputation, right big toe had also started ulcerating, then came another amputation. However, starting from the age of 23, she had started experiencing dysplasia in her fingers and hand as well. As the years adveanced, her bones became so weak that she had to had supportive operation that bone allografts were added to support tibiae. She also had two two operations due to pelvis fractures. Now, she can only walk with the help of ortheses. Her big toes had been amputated. She has a deepening overall osteopenia thus increased fracture risk (DEXA -2,2 Z , 25% total bone mineral density) in all of her body. Shehad syndromic axonal polyneuropathy- gangliopathy at her both feet, osteopenia-osteoporosis osteolysis and osteonecrosis in the MR findings at her both femurs, adenomatosis liquids at her tibiae. In addition, she had recurrent osteomyelitis at her feet and hands. Neuronal desensitiziation was obvious that her wounds and bone fractures were totally painless. As we drew her pedigree, we realized that among her first degree cousins and secondary degree cousins whose ages vary between 9 and 16, there were very similar symptoms. Gathering these information, we have utilized Simulconsult®- and pedigree to reach a conclusion. As a result, we concluded that she had HSAN2 disease that went undiagnosed for 25 years. An unexpected contribution from us to wound healing center raised great awareness among other medical professionals.

2202F

An automated drawing tool of pedigree, intending to use for genome-cohort studies. *A. Shimizu[1], K. Yamamoto[1,2], T. Tokutomi[2], K. Sobue[3,4], A. Fukushima[2,5].* 1) Division of Biomedical Information Analysis, Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Shiwa-gun, Iwate, Japan; 2) Department of Clinical Genetics, School of Medicine, Iwate Medical University, Shiwa-gun, Iwate, Japan; 3) Executive Director, Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Shiwa-gun, Iwate, Japan; 4) Department of Neuroscience, Institute for Biomedical Sciences, Iwate Medical University, Shiwa-gun, Iwate, Japan; 5) Division of Innovation and Education, Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Shiwa-gun, Iwate, Japan.

ObjectiveIn clinical genetics, genealogical information is extremely important for obtaining accurate genetic diagnoses. However, the creation of pedigree charts requires time and labor as they are typically created manually through interviews held on an individual basis and require specialized knowledge of clinical genetics, in addition to chart-creation skills. Although numerous large-scale studies, such as genome-cohort studies, have been conducted in recent years, accurate genealogical information remains necessary for the analysis of polymorphisms and diseases in the future. However, with the traditional method of pedigree chart creation, it is not possible to create pedigree charts using large amounts of genetic information obtained through interviews at a single recruiting event. We therefore developed novel software named “f-tree” that can support a user to collect genealogical information accurately and create pedigree charts, and has a variety of uses from large-scale genome-cohort studies to everyday medical care. Methodsf-tree creates pedigree charts based on a multiple-choice questionnaire regarding genealogical information. Pedigree charts are created in the following manner. 1) A multiple-choice questionnaire on genetic information is filled out by the participant or by an interviewer. 2) A person responsible for data entry inputs information from the questionnaires into f-tree. 3) f-tree automatically creates a pedigree chart. The process of chart creation is displayed on the f-tree screen in real-time, which allows for inspection during the creation process. 4) The created pedigree charts can be stored on electronic media or be exported into databases. Summary-When considering the future health of citizens, it is necessary for the general public to understand the principles of genetics. For this reason, the importance of basic genetics education has been pointed out. In such education, a proper understanding of pedigree charts is essential. f-tree is a new type tool that automatically create pedigree charts which enables even a less-experienced doctor and medical practitioner. We will soon release f-tree on our website (http://iwate-megabank. org/en/genetic/) as a freeware program and a free mobile app for the general public, so that it can be popularized and utilized not only in clinical and medical research, but also in educational settings.

2203F

The unintended birth of a second child with a genetic disorder in the same family – potential culprits and solutions. *M. Bembea[1,2], K. Kozma[1,2], C. M. Jurca[1,2].* 1) Genetics Department, Municipal Clinical Hospital dr. Gavril Curteanu Oradea, Oradea, Bihor, Romania; 2) Faculty of Medicine and Pharmacy Oradea.

BACKGROUND: Typically, in a family, only one child is affected by an unanticipated genetic disorder. After the first affected child, genetic counseling usually helps families to make decisions regarding a next pregnancy. In our setting, the unintended birth of a second child affected with the same condition is not uncommon. We hypothesize that the quality and certainty of the diagnosis of the first affected child, and the presence and effectiveness of genetic counseling, could be potential contributors to what the parents self-describe as the unintended birth of a second affected child. OBJECTIVES: To determine potential reasons for the unintended birth of a second child with the same genetic disorder. PATIENTS AND METHODS: This is a retrospective cohort study of 4,177 patients with genetic disorders in the evidence of a single county’s centralized genetics service, from 1984-2014. RESULTS: There were 148 (3. 5%) patients from 59 families who had at least one sibling affected with the same genetic disorder. Diagnosis of the first affected child in the family was full and clear for 19/59 (32%) families, partial or incomplete in 23/59 (39%) families and was not yet made for 17/59 (29%) families. Genetic counseling after the birth of the first affected child was done for 28/59 (47%) families. Of these, the staff ascertained good comprehension in only 8/28 (29%) families and poor comprehension in 20/28 (71%) families. Thirty-three families (56%) had only affected children (i. e. , one or all children affected). Thirteen families (22%) had a normal child born before the affected one, and other 13 families (22%) had a normal child born after the birth of an affected child. The mean time period between the first affected and the next affected child was 4. 8 years (range, 1 year - 26 years). DISCUSSION: We discuss possible explanations for these results and potential solutions to avoid this undesirable situation. CONCLUSIONS: The birth of a second affected child in a family poses special challenges to providers (to improve the process for timely diagnosis and for genetic counseling), to families (who require psychological and educational support) and to the community (social and economic issues). KEY WORDS: genetic counseling, affected siblings,.

2204F

"It's been a rollercoaster": Evaluating prospective father's experiences with abnormal prenatal microarray results. *L. Pilchman[1], K. J. Stumm[1], L. Conway[1], A. Werner-Lin[3], F. Barg[3], K. Kellom[4], B. A. Bernhardt[2].* 1) Department of Genetic Counseling , Arcadia University , Philadelphia, PA; 2) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3) School of Social Policy and Practice, University of Pennsylvania, Philadelphia, PA; 4) PolicyLab, Children's Hospital of Philadelphia, PA.

Background: Chromosome Microarray (CMA) has become a first tier diagnostic test in pediatrics, and is rapidly being introduced in the prenatal setting. However, interrogation of the entire genome leads to the discovery of copy number variants of unknown or variable clinical significance thereby complicating pregnancy decisions. The uncertainty associated with pathogenic or uncertain variants causes considerable anxiety for pregnant women undergoing testing, but little is known about the experiences of their male partners. The purpose of this study was to evaluate how prospective fathers experience abnormal prenatal microarray results. Methods: Twelve men completed semi-structured interviews addressing their experiences of receiving abnormal prenatal CMA results. Interviews were digitally recorded and transcribed verbatim. The transcripts were imported into NVivo 10 for coding and analyzed using directed content analysis. Results: Many men followed their wives' lead in deciding to undergo CMA with the intention of being supportive, respectful of her autonomy, and because there was no increased risk of miscarriage or cost. Men collaborated with their wives in the decision of whether or not to continue the pregnancy. To facilitate decision-making, partners relied on rational thought processes (as opposed to emotional or moral reasoning) considering factors such as the probability of clinical involvement, the fetus' expected quality of life and an anticipated parenting experience. Most did not anticipate the possibility or understand the implications of a variant result, and many expressed worry about the fetus' future. Men varied on whether they sought additional information elsewhere; many trusted their wives' robust research efforts, and to cope, a few sought information online. The impact of uncertain results combined with the excitement of becoming a father caused many to feel like they were on an "emotional rollercoaster. " Participants made recommendations for improving the CMA process, including the provision of educational media outlining the purpose, risks, benefits, and possible results of CMA. Discussion: These findings indicate that men take on varying roles in prenatal testing and care during pregnancy. Additional recommendations for counseling include encouraging partner involvement in prenatal care and educating couples to the possibility of identifying variants of uncertain or unknown significance.

2205F

Individual perceived health status and health values: Factors influencing self-initiated genome testing, risk perception and health actions in ill versus healthy persons. *C. Farrell[1], K. Eng[2], B. Holaday[1], J. Evans[3], R. Green[4], S. Roberts[5] for the PGen Study Group.* 1) Healthcare Genetics, Clemson University, Clemson, SC; 2) Roswell Park Cancer Institute, Buffalo, NY; 3) Department of Genetics, University of North Carolina School of Medicine, Chapel Hill, NC; 4) Harvard Medical School, Boston MA; 5) University of Michigan, School of Public Health, Ann Arbor, MI.

Purpose: Factors influencing self-initiated genome testing are unclear. This study aims to explore how the interplay between individuals' perceived health status and their actual medical diagnoses are related to the appraisal of, and response to, direct-to-consumer (DTC) genetic testing. **Methods**: 1464 DTC genome testing users who participated in the 2012 Impact of Personal Genomics (PGen) study were classified into 4 mutually exclusive health status groups: 1) Diagnosed ill [DI] participants reporting formal medical diagnoses and poor to fair health; 2) Medically managed [MM] had medical diagnoses but reported their health as good to excellent; Health in question [HQ] had no medical diagnoses but reported health as poor to fair; and Healthy [H]) had no medical diagnoses and good to excellent self-reported health. Analyses (Chi-square, t-tests, ANOVA and correlations) assessed differences across these groups in terms of perceived risk (of disease), motivations for testing, and values and interests specific to genome testing. **Results:** The majority of DTC consumers were classified as MM (65%), with H (20%), DI (14. 6%) and only 0. 4% in the HQ group. The DI group had a greater number of medical diagnoses than the MM group (M = 4. 4 vs. 2. 75), with both of these groups older on average than the H group (M = 51 vs. 50 vs. 38). Interest in health information was high (98-99%) in all groups. Each group differed significantly ($p<0.001$) from the other groups on two items (interest in learning about pharmacogenomic test results and learning about risk for other diseases), with the DI group having the highest percent of interest, MM an intermediate, and H the lowest percent. The DI and MM groups also differed significantly ($p<0.035$), while the MM and H groups did not (by Scheffe homogeneity test), on 5 of 7 items related to motivation for testing or personal value of genomic information (e. g. , creating a better plan for the future; reducing the risk of getting sick). Perceived risk was weakly correlated (. 272) with medical diagnosis status alone. In contrast, perceived health status alone, or combined with medical diagnosis status, demonstrated moderate correlations (. 301 and . 326, respectively; $p=0.01$). **Conclusions**: Assessing the concordance or discordance between individuals' perceived health status and actual medical diagnostic status can help understand how consumers, spanning ill and healthy persons, are likely to value and respond to DTC genomic testing services.

Families At Risk: Long-term Impact of Huntington's Presymptomatic Genetic Testing. *D. JH. Mathews[1], J. Bollinger[1], R. Dvoskin[1], J. Brandt[2].* 1) Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD; 2) Division of Medical Psychology, The Johns Hopkins Hospital, Baltimore, MD.

For decades, Huntington's disease has served as a model for how we think about genetic testing, and its benefits and risks for at-risk individuals and their families. In 1983, the gene for Huntington's disease (HD) was the first genetic disease mapped using DNA polymorphisms. Shortly thereafter, linkage tests were developed to allow for presymptomatic genetic testing for HD, and two clinical trials began to provide and study such testing. The Baltimore Huntington's Disease Project began in 1986 and enrolled 180 individuals in the first 10 years of the program. Early experience with this cohort influenced collective thinking about key issues related to genetic testing and the return and communication of test results; these challenges are still widely discussed and debated. As increasing numbers of genetic tests are being used to both directly and incidentally assay genes for adult-onset neurodegenerative disease, and as large-scale genetic testing is increasingly integrated into clinical care, it is critical that we understand the implications of presymptomatic testing for at-risk individuals and their family members, not just in the near-term, but over the course of the lives of individuals and their families. However, due to the relatively recent introduction of presymptomatic genetic testing into clinical care, few such studies exist. To address this gap, we are conducting a follow-up study with people who were enrolled in the original Hopkins presymptomatic testing study, their study partners, who accompanied them to counseling and testing/reporting sessions as a requirement of the study, and family members of tested individuals. Here we report the initial results from the first phase of our research, involving one-hour semi-structured interviews with original study participants and study partners. Interview topics include their testing experience, reasons for testing, communication of test results, and impact of testing on their mental health, relationships, and employment. These data will be used to guide focus groups with spouses and adult children of original study participants. Our findings will begin to fill an important gap in our knowledge about long-term implications of presymptomatic testing. Furthermore, they will have direct implications for guidelines regarding when and how to conduct genetic testing for the expanding list of adult-onset neurodegenerative diseases.

2207F

"Something extra on chromosome 5": Couples' understanding of positive prenatal chromosomal microarray analysis (CMA) results. *B. A. Bernhardt[1], A. Russell[2], S. A. Walser[1], R. J. Wapner[2].* 1) Translational Medicine and Human Genetics, Univ Pennsylvania, Philadelphia, PA; 2) Department of Obstetrics and Gynecology, Columbia University Medical Center, New York, NY.

CMA identifies copy number variants (CNVs) associated with known syndromes, risk for neuro-cognitive disorders, an uncertain phenotype, or normal development. When diagnosed prenatally, couples' understanding of the nature and consequences of CNVs impacts decision-making and coping. To assess understanding of positive prenatal CMA results, we conducted phone interviews with 28 women (2 terminating pregnancies and 26 continuing) and 13 male partners 4-8 weeks after receiving positive CMA results from genetic counselors. Transcript analysis assessed how CNVs were described, interpreted and understood phenotypically. We compared this with laboratory interpretation (pathogenic, likely pathogenic, variant of uncertain significance (VOUS), or likely benign). We found nearly all the women were able to describe the chromosome involved, whether the CNV was a deletion or duplication and the range of possible phenotypic effects. Conversely, the men used vaguer language and were much less clear about phenotypic involvement. All men and women know if the CNV was inherited or *de novo*. Most participants initially interpreted results as abnormal or uncertain. For couples who learned through parental testing that a parent carries the same CNV as the fetus, previously uncertain or abnormal results frequently were reinterpreted by the couple as meaning the baby would be unaffected, even if the CNV was classified by the lab as likely pathogenic or VOUS. Some couples receiving VOUS results were reassured by lack of definitive information suggesting a problem, while others were distressed by having limited information about the severity and possible phenotype associated with the CNV. When considering possible clinical involvement, couples tried to imagine the best and worst case scenario they might encounter as parents. Since most were reassured through ultrasound that the fetus was anatomically unaffected, concern focused on learning disabilities and autism risk. These findings suggest that women, but less so male partners, generally understand the nature and clinical implications of prenatal CMA results. Couples feel reassured, perhaps sometimes falsely so, when a CNV is inherited from a "normal" parent. When a CNV is *de novo* without ultrasound findings, even when some prognostic information is available, couples experience considerable uncertainty. Research is needed to identify counseling approaches to aid understanding and adjustment to uncertain results.

2208F

A double edged sword: being a *BRCA1/2* mutation carrier and a man with prostate cancer. *E. K. Bancroft[1,2], C. Moynihan[2], A. Ardern-Jones[1], A. Mitra[2,3], E. Castro[2,4], E. Page[2], N. Taylor[1], R. Eeles[2,1].* 1) Oncogenetics Team, Royal Marsden NHS Foundation Trust, London, United Kingdom; 2) Oncogenetics Team, Institute of Cancer Research, London, United Kingdom; 3) Department of Uro-oncology, University College Hospitals, London, United Kingdom; 4) Prostate Cancer Clinical Research Unit, Spanish National Cancer Research Centre (CNIO), Madrid, Spain.

An increased risk of breast and prostate cancer is observed in men with *BRCA1/2* mutations. No work has reported on the psychosocial impact of having both a *BRCA1/2* mutation and prostate cancer. Methods: Men identified as *BRCA1/2* mutation carriers and with prostate cancer were invited to participate in a qualitative interview study. Data were analysed using a Framework Approach. Masculinity theory was used to explore the impact on men who had been diagnosed with a *BRCA1/2* mutation, perceived as a 'female' condition and having prostate cancer, a uniquely male tumour. Results: 15 men were identified as eligible, of which 12 were interviewed. The umbrella concept of a 'Double Edged Sword' wove its' way through men's responses. Men responded in stereotypical masculine ways as well as exhibiting so called 'feminine' reactions. Despite men's awareness of carrier status, their BRCA mutation experience was described, as 'on the back burner'. The presence of the mutation was only relevant to men in terms of a 'bonus' enabling a pathway to early diagnosis of prostate cancer and responsibility towards family members, mainly daughters. Embodiment of prostate cancer took centre stage indicating a stain on men's biographical timelines, stoicism, control and 'normality'. However men appreciated certain aspects of care that did not 'fit' with masculine stereotypical responses. Conclusion: We suggest that health workers take a reflexive approach that is void of ideal male/female assumptions while respecting differences and similarities between males (and women) together with an exploration of men's needs that are sometimes invisible.

2209F

A UK-wide national audit of genetic testing in retinoblastoma suggests that transition care should be a priority for medical genetics. *A. C. Foster[1], I. Boyes[1], L. Burgess[1], S. Carless[1], V. Bowyer[1], S. Parkes[2], M. Olarinde[3], H. Jenkinson[4], M. Parulekar[4], J. Ainsworth[4], J. Kingston[5], E. Rosser[5], M. A. Reddy[3], T. Cole[1].* 1) Clinical Genetics Unit, Birmingham Women's Hospital NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 2) UK Cancer Registry; 3) Barts Health NHS Trust, London, United Kingdom; 4) Birmingham Children's Hospital NHS Foundation Trust, Birmingham, West Midlands, United Kingdom; 5) Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom.

Retinoblastoma is the most common malignant tumour of the eye in childhood, with all bilateral tumours and 14% of unilateral tumours due to an autosomal dominant mutation in the RB1 gene present in the germline. Genetic testing should be carried out in all cases to enable accurate risk assessment and inform appropriate medical management and genetic counseling for the affected individual, their siblings, and their future offspring. We carried out the first UK wide national audit of knowledge of genetic testing in patients with retinoblastoma and their families. Questionnaires were sent to contactable individuals in the UK between ages 16 and 45 to assess whether they had the genetic information required for their own management and that of their families. 292 individuals were included, 100 (34%) with bilateral disease and 192 (66%) with unilateral disease. Only 72% of patients with bilateral disease and 32% of patients with unilateral disease understood the genetic implications of retinoblastoma for themselves or family members. In both groups, individuals who did not recall having had a genetic test or did not know the results of testing were significantly less likely to correctly assess recurrence risk for their relatives (bilateral group $p<0.001$, unilateral group $p<0.001$). These individuals were also significantly less likely to have children (bilateral group $p=0.012$, unilateral group $p<0.001$), and yet were significantly more likely to request an appointment to discuss recurrence risks (bilateral group $p=0.005$, unilateral group $p=0.001$), indicating they wanted this information when made available. The results of the audit suggest that individuals with retinoblastoma may be making life choices based on inaccurate or incomplete information regarding recurrence risks and reproductive options. As retinoblastoma services are often seen as a paradigm for genetic medicine, these findings are likely to be representative of many rare genetic diseases, and indicate that a focus on transition care is urgently needed in the current era of mainstreaming genetics.

2210F

Disclosing genetic risk for coronary heart disease: perception of self-responsibility and reaction to risk disclosure in a randomized clinical trial (from the MI-GENES investigators). *S. Brown, H. Jouni, E. Austin, T. Marroush, I. Kullo, MI-GENES Investigators.* Division of Cardiovascular Diseases, Department of Medicine, Mayo Clinic, Rochester, MN.

Whether disclosing genetic risk for coronary heart disease (CHD) to individuals influences psychosocial parameters related to perception of self-responsibility and reaction to risk disclosure is unknown. The myocardial infarction genes (MI-GENES) trial randomized participants aged 45-65 years who were at intermediate risk for CHD based on conventional risk factors and not on statins, to receive their conventional risk score (CRS) or their CRS plus a genetic risk score (GRS) based on 28 susceptibility variants. CHD risk was disclosed by a genetic counselor and then discussed with a physician. Surveys to assess parameters related to self-responsibility (including intention to change and measure of locus control) and reaction to risk disclosure (including impact of events, reaction to risk, and decisional regret) were completed before and three and six months after risk disclosure. We assessed whether these behaviors differed by GRS disclosure. Results were reported as the mean difference (with standard error) in the score for each survey response; significance was determined by regression analysis. Over follow-up, GRS participants felt impacted by stressful life events more than CRS participants (1. 81 ± 0. 77,p=0. 02). Compared to CRS participants, GRS participants embraced a relatively predetermined view of their CHD risk (0. 48 ± 0. 20, p=0. 02), while recognizing their responsibility to appropriately care for themselves in order to avoid increasing their CHD risk (0. 37 ± 0. 17, p=0. 02). Intention to change, reaction to risk, and decisional regret did not differ significantly between the GRS and CRS groups. Disclosure of GRS for CHD resulted in greater measures of self-responsibility (particularly elements of locus control) and reaction to risk disclosure (including the stressful impact of events) in study participants. Self-responsibility and reaction to risk disclosure may serve as psychosocial determinants of the impact of disclosing CHD genetic risk in precision medicine.

2211F

Family advocacy and support in ultra-rare genetic diseases: Example of*OPHN1* mutations. *M. C. Towne[1], T. S. Schwartz[1], R. C. Pelletier[1], A. H. Beggs[1,3], I. A. Holm[1,3], P. B. Agrawal[1,2,3].* 1) Division of Genetics and Genomics and The Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA; 2) Division of Newborn Medicine, Boston Children's Hospital, Boston Children's Hospital, Boston, MA, USA; 3) Department of Pediatrics, Harvard Medical School, Boston, MA.

Patients with ultra-rare genetic disorders often feel isolated as little is known about their disorder. Connecting patients with the same disorder provides opportunities to learn more about the condition and offers families the chance to network and bond, giving them emotional support. Here we discuss an 18-year old male, referred to the Gene Discovery Core of The Manton Center for Orphan Disease Research (GDC) for molecular diagnostic evaluation of "Cohen-like" syndrome, and who was negative for *COH1* mutations responsible for most cases of Cohen syndrome. Whole exome sequencing identified a novel variant in *OPHN1* determined to be the likely cause of disease. However, the family wanted to know more and wanted to be connected with other people carrying *OPHN1* mutations. To support the desire of the family to find other individuals with an *OPHN1* mutation, we reached out to corresponding authors on published *OPHN1* case studies, however we had no success. We then approached commercial and academic laboratories offering clinical testing for *OPHN1*. A connection to another individual with an *OPHN1* mutation was made through one of those laboratories. Subsequently, through outreach efforts made by the affected families, the network expanded. We enrolled these additional families in GDC study and gathered their phenotypic information. Within a year, six families with *OPHN1* mutations were identified from around the world through patient outreach including: creating a disease-specific webpage, modifying existing open-access internet resources on the gene, and creating an email address monitored by family advocates. Not only were families connected through these efforts, but less than a year after the first two families were connected, a conference call to discuss drug trials on this condition with published authors, international experts on *OPHN1*, families, and patient advocates was held. Uncovering the genetic etiology for families is only the first step in providing complete care to a patient. Outreach efforts have connected six families with *OPHN1* mutations has connected six families. In addition, collaboration between families, researchers, clinicians, and the clinical diagnostic labs will potentially make a huge difference towards management of this ultra-rare condition.

2212F

Considerations for genetic testing of the partners of individuals with autosomal dominant cancer susceptibility syndromes that cause a severe recessive phenotype. *R. L. Bennett, L. Amendola, W. Raskind.* Dept Med/Div Med Gen, Univ Washington, Seattle, WA.

There are several autosomal dominant (AD) cancer susceptibility syndromes that are known to cause a severe recessive phenotype when two pathogenic variants (PVS) are inherited. Constitutional mismatch repair deficiency (CMMR-D) is caused by biallelic mutations in one of the Lynch syndrome genes (*MLH1*, *MSH2*, *MSH6*, *PMS2*). Individuals who are biallelic for PVS in *BRCA2* have Fanconi anemia, and severe phenotypes in offspring who are biallelic for *BRCA1* PVS and *PALB2* PVS have been described. Heterozygotes for an *ATM*pathogenic variant (PV)have an increased risk of breast and possibly other cancers, and those who are biallelic for PVS in *ATM*have ataxia-telangiectasia (AT). Increasingly, individuals heterozygous for PVS in *FH* are recognized to have an increased risk of renal cancer (HLRCC), and biallelic offspring have the severe metabolic disorder fumarate hydratase deficiency. It is standard practice to offer genetic counseling to couples when one of the partnersis heterozygous for a PV causingan autosomal recessive condition, even when the risk to have an affected childis less than 1%. For individuals who carry aPV in a gene associated with anAD cancer susceptibility syndrome where there are known founder mutations, the possibility of identifying a mutation in the partner may be high (such as for the Ashkenazi founder mutation in *BRCA2*, or the American founder mutation in *MSH2*). The carrier frequency of *ATM* is estimated to be as high as 1 in 100 in some populations, thus a person identified with a PV in *ATM*through testing for hereditary cancer syndromes would have as high as a 1 in 400 chance to have a child with AT. In this context, testing the partner of an individual who carries an ATM PV for mutations in *ATM* may be indicated. In contrast, for rare conditions like HLRCC genetic testing of partners may not be recommended given the low likelihood of having an affected child. The clinical evaluation of the partner including a detailed family history and consideration of the age and sex related penetrance of the condition should be taken into account. We discuss populations that may have higher risk to inherit biallelic muations in the AD cancer susceptibility genes and address genetic counseling issues including discussions of reproductive decision making, age at testing, insurance coverage for testing, identifying consanguineous relationships, and approaches to germline genetic testing.

2213F

Population Screening for Hereditary Cancer: Opinions from the General Public. *L. A. Cross[1], E. Lawrence[1], R. E. Grubs[1], A. Durst[1], R. Jankowitz[2], D. Thull[1,2], D. Stephan[1].* 1) Human Genetics, University of Pittsburgh, Pittsburgh, PA; 2) Hematology and Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA.

Approximately 10% of cancers are due to a mutation in a single gene. Testing technologies, which detect genetic mutations associated with hereditary cancer, continue to improve to be more accurate and affordable. With this, population screening to identify high-risk individuals and manage them appropriately becomes feasible. This study aims to examine how individuals in the general population view screening for hereditary cancer syndromes without a family history, as well as potential psychosocial impacts. We developed a 57-question survey administered through the Qualtrics Survey System to students at the University of Pittsburgh, University of Northern Iowa, and will be delivered to Amazon Mechanical Turks. The study population currently consists of individuals 18–50 years old (89 female, 150 male, 1 unspecified). Participants were initially asked if they would want to participate in a screening program for hereditary cancer syndromes. 63% (152/240) wanted to participate now, 31% (74/240) would consider screening later in life and 6% (14/240) would never consider screening. The 226 participants interested in screening were presented with 5 scenarios in the context of population screening to evaluate the psychosocial impacts using both quantitative and qualitative means. The scenarios posed involved receiving results that increased the cancer risk to 15-25%, 50%, and 80%, as well as 2 scenarios with a 0% increased cancer risk, one with a diagnosis of cancer 15 years later. At the 50% level, 40% of respondents stated it would affect daily life, 45% stated it would affect mental health, 14% stated it would affect the ability to find a partner, and 9% stated it would affect the ability to find/keep a job. After the scenarios, 5% (11/226) indicated they would no longer want to participate in population screening. This data suggests the majority of participants are interested in population screening for a hereditary cancer predisposition. Recent FDA guidance is unclear if mutation carrier status falls under the loophole allowing “carrier tests” to be delivered with no physician intermediary. Our data suggests that the need for genetic counseling and other support is important. The recent launch of low cost *BRCA1/2* tests in the marketplace with initial utility and cost savings of population-based screening are exciting, but should be coupled with counseling support for all consumers and downstream clinical connectivity for mutation positive consumers.

2214F

Measuring Awareness and Identifying Misconceptions About Genetic Counseling Services and Utilizing Television to Educate. *D. Goldberg[1], M. Bocian[1], K. Singh[1], K. Osann[1], W. W. Grody[2], J. Austin[3]*. 1) University of California Irvine, Irvine, CA; 2) University of California Los Angeles, Los Angeles, CA; 3) University of British Columbia, Vancouver, BC, Canada.

Understanding awareness and perceptions of genetic counseling (GC) is important in identifying and overcoming potential barriers to GC services. However, there are relatively few empirical data regarding these factors among US-based populations. To address this, we attended various community events for the general public, disability community, and new parents and recruited participants for a survey-based study comprising demographic questions, closed-ended knowledge-based and awareness questions, and open text sections. We applied descriptive statistics to responses about demographics, awareness of GC, purposes of GC, and perceptions of GC practice. In total, 320 individuals participated, including 69 from the general public, 209 from the disability community, and 42 from the new parent community. Slightly more than half of respondents (n =173, 54%) had heard of GC. Risk assessment and counseling were among the most frequently cited activities attributed to genetic counselors; a few felt that GC was related to eugenics. Respondents thought that GC aims to prevent genetic disorders (n=82, 74%), helps people find their ethnic origins and understand their ancestry (n=176, 55%), advises people whether to have children (n=140, 44%), and helps couples have children with desirable characteristics (n=126, 39%). Our data showed the majority of participants preferred to watch a medical thriller involving genetic counseling, followed by documentary series; comedy was rated the lowest. These data revealed gaps in awareness of GC and misperceptions about its purpose and can be useful in devising targeted interventions by developing entertainment-based education to improve public knowledge of genetic health and the roles of GCs.

2215F

Evolution of Genetic Counseling in Genomic Medicine-Experiences from Mayo Clinic Center for Individualized Medicine. *K. Hunt[1], B. McLaughlin[1], T. Kruisselbrink[2], K. Guthrie[3], K. Lazaridis[2], T. McAllister[2], M. Ferber[2], E. Klee[2], E. Winkler[2], K. Johnson[4], K. Schahl[4], E. Wieben[2].* 1) Hem/Onc, Mayo Clinic, Scottsdale, AZ; 2) Center for Individualized Medicine, Rochester, MN; 3) Center for Individualized Medicine, Jacksonville, FL; 4) InformedDNA, St. Petersburg, FL.

Statement of Purpose: The role(s) of genetic counselors need to evolve at a pace concomitant with the integration of next-generation sequencing (NGS) into clinical care. Genomic testing (multi-gene panel tests, exome and genome sequencing) is associated with: more complex informed consent discussions, scalability issues surrounding genomic data, challenges with variant classification and healthcare management implications (limited or no guidelines), ethical issues associated with database collection and return of research participants' results and the ongoing need to educate medical providers and the public about the latest genomic advances. These challenges have resulted in the development of new roles for genetic counselors and the advancement of genetic counseling techniques and skills. **Methods Used:** The Center for Individualized Medicine (CIM) designed and opened an Individualized Medicine (IM) Clinic in 2012 with the goal of integrating personalized medicine into clinical care. The initial phase of this project was to implement an Individualized Medicine (IM) Clinic with three distinct services: 1. Oncology Genomics, 2. Diagnostic Odyssey and 3. Healthy Genome Sequencing. Another core component of CIM is the Biobank Program. **Summary of Results:** Four new genetic counselors were hired between three Mayo Clinic locations to support the advancement of genomic testing into clinical practice. In addition, existing genetic counselors at the three sites were recruited to contribute to the development of the IM clinics. The roles and responsibilities of the genetic counselors within the IM clinic were expanded to support the unique elements and challenges of genomic medicine. Expanded functions of the genetic counselor include: content development for participant interactions within the Biobank and developing plans with investigators on return of results, variant interpretation assistance, integration of genomic results into clinical care, expanded genomic counseling sessions that incorporate discussions about incidental findings, implications of a variant of uncertain significance (VUS) and potential need for long-term follow-up and re-testing and developing patient and physician educational resources. As a result of these efforts, the roles and responsibilities of genetic counselors are evolving to meet the needs of the advancing genomic technologies and the subsequent challenges incorporating these technologies into patient care.

2216F

NCBI Hackathons: Community Driven User Centered Design of Software to Interface with Genomics Datasets. *B. Busby.* NCBI, Bethesda, MD.

After we established that genomics professionals from the community could build deployable software for genomic analysis in an educational hackathon setting, (http://dx. doi. org/10. 1101/018085) we wanted to go farther with implicitly user-centered software prototyping. Therefore we identified three general categories where available open-source software tools to interface with NCBI datasets were lacking, and set out to build deployable software prototypes, guided by members of the genomics community. The three categories we identified were RNA-seq, translational genomics, and education/democratization of access. We built nine teams of volunteers, three for each category, drawing on the previous experience of these individuals, as well as their motivations for attendance. Drawing from our experiences in the January 2015 hackathon, we understood that the major goal of attendees is to finish deployable software, and therefore we endeavored to enable August attendees to do so by breaking software production into smaller pieces, to enable attendees to work through them in three days and then asking three veteran hackathoners (who are experienced Genomics professionals) to help attendees stitch the work together, and write tests for the resultant software from the other two categories. The resultant software from NCBI hackathons is freely available under a creative commons license at github. com/DCGenomics.

2217F

Best Practices in Genetic Cancer Risk Assessment: Delivery Models and Barriers in Community Settings. *I. Solomon, B. Nehoray, M. Niell-Swiller, C. Rybak, K. Yang, J. Weitzel, K. Blazer.* Clinical Cancer Genetics, City of Hope National Medical Center, Duarte, CA.

Purpose: Genetic cancer risk assessment (GCRA) is an interdisciplinary clinical service that incorporates genetics, oncology, and patient/family counseling skills to identify and prescribe personalized screening and preventive care for individuals with increased cancer risk. Advances in genetic technologies are fueling demands for GCRA services in community settings. This study explored practices and needs of 7 cohorts of community-based clinicians who participated in an interdisplinary program of CME-accredited GCRA training and practice support from 2010-2015. **Methods:** A two-part survey comprised of check boxes, ratings scales and open-ended prompts addressing GCRA practice issues was administered to course participants after distance learning and prior to face-to-face workshops. Descriptive and comparative analyses were performed with SAS v. and qualitative analysis was conducted on open-ended responses. **Results:** Surveys were completed by 277 participants: 130 MDs (47%), 48 genetic counselors (GCs) (17%), 93 nurses (33%), 6 other (2%); 78% dedicate <50% of their time to GCRA, and 59% planned to expand these services. A majority (84%) conducted initial GCRA sessions in-person; 62% conducted in-person results disclosures; 32% reported using a multidisciplinary team approach to GCRA. More than half (58%) spent >1 hour with patients for the initial GCRA session; 80% spent >30 minutes for results disclosure counseling. Compared to MDs, GCs more often reported that they adequately reviewed basic genetics, family history, inherited syndromes, and interpretation/communication of test results during GCRA sessions; GCs and Nurses more frequently provided resources for GCRA patients (p<. 05 for all comparisons). No significant differences were observed by cohort. GCRA practice workshop outcomes revealed lack of time, financial compensation and administrative support, and need for continuing education as the most significant barriers to expanding best practices in GCRA and research collaboration across all practice settings. **Conclusion:** Our findings suggest that motivated community clinicians are dedicating significant resources to developing best practices in GCRA. This demonstrates the value of interdisciplinary team-based training, and points to the need for continuing education and support for practice and research collaborations for community-based providers.

2218F

The GEC-KO Website: Genetics education for primary care providers. *J. C. Carroll[1,2], S. Morrison[3,4], J. Allanson[4,5].* 1) Family and Community Medicine, University of Toronto, Toronto, ON, Canada; 2) Family and Community Medicine, Mount Sinai Hospital, Toronto, ON, Canada; 3) Genetics Education Canada Knowledge Organization, Ottawa, ON, Canada; 4) Children's Hospital of Eastern Ontario, Ottawa, ON, Canada; 5) University of Ottawa, Ottawa, ON, Canada.

Background: Without integration into primary care, the promises of genomic medicine for patients are unlikely to be fully realized. Internationally, primary care providers have expressed lack of knowledge of and confidence in core primary care genetics competencies. Needs assessments have indicated that relevant, brief, reliable, evidence-based, up-to-date primary care specific resources are essential. The GEC-KO website (Genetics Education Canada-Knowledge Organization www. geneticseducation. ca) had a soft launch in late 2013 as an accessible platform for resources and tools designed to increase genetics literacy in healthcare professionals. It is one component of a larger educational program facilitating translation of research and enabling development, collection, dissemination and evaluation of genetics educational materials. Educational materials on the website are designed to meet the needs of Canadian primary care providers and are informed by previous work evaluating primary care genomics knowledge translation interventions. Purpose: To describe the types of educational materials on the GEC-KO website and provide analytics which assess the pattern of use of the website and demographics of users. Methods: Google analytics were used to assess website use comparing three 6 month periods since the soft launch of the 2013 website. Results: GEC-KO educational materials include point-of-care tools, summaries of genetic disorders and referral and testing guidelines, and contact information for genetics clinics. In the 6 month period from Nov 1 2014 to April 30 2015, 2,021 individuals accessed the site, 82% of them new users. This was an increase from 465 and 860 users in the previous two 6 month periods. There were 5,333 page views, with an average of 2. 18 pages/session. Users included those from Canada (50%), USA (13%), Brazil (8. 5%), and France (2%). Users were directed to the site by referral from another site (39%), organic search using search engines such as Google (33%), direct URL address (25%) and a small number through social media (2. 5%). Top pages accessed have varied over time but include hemochromatosis, non-invasive prenatal testing and genetics clinics contact information. Conclusions: Early results show that users are accessing these relevant, evidence-based up-to-date, concise, accessible educational resources. More work is needed to evaluate these resources and whether they change practice and patient outcomes.

2219F

The Role of Graduate Year and Training in Cancer Genetics Knowledge in Primary Care Physicians. *V. Chan[1, 4], D. Tegay[2], W. Blazey[3], S. Koehler[2], B. Krishnamachari[4].* 1) Academic Medicine Scholars Program, NYIT College of Osteopathic Medicine, Old Westbury, NY; 2) Department of Medicine, NYIT College of Osteopathic Medicine, Old Westbury, NY; 3) Office of Academic Affairs, NYIT College of Osteopathic Medicine, Old Westbury, NY; 4) Division of Research, NYIT College of Osteopathic Medicine, Old Westbury, NY.

INTRODUCTION Knowledge about cancer genetic testing can aid cancer screening and prevention in high-risk patients. In 1996 and 2003, the American Society of Clinical Oncology (ASCO) respectively issued the original and updated ASCO Statement on Genetic Testing for Cancer Susceptibility, setting recommendations for cancer genetic testing and clinical practice. Physicians graduating before 1996 or without cancer genetics training may not have adequate exposure to current standards of care for hereditary cancer syndromes. We hypothesized that physicians who graduated after the ASCO guidelines and reported training would have greater cancer genetics knowledge. **METHODS** A survey was administered to predominantly primary care physicians evaluating their graduation date and cancer genetics training, practice patterns, and knowledge. Age-adjusted odds ratios (ORs) and their 95% confidence intervals (CIs) were calculated using unconditional logistic regression. **RESULTS** 159 physicians completed the survey. Graduates after 1996, compared to graduates before, were more likely to respond correctly to the items, "For cancer syndromes affecting most women, maternal history is more important than paternal history" (OR=5. 79, 95% CI=2. 60–12. 9) and "The BRCA mutations found in Ashkenazi Jewish individuals are generally one of three specific mutation" (OR=3. 29, 95% CI=1. 42-7. 60). In addition to the above items, graduates after 2003, compared to graduates before, were more likely to correctly respond to "Genetic sequencing will detect all types of genetic mutations" (OR=2. 64, 95% CI=1. 04–6. 75). While graduates after 1996, compared to graduates before, were more likely to receive cancer genetics training in medical school (OR= 3. 70, 95% CI=1. 74-7. 84) and residency (OR=2. 57, 95% CI=1. 27-5. 14), they were also likely to be less likely to receive continuing medical education (OR=0. 16, 95% CI=0. 07–0. 34). Nearly 90% of physicians in both groups expressed interest in participating in future training on hereditary cancer risk assessment. **CONCLUSION** To our knowledge, this study is the first to analyze physician graduation date and cancer genetics training and knowledge. This study suggests that there is a need for more genetics training in physicians who graduated before the original and revised ASCO guidelines.

2220F

Blended Learning for Primary Care Providers in Cancer Genetics Management. *K. Reed[1], E. Edelman[1], T. Ingram[1], M. Dougherty[2].* 1) Clinical and Continuing Education Program, The Jackson Laboratory, Bar Harbor, ME; 2) Education Dept, ASHG, Bethesda, MD.

Changing provider behavior, as is necessary for the integration of genetics into clinical care, requires more than a single educational intervention. Educational programs that focus on competencies, multiple instructional strategies and repeated exposures to key messages have been associated with improved outcomes in continuing education. The Jackson Laboratory and the American Society of Human Genetics developed an educational program to improve primary care providers' (PCPs) clinical skills in assessing and managing genetic risk for cancer. This blended learning program consists of a 6 ½ hour in-person workshop and 12 months of digital communications. The program addresses competencies related to assessing a targeted family history; assessing the clinical utility of testing; facilitating patient decision-making; and using guidelines to manage care. The program was piloted with 21 early adopter PCPs in November 2014. Participants completed knowledge, attitudes, and confidence assessments pre, post and 4 months post, which were analyzed by Fisher exact tests. Immediately post-workshop, PCPs demonstrated improved confidence in their ability to determine appropriate referrals, discuss the benefits and limitations of genetic testing, provide counseling about management related to genetic information, and improved overall confidence in genetics of hereditary cancer (all $p \leq 0.01$), as well as improved knowledge on interpreting genetic test results ($p=0.02$). The participants' confidence and knowledge levels at 4 months post-workshop returned to nearly pre-workshop levels. Of the 4 monthly communications received post-workshop, 19-71% participants visited the associated webpage and 11-63% of those engaged with the respective educational intervention. These results indicate that our approach for the workshop was effective in improving confidence and knowledge to incorporate genetics. However, we did not observe sustained gains 4 months post-workshop, which we attribute, in part, to the lack of participant engagement with the reinforcing activities. We need to identify effective approaches to engage participants with digital resources. As we implement the workshop more broadly, we will refine and test different communication approaches for ongoing engagement to maximize the impact of blended education - interactive in-person education and reinforcing digital communications - on practice change.

2221F

A co-ordinated national approach to workforce transformation: Health Education England's Genomics Education Programme. *A. Seller[1, 2], M. Bishop[1], JP. Maytum[1, 3], V. Davison[1, 3], S. L. Hill[1, 3], Genomics Education Programme Team.* 1) Genomics Education Programme , Health Education England , Birmingham , United Kingdom; 2) Oxford Regional Genetics Laboratories, Oxford University Hospitals NHS Trust, Oxford, United Kingdom; 3) NHS England, Skipton House, 80 London Road, London SE1 6LH, United Kingdom.

England aims to become the first country to introduce genomic technologies into routine healthcare, and has launched the 100,000 Genomes Project, led by Genomics England, to sequence 100,000 genomes from patients with cancer and rare diseases by Dec 2017. This ambitious project, combined with the integrated nature of England's National Health Service (NHS), provides a unique opportunity to implement a co-ordinated approach to workforce transformation to successfully embed genomic medicine into mainstream clinical practice. The Health Education England Genomics Education Programme (GEP) was established with a threefold purpose: to support those NHS staff directly working on the 100,000 Genomes Project through NHS Genomic Medicine Centres; to support the wider transformation of NHS services through genomic medicine and to upskill existing NHS staff. Our strategic approach provides a range of tailored education and training that meets the learning and professional needs of staff, based on their interface with genomic medicine. Key achievements to date include:1. Establishing an active web platform (www. genomicseducation. hee. nhs. uk), supported by social media (@genomicsedu)2. Developing a multiprofessional Masters in Genomic Medicine to be delivered by a network of 9 universities, with individual course modules available for continuing professional development. 3. Direct funding of 550 Masters places & 1000 course modules4. Development of free online courses, including introductions to genomics & bioinformatics and a course supporting the consent requirements of the 100,000 Genomes Project5. Increasing workforce capacity & capability by commissioning 27 doctoral-level scientist training positions in Genetics and in Molecular Pathology of Acquired Disease6. Funding a national network of genetic diabetes nursesEarly indications that the workforce is engaging with our programme is evidenced by the number of registered learners (1,382) and rapid growth on social media (c3,100 followers). Preliminary findings indicate our resources meet learner needs: 95. 2% of participants state staff should complete the consent module before recruiting patients to the 100,000 Genomes Project. The GEP's work will continue to be underpinned by this evidence-based approach to ensure the strategy for workforce transformation is effective. While the results are facilitated by our integrated NHS, this structured approach is transferable to other healthcare systems.

2222F

Pharmacogenomics Assessment in a Current Internal Medicine Practice. *C. R. Vitek, T. B. Curry, P. J. Caraballo, J. Wilson, J. Giri, C. M. Formea, W. T. Nicholson.* Center for Individualized Medicine, Mayo Clinic, Rochester, MN.

Background: Pharmacogenomics is the union of individual genetics and pharmacology. Current expansion for use of pharmacogenomics at the bedside is underway, accelerated by initiatives in personalized medicine. Many providers that were unexposed to pharmacogenomics concepts during training are now required to apply this science to therapeutic decisions. It is essential that health care providers are knowledgeable in these concepts as medicine advances. Methods: As part of an institutional educational grant, an evaluation was conducted to assess self-perceived confidence in pharmacogenomic knowledge and the requirement for additional education for practicing internist. An e-mail-based assessment which consisted of a 15-question, multiple-choice survey was provided to 145 internal medicine practitioners. These included physicians, nurse practitioners, and physician assistants within the Division of General Internal Medicine at Mayo Clinic. The assessment tool employed a Likert scale and was administered using REDCap® program software. Results: A total of 43. 4% (63/145) surveys were completed. Over 90% (58/63) of the respondents agreed pharmacogenomics was relevant to their current clinical practice. These 90% (58/63) also agreed they should be able to provide information to patients on appropriate use of pharmacogenomics testing. However, when self-perceived knowledge was assessed, only 24% (15/63) agreed they could identify medications that require pharmacogenomic testing. Additionally, 84% (53/63) disagreed they could apply the results of pharmacogenomic tests to drug therapy selection, dosing, or monitoring,Conclusions: Overall, internal medicine practitioners believed that pharmacogenomics was relevant to their current clinical practice and they should be able to provide information to patients. However, most practitioners did not feel confident in their knowledge of applicable medications or their ability to apply the results clinically. These outcomes indicate an opportunity to develop and provide clinically applicable pharmacogenomics education to improve practitioner knowledge.

2223F

Workshop in Applied Genomic Medicine. *A. D. Gilbert[1,2], C. R. M Marshall[1,5,6], P. Ray[1,3,4,5,6], S. W. Scherer[1,3,4,5], R. D. Cohn[1,2,3,4], S. Bowdin[1,2].* 1) Centre for Genetic Medicine, The Hospital for Sick Children, Toronto , Ontario, Canada; 2) Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, ON, Canada; 3) Program in Genetics and Genome Biology, Research Institute, The Hospital for Sick Children, Toronto, ON, Canada; 4) Department of Paediatrics and Molecular Genetics, University of Toronto, Toronto, ON, Canada; 5) The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, ON, Canada; 6) Genome Diagnostics, Department of Paediatric Laboratory Medicine, The Hosptial for Sick Children, Toronto, ON, Canada.

Background: The completion of the Human Genome Project and the subsequent introduction of clinical genome and exome sequencing (CGES) have placed clinical genetics healthcare professionals (CGHP) at the forefront of genomic medicine. These new diagnostic modalities are changing not only the scope of medicine but the overall scope of practice for the CGHP. Providing accessible venues for geneticists and other health care providers to acquire the skills necessary to integrate CGES into patient care is of paramount importance. Over the last two years, a team from SickKids, The Centre for Applied Genomics (TCAG) and the University of Toronto has been developing a concept of introducing genomic medicine into paediatric healthcare. With this experience, the team has designed a workshop that addresses the evolving educational needs. **Goals:** At the end of this workshop, participants will be able to: integrate CGES into their clinical practice, assess phenotypic and bioinformatics data, debate counseling and ethical considerations, and describe translational and research methodologies. **Method:** We have designed a 2. 5 day applied genomic medicine case-based Workshop combining a didactic component and interactive breakout sessions, focusing on the key components of performing clinical genomic sequencing and returning results. This is hosted by SickKids Hospital with experts from Canada, the US and the UK comprising the team of instructors and facilitators. A target audience of clinical genetics trainees and practicing clinicians; molecular, biochemical, and cytogeneticists; genetic counsellors, and bioinformaticians working in the field of genomics, nationally and internationally, will be encouraged to attend. To ensure the participation of both geneticists in training and geneticists in underprivileged nations, scholarships will be available. **Outcome Measures:** Workshop participants will complete a pre-workshop questionnaire to capture current knowledge, methods and practices regarding CGES. A post-workshop survey will be administered to determine whether or not the attendee has achieved their goals. Finally, a 6 month follow-up evaluation will be sent to all attendees to obtain information regarding potential changes and/or improvements in the application of CGES. If successful the workshop will be offered every year in Toronto or at other international venues.

2224F

GTR, ClinicalTrials. gov, and ClinVar: NCBI resources that improve access to information about research testing. *W. S. Rubinstein, A. J. Malheiro, D. R. Maglott, B. L. Kattman, V. Hem, B. Gu, M. Ovetsky, K. S. Katz, S. Chitipiralla, G. Song, M. J. Landrum, J. M. Lee.* National Institutes of Health, National Library of Medicine, National Center for Biotechnology Information, Bethesda, MD.

Scientists, clinicians, patients and families all have an interest in access to information related to research-based genetic testing. This information is dispersed among the many institutions supporting such studies. The patient advocacy community has become a driving force in connecting participants and genetic research studies, and the research community has organized around collection of standardized data elements. ClinicalTrials. gov has redoubled efforts to gather study results, but does not organize around genetic topics. NCBI integrates information about genetic tests, studies, and research results to enhance access to and enrollment in research studies and to promote discovery and human health. The NIH Genetic Testing Registry (GTR®; http://www. ncbi. nlm. nih. gov/gtr/) is a free online resource supporting unrestricted access to comprehensive genetic test details and contextually relevant information. To our knowledge, GTR is the only website that supports access to genetic research tests performed worldwide with detailed information about the tests and associated studies. As of June 2015, GTR has 261 research tests covering 384 phenotypes offered by 58 laboratories in 11 countries. In addition to the test description, research tests include study information such as eligibility criteria, participation requirements, study site location, investigators, and study contact information. Test providers can offer details about whether or not participants have an opportunity to learn about the results of the research test and whether confirmation may be done in a CLIA-certified lab, with information about possible associated costs. Test providers can provide a downloadable study consent form and a ClinicalTrials. gov identifier that supports access to further study details. When results are obtained, submitters to ClinVar (http://www. ncbi. nlm. nih. gov/clinvar/) can document the methods used to obtain data by citing the GTR test accession. The purpose of research tests is categorized by submitters as either a test performed to contribute to generalizable knowledge or for a laboratory to generate data to make technical improvements to a test. 'Contribute to generalizable knowledge' is applicable if the intent is to publish the study results and/or the study protocol is approved by a research ethics committee. The integration of GTR, ClinicalTrials. gov, and ClinVar thus advances public health and research into the genetic basis of health and disease.

2225F

Knowledge and attitudes of nurses about a population-based education and carrier screening program for recessive diseases in Cree communities of Northern Quebec. *J. Le Clerc-Blain[1], V. Gosselin[2], A. Bearskin[3], J. E. Torrie[2], G. A. Mitchell[1,4,5], B. J. Wilson[6], A. Richter[1,4,5], A-M. Laberge[1,4,5].* 1) Research Center, CHU Sainte-Justine, Montreal, QC, Canada; 2) Cree Board of Health and Social Services of James Bay, Chisasibi, QC, Canada; 3) Eeyou Awaash Foundation, Chisasibi, QC, Canada; 4) Medical Genetics Division, CHU Sainte-Justine, Montreal, QC, Canada; 5) Department of Pediatrics, University of Montreal, Montreal, QC, Canada; 6) School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, Ottawa, ON, Canada.

BACKGROUND: A population-based educational and carrier screening program (ECSP) was started in 2006 for Cree encephalitis (CE) and Cree leukoencephalopathy (CLE), two neurodegenerative autosomal recessive conditions with high carrier rates in James Bay Cree communities (Canada). Developed by local health authorities in collaboration with the Eeyou Awaash Foundation (EAF; a community family support group), the CE-CLE ECSP informs the population about CE-CLE, availability of carrier screening, and reproductive options for at-risk couples. **OBJECTIVE:** To describe knowledge and attitudes of nurses working in Cree communities about the CE-CLE ECSP. **METHODOLOGY:** Surveys were handed out to health professionals attending the Cree Board of Health and Social Services of James Bay's (CBHSSJB) Annual Nurses Training in November 2014. Data was collected on demographics, knowledge of CE-CLE (clinical features, myths, inheritance, carrier risk), and attitudes about the program. Descriptive statistics are reported. **RESULTS:** Of 86 meeting attendees, 80 nurses answered the survey. The majority (75/80) was aware that the CE-CLE ECSP is offered on the territory. Participants scored high marks on the disease knowledge questions, but less so on inheritance patterns, prenatal diagnosis, and program activities. Most considered that their role is to refer individuals with positive family history (66/80), to refer pregnant women (63/80), and to give information about the CE-CLE ECSP to individuals of reproductive age (62/80). One third of participants (26/80) felt they did their job when clients chose to do carrier testing. A few felt they did not do their job when someone refused carrier testing (6/80), or perceived some pressure to screen all those eligible (17/80). **FURTHER STUDIES:** We are continuing to administer surveys to other local health professionals (nurses, community workers, community health workers, physicians) who were not present at the Nurses Training. **CONCLUSION:** Participants are aware of the program. General knowledge is satisfactory. Some participants equated success with clients choosing to be tested, or felt pressured to screen all those eligible. This suggests that a subset of nurses are not fully informed about the mission of the CE-CLE ECSP, which is to make carrier screening available on a voluntary basis to those wanting to know their carrier status for reproductive decision-making. Thus, clearer communication of the program's mission is needed.

2226F

Residents as Teachers and Leaners: Transitioning Traditional Seminar Series to Team-Based Learning to Prepare Genetics Residents to be Teachers. *D. S. Regier[1], D. H. Hadley[2], P. S. Hart[2], M. Muenke[2].* 1) Childrens National Health System, Washington, DC; 2) National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Geneticists need to be not only experts in genetics and genomics but need to be able to share this expertise with students and other health care professionals. This is a very lofty goal for a group of trainees without formal training in educational theory, and many trainees may have never participated in emerging education styles, such as team-based learning (TBL) and the flipped classroom (FC). When these trainees enter their first faculty role, they are often unprepared to participate in educational programs using these styles, and may be less willing or enthusiastic about teaching. By improving trainee's confidence in their ability to educate using emerging educational styles, we propose that this may improve their ability to serve as educational leaders. A TBL seminar series was developed for the 2013-14 academic year. Residents and fellows led sessions designed to teach genetic disease or techniques. Learners took turns being the Learner Leader for each session and created the curriculum for the TBL. During the second year of intervention, 2014-2015 academic year, no additional changes were made to allow for all learners to have an opportunity to implement this teaching style. Participants increased their confidence in leading both participating in and leading a TBL session. Atbaseline, learners were asked to quantify their comfort level with leading sessions using a Likert scale. This was scored after participating in a session with an experienced TBL presenter. Thirty-three percent of learners reported that they were comfortable with leading a TBL session with some help; none willing to mentor another trainee. After one year of participating in TBL classrooms, 80% of participants reported themselves as confident enough with the teaching style to either facilitate a TBL session alone or be a mentor for new trainees preparing a TBL session. Learners reported increased engagement and knowledge retention, based on free text comments regarding the class changes. After two years, learners were unwilling to return to a traditional didactic-style series due to the improved learning environment of the TBL sessions. Overall, this intervention has increased learner's confidence in leading PBL sessions. Further studies are needed to determine if these interventions improve learner's ability to communicate with others in the medical fields, foster genetic and genomic literacy and/or improve recruitment to the field of genetics.

2227F

Developing Online Learning Modules for Medical Genetics Residency Training. *T. Wang[1,2], H. Vernon[1,2,6], M. Gunay-Aygun[1,2], V. Corson[1,3], J. Axilbund[4], G. MacCarrick[1], C. Applegate[1], A. Gherman[1], P. Sosnay[1,5], J. Bodurtha[1,2,6], D. Valle[1,2].* 1) Inst Gen Med, Johns Hopkins Univ, Baltimore, MD; 2) Department of Pediatrics, Johns Hopkins University, Baltimore, MD; 3) Department of OBGYN, Johns Hopkins University, Baltimore, MD; 4) Department of Oncology, Johns Hopkins University, Baltimore, MD; 5) Department of Medicine, Johns Hopkins University, Baltimore, MD; 6) Kennedy Krieger Institute, Baltimore, MD.

With rapid advances in genomics technology and information from the Human Genome Project, medical genetics has progressed from the study of rare Mendelian diseases to a rapidly expanding appreciation of the genetic contribution to all diseases in all areas of clinical medicine. To meet the challenges of training physician medical geneticist in the 21st century, the American College of Medical Genetics (ACMG) has published 65 core competency areas (>300 specific competencies) that are required for medical genetics residents to achieve during their clinical training. The performance of each resident in these competency areas will be evaluated as a part of the ACGME milestone program. However, no systematic learning and evaluation tools are readily available to assist individual residency programs to achieve these training objectives. We have developed online, case-based learning modules to cover all core-competency areas outlined by the ACMG during the 18 months of required clinical residency training in medical genetics. Each learning module is focused on 1-2 clinical competency areas consisting of relevant clinical cases, key teaching points, practice guidelines, core clinical and/or research articles, and pre- and post-tests. These modules are housed at our residency education website (https://igm. jhmi. edu/residency-main) with password-protected access. Each resident is required to complete one learning module during a relevant clinical rotation (2 weeks) and participate in a focused teaching and evaluation session with an attending geneticist at the end of the rotation. Progress of the residents toward learning objectives is measured by pre- and post-tests, feedback from attending physicians, and in-training examination (ITE). These data are collected as a part of milestone-based evaluations for individual resident during his/her medical genetics residency training. We are piloting these learning modules for medical genetics residents during their first and second years of clinical rotations at the Johns Hopkins Hospital and affiliated training sites. We anticipate that these learning modules will be a valuable training tool for medical genetics residency programs to achieve and evaluate clinical competencies for their trainees.

2228F

Development of a competency-based genomic education resource for physicians. *K. W. Weitzel[1], E. Edelman[2], R. Roberts[3], B. Korf[4], M. Murray[5], J. Jenkins[6], ISCC Education Products Working Group.* 1) Personalized Medicine Program, University of Florida College of Pharmacy, Gainesville, FL; 2) Genomic Education, The Jackson Laboratory, Bar Harbor, ME; 3) University of Ottawa Heart Institute, Ottawa, ON; 4) Department of Genetics, University of Alabama, Birmingham, AL; 5) Genomic Medicine Institute, Geisinger Health System, Wilkes Barre, PA; 6) Genomic Healthcare Branch, National Human Genome Research Institute, Bethesda, MD.

Background: Faced with an increasing number of clinically relevant genomic applications, physicians have expressed a need for improved knowledge/skills in genetic risk assessment, testing, and management. While some groups are developing physician educational resources, there has been limited coordination of these efforts, and no single resource addresses this gap. **Objective**: We describe the development and initial assessment of a novel repository of peer-reviewed genetic/genomic educational resources for physicians. **Methods**: The Genetics/Genomics Competency Center (G2C2; http://g-2-c-2. org/) is an online repository created to facilitate development, access, and dissemination of competency-based educational resources for healthcare providers and educators. In collaboration with G2C2, we developed competency-based criteria and a peer-review process to identify and evaluate educational resources aligned with physician needs. Resources were solicited from member organizations of the Inter-Society Coordinating Committee for Practitioner Education in Genetics (ISCC), evaluated for G2C2 inclusion based on ISCC-developed physician competencies in genomic medicine, and mapped to these competencies. Resources became available on G2C2 in June 2014; usage data for physician resources was collected for a 6-month period post-launch. **Results:** A total of 87% (77 of 89) of submitted resources were accepted, which addressed all physician competency domains (family history, genomic testing, patient treatment based on results, and somatic and microbial genomics). The most common reason for declining a resource was limited scope or patient applicability. Most resources addressed genomic testing, and microbial genomics was addressed the least. Accepted resource types included websites (32%), guidelines and policies (17%), courses (12%), documents (12%), books (6%), articles (5%) and other (18%), with 13% providing CME credit. From January to June 2015, 191 users accessed these resources in 261 sessions and viewed an average of 9 pages/session. **Discussion:** Using a robust quality assessment process, we developed a peer-reviewed, competency-based repository for curating physician genomic educational resources and identified needs for additional materials (e. g. , microbial genomics). Future efforts will seek to grow the available resources and expand the number of clinicians and educators who use G2C2 to access genetic/genomic education.

2229F

Touching Triton: building student understanding of common complex disease risk. *A. Hott, K. East, M. Loftin, N. Lamb.* Educational Outreach, HudsonAlpha, Huntsville, AL.

Life science classrooms often emphasize the exception to the rule when it comes to teaching genetics, focusing heavily on rare single gene and Mendelian traits. In contrast, the vast majority of human traits and diseases are caused by more complicated interactions between genetic and environmental factors. Research indicates that students have a deterministic view of genetics, generalize Mendelian inheritance patterns to all traits and have unrealistic expectations of genetic technologies (Mills Shaw et al. , 2008). The challenge lies in how to help students analyze complex disease risk with a lack of curriculum materials (Lewis and Wood-Robinson 2000, Lewis and Kattmann, 2004). Providing open access to both content resources and an engaging storyline can be achieved using a serious game model (Gee, 2005, Wong et al. , 2007, Annetta et al. , 2009). Touching Triton was developed as a serious game where students are asked to analyze data from a medical record, family history and genomic report in order to develop an overall lifetime risk estimate of six common complex diseases. Evaluation of student performance shows significant learning gains in key content areas along with a high level of engagement.

2230F

Considering Genetics Education Through the Lens of Cognitive and Developmental Psychology. *M. Peffer, M. Renken.* Georgia State University, Decatur, GA.

relationship between student's spatial reasoning skill and genetics misconceptions and (2) assessment of a genetics problem-based learning (PBL) unit with elementary school students. As students enter adolescence, their understanding of genetics necessitates additional focus on the mechanistic basis of genetics, which requires high demands on the learners' spatial reasoning. Previous work indicated that spatial reasoning skills are essential to success in STEM fields. To determine if spatial reasoning ability is related to genetics misconceptions in high school students, we assessed spatial reasoning aptitude using the Project Talent items and genetics misconceptions using questions from the AAAS Project 2061 database. Our preliminary work indicates students who score higher on abstract reasoning and 3D, but not 2D visualization have fewer genetics misconceptions. Our current work examines if improving students' spatial reasoning skills alongside standard genetics curricula will result in an enhanced understanding of genetics. This work offers a novel approach for improving genetics education in adolescents by focusing on the cognitive processes underlying genetics understanding. Very little is known about how students in early grades learn genetics. We designed and implemented a PBL unit for first through fifth graders. Working in multi-age groups, students completed a unit that required students to learn the principles of heredity and evolution and apply them to make predictions about how a fictitious species would evolve. We found that engaging young students in a multi-age genetics PBL unit resulted in improvement in students' understanding of common genetics misconceptions as shown by pre and post unit tests. Consequently, genetics PBL instruction may be effective in situating younger students' genetics learning as to minimize the development of common genetics misconceptions during the early years.

2231F

An Educational Program on Human Genetics in Japan: KYOTO MODEL ; by developing a MANGA cartoon media that can enhance importance of awareness of family health history. *Y. Hiraoka, M. Torishima, N. Akiyama, T. Wada, S. Kosugi.* Medical Ethics and Medical Genetics, Kyoto Univ. Graduate Sch. Medicine, Kyoto, Kyoto, Japan.

[Background] Today genetic technology has been rapidly advancing and genetic testing is largely available in medical practice. In Japan, little chance to learn human genetics at school, and we, genetic counselors and medical geneticists, must play a vital role to promote human genetics literacy of the public for providing optimal genetics service. “Family health history” (1) is an accessible tool that can captures genetics information, lifestyle and environmental factors, (2) allows health care providers to diagnose conditions and to assess risks and (3) increases health and genetics knowledge for the individual and the family. In this study, we developed a MANGA booklet, as a new educational implement of human genetics and family health history, and measure the effectiveness of this new tool for improving human genetic literacy of the public. Japanese MANGA, or a book in cartoon fashion, has been a widely spreading subculture in the world now, and therefore, could be one of the useful ways in human genetics education. [Study] We developed a new type of tool, the MANGA booklet, for improving human genetic literacy. The booklet has basic information about (1) human genetics including diversity of genes and environmental risks, and about (2) family health history, including instructions for gathering detailed medical information for individual family members and instructions to create a pedigree chart, which helps medical providers to predict and identify risks for many common diseases. These were assessed by certified specialists in medical genetics and genetic counselors. And we discussed with cartoonists to remake the MANGA style to be a more accessible and useful tool. As a preliminary study, we are now interviewing the undergraduates at our university to validate the booklet. [Discussion] Family health history is “the first genetic test” in medical practice or genetic counseling. And it is important for both healthy and sick persons to have correct information of their familial information for their own health. The MANGA tool that we have developed seemed to be a practical tool to interest the public in human genetics, and help them learn familial and own health status. We expected it to be accessible, easy to comprehend human genetics and family health history. We are also planning to translate the MANGA textbook into other languages to be available in many countries.

2232F

Genetics Home Reference: Educating the General Public about Precision Medicine. *H. Collins[1], S. Calvo[2], K. Greenberg[1], L. Forman Neall[3], S. Morrison[2].* 1) ICF International, Fairfax, VA; 2) U. S. National Library of Medicine, NIH, Bethesda, MD; 3) Medical Science and Computing, LLC, Rockville, MD.

Clinicians and researchers use precision medicine to assess the impact of genetic, environmental, and lifestyle factors as part of individual variability. This approach targets specialized treatment and prevention strategies for diseases. While much work is needed to build the tools necessary for clinicians and researchers to use a precision medicine model, the general public also needs a resource that explains the concept of precision medicine and elucidates the details of the genetic variables involved. For the past 12 years, Genetics Home Reference (GHR; http://ghr. nlm. nih. gov/) has become a trusted consumer website of the U. S. National Library of Medicine. GHR conveys complex genetic information to the public through brief, plain language summaries of genetic conditions and associated genes with related links to outside resources. GHR is intended as a resource for patients, families, and the general public needing information about genomic medicine. Many of the more than 1,000 genetic condition summaries provided on the GHR website are relevant to precision medicine, including cancers, immune deficiencies and dysfunctions, enzyme deficiencies, multifactorial conditions that involve gene—environment interactions, and drug sensitivities. GHR also has detailed information on more than 1,200 genes, describing their normal function and how their variations contribute to changes in health. Chromosomal changes and their contribution to human disease are also discussed on the GHR website. GHR provides a primer called *Help Me Understand Genetics*, which has chapters discussing pharmacogenomics, genetic testing, diagnosis and treatment, and genomic research. The primer also provides information about precision medicine, including the President’s Precision Medicine Initiative and the potential benefits and challenges of this approach. This presentation describes the resources that GHR provides to engage the public in various aspects of precision medicine. It also includes important context that consumers need to fully understand precision medicine, such as information about genetic conditions, gene function and variability, and overviews of genetic concepts. We discuss how GHR can involve healthcare consumers in the precision medicine conversation by giving them easy-to-understand tools that cover both the genetic causes of disease and the factors that play a role in disease variability.

Personal Genetics Education Project: A multifaceted and interdisciplinary approach to public engagement about personal genetics. *M. Gelbart, D. Waring, L. Tomaselli, M. Shea, T. Wu.* Personal Genetics Education Project, Harvard Medical School, Boston, MA.

Through its direct engagement with public audiences, the Personal Genetics Education Project (pgEd. org) at Harvard Medical School experiences on a near-daily basis the growing gap between what genetics is making possible and what many people realize. pgEd sets out to catalyze a spark, striving within as little as five minutes to inspire people’s imaginations about the possibilities and complexities of where genetics is heading. The three overarching goals of pgEd are (1) to decrease fear of, or reluctance to engage on, the topic of genetics, (2) to instill confidence in individuals so that they will feel comfortable asking questions about genetics, and (3) to promote acceptance of diversity. We focus on instilling curiosity, seeking to lower the barriers that inhibit nonscientists from learning more about genetics. We engage audiences through the entertainment industry, an on-going series of Congressional briefings, social media, as well as in high schools and most recently libraries and faith communities. We rely on topics that fascinate people, the ones that they cannot get out of their minds – woolly mammoths, space travel, personal stories, and the stickiest of ethical dilemmas surrounding reproductive technologies, privacy and consent, and the uses of DNA in the criminal justice system. We findthat individuals are captivated by these topics and interested to learn more. We also find that individuals are impressed and grateful that scientists feel a responsibility to engage in these conversations. Though pgEd does not set out to bring people into science, this is a most fortunate unintended consequence.

2234F

Public attitude towards governance of consumer targeted genetic testing and secondary use for research in Japan. *K. Muto[1], A. Nagai[2], Z. Yamagata[2].* 1) The University of Tokyo, Tokyo, Japan; 2) Yamanshi University, Chuo, Japan.

Background: In 2014, several Japanese industries announced the launch of DTC (direct-to-consumer) personal genetic testing services in Japan. The Ministry of Trade and Industry (METI) has encouraged an industrial association, Council for Protection of Individual Genetic Information (CPIGI), to prepare an accreditation system based on their best practice guidelines. On the other hands, the Ministry of Health, Labour and Welfare started to discuss the definitions of "diagnosis" to regulate DTC personal genetic testing services. Currently, the Japanese Diet is revising the Act on Protection of Personal Information in which personal genome data hasn't been covered. However, we still do not have enough data on public attitudes towards these services and regulation. Methods: Cross-sectional and anonymous online surveys were administrated to men and women in Japan in March 2014 and March 2015. Participants of these studies have been extracted so as not to overlap from the survey panel. The questionnaires included questions concerning genetic knowledge, attitudes towards genetic testing and regulations governing DTC personal genetic testing services. We compared the data of these surveys and past relevant dataset. Results: The mean age of the respondents was 45. 7 ± 14. 0 years in 2014 and 45. 8 ± 14. 0 years in 2015. The percentage of the respondents who haven't known the term "genome" was lower than "gene", "DNA" and "iPS Cell". The percentage of the respondents who knew about DTC personal genetic testing services was 32. 9% in 2015, which is higher than in the 2014 survey by 10 points. The percentage who were willing to purchase or who had purchased these services was almost the same level. The results of willingness to undergo 6 types of genetic testing by scientific evidence. More respondents in 2015 (35. 4%) allowed the secondary use of genomic data for medical research than in 2014 (28. 6%). The percentage of respondents who wanted to receive personal results were 34. 3% in 2014 and 33. 6% in 2015. Discussions: The Japanese public showed slightly more positive attitudes towards DTC personal genetic testing services and the secondary use for medical research. However, more than 50% of our respondents couldn't understand the meaning of scientific evidences. There may be a possibility of affecting the attitude about the future of the services.

2235F

Documentary on thalassemia: a public awareness initiative. *I. Panigrahi[1], A. Chaudhary[2].* 1) Pediatrics, PGIMER, Chandigarh, Chandigarh (UT), India; 2) Pathology, DMCH, Darbhanga, Bihar.

Thalassemia is a public health problem in India with carrier rates from 3-17% in several communities especially in north India. The documentary has been made to increase awareness on thalassemia especially for the public and the availability of preventive measures. During a CME on thalassemia at Darbhanga in April this year, this was planned, and assistance was taken for cartoons/puppets also from the Puppet Theatre Chandigarh. This documentary is available on DVD and also incorporates a thalassemia song that describes the pain and problems of thalassemia patients. The draft of the song is available on YouTube also. The short film of around 12 minutes narrates the basics, management and complications in thalassemia in simple lucid language. Photographs, illustrations, videos and puppet characters like animated red cell are used in the film. The film is narrated by a voice over artistein Hindi, a language understood by most Indians, but subtitles are in English, including for the song. Key messages are given at the end of the film.

2236F

Development of an interactive online clinical whole genome sequencing educational and engagement tool. *E. Ramos, S. Waleetorncheepsawat, R. Maile, K. Sherman, L. Nguyen, K. Rhodes, S. Coon, V. M. Raymond.* Illumina, Inc. , San Diego, CA.

The medical, psychosocial, and social promise of clinical whole genome sequencing (cWGS) is sometimes overshadowed by the vast amounts of complex data, difficulty in translating data into actionable information, and the need to communicate information in lay language. Existing websites allow genomic exploration but are neither consumer friendly nor routinely include educational or interactive components. We developed a free, web-based, Understand Your Genome® Community where adults who are presumed to be healthy and who have undergone a cWGS Predisposition Screen can explore their genome using the MyGenome application. Those who have not had cWGS can also join and explore a demonstration genome. The goal is to create an interactive, engaging workspace to increase individual genomic literacy and expand the personal utility of cWGS data. Individuals learn about medical conditions, including clinically significant variants in Mendelian disorders and pharmacogenomic indications identified through their screening and can link to educational web resources. Individuals can access variant information (e. g. allele frequency, gene callability, disease inheritance patterns and amino acid changes). As individuals become aware of other variants of interest through academic or lay literature, they can use the chromosome browser feature to navigate to these areas within their genome and identify their variation at that position. Participant feedback has been positive. Website statistics demonstrate frequent and return visits. Participants overwhelmingly request the ability to follow genomic discoveries, research their variants, share genomic information with family, friends and health care providers, and donate their genome to research. Participants are also interested in networking and identifying individuals within the community with similar genomic findings. The development of a free, online educational community has been received positively by individuals engaged in cWGS. As we continue to explore the utilization of genomic information in a healthy adult population and redefine "value" in terms of genomic information, understanding the motivations for sharing genomic information and the opinions on the key components and features of the this community will be important in maintaining active engagement by members.

2237F

People's attitude toward genetic testing for children and informed consent/assent in Japan. *I. Ishiyama[1], Z. Yamagata[2], J. Minari[3], G. Yoshizawa[3], K. Kato[3].* 1) Tokoha University, Fuji, Shizuoka, Japan; 2) University of Yamanashi, Chuo, Yamanashi, Japan; 3) Osaka University, Suita, Osaka, Japan.

[Purpose] We've been conducting nationwide questionnaire surveys since 2005 to 2014 in order to explore attitude change on genomic studies of the general public in Japan. The aim of this study was to clarify the attitude change of Japanese general public toward genetic testing of disease susceptibilities for children, to assess people's opinion on the children's appropriate age of consent/assent in research collecting human biological specimens, and to examine the factors related to these attitudes. [Methods] In 2005, 2009 and 2014 surveys, peoples (age, 20-69) were selected from the Japanese general population by a stratified two-phase sampling method. They were queried about the following topics by mail: (1) attitude toward genetic testing for disease susceptibilities of children on common diseases which will be able to be prevented or controlled, (2) appropriate age of children to be sought consent/assent by researchers participating research providing biological specimens, (3) awareness of self-condition on health, (4) level of genomic literacy, and (5) demographic and socioeconomic background. Datasets were examined using χ^2test, one-way ANOVA and logistic regression models. [Results]The response rate was 54. 3% (2,171/4,000) in 2005, 52. 5% (2,009/4,000) in 2009, and 56. 4%(1,354/2,400) in 2014. The genetic testing for disease susceptibilities of children for common diseases was favored by 55. 5% people in 2005; 58. 8% in 2009; and 50. 3% in 2014. A difference in the attitudes was observed. Having high level of genomic literacy showed positive relation with the favorable attitude, having a child (or children) actually showed negative relation, and awareness of self-condition on health showed no relation. Concerning literacy and favorable attitude, there was a strong relation in males but a partial relation in females in 2014 survey. In regard to questionnaires of appropriate age of children to be sought consent/assent for providing biological specimens in 2014 survey, 1. 3% people answered 5years, 3. 3%:7years, 15. 1%:10years, 25. 4%:13years, 24. 9%:16years, 12. 9%:18years, 4. 4% answered collecting biological specimens should not be allowed in the cases of minors, and 12. 7% answered I don't know. Peoples with high level of literacy tended to make a response of younger age. Assessing the competence of a child to consent/assent and the best process of seeking consent/assent should be discussed in Japanese society.

Overcoming Technical Barriers to Incorporate Molecular Structures in Teaching with Molecule World™ on the iPad and iPhone. *TM. Smith, SG. Porter.* Digital World Biology, Seattle, WA.

It is impossible to grasp fundamental concepts of genetic variation without understanding the relationship between sequence, structure, and function. While an abundance of data resources can be used to help students' understand these relationships, they are underutilized because easy-to-use tools are not yet commonplace. Filling the gap between the embarrassment of data riches and practical classroom use requires user-friendly tools, content that demonstrates specific applications with interesting stories, and packages that combine instruction, assessments, and inquiry-based investigations. Finally, in our experience teaching bioinformatics, we have observed that, when given a choice, many students prefer to use their mobile devices instead of desktop computers. Consequently, to acquaint students with bioinformatics, the educational tools and materials need to be operable on these devices. In response to nearly two hundred interviews with K-12 and college teachers and students, we created the Molecule World™ iPad and iPhone apps to display 3D-data from multiple structure databases (MMDB, PDB, and PubChem). Molecule World employs a novel rendering engine that allows us to uniquely highlight chemical properties and sequence orientation. The ability to display and highlight sequences within molecular complexes enables exploration into the relationships between sequence, structure, and function in new ways. In comparison to desktop programs, students and teachers have communicated that Molecule World overcomes the obstacles associated with installing software and understanding complicated user interfaces. Other data, collected in professional development workshops, and bioinformatics courses, along with summer technical camps with high-school students, support the hypothesis that being able to view and simultaneously interact with data improves teaching capabilities and student engagement. Work supported by NSF grant IIP 1315426.

Teaching meiosis brings together concepts from four different areas. *D. L. Newman[1], K. DeOca[1,2], C. M. Catavero[1], E. Zajicek[1], L. K. Wright[1].* 1) Gosnell School of Life Sciences, Rochester Institute of Technology, Rochester, NY; 2) Department of Biology and Marine Science, Jacksonville University, Jacksonville, FL.

Although the topic of meiosis is brought up numerous times during a typical undergraduate biology program, most undergraduates have only a superficial and/or deeply flawed model of this process. Biology education research has been documenting this phenomenon for decades and researchers have identified numerous misconceptions that students hold about meiosis. Many of these findings are presented as isolated areas of confusion, not tied in with holistic conceptual understanding. Based on results from an assessment instrument that we developed and validated using methodology from the DBER literature we have developed a framework that we feel explains the gaps in students' knowledge. Deep analysis of textbooks, interviews, and classroom artifacts revealed that meiosis is neither a single concept nor is it based on a single biological principle. In fact, it brings together several disparate broader topics: chromosome structure, ploidy, homology, and molecular mechanism. We have validated the importance of these themes through alignment with published concept inventories and interviews with biology experts. Using this framework we analyzed 17 college-level biology textbooks and found that information related to these four major themes are often missing, hidden (perhaps obvious to an expert but not a novice), or are found in a chapter that follows the discussion about meiosis. We suggest a new framework for teaching about meiosis based on linking foundational knowledge of these four topics to discussions of cell division. Future work will investigate the effectiveness of this approach.

Quick Medical Genetics: A YouTube channel for clinical genetics education. *P. M. Boone.* Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Purpose: Online videos are a potential resource for clinical genetics education. Yet, such videos lag behind textbooks, review articles, and online encyclopedias (e. g. OMIM, GeneReviews) in comprehensiveness and availability. Thus, I sought to establish a collection of clinical genetics lectures on YouTube, the most utilized source of free online videos. **Methods:** A YouTube channel, Quick Medical GeneticsTM (https://www. youtube. com/c/quickmedicalgenetics), was created and nine video lectures were piloted. Videos were short (< 15 min), focused on a single genetic disorder (e. g. ataxia-telangiectasia) or a family of genetic disorders (e. g. disorders of galactose metabolism), and were created with an anticipated audience of both trainees and medical professionals. **Results:** The videos were viewed 1,132 times over a four-month pilot phase. The average view time was 4 min 14 sec, for a total of 4,736 minutes watched. Individuals in 96 countries watched the videos, the top 5 viewer origins being the United States, United Kingdom, India, Saudi Arabia, and Egypt. Thirty-four individuals subscribed to the channel. **Conclusions:** The Quick Medical GeneticsTM YouTube channel is a collection of free, easily accessible educational videos about genetic disorders. In a pilot phase, viewers from dozens of countries watched thousands of minutes of content. In order to be scalable to the large number of known genetic disorders, input from the genetics community will be necessary. Thus, I welcome videos from genetics trainees and professionals; please inquire at quickmedicalgenetics@gmail. com.

Learning across the lifespan: a team-based approach to genomics education for high school students to practicing professionals. *E. Edelman, W. Barter, J. Corrigan, T. Ingram, L. John, K. LaRue, M. McKernan, W. Nakonechy, K. Reed, C. Wray, T. Litwin.* Genomic Education, The Jackson Laboratory, Bar Harbor, ME & Farmington, CT.

Realizing the promise of precision medicine will require a medical and scientific community conversant in genomics. While efforts exist to educate specific audiences about genetics and genomics, these activities often happen in isolation from one another and may not support the cross-discipline discussion and understanding critical for broad genomic literacy. Furthermore, training programs that focus on a single audience or delivery approach diminish the capacity to leverage successful models and efficiently adapt existing resources. We describe a unique model for lifelong genomics learning, from high school to continuing education. The Jackson Laboratory (JAX) has created an ecosystem in which a multidisciplinary educational team, embedded within a research institute, seeks to empower learners to join the shared quest to improve human health through education, research and collaboration. Under the aegis of JAX Genomic Education (GE), 5 core programs address the needs of diverse learners. (1)The STEM and Undergraduate Education program provides authentic research experiences to students as well as professional development and inquiry-based classroom modules for high school STEM teachers. (2)The Genomics Workforce Consortium delivers professional development for college faculty, expertise in curriculum review for community colleges and research and internships for students. (3)The Pre- and Postdoctoral Education program provides resources for 64 postdoctoral associates and 25 Ph. D. candidates, including a program focused on skill development in communication, management and entrepreneurship to help themsucceed as independent scientists. (4)The Courses and Conferences program leverages the scientific expertise within JAX and delivers courses in medical and mammalian genetics and genomic techniques to scientists. (5)The Clinical and Continuing Education programempowers healthcare professionals to integrate genomics into their clinical practice by providing competency-based CME and clinical tools. GE Online & Digital supports digital collaboration and learning tools in all JAX programs, facilitating access and engagement through scalable online courses. Being housed within the same office and working collaboratively allows JAX GE to leverage internal expertise and learner feedback to develop cross-disciplinary opportunities. This approach to genomics education enables us to better meet the needs of our learners and prepare the workforce for genomic medicine.

2242W

Costs of clinical decision support for genomic tests may be greater than the cost of initial genomic testing. *P. C. Mathias[1], P. Tarczy-Hornoch[2], B. H. Shirts[1].* 1) Laboratory Medicine, University of Washington, Seattle, WA; 2) Biomedical Informatics and Medical Education, University of Washington, Seattle, WA.

For optimal personalized medicine a physician will need to be aware of genetic results from testing performed years earlier, as rare genomic findings may alter clinical care for a fraction of patients. Well-designed active clinical decision support (CDS) alerts within an electronic health record are important for incorporating genomic data into clinical workflows. Via mathematical modeling we evaluated potential costs of design, implementation, and maintenance of CDS for genomic medicine in a variety of scenarios. For our modeling we made a number of assumptions. We assumed the costs of designing, building, and implementing a single genetic CDS rule is about $7. 5K We assumed that CDS rules would need to be in place 20 to 30 years before they would be used for the average individual. CDS rules must be maintained over this time, assumed to be 15-20% of implementation costs. The lifetime costs of maintaining CDS rules and support systems for precision medicine were thus assumed to be 4 to 6 times the cost of initial rule implementation. As an example of one scenario we looked at genomic testing in 2% of the population, and local CDS implementation for 10 actionable variants improving care for 1% of the individuals tested. With assumptions above we found that the cost of communicating genomic information to a physician at the point of care could be about $26K per patient benefiting from the genomic information. If additional variants lead to actionable findings in a higher fraction of patients, efficiently implementing multiple CDS rules will decrease CDS costs per patient receiving benefit. Efficiencies of scale from sharing CDS rule implementation across many institutions or implementation of genomic testing in a greater proportion of patients could reduce per patient genomic CDS costs. We modeled scenarios across a range of assumptions and found that in many scenarios per-patient cost of the electronic communication of genetic information using CDS was greater than the cost of initial genomic testing and annotation. Only in scenarios that include mobility of genomic data across institutions, cooperation between institutions for CDS, and widespread genomic testing will precision medicine become cost effective. Our modeling suggests additional inter-institutional efforts to build efficient, scalable systems for communicating genetic test results and actionable interpretations at the point of care are needed to decrease cost of genomic decision support.

2243W

A cost effective in house method for HIV genotyping – circumventing the use of costly kits for developing countries. *M. Mitne-Neto, M. G. S. Barth, C. M. Moreira, P. R. Sacramento, C. P. Reys, M. T. dos Santos, A. M. Fraga.* R&D, Fleruy Group, São Paulo, Brazil.

Statement of purpose: More than two hundred thousand Brazilians carry the Human Immunodeficiency Virus (HIV). Brazil offers freely treatment for infected patients, which costs US$427 million per year for the Federal government. The proper patient management requires HIV genotyping, aiming to identify mutations promoting resistance to each of the effective drugs. The Trugene HIV genotyping assay (Siemens) was one of the main assays available in the market, however, its worldwide discontinuity surprised private laboratories and those working for the Brazilian healthcare system. Methods: In order to circumvent this situation we developed an in house method that allows the sequencing of the Protease and Reverse Transcriptase regions and compared its performance with the Siemens assay. Primers for One-Step RT-PCR were designed to amplify a 1300bp region, followed by a nested PCR and traditional Sanger sequencing. Resulting sequences were submitted to the HIV Drug Resistance Database – Stanford University. In order to validate the method fourteen samples (subtypes B / C / F) that were previously genotyped by the Trugene system were evaluated in the new workflow. Results: Susceptibility profile, classified as High Level of Resistance, Susceptible, Potential low-level resistance and Low level resistance showed 100% concordance on all samples, through the 20 evaluated drugs, between the two platforms. Main and minor resistance mutations to protease inhibitors, nucleoside reverse transcriptase inhibitors and non-nucleoside reverse transcriptase inhibitors also showed 100% concordance between the two platforms over all the 14 samples. The lower limit of detection was established as 2000 copies/mL for the in house system by the evaluation of 5 separated aliquots of the same sample. The implementation of this methodology has a great economy impact, since it reduces reagents costs by 40% and the analyst hands on time by 50%. Additionally, our assay design allows the immediate transfer of amplified regions to next generation sequencing, which is still under evaluation, in order to identify mutations that are under the 20% allele burden cutoff. In summary, we developed a cost effective in house method for HIV genotyping, which is cheaper and faster than the previously offered kits in the market. This data is of special interest of developing countries due to the highly costs related to HIV proper treatment.

2244W

Attitudes towards receiving genetic information on susceptibility to the effects of arsenic exposure in rural Bangladesh. *B. Pierce[1], M. Eunus[2], M. Rahman[2], B. Barmon[2], A. Ahmed[2], R. Hasan[2], T. Islam[2], H. Ahsan[1].* 1) Public Health Sciences, University of Chicago, Chicago, IL; 2) U Chicago Research Bangladesh Ltd. , Dhaka, Bangladesh.

Exposure to arsenic, a known carcinogen, is a serious global health issue that has been linked to risk for cancer, cardiovascular conditions, and overall mortality. In Bangladesh, >50 million people consume water from naturally-contaminated wells with arsenic exceeding >10 µg/L. Our group and others have demonstrated that genetic variation near the arsenic methytransferase gene (*AS3MT,* 10q24. 32) is associated with arsenic metabolism efficiency (measured as urinary arsenic metabolites) and is the major common determinant of arsenic metabolism in the genome. Individuals who are slow metabolizers due to 10q24. 32 genotype have higher risk for arsenical skin lesions -- the classical sign of arsenic toxicity. In light of this emerging knowledge and its potential for identifying high-risk individuals, we conducted a survey of 200 participants in the Health Effects of Arsenic Longitudinal Study (HEALS) to assess attitudes towards receiving genetic information related to arsenic toxicity risk. Returning genetic information has the potential to increase the efficacy of an ongoing exposure-reduction program in HEALS by further motivating highly-susceptibility individuals to avoid contaminated water sources. Among 200 consecutive participants visiting our primary care clinic who agreed to participate in this study, 100% were interested in receiving genetic information, and 91% indicated that such information would motivate them to reduce their exposure. Over 99% of respondents indicated that they would disclose their genotype status to family, and 59% reported they would be comfortable disclosing their status to non-family members. Individuals with no formal education were less likely to be concerned about arsenic exposure than individuals with some education (p=0. 02), but low- and high-education groups reported similar levels of motivation to reduce exposure in response to genetic information. To our knowledge, this is the first assessment of attitudes towards genetic testing in Bangladesh, and the first such assessment related to susceptibility to arsenic toxicity. Our results indicate that a) individuals living in arsenic-exposed regions are interested to know if they are at increased risk and b) sharing genetic information with high-risk individuals may provide additional motivation to reduce exposure. Additional research is needed to estimate the impact of returning genetic results on health behaviors and outcomes and to assess potential harms.

2245W

Cost-Benefit Analysis of Genomic Testing Vs. Standard Genetic Testing in Inpatient Population. *A. Khromykh[1], B. Solomon[1,3], F. Moeckel[1], D. Bodian[1], R. Baveja[2,3], J. Vockley[1], J. Niederhuber[1].* 1) Inova Translation Medicine Institute, Inova Fairfax Hospital, Falls Church, VA; 2) Fairfax Neonatal Associates at Inova Hospital for Children, Falls Church, VA,; 3) Inova Children's Hospital, Falls Church, VA,.

PurposeAs the cost of WGS is rapidly decreasing and analytic capabilities evolve, WGS and related modalities are becoming increasingly usable. In order to harness the potential of clinically-based WGS, we are conducting a research study to detect novel genomic etiologies as well as assessing the application of WGS as a diagnostic tool in real-time clinical practice. **Methods**We utilize trio-based WGS, RNA expression, methylation, and miRNA characterization in order to investigate potential molecular etiologies of the congenital disease. Genetic workup data was obtained through thorough review of probands' electronic medical records. Cost averaging was calculated based on actual reimbursements to the hospital (these negotiated rates are ~40-60% lower than market price). **Results**The average cost of standard genetic/etiologic laboratory tests was $3,500 per patient. We were not only able bioinformatically identify the causative genetic/genomic mutations in multiple probands in our cohort population utilizing WGS, but also that cost of clinical genetic/etiological testing was 2-3 times greater than research-based cost of sequencing the whole genome. **Conclusion**Our preliminary data confirms that trio-based WGS can provide answers to patients and families with undiagnosed disorders, as well as the novel finding that research-based WGS may already be considered a cost-effective alternative to the standard genetic work-up. Further, WGS can act as an immediate diagnostic tool, and can also provide additional clinical utility related to a wide range of genomic-related health information.

2246W

Annotating rare diseases with HPO terms: a new Orphanet service to refine phenotype-genotype correlations. *A. Olry[1], C. Prévot[1], C. Jaramillo[1], C. Gonthier[1], S. Janmaat[1], V. Lanneau[1], S. Gérard[1], M. Hanauer[1], PN. Robinson[2], A. Rath[1].* 1) INSERM, US14 - ORPHANET, Paris, France; 2) Institute for Medical Genetics, Charité-Universitätsmedizin Berlin, 13353 Berlin, GERMANY.

Detailed phenotype data, combined with ever-increasing amounts of genomic data, have an enormous potential to accelerate the identification of disease-associated genes and clinically actionable variants. The harmonization of phenomic information including disorders and phenotype traits that are stored in different systems (patient records, databases, registries) in a non-standardized way, is a cornerstone for the data integration needed for translational research. In order to contribute to the harmonization of phenotype and rare disease (RD) data, two resources that are now considered as standard are being integrated: the Orphanet RD nomenclature and its ontological version ORDO, and the Human Phenotype Ontology (HPO), by annotating the Orphanet nomenclature with HPO terms. The interoperable phenotype core terminology produced by the International Consortium for Human Phenotype Terminology (ICHPT) was used to align the Orphanet thesaurus of clinical signs, to which RD were already annotated, to HPO terms. The annotations were manually reviewed and refined, and further annotation with HPO was conducted. The 2689 RDs initially annotated with the clinical signs of the Orphanet thesaurus are now annotated with HPO. Additional information was also produced:- Estimated frequency of the annotated HPO terms in the patient population (very frequent, frequent and occasional),- Whether the annotated HPO term is a major diagnostic criterion or a pathognomonic feature of the RD. This work improves both of these standard resources. HPO annotations increased considerably the phenotypic description of RD, with 4,508 HPO terms now used compared to the 1,273 clinical signs previously used in the Orphanet thesaurus of signs and symptoms. On the other hand, HPO will be enriched as around 370 missing phenotypic terms have already been identified. Furthermore, Orphanet provides genes associated to RDs annotated with HPO terms, opening new avenues for a better interpretation of phenotype-genotype correlations. Finally, interfacing these two standard resources will allow the integration of clinically well-defined RD in repositories already using HPO and/or other terminologies already mapped with the Orphanet nomenclature, including OMIM. These annotations will be freely available at Orphadata (www. orphadata. org). This pilot study will be expanded in the future by the collaborative development of tools for medical biocuration as well as interoperable RD resources for the community.

Thalassemia in Egypt: Paving the way for prevention and cure. *G. Y. El-Kamah[1], K. Amr[2], A. AbdelNeam[2], E. Bayoumy[2], M. Ghandour[1], H. Ahmed[1].* 1) Clinical Genetics department, Human Genetics and Genome Research division, National Research Centre, Cairo, Egypt; 2) medical molecular genetics department, Human Genetics and Genome Research division, National Research Centre, Cairo, Egypt.

Introduction: Beta thalassemia is one of the most common human genetic disorders, and represents a major public health problem**.** In Egypt, beta-thalassemia mutations occur at high frequency with a carrier incidence of about 9-10%. **Objective: D**efining the spectrum of mutations among Egyptian beta-thalassemia patients. Studying whether suggested genetic determinants can predict phenotypic severity and its impact on genetic counseling as an important step in providing proper counseling & disease control. **Methodology:** This is a prospective cross-sectional study performed from 2005 till 2015 in the Hereditary Blood Disorders Clinic. 500 Egyptian beta thalassemia cases were included. Clinical data were recorded followed by molecular analysis & mutations detection. **Results:** Twenty-six mutations are identified till date. The five most prevalent mutations were as previously reported IVS-I-110 (G>A), IVS-I-6 (T>C), IVS-I-1 (G>A), IVS II-745 (C->G) and IVS II-848 (C->G) accounting for more than 80% of the independent characterized chromosomes. The five mutations responsible for 80% of our cases are all Mediterranean in origin except IVS II-848, which is considered Egyptian. Comparing Egyptian mutations' spectrum to previous reports 21 other (novel & known) mutations were characterized. Type of beta-thalassemia mutation &/or determinants was not persistently correlating with the phenotypic outcome. No intra-familial heterogeneity was detected among our included family members helping genetic & prenatal counseling. **Conclusion:** the study helped in providing better counseling however**,** further mutations characterization and genetic modifiers studies are needed for the clarification of phenotypic heterogeneity. Also, immunological determinants, their prognostic values & psychosocial impact of the disease on thalassemia patients and their families are in progress.

2248W

Views of patients regarding universal Lynch Syndrome screening. *T. Hyams[1], D. Bowen[1], S. Shiovitz[2,3], M. Miller[1], W. M. Grady[3], W. Burke[1].* 1) Department of Bioethics and Humanities, University of Washington, Seattle , WA; 2) University of Washington, Division of Oncology, Seattle, WA; 3) Fred Hutchinson Cancer Research Center, Clinical Research Division, Seattle, WA.

Approximately 2-5% of the annual 150,000 colorectal cancer (CRC) cases diagnosed in the United States are attributable to Lynch Syndrome (LS), a familial cancer syndrome. . The lifetime CRC risk in individuals with LS is estimated to be ~40- 82%, which is much higher than the population's CRC risk of 5%. In 2009, the Evaluation of Genomic Applications in Practice and Prevention working group recommended universal screening for newly diagnosed CRC patients using microsatellite instability (MSI) and mismatch repair immunohistochemistry (IHC) to provide appropriate management for identified patients and their family members. This would include genetic testing and, if appropriate, offering early cancer detection interventions. . The purpose of this abstract is to describe the experiences of CRC patients with universal screening. We approached and interviewed 10 patients diagnosed with CRC in the Multidisciplinary CRC Clinic at the Seattle Cancer Care Alliance, a collaborative outpatient facility of the University of Washington and the Fred Hutchinson Cancer Research Center. The purpose of the interviews was to explore patient experiences with universal testing for MSI and IHC and family interactions about CRC risk and testing. We sent a letter, and then called patients with an invitation to participate in the telephone interview. Interviews lasted 60 minutes and were recorded and then transcribed for analysis. In general, patients did not remember providing consent for MSI/IHC testing, nor did they remember receiving results. No patients objected to being tested, even those that did not remember the process. Trusting the provider to make important recommendations was a theme in the interviews, as was being overwhelmed with procedures and activities after diagnosis. Few patients had talked to their family members about familial cancer risks since the diagnosis. Most patients reported that they would talk to family members if it were important to the family members' health, and most wanted assistance with family communication. All patients were offered contact with a genetic counselor to answer questions after the interview was over. Identification of key themes in discussion the LS testing process has important implications for future universal testing. Our evaluation has helped to identify ways to assist patients and families with issues surrounding universal LS screening.

A SMARTer way to set genomic test reports on FHIR. *M. S. Williams[1], J. A. Billet[2], G. J. Moore[2].* 1) Genomic Medicine Institute Geisinger Health System, Danville, PA; 2) Institute for Advance Applications, Geisinger Health System, Danville, PA.

As genome sequencing moves into the clinic, innovative approaches to present the results to patients and providers are needed given the complexity and dynamic nature of the results. More control by the patients is desirable as the genomic data has persistent relevance to the patients' health care. We have worked with patients and families to develop a patient-facing genomic test report. In this paper we describe implementation of an interactive patient facing genomic testing in the electronic health record (EHR). Most EHRs do not have the capability to support the advanced functionality of our report. We utilized an internally developed application, COMPASSTM, to develop the dynamic genomic test report. COMPASSTM employs its own application program interface (API) and other service-based architectures to seamlessly integrate into the EHR. This architecture is being utilized to put COMPASSTM on the path of an emerging open standards approach for sharing healthcare information called Fast Interoperable Health Resources (FHIR®). In order to present information to patients and family within the patient portal tethered to the EHR, an API called SMART will be utilized upon industry adoption. SMART on FHIR is an emerging open standards-based technology stack that allows integration of clinical, genomic and related data for both the patient and provider report. The genomic report has been integrated with our Epic EHR and is being tested in a prospective randomized comparative effectiveness trial. The primary outcome of the study is the impact of the dynamic and interactive patient and provider reports on communication, patient and provider satisfaction and patient engagement. Feedback on the functionality and usability of the report is used for iterative improvement. This approach to reporting genomic reports using a standards-based approach has the potential to be generalizable across certified EHRs and has the potential to transform communication of genomic results.

Evaluation and Optimization of a Universal Lynch Syndrome Screening Program at Geisinger Health System. *A. Kulchak Rahm, N. S. Kip, S. Guha, A. Fan, H. G. Kaspar, J. L. Williams, R. Gogoi, Z. Chen, D. Davis, M. S. Williams.* Genomic Medicine, Geisinger Health System, Danville, PA.

Background: Universal Lynch Syndrome screening (ULS), a genomics objective of Healthy People 2020, is defined as tumor screening of all individuals newly diagnosed with colorectal (CRC) or endometrial cancer (EC) and has been variably implemented in multiple health systems. ULS was instituted at Geisinger Health System in 2009 for CRC and optimized to include immunohistochemical (IHC) screening of all CRC resected tumors, with reflexive *BRAF* and *MLH1* promoter hypermethylation (PHM) testing through pathologists in May, 2014. EC tumor screening started in 2012, but was limited to age ≤60 or age >60 with specific tumor histology; without reflexive PHM testing. **Methods**: Two genetic counselors and a molecular pathologist evaluated all EC and CRC patients with IHC testing since 2012. Results and care gaps were presented to pathologists, genetics services, gynecologic oncologists and ethics. **Results**: Since optimization, 132 CRC biopsies and resections were sent to pathology to be screened for mismatch repair proteins (MMRs) by IHC, and for *KRAS, BRAF* mutations by PCR. 17 (13%) patients had MLH1/PMS2 loss and 1 (0. 8%) had PMS2 loss. Of those with MLH1 loss, 15 (88%) were reflexed to *BRAF* and PHM testing, with 3 (18%) found to be *BRAF* negative. Of those, 2 (66%) had PHM; the patient without PHM was referred to genetics for evaluation, as was the patient with PMS2 loss by IHC. For EC, 161 EC patients were screened by IHC (n=152 ≤60 and n=19 >60) since 2012; of whom 30 (18%) had loss of MLH1/PMS2 and 11 (7%) had MSH2 or MSH6 loss. Only 10 patients with MLH1 loss (33%) had PHM testing (*BRAF* testing is not indicated in EC). Of the 20 remaining EC patients, 6 (30%) were referred to genetics prior to PHM testing and 14 (70%) had no additional follow-up. Of patients with MSH2 or MSH6 loss, 10 (91%) were referred to genetics. **Conclusion**: After comparing the optimized CRC program and the limited EC program, we determined that reflex testing by pathologists appropriately specified patients at risk for LS and reduced over-referral to genetics. It was also determined that the limited EC tumor protocol was resulting in incomplete screening and over-referral to genetics. Engagement of multiple stakeholders and clarification of policy goals resulted in agreement to add EC tumor screening to the existing ULS program with reflexive PHM testing by pathologists to improve LS patient identification and facilitate appropriate care.

2251W

Qualitative Assessment of the Veterans Health Administration Telegenomic Clinic Implementation. *B. Lerner[1], N. McIntosh[1], M. Meterko[1], S. Wiltsey-Stirman[1], V. Venne[2].* 1) Center for Healthcare Organization & Implementation Research , Veterans Health Administration, Boston, MA; 2) Genomic Medicine Service, VA Salt Lake City Health Care System, Veterans Health Administration, Salt Lake City, UT.

ObjectivesSince 2010 the Veterans Health Administration's (VA) Genomic Medicine Service (GMS), based in Salt Lake City, has been working to create a VA-wide Telehealth Genomics program to increase Veteran access to genomic services. Participating VA facilities must complete a complex process that requires engaging several clinical and administrative departments and giving GMS providers laboratory ordering privileges and access to patient records. Experience with the first 40 adopters showed significant variation in a facility's ability to expeditiously implement this program. The goal of this study was to evaluate the implementation process and identify best practices to facilitate more efficient adoption of Telegenomics as the program expands to the 153 VA facilities and outlying clinic locations. **Methods**We ranked 40 facilities on implementation efficiency based on subjective and objective criteria, and selected three "high" and two "low" facilities for this formative evaluation study. We interviewed personnel involved in the implementation including project leaders (Telehealth Coordinators (TCs)), technical staff, chief medical officers, pathology directors, and referring providers at each facility about their implementation experiences. Several GMS staff were also interviewed. We analyzed data using deductive coding based on the Implementation Science conceptual framework, Consolidated Framework for Implementation Research (CFIR). Concepts and themes related to implementation facilitators and barriers were identified, as were recommendations to improve the process. **Results**We conducted 43 interviews. At the efficient facilities, TCs had strong project management skills and understood the sequence of steps and roles of people needed for clinic implementation. They also relied heavily on well-established relationships and good communication with the relevant departments. Also, clinicians and the laboratory director at these facilities were advocates for Telegenomics. TCs from inefficient facilities had limited prior inter-department relationships and communication skills, and/or lacked an overarching understanding of the implementation process. **Conclusions**The efficiency of implementing Telegenomics may be improved by providing TCs tools to better manage the implementation process, including guidance for the development of inter-departmental relationships and channels of communication.

2252W

Genomics and personalized medicine in primary care: a professional engagement study using a novel, theory-informed workshop approach. *B. J. Wilson[1], C. A. Catley[2], J. Little[1], S. G. Nicholls[1], J. C. Carroll[3], H. Etchegary[4], M. Taljaard[5], CIHR Emerging Team in Genomics in Screening.* 1) School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, ON, Canada; 2) Clinical Epidemiology Program, Ottawa Hospital Research Institute, Ottawa, ON, Canada; 3) Department of Family & Community Medicine, Mount Sinai Hospital, University of Toronto, ON, Canada; 4) Craig L. Dobbin Centre for Genetics, Memorial University, NL, Canada; 5) Centre for Practice Changing Research, Ottawa Hospital Research Institute, Ottawa, ON, Canada.

Background:Studies consistently suggest that primary care professionals see great potential in genomics and personalized medicine, but hold reservations about its current utility for their own practice. These observations have changed little in fifteen years; methods which go beyond surveys and common qualitative methods are required if we are to capture insights useful for designing effective primary care implementation strategies for such emerging technologies. We designed a workshop approach, adaptable for online implementation, to address this concern. Objective:To evaluate the utility of a deliberative workshop approach as a method to identify issues that primary care physicians and nurses perceive as salient to the successful adoption and implementation of genomics and personalized medicine in practice. Methods:We developed a prototype professional engagement approach informed by Kirkpatrick's educational hierarchy (relating to educational goals about genomics as a new technology) and the Theoretical Domains Framework (relating to the comprehensive behavioral aspects of using a new technology). It comprised (a) a standardized background on genomics and personalized medicine, (b) hypothetical case studies chosen to reflect the congruence between some potential uses of genomics and current primary care activities (e. g. , disease risk assessment), (c) pauses for facilitated deliberation or reflection, and (d) embedded self-completion surveys. We recruited family physicians and primary care nurses working in Ontario, Canada, to participate (in-person or online formats). We conducted descriptive analyses of the quantitative and qualitative data. Results:Twenty physicians and 44 nurses participated (34 in-person, 30 online). Baseline analyses showed no differences by professional group or workshop format in perceptions of genomics or assessments of clinical utility. Pre-post quantitative comparisons indicated shifts to more positive judgments of likely utility for personalized medicine in general, and for the systematic use of family history information (one of the case studies), but not for genomic profiling for CRC risk or type 1 diabetes risk prediction (the other case studies). Dominant themes in qualitative analyses indicated both positive and negative beliefs about the consequences of using genomics in practice, and perceived challenges with integration into practice. We noted more extensive qualitative data from online than in-person participants.

2253W

Optimizing the Design of a Population-Based Reflex Testing Program for Lynch Syndrome in Ontario: Health Care Providers' Perspectives. *Y. Bombard[1, 2], L. Rozmovits[3], A. Sorvari[2], C. Daly[2], J. C. Carroll[1,4], E. Kennedy[1,4], S. Gallinger[1,4], L. Rabeneck[5], N. N. Baxter[1,2].* 1) University of Toronto, Toronto, Ontario, Canada; 2) St Michael's Hospital, Toronto, Ontario, Canada; 3) Independent Qualitative Researcher, Toronto, Ontario, Canada; 4) Mount Sinai Hospital, Toronto, Ontario, Canada; 5) Cancer Care Ontario, Toronto, Ontario, Canada.

Background: Lynch syndrome (LS) is a relatively common genetic syndrome, which increases the risk of colorectal and endometrial cancers. Universal IHC or MSI testing (reflex testing) of colorectal tumours can identify at-risk relatives but there is variation in access and debate about providing informed consent or an opt-out. We explored health care providers' (HCPs) experiences managing LS to inform the design of Ontario's reflex testing program. **Methods:** We conducted qualitative interviews with Ontario HCPs with experience managing LS patients or an interest in colorectal cancer (CRC) screening. Participants included CRC surgeons (n=6), general surgeons (n=5), genetic counsellors (GC;n=7), medical oncologists (n=2), primary care providers (n=3) and a gastroenterologist. Interviews focused on information provision, opt-out, result notification and support for subsequent options. Participants constituted a convenience sample recruited through referrals from the research team supplemented by snowball sampling. Qualitative data were analyzed using content analysis and constant comparison techniques. **Results:** HCPs experiences and perceptions of current practice pointed to inconsistent management of suspected LS patients, variation in IHC testing practice and challenges in GC service delivery. Limited resources, active treatment and complex family history questionnaires presented barriers to accessing GC. Providers supported a reflex testing program due to the lack of coordinated care, under-ascertainment of LS patients and opportunity to standardize the increasing use of genomic tests in practice. While most supported an opt-out, two positions emerged as when to provide an opt-out. Most endorsed an opt-out after reflex testing because they felt IHC testing is akin to other pathology, which is not optional; but some preferred the opt-out before testing out of concern for patients experiencing distress, insurance discrimination or a diagnostic odyssey that may turn out to be inconclusive. **Conclusions:** Current practice supports the need for a reflex testing program, which can reduce inconsistencies in referrals and improve coordinated care for LS. Results highlight opportunities to optimize delivery of care, which include increased genetics resources and provider awareness of LS. However, how to support meaningful information provision to enable an opt-out without jeopardizing uptake of screeningand its public health benefit remains a larger policy challenge.

2254W

Cohort profile: Taiwan Biobank (TWB) for the future of next generations. *C. N. Hsiung[1,2], C. Y. Shen[1,2].* 1) Taiwan Biobank, Academia Sinica, Taipei Taiwan; 2) Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan.

To understand the relationship between genetics, environmental exposure, diet, and the etiology/progression of disease, the Taiwan Biobank is establishing a scientific infrastructure accessible to biomedical researchers. Through the recruitment and follow-up of a cohort of 200,000 individuals from the general population with no history of cancer and another of 100,000 patients with chronic diseases of public health importance from medical centers, the Taiwan Biobank aims to improve the health of future generations and facilitate genomic research in the post-genomic era in Taiwan. Currently, more than 38,000 participants from different parts of Taiwan had been recruited, and more than 700,000 of biospecimens, including blood, urine and DNA, had been collected. The structured questionnaire had been administrated to each participant to collect information regarding risk factors, dietary patterns, life style, and family history of diseases. Physical examinations, hematology, and biochemistry measurements were measured. Whole-genome genotyping information of 7,203 individuals using TWBv1. 0 chip (653,291 SNPs, specifically for the Han Chinese in Taiwan) were obtained. Whole Genome Sequencing of 1,000 individuals had been completed. By using these health-related information and the results of genome-wide studies, a preliminary prediction model to type 2 diabetes was proposed with good accuracy. These information and specimen have been released for application in the nation. The rationale for this huge and challenging effort is the development of personalized medicine, in which the progressive elucidation of risk factors and the molecular pathogenesis of disease will both improve disease prevention and facilitate therapy development at the individual level.

Benefits and Limitations of a Multidisciplinary Approach to Individualized Management of Cornelia de Lange Syndrome and Related Diagnoses. *K. January[1, 5], S. Noon[1], K. Loomes[2], A. Harrington[3], M. Deardorff[1, 6], M. Pipan[4, 6], L. Conway[5], I. Krantz[1, 6].* 1) Division of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Gastroenterology, Hepatology and Nutrition, The Children's Hospital of Philadelphia, Philadelphia, PA; 3) Division of Physical Therapy, The Children's Hospital of Philadelphia, Philadelphia, PA; 4) Division of Child Development, The Children's Hospital of Philadelphia, Philadelphia, PA; 5) Arcadia University Genetic Counseling Program, Glenside, PA; 6) The Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.

Given the clinical complexities of Cornelia de Lange Syndrome (CdLS), the Center for CdLS and Related Diagnoses at The Children's Hospital of Philadelphia (CHOP) and The Multidisciplinary Clinic for Adolescents and Adults at Greater Baltimore Medical Center (GBMC) were established to develop a comprehensive approach to clinical management and research issues relevant to CdLS. Little work has been done to evaluate the general utility of a multispecialty approach to patient care. Previous research demonstrates several advantages and disadvantages of multispecialty care. This research aims to better understand the benefits and limitations of a multidisciplinary clinic setting for individuals with CdLS and related diagnoses. Parents of children with CdLS and related diagnoses who have visited a multidisciplinary clinic (N=52) and who have not visited a multidisciplinary clinic (N=69) were surveyed to investigate their attitudes. 90. 0% of multispecialty clinic attendees indicated a preference for multidisciplinary care. However, some respondents cited a need for additional clinic services including more opportunity to meet with other specialists (N=20), such as behavioral health, and increased information about research studies (N=15). Travel distance and expenses often prevented families' multidisciplinary clinic attendance (N=41 and N=35 respectively). Despite identified limitations, these findings contribute to the evidence demonstrating the utility of a multispecialty approach to patient care. This approach ultimately has the potential to not just improve healthcare for individuals with CdLS but for those with medically complex diagnoses in general.

Integrating genomic medicine across a healthcare system. *S. L. Hill, R. Cashman, S. Chapman, L. Quayle, J. Fisher, JP. Maytum, J. Stewart.* NHS England, London, UK.

England has embarked on an ambitious programme to integrate genomic medicine across its integrated National Health Service (NHS) through the creation of a network of NHS Genomic Medicine Centres (GMCs). This programme has been elicited by the 100,000 Genomes Project – the nationwide initiative to sequence 100,000 genomes from patients & families with rare disease and cancer. NHS England committed to putting in place arrangements to enable the acquisition of samples and accompanying clinical data of sufficient quality to enable whole genome sequencing under the contractual arrangements for the Project. The GMCs work in partnership with national partners Genomics England (a company owned by the UK Department of Health, set up to deliver the 100,000 Genomes Project) and Illumina (the company Genomics England procured to deliver the sequencing and support the analysis of the resulting genome). A transparent and rigorous procurement exercise was conducted in 2014 to commission and designate the first ever Genomic Medicine Centres. This was underpinned by a common contract and service specification which sets out in detail the responsibilities and operation of all of the organisations delivering genomic services. The service specification detailed every element of the sample and data pipeline in participants with rare disease and cancer (from acquisition to validation of whole genome sequence findings to feedback to clinical teams and participants) and provides not just the contractual basis for service delivery but a baseline for measuring improvement and the quality of outcomes. The contract, service specification and networked structure for the GMCs serves as a catalyst to a broader transformation programme to introduce genomic technologies into clinical care across the NHS in England in a systematic and sustainable way for public and patient benefit, to support scientific endeavour and diagnostic delivery and industry collaborations. This approach has brought in a new era of innovation and co-operation between healthcare organisations and is already showing good results. NHS GMCs have adopted innovative patient and public co-production to design their genomics services, created genomics multi-disciplinary teams spanning a multitude of specialisms, driven creative workforce training and forward-thinking approaches to informatics.

2257W

Medical Transition Checklists for Mobile Applications. *J. A. Dixon[1], S. M. Dixon[2], J. Dehlinger[1].* 1) Department of Computer and Information Sciences, Towson University, Towson, MD; 2) Department of Pediatrics University of Maryland School of Medicine, Baltimore, MD.

Supervised medical transition, usually under the care of a genetics team, is now considered to be a best practice in the management of individuals with a chronic disease. In response, many states and organizations have created paper-based checklist guidelines to help individuals navigate this process. However, these paper-based systems are often inconsistent and incomplete. Individuals undergoing medical transition today are digital natives and would benefit from a transition process in a medium they are familiar with. As evidence of this, an online survey was posted to five online support groups for individuals with chronic conditions where participants were asked whether they would consider using a web-based application that would assist with medical transition. Nearly half of the respondents (49. 18%; n=30/61) reported that they would consider using a web-based application to help with the medical transition process.

To address this need, this work describes a fully-functional prototype mobile application that was developed to replace, and improve upon, the existing paper-based medical transition processes. The design of the application included: 1. examining existing literature to develop a comprehensive task and skills list based on medical transition guidelines; 2. analyzing six publically available, paper-based transition models to develop a common, core set of recurring themes and concepts; and, 3. verifying the tasks, concepts and categorized thematic skill sets through semi-structured interviews with three clinical geneticists for critique, completeness, organization and medical relevancy. The resulting mobile application incorporates these design considerations to provide a comprehensive list of tasks and important information to understand as well as an organized approach for how to best achieve them. Specifically, the mobile application provides dedicated functionality for documenting patient data, insurance information, healthcare team information, medical conditions information, medication/pharmacy/medical equipment information, network of support, care management, and transition assessment and completion checklists. The application is undergoing extensive usability testing with initial positive results.

This work is part of a larger effort to enable a cost effective and efficient medical transition solution that empowers individuals going through the medical transition process.

2258W

Assessing provider barriers to implementation of genetic testing for common disease risk in the GUARDD (Genetic testing to Understand and Address Renal Disease Disparities) study. *N. S. Abul-Husn[1,2], M. A. Ramos[3], R. Negron[4], M. Rodriguez[3], T. Sabin[3], R. E. Zinberg[2], K. Fei[3], D. Hauser[5,6], N. Calman[5,6], C. R. Horowitz[3], E. P. Bottinger[1].* 1) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, NY; 4) Yale Institute for Network Science, Yale University, New Haven, CT; 5) The Institute for Family Health, New York, NY; 6) Department of Family Medicine and Community Health, Icahn School of Medicine at Mount Sinai, New York, NY.

Although healthcare providers are enthusiastic about the potential for genomics to improve patient care, certain barriers may prevent them from effectively adopting genomic medicine. We intend to identify these barriers, to help address practical challenges to implementation and enhance uptake of this emerging field. The GUARDD (**G**enetic testing to **U**nderstand and **A**ddress **R**enal **D**isease **D**isparities) study, a project of the NHGRI IGNITE (**I**mplementing **G**e**N**omics **I**n prac**T**ic**E**) Network, integrates *APOL1* genotype and associated kidney disease risk into the primary care management of hypertension in African ancestry patients. A survey was developed incorporating established constructs of effective implementation from the Consolidated Framework for Implementation Research, including knowledge and beliefs, self-efficacy, access to information, and perceived advantage of implementation. This was distributed to primary care providers practicing in three federally qualified community health centers and two academic primary care facilities in New York City immediately prior to the study onset. Data from the first 253 providers (63% residents, 31% attendings or fellows, 6% physician's assistants or nurse practitioners) revealed that the majority of providers (68%) agreed that genetic testing for common diseases was clinically useful. Over a third (38%) felt that their training had prepared them to work with patients at high risk for genetic conditions. A quarter (27%) believed that *APOL1* genetic testing would be important for patient care, but only 7% were confident in their ability to use *APOL1* genetic test results. Few providers (22%) felt that they could find reliable information to communicate *APOL1* genetic risk while caring for patients. The majority thought it would be helpful to have patient handouts (75%) and information about managing high-risk patients (77%) available through the electronic health record. These findings suggest that, despite being optimistic about genetic testing for common disease risk, providers have a deficit in their familiarity and confidence with utilizing genetic risk information in the primary care setting. This indicates that continuing genomic education, readily accessible tools to help communicate genetic risk at the point of care, and specific guidelines for the management of high-risk patients are needed. These data highlight some of the barriers hindering genomic medicine uptake and will inform approaches for improved implementation.

2259W

Next-generation sequencing identifies miRNAs in peripheral blood of African Americans related to metabolic syndrome and abdominal obesity. *S. Y. Gebreab, G. Amadou, P. Riestra, R. J. Khan, S. K. Sen, A. R. Davis, S. K. Davis, G. H. Gibbons.* Metabolic, Cardiovascular and Inflammatory Disease, National Human Genome Research Institute (NHGRI), NIH, Bethesda, MD.

Metabolic syndrome (MetS) is a major public health concern in the African American population due to high prevalence of abdominal obesity, hypertension, diabetes mellitus, and hyperglycemia in this population. Furthermore, MetS is attributed to increased risk of cardiovascular disease, including coronary heart disease and stroke in African Americans. Although MetS is strongly influenced by lifestyle and genetic factors, little is known about the molecular underpinnings of MetS in African Americans. MicroRNAs (miRNAs) mediate posttranscriptional gene expression and play an important role in maintaining metabolic homeostasis; hence, it is possible that they contribute to MetS physiopathology and its components. In the present study, we identify differentially expressed miRNAs in peripheral blood from African Americans with MetS and abdominal obesity using massively parallel sequencing of miRNA (miRNA-Seq). We analyzed miRNAs from 110 African Americans (15 with MetS vs. 95 without MetS subjects, and 57 with obese vs. 53 normal subjects) obtained from the Minority Health Genomics and Translational Research Bio-Repository Database (MH-GRID) study. After adjusting for age, sex, smoking, socioeconomic status and alcohol consumption, we identified a total of seven miRNAs: hsa-miR-378i, hsa-miR-483, hsa-miR-193b, hsa-mir-215, let-7b, hsa-mir-874, and hsa-mir-22 that were significantly up-or down-regulated in MetS and abdominal obesity. These miRNAs were previously identified in animal and human studies linked to human adipogenses and MetS. Although our study is preliminary, our results demonstrate that miRNA-Seq has the potential to help elucidate the underlying molecular mechanisms of MetS and abdominal obesity and to identify novel biomarkers for therapeutic targets of Mets and obesity related diseases in the African American population. Future research is warranted to elucidate the functional consequences of these miRNAs in relation to MetS and abdominal obesity.

2260W

Family history taking in pediatrics: it's much more than just a checklist. *L. Tessier[1], J. C. Brehaut[2], B. K. Potter[3], P. Chakraborty[1,4], J. C. Carroll[5], B. Wilson[3] on behalf of the CIHR Emerging Team in Genomics in Screening.* 1) Newborn Screening Ontario, Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 2) Clinical Epidemiology Program, Ottawa Hospital Research Institute, ON, Canada; 3) School of Epidemiology, Public Health and Preventive Medicine, University of Ottawa, ON, Canada; 4) Department of Pediatrics, University of Ottawa, ON, Canada; 5) Family Medicine, Mount Sinai Hospital, University of Toronto, ON, Canada.

Background: Family history (FH) is a risk factor for many conditions in pediatric practice; interest has increased in supporting systematic FH taking in this area by identifying core conditions for enquiry and developing point of care tools. There is little published about current practice to inform implementing such changes. Objectives: To inform future FH taking interventions by identifying pediatricians' perceptions, attitudes, beliefs, and current practices. Methods: The Theoretical Domains Framework (TDF) was used to develop a comprehensive interview scheme. Semi-structured interviews were conducted with pediatricians practising in the Ottawa, Canada region. Analysis was by the constant comparison method, using a thematic approach. Results: The data revealed FH taking to be a firmly embedded, but surprisingly complex, aspect of pediatric practice. Participants described FH as part of regular, holistic care, extending to social and interpersonal, as well as clinical purposes; in addition to disease risk assessment, FH information helped clarify diagnosis, and select medication; tailor the overall patient management based on family circumstances; and provide psychosocial support for parents. It was also used as a method to build a relationship with parents/carers. FH and social history information were inextricably linked and often appeared to be the same concept in participants' minds. Participating pediatricians generally expressed confidence in their FH skills and reported tailoring their approach according to experience, after initial training early in their career. While acknowledging some challenges in ensuring accuracy, they were attuned to nuances in their interactions with parents and children which would affect whether, and what, they were told about illness in the family. Most were not concerned about formal evidence, and would not change their practice except for "good reason". Conclusion: The use of the TDF helped ensure a comprehensive approach to FH taking in pediatric practice. The findings suggest that FH taking in this setting is a complex activity, embedded in routine care. Recommendations for systematic enquiry about specific conditions cannot be seen as a simple additional activity to current practice. Efforts to make FH taking more systematic may founder if they fail to take into account pediatricians' attitudes, perspectives, and practices. Further studies should explore and seek to confirm and expand our observations.

Mitochondrial Disease Patients' Motivations and Barriers to Participate in Clinical Trial. *Z. Zolkipli Cunningham[1], A. Stoddart[2,3], E. McCormick[2], R. Xiao[4], M. Falk[2,5].* 1) Division of Neurology, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA 19104; 3) Arcadia University, Glenside, PA 19038; 4) Department of Biostatistics and Epidemiology, University of Pennsylvania, PA 19104; 5) University of Pennsylvania Perelman School of Medicine, Philadelphia, PA 19014.

Background We investigated the motivations and barriers for clinical trials participation in mitochondrial disease patients. **Methods** An initial survey was performed on pediatric and adult patients with definite or possible/probable mitochondrial disease from the Children's Hospital of Philadelphia (n=30/67 respondents). Validation was performed in a larger cohort of U. S. patients self-identified as having mitochondrial disease through the Rare Disease Clinical Research Network (RDCRN) contact registry (n=290/1119 respondents). **Results** In the survey of CHOP-enrolled subjects, the response rate was 45%, with completed surveys returned for 15 children and 15 adults. The top 3 symptoms for clinical trial participation were developmental delay, muscle weakness, and seizures for affected children, whereas adults prioritized muscle weakness, exercise intolerance, and chronic fatigue. In the RDCRN validation survey, the response rate was 26%, with completed surveys returned for 121 children and 169 adults. Chronic fatigue, muscle weakness and exercise intolerance were the top 3 motivating symptoms for clinical trial participation. Motivating factors in both surveys related to treatment characteristics included if the study drug was a vitamin, antioxidant, natural or plant-derivative; a pill; self-administered; administered once daily; received by all participants; and guaranteed provision to patients at the end of the study. Relative barriers to study participation included a trial of a new drug, requirement to discontinue current medications, and symptomatic progression. Indeed, trial drop-out upon disease progression was predicted by 40-47% of adults and 54-67% of children. Regarding study design, daily or weekly blood draws and a requirement to pay to participate were relative barriers. Not having to travel or only traveling within the same city, financial reimbursements, and participating in later-stage (phase 3) studies were motivating factors. Pediatric and adult populations did not differ in the relative influence of treatment type or trial design. Study limitations include self-reporting of disease status in the RDCRN cohort and potential completion bias. **Conclusions** As the mitochondrial disease patient community sits on the eve of having the opportunity to participate in a burgeoning array of clinical intervention trials, patient motivations and deterrents should be seriously considered to tailor trial design for this complex disease population.

Geriatrics disease-burden from genetics point of view. *B. Ganguly[1], K. Sen[2], N Kadam[2]*. 1) MGM Center for Genetic & Diagnosis, MGM New Bombay Hospital, New Mumbai, Maharashtra, India; 2) MGM New Bombay Hospital, New Mumbai, Maharashtra, India.

Stem cells are immortal, ever young and unspecified with high self-replication process. Hence stem cells are being increasingly considered in cell-based therapy in regenerative medicine. Despite having such stem cells in the body, every organism ages with bundles of ailments. In human, aging is directly proportional to increase in health problems involving almost all organs. Among all systems, the circulatory machinery stands first in all ages over 60 years. In India, 60 years is considered as the onset of aging while people retire from work. A survey on five-year hospital record on 46000 cases aged over 60 years revealed 25% affected with cardiovascular system followed by 20% with general complication of cold/cough/fever and GI disorientation. An equal damage was observed in nephrological and orthopedic systems, which measures ~9%; however, a difference of double was evidenced in males and females for the former and later systems respectively. Human aging is not merely a consequence of wear and tear, but rather it is the inefficient or lack of replacement of these spare parts that leads to aging. Externally, dictation of aging starts from changes in hair and skin, which are otherwise self-generating from the committed stem cells, and thus, this phenomenon declares death of stem cells. Similar incidences are noticed in wearing out of human teeth, and also remarkable reproductive senescence in females. The unsolved puzzle of aging and genetic programming is under extensive investigation including GWAS (Eg. Werner syndrome), GxE epigenetic impact (e. g. identical twins), copy number variation in the whole genome, etc. In Indian scenario, predominant susceptibility to cardiovascular disorder after 60 years is related to stress for transition from ‘income-to-noincome’ state (retirement from work). Significant osteoarthritis problem in females is undoubtedly associated with ageing of ovaries and its genetic program; however, nutritional status of Indian women aged over 60 years is expected to have epigenetic control over expression of genes responsible for releasing necessary hormones. In quest of death of stem cells in different organs, it has been reported that loss of miRNAs and disruption of BIM protein disarray the survival and death of stem cells. Investigation on death-resistance of cancer cells i. e. mutated stem cells, and understanding gene expression in elderly over 60 years would establish avenues for curbing age-related diseases and early aging.

Plasma Amino Acid and Urine Organic Acid Profiles of Filipino Patients with Maple Syrup Urine Disease (MSUD) and Correlation with their Neurologic Features. *M. D. Chiong[1], M. A. Tan[2], C. P. Cordero[3], E. D. Fodra[4], J. S. Manliguis[4], C. P. Lopez[4], L. M. Dalmacio[5].* 1) Clinical and Metabolic Genetics, Institute of Human Genetics, National Institutes of Health, Manila, Manila, Philippines; 2) Department of Pediatrics, Section of Pediatric Neurology, Philippine General Hospital; 3) Department of Clinical Epidemiology, University of the Philippines Manila, Philippines; 4) Biochemical Genetics Laboratory, Institute of Human Genetics, National Institutes of Health; 5) Department of Biochemistry, College of Medicine University of the Philippines Manila, Philippines.

Background: Maple syrup urine disease (MSUD) is the most common inborn error of metabolism in the country. The main cause of the neuropathology is not well established although the accumulation of branched chain amino acids (BCAA) and alteration in large neutral amino acids (LNAA) as well as energy deprivation have been suggested. **Objectives:** It is the aim of the study to determine the plasma amino acid and urine organic acid profiles of Filipino patients with MSUD and correlate the findings with their neurologic features. **Methodology:** Twenty six Filipino patients confirmed to have MSUD were studied and their results were compared with 26 age and sex matched controls. Their neurologic features were reviewed and correlated with the results of their plasma amino acid and urine organic acid profiles. **Results:** Majority of the patients with MSUD had developmental delay/intellectual disability (88%), speech delay (69%) and seizures (65%). The amino acid profile of MSUD patients revealed low glutamine and alanine with high levels of leucine, isoleucine, phenylalanine, threonine and alloisoleucine compared to controls ($p<0.05$). The urine organic acids showed significantly elevated excretion of the branched chain ketoacids and succinate ($p<0.05$), however other Krebs cycle metabolites were not found in significant amounts. There were no metabolite markers in the amino acids or organic acids that correlated significantly with the neurologic features. The most remarkable finding was the discriminant analysis done on 7 clinically and statistically significant important amino acids in the plasma wherein elevations in leucine, isoleucine, alloisoleucine, phenylalanine and threonine, and decreased levels of glutamine and alanine clearly defined the boundary between an MSUD case and control. **Conclusion:** The findings suggest that there could be altered LNAA metabolism among patients with MSUD when the BCAAs are elevated. A set of plasma amino profile comprising of 7 amino acids may be suggestive of MSUD if altogether present. The urine organic acid analysis showed elevated excretions of the branched chain ketoacids and succinate. However, the biochemical findings were not significantly correlated with the neurologic features of patients with MSUD thus, there could be other unknown factors that cause the neurologic impairments in MSUD other than the elevated BCAAs and corresponding ketoacids or elevated LNAAs. .

2264F

Whole exome sequencing identifies a novel frameshift variant causing familial hypomagnesemia with secondary hypocalcemia: a case report. *M. K. Azim[1], A. Mehnaz[2], J. Zahid Ahmed[2], G. Mujtaba[1].* 1) Jamil-ur-Rehman Center for Genome Research, International Center for Chemical and Biological Sciences, University of Karachi, Karachi, Pakistan; 2) Department of Pediatrics, Dow Medical College, Dow University of Health Sciences, Karachi, Pakistan.

Hypomagnesemia with secondary hypocalcemia is a rare autosomal-recessive disorder characterized by intense hypomagnesemia associated with hypocalcemia. Mutations in the *TRPM6* gene, encoding the epithelial Mg2+ channel TRPM6 have been proven to be the molecular cause of this disease. The purpose of this study was to search for causal mutations in a 2 months old male patient of hypomagnesemia from a consanguineous marriage. Biochemical analyses confirmed the diagnosis of HSH due to primary gastrointestinal loss of magnesium. Whole exome sequencing of the trio (i. e. proband and both parents) was carried out using Complete Genomics sequencing followed by standard bioinformatics analysis. Exome sequence coverage, number of variants, percentage of known variants and the Ti/Tv ratio were calculated. Mean coverage of the target regions ranged between 40-50X. ANNOVAR was used to annotate functional consequences of genetic variation from exome sequencing data. After variant filtering, 12 candidate variants were identified. Analysis of these variants showed several missense mutations and deletion of two base pairs (at 9:77377267) in exonic region of *TRPM6* which resulted in a novel frameshift mutation. These mutations in *TRPM6* were confirmed by Sanger sequencing. With these investigations in hand, the patient was managed with calcium gluconate and magnesium sulphate. The patient remained asymptomatic and was developmentally and neurologically normal till his last follow up.

the natural history protocol on congenital disorders of glycosylation. *L. Wolfe[1], C. Lam[1], C. F[1], w. G[1], D. Krasnewich[2].* 1) Office of the Clinical Director, NIH/NHGRI, Bethesda; 2) 2National Institute of General Medical Sciences, National Institutes of Health, Bethesda, MD, USA.

Background: Congenital disorders of glycosylation (CDGs) are a group of more than 100 inborn errors in the glycan modification of proteins, lipids, or other biomolecules. Due to the rarity of these disorders, their protean clinical manifestations, and absence of clinical protocols dedicated to their study, their natural histories remain largely unknown. The goal of our new protocol is to systematically characterize the different types of CDGs. Here we report the cohort of individuals who have been evaluated under our protocol thus far and discuss interesting findings in these cases. *Methods*: NHGRI study 14-HG-0071 “Clinical and Basic Investigations into Known and Suspected Congenital Disorders of Glycosylation” (identifier: NCT02089789) was approved in March, 2014 and enrolled its first subject in May, 2014. Under this protocol, subjects are admitted into the National Institutes of Health Clinical Center and undergo blood and urine collection, skin biopsy, clinical photography, radiographic evaluations, and clinical examinations. *Results*: Since the protocol’s approval, we have evaluated 28 individuals and have over 25 additional individuals awaiting admission. The specific subtypes we have seen include subjects with NGLY1-CDG, SDR5A3-CDG, ALG8-CDG, ALG12-CDG, ALG13-CDG, PMM2-CDG, PGM1-CDG, ALG1-CDG, ALG2-CDG, MOGS-CDG and GMPPB-CDG. Subjects pending evaluations include patients with NGLY1-CDG, PMM2-CDG, MOGS-CDG, ALG13-CDG, COG5-CDG and several individuals with single mutations in multiple CDG genes and phenotypes consistent with a CDG. Novel findings include: 1) increased antibody titers to rubella and rubeola vaccines in patients with SDR5A3-CDG, NGLY1-CDG, and ALG1-CDG; 2) low CSF protein, albumin, IgG and neurotransmitter concentrations in patients with NGLY1-CDG; 3) hypohidrosis in individuals with NGLY1-CDG; 4) normal peripheral hearing with consistently dysynchronous and delayed transmission through the brainstem on ABR exams in patients with NGLY1-CDG; 5) elevated urine glycosaminoglycans in individuals with NGLY1-CDG, and 6) low tear production in patients with NGLY1-CDG, ALG1-CDG, and GMPPB-CDG. *Conclusions*: We are actively recruiting patients from families willing to participate in our ongoing natural history protocol on CDGs. Our efforts to robustly characterize this group of disorders will enhance our understanding of the expected course in different subtypes of CDGs, and pave the way for future therapeutic trials.

Toward identification of the pathogenic cell type driving calcification in pseudoxanthoma elasticum. *S. G. Ziegler[1,2], C. R. Ferreira[3], T. J. Creamer[1], D. S. Warren[1], L. Goff[1], A. B. Pinkerton[4], J. L. Millan[4], W. A. Gahl[3], H. C. Dietz[1,2].* 1) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) HHMI, Chevy Chase, MD; 3) Medical Genetics Branch, NHGRI, NIH, Bethesda, MD; 4) Sanford-Burnham Medical Research Institute, La Jolla, CA.

Biallelic mutations in *ABCC6*, an ATP-dependent transporter whose ligand remains unknown, cause pseudoxanthoma elasticum (PXE) characterized by adult-onset elastic fiber calcification in the eyes, skin, and vessels. Strong expression of ABCC6 in the liver supported the prevailing view that peripheral tissue calcification in PXE reflects failed liver secretion of an endocrine inhibitor of calcification. Contrary to this view, we found that fibroblasts cultured from patients with biallelic mutations in *ABCC6* had increased levels of tissue non-specific alkaline phosphatase (TNAP) and showed a strong tendency for induced calcification that can be prevented by a TNAP inhibitor. Breakdown products of ATP regulate TNAP activity, suggesting that PXE is caused by local defects in extracellular ATP metabolism. To determine the biologically relevant cell type driving PXE pathogenesis, we generated a conditional *Abcc6* mouse model. The initial site of calcification in PXE mice is the fibrous capsule surrounding the muzzle vibrissae and appears at 20 weeks of age when *Abcc6* is constitutively deleted using CMV-Cre or in a complete *Abcc6* knockout. However, robust liver-specific deletion of *Abcc6* using albumin-Cre failed to induce calcification at 20 weeks; the same was true for Cre drivers specific for vascular smooth muscle, vascular endothelium, bone marrow, renal tubular cells, pericytes, fibroblasts, adipocytes, and the craniofacial mesenchyme. Curiously, albumin-Cre mediated deletion of *Abcc6* associated with poorly penetrant and mild vibrissae calcification at 1 year of age. We speculated that delayed albumin-Cre induced calcification manifests local (as opposed to hepatic) allele recombination in peripheral calcification-prone tissues. Consistent with this hypothesis, a cross between mTmG reporter and albumin-Cre mice revealed postnatal (adult) local transition of a discrete cell population in the muzzle fibrous capsule to a GFP-positive state (indicating recombination). FACS and RNASeq analysis of GFP+ cells suggest that they represent a specialized multipotent progenitor lineage. These data suggest particular relevance and vulnerability of cells recruited to sites requiring chronic tissue maintenance or repair in the predisposition to calcification imposed by ABCC6 deficiency; this model reconciles multiple phenotypic aspects of PXE-associated calcification including age-dependence and spatial focality, and has the potential to inform novel therapeutic strategies.

Congenital Protein Losing Enteropathy: An inborn error of lipid metabolism due to *DGAT1* mutations. *H. Pri Chen[1,2,3], J. Stephen[1], T. Vilboux[1,4], Y. Haberman[5,6], B. Pode-Shakked[3,7,8], O. Barel[9], A. Di Segni[9], E. Eyal[9], G. Hout-Siloni[9], A. Lahad[5], T. Shalem[5], G. Rechavi[3,9], B. Weiss[3,5], Y. Anikster[3,7], W. A. Gahl[1,2,10], M. C. Malicdan[1,2,10].* 1) Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland, USA; 2) NIH Undiagnosed Diseases Program, Common Fund, Office of the Director, National Institutes of Health, Bethesda, Maryland, USA; 3) Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 4) Inova Translational Medical Institute, Fairfax, Virginia, USA; 5) Division of Pediatric Gastroenterology, Hepatology and Nutrition, Edmond and Lily Safra Children's Hospital; 6) Cincinnati Children's Hospital Medical Center, OH, USA; 7) Metabolic Disease Unit, Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Tel-Hashomer, Israel; 8) The Dr Pinchas Borenstein Talpiot Medical Leadership Program, Sheba Medical Center, Tel-Hashomer, Israel; 9) Sheba Cancer Research Center, Sheba Medical Center, Tel-Hashomer, Israel; 10) Office of the Clinical Director, NHGRI, National Institutes of Health, Bethesda, Maryland, USA.

Statement of Purpose: Protein Losing Enteropathy (PLE) is a clinical disorder of protein loss from the gastrointestinal system that results in hypoproteinemia and malnutrition. PLE is associated with a wide range of gastrointestinal disorders, including a unique syndrome associated with biallelic mutations in the *DGAT1* gene. Although previously identified in a single family, *DGAT1* mutations could be responsible for many undiagnosed cases of PLE in infancy. **Methods:** We investigated three children in two families presenting with severe diarrhea, hypoalbuminemia and PLE, using clinical studies, homozygosity mapping, exome sequencing, and expression studies at the transcript and protein levels. **Results:** In one family, homozygosity mapping using SNP arrays marked the *DGAT1* gene as the best candidate gene for causing PLE in the proband. Sequencing of the *DGAT1* coding region, including exon-intron boundaries and the promoter, identified a novel homozygous missense mutation, NM_012079. 5: c. 884T>C, Leu295Pro in the highly conserved Membrane Bound O-acyl Transferase (MBOAT) domain. In the second family, exome sequencing identified a previously reported splice site mutation in intron 8. Expression studies and western blotting verified reduced amounts of DGAT1. **Conclusions:** These cases of DGAT1 deficiency extend the molecular and phenotypic spectrum of this rare condition, which may be a more common cause of PLE than previously recognized.

Progression of behavioral and CNS deficits in a murine model of chronic neuronopathic Gaucher Disease. *Y. Sun[1,3], M. Dai[2], B. Liou[1], X. Wang[2], B. Swope[2,3], V. Inskeep[1], W. Zhang[4], G. A. Grabowski[5], D. Pan[2,3].* 1) Division of Human Genetics, Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) Experimental Hematology and Cancer Biology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 3) Department of Pediatrics, University of Cincinnati School of Medicine, Cincinnati, OH; 4) Division of Pathology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 5) Synageva BioPharma Corp, Lexington, MA.

The neuronopathic Gaucher Disease (nGD, Types 2 and 3) is the most frequent variant of Gaucher disease world-wide and has no effective specific treatment. Mutations of *GBA1* lead to defective acid β-glucosidase function and resultant accumulation of its substrates, glucosylceramide (GC) and glucosylsphingosine (GS). The CNS deficits in nGD were characterized by chronological behavioral profiles and the age of onset in a chronic nGD mouse model (9V/null). Abnormal weight gain emerged in 9V/null mice at 9- and 12-months for female and male mice, respectively. Compared to WT mice, significantly increased ratios of tissue to body weight were present for livers starting at 9-months and for spleen at 24-month, indicating the ages of onset for hepato- and spleno-megaly in 9V/null. Progressive brain accumulations of substrates were found in 9V/null mice as early as 6-months for GC and 3-months for GS. α-Synuclein, which is central to pathology in Parkinson's diseases, was progressively increased in 9V/null cortex from 6 to 12 month by immunoblotting analysis. α-Synuclein aggregates were distributed in neurons and astrocytes in hippocampus and cerebral cortex and P-Tau signals, a marker for neurodegeneration, were strong in cerebral cortex, hippocampus and cerebellum in 12-month 9V/null mice. Repeated open-field tests of the 9V/null mice compared to WT mice showed less habituation to the environment by spending less time grooming and more time exploring the open field by 9-months and older, indicating the onset of short-term memory deficits. In marble burying test, the 9V/null mice had a shorter latency to initiate burying activity at 6-months, but the latency increased significantly starting at 12-months and buried significantly more marbles to completion than the WT group, suggesting an abnormal response to the instinctive behavior and an abnormal activity in non-associative anxiety-like behavior. The conditional fear tests revealed that the 9V/null mice froze less than age- and gender-matched WT by12-months, indicating hippocampus-related memory defects. 9V/null mice showed abnormal gait that reached significance after 9-months. Unlike several acute nGD mouse models with death in 14-45 days, the chronic nature of the 9V/null neurobehavioral dysfunction, biochemical, and histopathological abnormalities provide a novel foundation for experimental designs to gain understanding of the progressive pathogenesis and evaluation of potential CNS therapies for nGD.

2269T

Behavioral and cholinergic pathway abnormalities in male MPS IIIB mice. *S. Le[1], S. Kan[1], B. Benedict[1], Q. Bui[1], J. Cushman[2], M. Sands[3], P. Dickson[1].* 1) Department of Pediatrics, LA Biomed at Harbor-UCLA, Torrance, CA; 2) Behavioral Testing Core, UCLA, Los Angeles, CA; 3) Department of Medicine, Washington University in Saint Louis School of Medicine, St. Louis, MO.

Mucopolysaccharidosis type IIIB (MPS IIIB or Sanfilippo B) causes progressive neurological deterioration. Patients with MPS IIIB have reduced fear associated with volume loss in the amygdala. In this study, we used 12 MPS IIIB and 12 littermate controls male mice age 16-20 weeks to determine whether this model would be similarly affected as human patients. Affected mice showed reduced anxiety, with a decrease in the number of stretch-attend postures during the elevated plus maze (p=0. 01, F=13. 7), an increased tendency to approach a novel mouse (p=0. 067, F=3. 66), and an increased tendency to linger in the center of an open field (p=0. 032, F=5. 28). Radial arm maze testing showed a longer latency to find reward during training (p=0. 025, F=5. 96). Acetylcholinesterase (AChE) activity staining and stereology volume measurement of amygdale were performed on MPS IIIB mice aged 41-42 weeks. Upon staining, we noticed an overall reduction in AChE activity staining in affected animals. To verify our observation, we measured AChE and choline acetyltransferase (ChAT) activity in whole brain homogenates of the mice that were used in the behavioral experiment. We found a 12. 4% reduction in mean AChE activity (p<0. 001) and no difference in ChAT activity in affected animals. However, as the amygdala may be specifically affected in MPS IIIB, we further evaluated AChE and ChAT in MPS IIIB affected mice and carrier controls using a hemicoronal section (thickness 2 mm) that contained amygdala. AChE activity was 25% lower (p=0. 006) and ChAT activity 14% lower (p=0. 002) in affected animals in that section of the brain. Cholinergic pathways are affected in adult-onset dementias, including Alzheimer disease. Our results suggest that male MPS IIIB mice display neurobehavioral deficits at a relatively early age, and that as in adult dementias, they may display deficits in cholinergic pathways.

2270F

Rare non-synonymous variations in the human ferroportin iron transporter gene (haemochromatosis type 4): the quest for causal mutations. *G. Le Gac[1,3], I. Callebaut[2], S. Pissard[4], C. Kannengiesser[5], V. Gérolami[6], C. Ged[7], F. Cartault[9], J. Rochette[8], C. Ka[3], C. Férec[3].* 1) Human Molecular Genetics , Inserm U1078, BREST, France; 2) IMPMC, Sorbonne Universités - UMR CNRS 7590, UPMC Univ Paris 06, Muséum d'Histoire Naturelle, IRD UMR 206, Paris, France; 3) Inserm U1078, Université de Brest, SFR SnInBioS, CHRU de Brest, Laboratoire de Génétique Moléculaire et d'Histocompatibilité, Etablissement Français du Sang - Bretagne, Brest, France; 4) UPEC (Université Paris Est Creteil), GHU Henri Mondor, Laboratoire de Génétique, Créteil, France; 5) Inserm U1149 - Center for Research on Inflammation, Université Paris Diderot, AP-HP, Hôpital Bichat, Département de Génétique, Paris, France; 6) CHU de Marseille, Hôpital Conception, Biologie Moléculaire; 7) Inserm U1035, Biothérapies des Maladies Génétiques et Cancers, Université de Bordeaux, CHU de Bordeaux, Pôle de Biologie et Pathologie, Bordeaux, France; 8) UPJV EA4666, CHU d'Amiens, Laboratoire de Génétique Moléculaire, Amiens, France; 9) CHU de la Réunion, Service de Génétique, Saint-Denis, France;9Inserm CIC0502, CHRU de Brest, Brest, France.

Haemochromatosis type 4 is a rare form of primary iron overload transmitted as an autosomal dominant trait caused by mutations in the gene encoding the iron transport protein ferroportin 1 (*SLC40A1*). *SLC40A1* mutations fall into two functional categories (loss- versus gain-of-function) underlying two distinct clinical entities (haemochromatosis type 4A-B). However, the vast majority of *SLC40A1* mutations are rare missense variations, with only a few showing strong evidence of causality. The present study reports the results of an integrated approach collecting genetic and phenotypic data from 44 suspected haemochromatosis type 4 patients, with comprehensive structural (3D model) and functional annotations. 1,2 Causality was demonstrated for 10 missense variants, showing a clear dichotomy between the two haemochromatosis type 4 subtypes. Two subgroups of loss-of-function mutations were distinguished: one impairing cell surface expression and one altering only iron egress. A new gain-of-function mutation was identified, and the degradation of ferroportin on hepcidin binding was shown to probably depend on the integrity of a large extracellular loop outside of the hepcidin-binding domain. Eight further missense variations, on the other hand, were shown to have no discernible effects at either protein or RNA level; these were found in apparently isolated patients and were associated with a less severe phenotype. The present findings illustrate the importance of combining in-silico and biochemical approaches to fully distinguish pathogenic *SLC40A1* mutations from benign variants. This has profound implications for patient management. 1 Le Gac G *et al.* Hum Mut. 2013;34:1371-802 Callebaut I *et al.* Hum Mol Genet. 2014;23:4479-90.

A Zebrafish Knockout of Argininosuccinate Lyase Separates Ureagenic and Biosynthetic Functions. *O. A. Shchelochkov[1], R. Bowman[1], L. Teesch[2], L. Yu[3], C. M. Brenner[4], R. A. Cornell[5].* 1) Stead Department of Pediatrics, University of Iowa Hospitals & Clinics, Iowa City, IA; 2) Mass Spectrometry Facility, University of Iowa, Iowa City, IA; 3) NMR Core Facility, University of Iowa, Iowa City, IA; 4) Carver College of Medicine, Iowa City, IA; 5) Anatomy & Cell Biology, University of Iowa, Iowa City, IA.

Argininosuccinate lyase (ASL) deficiency is a urea cycle disorder characterized by hyperammonemia and complications unrelated to hyperammonemic injury. Notably, liver dysfunction, hypertension and intellectual disability can occur in the absence of discernable hyperammonemia. In addition, urea cycle enzymes are expressed in a variety of cells that do not produce urea. We hypothesize that impaired metabolism of arginine and its downstream metabolites is responsible for non-hyperammonemic complications. However, a barrier towards characterizing the role of ASL in non-hyperammonemic complications is the difficulty in separating the ureagenic and biosynthetic functions of this enzyme. Though zebrafish excrete ammonia through their gills, the zebrafish genome encodes orthologues of all genes that would be termed urea cycle components. We therefore chose the zebrafish as a model to determine the non-ureagenic functions of ASL. Using TALEN technology, we generated a homozygous ASL knockout. Tissue amino acid analysis of ASL knockout larva showed the presence of argininosuccinic acid, a specific biochemical marker of ASL deficiency. Development was normal and the fish were viable and fertile for the first 4 months of life. However, ASL knockouts exhibited reduced reproduction after 4 months and failure to thrive by age 8. 5 months at which time mutants averaged less than 60% of the body weight and less than 90% of the length of wild-types (WT), $p < 0.01$ for each growth deficit. To further characterize ASL function in zebrafish, we monitored urea synthesis in the first 2 days post fertilization. This analysis indicates a functional urea cycle at this time point as WT embryos produced 361 mM urea. However, exposure of WT embryos to [15]NH4Cl led to incorporation into glutamine and citrulline but not into urea. Moreover, survival of embryos exposed to 5 mM ammonia chloride was equivalent in WT and ASL-deficient embryos. To test the hypothesis that ASL is essential for arginine synthesis, we soaked WT and ASL-deficient embryos in 4-amino-5-methylamino-2',7'-difluorofluorescein diacetate, a fluorescent nitric oxide (NO) probe. Mutants showed ~30% decreased fluorescence in comparison to WT ($p < 0.05$) supporting the notion that ASL is necessary in production of NO derived from arginine. These findings suggest that despite a functional urea cycle in embryos, ASL is not required for resistance to ammonia toxicity but is involved in synthesis of endogenous arginine and NO.

2272F

Insights into the pathophysiology of propionic acidemia provided by metabolomic analysis. *M. J. Miller[1], A. D. Kennedy[2], T. R. Donti[1], P. S. Atwal[1], L. A. Miller[2], M. V. Milburn[2], J. A. Ryals[2], Q. Sun[1], V. R. Sutton[1], S. H. Elsea[1].* 1) Dept. of Molecular and Human Genetics, Medical Genetics Laboratory, Baylor College of Medicine, Houston, TX; 2) Metabolon Inc. , Durham, NC.

Propionic acidemia is an autosomal recessive multisystem disorder that often presents in the neonatal period with acidosis, vomiting, and lethargy. More variable features include hyperammonemia as well as cardiovascular, central nervous system, gastrointestinal, immune, and renal symptoms. Underlying these phenotypic outcomes are myriad primary and secondary metabolic pathway perturbations which are not completely understood. To further explore the complex biochemical basis of this disease, we used a state-of-the-art metabolomic platform to analyze 9 plasma specimens collected from 8 different patients with propionic acidemia, one of whom had received a liver transplant. Of the approximately 900 small molecule analytes detected by this analysis, ~200 showed a significant perturbation (false discovery rate <0. 05) in patients with propionic acidemia when compared to a cohort of 70 individuals without this disease. The list of significantly perturbed analytes includes multiple biomarkers within the branch chain amino acid (BCAA) metabolic pathway, diet/treatment related compounds, and spectrally unique but, as of yet, unknown biochemicals. Numerous significant analyte perturbations were also detected in metabolic pathways interconnected with the BCAA pathway including previously reported dysregulation of the TCA and urea cycles. Building on these earlier findings we identified a significant reduction of the plasma levels of the urea cycle compound N-acetylglutamate and significant perturbations of the TCA cycle intermediates fumarate and malate (accumulation) as well as succinylcarnitine, cis-aconitate, and citrate (reduction). While marked elevations of many classic propionic acidemia biomarkers persisted in the patient with a donor liver, N-acetylglutamate as well as succinylcarnitine, cis-aconitate, and citrate appeared to normalize thus providing insights into the metabolic changes that occur after transplant. Taken together, these data lend additional support to a growing body of evidence advocating for the expanded use of the N-acetylglutamate analog, carglumic acid, as well as citrate in the critical care of patients with propionic acidemia. More generally, our results shed light on the pathophysiology of propionic acidemia and highlight the potential of metabolomic analyses to improve surveillance and treatment of patients with inborn errors of metabolism.

Musculardystrophy and Mitochondrial ca^{+2} up take disorder. *W. M. EYAID[1], W. shehhi[1], K. Dress[1], M. Balwi[3], w. Twaijri[1], A. Alassiri[4], V. K. Mootha[2].* 1) PEDIATRICS, KING ABDULAZIZ MEDICAL CITY, RIYADH, CENTRAL, Saudi Arabia; 2) Center for Human Genetic Research, Massachusetts General Hospital, Boston, Massachusetts 02114, USA; 3) Dep. of pathology-molecular lab. KING ABDULAZIZ MEDICAL CITY, RIYADH, CENTRAL, Saudi Arabia; 4) Dep. of pathology-anatomical pathology,KING ABDULAZIZ MEDICAL CITY, RIYADH, CENTRAL, Saudi Arabia.

Mitochondrial calcium uptake has a central role in cell physiology by stimulating ATP production, shaping cytosolic calcium transients and regulating cell death. Mitochondrial Ca+2 uptake is mediated by the Ca+2 uniporter complex in the inner mitochondrial membrane, MCU. The MICU1 is a subunit of the MCU. It regulates channel opening in response to intracellular calcium content and calcium transients. Here we report a mutation in the MICU1 gene in two brothers who presented with incidental finding of elevated creatinine kinase, CK level. Both of them are having mild proximal weakness, and have no abnormal movement or learning difficulty. Muscle biopsy showed minimal myopathic changes. The Whole Exome Sequencing, WES showed that they are having homozygous mutation c. 547C>T (p. Q183X) in the MUC1 gene, and both parents were heterozygous. This is the second report in the literature of human mutation in the MUC1 gene. Our cases' clinical presentation is different from the cases reported before. Although Mutations in the MICU1 gene are directly linked to a form of neuromuscular disease, however, it is still unknown how these mutations lead to myopathy precisely.

1-^{13}C-Propionate Oxidation as a Measure of Hepatic Methylmalonyl-CoA Mutase (MUT) Function in Methylmalonic Acidemia (MMA). *I. Manoli[1], E. Harrington[1], S. Smith[2], J. Hattenbach[2], J. L. Sloan[1], K. Y. Chen[2], C. P. Venditti[1].* 1) Genetics and Molecular Biology Branch, NHGRI, NIH, Bethesda, MD; 2) Clinical Endocrinology Branch, NIDDK, NIH, Bethesda, MD.

Isolated methylmalonic acidemia (MMA), caused by a defect in methylmalonyl-CoA mutase (MUT) or its cofactor adenosylcobalamin (*cblA*, *cblB*, *cblD*-MMA), is characterized by increased morbidity and mortality. Elective liver (LT) or combined liver and kidney transplantation (LKT) are required to stabilize the most severely affected patients but do not correct the circulating metabolite perturbations. Studies in MMA mice have proven that 1-13C-propionate oxidation can be used to track whole body MUT activity conferred by viral or germ line transgenes, even in the presence of an expanded tracee pool and have encouraged translation to patients, with the aim of using this approach as one of the outcome measures in gene therapy trials. We measured sodium-1-13C-propionate oxidation in 27 patients with isolated MMA (*mut0* N=16, *mut-* N=6, *cblA* N=5, *cblB* N=1, age range 4-41y), 6 healthy volunteers (age range 21-33y) and 13 heterozygote controls (age range 35-62y). Resting energy expenditure was measured and serial breath samples were collected over 2 hours following an oral single bolus of 0. 5mg/kg of the tracer. Conversion of the majority of the labeled propionate to 13CO2 occured within 30 min in controls. Four healthy volunteers repeated the study three times each in order to evaluate inter- and intra-individual variability. The results demonstrated excellent reproducibility. Similarly, reproducibility was established with repeat testing in 8 MMA patients at separate times, despite a different plasma methylmalonic acid pool in two patients (1741 *vs* 2246 and 2260 vs 719 µmol/L). Decreased propionate oxidation was observed in all MMA patients vs. controls (P<0. 0001). The most severe patients, who carried two stop mutations (N=3), showed almost no oxidation of label, despite an isolated KT in one patient. In contrast, LKT recipients (N=2) showed a complete restoration of oxidation rates to control levels (P=0. 004 compared to non-transplanted patients), while only minimal oxidation was evident in a recipient after an auxiliary liver allograft post KT. B12-responsive patients with KT (N=2) showed near normal recovery, while a significant difference in measured activity was observed in one *cblA* patient pre and post B12 injection. 13C breath testing represents a non-invasive method to assess whole body *in vivo* MUT activity and could be used as prognostic or outcome measure for interventions, such as B12 supplementation, transplantation and gene or cell-therapy in MMA.

Gaucher Type 2 Neural Models from Human Induced Pluripotent Stem Cells Cindy E. McKinney, Ph. D. , Megan Corrigan-Cummins, OMS, Katherine Baumgarner, M. S. Stem Cell Lab, Edward Via College of Osteopathic Medicine (VCOM-CC) and Gibbs Research Institute, Spartanburg, SC. *C. McKinney, M. Corrigan-Cummins, K. Baumgarner.* Genetics and Biochemistry and Stem Cell Lab, Edward Via College of Osteopathic Medicine and Gibbs Research Institute, Spartanburg, SC.

The ability to reprogram a variety of human tissue sources (for example; blood PBMCs and fibroblasts) to create human induced pluripotent stem cells (hiPSC) has profound implications for studies of neurodevelopmental disease and for applications in regenerative medicine. Derivation of neuronal cells *in vitro,* by differentiating Gaucher type 2 (GD2) hiPSCs, allows for characterization and manipulation of these cells in the hope of providing insights into this fatal neurodegenerative genetic disorder. Previous studies were limited by constraints in obtaining GD2 patient and control brain tissues. The access provided by GD2 hiPSC derived neural models allows for (1) the opportunity to study cellular function in the GD2 cells and (2) the opportunity to develop drug therapy modalities that can be tested in these models and potentially moved to pharmacological development. We have obtained GD2 fibroblasts from the NIGMS Biorepsoitory (Coriell Institute) where some lines are L444P homozygotes or L444P compound heterozygotes. Control neonatal fibroblasts (BJ from ATCC) and control PBMCs from VCOM student donors were also obtained as controls. We have created hiPSC lines from all of these sources by reprogramming with the four Yamanaka factors using a non-integrating Sendai virus carrier. Characterization of these hiPSC includes screens for mycoplasma and STRs, karyotyping and immunocytochemistry for hiPSC pluripotent markers (Oct4, Sox2, Nanog, TRA1-60 and SSEA4). *In vitro* differentiation protocols show these lines are capable of generating endoderm, mesoderm and ectoderm tissues. Using Western blots, we have compared glucocerebrosidase levels in the fibroblasts and hiPSC lines with a control lysosomal protein (LIMP-2) and a housekeeping enzyme (GAPDH). Digital droplet PCR (ddPCR) using cDNA made from the cell lines shows the original GD2 fibroblasts lines have decreased GBA1 (lysosomal glucocerebrosidase) gene expression and a moderate increase in GBA2 (non-lysosomal glucocerebrosidase) gene expression compared to controls. Using the GD2 and control hiPSC lines, we derived neural progenitor cells (NPCs) expressing the neuromarkers, nestin and/or hSynapsin-EGFP. The expression of EGFP from the hSyapsin promoter in the NPCs allows for cell sorting of a homogeneous population of NPCs. The GD2 derived NPC are being further differentiated to neurons and astrocytes.

2276F

Clarifying the Phenotype of *NGLY1* Deficiency, the First Congenital Disorder of Deglycosylation. *C. Lam[1], C. Ferreira[1], D. Krasnewich[2], C. Toro[3], L. Latham[1], W. Zein[4], T. Lehky[5], C. Brewer[6], K. King[6], C. Wassif[6], S. Rosenzweig[7], J. Lyons[8], W. Gahl[1, 3], L. Wolfe[1, 3].* 1) NHGRI, NIH, Bethesda, MD; 2) NIGMS, NIH, Bethesda, MD; 3) UDP, NIH, Bethesda, MD; 4) NEI, NIH, Bethesda, MD; 5) NINDS, NIH, Bethesda, MD; 6) NIDCD, NIH, Bethesda, MD; 7) CC, NIH, Bethesda, MD; 8) NIAID, NIH, Bethesda, MD.

Background: *NGLY1* deficiency was first described to cause human disease in 2012. Encoded by *NGLY1*, N-glycanase 1 is a cytosolic enzyme that catalyzes the cleavage of the beta-aspartyl glycosylamine bond of N-linked glycoproteins releasing intact N-glycan species from proteins bound for degradation. Thus far, the human phenotype for *NGLY1* deficiency has been described in the literature in case reports and chart reviews. In this study, we clarify the clinical spectrum of *NGLY1* deficiency through a prospective natural history protocol. *Methods*: Subjects with *NGLY1* deficiency were enrolled in the NHGRI study 14-HG-0071 (NCT02089789), and 76-HG-0238 (NCT00369421). Under these protocols, subjects were admitted to the NIH Clinical Center and underwent evaluations using established clinical, radiographic, biochemical, and molecular methods. *Results*: We have evaluated 12 patients ages 2 to 21 with confirmed, biallelic, pathogenic *NGLY1* mutations. In these subjects, we explored previously reported clinical characteristics. We found decreased tear production (10/11 subjects), peripheral retinal pigmentary changes (6/11), optic nerve pallor (7/11), small cerebrum (7/11) and cerebellum (3/11), deficit of N-acetylaspartate (10/11) and elevated cerebral choline (4/11), history of seizures (6/12), axonal and/or demyelinating sensorimotor polyneuropathy (11/11), decreased sweat response (8/11), normal or near normal peripheral hearing sensitivity (9/11) with delayed and dyssynchronous transmission through the brainstem (9/11), mostly resolved transaminitis (8/9), abnormal liver texture on ultrasound (4/12), delayed bone age (8/10), complex hyperkinetic movement disorder (12/12), and global developmental delay with socialization as a relative strength (11/11). Additionally, we identified previously unreported features including consistently low CSF protein and CSF albumin, hyper-immune response to the rubella or rubeola vaccination (9/11), and a lower than predicted resting energy expenditure (9/12). *Discussion*: This study constitutes the largest case series of patients with *NGLY1* deficiency reported so far. Our prospective phenotyping has allowed us to expand the clinical spectrum of this disorder, and has led to the hypothesis that hypo-glycosylation contributes to the pathogenesis, given the phenotypic overlap between *NGLY1* deficiency and congenital disorders of glycosylation. We hope that these data will aid in development and evaluation of therapies for this disorder.

2277T

Hyperammonemia due to carbonic anhydrase VA deficiency: a case report. *H. H. C. Lee[1,2], E. Gorman[1], K. Bagley[1], V. W. Zhang[1], L. J. Wong[1], J. Zhang[1].* 1) Mitochondrial Laboratory, Baylor Miraca Genetics Laboratories, Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Kowloon West Cluster Laboratory Genetic Service, Department of Pathology, Princess Margaret Hospital, Hong Kong.

BACKGROUND. *CA5A* encodes the intramitochondrial carbonic anhydrase type VA [MIM 114761], which provides bicarbonate for various mitochondrial enzymes including those involved in the urea cycle. A deficiency of this carbonic anhydrase caused by homozygous mutations was recently reported to cause hyperammonemia similar to that in proximal urea cycle defects, with inter- and intra-familial variability [MIM 615751]. **MATERIALS AND METHODS.** Cases received for testing for proximal urea cycle defects from May 2006 to April 2015 were retrieved from the Laboratory database. Clinical details submitted on the requisition forms were reviewed: those with lactic acidosis, hypoglycemia, hypocitrullinemia or positive newborn screening but with negative molecular results, as well as those tested negative with panels of urea cycle defects testing, were selected for *CA5A* Sanger sequencing. All seven coding exons were amplified and sequenced with gene-specific primers. **RESULTS**. A total of 909 cases (from 884 families) were retrieved and reviewed. Two samples were insufficient on arrival; 10 further tests were cancelled and not analyzed after requisition. Among the remaining 897 cases from 876 families, 54 were selected for Sanger sequencing of *CA5A*. Apparently homozygous NM_001739. 1(*CA5A*):c. 555G>A, a splice site mutation previously reported in Russian patients, was detected in one case born to non-consanguineous parents. The test was requested in 2011 when the child was 21 months old, who presented with hyperammonemia, hypoglycemia, acute mental status change and lactic acidosis; previous analyses for *CPS1*, *NAGS* and *OTC* were negative. **CONCLUSION.** Carbonic anhydrase VA deficiency is a rare but important cause of hyperammonemia that should be considered together with other urea cycle defects. Regarding the presence of pseudogenes, gene-specific primers could facilitate amplification and sequencing of the true gene. Other clinical and biochemical information would aid case selection for *CA5A* analysis.

2278F

Efficacy of an Electronic Medical Record Tool for Improving Detection of Hyperammonemia in Neonates - A Two-Year Data Review. *S. A. S. Vergano[1,2], F. Cusick[3], N. Sondheimer[4,5].* 1) Medical Genetics and Metabolism, Children's Hospital of The King's Daughters, Norfolk, VA; 2) Department of Pediatrics, Eastern Virginia Medical School, Norfolk, VA; 3) Information Services, The Children's Hospital of Philadelphia, Philadelphia, PA; 4) Department of Metabolism, The Children's Hospital of Philadelphia, PA; 5) Department of Pediatrics, Perelman School of Medicine, Philadelphia, PA.

Hyperammonemia is a rare but life-threatening condition in neonates that requires prompt recognition and treatment. The causes of hyperammonemia can be many and include liver failure, medications, infection, and inborn errors of metabolism (IEM). The latter is often the most difficult to recognize, as the symptoms of hyperammonemia often mimic other more common situations, including sepsis. Due to the rarity of IEMs, hyperammonemia is often not diagnosed until much later in an infant's course, after irreversible brain damage has occurred. In an attempt to improve detection rates of hyperammonemia in neonates, a Best Practice Alert (BPA) was created at The Children's Hospital of Philadelphia (CHOP) through the EPIC(c) electronic medical record program. The alert was created to fire on infants 2-7 days of age on whom a first-time blood gas was obtained. The details and methods of the creation of the BPA were then published in Molecular Genetics and Metabolism (Vergano et al, 2013). Since then, the BPA has become a software package owned by EPIC(c) which can be purchased by other hospitals wishing to utilize the alert. In April of 2014, it was installed within the Sentara Health System in Eastern Virginia. We reviewed the data generated from the BPA since its implementation in both institutions to determine the efficacy of the tool in identifying infants with hyperammonemia secondary to IEMs. At CHOP, the alert has fired almost 1000 times, resulting in about 160 orders of ammonia levels, and identifying one infant with hyperammonemia with MMA. This is consistent with the low positive-predictive value anticipated with this tool (<1%) and the overall prevalence of IEMs, estimated at about 10-15/100,000 births. At Sentara, the alert has fired 114 times and correctly identified one hyperammonemic infant with an FAOD. There do not appear to have been any neonates with hyperammonemia who met inclusion criteria for the alert and were subsequently missed. We report here the statistics from this BPA in two institutions to evaluate its the utility and efficacy. Thus far, it has identified those infants for whom it was targeted, with no apparent false negative results. We hope this potentially life-saving electronic alert will continue be implemented in other hospitals and health systems across the country, enabling faster recognition of hyperammonemia, and ultimately improve the outcomes of children with these condition.

2279T

Development of a new MRM-MS assay for the diagnosis of Morquio Syndrome in Dried Blood Spots. *C. Cozma[1], S. Eichler[1], S. Oppermann[1], M. I. Iurascu[1], A. K. Giese[2], A. Rolfs[1,2].* 1) Centogene AG, Rostock, Germany; 2) Albrecht-Kossel-Institute, University of Rostock, Rostock, Germany.

Background and aims: Mucopolysaccharidosis IVA (MPS IVA; Morquio A disease) is an autosomal recessive disease caused and characterized by a decreased activity of N-acetylgalactosamine-6-sulfate sulfatase (*GALNS*, EC 3. 1. 6. 4), resulting in accumulation of glycosaminoglycans in tissues that lead to secondary organ damage. Recently approved enzyme replacement therapy renders the easy and early identification of MPS IVA of out-most importance. We propose a completely new assay for the stable and reproducible detection of *GALNS* deficiency in dry blood spots (DBS). **Methods:** For the validation blood samples were taken from 59 healthy individuals and 24 randomly selected genetically confirmed MPS IVA patients. The MPS IVA patients presented 18 different *GALNS* mutations, 11 of which never before described in literature. All patients presented MPS IVA phenotype and a low *GALNS* activity in leucocytes. The material extracted from DBS was incubated with a 4-methylumbelliferyl-β-D-galactopyranoside-6-sulfate as a specific substrate for *GALNS*. In a second step the intermediary enzymatic product is incubated with beta-galactosidase. Final product, 4-methylumbelliferone, obtained after adding exogenous beta-galactosidase, was quantified by LC/MRM-MS (liquid-chromatography/multiple-reaction-monitoring mass-spectrometry). 4-propyl-5-hydroxy-7-methyl-2h-chromen-2-one was used as internal standard, a compound with a similar molecular structure and fragmentation pattern in negative ion mode as 4-methylumbelliferone. **Results:** The enzymatic assay yielded a positive and negative predictive value of 1. 0 for genetically confirmed MPS IVA patients (*GALNS* activity of 0. 35 ± 0. 21 µmol/L/h) and for controls with normal *GALNS* activity (23. 1 ± 5. 3 µmol/L/h). With present enzymatic conditions, the reaction yield in dried blood spots is at least 20 fold higher than any previously reported data with other assays. **Conclusion:** The present LC/MRM-MS based assay for MPS IVA diagnosis provides an easy, highly-standardized, accurate and innovative quantification of the enzymatic product in vitro and distinguishes perfectly between MPS IVA affected patients and normal controls. This technique will significantly simplify the early detection of MPS IVA patients.

2280F

Cerebrotendinous xanthomatosis in an adult with soft tissue masses andprogressive neurological decline. *A. Alhariri[1], V. OZA[2], K. HAMILTON[4], K. CORDORO[2], M. MALLOY[3], A. SLAVOTINEK[1].* 1) Medical Genetics Division, UCSF, SAN FRANCISCO, CA; 2) Department of Dermatology, UCSF, SAN FRANCISCO, CA; 3) Department of Medicine, UCSF, SAN FRANCISCO, CA; 4) Department of Neurology, UCSF, SAN FRANCISCO, CA.

Cerebrotendinous xanthomatosis (CTX) is a treatable autosomal recessivelipid storage inborn error of metabolism. It is caused by genetic deficiency of the 27-hydroxylase enzyme (encoded by CYP27A1 gene on 2q35). It is important for cholesterol metabolism, especially in bile acid synthesis and in the 25-hydroxylation of vitamin D3 in the liver. Reduced bile acid synthesis and cholestanol accumulation in the tissues cause the disease. Clinical manifestations can vary in the onset and affected organs. Major manifestations include infantile onset chronic diarrhea, childhood cataracts, adult onset tendon-distributed xanthomas, adult onset progressive neurologic impairment and less frequently, coronary heart disease, osteoporosis and optic disc and retina abnormalities. Early diagnosis and treatment with chenodeoxycholic acid may prevent further complications, mainly neurological manifestations. Here we present a 36 year old Cantonese male who was referred to medical genetics for evaluation of progressive spastic paraplegia and large, soft tissue masses in ankles. He started to have symptoms around age 20 years. He presented with multiple soft tissue lesions at bilateral Achilles tendons that were 5-10 cm in size, a soft tissue lesion at the right posterior elbow and progressive ataxia requiring wheelchair for ambulation. No history of diarrhea. Family history is unremarkable. Brain and cervical spine MRI showed global cerebral and cerebellar volume loss and extensive non-enhancing white matter symmetric hyperintensities. His cholestanol levels were 10 fold above upper normal limits 34. 76 ug/ml (0. 86 to 3. 71). Eye exam showed mild cataract. His fasting lipid profile showed total cholesterol 198 (<200 mg/dL), triglycerides 184 (<150 mg/dL), HDL 66 (>39 mg/dL), LDL 95 (<130 mg/dL). Skin biopsy confirmed xanthomas. Chenodeoxycholic acid (CDCA) 250 mg twice daily will be started. Testing for CYP27A1 mutations is pending. We conclude that the diagnosis of CTX might be suggested by soft tissue tumors at the tendons distribution along with progressive neurologic decline, cataract and other manifestations of cholestanol deposits in multiple tissues. Diagnosis can be made by clinical presentation, elevated serum cholestanol levels, evidence of xanthomas in soft tissue growths and molecular testing for CYP27A1 gene mutations. Establishing an early diagnosis of CTX may prevent the neurological decline and improve the morbidity and mortality of this condition.

Schulz[8].* 1) BioMarin Pharmaceutical Inc. , Novato, CA, USA; 2) MRC Laboratory for Molecular Cell Biology, University College London, London, UK; 3) Department of Genetic Medicine, Weill Cornell Medical College, New York, NY, USA; 4) Department of Pediatric Neurology, Nationwide Children's Hospital, The Ohio State University, Columbus, OH, USA; 5) Advanced Clinical Research Center, Southern Tohoku Brain Research Center, Kawasaki, Japan; 6) SA Pathology, North Adelaide, South Australia, Australia; 7) Department of Pediatric Neurology, Trousseau Hospital, CHU Paris Est, Paris, France; 8) Department of Pediatrics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 9) Department of Medical Genetics, School of Medicine of Ribeirao Preto, University of São Paulo, São Paulo, Brazil; 10) Universidad Nacional de Córdoba, Facultad de Ciencias Médicas, Cordoba, Argentina; 11) Sanford Children's Health Research Center, Sioux Falls, South Dakota, USA; 12) Pediatric Neurology, Hospital Universitario Marqués de Valdecilla, Cantabria, Spain; 13) Department of Neurological and Movement Sciences-Neurology, University of Verona, Verona, Italy.

Background: CLN2 disorder is a lysosomal storage disorder resulting from TPP1 enzyme deficiency that causes progressive neurological degeneration and early mortality. CLN2 disorder is rare and often unsuspected, leading to delays in diagnosis. **Methods:** In late 2014, 18 international CLN2 experts (clinicians, academic researchers, and laboratory directors) answered a comprehensive survey on CLN2 disorder and a subset met to discuss experiences, current practices and shortcomings in diagnosis of CLN2. **Results:** 70% of laboratory experts considered the standard for CLN2 diagnosis to be a demonstrated decrease in TPP1 enzyme activity, with the remaining experts favoring molecular detection of pathogenic *CLN2*/*TPP1* mutations. Delays in the diagnosis of CLN2 were identified as a crucial concern: 82% of the group responded that patient referral to a specialist can typically take longer than one year. Laboratory experts identified the challenge in reaching a suspicion of CLN2 (50%) and lack of awareness of available tests (83%) as common reasons for delays. **Discussion:** Experts agreed that reliable techniques exist for CLN2 diagnosis and identified timely referral as a key challenge. An upcoming CLN2 expert meeting will define laboratory-based screening and diagnostic guidelines in order to establish best practices for use of biochemical genetics testing in CLN2 diagnosis.

2282F

Inborn errors of metabolism in the molecular era: will biochemical analyses became a second-tier test? *L. S. A. Costa[1,2], F. B PIAZZON[1,2], F. P MONTEIRO[2], J. P. KITAJIMA[2], I. CORREIA[2], M. DELLAMANO[2], E. L. FREITAS[2], D. SCHLESINGER[2], C. BUENO[1], F. KOK[1,2].* 1) UNIVERSIDADE DE São PAULO - USP-SP, SAO PAULO, SAO PAULO, Brazil; 2) MENDELICS GENOMIC ANALYSIS, SAO PAULO - SP, BRAZIL.

Molecular analysis using next-generation sequence (NGS) technology already has a huge impact in clinical practice and is a fast and reliable way to provide diagnosis for rare, atypical or genetically heterogeneous conditions. In the past 2 years, we performed 720 clinical whole exome sequencing (WES) and identified 63 different IEM in 76 individuals, 35 of them without a previous suspicion of IEM. Diagnosed conditions belonged to the following group of diseases: LSD (13), peroxisomal (2), mitochondrial (13), amino acids (7), CDGs (6), GSD (3), neurotransmitter (3), nucleotides (3), metal (2), organic & FAO (7) and other (18). Among the IEM diagnosed, many conditions had only a couple of reports, as the X-linked SSR4-CDG, the purine synthesis ATIC deficiency, the inositol glycan anchor synthesis defect PGAP1, PGAP2 and PIGO and the isoleucine metabolism EHCS1 deficiency. A biochemical confirmatory test was performed when appropriate. In countries with limited access to biochemical tests, the use of WES might overcome most of diagnostic hurdles related to turnaround time, quality, cost, availability and dependence on overseas service provider. With a single test, we may answer several different questions.

2283T

Screening for mucopolysaccharidosis disorders in children and young adults presenting with bilateral hip disease. *G. Scharer[1], N. Mendelsohn[1], P. Stasikelis[4], S. Gutknecht[2], B. Smith[3], T. Wood[3], D. Pond[1], A. Bellomo[3], R. Olson[1], L. Read[1], K. Mason[4], T. Ramsey[3], L. Pollard[3], M. Barrett[1], C. Rogers[3,4].* 1) Children's Hospitals and Clinics of Minnesota, Minneapolis, MN, United States; 2) Gillette Children's Specialty HealthCare, St. Paul, MN, United States; 3) Greenwood Genetic Center, Greenwood, SC, United States; 4) Greenville Shriners Hospital, Greenville, SC, United States.

Introduction: Mucopolysaccharidosis (MPS) IVA and MPS VI are usually diagnosed by testing urine for elevated mucopolysaccharides followed by confirmatory enzyme testing for deficient N-acetylgalactosamine-6-sulfatase (GALNS) or arylsulfatase B (ARSB), respectively. Urine testing can be inconclusive. A 10-year-old boy with bilateral hip pain beginning at 9 years old was diagnosed with Legg-Calve-Perthes (LCP) and subtle spine abnormalities. Quantitative urine testing was normal, but thin layer chromatography revealed dermatan sulfate. Enzyme testing confirmed MPS VI. Two MPS IVA patients presented with hip dysplasia, joint pain, and normal or mildly elevated urine testing for glycosaminoglycans. Enzyme testing confirmed MPS IVA. Bilateral hip disease is documented as an early finding in MPS. We hypothesized enzyme testing in patients with bilateral hip disease may detect attenuated MPS IVA or VI. **Methods:** Participants were selected from 2 healthcare systems in Minnesota (ages ≤21 years) and 1 in South Carolina (SC) (ages <19 years) with diagnoses of bilateral spondyloepiphyseal dysplasia, multiple epiphyseal dysplasia (MED), LCP, unclassified skeletal hip dysplasia, or multi-joint pain (SC only). Blood samples collected for leukocyte enzyme testing (GALNS, ARSB) were analyzed by Greenwood Genetic Center using standard procedures. Abnormal results led to sequencing the associated gene. **Results:** In total, 3,652 charts were reviewed, 139 were eligible, and 39 patients enrolled. One was diagnosed with MPS IVA—a 10-year-old girl with a misdiagnosis of MED, presented with hip and shoulder pain, short stature, and mildly flat facies. Radiographs suggested attenuated MPS IVA. GALNS enzyme activity was deficient, and 2 pathogenic changes were found in the *GALNS* gene (p. D233N, p. P498S). Another patient had low arylsulfatase B activity (28. 2, normal 57-493), which was normal (85. 7) upon repeat analysis. Sequencing of *ARSB* revealed 2 polymorphisms (p. V358M, p. S384N), each of which causes moderately reduced enzyme activity *in vitro*, likely explaining the enzyme results. **Conclusion:** MPS VI and MPS IVA are rare disorders with hip disease as a common symptom. Of the 39 patients enrolled in the study, one was diagnosed with MPS IVA. The authors suggest consideration of MPS disease in children with bilateral hip disease to include enzyme screening.

2284F

Exome sequencing to identify the genetic bases for lysosomal storage diseases of unknown etiology. *J. Xing[1, 2], N. Wang[1, 2], E. Gedvilaite[1], Y. Zhang[1, 2], D. Kumar[3], R. Donnelly[4], D. Sleat[5, 6], P. Lobel[5, 6].* 1) Dept of Genetics, Rutgers University, Piscataway, NJ; 2) Human Genetics Institute of New Jersey, Rutgers University, Piscataway, NJ; 3) Waksman Institute of Microbiology, Rutgers University, Piscataway, NJ; 4) Molecular Resource Facility, Rutgers - New Jersey Medical School, Newark, NJ; 5) Center for Advanced Biotechnology and Medicine, Rutgers University, Piscataway, NJ; 6) Dept of Biochemistry and Molecular Biology, Robert Wood Johnson Medical School, Rutgers University, Piscataway, NJ.

Lysosomes are membrane-bound, acidic eukaryotic cellular organelles. As an enzyme container, they play important roles in the degradation of macromolecules. Monogenic mutations resulting in the loss of enzyme activities in the lysosome may lead to severe health problem, such as neurodegeneration, early death, etc. These conditions are categorized as lysosome storage diseases (LSDs). The diagnosis of LSDs is typically straightforward, but in some cases, mutations that result in atypical clinical presentation or defects in previously undescribed lysosomal disease genes may complicate the identification of the underlying genetic defect. Here, we performed whole exome sequencing on 14 suspected LSD cases, with the goal of finding the causal mutations in each case. From the raw sequence data, we first identified DNA variants in each individual using three variant discovery pipelines: the Genome Analysis Toolkit, LifeScope and CLC Genomics Workbench. We then used the Variant Annotation Analysis Selection Tool (VAAST) to prioritize disease-causing mutations in 848 candidate LSD genes. As a probabilistic disease gene finder, VAAST integrates allele frequency, amino acid substitution severity and conservation information into a composite likelihood framework. Different from hard filtering methods, VAAST preserves all the candidates by listing them according to their disease-causing potential. So far a number of candidate variants have been identified, and we are performing downstream mutation validation and proteomic analyses to investigate the potential connection between our candidate variants and LSDs. Our project makes use of bioinformatics analyses to decode enormous exome sequencing data, narrowing down candidate lists and largely increasing the efficiency of downstream proteomic studies. Our results will shed light on the genetic basis of LSDs.

2285T

Niemann-Pick disease type B: a not rare diagnosis in patients referred for investigation of Gaucher disease type 1. *R. Giugliani, F. M. Sebastiao, K. Michelin-Tirelli, F. Bitencourt, F. B. Trapp, M. G. Burin.* Medical Genetics Service, HCPA/UFRGS, Porto Alegre, RS, Brazil.

The Laboratory of Inborn Errors of Metabolism/Medical Genetics Service/Hospital de Clínicas de Porto Alegre is a reference center for the diagnosis of lysosomal storage diseases (LSDs) in Brazil, including Gaucher disease (GD) and Niemann-Pick disease (NPD). GD is caused by β-glucosidase deficiency and classified as GD type 1 (GD-1), more attenuated and more common, known as non neurophatic, and GD type 2 and GD 3, more severe forms with neurological involvement. NPD is caused by acid sphingomyelinase deficiency and can be classified as NPD type A, a severe form with massive visceromegaly and early and pronounced neurological deterioration, with low life expectance, or as NPD type B (NPD-B), a more attenuated type, with little or none neurological involvement, with patients surviving into adulthood. GD-1 and NPD-B have several clinical manifestations in common, as marked hepatosplenomegaly and hematological problems, and in both conditions plasma chitotriosidase is usually increased. Therefore, when there is a clinical suspicion of GD-1, it is important to think in NPD-B as diagnostic possibility as well. Final diagnosis is usually obtained by the identification of the specific enzyme deficiency in leukocytes or fibroblasts. The purpose of this work was to identify the proportion of cases diagnosed as NPD-B in our lab in whom the initial suspicion was GD-1. We performed a retrospective analysis of our records (from 1988 to 2015) of all patients in whom acid sphingomyelinase deficiency was identified. We retrieved 202 NPD cases, being 89 of them with NPD-B, 22 with NPD-A, and 91 who could not be classified as no phenotypical information was available. In the 89 known cases of NPD-B, 18 (20 %) where referred with the initial suspicion of GD-1 (surprisingly, in 3 of them there was a biochemical diagnosis of GD-1 established in another lab). The main signs and symptoms in the 18 cases of NPD-B in whom the first suspicion was GD-1 were hepatosplenomegaly, anemia, thrombocytopenia, pancytopenia, and growth retardation, quite common in GD-1 as well. These results highlight the need to investigate NPD-B (through the measurement of acid sphingomyelinase activity) in all cases with GD-1 suspicion in whom this diagnosis was not confirmed, once, in our experience, 20% of NPD-B diagnoses were obtained incidentally in patients referred for the investigation of GD-1. The correct identification of NPD-B becomes more important as ERT for this disease is being developed.

2286F

Comprehensive screening of Urine sample for Metabolic Disorder using Gas Chromatography /Mass spectrometry. *B. Varughese, C. KUMARI, P. KADAM, S. K. POLIPALLI, S. KAPOOR.* PEDIATRICS RESEARCH AND GENETIC LAB, DEPARTMENT OF PEDIATRICS, MAULANA AZAD MEDICAL COLLEGE AND UNIVERSITY OF DELHI, DELHI, India.

Background & Aim:GC-MS has been widely used worldwide in the diagnosis of IEM because of its high sensitivity, accuracy and effectiveness in the analysis of multiple compounds simultaneously. We understand the need for a rapid and precise diagnosis in the clinically suspected metabolic disorders in New Born Screening in India. This study was designed to investigate the organic acid profile in clinically suspected metabolic disorder patients. Material and Method:Over a period of one year (2014-2015), a total of 1500 clinically suspected children were screened for metabolic abnormalities. Urine samples were analyzed for abnormal constituents like ammonia, lactate, reducing sugar, proteins, ketone bodies by routine laboratory chemical tests. Organic Acid extraction from urine was carried out using ethyl acetate followed by derivatization using N,O- bis- trimethylsilyltrifluroacetamide (BSTFA) and analysed for phenylketones, organic acids, ketoacids, succinylaccetone & glycines by GC/MS analysis supported by NIST v 2. 0g mass spectra library. Results:Out of 1500 screened only 37 (2. 46%) children were diagnosed to have IEM . In our study , the most common cases reported are, Lactic acidosis 13 (35. 1 %) ,Glutaric acidemia 6 (16. 2%), Methylmalonic aciduria 5 (13. 5%), followed by Tyrosinemia, Neuroblastoma, Maple syrup urine disorder , Gama- Amino butyric aciduria which collectively contributes 8 (5. 40%). Isovaleric acidemia 1 (2. 7 %) , Citrullinemia, Beta- Ketothiolase deficiency 1 (2. 7 %), propionic acidemia 1 (2. 7 %) and orotic aciduria1 (2. 7 %) . The common clinical manifestations observed among all participants were neurological features like convulsions (25. 7%), delayed milestones (17. 9%), and followed by metabolic acidosis (17. 2%) and hypoglycemia (10. 1%). Conclusion: High index of suspicion from clinicians supported by preliminary screening tests can aid in early presumptive diagnosis, which helps in initiating early treatment to prevent lethal neurological complications.

2287T

Clinical metabolomic profiling for the diagnosis of neurometabolic disorders associated with seizures and global developmental delay.

T. Donti[1], G. Cappuccio[2], M. Miller[1], P. Atwal[1], A. Kennedy[3], L. Miller[3], M. Milburn[3], J. Ryals[3], A. Cardon[4], C. Bacino[1], L. Emrick[1,4], J. Hertecant[5], A. Beaudet[1], M. Bainbridge[1], B. Graham[1], Q. Sun[1], V. R. Sutton[1], S. Elsea[1]. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Translational Medical Sciences, Section of Pediatrics, Federico II University, Naples, Italy; 3) Metabolon Inc. , Durham, NC; 4) Section of Pediatric Neurology and Neuroscience, Baylor College of Medicine, Houston, TX; 5) Tawam Hospital, UAE.

Neurometabolic disorders may present in infancy or early childhood with seizures, hypotonia and developmental delay or other focal neurologic signs. In individuals presenting with undifferentiated phenotypes such as developmental delay, hypotonia and seizures, the list of differential diagnoses is often very long and includes metabolic/neurometabolic, genomic, and other Mendelian disorders. We have previously documented the ability of untargeted metabolomic profiling to diagnose a variety of amino acid, organic acid, and fatty acid oxidation disorders. The untargeted nature of global metabolomic profiling allows screening for many metabolic disorders in one plasma sample. Here, we report 5 patients with various neurometabolic disorders identifiable by metabolomic analysis of plasma. The disorders include aromatic amino acid decarboxylase (AADC) deficiency, 4-aminobutyrate aminotransferase (ABAT) deficiency, adenylosuccinate lyase (ADSL) deficiency, citrate transporter deficiency, and urocanase deficiency. Four of the five (all except ADSL) had variants of uncertain significance (VUS) in related genes on whole exome sequencing (WES) which prompted the metabolomic profiling. We observed elevations of 3-methoxytyrosine, 2-pyrrolidinone, succinyladenosine, citrate and imidazole propionic acid in AADC, ABAT, ADSL, citrate transporter and urocanase deficiency, respectively. The perturbations in the metabolomic profile of plasma from these patients are unique and specific for these particular disorders. The standard diagnostic test for AADC, ABAT, and ADSL deficiency is CSF neurotransmitter analysis (although our patient with ABAT had this test and the panel did not include GABA or other diagnostic metabolites) and for urocanase deficiency, it is an enzyme activity assay from a liver biopsy. Citrate transporter deficiency is a rare disorder for which no clinically-available biochemical test is available. These cases demonstrate the ability of untargeted metabolomic profiling in confirming VUS found on WES, as well as the ability to use metabolomic profiling alone to screen for a wide range of metabolic/neurometabolic disorders.

2288F

Known and Novel ATP6 Mutations in the Mitochondrial Genome: Delineation of the phenotypic spectrum and functional effects.

R. D. Ganetzky[1], E. McCormick[1, 2], E. Polyak[1, 2], M. Peng[1, 2], M. Bennett[3], E. Nakamaru-Ogiso[4], R. Rodenburg[5,6], M. J. Falk[1,2]. 1) Section of Biochemical Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Clinical Genetics, Children's Hospital of Philadelphia; 3) Department of Pathology, Children's Hospital of Philadelphia; 4) ohnson Research Foundation, Department of Biochemistry and Biophysics, Perelman School of Medicine, University of Pennsylvania; 5) VU University Medical Center; 6) Department of Pediatrics, Radboud University Nijmegen Medical Center.

BACKGROUND: ATP synthase (complex V, CV) is an essential mitochondrial OXPHOS complex, wherein the proton gradient generated by the electron transport system is dissipated to generate energy as ATP. Ten pathogenic mutations have previously been reported in *ATP6*, one of two mtDNA-encoded complex V subunits. Clinical phenotypes that have been reported in association with *ATP6* mutations include primary lactic acidosis, Leigh syndrome and NARP. A growing number of novel *ATP6* variants of uncertain significance (VUS) have been found in a range of other phenotypic presentations. The lack of CLIA-approved functional assays to validate complex V functional effects prohibits accurate classification of novel *ATP6* variants. **METHODS:** A systematic review was performed of all reported *ATP6* mutations. Clinical and biochemical phenotypes were also evaluated in 8 patients from 6 families who have novel VUS in *ATP6* seen at The Children's Hospital of Philadelphia. Functional validation is underway of 4 methods to assess complex V activity/function: 1) spectrophotometric CV enzyme activity analysis, 2) blue native gel analysis with in-gel CV activity assay, 3) fluorometric assay of ATP synthetic rate, and 4) high-resolution respirometry analysis of integrated OXPHOS capacity with simultaneous fluorescence analysis of membrane potential (Oxygraph-2K, Oroboros). **RESULTS:** We have collated all reported *ATP6* phenotypes, functional effects of individual variants, functional assay results, inheritance, and heteroplasmy loads. A high correlation exists between heteroplasmy load and phenotype in reported pathogenic *ATP6* mutations. Proposed pathophysiology includes inefficient coupling between proton transport and ATP synthesis, loss of proton transport and accumulation of reactive oxygen species. Functional analyses are underway with to assess each assay's relative sensitivity, specificity, cost, and ease of use. Subsequently, these methods will be applied to assess CV activity in patient fibroblasts and cybrids from individuals with VUS in *ATP6*. **CONCLUSION:** While a handful of *ATP6* mutations have been validated to cause classical mitochondrial disease phenotypes, determining the functional relevance of novel *ATP6* variants being identified in additional phenotypes is a challenge. Assessing multiple diagnostic modalities will enable the development of robust clinical diagnostic assays to inform the clinical significance of novel *ATP6* mutations.

2289T

Extremely skewed X-inactivation leading to a manifestation of mucopolysaccharidosis type II in a female patient. *L. Dvorakova[1], M. Reboun[1], T. Veselkova[1], J. Vcelak[2], G. Storkanova[1], L. Stolnaja[1], M. Hrebicek[1], D. Musalkova[1], H. Poupetova[1], K. Peskova[1], J. Zeman[3].* 1) Inst Inherit Metabol Disorders, General University Hospital, Prague 2, Czech Republic; 2) Institute of Endocrinology, Prague, Czech Republic; 3) Department of Paediatrics and Adolescent Medicine, General University Hospital in Prague and First Faculty of Medicine, Charles University in Prague, Czech Republic.

Mucopolysaccharidosis type II (Hunter syndrome, MPS II, OMIM 309900) is an X-linked recessively inherited lysosomal storage disorder resulting from a deficiency of iduronate-2-sulfatase activity (IDS, EC 3. 1. 6. 13). The vast majority of patients are males, while only 16 female patients have been reported so far. We present a 3-year old girl with coarse face, mild hepatosplenomegaly, dysostosis multiplex and mild psychomotor retardation. Enzyme assay performed in both leukocytes and serum showed deficiency of IDS activity comparable to hemizygous MPS II patients. Diagnosis of MPS II was also established at the molecular level. A heterozygous substitution c. 1403G>A (p. Arg468Gln), a common MPS II mutation, was found as an apparent *de novo* change in her *IDS* gene. No other mutation, deletion, splicing mutation or recombination *IDS-IDS2*, which could explain the manifestation of MPS II in the girl was found. The analyses of the patient's cDNA using Sanger sequencing as well as NGS showed that only the mutated allele was transcribed. This finding led to a suspicion of X-chromosome skewing. Both approaches used for determination of X-inactivation status, DNA-methylation analysis and transcription-based assay, identically showed preferential inactivation of maternal allele (96/4 to 99/1) in patient's blood leukocytes and buccal swabs. Our results confirm that while overwhelming majority of MPS II carriers are asymptomatic, almost exclusive expression of the mutated allele due to extremely skewed X-inactivation leads to manifestation MPS II in females. Support: IGA MZ CR NT 14015, RVO-VFN64165/2012, PRVOUK-P24/LF1/3, GAUK No. 42314, MZ CR - RVO (EU, 00023761).

Genetic investigation of Maple Syrup Urine Disease in Iranian population. *M. Abiri[1], M. R Alaei[2], S. Dabagh Bagheri[3], H. Bagherian[4], S. Zeinali[4,5].* 1) Medical Genetics, Tehran university of medical sciences, Tehran, Iran; 2) Mohammad Reza Alaei, Pediatric Endocrinology and Metabolism, Mofid Children's Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran,MD; 3) Samira Dabagh Bagheri,Medical Genetics Laboratory, Kawsar Human Genetics Research Center, Tehran, Iran,BSc; 4) Hamideh Bagherian,Medical Genetics Laboratory, Kawsar Human Genetics Research Center, Tehran, Iran, MD; 5) Sirous Zeinali, Department of Molecular Medicine, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Iran, PHD.

Maple syrup urine disease (MSUD; OMIM 248600) is a rare inborn error of metabolism with the population incidence of 1:185. 000. The disease frequency is higher in population with higher rate of consanguineous marriage. Also, Iran is an immense country with 38. 6% rate of consanguineous marriage. So it is expected to have a higher rate of patients. So in our country early detection of the disease and disease management using special diets or the other forms of therapy is very important. Untreated patients die soon after the birth and if not they may show different physical and mental abnormalities. The disease mainly caused by deficient activity of a mitochondrial enzyme called BCKD (BCKD; EC 1. 2. 4. 4.) complex. It is a branched-chain α-keto acid dehydrogenase complex which catalyze oxidative decarboxylation of branched-chainα-keto acids that derived from branched-chain amino acids (BCAA). Improper activity of the enzyme complex leads to accumulation of leucine, isoleucine and valine and their respective metabolites in cells and body fluid. Phenotypic expression of the disease depends on the amount of BCKAD activity. Different types of mutation have been previously disclosed in *BCKDHA, BCKDHB, DBT* and *DLD* gene in other populations. Since the MSUD mutational spectrum has not previously investigated in Iran, this study aims to investigate the molecular basis and biochemical profile of patients. Here in, we surveyed clinical and biochemical profile of 26 MSUD families. Now, molecular genetic testing of 15 cases is available and the others are still ongoing. In this study, we used 2 sets of polymorphic STR markers linked to the mentioned genes to find the probable pathogenic gene in families quickly and indirectly. STR markers were selected based on their heterozygosity in Iranian population. Then to find the exact pathogenic change, mutation analysis of probable gene/ genes was done by amplification of all exons and flanking intronic sequences, followed by bidirectional sequencing. All identified mutations were novel except one that reported previously in Turkish population. Also our findings show that there is no hot spot mutation in any of the investigated gene and mutations are scattered thought the mentioned genes. *BCKDHA* gene was the most common gene involved in genetic status of Iran. Structural modellings of the novel mutations were done by different available soft wares to predict the severity and probable clinical consequence.

2291T

Unique presentation of LHON/MELAS overlap syndrome caused by very rare mutation in *MTND5*. *T. Honzik[1], P. Liskova[2, 3], M. Tesarova[1], V. Kucerova Vidrova[1], H. Hansikova[1], H. Kolarova[1].* 1) Dpt of Pediatrics, First Fac. Med. , Charles Univ, Gen Univ Hosp, Prague, Czech Republic; 2) Lab of Biol Pat of the Eye, Inst of Inherit Metab Dis, First Fac. Med. , Charles Univ, Gen Univ Hosp, Prague, Czech Republic; 3) Dpt of Ophthalmology, First Fac. Med. , Charles Univ, Gen Univ Hosp, Prague, Czech Republic.

Background: Leber hereditary optic neuropathy (LHON) and mitochondrial encephalopathy, myopathy, lactic acidosis and stroke-like episodes (MELAS) syndromes are mitochondrially inherited disorders characterized by acute visual failure and variable multiorgan system presentation, respectively. *Materials and Methods:* A 12-year-old girl with otherwise unremarkable medical history presented with abrupt, painless loss of vision. Over the next months, she developed moderate sensorineural hearing loss, vertigo, migraines, anhedonia and thyroiditis. Ocular fundoscopic examination confirmed bilateral optic nerve atrophy. Metabolic workup documented elevated cerebrospinal fluid lactate. Initial genetic analyses excluded three of the most common LHON mutations in our patient. Subsequently, Sanger sequencing of the entire mitochondrial DNA (mtDNA) genome was performed. *Results:* Whole mtDNA sequencing revealed a pathogenic heteroplasmic mutation m. 13046T>C in *MTND5* encoding the ND5 subunit of complex I. This particular variant has been previously described in a single case report of MELAS/Leigh syndrome. Based on the constellation of clinical symptoms in our patient, we diagnose the condition as LHON/MELAS overlap syndrome. *Conclusions:* We describe a unique presentation of LHON/MELAS overlap syndrome resulting from m. 13046T>C mutation in a 12-year-old girl. In patients with sudden vision loss in which three of the most common LHON mitochondrial mutations have been ruled out, molecular genetic examination should be extended to other mtDNA-encoded subunits of *MTND5* complex I. Furthermore, atypical clinical presentations must be considered, even in well-described phenotypes. *This work was supported by grants IGA NT 14156/3, IGA NT 13114/4, GAUK 38515/2015 and by institutional research support by Charles University in Prague (PRVOUK P24/LF1/3, RVO-VFN 64165, SVV UK 260148/2015).* .

Identification of a novel deletion in the *PEX1* gene resulting in partial PEX1 protein function in patients with Zellweger Spectrum Disorder. *E. Di Pietro[1], C. Argyriou[1], P. Saberian[1], S. Birjandian[1], S. J. Steinberg[2], N. E. Braverman[1].* 1) Department of Human Genetics, Research Institute of the MUHC, Montreal, PQ, Canada; 2) 2McKusick Nathans Institute of Genetic Medicine , Johns Hopkins School of Medicine, Baltimore, Maryland.

Zellweger spectrum disorder is a group of autosomal recessive multi-systemic disorders that are caused by defects in any one of 13 PEX genes that encode PEX proteins, or peroxins, required for peroxisome assembly. Clinical severity ranges from severe to milder and is largely correlated to the effect of the PEX gene mutations on the function of the encoded protein. The majority of reported mutations are in the PEX1 gene, and a common mutation, PEX1-G843D, encodes a protein with residual function and an intermediate- milder phenotype. The PEX1 protein is a AAA protein (ATPases Associated with diverse cellular Activities) that forms a hetero-hexamer with the PEX6 AAA protein to generate a peroxisome associated complex that recycles the PEX5 receptor from the peroxisome membrane to the cytosol in order to ensure additional rounds of matrix protein import. Here we report the identification of novel, overlapping terminal deletions in the PEX1 gene in 3 unrelated patients with intermediate-milder ZSD phenotypes. We identified the deletions, c. 3767+334_c. 3852*3356 in two patients and c. 3767+451_c. 3852*5312 in one patient, each in compound heterozygosity with a PEX1 null allele. We characterized the cDNA and the resulting protein, which is truncated at the end of exon 23. The level of PEX1 protein is reduced in patient cell lines. Remarkably, the truncated protein retains residual function. There is residual matrix protein import in patient cell lines and expression of the truncated protein in a PEX1 null cell line resulted in approximately 50% recovery of peroxisomal import as compared with expression of normal PEX1 protein. We show that treatment with Betaine, a nonspecific chemical chaperone, also improved peroxisome assembly in the PEX1 exon 24-deletion cell lines. We conclude that the truncated PEX1 protein is responsible for the milder patient phenotype and that betaine treatment could be considered in patients with this allele.

2293T

International Fabry Disease Genotype/Phenotype Database: Phenotypic Classification of 46 novel pathogenic *GLA* mutations for Type 1 "classic" or Type 2 "Later-Onset" Phenotype by clinical, *in vitro* expression and *in silico* analyses. *D. O. Doheny, C. Sollis-Villa, S. Kadirvel, B. H. Lee, B. Chen, I. Nazarenko, R. Montel, R. Srinivasan, M. Yasuda, C. Yu, R. J. Desnick.* Genetics & Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY.

X-linked Fabry disease results from mutations in the α-galactosidase A gene (*GLA*) that lead to the absent or deficient activity of α-galactosidase A (α-Gal A), and progressive accumulation of glycosphingolipids with terminal a-galactosyl moieties. Mutations causing the severe, early-onset Type 1 "classic" phenotype result in ecssentially no α-Gal A activity in affected males and include nonsense, frameshift, consensus splice site, large deletions/insertions and specific missense mutations. Mutations causing the Type 2 "later-onset" phenotype encode residual α-Gal A activity and include alternative splicing and specific missense mutations. Notably, certain common missense mutations are benign or likely benign, including encoding E66Q, SI26G, c. 639+6A>C and D313Y as well as R118C and A143T, previously thought to cause the Type 2 phenotype. From 2005 to 2015, 2912 individuals were tested, including 1056 (36. 3%) probands of which 351 were mutation positive (217 males, 134 females). The 5 most common reported mutations were encoding N215S, R363H, R112C, R227X, and R112H. Noteably, 46 novel *GLA* mutations were identified: 14 (30%) were clearly novel Type 1 mutations including 1 nonsense (Q57X), 6 deletions (c. 59_84del26, c. 234delA, c. 966delC, c. 1193_1196delAATG, c. 1226_1231delCCACAG, and large deletion of exons 2-7,), 3 insertions (c. 147_148insCGC, c. 966insC, c. 1094dupA), 1 double missense mutation (novel R4M and previously reported Y207S), and 3 consensus splice site mutations (IVS3+2T>C, IVS5-1G>A, IVS6+1delG). Mutations causing the Type 2 phenotype included two alternative splicing defects (IVS4+876T>G, IVS4+878T>C). In addition, there were 30 (65%) novel missense mutations encoding (L19Q, L21P, L21R, A37P, E48Q, G80D, Y86H, C90R, C90Y, Y134D, T141N, L167V, R196G, I198T, V199A, S201P, E203D, Y207H, I232S, W245G, A257D, V269E, G274R, M290T, G360R, Q250H, C378S, C382R, P389L, L417R) which could cause the Type 1 or 2 phenotype. To determine the pathogenicity and phenotype of the missense lesions, clinical data, *in vitro* expression assays, and *in silico* structural studies are underway. These studies are essential to predict the clinical phenotype of patients with pathogenic mutations and to identify likely benign lesions, particularly for cascade family testing and newborn screening, and for appropriate therapeutic intervention, including early enzyme therapy in Type 1 classically affected males.

2294F

Molecular and functional characterization of mutations in Congenital Adrenal Hyperplasia patients (CYP21A2 gene): functional genomics. *R. Prasad[1], R. Khajuria[1], R. walia[2], A. Bhansali[2].* 1) Biochemistry, PGIMER, Chandigarh, Chandigarh, India; 2) Endocrinology,PGIMERchandigarh,chandigarh,india.

Congenital Adrenal Hyperplasia (CAH) is autosomal recessive disease, with a wide range of clinical manifestations from severe classical form to late onset form. Our aim was to determine the frequency of common CYP21A2 gene mutations, identify novel mutations and their functional analysis. Clinical and hormonal evaluations were used to categorize the patients in Salt Wasting (SW), Simple Virilizing (SV) and Non Classical (NC) forms. Molecular analysis of CYP21A2 was performed in 55 patients for detection of common mutations viz gene deletion,Q318X, R356W, V281L, i2g, F306 + T or L307 frame shift mutation and P267L. Polymorphisms viz D183E & S268T were identified in 55 patients and 55 controls. Novel mutations were identified by SSCP technique and subsequently sequencing of amplified product. Functional implication of novel mutations was analyzed by construction of mutant plasmids by site-directed mutagenesis and subsequently by their in vitro expression in COS-7 cells. Mutation severity was assessed by calculating enzyme activity and their kinetic constant of respective mutants. Mutation severity prediction softwares namely PROVEAN, SIFT and polyphen were used to predict the effect of novel mutations on 21-hydroxylase enzyme. Disease causing mutations were identified in patients comprising SW (n=14), SV (n=26) and NC(n=15). 8 bp gene deletion was found in 10 patients (18. 1 %) in homozygous condition whereas heterozygous condition prevailed among 5 patients (9%). Frequency of other known mutations were R356W mutation (12. 7 %), Q318x (14. 5 %) ,V281L (12. 2 %), i2g (13. 6 %), F306 + T (12. 7 %) and P267L (5. 4 %). H365N, F306V, P357P, D234D are novel mutations in CYP21A2 gene. Each novel mutation was present at frequency of 1. 8 %. H365N mutant retained 63. 23 % enzyme activity while F306V mutant had 46. 13% activity as compared to wild type enzyme for 17OHP as substrate. H365N mutant had 64. 17 % activity while F306V mutant had 57. 77 % activity as compared to wild type enzyme for progesterone as substrate. Kinetic analysis reveals significant alteration in kinetic constant of mutant to that of wild type. Further, there was significant change in activation energy of mutant to that of wild type. Polyphen-2 predicts that F306V and H365N are probably damaging mutations. PROVEAN assigns H365N and F306V as deleterious mutations. SIFT predicts that both the novel mutations affect protein function as a result of substitution of amino acid at the respective positions.

2295T

Severe Fetal Onset of Glycogenosis type IV (Andersen disease) Presenting as Hydrops Fetalis – Report of a case. *H. Alrukban[1], P. Shannon[2], R. Tietelbaum[3], D. Chitayat[1,3].* 1) Genetics and Metabolics, The Hospital For Sick Childrens, toronto, Canada; 2) Department of Laboratory Medicine and Pathobiology and Department of Obstetrics and Gynecology; 3) The Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, University of Toronto, Toronto, Ontario, Canada.

Glycogen storage disease type 4 is an autosomal recessive disease caused by mutation in Glycogen branching enzyme (GBE) gene. This enzyme catalyzes the attachment of short glucosyl chains to a naked peripheral chain of nascent glycogen. Deficiency results in abnormal structure, known as polyglucosan that has longer chain lengths and fewer branch points. It accumulates in various body tissues including liver, muscles, nervous system and heart. The clinical presentation involves the classic liver form leading to liver cirrhosis and failure and the rare neuromuscular form. The neuromuscular presentation is variable in severity and onset and includes congenital, juvenile and adult presentations. The congenital type is characterized by antenatal polyhydrominos, hydrops fetalis and decreased fetal movement in the third trimester caused by accumulation of the polyglucosan in the skeletal and neural tissues. Affected babies present with hypotonia, hyporeflexia, cardiac dysfunction, and arthrogryposis. Majority of the cases required immediate resuscitation and respiratory support and died in the neonatal period. We report a male neonate who was born to a consanguineous couple of Indian descent, who had lost a previous baby 30 minutes after his birth with limited information on the cause of death. Their current pregnancy was complicated with hydrops fetalis of an unknown etiology. The baby died shortly after birth despite vigorous resuscitation. On autopsy examination he was found to have a myopathic face with small mouth and high arched palate, subcutaneous edema and bilateral mild talipes. The lungs were hypoplastic and the myocardium of the right ventricle appeared thickened. Microscopic examination demonstrated innumerable polyglucosan bodies in the skeletal muscle, myocardium, liver and central nervous system consistent with GSD4. Sequencing the GBE1 gene showed a homozygous novel missense mutation, c. 321G_A, predicted to result in premature protein termination (p. Trp107*). This finding expands the spectrum of mutations associated with the congenital form. To date total of 38 mutations in the GBE1 gene have been reported with different phenotypes and include missense, nonsense, insertion, deletion and splice site mutations. Majority of the mutations reported with the congenital type cause truncation of the protein, explaining the severity of the phenotype. Our case shows the importance of a thorough autopsy in delineating the etiology of hydrops fetalis.

2296F

Evidence of inflammation in organs of male reproductive tract of the MPS I mouse model. *V. D Almeida[1], C. C. Nascimento[1], O. Aguiar-Jr[2].* 1) Psychobiology, Univ Federal de Sao Paulo, Sao Paulo, Sao Paulo, Brazil; 2) Biosciences, Univ Federal de Sao Paulo, Sao Paulo, Brazil.

Several pathophysiologic mechanisms have been described in mucopolysaccharidoses (MPS) resulting in cellular, tissue and organ damage, demonstrated in patients and animal models. We have previously investigated some male reproductive parameters in MPS I murine model and detected lower sperm production, lower weight of seminal vesicles and testicular histopathological alterations, especially in the interstitial compartment, including high number of vacuolated cells and a higher interstitial area when compared to controls. In order to investigate these alterations in more detail, we evaluated the testicular ultrastructure of 6-month-old *Idua*-/- C56BL mice by transmission electron microscopy and examined the histology of epididymis, seminal vesicles and prostate. In testicular analysis, we detected some cell types that appear to be inflammatory infiltrates completely full of vacuoles, with lysosomal characteristics. Testicular macrophages interact in a paracrine way with Leydig cells and interfere in testosterone production, a potent androgen important for signaling in many tissues, besides reproductive tract. Considering that the observed cell types are indeed infiltrated macrophages, it is possible that testosterone production is unbalanced, which may also explain part of the symptomatology of the disease. Interestingly, these inflammatory infiltrates have also been identified in histological sections of epididymis, seminal vesicles and prostate. Inflammation is the cause of a significant portion of the morbidities and progressive decline suffered by MPS patients. However, the alterations observed in these structures have not been previously described. Cells of the immune system seem to be present in these infiltrates and we hypothesize that macrophages could be responsible for an inflammatory cascade related to damage or dysfunction caused by lysosomal storage in the male reproductive tract.

2297T

A new disorder of O-glycosylation due to a mutation in the X-linked OGT gene is associated with microcephaly, epilepsy, abnormal sleep architecture, intellectual disability and hypothyroidism. *A. Huq, F. Serajee.* Dept Pediatric Neurology, Children's Hosp Michigan, Detroit, MI.

Background: OGT gene on Xq13 encodes a glycosyltransferase that transfers a single N-acetylglucosamine from UDP-GlcNAc to a serine or threonine residue in many cytoplasmic and nuclear proteins. It is involved in cellular processes including chromatin structure, glucose homeostasis, and circadian oscillation of clock genes. Currently mutation in OGT is not known to cause any Mendelian disorder in human. Case Report: We studied a 6-year-old boy with microcephaly, intellectual disability, hypothyroidism, abnormal sleep pattern, nystagmus and epilepsy. His EEG revealed disorganized background and absent sleep spindle in addition to epileptiform waves. Investigations revealed an abnormal oligosaccharide pattern in urine. Exome sequencing was performed using genomic DNA isolated from the patient, parents and a healthy brother. Results: Exome sequencing revealed a hemizygous c. 775G>A (pA259T) mutation in exon 7 of the X-linked gene OGT causing the alanine at amino acid position 259 to be replaced by threonine. Mother was heterozygous for this alteration, while father and healthy brother did not show this change. The alteration is not observed in healthy cohorts, conserved throughout evolution and is predicted to be deleterious by in silico models. The p259 amino acid is located in the sixth tetratricopeptide repeat, important for binding to protein substrates and transfer of N-acetylglucosamine. Conclusion: Our patient's phenotype is consistent with OGT gene function and observed phenotype in mice with altered OGT. That mutations in an interacting protein of OGT (HCFC1) cause microcephaly, developmental delay and intractable epilepsy is also notable. Our patient likely represents a new disorder of O-glycosylation resulting from mutation in OGT gene.

The common MERRF mutation in a three generation pedigree with multiple symmetric lipomatosis. *S. Seneca[1], N. Revencu[2], J. Smet[3], A. Vanlander[3], K. Stouffs[1], A. Gheldof[1], R. Van Coster[3], L. De Meirleir[4], M. Bonduelle[1].* 1) Center for Medical Genetics, UZ Brussel & REGE, Vrije Universiteit brussel, Brussels, Belgium; 2) Center for Human Genetics, Catholic University of Louvain, Brussels, Belgium; 3) Department of Paediatric Neurology and Metabolism, Ghent University Hospital, Ghent, Belgium; 4) Department of Paediatric Neurology and REGE, UZ Brussel & Vrije Universiteit Brussel, Brussels, Belgium.

Background : Disorders of OXPHOS are among the most common conditions of metabolic disorders with mutations in both the mitochondrial and nuclear genomes underlying these diseases. Mutational hotspot positions of the mtDNA include the recurrent m. 8344A>G MERRF mutation in the *MT-TK* gene. Mitochondrial disorders often present as a multisystem disease with a very heterogeneous phenotype for an identical mutation, even within the same family. **Objective** : We investigated a possible mitochondrial dysfunction in a patient with multiple symmetric lipomatosis (MSL) by assessing the integrity of the mtDNA and investigating OXPHOS complex activities with, respectively, molecular and biochemical assays in several tissues of the index case. **Results** : Molecular investigation of the mitochondrial genome identified the presence of the common m. 8344A>G MERRF mutation in the *MT-TK* (tRNA Lys) gene of leukocytes, skeletal muscle and adipose tissue. Spectrophotometric analysis of muscle tissue revealed a decreased complexIV enzymatic activity. In addition, BN-PAGE analysis documented overall low activity of complexesI, III, and IV, and subcomplexes of complexV. The presence of the m. 8344A>G mutation was also seen in several other members of this pedigree, at least inthree generations. **Conclusions** : Multiple symmetric lipomatosis (MSL), also known as Launois–Bensaude syndrome or Madelung's disease, is a rare disorder predominantly seen in middle-aged male patients. In the past, publications have suggested, among others, an association with mitochondrial dysfunction. Although the typical manifestations of myoclonic epilepsy and ragged-red fibers disease were not present in our index patient, his mtDNA tested positive for the presence of the classic MERRF mutation. Therefore, we suggest that investigation of the mitochondrial genome in patients presenting with a familial history of MSL might be indicated. The common MERRF mutation can cause severe cellular dysfunction with a fatal outcome.

2299T

A distinct type of 3-methylglutaconic aciduria due to a mutation in the Translocase of Inner Mitochondrial Membrane 50 (*TIMM50*) gene. *F. Serajee, A. Huq.* Pediatrics, Wayne State University, Detroit, MI.

BACKGROUND: 3-methylglutaconic aciduria is a heterogeneous group of disorders and include several inborn errors of metabolism biochemically characterized by increased urinary excretion of 3-methylglutaconic acid. Defective leucine metabolism and various disorders affecting mitochondrial function have been identified as causes of conditions in which 3-methylglutaconic aciduria is a distinctive feature. We report a homozygous mutation in mitochondrial TIMM50 gene in a family with 3 affected siblings with a distinctive type of 3-methylglutaconic aciduria. METHODS: We investigated a patient of South Asian ancestry with intractable epilepsy, microcephaly, developmental delay, visual deficit spastic quadriplegia. Metabolic testing revealed large amount of 3-methylglutaconic acid in urine. Parents were consanguineous and two earlier-born sisters of the patient had a similar phenotype, 3-methylglutaconic aciduria and unexpected death after an infection during a visit to their country of origin. Detailed clinical history, imaging, EEG and metabolic testing were obtained for all affected persons. Full exome sequencing was performed using genomic DNA isolated from one surviving patient, two healthy siblings and both parents. RESULTS: Exome sequencing identified a homozygous c. 1114G>A (p. G372S) mutation in the gene TIMM50. There were no other candidate alterations in exome that could explain the phenotype in the proband. The G372 amino acid position in TIMM50 gene is completely conserved in eukaryotes all the way from the yeast Saccharomyces cerevisiae to humans. The p. G372S alteration is predicted to be probably damaging and deleterious by PolyPhen and SIFT in silico analyses, respectively. The p. G372S alteration is located in the conserved C-terminal domain of the Tim50 protein that interacts with the N-terminal domain of the Tim23 protein in the intermembrane space and regulates mitochondrial protein import of presequence-containing polypeptides Both parents are heterozygous. The patient's healthy sister is homozygous normal and her healthy brother is heterozygous. The segregation pattern is consistent with the TIMM50 gene mutation being the etiology of patient's 3-methylglutaconic aciduria. CONCLUSION: TIMM50 gene mutation results in a novel mitochondrial membrane associated disorders with 3-methyl glutaconic aciduria.

Introduction: Cerebral creatine deficiency syndromes (CCDS) are caused by genetic defects in L-arginine:glycine amidinotransferase (AGAT), guanidinoacetate methyltransferase (GAMT) , and creatine transporter 1 (encoded by *SLC6A8*). SLC6A8 deficiency leading cause of CCDS, is estimated to account for 1-2percentofmaleswith ID. The common clinical features of CCDS are intellectual disability (ID), speech delay, autistic behavior, and seizure. CCDS can be diagnosed bymeasurement of urinary creatine (CR), guanidinoacetic acid (GA), and creatinine (CN) in urine, decreased peak of creatine in magnetic resonance spectroscopy (1H-MRS) of thebrain, and molecular genetic analysis. Three types of CCDS can be differentiated from the abnormal ratio of CR to CN, or GA to CN in urine. Recently we have established a simple high performance liquid chromatography (HPLC) method to quantify CR, GA, and CN in urine and diagnosed 6 families with CCDS in Japan. We reviewed identified mutations in *SLC6A8*of 10 patients from 5 families and*GAMT*of one patient, and the results of their urinary analysis. **Methods:**The separation of CR, GA, and CN in urine was performed on a ion chromatography column with UV detection. Genomic DNA and RNA extracted from the leucocytes of patients, were subjected to PCR and Sanger sequencing. **Results:**CR, GA, and CN were separated clearly using ion chromatography column. We succeeded to detect 5 families with SLC6A8 deficiency and one patient with GAMT deficiency. **Conclusion:**HPLC method would contribute to early diagnosis and intervention for patients with CCDS. CCDS, especially AGAT or GAMT deficiency, can be treatable with creatine, andSLC6A8 deficiencymay be treatable with cyclocreatine in the near future. Most patients withSLC6A8 deficiency appear to remain undiagnosed in Japan, and the systematic screening system should be established using this method.

Characterizing the genetic basis of Leigh Syndrome, the most common mitochondrial disorder affecting children. *N. J. Lake[1,2], A. G. Compton[1,2], S. E. Calvo[3,4,5], V. K. Mootha[3,4,5], D. R. Thorburn[1,2,6]*. 1) Murdoch Childrens Research Institute, Melbourne, Victoria, Australia; 2) Department of Paediatrics, University of Melbourne, Australia; 3) Howard Hughes Medical Institute and Department of Molecular Biology, Massachusetts General Hospital, Boston, USA; 4) Department of Systems Biology, Harvard Medical School, Boston, USA; 5) Broad Institute of Harvard and MIT, Boston, USA; 6) Victorian Clinical Genetic Services, Royal Children's Hospital, Melbourne, Australia.

Leigh syndrome (LS) is the most common pediatric clinical presentation of inherited mitochondrial energy generation disorders. LS is genetically heterogeneous, and can be caused by mutations in over 70 different genes. Here we present an update on 67 patients from a previously ascertained cohort, comprised of 35 patients with definite LS and 32 Leigh-like patients, diagnosed according to stringent diagnostic criteria. At the time of publication in 1996[1], the genetic basis of ~25% (18 patients) was known. Using contemporary technologies, including massively parallel sequencing (MPS), we have now established the genetic basis of disease in 75% of the cohort (50 patients), including in 34 of the 35 LS patients and 16 of 32 patients with Leigh-like syndrome. Pathogenic mutations in seventeen different disease genes and a mitochondrial DNA deletion were identified. Our results reveal multiple novel pathogenic mutations in known LS disease genes including 3 in *SLC19A3*, and expand the phenotypic spectrum of known LS disease genes such as *SERAC1*. Furthermore we expand the phenotypic spectrum of known mitochondrial disease genes to include LS such as *C10orf2*. The mutations were inherited in a maternal (46%), autosomal recessive (42%) or X-linked (12%) manner. The identified disease genes encoded proteins associated with the activity of oxidative phosphorylation (OXPHOS) complexes I (26%), IV (18%), V (22%) or pyruvate dehydrogenase (22%). Molecular defects in genes associated with a combined OXPHOS deficiency were observed in 12% of patients. We also show examples where routine approaches would have missed the genetic diagnosis or resulted in miscalling of the causative mutations, and illustrate how careful analysis of MPS data can achieve a genetic diagnosis where routine filtering failed to identify any candidates. Overall, our results highlight the significant genetic heterogeneity underlying LS, and provide key insight into the etiological basis of disease in a large well characterized cohort. Evaluation of diagnostic outcomes from the application of MPS will facilitate the development of diagnostic clinical exome testing in LS patients. 1. Rahman S, Blok RB, Dahl HH, et al. Leigh syndrome: clinical features and biochemical and DNA abnormalities. Ann Neurol. 1996 Mar;39(3):343-51.

Anaemia represents a heterogeneous group of hematologic diseases, which can be induced by plenty of genetic and risk factors. Although the association of mitochondrial dysfunction and hematologic pathology is generally known, the underlying pathologic factors with regard to evolving anaemias are poorly characterized. In this study, we report on three patients, who manifested profound cytochrome c oxidase deficiency combined with anaemia. Genetic causes of their OXPHOS deficiency were found with the use of targeted sequencing of mitochondrial exome and SNP microarray analysis. A rarely occurring pathological 6-kbp homozygous deletion was identified in two unrelated patients affecting the *PUS1* gene, which remarkably leads to different disease-phenotype in both patients. Two previously characterized deleterious missense sequence variations of *COX10* gene (p. Asn204Lys; p. Pro225Leu) were identified in the third patient, however, their combination has not been reported yet, which may imply the variant patient disease-phenotype. Based on our results and current knowledge, we suggest the infantile deficiency of *PUS1* and *COX10* to be classified as the early fatal and slowly progressive forms. To conclude, mitochondrial disorders manifest poor phenotype-genotype correlation even in the patients with the same causal mutations. *This study was supported by grants RVO-VFN64165/2012, IGA NT13114-4, IGA NT14156–3 and GAČR 14-36804G.* .

Glutaric acidemia type 1 (GA-1, OMIM 231670) is an autosomal recessive inborn error of metabolism caused by the deficiency of glutaryl-CoA dehydrogenase. We present a retrospective analysis of clinical profile and mutation analysis in twenty six unrelated families with affected children (27 cases total). The mean age at onset of illness was 9. 7 months (+/-11. 07) whereas the mean age at referral for molecular diagnosis was 35. 81 months (+/- 32. 9). Patients were referred from different states of India (Karnataka, Maharashtra, Tamil Nadu, Gujarat, Andhra Pradesh, Uttar Pradesh, Punjab and Jammu and Kashmir). Clinical presentation varied from asymptomatic, acute encephalitis followed by neuro-regression and chronic developmental delay. Macrocephaly was present in 16/27 cases, dystonia was present in 23/27 cases. Patients underwent blood tandem mass spectrometry and/or urine gas chromatography mass spectrometry. Neuroimaging demonstrated batwing appearance in 95% cases. Sequencing of GCDH gene was done covering all exons and exon-intron boundaries. Mutations could be identified in nineteen families, whereas no mutations could be identified in four families. Molecular analysis is ongoing in four families. Mutations identified include novel ones such as p. P217S, p. L179V, p. L345P, c. 1167delG, p. K377R, p. M100T, p. T344T, p. W225X, p. G269S, p. H403Y, p. L424P, p. S255P, p. N373K and known mutations such as p. R402W, p. L179R, p. M339V, p. A433V, p. R402Q, c. 1173delG and p. R128Q. Using *in silico* analysis, mutations were shown to be affecting the residues responsible for homotetramer formation of the glutaryl coA dehydrogenase protein. This is the largest mutation proven series of glutaric aciduria type 1 from India till date.

2304F

A synonymous splice site variant in *MTHFR* gene causing hyperhomocysteinemia with severe neurological dysfunction that was successfully reversed with early initiation of medical therapy. *D. Reed[1], H. Dai[2], A. Conner[1], J. Zhang[2], L. Wong[2], K. Oishi[1].* 1) Genetics & Genomic Sciences, Mt. Sinai School of Medicine, New York, NY; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Introduction: Methylenetetrahydrofolate reductase(MTHFR) is an enzyme encoded by the *MTHFR* gene to form 5-methyltetrahydrofolate, a cofactor for methionine synthase. Loss of function mutations cause a rare autosomal recessive severe neurological dysfunction characterized by sudden respiratory failure, coma, neonatal seizures and death. We identified a homozygous synonymous splicing variant in *MTHFR* in an infant with sudden severe neurological depression. **Case:** The patient was a 3 week old female born to consanguineous Pakistani parents. At 17 days, she had a sudden onset of lethargy, poor feeding and cyanosis. She was intubated in the ER and at 20 days old started having seizures. She was non-dysmorphic, edematous and comatose with flaccid hypotonia, absent reflexes and a markedly distended bladder. Biochemical analyses demonstrated elevated plasma homocysteine and decreased methionine levels with absence of methylmalonic acid accumulation, consistent with hyperhomocysteinemia. SNP microarray did not show any microdeletions or duplications. Treatment for presumptive MTHFR deficiency with folinic acid, vitamin B6 and hydroxycobalamin was started. Within days her neurological function was fully recovered. **Methods:** Genomic DNA and total RNA were isolated. Next generation and Sanger sequencing were performed. RT and Real-time PCR were used to verify the transcription patterns of *MTHFR* in the proband and her parents. **Results:** We identified a homozygous synonymous splicing variant c. 1530G>A (p. Lys510Lys). With RT-PCR a significant reduction of wild type transcript in the parents and abolished expression in the proband was seen. The exon 9 skipping form was the major transcript in the proband and was absent in the control. A transcript with a 5bp GTGTG insertion at the 3' end of exon 9 and a novel shorter transcript skipping exon 9 and 10 was identified. Her heterozygous parents expressed normal and truncated transcripts. The variant was seen not in the region of homozygosity on microarray, indicating a possible founder effect for this variant. **Conclusions:** We identified a homozygous c. 1530G>A variant in the *MTHFR* gene in a newborn with hyperhomocysteinemia and sudden severe neurological dysfunction. The variant results in much higher expression of abnormal transcripts that may lead to non-functional MTHFR protein. Rapid initiation of treatment can reverse the severe neurological presentation of MTHFR deficiency and is essential for improving the prognosis.

2305T

Prevalence and severity of non-motor manifestations associated with parkinsonism in patients with Gaucher disease and *GBA1* mutation carriers. *G. Lopez[1], J. Kim[1], D. Cintron[3], E. Wiggs[2], C. Groden[1], E. Sidransky[1].* 1) NHGRI/NIH, Bethesda, MD; 2) NINDS/NIH, Bethesda, MD; 3) PHSU, Ponce, PR.

Objective: To identify the prevalence and severity of non-motor symptoms in a group of patients at risk for developing Parkinson disease (PD). **Background:** The link between mutations in the glucocerebrosidase gene (*GBA1*) and the risk for the development of parkinsonism is well-established in the literature. The prevalence of non-motor symptoms associated with sporadic PD that may be present years before motor manifestations has not been explored in subjects affected with Gaucher disease or carrying *GBA1* mutations without clinical evidence of parkinsonism. **Design/methods**: Patients with Gaucher disease or mutation carriers with a family history of Parkinson disease were longitudinally evaluated at the National Institutes of Health, National Human Genome Research Institute Genetics clinic. A series of validated scales assessing depression, fatigue, restless legs symptoms, olfactory function, anxiety, and cognition were administered during their evaluation. Complete physical and neurological evaluations were done to confirm the absence of parkinsonian motor features. **Results:** Sleep disturbances were more frequently reported by patients with Gaucher disease and mutation carriers compared to unaffected individuals, but less frequently than by patients with parkinsonism. Interestingly, anxiety scores were high in subjects with Gaucher Disease and mutation carriers. **Conclusions:** Continued longitudinal evaluation of patients with Gaucher disease and carriers of *GBA1* mutations may help identify a pre-motor phase in this cohort at risk of developing parkinsonism. This pre-motor profile may suggest specific neurotransmitters involved in neurodegeneration and contribute to a better understanding of the association between lysosomal dysfunction and alpha-synuclein aggregation.

2306F

Cognative assessment of patients with type 3 Gaucher disease. *E. Wiggs[1], G. Lopez[1], J. Kim[1], O. Goker-Alpan[1,2], R. Schiffmann[1,3], E. Sidransky[1].* 1) Medical Genetics Branch, NHGRI, NIH, Bethesda, MD; 2) Baylor Institute of Metabolic Disease, Dallas Tx; 3) O&O Alpan, LLC. Fairfax, VA.

BACKGROUND: Neuronopathic Gaucher disease presents with diverse neurological manifestations including cognitive impairment. Standardized tests of intellectual ability were individually administered to monitor change over time, as well as to probe for patterns between subjects and within subjects. METHOD: Twenty-seven patients (13 males) with type 3 Gaucher disease were assessed using either a Wechsler IQ scale (N=25) or a structured interview of the parent when the patient was either too young or too impaired to respond accurately to the individual IQ test (N=2). Twenty-one had repeated follow-up. All patients were being treated with enzyme replacement at the time of assessment. RESULTS: At the initial evaluation, the mean Full Scale IQ was 74. 26 +/- 25. 13 (N=25) (mean= 100 +/- 15) with a range from 40 (profound intellectual deficiency) to 124 (superior intellectual ability). Four of the 25 subjects had Full Scale IQ scores of 100 or higher. Subsequent evaluations completed 2-9 years later, revealed a mean of 78. 1 +/- 25. 9; an insignificant difference. One child had seven evaluations over a ten year period and the scores remained stable throughout this interval. There was no correlation between genotype and IQ scores, and among 20 patients known to have genotype L444P/L444P, Full Scale IQ scores ranged from 40-124. However, differences between verbal ability and nonverbal ability were identified, which were most pronounced among patients with average or near average IQ scores. Of the nine with Full Scale IQ scores over 90 (25th percentile), eight had lower nonverbal ability (mean difference = 13. 5 with a range of 4 to 38 points). DISCUSSION: Cognition, as reflected by IQ testing, was quite variable among subjects with type 3 Gaucher disease ranging from individuals with superior intellectual ability to others with profound intellectual deficiency. The degree of intellectual impairment did not correlate with the patient's age or genotype. Results tended to remain stable over the time interval studied and were not affected by enzyme replacement therapy. The observed discrepancy between verbal and nonverbal abilities identifies a potential learning issue that requires the attention of educators and caregivers.

2307T

Prospective Natural History Study of Mucopolysaccharidosis Types IIIA and B (Sanfilippo). *K. L. McBride[1, 2], K. Bain[2], K. Kunkler[3], K. McNally[4], R. Grimes[4], N. Zumberge[5], L. Martin[5], S. C. Aylward[6], L. Alfano[7], K. Berry[7], L. Lowes[7], M. Corridore[8], C. McKee[8], D. A. McCarty[3], H. Fu[3], K. M. Flanigan[2, 3, 7].* 1) Center for Cardiovascular and Pulmonary Research, Nationwide Children's Hospital, Columbus, OH; 2) Department of Pediatrics, Ohio State University, Columbus OH; 3) Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH; 4) Center for Biobehavioral Health, Nationwide Children's Hospital, Columbus, OH; 5) Department of Radiology, Nationwide Children's Hospital, Columbus, OH; 6) Section of Neurology, Nationwide Children's Hospital, Columbus, OH; 7) Department of Physical Therapy, Nationwide Children's Hospital, Columbus, OH; 8) Department of Anesthesiology, Nationwide Children's Hospital, Columbus, OH.

Mucopolysaccharidosis (MPS) type III (Sanfilippo) is a group of 4 enzyme deficiencies leading to tissue accumulation of heparin sulfate. CNS disease is prominent with initial normal development then cognitive decline, hyperactivity, and death. Somatic findings are modest. This study will prospectively assess individual longitudinal disease progression in MPS IIIA and IIIB to define suitable outcomes for future gene transfer trials. Inclusion criteria are age >2 yrs with confirmed MPS IIIA or B and neurologic dysfunction. Planned visits are at 0, 6, and 12 months. 15 IIIA (M=9, F=6; age 5. 0 +/- 1. 9 y) and 10 IIIB subjects (M=8, F=2; age 8. 7+/- 3. 2 y) have completed baseline evaluation; 10 total have finished 12 months. Anesthesia was administered safely >30 times for MRI. Baseline tests showed declines in Leiter, Mullen, and Vineland scales and the Pediatric Evaluation of Disability Inventory as a function of age. Skills peaked at 2. 5-3. 0 year level, with a slight continued mobility gain at early ages before decline. Several subjects had a measure floor effect. The Child Behavior Checklist had scattered results with little change from 0 to 6 months. The 10 meter, six minute, and four-stair walk proved difficult to administer reliably. Actigraphy data suggests reduced sleep efficiency and increased time awake. Serum ALT is high and increases with age. Urine GAG levels decline steeply as a function of age, approaching normal in older subjects. Baseline brain MRI changes (observed as young as 3 yrs) included cerebral volume loss, primarily of white matter. MRS showed decreased N-acetylaspartate:creatine ratios in white and grey matter, with a reduction in choline to creatine ratios in grey matter. Average MRI liver volume was 2. 2X normal, and spleen size was 1. 9X normal. CSF protein rose with age, and may reflect BBB damage with protein leakage or inflammatory proteins. Preliminary data analysis suggests several outcome measures could be used in a gene transfer study, including cognitive function by the Leiter and Mullen, adaptive functions via the Vineland parent interview; liver and spleen size by MRI, and MRI spectroscopy markers. The utility of the CBCL as an assessment of change over time is uncertain. 6MW tests will not be useful in this population. Urine GAG decline with age will need to be incorporated into efficacy measures to avoid incorrect interpretation, and increased serum ALT and CSF protein will need to be accounted for in safety monitoring.

2308F

Autopsy findings in Gaucher disease indicate variability in response to therapy. *D. K. Borger[1], G. Lopez[1], J. Kim[1], M. Allgaeue[2], H-W. Wang[2], E. Sidransky[1].* 1) Medical Genetics Branch, NHGRI, NIH, Bethesda, MD. , Select a Country; 2) Laboratory of Pathology, NCI,NIH. Bethesda, MD.

Gaucher disease (GD), the inherited deficiency of the lysosomal enzyme glucocerebrosidase, exhibits considerable phenotypic diversity. Over the past two decades many patients with GD have been treated with enzyme replacement therapy (ERT), intravenous infusions of recombinant glucocerebrosidase. Clinically, ERT results in significant improvements in the visceral and boney manifestations, but there have been few pathologic studies documenting reversal of disease. We reviewed the pathologic findings of five adult patients with GD where full autopsy studies were performed. All five were referred to the NIH Clinical Center, and autopsies were performed primarily because of the development of parkinsonian manifestations. The five patients included four females and one male and age at diagnosis of GD disease ranged from 8-47 years, with most diagnosed by age 19. Four underwent splenectomy prior to the availability of ERT. The age at death was between 53-70 years (mean 60 years). All were diagnosed by deficient levels of glucocerebrosidase as well as by genotype, which included two patients with N370S/c. 84insG, and one each with N370S/L444P, N370S/N370S and D409H/L444P. All five patients received ERT for 4-22 years in doses between 60-400IU/kg/month. Remarkably, at autopsy two patients had no evidence of any Gaucher cells, the characteristic pathologic finding in GD, in the liver, spleen, bone marrow or lungs. These patients did not have the longest duration or highest doses of ERT. One patient had a relatively low disease burden, with occasional Gaucher cells in the bone marrow, but none in the liver, lungs or GI tract. The fourth patient was also noted to have a moderate disease burden, with occasional Gaucher cells seen in the liver and leptomeninges. Interestingly, the fifth patient, who received the longest duration (22 years) and highest doses of ERT (up to 100IU/Kg/week prior to her death) had significant Gaucher pathology including extensive involvement of her liver, bone marrow and lungs. Furthermore Gaucher cells were found in her pancreas, small intestine, adipose tissue of the breast, lymph nodes, and eyes. The autopsy studies demonstrate a wide range of disease involvement in treated patients, not specifically associated with age, genotype, duration and dose of therapy or splenectomy. Such studies will be important for the identification of genetic or environmental modifiers impacting disease pathogenesis, burden and response to therapy.

2309T

Erythropoietic Protoporphyria (EPP) and X-Linked Protoporphyria (XLP): Clinical, Biochemical and Molecular Characterization of North American Patients. *M. Balwani[1], H. Naik[1], K. E Anderson[2], D. M Bissell[3], J. Bloomer[4], H. L Bonkovsky[5], J. D Phillips[6], J. Overbey[7], I. Peter[1], R. J Desnick[1], Porphyrias Consortium of the Rare Diseases Clinical Research Network.* 1) Genetics and Genomic Science, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Preventive Medicine and Community Health, University of Texas Medical Branch, Galveston, TX,; 3) Department of Medicine, University of California, San Francisco, CA; 4) Department of Medicine, University of Alabama, Birmingham, AL; 5) Department of Internal Medicine, Wake Forest University School of Medicine, Winston-Salem, NC; 6) Department of Internal Medicine, University of Utah, Salt Lake City, UT; 7) Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York, NY.

EPP and XLP are inborn errors of heme biosynthesis with the same phenotype, but resulting from autosomal recessive ferrochelatase (*FECH)* gene mutations or erythroid-specific 5-aminolevulinate synthase (*ALAS2*) gene mutations, respectively. They are characterized by severe, painful photosensitivity and markedly elevated erythrocyte protoporphyrin (PP) levels. Liver dysfunction/liver failure can occur in ~5% of patients. Here, we present clinical, biochemical and genetic features in 211 (190 EPP, 21 XLP) North American patients. Biochemically and/or mutation confirmed patients were enrolled into the Longitudinal Study of the Porphyrias [clinicaltrials. gov: NCT01561157] from 2010 to 2015. Median age of the patients was 36 years (range: 3-77 years; males: females, 1:1) and 94 % were Caucasian. Median age of symptom onset for EPP patients was 3 years (n=149) and XLP males was 2. 3 years (n=6). 61% of EPP patients and all XLP males reported symptom onset in ≤30 minutes of sun exposure. XLP females (n=11) had variable degrees of sun sensitivity, with 5 reporting symptoms ≤30 minutes of sun exposure and others with no symptoms. 45% of patients reported 3-10 painful phototoxic episodes in a year with a majority of patients taking 1-3 days to recover. Most described the phototoxic pain as “burning” (95%), “tingling” (82%) and/or “itching” (80%). Elevated liver function tests were reported in 30% of patients. Two patients had liver transplants. Anemia was noted in 47% of EPP, and 30% and 78% of XLP male and female patients, respectively. Of the 181 patients genotyped, all XLP patients had an *ALAS2* mutation and 158 had a *FECH* mutation in *trans* with the common low expression allele; 4 patients did not have an identifiable mutation in *FECH* or *ALAS2*. *FECH* mutations included missense (28%), deletions (27%), consensus splice site (23%), and nonsense (17%) lesions. Mean erythrocyte PP levels were significantly higher in XLP males (mean 4251 ug/dL) as compared to EPP patients (mean 1759 ug/dL). XLP females had markedly variable PP levels (range 201 to7544 ug/dL) consistent with clinical symptoms. Baseline data from EPP and XLP patients shows that most patients presented clinically with acute cutaneous photosensitivity in early childhood; the most common symptom being burning pain. Higher PP levels were associated with decreased time to burn and increased risk of liver dysfunction indicating that PP levels are a major determinant of disease severity in these patients.

2310F

Novel report of phosphoserine phosphatase deficiency presenting in an adult. *H. M. Byers[1], R. L. Bennett[1], E. Malouf[1], M. D. Weiss[2], J. Feng[1], C. R. Scott[1], S. Jayadev[1,2].* 1) Division of Medical Genetics, University of Washington, Seattle, WA; 2) Department of Neurology, University of Washington, Seattle, WA.

Serine is a non-essential amino acid that plays a vital role in proper development and functioning of the central nervous system. Serine deficiency syndrome consists of a group of autosomal recessive, inborn errors of metabolismresulting from a deficiency in ofone threeenzymes in the serine biosynthesis pathway: phosphoglycerate dehydrogenase (PHGDH), phosphoserine aminotransferase (PSAT) or phosphoserine phosphatase (PSPH). Serine deficiencycan cause microcephaly, intellectual disability, seizures, and psychomotor retardation in children and severe axonal neuropathy in the adult. Of critical importance to clinical care of these patients, serine deficiency syndrome is treatable. Although the first case of phosphoserine phosphatase deficiency (MIM #172480) was described nearly twenty years ago, only eight cases have been reported, all in children. We describe the novel presentation of phosphoserine phosphatase deficiency in an adult, expanding the currently understood phenotype. The patient is a 37-year-old woman with lifelong intellectual disability, childhood onset epilepsy (absence seizures) and microcephaly. At age twenty, she developed lower extremity hypertonia, abnormal gait and progressively severe axonal neuropathy. Contractures in her hands and fingers were noted from age thirty-two. Clinical presentation was concerning for metabolic neuropathy. Electromyogram and nerve conduction studies confirmed axonal neuropathy. Brain magnetic resonance imaging showed no abnormalities. Plasma amino acid evaluationshowed markedly low serine and moderately low glycine. Molecular testing revealed two novel, compound heterozygous mutations in phosphoserine phosphatase (*PSPH*, NM_004577. 3)*:* c. 131T>G (p. Val44Gly) and c. 421G>A (p. Gly141Ser). Treatment with oral serine resulted in improvement of plasma amino acid laboratory values and a subjective increase in energy. This is the first report of phosphoserine phosphatase deficiency presenting in an adult.

2311T

Pancreatitis and Maple Syrup Urine Disease. *J. Duis[1], A. Hamosh[1], C. Koerner[1], A. Pipitone[1], V. Kumbhari[2], G. Maegawa[1], D. Valle[1], M. Gunay-Aygun[1].* 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins, Baltimore, MD; 2) Department of Medicine, Gastroenterology, Johns Hopkins, Baltimore, MD.

Maple syrup urine disease (MSUD) is an autosomal recessive disorder of branched-chain amino acid degradation caused by deficiency of the branched-chain α-keto acid dehydrogenase complex. Classically, MSUD presents in the neonatal period with poor feeding, irritability, lethargy, and progressive neurological deterioration. Treatment consists of a diet restricted in natural, branched-chain amino acids (BCAA) containing protein, and supplementation of non-BCAA, valine and isoleucine. Individuals with the disorder present with acute metabolic decompensation in the setting of increased catabolism. With the implementation of newborn screening, early detection of children with MSUD likely will redefine what is known about the natural history and complications of the disease. Rarely, pancreatitis, defined as the presence of the reversible inflammation within the pancreatic parenchyma, is reported as a complication of MSUD. Unlike the organic acidemias, in which pancreatitis is a more clearly described complication, in MSUD, the experience with this complication is more varied. Some report this complication at day two to three of hospitalization in the setting of improved metabolic control after an acute presentation with markedly elevated leucine levels. Reports in the literature are varied and include patients with chronic pancreatitis, acute hemorrhagic pancreatitis, and pancreatitis that developed during an inpatient hospital stay for gastroenteritis. We report a case of a 13-year-old male with MSUD with recurrent pancreatitis in the setting of ansa pancreatica, a rare anatomical variant of pancreatic ducts. We draw on our experiences from his multiple recurrences including leucine levels at the time of presentation, clinical presentation, imaging, and lab findings to help understand pancreatitis as a complication of MSUD. In addition, we discuss other patients with MSUD who have presented to our center with pancreatitis and compare these experiences to further characterize pancreatitis in this patient cohort. We discuss the possible underlying mechanisms and attempt to develop an understanding of the circumstances under which patients with MSUD are likely to develop this complication to optimize clinical care of these patients.

2312F

Phenotypes and genotypes of 35 cases with betaketothiolase deficiency in a Vietnamese referral center. *K. Nguyen[1], D. Vu[1], H. Nguyen[1], S. Yamaguchi[2], T. Fukao[3].* 1) Department of Endocrinology, Metabolism, Genetics, National Hospital of Pediatrics, Hanoi, Viet Nam; 2) Shimane University School of Medicine, Japan; 3) Graduate School of Medicine, Gifu University, Japan.

Betaketothiolase (T2) deficiency is rare inherited metabolic disease worldwide. But it is the most common organic aciduria in Vietnam with 35 cases. *Objectives:* to describe phenotypes, genotypes of T2 deficiency. *Methods:* descriptive study of 35 patients with T2 deficiency at National Hospital of Pediatrics - Hanoi - Vietnam from 2005 to 2012. 21 cases from 19 families were analyzed of *T2* gene. *Results:* 35 patients were born to 30 unrelated families and unconsanguinity parents. 33/35 patients presented crisis of ketone acidosis. One case was diagnosed without symptom at 3 days of age but developed the crisis at 6 months of age. One case was asymptomatic until now (5 years old). Mean onset of the first crisis was 13. 1 months. Clinical features of the crises were dehydration, tarchypnea, lethargy/coma and triggered by infections. Laboratory of the crises showed 100 % severe ketone metabolic acidosis (pH: 6. 5 - 7. 05), leukocytosis. 94% cases recovered from the 1st crisis and 79% cases had normal development. 20/35 patients had recurrent crisis. 21/21 patients were found homozygous/compound heterozygous mutations of *T2* gene. Five different mutations have been identified. And R208X is the most common mutation in Vietnam (70% of mutant allele) as well as in the world. *Conclusions:* The biggest T2 deficiency patients were identified in a Vietnam center (account 1/3 total cases in the world). Worldwide, there are no common mutations of *T2* gene found except common R208X mutation in Vietnam.

2313T

Mice lacking Cox10 in T-lymphocytes recapitulate the immune phenotype of a cohort of patients with primary mitochondrial disease. *P. J. McGuire[1], S. Pacheco[2], M. K. Koenig[2], E. Barca[3], S. DiMauro[3], T. Tarasenko[1].* 1) National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 2) Department of Pediatrics, The University of Texas Health Science Center, Houston, TX; 3) Department of Neurology, Columbia University Medical Center, New York, NY.

Immune cells undergo major changes in cellular energy metabolism during proliferation and differentiation. This area of immunometabolism has recently seen a resurgence, however, studying primary mitochondrial disease (pMD) as a translational model system for understanding immune cell bioenergetics is unique. Immune dysfunction in patients with pMD is under appreciated. In a cohort of patients with pMD (N=55) clinical and laboratory data suggested defects in cellular and humoral immunity marked by frequent respiratory tract viral infections (64%) including upper respiratory viral infections, pneumonia and sinusitis. Twelve patients (22%) had functional immunodeficiency requiring IVIG replacement therapy. Flow cytometry revealed elevated naïve T-cells concomitant with low memory T-cells (CD45RO+). Via enzymatic and bioenergetic evaluation, we demonstrated that mitochondrial dysfunction can be traced to peripheral blood mononuclear cells in pMD, suggesting that the immune defects seen may result from a cell-intrinsic energy deficiency. In order to study cell-intrinsic defects in bioenergetics, we created a mouse model with an isolated cytochrome c oxidase (COX) deficiency by disrupting the *Cox10* gene in T-cells using a cre-recombinase system. Cox10flox/flox;CD4Cre/+ mice show good viability and display isolated COX deficiency in T-cells, manifesting as decreased cell numbers and proliferation, enhanced cell death (24% increase), and abnormal differentiation with reduced memory T-cells (22% decrease). Immunization with the T-cell dependent protein antigen (NP-CGG) resulted in decreased antigen specific IgG titers (60% decrease). Infection with influenza lead to the reduced production of viral specific memory T-cells in Cox10flox/flox; CD4Cre/+ mice. In addition, Cox10flox/flox; CD4Cre/+ mice were unable to clear influenza infection as reflected by significantly increased lung titers (P = 0. 03). Mechanistically, these defects in cellular function could be traced to the early stages of activation and are reflective of T-cell bioenergetic deficiency. In summary, we have successfully created an animal model system of T-cell intrinsic mitochondrial dysfunction, which recapitulates components of the immune phenotype seen in a subset of patients with pMD. These studies will not only help define the role of mitochondrial bioenergetics in immune cell function, which is of great interest in immunology, but will also expand this under-recognized phenotype of pMD.

2314F

Novel TATA Box Promoter Mutation in SUCLG1: Expansion of the Phenotype. *J. L. Fraser[1, 2], J. L. Sloan[2], S. I. Berger[1], I. Manoli[2], G. M. Rice[3], C. P. Venditti[2].* 1) Medical Genetics Training Program, National Human Genome Research Institute, Bethesda, MD; 2) Organic Acids Research Section, National Human Genome Research Institute, Bethesda, MD; 3) Department of Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, WI.

We present a 12 year old female, born to second cousin consanguineous parents, with mild methylmalonic acidemia, failure to thrive, and multisystemic disease. She presented in early infancy with severe axial hypotonia and developmental delays. She had lactic acidosis and hypoglycemia on fasting as an infant; in studies from muscle biopsy and fibroblasts, respiratory chain enzyme activities were normal, with no ragged red fibers on muscle histology. The patient also presented in mid-childhood with Raynaud phenomenon, ulcerations, low immunoglobulins without frequent infections, and proximal tubule dysfunction including tubular proteinuria, phosphaturia, and glycosuria. At 12 years, she had severe choreoathetosis and ataxia, with cystic necrosis of the basal ganglia and lactate peaks on MRS in affected brain regions. While moderately delayed, she has required no respiratory support or g-tube feedings, has functional receptive language abilities, and is able to sit and ambulate independently, despite use of a wheelchair for long-distances due to fatigability and instability. She has significant attentional deficits and obsessive-compulsive tendencies. Her clinical and laboratory symptoms prompted an exhaustive but unrevealing evaluation, which included sequencing of SUCLG1 and SUCLA2. After thorough phenotyping was performed under a NIH natural history clinical protocol for methylmalonic acidemia (clinicaltrials. gov identifier NCT00078078), a genomic evaluation using a dense whole genome array (CGH+SNP) demonstrated 65 Mb (2. 2%) of homozygous sequence. Exome sequencing data, analyzed using VarSifter and filtered to prioritize candidate genes within regions of homozygosity, identified a probable pathogenic variant that alters the TATA box in the SUCLG1 promoter (chr2:84686610 T>C). Western analysis of patient fibroblast extracts demonstrated markedly decreased expression of all subunits of the succinate-coenzyme A ligase complex compared to a maternal heterozygote control . We suggest that a promoter mutation has resulted in reduced transcription of SUCLG1, diminished protein expression and a concomitant decrease in other succinate-coenzyme A ligase complex subunits. Trace SUCLG1 expression and activity likely accounts for the attenuated phenotype displayed by this patient as compared to others previously reported. Promoter-reporter studies and expression analyses will further define the pathogenicity of the TATA box variant identified in this study.

2315T

Inborn errors of metabolism spectrum of MS/MS target diseases in Vietnam. *V. Dung[1], K. Nguyen[1], M. Nguyen[1], T. Bui[1], N. Can[1], H. Nguyen[1], H. Le[1], T. Fukao[2], S. Yamaguchi[3].* 1) Metabolism and Genetics, National Hospital of Ped. Hanoi, Viet Nam; 2) Department of Pediatrics, Graduate School of Medicine, Gifu University. Japan; 3) Department of Pediatrics - Shimane University School of Medicine. Izumo, Japan.

Vietnam is the easternmost country on the Indochina Peninsula in Southeast Asia. With an estimated 90 million inhabitants as of 2013, it is the world's 13th-most-populous country, and the eighth-most-populous Asian country. Congenital anomalies accounted about 22% of causes of deaths in children under-5 (2010). The first service for IEMs was set up at the Northern referral center of Pediatrics – National Hospital of Pediatrics, Hanoi (NHP) in 2004 officially. The NHP in Ha Noi provides services to the population of north VietNam (~30 million people). **Objectives**: The aim of this report is to highlight disease spectrum of MS/MS target disease in Vietnam. **Methods:** 2405 high-risk cases with IEMs were studied at NHP during 10 years (2005-2014). Dry blood and urine samples were analyzed using MS/MS (amino acid & acylcarnitine analysis) & GC/MS (organic acid anaysis) for screening from 2005. Organic acids analysis for fresh urine samples was performed using GC/MS and amino acid analysis for plasma samples were performed using HPLC for confirmation of diagnosis. **Results:** Oganic acidemia (OAs), amino acid disorders (AAs), urea cycle disorders (UCDs) and fatty acid oxidation disorders (FAOD) were identified in 240/2405 cases (9. 9%). 121/240 patients (50. 4%) were OAs with 12 different disorders: BKT (34 cases), PPA (21 cases), 5-oxoprolinuria (19 cases), MMA (15 cases), Glutaricaciduria type II (GA II) (11 cases), 3-methylglutaconic aciduria (4 cases), Isovaleric academia (4 cases), Multiple carboxylase deficiency (MCD) (2 cases), 3-methylcrotonylCoA carboxylase deficiency (2 cases). 43/240 patients (17. 9%) were amino acid disorders including 36 cases with MSUD, 7 cases with PKU and 1 case with Tyrosinemia type 1. 38/240 patients (15. 8%) were UCDs including OTC deficiency (15 cases), Citrulinemia type 1 (10 case) and Argininosuccinic aciduria (1 case). 39/240 patients (16. 3%) were FAOD including SCAD (3 cases), MCAD (3 cases), VLCAD (8 cases), LCAD (2 cases), CPT 2 (8 cases), CPT 1 (1 case) and Primary carnitine deficiency (14 cases). Mortality rate was reduced from 50% in 2005 to 9% in 2014. **Conclusions:** Treatable conditions of IEMs were most common in Vietnamese patient identified using MS/MS. Expending newborn screening using MS/MS should be introduced to reduce mortality in Vietnamese children.

Five years of newborn screening of inherited metabolic disorders in the Czech Republic. *K. Peskova[1], J. Bartl[1], P. Chrastina[1], L. Dvorakova[1], H. Vlaskova[1], L. Fajkusova[2], D. Friedecky[3], E. Hlidkova[3], R. Pazdirkova[4], D. Prochazkova[5], P. Jesina[1], Z. Hruba[2], T. Adam[3], V. Kozich[1].* 1) Inst Inherit Metabol Disorders, General University Hospital, Prague 2, Czech Republic; 2) Faculty of Medicine and University Hospital, Center of Molecular Biology and Gene Therapy, Masaryk University, Brno, Czech Republic; 3) Laboratory for Inherited Metabolic Disorders, Department of Clinical Biochemistry, University Hospital Olomouc, Czech Republic; 4) Third Faculty of Medicine and University Hospital Kralovske Vinohrady, Department of Pediatrics, Charles University, Prague, Czech Republic; 5) Faculty of Medicine and University Hospital, Department of Pediatrics, Masaryk University, Brno, Czech Republic.

Background:Early diagnosis of inherited metabolic disorders (IMD) enables better prognosis, treatment and survival of patients. After five years, we present the results of newborn screening program in the Czech Republic including 10 IMDs. International project Region4Screening recommends quality criteria for newborn screening of 30 IMD: the total detection rate of patients better than 1:3,000, the positive predictive value higher than 20 % and false positive rate lower than 0. 3 % of testing newborns. Methods:Amino acids and acylcarnitines were extracted from dried blood spot samples and analyzed by tandem mass spectrometry using kit MassChrom Amino Acids and Acylcarnitines. Molecular genetic analysis of phenylketonuria/hyperphenyalaninemia (*PAH*), MCAD deficiency (*ACADM*), LCHAD deficiency (*HADHA*) and glutaric aciduria type I (*GCDH*) was performed using Sanger sequencing. Results:Between October 2009 and December 2014 we analyzed samples from 577,756 newborns. We detected 166 patients with subsequently confirmed IMD. We detected 110 patient with phenylketonuria/hyperphenylalaninemia (PKU/HPA), 29 patients with MCAD deficiency, 10 patients with LCHAD deficiency, 4 patients with VLCAD deficiency, 3 patients with glutaric aciduria type I, 3 patients with isovaleric aciduria, 3 patients with hydroxyprolinemia, 2 patients with leucinosis and 2 patients with CPT I deficiency. One patient with intermittent MSUD was not recognized. The positive predictive value was 26. 2 % and false positive rate 0. 08 %. The total detection rate was 1:3,500. For the most frequent diseases (PKU/HPA 1:5,200; MCAD deficiency 1:19,900 and LCHAD deficiency 1:64,200) frequencies of pathological alleles and its geographical distribution in regions were evaluated. In the patients with PKU/HPA, MCAD deficiency, LCHAD deficiency and glutaric aciduria type I we have identified 51, 8, 6 and 6 different mutations, respectively. Conclusion:The results are in agreement with Region4Screening target performance. Nevertheless, our laboratory algorithms are still being optimized in order to reduce number of false positive cases. Nowadays, we propose to extend the newborn screening panel from 10 to 15 IMDs by adding citrullinemia type I, argininemia, CBS/methylenetetrahydrofolate reductase deficiency and biotinidase deficiency. Other 10 IMDs could be detected secondarily. Supported by MZ CR – RVO VFN64165 and OPPK CZ. 2. 16/3. 1. 00/24012.

2317T

Neonatal Screening of Lysosomal Storage Diseases in a Cohort of Mexican Population. *J. Navarrete[1], D. Cervantes[1], A. Limon[2], J. Ramírez[3].* 1) Dept Gen, Hosp Sur PEMEX, Mexico City, Distrito Federal, Mexico; 2) Dept Ped, Hosp Sur PEMEX, Mexico City, Distrito Fedral, Mexico; 3) Dept. Ped, Villahermosa PEMEX, Villahermosa, Tabasco, Mexico.

The goal of newborn screening is an early detection of inborn errors of metabolism diseases. In Mexico we began newborn screening since 1977 with very few inborn errors of metabolism such as phenylketonuria, galactosemia, congenital hypothyroidism, sickle cell anemia and cystic fibrosis. (1)Petróleos Mexicanos is a big governmental institution with approximately 15,000 workers with their families. Since 2005 a larger screening has been done to all newborns in this institution through all the country. We tested a total of 69 inborn errors of metabolism including most aminoacidopathies, acidurias, hemoglobinopathies, G6PD deficiencyiy, adrenal hyperplasia, cystic fibrosis and biotinidase deficiency among the most important ones. Since August 2012 we included some lysosomal storage diseases such as Gaucher disease, Niemann-Pick type A and B diseases, Pompe disease, Krabbe disease, Fabry disease and MPS I(2). We analyzed our results from August 2012 to May 2015. We found 10 patients with a lysosomal storage disorder, 5 with Fabry disease, 4 with Pompe disease and 1 with MPS1. We confirmed diagnoses with enzyme activity and mutational analyses and we studied the whole family finding new affected members. These findings give us the opportunity to make genotype-phentype correlation for the early treatment of these diseases and close follow-up.

2318F

Newborn screening for Mucopolysaccharidoses: a pilot study in 1276 samples. *F. Kubaski[1,2], R. W. Mason[1,2], R. Giugliani[3,4], S. Yamaguchi[5], Y. Suzuki[6], J. Hanai[7], A. M. Montaño[8], S. Tomatsu[1,2].* 1) Department of Biological Sciences, University of Delaware; 2) Nemours-Alfred I duPont Children Hospital, Newark, DE; 3) Medical Genetics Service-Hospital de Clinicas de Porto Alegre-HCPA; 4) Department of Genetics/ Universidade Federal do Rio Grande do Sul; 5) Shimane University; 6) Gifu University; 7) Sapporo University; 8) Saint Louis University.

Mucopolysaccharidoses (MPSs) are genetic disorders caused by deficiency of lysosomal enzymes responsible for the catabolism of glycosaminoglycans (GAGs). There are 11 known enzyme deficiencies leading to seven main types of MPS. Together, they are estimated to occur in 1 of 22,000 live births. The phenotype is variable and progressive being the patients are asymptomatic at birth and diagnosed only when they already have signs and symptoms of the disease. Specific treatment is already available for several MPSs, and there are evidences that better outcome of therapy occurs when it is started early. Thus, early diagnosis is extremely relevant to allow better treatment as well as prognosis. The current study aims to develop a pilot study with 1276 samples for newborn screening of MPSs. We developed a protocol for GAG measurement using liquid chromatography mass spectrometry (LC-MS/MS). Dried blood spots from 1276 controls were used to determine cutoffs for two subclasses of sulfation of heparan sulfate (0S, NS). Disaccharides were produced by specific enzyme digestion with heparitinase and were quantified by negative electron ion mode of multiple reaction monitoring. Dried blood spots obtained at birth from patients who were subsequently diagnosed with MPS (MPS I= 6, MPS II= 2, MPS III= 5) were also examined. The average values for each subclass of HS in controls was HS-0S= 33. 3 ng/ml (+26. 3), HS-NS= 9. 2ng/ml (+16. 5), 14. 4 (+28. 7). Average for MPS patients for HS-0S=205. 09 ng/ml (range: 113-312 ng/ml), HS-NS: 58. 69 ng/ml (range: 31-80. 4 ng/ml). Cutoffs were defined as 3SD values (HS-0S>112. 2ng/ml, HS-NS>51. 4ng/ml). All MPS I, II and III newborn patients had higher HS-0S than control samples. We conclude that HS-0S and HS-NS are biomarkers potentially useful for the newborn screening of newborn of MPS I, II, and III.

The use of next generation sequencing in metabolic disease screening and diagnosis of newborns (California NBSeq). *R. L. Nussbaum[1,6], S. E. Brenner[1,2], F. Chen[1], R. J. Currier[3], B. Dispensa[1], B. A. Koenig[1], M. Kvale[1], P. Kwok[1], R. Lao[1], S. D. Mooney[4], J. M. Puck[1], N. Risch[1], J. Shieh[1], S. Rajgopal[5], B. Zerbe[1].* 1) UCSF, San Francisco, CA; 2) UC Berkeley, Berkeley, CA; 3) Newborn Screening Program California Department of Public Health Richmond, CA; 4) University of Washington, Seattle, WA; 5) TATA Consultancy Services Innovation Laboratories, Hyderabad, India; 6) Invitae Inc.

Purpose: NBSeq is the California component of the NSIGHT project, a NICHD/NHGRI funded program designed to explore the use of next generation sequencing in screening and diagnosis of newborns. California NBSeq is asking (1) can next-generation sequencing (NGS) improve the sensitivity or specificity of current newborn screening tests, (2) can NGS improve current newborn screening programs by shortening time-to-diagnosis following a positive screening test, (3) can NGS extend the scope of newborn screening programs to new disorders for which there are currently no screening modalities, and (4) how would NGS impact the legal, social and ethical frameworks that underpin newborn screening? **Methods:** We are using archived newborn blood spots screened for an amino acid, organic acid, or fatty acid oxidation disorder, and unaffected controls, and performing whole-exome sequencing in a blinded fashion to determine sensitivity and specificity. Our project will examine ~1600 newborn spots, consisting primarily of all confirmed true positives and false negatives, as well as a sample of false positive and true negative newborn blood spots, selected from among ~2. 4 million samples (2. 2 million regular nursery and ~216,000 NICU samples) screened in California between 2009-2013 inclusive using MS/MS. Sequence analysis will be limited to genes relevant to the metabolic disorders targeted by current screening programs. **Preliminary Results:** Two 3 mm punches from newborn blood spots stored for as long as 35 years yielded 620 ng (+ 238 ng) of DNA, with some outliers. Library fragment size, NGS quality and gene/exon coverage for the first 188 NBS samples were adequate for interrogating genes relevant to the metabolic disorders targeted by current screening programs. Our results demonstrate that dried blood spots provide a reliable DNA source for whole exome sequencing.

2320F

Improved quality of life with dietary interventions in a biochemically stable child with maple syrup urine disease. *M. Rasberry[1], B. C. Lanpher[2], K. Cusmano-Ozog[1], D. S. Regier[1].* 1) Children's National Medical Center, Washington, DC; 2) Mayo Clinic, Rochester, MN.

Maple Syrup Urine Disease (MSUD) is caused by a deficiency in the first stepof the metabolism of the branch chain amino acids (BCAA), leucine (leu), isoleucine, and valine. This leads to a build-up of these three amino acids and accumulation of the side-reaction metabolite alloisoleucine. The build-up of leu has been associated with lethargy, encephalopathy, coma, and death in the most severe cases. Case reports have identified patients with mild and intermittent forms of MSUD. Here we report a five year old girl with a new diagnosis of MSUD after a prolonged hospitalization for dehydration secondary to a viral illness. She presented to a community hospital when she was found to be overly sleepy following a night of gastrointestinal illness. She was admitted to a pediatric unit when she appeared too sleepy to maintain her hydration state. Over the following 3 days she developed ataxia, which improved with intravenous fluids. The pediatric hospitalist team contacted our referral center on-call physician due to her slow recovery and prolonged ketonuria. She was found to have massively elevated leu, isoleucine, and alloisoleucine levels. Prior to diagnosis, she was adverse to high protein foods such as meat and had a strong preference for fruits and vegetables. At the time of diagnosis, BCAA-free formula was started to provide 0. 8 g/kg/d of medical protein and started a protein restriction with a goal protein intake of 1. 0 – 1. 2 g/kg/d of natural protein. After one month on diet, she had improved emotional lability, increased concentration, improved school performance, and commented "my brain feels better with my new milk". After 6 months on diet, the family noted significant improvements in socialization, behaviors, school outcomes, and overall mood. During this same time period, her BCAA profiles stayed in the low-normal range, based on monthly evaluations. This case suggests that patients with prolonged ketonuria or dehydration-type symptoms should raise a red flag for inborn errors of metabolism and have screening with plasma amino acids and urine organic acids. Her newborn screening results were normal at that time; however, she would have been flagged as having leucine elevation using current state standards. Furthermore, minimal dietary intervention leads to significant improvement in patient quality of life, even when laboratory values remain unchanged with the intervention as in this case of mild/intermittent MSUD.

2321T

Neurotransmitters and Blood Phenylalanine in Phenylketonuria. *S. Yano[1], K. Moseley[1], X. Fu[2], C. Azen[3].* 1) Genetics Pediatrics, USC, Los Angeles, CA; 2) Pathology, Children's Hospital Los Angeles, USC Los Angeles, CA; 3) Clinical and Translational Science Institute, USC Los Angeles, CA.

Background Phenylketonuria (PKU) is a common genetic metabolic disorder causing intellectual disability due to phenylalanine (Phe) hydroxylase (PAH) deficiency. Newborn screening has been introduced for early diagnosis and dietary intervention based on blood Phe levels. Sapropterin, a synthetic form of tetrahydrobiopterin, is also used as a cofactor for PAH. PKU individuals with excellent blood Phe control recently have been reported to have a higher prevalence of neuropsychological deficits including decreased executive functioning and internalizing disorders. Abnormal neurotransmitter metabolism, particularly decreased serotonin and dopamine synthesis in the brain, is believed to be involved. Melatonin, a serotonin metabolite synthesized in the brain, and dopamine which originates from systemic neuronal cells including the brain, reported as useful peripheral biomarkers for brain serotonin and dopamine metabolism, respectively. *Methods* To evaluate brain serotonin and dopamine metabolism, nine adults with PKU completed our study consisting of four 4-week phases: (1) Large neutral amino acid (LNAA) supplementation, (2) Washout, (3) Sapropterin therapy, and (4) LNAA with sapropterin therapy. An overnight protocol measured plasma amino acids, serum melatonin, and urine 6-sulfatoxymelatonin and dopamine in first void urine after each phase. *Results* The relationship between serum melatonin and Phe showed a significant negative slope (p=0. 0005) with a trend toward differing slopes among individual subjects (p=0. 066). However, serum melatonin levels varied widely at a given Phe level. There was a negative association overall between Phe and urine dopamine (P=0. 047). *Conclusion* Blood Phe levels alone do not determine the CNS neurotransmitter metabolism among individuals with PKU. Monitoring with these peripheral biomarkers may individualize treatment to optimize brain neurotransmitter metabolism.

2322F

Combination therapy in a patient with chronic neuronopathic Gaucher disease: potential positive effect of early treatment. *F. Ceravolo, M. Grisolia, M. T. Moricca, F. Falvo, S. Sestito, A. Nicoletti, D. Concolino.* Department of Pediatric, University of Catanzaro, Catanzaro, Italy.

The chronic neuronopathic form of Gaucher Disease (NGD) is characterized by a later onset of neurological symptoms and a more protracted neurological and visceral involvement. The first clinical signs of neurological involvement appear at the median age of 2 years and the major manifestation is early development of horizontal supranuclear gaze palsy followed by cognitive impairment, myoclonic epilepsy, ataxia and spasticity which develop as the illness progresses. Treatment consists in enzyme replacement therapy (ERT) with recombinant enzyme: glucocerobrosidase (GBA). ERT has shown to improves haematological and bone disease but the enzyme is not able to cross the blood-brain barrier (BBB), preventing the neurological manifestation. The substrate reduction therapy (SRT) is based on the iminosugar, miglustat, an inhibitor of the glucosylceramide synthase, the enzyme that catalyzes the first step in glycosphingolipids synthesis. According to its chemical/physical properties, miglustat can cross the BBB. Some reports have shown the efficacy of miglustat, used in combination with ERT, in treating or preventing the neurological symptoms in patients affected by chronic NGD. We report of a 7 years old boy with chronic NGD who received an early treatment with combination therapy. Diagnosis was suspected at the age of 16 months for anemia, thrombocytopenia and splenomegaly. Biochemical exams revealed an elevated level of Chitotriosidase activity: 508 nmol/mg prot (n. v. 5. 9 - 41 nmol/mg prot), and a reduced Beta Glucosidase activity : 2nmol/mg/prot (n. v. 4. 5 – 18 nmol/mg/prot). Molecular analysis showed an homozygosity for L444P mutation in Beta-Glucosidase gene confirming the diagnosis of chronic NGD . The patient began ERT at the dosage of 60 U/Kg/every 2 weeks and at the age of two he also started the SRT with miglustat. At present the patient doesn't show any sign of neurological impairment: no saccadic movement velocity reduction; normal visual evoked potential (VEP) and auditory brain responses (ABR). Finally he has no cognitive impairment and regularly attends at school. This finding is in contrast with the natural evolution of homozygous L444P in NGD patients worldwide and, more interestingly, with our personal records (data not published) consisting in 5 older patients with the same genotype, all comings from the same restricted geographical area , who were only treated with ERT and presented neurological impairment in the first 5 years of life.

2323T

Strategy to assess the pharmacokinetics of a proprietary human acid α-glucosidase with high mannose 6-phosphate during its development as a potential next-generation treatment for Pompe disease. *E. R. Benjamin, R. Hamler, R. Khanna, D. Hilliard, S. Xu, K. Valenzano, R. Gotschall, H. Do, F. K. Johnson.* Translational Science, Amicus Therapeutics, Cranbury, NJ.

Pompe disease is a lysosomal storage disorder that results from deficiency in acid α-glucosidase (GAA) activity, and is characterized by lysosomal glycogen accumulation. The current treatment is enzyme replacement therapy (ERT) using recombinant human GAA (rhGAA). The targeting and uptake of rhGAA into lysosomes requires mannose-6-phosphate (M6P), a specialized carbohydrate which binds to cation-independent M6P receptors (CIMPR) at the cell surface. The quality and quantity of M6P on existing ERT is not optimal, which limits lysosomal targeting. While existing ERTs provide some clinical benefit, unmet needs still exist due to inadequate muscle uptake. We have developed a novel rhGAA enzyme with significantly higher M6P content compared to existing products. This new rhGAA (designated as ATB200) binds the CIMPR with high affinity *in vitro*, and is more efficiently internalized by skeletal muscle myoblasts. Co-administration of a pharmacological chaperone to stabilize the ERT and prevent inactivation provides additive benefits. To support the development of ATB200, a comprehensive approach to assess the pharmacokinetics was developed. The measurement of circulating active enzyme by rhGAA activity assay is complemented with an absolute quantitative method to measure total rhGAA protein. The latter utilizes LC-MS/MS quantification of ATB200-specific "signature" peptides after trypsin digestion of proteins present in plasma samples. The method has been analytically validated in rat and monkey plasma. Pre-specified assay acceptance criteria for precision [% Coefficient of Variation ≤20% (25% for LLOQ)], accuracy [% Difference from Nominal ≤20% (25% for LLOQ)] [LLOQ=0. 500 µg/mL], and other parameters (e. g. , selectivity in matrix±high concentration anti-rhGAA antibodies, dilution linearity, stability) were met. In a single-dose research study in rats, total ATB200 protein levels were measured in plasma up to 24 hours after 10-minute intravenous (IV) infusion. Total ATB200 protein concentrations closely matched those of active ATB200 at time points up to 4 hours. At later time points, the concentrations of active ATB200 were progressively lower compared to total ATB200 protein. The systemic exposure (AUC0-24h and Cmax) increased in a greater than dose-proportional manner. These data demonstrate that characterization of the pharmacokinetics of both active and total ATB200 is relevant for this high M6P rhGAA, a potential next-generation treatment for Pompe disease.

2324F

Diagnosis of a mild case of mucopolysaccharidosis type II (Hunter disease) in a 3-year old girl: to treat or not to treat? *A. M. Laberge, P. Allard, G. A. Mitchell.* Service de genetique medicale, CHU Sainte-Justine, Montreal, Quebec, Canada.

A 3-year old girl was admitted for respiratory distress following tonsillectomy. Language delay, frontal bossing, and midface hypoplasia were noted, prompting genetics referral. Medical history included recurrent pneumonia, and an episode of febrile seizure. Growth and head circumference were at the 50th centile. Family history was unremarkable. She had mild hepatosplenomegaly, bilateral mild to moderate mixed hearing loss and chest X-ray showed broadened ribs and ovoid vertebral bodies, suggesting a lysosomal storage disorder. Cardiac and ophthalmological evaluations were normal. Urine MPS were elevated: 52. 9 mg/mmol creatinine (control 6. 9 +/- 3. 7). Qualitative analysis showed a majority of dermatan and heparan sulfate. Alpha-iduronidase activity was normal. Iduronate sulfatase activity was very low: 0. 05 nmol/h/mg prot (median 10. 7 (8. 8-17. 7)). Sequencing of IDS identified a heterozygous pathogenic mutation: c. 1122C>T. Karyotype was normal. Methylation analysis for X-inactivation showed complete inactivation bias in leukocytes. Brain MRI was normal except for wide Virchow-Robin spaces. Skeletal survey was consistent with dysostosis multiplex, but joint mobility was normal. Neurological assessment revealed only deafness and associated language delay. There are only a handful of reported cases of MPS II in girls, with variable severity. Studies in males have shown that enzyme replacement therapy (ERT) may improve/stabilize visceromegaly, lung function, joint mobility, and cardiac valve regurgitation. ERT requires weekly infusions and is expensive, which can represent a burden for the family. Evidence about ERT in females is limited to 3 cases, all more severely affected than our case at the same age (Manara et al, 2010; Jurecka et al, 2012). All had neurological involvement and started ERT after age 5 (5. 8 yrs, 9 yrs, and 7 yrs, respectively), which led to disease stabilization, except for progression of neurological involvement in 2/3 cases. The pros and cons of ERT were discussed with the mother and it was mutually agreed to postpone ERT for the time being because the patient currently has no functional limitations that would be expected to respond to ERT. We will continue to closely monitor diseaseprogression and reconsider ERT accordingly. This case highlights how trying it can be to decide when to start treatment (i. e. when the treatment burden is worth the benefit)in mild cases of a disease, when evidence is limited.

2325T

Human Recombinant Arginase Enzyme:A Potential New Therapy for Arginase Deficiency. *L. Burrage[1,2], Q. Sun[1], S. Elsea[1], M. Jiang[1], S. Nagamani[1,2], A. Frankel[3], E. Stone[4], G. Georgiou[4], B. Lee[1,2], Members of the Urea Cycle Disorders Consortium.* 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Texas Children's Hospital, Houston, TX; 3) Simmons Comprehensive Cancer Center, UT Southwestern Medical Center, Dallas, TX; 4) Department of Chemical Engineering, The University of Texas at Austin, Austin, TX.

Arginase deficiency is characterized by elevated plasma arginine levels as the result of a deficiency of arginase 1, a cytosolic urea cycle enzyme. Clinically, patients with arginase deficiency present with spastic diplegia, developmental delay or intellectual disability, seizures, and growth deficiency. In contrast to other urea cycle disorders, recurrent, severe hyperammonemia is a less frequent complication. Normalization or near-normalization of plasma arginine levels is the consensus goal of treatment in arginase deficiency because arginine and its metabolites are believed to contribute to the neurologic features of this disorder. However, no studies have evaluated the efficacy of current treatment strategies for the disorder. To this end, we analyzed longitudinal data from patients (n=22) with arginase deficiency who are enrolled in a natural history study conducted by the Urea Cycle Disorders Consortium. Our analyses revealed that 97% of plasma arginine levels in subjects with arginase deficiency were above the normal range despite standard treatment, which typically consisted of protein restriction and nitrogen-scavenging agents. Moreover, only 55% of patients with arginase deficiency reported one or more hyperammonemia episodes with most patients (mean age: 14. 7 years, range: 0-50 years) reporting fewer than five total lifetime reports of hyperammonemia. These data indicate that normalization of plasma arginine is challenging in this disorder. Recently, recombinant arginine-degrading enzymes have been introduced as a therapeutic strategy for various forms of cancer. We tested whether one of these enzymes, a pegylated human recombinant arginase 1 (AEB1102), reduces plasma arginine in two murine models of arginase deficiency. In both the neonatal and adult arginase deficient mouse models, AEB1102 administration resulted in reduced plasma arginine levels after repeated dosing. Despite improved plasma arginine levels, enzyme administration did not result in improved survival likely because this pegylated enzyme does not enter the liver and thus, does not ameliorate urea cycle dysfunction and resulting hyperammonemia that accounts for lethality. Given that elevated plasma arginine rather than hyperammonemia is the major treatment challenge in patients with arginase deficiency, we propose that AEB1102 may have therapeutic potential as an arginine-reducing agent in patients with arginase deficiency.

2326F

Familial Hypercholesterolemia (FH): treatment of an Italian family by LDL-apheresis (LDL-a). *A. Saluto[1], F. Napoli[1], T. Beltramo[1], O. Camerini[1], K. Bonomo[2], P. Ottone[1].* 1) Laboratory of Immunohematology, S. Luigi Gonzaga University Hospital, Orbassano (TO), Italy; 2) Division of Metabolic Disorders, S. Luigi Gonzaga University Hospital, Orbassano (TO), Italy.

FH is a common genetic disorder inherited in an autosomal dominant way with a prevalence of approximately 1 in 300-500 for heterozygotes in North America and Europe. It is characterized by elevated Low-Density Lipoprotein Cholesterol (LDL-C) which causes the accumulation of cholesterol in the arterial wall resulting in accelerated atherosclerosis and premature cardiovascular disease; typical external signs are xanthomas and arcus lipoides. FH is genetically heterogeneous as it can be caused by defects in at least three different genes that encode proteins involved in the hepatic clearance of LDL-C. These defects may be due to mutations in the gene coding LDL-R (classic FH or ADH-1), in the gene coding for the APOB (ADH-2) or in the gene coding for the enzyme PCSK9 (ADH-3). Mutations in LDL-R gene are the most frequent cause of FH (from 90% to 95%); more than 1. 700 different mutations have been characterized (Vogt et al, 2015). We have a family, referred to our centre, with the mutation, c. 68-?_1845+?del,p. (V23Gfs*29), a 24 kb deletion eliminating exons 2-12, named "FH-Pavia" (Bertolini et al, 1992): the father (subject I-1), heterozygous is 51 years old, the son (subject II-1) and the daughter (subject II-2) homozygous are respectively 18 and 16 years old. The three patients were treated with Rosuvastatin at maximum levels and underwent LDL-a every two weeks. As for the subject I-1 we used the HELP method (heparin-induced extracorporeal LDL precipitation), whereas for the subjects II-1 and II-2 the DSA method (dextran sulphate adsorption) was applied. Total cholesterol, LDL-C, HDL-C and triglycerides were calculated before and immediately after apheresis. We observed an average reduction of total cholesterol (57% in the heterozygous subject, 79% in the homozygous subjects), of LDL-C (61. 6% in the heterozygous subject, 83% in the homozygous subjects) of HDL-C and triglycerides (similar values for the three patients). Our work was performed to get more information on lipid apheresis and to evaluate the effectiveness in lowering lipid values in heterozygous and homozygous subjects; it shows that LDL-a notably lowers total cholesterol, LDL-C and, to a much lesser degree, HDL-C and triglycerides. The follow-up of the patients reveals the complete regression of xanthomas and suggests a reduced risk of cardiac events after apheresis.

2327T

Utility of citrulline supplementation in treating hypoargininemia in children with MELAS syndrome. *A. W. El-Hattab[1, 2], L. T. Emrick[1, 3], S. Chanprasert[1, 3], J. W. Hsu[4], M. Almannai[1, 3], W. J. Craigen[1, 3], F. Jahoor[4], F. Scaglia[1, 3].* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas, USA; 2) Division of Clinical Genetics and Metabolic Disorders, Tawam Hospital, Al-Ain, United Arab Emirates; 3) Texas Children's Hospital, Houston, Texas, USA; 4) Children's Nutrition Research Center, Baylor College of Medicine, Houston, Texas, USA.

Mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes (MELAS) is a frequent mitochondrial disorder. There is growing evidence that nitric oxide (NO) deficiency occurs in MELAS and results in impaired blood perfusion that can contribute to several complications including stroke-like episodes, myopathy, and lactic acidosis. The etiology of NO deficiency in MELAS is multifactorial with the decreased availability of NO precursors, arginine and citrulline, playing a major role. Previous studies demonstrated hypoargininemia and hypocitrullinemia in adults with MELAS. In this study we initially measured plasma amino acids in 5 children with MELAS at baseline and then after 48 hours of oral arginine supplementation. After a 2-week wash-out period, plasma amino acids were measured again at baseline and after citrulline supplementation. We also measured plasma amino acids in 5 healthy control children once at baseline. The age of children with MELAS ranged from 4 to 16 years and of the control group from 7 to 16 years. The baseline mean plasma arginine in children with MELAS was significantly lower than the control group (61. 3±5. 3 vs. 151. 3±18. 4 μM, p<0. 05). However, the baseline mean plasma citrulline was not significantly different between both groups. In children with MELAS arginine supplementation resulted in raising plasma arginine (58. 5±5. 2χ184. 3±14. 2 μM, p<0. 05) but not plasma citrulline. Interestingly, citrulline supplementation resulted in a more significant raise in plasma arginine (64. 1±5. 7χ257. 1±21. 3 μM, p<0. 05) and plasma citrulline (21. 3±7. 0χ155. 6±37. 7, p<0. 05). We have also used isotope infusion technique to assess NO production in the children with MELAS before and after arginine or citrulline supplementation. The measurement of isotopic enrichment is currently ongoing. Hypoargininemia and hypocitrullinemia have been previously described in adults with MELAS syndrome and can contribute to the NO deficiency in this syndrome. Arginine and citrulline supplementations have been suggested to be of therapeutic utility in MELAS through their ability of restoring NO production. In this study we provide evidence that children with MELAS also exhibit hypoargininemia. Citrulline supplementation was superior to arginine supplementation in raising both plasma arginine and citrulline in children with MELAS. This study adds more evidence to the utility of citrulline supplementation as one of the therapeutic options in MELAS syndrome.

Aggresomes formation and negative gain of function as alternative molecular mechanism in patients affected by phenylketonuria: implications for the therapy. *G. Bonapace[1], M. T. Moricca[1], F. Ceravolo[1], I. Mascaro[1], P. Strisciuglio[2], D. Concolino[1].* 1) Pediatrics, Faculty of Medicine University Magna Graecia, Viale Europa Catanzaro, Italy; 2) Dept of Pediatrics University Federico II Naples.

Phenylketonuria (PKU MIM 261600) is a human metabolic disease caused by mutations in phenylalanine hydroxylase gene (PAH) and is inherited in an autosomal recessive Mendelian fashion. Phenylalanine hydroxylase (PAH also known as phenylalanine 4-monooxygenase EC 1,14,16,11) catalyzes the rate-limiting step in L-Phenylalanine (L-Phe) catabolism in liver, using tetrahydrobiopterin (BH_4) and dioxygen as additional cosubstrates. PKU mutations are associated with impairment of PAH activity, leading to accumulation of L-Phe in plasma, and neurological damage in untreated patients Even though an early dietary treatment, consisting of a low protein diet with L-Phe restriction, can prevent the development of metabolic and pathological sequelae, the social burden of this treatment and the reduced patient'compliance, have led to search for new therapeutic approaches. To set a novel terapeutic approach for treating this disease we studied the aggregosome formation and the negative gain of functionusing is the c. 143C>T (L48S) PAH mutation as model. L48S is a well documented PAH misfolding mutation characterized by a progressive clinical worsening, and described as inconsistent in BH_4 responsive patients. The experimental hypothesis we testedis based on the formation of intracellulat toxic soluble aggregates induced by the mutant protein. Based on this mechanisms and on the observation that most of PKU patients are compound heterozigous for two different mutations, we hypothesize that in the patients carrying the L48S misfolding mutation in association with a second mutatedallele that retains some residual enzymic activity the formation of solubile aggregates can take pace and that these aggregates couldtrigger a generalized cell disfunction explaining the observed worsening of the clinical phenotype. By using electroporation we transfected HEK 293 cells with an expression vector carrying PAH WT, or PAHL48Sand demonstratedthe aggregosome formation and the loss of biological activity in the L48S transfected cells. By using 1-Deoxynojirimycin hydrocloride also described as a HSP70 inducers, we were able todecrease the amount of aggregated L48S protein in a dose response in comparison to untreated cells, to rescue the biological activity without any effect onthe HEK cells based on morphology and biochemical evaluation. Wepropose aggresomes formation as novel molecular mechanism in PKU with very interesting implications for the therapy

.

A Pilot Open Label Trial Assessing the Safety and Efficacy of Betaine in Patients with a Peroxisome Biogenesis Disorder (PBD) and PEX1-Gly843Asp (G843D) Genotype. *N. E. Braverman[1, 2], F. Plourde[2], R. Cooper[3], R. O. Jones[4], A. B. Moser[4], W. Rizzo[3].* 1) Human Genetics, McGill University, Montreal, QC, Canada; 2) Department of Pediatrics, McGill University Health Center, Montreal, QC, Canada; 3) Department of Pediatrics, University of Nebraska Medical Center, Omaha, NE, USA; 4) Department of Neurogenetics, Kennedy Krieger Institute, Johns Hopkins Hospital, Baltimore, MD, USA.

Introduction: The PBD are a heterogeneous group of disorders with a wide clinical spectrum and no therapy. A common mutation encodes a misfolded, degraded protein with residual function, PEX1-G843D. Betaine was identified as a non-specific chemical chaperone drug that rescued peroxisomal matrix protein import and plasmalogen levels in PEX1-G843D patient fibroblast lines. Thus we sought to determine if betaine was safe and effective as a treatment for PEX1-G843D patients. *Study description:* Two centers participated in this study. Ten patients with a PEX1-G843D genotype received betaine orally for 6 months at a dose of 3, 6 or 12 gms daily, depending on age or body weight. Age range was 11 months - 31 years; two patients were PEX1-G843D homozygotes and 8 were PEX1-G843D/null genotypes. Patients were examined at baseline and 6 months. Betaine effect was assessed by measurement of peroxisome metabolites that reflect clinical disease: very long chain fatty acids, pipecolic acid, plasmalogens and C27 bile acids. Peroxisome function tests were done twice before the trial (to provide baseline values), and at 6 months. *Results:* Betaine was tolerated well in all patients. There were large intra-and inter-individual variations in peroxisome functions at each time point. Statistically significant trends (paired sample t-tests) were observed for plasma pristanic/phytanic acid ratio decreased by 32%, pipecolic acid decreased by 20%, RBC membrane C26:1 decreased by 23% and C26/C22 ratio decreased by 10%. In the two PEX1-G843D homozygotes, RBC membrane plasmalogens increased by 50%. *Conclusions:* Although promising trends were observed, betaine did not overall improve peroxisome functions in a 6 month trial at the dosage used. Blood metabolite markers may be less sensitive than direct measurements of cell responses and plasma betaine levels achieved were below that used in the cell lines. To improve future clinical trial designs, baseline variation in peroxisome functions in PBD patients must be established. Other biomarkers with less intrinsic variation and clinical endpoints should be investigated. Larger patient numbers and crossover or placebo-controlled designs are indicated to overcome the effect of variation.

2330F

Long term follow up of 17 patients with methylmalonic acidemiafollowing solid organ transplantation. *J. L. Sloan, I. Manoli, C. P. Venditti.* NIH/NHGRI/GMBB, Bethesda, MD.

Methylmalonic acidemia (MMA) is a devastating disorder, often recalcitrant to medical management. Solid organ transplantation, including liver (LT), combined liver-kidney (LKT) or kidney transplantation (KT), has been used as a therapy since the 1990's yet, there is limited information on long- term outcomes of transplant recipients and no guidelines regarding indications for transplant. We describe the natural history up to 16. 9y post-transplant in 17 individuals with MMA (15 mut, 1 cblA, 1 cblB) followed at the NIH Clinical Center as part of a dedicated natural history study (clinicaltrails. gov identifier NCT00078078). There were 3 LT, 9 LKT and 5 KT recipients in our cohort with mean follow up since transplant of 5. 5 yrs (range 0. 8-16. 9 yrs). LT recipients were transplanted younger (mean 2. 1y) than LKT (mean 15. 2y). 10/22 of the MUT alleles in LT and LKT patients were null. Although all 12 patients status post LT or LKT remained metabolically stable (77. 3 yrs combined follow-up), two LT patients displayed renal disease requiring subsequent KT. Two LKT recipients developed severe neurological complications (2 months, 5 yrs later) despite adequate metabolic control. In addition, one mut0 patient with isolated KT suffered repeated metabolic decompensations and developed optic nerve atrophy 3 yrs post-transplant. Improvement in metabolic parameters was observed following transplantation (72-93% decrease), primarily due to correction of renal function, but all had persistently elevated methylmalonic acid in plasma (71-1383 μM, nl <0. 4) and urine (166-4446 mmol/mol cr, nl<3). Despite the massive MMA elevations, two LKT patients >15 yrs post transplant had eGFR >40 ml/min/1. 73m2. Studies in this patient group, the largest assembled to date, afford the following conclusions: 1. LT and LKT, but not isolated KT, completely prevent ketoacidotic crises. 2. After LT, patients can develop renal failure and therefore require careful monitoring and this is also a theoretical risk for LKT and KT patients. 3. Although solid organ transplantation improves biochemical parameters, adequate metabolic control is required following the procedure due to the risk for MMA related complications e. g. optic nerve atrophy, neurological complications. Further studies are needed on the association of genotype and metabolic correlations pre- and post-procedure and the outcomes achieved, to develop guidelines about the optimal timing and procedure indicated for each patient.

2331T

Auditory pathway findings in Smith-Lemli-Opitz syndrome (SLOS). *T. Pointon[1], D. Hayes[2], E. R. Elias[3].* 1) University of Colorado School of Medicine, Aurora, CO; 2) Department of Physical Medicine and Rehabilitation, University of Colorado School of Medicine, Aurora, CO; 3) Department of Pediatrics and Genetics, University of Colorado School of Medicine, Aurora, CO.

Introduction: Smith-Lemli-Opitz syndrome (SLOS) is an autosomal recessive condition caused by mutations in the*DHCR7*gene which codes for 7-dehydrocholesterol reductase, the final enzyme in the cholesterol biosynthetic pathway. This results in cholesterol deficiency and accumulation of sterol precursors 7- and 8-dehydrocholesterol (7-DHC and 8-DHC). Patients with SLOS present with a complex phenotype including cognitive disabilities, autism, hearing loss, and progressive retinal dystrophy. Both sensorineural and conductive hearing loss are observed in SLOS. While retinal dysfunction has been reported, variations in the auditory pathway have not previously been described in SLOS. The goal of this study was to analyze neural conduction through the auditory pathway to better understand the pathophysiology of hearing loss in SLOS. **Methods**: Auditory brainstem response (ABR) was measured serially in 16 SLOS patients being treated with cholesterol supplementation and the antioxidant preparation AquADEKS® under an IRB approved protocol. Data was collected at baseline, then annually after beginning treatment. ABR data was assessed to determine hearing status and time required for neural conduction through the auditory brainstem pathway. **Results**: Prolonged neural conduction through the auditory brainstem pathway was observed in 6 out of 16 patients with SLOS. Of these patients, 3 had sensorineural and/or conductive hearing loss. Normal auditory brainstem neural conduction was observed in 9 out of 16 SLOS patients. Of these, 6 had sensorineural and/or conductive hearing loss. Complete sensorineural deafness was found in one patient, thus no ABR data could be collected. **Conclusion**: These data suggest that the metabolic alterations in SLOS negatively impact neural conduction through the auditory system in a subset of patients. Variation in auditory neural conduction seen among patients with SLOS is likely multifactorial. It is hypothesized that cholesterol deficiency contributes to neuronal membrane instability, altered functioning of ion channels and decreased myelination of axons. In addition, oxidation of 7-DHC and 8-DHC into toxic oxysterol byproducts, which cause neuronal death and retinal dysfunction, may also contribute to altered function in the auditory system. Current studies are underway to further investigate the effect that treatment has on these auditory findings and to determine if age at treatment initiation plays a role in outcomes.

A Replication study of 49 Type 2 Diabetes Risk Variants in a Punjabi Pakistani Population. *A. Zia[1], X. Wang[2], A. Bhatti[1], F. Y. Demirci[2], W. Zhao[3], A. Rasheed[4], M. Samuel[4], A. K. Kiani[1], M. Ismail[5], J. Zafar[6], P. John[1], D. Saleheen[4,7], M. I. Kamboh[2].* 1) Atta ur Rahman School of Applied Biosciences (ASAB, National University of Sciences and Technology (NUST), Islamabad, NA, Pakistan; 2) Department of Human Genetics, Graduate School of Public Health, University of Pittsburgh, PA, USA; 3) Institute of Translational medicine and human genetics, Department of Medicine, University of Pennsylvania, PA, USA; 4) Center for Non-communicable diseases, Karachi, Pakistan; 5) Institute of Biomedical and Genetic Engineering (IBGE), Islamabad, Pakistan; 6) Pakistan Institute of Medical Sciences (PIMS), Islamabad, Pakistan; 7) Department of Biostatistics and Epidemiology, University of Pennsylvania, PA, USA.

Background: The burden of type-2 diabetes is alarmingly high in South Asia, a region that has many genetically diverse ethnic populations. Genome-wide association studies (GWAS) conducted largely in European populations have identified a number of loci predisposing to T2D risk, however the relevance of such genetic loci in many South Asian sub-ethnicities remain elusive. The aim of this study was to replicate 49 SNPs previously identified through GWAS in Punjabis living in Pakistan. **Methods:** We examined the association of 49 SNPs in 853 T2D cases and 1,945 controls using additive logistic regression models after adjusting for age and gender. **Results:** Of the 49 SNPs investigated, 16 SNPs were associated with T2D risk in Punjabis in a direction consistent with prior published reports. The most significant association was found for rs7903146 at the *TCF7L2* locus. For a per unit increase in the risk score comprising of all the 49 SNPs, odds ratio in association with T2D risk was 1. 16 (95% CI 1. 13-1. 19, P<2. 0E-16). **Conclusion:** These results suggest that a large number of T2D susceptibility loci are shared between Europeans and Punjabis living in Pakistan.

2333T

Gene Expression Profiles of LPL Deficiency Reveal LPL-Independent Pathways of Triglyceride Metabolism. *D. Gaudet, D. Brisson, K. Tremblay.* Université de Montréal Community Genomic Medicine Centre and ECOGENE-21, Chicoutimi, QC, Canada.

Background: Lipoprotein lipase deficiency (LPLD), a rare autosomal recessive disease, is a major cause of extreme hypertriglyceridemia (hyperTG). However, patients with LPLD do not exponentially accumulate TGs, and thus, must have access to a LPL-independent rescue pathway to survive. Recent data support APOC3 as a key regulator of LPL-independent pathways of TG metabolism. These pathways remain however to be identified. **Aim:** To investigate gene expression profile of patients presenting a wide spectrum of LPL activity. **Methods:** A total of 51 consenting subjects participated in this study. Prior to the analyses, patients were divided into three groups covering a wide spectrum of LPL activity: 15 homozygotes for null LPL gene mutations and less than 3% of LPL activity (HoLPL); 22 heterozygotes for null LPL mutations and 50% of normal LPL activity (HeLPL); and 14 normolipemic controls (wild-type LPL). The gene expression profiles of the HoLPL and HeLPL was compared to the control subjects profile. RNA samples were extracted from whole blood PAXgene and hybridized on Affymetrix Human Gene 2. 0 ST Array according to manufacturer procedures. Robust Mutli-Array normalization has been applied on the probe raw intensities. Differential expression moderated T-tests between studied groups were performed using the Bioconductor package Limma. False discovery rate (FDR) estimation was carried out using the Benjamini-Hochberg method. Biological pathways of the differentially expressed probes have been analyzed using the Qiagen Ingenuity Pathway Analysis software. **Results:** The studied groups allowed to conduct three differential analyses on a total of 48,226 detected probes. At a p-value < 0. 01, a FDR of 5% and a >2-fold down-expression (down) or over-expression (over) significance levels, 143 probes have been found differentially expressed in HoLPL and 65 in HeLPL compared to healthy controls. Of the identified probes, 59 are shared by both HoLPL and HeLPL; 84 are specific to HoLPL [70 down (38 annotated;32 non-annotated) and 16 over (8 annotated;6 non-annotated)]; and 6 are specific to HeLPL [5 down (1 annotated; 4 non-annotated) and 1 over annotated probe]. Most of the annotated genes are involved in circadian, inflammatory, immune or signaling pathways, docking systems or receptor-mediated clearance mechanisms. **Conclusion:** These results reveal gene expression signatures of a wide spectrum of LPL activity and suggest LPL-independent mechanisms of TG metabolism.

2334F

Novel *NPC* variants causing severe Niemann Pick C deficiency. *K. Chao[1], C. Adams[1], L. Fleming[3], L. A. Wolfe[1,2], W. A. Gahl[1,2], C. Toro[1], D. R. Adams[1,2].* 1) NIH Undiagnosed Diseases Program, National Institutes of Health, Bethesda, MD; 2) Office of the Clinical Director, National Human Genome Research Institute, Bethesda, MD; 3) National Human Genome Research Institute, Medical Genetics Branch, Bethesda, MD.

Introduction: We present a 5-year-old African-American male who was diagnosed with Niemann Pick C deficiency (NPC). His case is remarkable for some unusual features of NPC and for a set of DNA mutations that were challenging to detect with the exome analysis pipeline at the time. The clinical course began with normal development until 15-18 months of age, when he was noted to have difficulty walking. By age 2 he was ataxic; by 2-1/2 he could not stand independently. Communication skills also deteriorated: at 26 months he showed language comprehension and expression to the 9-12 month range. He became non-verbal by age 3. At age 4, he developed recurrent episodes of respiratory failure and had at least one episode of cardiopulmonary arrest secondary to aspiration. Extensive evaluations were performed prior to admission at NIH including muscle biopsy, chromosomal microarray, lysosomal storage panel, and biochemical measurements. Muscle pathology showed abnormal but non-diagnostic findings including abnormal mitochondrial morphology. MRI brain imaging showed non-specific white-matter changes. **Methods:** Abnormal results detected during his NIH admission included a nerve conduction study with decreased CMAP amplitude and decreased conduction velocity in several nerves. Needle EMG showed decreased insertional activity in all muscles and muscle atrophy. EEG revealed nearly continuous diffuse posterior predominant 1-2 Hz high voltage irregular spikes and slow wave discharges. Muscle mitochondrial DNA copy number was 29% suggestive of a mitochondrial depletion syndrome. Leukocyte coenzyme Q-10 levels were elevated at 188 picomole/mg. Abdominal ultrasound showed borderline large liver and spleen sizes (12. 2 cm and 9. 5 cm). **Results:** Research exome revealed two novel variants in *NPC1:* a c. 3266A>G mutation inherited from the mother and a de novo c. 2119C>T mutation. Follow up fibroblast cholesterol esterification was 0%. **Discussion/Conclusions:** This case of Neiman Pick C disease highlights a severe disease course. In addition, it was a challenge for our exome analysis pipeline. Mendelian-inconsistent mutations make up a substantial portion of the noise seen in exome genotype results. We use consistent segregation as a component of variant filtration. This case featured one allele that was Mendelian-inconsistent due to a true-positive new-dominant mechanism and has prompted us to develop new approaches to filter variants that may form compound heterozygous pairings.

2335T

Erythropoietic Protoporphyria: Investigation and Evaluation of Potential Pathogenicity of Ferrochelatse (FECH) Mutations in Genomic Databases. *W. Qiao, M. Balwani, R. Srinivasan, M. Yasuda, R. Desnick.* Icahn School of Medicine at Mount Sinai, New York, NY.

Erythropoietic protoporphyria (EPP) is an autosomal recessive inborn error of heme biosynthesis resulting from loss-of-function mutations in the ferrochelatase (*FECH*) gene, which encodes the enzyme that inserts iron into protoporphyrin IX (PP) to form heme. EPP is characterized by the accumulation of PP in the erythron, and patients experience severe phototoxic pain when exposed to sunlight. The prevalence of EPP in Western Europe ranges from 1:75,000 to 200,000. Most EPP patients identified in North America are Caucasians. ~4 % of EPP patients carry two *FECH* loss-of-function mutations, while the majority carry one *FECH* loss-of-function mutation and the common *FECH* low expression allele, IVS3-48T>C, which occurs in about 10% of Caucasians. These mutations reduce overall *FECH* activity to < 35% of normal, causing symptoms. To date, over 190 pathogenic *FECH* mutations causing EPP have been reported (Human Gene Mutation Database). However, the effect of *FECH* missense mutations on enzyme activity have not been characterized for most. Interrogation of the 1000 Genomes and the Exome Sequencing Project (*ESP*) databases revealed 33 *FECH* variants in all racial and ethnic groups, 29 missense variants and 4 at or near consensus splice sites, including 10 reported pathogenic mutations. In Caucasians, there were 21 missense and 3 intronic variants, including 9 reported pathogenic mutations. Overall frequency in Caucasians was about 16% for both databases, with the frequency of R96Q being ~15%, while the others ranged from 0. 01 to 2%. All 29 missense variants were evaluated by *in silico* pathogenicity prediction programs and eukaryotically expressed *in vitro* to determine their *FECH* catalytic activity. The *in silico* studies predicted 6 variants as “pathogenic”, 17 as “ambiguous” and 6 as “likely benign”. The *in vitro* expression assays revealed that 4 variants (encoding D274N, Q285R, P334L, L405F) had < 10% of expressed wild-type (WT) activity, confirming their pathogenicity. 13 Variants, including 2 previously reported mutations (G55C, P62R), had > 40% WT activity, suggesting that they are likely benign. The combined frequency of the G55C and P62R alleles among Caucasians is ~2. 0%, further supporting that they are not pathogenic. Taken together, these studies emphasize the importance of functional characterization of missense variants. .

2336F

Topic: Mucopolysaccharidosis type IIID (Sanfilippo syndrome type D): Initial characterization of the murine model. *M. Jamil[1], E. M. Snella[1], S. Q. Le[2], S. Kan[2], B. C. Birtcil[3], P. I. Dickson[2], N. M. Ellinwood[1], J. D. Smith[3].* 1) Iowa State University College of Agriculture and Life Sciences, Ames, IA USA; 2) Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA USA; 3) Iowa State University College of Veterinary Medicine , Ames, IA USA.

The mucopolysaccharidoses (MPSs) are lysosomal storage enzymopathies that result in storage of glycosaminoglycans (GAGs). Symptoms include somatic and CNS signs. Storage of the GAG heparin sulfate (HS) cause MPSs with fatal pediatric neurodegenerative disease. The MPS with predominate CNS disease is MPS III (Sanfilippo syndrome), a heterogeneous HS storage disorder of 5 subtypes (IIIA-IIIE). Of the four MPS IIIs in humans, all but IIID have mouse models. Herein we describe the first N-acetyleglucoseamine-6-sulfatase (GNS) deficient murine model of MPS IIID. A knockout mouse was generated at Taconic Artemis GmbH that removed exons 2 to 13 of the 14 exons in GNS. Both the founding the embryonic stem cells and the chimera mates were from a C57BL/6 background. The production of GNS -/- mice, diagnosed by PCR, confirmed to the expected numbers for a simple recessive Mendelian pattern. Initial characterization involved comparison of affected mice at 4 and 13 months of age with litter and sex matched GNS+/+ mice. At 13 months of age, the GNS-/- mouse had an enlarged urinary bladder (1. 1 ml urine), moderate hepatomegaly, decreased abdominal fat, and an unkempt pelage. Hematoxylin and eosin (HE) stained histological sections showed extensive vacuolation of hepatocytes, foamy vacuolation of segments of renal cortical tubular epithelia, vacuolation of neurons in the brain, and extensive loss of Purkinje cells seen in the cerebellum. Additionally, numerous neurons had cytoplasmic granular storage in Luxol fast blue (LFB) stained sections of brain. Four month old affected mice had no significant abnormalities seen on gross exam, mild vacuolation of hepatocytes on HE, and infrequently observed LFB positively stained neurons in the CNS. Biochemical analysis of 4 month old mouse tissues found no detectable GNS activity in affected versus control mice. The murine model of MPS IIID showed similar gross and histological findings to other MPS III murine models, including urine retention, and marked liver, renal, and CNS storage. Neuronal vacuolation and severe Purkinje cell loss is comparable to findings in other MPS III models. Extensive hepatocellular vacuolation is consistent with heparan sulfate storage, and the LFB positive staining of neurons is consistent with the known secondary CNS storage of glycosphingolipids in MPS III. This new model will be useful to further study the pathogenesis and therapy of human MPS IIID.

Large scale screening for lysosomal storage disorders in minority groups. *R. Iimgala[1,2], C. Sejpal[1,2], C. Cross[3], M. Gondre-Lewis[3], O. Goker-Alpan[3].* 1) Lysosomal and Rare Disorders Research and Treatment Center, Fairfax, VA; 2) O and O Alpan, LLC, Fairfax, VA; 3) Howard University School of Medicine, Washington, DC.

Introduction: Lysosomal Storage Disorders (LSDs) are a group of over 40 inherited disorders, where affected individuals exhibit symptoms that become progressively worse, often prior to access to testing and diagnosis. Although many LSDs are considered panethnic, the incidence for individual disorders is highly variable. LSDs challenge the current healthcare system, not only because of diagnostic delays, but also variable access to very expensive therapies. To highlight diagnostic challenges originating from ambiguous clinical manifestations, we initiated a large scale screening for "treatable forms" of LSDs with a special focus on under-represented minority groups. **Subjects:** The study population is comprised of anonymized patients in the Washington, D. C. metro area seeking healthcare for varied reasons. 85% of the patients are African-American and 7% of are Hispanic, and the remainder report as white, other, or American Indian. The aim is to compile results from at least 10,000 unique samples and include subjects of both genders in the screening. **Methods:** Under IRB approved protocols (NCT02120235 and IRB-14-MED-09), dried blood spots are prepared from anonymized peripheral blood samples within 24 hrs of draw and miniaturized fluorometric enzyme assays are performed using 4-Methylumbelliferyl substrates specific for a-galactosidase (Fabry disease), a-glucosidase (Pompe disease), b-glucosidase (Gaucher disease), chitotriosidase (Gaucher and Niemann-Pick C disease) and b-galactosidase (Gangliosidosis) enzymes. All assays are performed in triplicates in 384-well format and fluorescence is measured using a spectrophotometric plate reader. Reference ranges for all the enzyme assays are established using n=40 random normal subjects with no known symptoms of any of the LSDs. **Results and Conclusions:** Preliminary findings resulting in positive diagnosis are highlighted to indicate prevalence rates for individual LSDs in minority groups primarily represented by those of African-American and African and Afro-Caribbean descent. Incidence rates are compared to results from newborn screening for LSDs. Since our study focuses on adults and children already under clinical care for various symptoms, the study is expected to result in differential prevalence rates for the LSDs tested, and will highlight the importance of such large scale screening on early diagnosis of LSDs and prompt intervention in minority groups with varied access to healthcare and genetic testing.

Whole-exome sequencing identifies *ECHS1* mutations in Leigh syndrome. . *M. Tetreault[1,2], H. Antonicka[3], S. Fahiminiya[1,2], GA. Mitchell[4,5], MT. Geragthy[6], M. Lines[6], KM. Boycott[6], EA. Shoubridge[1,3], JJ. Mitchell[7], JL. Michaud[4,5,8], J. Majewski[1,2], Care4Rare Canada Consortium.* 1) Department of Human Genetics, McGill University, Montreal, QC H3A 1B1, Canada; 2) McGill University and Genome Quebec Innovation Center, Montreal, QC H3A 1A4, Canada; 3) Montreal Neurological Institute, McGill University, Montreal, QC H3A 2B4, Canada; 4) Department of Pediatrics, Universite de Montreal, Montreal, QC H3T 1C5, Canada; 5) CHU Sainte-Justine Research Center, Montreal, QC H3T 1C5, Canada; 6) Children's Hospital of Eastern Ontario Research Institute, University of Ottawa, Ottawa, ON K1H 8L1, Canada; 7) Department of Pediatrics, Montreal Children's Hospital, Montreal, QC H3H 1P3, Canada; 8) Department of Neurosciences, Universite de Montreal, Montreal, QC H3C 3J7, Canada.

Leigh syndrome (LS) is a rare heterogeneous progressive neurodegenerative disorder usually presenting in infancy or early childhood. Clinical presentation is variable and includes psychomotor delay or regression, acute neurological or acidotic episodes, hypotonia, ataxia, spasticity, movement disorders, and corresponding anomalies of the basal ganglia and brain stem on magnetic resonance imaging. To date, 35 genes have been associated with LS, mostly involved in mitochondrial respiratory chain function and encoded in either nuclear or mitochondrial DNA. We used whole-exome sequencing to identify disease-causing variants in four patients with basal ganglia abnormalities and clinical presentations consistent with LS. Compound heterozygote variants in *ECHS1,* encoding the enzyme enoyl-CoA hydratase were identified. One missense variant (p. Thr180Ala) was common to all four patients and the haplotype surrounding this variant was also shared, suggesting a common ancestor of French-Canadian origin. Rare mutations in *ECHS1* as well as in *HIBCH*, the enzyme downstream in the valine degradation pathway, have been associated with LS or LS-like disorders. A clear clinical overlap is observed between our patients and the reported cases with ECHS1 or HIBCH deficiency. The main clinical features observed in our cohort are T2 hyperintense signal in the globus pallidus and putamen, failure to thrive, developmental delay or regression, and nystagmus. Respiratory chain studies are not strikingly abnormal in our patients: one patient had a mild reduction of complex I and III and another of complex IV. The identification of four additional patients with mutations in *ECHS1* highlights the emerging importance of this pathway in LS.

2339T

Measurement of markers of urinary oxidative stress in methylmalonic aciduria, propionic aciduria and Barth syndrome. *K. Victor, H. Vernon.* McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD.

Oxidative stress is an increasingly recognized mechanism of cellular pathology in disorders of intermediary mitochondrial metabolism, and defining its' role in specific disorders could have implications for targeted therapy. Therefore, in order to explore the possible imbalance between the production of reactive oxygen species and antioxidant reserve in three disorders involving mitochondrial function, methylmalonic aciduria (MMA) and propionic aciduria (PA), Barth syndrome (BTHS), we assessed multiple urinary markers of oxidative stress. These disorders are classified as organic acidurias, but have different roles in mitochondrial intermediary metabolism. MMA and PA are closely related disorders of branch chain amino acid metabolism, and Barth Syndrome is a disorder of cardiolipin remodeling. We measured protein oxidation (via urine di-tyrosine levels), lipid oxidation (via urine 15-F2t-isoprostane level) and urine antioxidant capacity in 8 individuals with MMA, 4 individuals with PA , 8 individuals with BTHS, and 5 controls. The average urine di-tyrosine level in MMA was 4. 87x105 FU/ mg Cr +/-1. 28x105 (SD), in PA was 9. 39x105 FU/ mg Cr +/-2. 72x105(SD), in BTHS was 1. 17x106 FU/ mg Cr +/-9. 83x105(SD), and in controls was 1. 43x105 FU/mg Cr +/-5. 74x104(SD). MMA, PA and BTHS samples all had significantly higher di-tyrosine levels when compared to controls (p-values <0. 05). The urine 15-F2t- isoprostane levels, as determined by a competitive enzyme-linked immunosorbent assay (ELISA), was not significantly different between MMA, PA, BTHS or control groups. The urine antioxidant capacity in MMA was 0. 83 mM Trolox +/-0. 53 (SD), in PA was 1. 34 mM Trolox+/-1. 37 (SD), in BTHS was 1. 21 mM Trolox+/-0. 72 (SD), and in controls was 2. 71 mM Trolox+/-1. 12 (SD). The controls had significantly higher urine antioxidant capacity than the MMA cohort (p-value of 0. 007) and the BTHS cohort (p-value of 0. 03). These results suggest that oxidant stress may play a significant role in the pathophysiology of these three mitochondrial-associated disorders, but with differing biochemical consequences, and that correction of antioxidant capacity could be a viable target for therapeutic intervention in MMA, BTHS, and possibly PA.

Can a heterozygous c. 1880_1881del (p. S627fs) novel pathogenic mutation in the NDUFS1 gene cause mitochondrial Complex I deficiency? *S. Yang, D. Regier, K. Chapman.* Genetics & Metabolism, Children's National Health System, Washington, DC.

Liver involvement can be seen as a common feature in childhood mitochondrial disorder; it may appear as neonatal or early childhood liver failure. The numbers of genes that have been associated with mitochondria disorders have continued to expand. NDUFS1 is a nuclear-encoded mitochondrial gene which encodes the largest subunit of respiratory chain complex I. Complex I deficiency is the most frequently encountered in mitochondrial disorders, and NDUFS1 is one of several mutational hot spot genes for isolated complex I deficiency. We present a family with two children who both had acute fulminant liver failure around 10 months of age. The older girl recovered, however her younger brother died before a liver transplant could be performed. The 7-year-old girl also has had elevated transaminase levels and abnormal LFTs in conjunction with illness. Otherwise, she is healthy and developmentally normal in between illness episodes. Family history is positive for other paternal family members (including father, uncle, and possible grandfather) with asymptomatic elevated liver enzyme. Along with many differential diagnoses for these relatives, mitochondrial dysfunction was suspected. The Whole Exome Sequencing was offered to the family after an extensive amount of genetic testing was done without providing a diagnosis. A paternally inherited novel variant in the NDUFS1 gene was reported, and this variant is predicted to be pathogenic. Targeted mutation analysis was subsequently performed on the deceased brother's tissues as well as the paternal uncle who also has had abnormal LFTs. Both of them were found to carry the same pathogenic mutation. Since only one pathogenic variant in NDUFS1 gene was identified in multiple family members, either with acute liver failure or a history of asymptomatic elevated liver enzyme, the assumption we have is that this is an autosomal dominantly inherited disease. We propose that the heterozygous c. 1880_1881del (p. S627fs) mutation represents a novel pathogenic variant in NDUFS1 and acts in a dominant manner.

2341T

Evaluating Neutral Lipid and Phospholipid Contents of Lipid Droplets in Fibroblast Cells from Patients with Peroxisomal Disorders. *W. Fallatah[1,2], P. Dranchak[3], JG. Hacia[4], NE. Braverman[1].* 1) Department of Human Genetics, McGill University-Montreal Children's Hospital Research Institute, Montreal, QC, Canada; 2) Department of Genetic Medicine, King Abdul-Aziz University, Jeddah, Saudi Arabia; 3) National Center for Advancing Translational Sciences, National Institutes of Health, Rockville, MD, USA; 4) Department of Biochemistry and Molecular Biology, Broad Center for Regenerative Medicine and Stem Cell Research, University of Southern California, Los Angeles, CA, USA.

Peroxisomes and lipid droplets (LDs) are discrete intracellular organelles that play a significant role in regulating cellular lipid metabolism. While the main functions of peroxisome are fatty acid beta-oxidation and ether phospholipid biosynthesis, LD has a critical role in regulating intracellular lipid storage. During cellular stress like starvation the cell can survive by utilizing the fat stored in LDs as a source of energy. Accumulation of LDs has been reported in C. elegans with defective peroxisomal b oxidation (MAOC-1/DHS- 28/DAF-22 genes) and defective peroxisome assembly (PRX10, the ortholog of the human PEX10 gene). LDs also accumulate in liver tissue from mice with defective peroxisome assembly (Pex11α). We previously studied the neutral lipid and phospholipid contents of LDs in peroxisome-deficient Chinese Hamster Ovary (CHO) cells and we found that the neutral lipid content of the LDs is significantly higher in PEX2-null CHO cells during normal cellular growth and under starvation compared to wild type CHO cells. Therefore peroxisomes are likely to play a role in regulating LDs. Our objective of the current study is to evaluate the neutral lipid and phospholipid contents of LDs in fibroblast cell lines from patients with peroxisomal disorders under normal and starvation condition. We are studying LD numbers by their content of either neutral lipids or phospholipids in fibroblast cell lines from patients with defective peroxisome assembly in 13 different PEX genes. We will use the green neutral lipid and red phospholipid specific immunofluorescence staining (LipidTOX™) to compare the contents of LDs between control and PEX gene-deficient fibroblast cell lines under normal and starvation conditions. This study highlights another pathway of intracellular organelle communication between peroxisomes and LDs, and helps us to understand pathophysiology in the peroxisomal biogenesis disorders.

2342F

Acute intermittent porphyria (AIP): high incidence of pathogenic hydroxymethylbilane synthase non-synonymous variants in genomic databases suggests other predisposing genetic and/or environmental factors for acute attacks. *B. Chen, J. Hakenberg, C. Solis-Villa, R. Srinivasan, D. Doheny, I. Peter, R. Chen, D. Bishop, M. Yasuda, R. Desnick.* Genetics and Genomics Sciences, Mount Sinai School of Medicine, New York, NY.

AIP is an autosomal dominant hepatic porphyria due to the half-normal activity of the heme biosynthetic enzyme, hydroxymethylbilane synthase (HMBS). Symptomatic individuals experience life-threatening acute neurovisceral attacks that are triggered by factors that induce the up-regulation of hepatic 5'-aminolevulinic acid synthase (ALAS1) with resultant accumulation of neurotoxic porphyrin precursors, aminolevulinic acid (ALA) and porphobilinogen (PBG). To date, over 360 *HMBS* pathogenic mutations have been reported in the Human Gene Mutation Database (HGMD). The disease prevalence in Western Europe was estimated at 1 in 160,000 to 220,000 (Elder et al, 2013). However, the frequency of pathogenic *HMBS* mutations that markedly reduce enzyme activity and the actual disease penetrance remain unknown. To estimate the prevalence of likely pathogenic *HMBS* mutations, we interrogated the 1000 Genomes Project and the NHLBI Exome Sequencing Project (ESP) databases. Among Caucasians, 13 non-synonymous (NS) and 9 synonymous (S) variants were identified. Allele frequencies for the 13 NS variants ranged from <0. 01% to 0. 28%. Of the 9 S variants, 4 encoding T35T, S45S, L161L, V202V were predicted to affect splice site enhancers or silencers, possibly causing splicing defects. Of the 13 NS variants, 4 encoding E86V, R195C, R225Q, R321H were reported as pathogenic in the HGMD. All NS variants were evaluated by 14 *in silico* prediction programs and prokaryotically expressed *in vitro* to assess their pathogenicity. *In silico* programs predicted 5 variants as "pathogenic" (encoding D65H, I71T, A122P, R195C, R225Q), 2 (R246H, R355Q) as "ambiguous", the remaining 6 as "likely benign". *In vitro* HMBS expression revealed that A122P and R195C mutant proteins are pathogenic with ~ 3% of expressed wild-type (WT) activity**.** All other NS variants, including 3 previously reported in HGMD (E86V, R225Q, R321H), had 60 – 110% of expressed WT activity and had > 60% of WT thermostability**.** Notably, the combined frequency of the 2 pathogenic *HMBS* alleles, A122P and R195C, is ~ 0. 02% (1 in 2500). Thus, the penetrance of AIP would be low, ~ 2% or lower among AIP heterozygotes, as the prevalence of patients with acute attacks is estimated ~1 in 200,000 in Europe. These results reiterate the importance of functional studies of gene variants and suggest that modifying genes and/or environmental factors are involved in the pathogenesis of acute attacks of AIP.

X chromosome inactivation in 82 female patients with Fabry disease. *L. Echevarria[1,2], I. E. Jurca-Simina[2], K. Benistan[2], S. Ben Khaled[2], C. Boucly[2], L. Cuisset[3], L. Gadi[2], F. Jabbour[2], C. Jauny[2], S. Medaouri[1], R. Y. Carlier[2], D. P. Germain[1,2,4].* 1) University of Versailles, Division of Medical Genetics, 78180 Montigny, France; 2) French Referral Center for Fabry disease and inherited disorders of connective tissue, 92380 Garches, France; 3) University Paris V Descartes, Laboratory of Biochemistry and Molecular Biology, CHU Cochin, 75014 Paris, France; 4) University of Versailles, UMR 1179, 78180 Montigny, France.

Background: Fabry disease (FD) is an X-linked genetic disorder caused by the deficient activity of lysosomal alpha-galactosidase. While males are usually severely affected, clinical presentation in female patients may be more variable ranging from asymptomatic to, occasionally, as severely affected as male patients. **Aims**: To evaluate the existence of skewed X chromosome inactivation (XCI) in females with FD, its concordance between tissues, and its contribution to the phenotype. **Methods**: 82 females with FD were enrolled. Clinical and biological work-up included two global scores (MSSI and DS3), cardiac magnetic resonance imaging, measured glomerular filtration rate using the 51Cr EDTA method, cerebral magnetic resonance imaging, pain assessment, and measurement of alpha-galactosidase activity. XCI was analysed in 4 tissues using *HUMARA*, *PCSK1N* and *SLITRK4* genes methylation studies. **Results**: Skewed XCI was found in 26% of the study population. A correlation was found in XCI patterns between blood and the other analysed tissues. Significant differences in residual alpha-galactosidase levels, severity scores, progression of cardiomyopathy, deterioration of kidney function and distribution of angiokeratoma, with the direction and degree of skewing of XCI were evidenced. Analyses of neurological involvement are ongoing. **Conclusion**: X chromosome inactivation is a significant modifier of the clinical phenotype in female patients with Fabry disease.

Trisomy 8 mosaicism in Colombia. *P. Paez[1], AM. Gómez[2].* 1) Universidad el Bosque, Facultad de Medicina, grupo IINGM, Bogotá, Colombia; 2) Hospital Universitario Clínica San Rafael, Bogotá, Colombia.

Introduction. We describe a case of trisomy 8 mosaicism (T8M) in Colombia; this is the second case from Colombia reported in the literature and the first one of an adult female that has been followed up for a long time. We compare the findings of this case with those reported previously, including the first Colombian patient. Case description. A 19-year-old female born from a normal first pregnancy and from healthy parents was referred for evaluation because of developmental delay. The child showed speech difficulties and cognitive delay. She presents facial dysmorphism and orthopedic anomalies: camptodactyly of second through fifth fingers, scoliosis, and deep plantar creases; urogenital anomalies: left double urinary collecting system and right double renal pelvis. Her karyotype revealed a trisomy 8 mosaicism (47,XX,+8[40]/46,XX[10]), and neuroimaging showed agenesis of corpus callosum. Discusion. Warkany syndrome or trisomy 8 is a rare clinical condition with a frequency of about 1:25000 to 1:50000 births that more frequently appears as trisomy 8 mosaicism (85%). The prevalence of this syndrome in Colombia is unknown. This patient presents the classical phenotype: facial dysmorphism, camptodactyly, deep plantar furrows, cognitive delay, urogenital anomalies, and agenesis of corpus callosum. These findings were less flourished in the first Colombian case that only presented facial dysmorphism, developmental delay, and scoliosis. This is in agreement with the high phenotypic variability described among affected patients. About 25% of patients with T8M present congenital heart defects and there is an increased incidence of hematologic malignancies. Nevertheless, Colombian patients are negative for cardiac disease or malignances. The condition arises post-cygotically through a mitotic error with the consequence of a dosage effect. However, the phenotypic variability between patients (like that of Colombian patients) has not yet been understood. Recently, it has been described in trisomic fibroblasts a characteristic expression and methylation pattern even on genes at other chromosomes, which in cooperation with the gene dosage effect of genes on the chromosome 8 may explain the clinical features and elevated cancer risk seen in these patients. Finally, the deregulation of some genes like AGPAT6, CPXM2, CRYAB, has been reported as an explanation for cognitive delay.

2345T

A genetic liability model explains the sex bias in neurodevelopmental disorders. *A. Polyak[1], J. Rosenfeld[2,3], S. Girirajan[1,4].* 1) Biochemistry and Molecular Biology, Pennsylvania State University, University Park, PA; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Signature Genomic Laboratories, PerkinElmer, Inc. , Spokane, WA; 4) Department of Anthropology, Pennsylvania State University, University Park, PA.

Neurodevelopmental disorders such as autism and intellectual disability/developmental delay (ID/DD) have been associated with a significant sex bias with a diagnosis skewed towards males. A systematic assessment of this bias has been confounded by factors such as phenotypic and genetic heterogeneity, and a history of neuropsychiatric phenotypes often reported in the families of affected individuals. To assess the extent of sex bias within these factors, we analyzed the frequency of comorbid features, magnitude of genetic load, and the existence of family history within 32,155 individuals ascertained clinically for autism or ID/DD, including subset of 8,373 individuals carrying rare copy number variants (CNVs). We find that females are more likely to manifest comorbid features within both autism (p=2. 9×10-6, OR=1. 34) and ID/DD (p=7. 2×10-4, OR=1. 08) cohorts. The male to female ratio of ascertainment for ID/DD and autism was contingent upon the presence of specific comorbid features, ranging from 8:1 for autism with psychiatric comorbidities, to 2. 5:1 for autism with epilepsy. This ratio was also contingent on specific CNVs, ranging from 8:1 observed in autistic individuals carrying 22q11. 2 duplication and 1. 3:1 in those carrying 16p11. 2 deletion. Males between ages 12 and 18 years showed a higher frequency of comorbid features than those younger than 5 years for autism (p=0. 004, OR=1. 10) or ID/DD (p=3. 4×10-4, OR=1. 20). However, females showed little change in the frequency of comorbid features across the developmental stages. Further, females showed a higher frequency of large CNVs compared to males when comorbidities were considered separately or in aggregate, a phenomenon, which diminished when applied to severely ascertained cohorts. Affected males showed family histories such as autism (p=0. 04) or specific learning disabilities (p=0. 05) while females showed family histories of growth abnormalities (p=0. 03). Our results suggest a model where the genetic liability for the manifestation of neurodevelopmental phenotypes exist at different thresholds between males and females. These thresholds can be altered by the frequency and type of comorbid features, presence of disease-associated deletions and duplications, and a pre-existing family history of related phenotypes.

2346F

De novo deletion 2 (q 14. 1q21. 1) and association with attention deficit and hyperactivity. *J. G. Pappas[1], K. E. Daley[1], M. J. Messito[2], E. Brent[3], K. M. Hopkins[3].* 1) Dept Pediatrics, Clin Genetic Scvs, New York Univ, Sch Med, New York, NY; 2) Dept Pediatrics, New York Univ, Sch Med, New York, NY; 3) Dept Pediatrics, Division of Developmental and Behavioral Pediatrics, New York Univ, Sch Med, New York, NY.

De novo interstitial deletions of chromosome 2q that include band 2q14. 3 are rare. A published case report that includes a review of eight cases with variable breakpoints revealed common facial features, cognitive disability and attention deficit hyperactivity disorder (ADHD) (Grealy MT et al, 2014). We present an eight year old boy with de novo interstitial deletion 2q, language and learning difficulties (LLD) and severe ADHD. There is only one published case with deletion breakpoints similar to ours (Baker KL et al, 2001). Our case was born full-term to 21 year old. Pregnancy and delivery were uncomplicated. His birth weight was 3650 grams at the 75th centile, birth length 52 cm at the 75th centile and his head circumference 35. 5 cm at the 50th centile. He achieved his early motor milestones normally and he walked at age 15 months. Speech delay was ascertained at age two because he was unable to combine words and speech therapy was initiated. He had clinical and laboratory genetic evaluation at age three and a half. His weight was 19. 6 kilograms at the 97th centile, height 106. 5 cm at the 97th centile and his head circumference 50. 5 cm at the 50th centile. He had elongated face, large forward facing ears, single midline hair whorl and likely familial large forehead and midface hypoplasia present also in his mother. Routine peripheral blood karyotype reveled 46,XY,del(2)(q13q21. 1). Parental karyotypes were normal. Cardiac evaluation including echocardiography and renal ultrasound were normal in our case. Follow-up at age 7 revealed severe ADHD and LLD. Microarray (oligonucleotide, single nucleotide polymorphism, Affymetrix CytoScan HD) defined the breakpoints of the deletion as 2q14. 1q21. 1(114,949,093-131,610,682)x1 [hg19]. Our case shares ADHD, LLD, facial features and tall stature with the only published case with similar deletion (Baker KL et al, 2001). Other cases with deletions overlapping our case's deletionpresented with cognitive disability and various craniofacial abnormalities with large prominent forehead in six out ofnine published cases (Grealy MT et al, 2014). The ADHD was a striking feature of our case and it is shared with the published case with similar breakpoints. The CNTNAP5 gene is included in the deletion and its haploinsufficiency may be associated with ADHD (Pagnamenta AT et al, 2010). Our case contributes to delineation of the phenotype of the deletion 2(q14. 1q21. 1) and the association of CNPNAP5 haploinsufficiency with ADHD.

2347W

10-year-old Female with *KANSL1* Mutation and First Reported Case of Normal Intelligence. *C. Keen[1], C. Samango-Sprouse[1, 2, 3, 4], H. Dubbs[5], E. H. Zackai[6].* 1) The Focus Foundation, Davidsonville, MD; 2) Neurodevelopmental Diagnostic Center, Davidsonville, MD; 3) George Washington University, Department of Pediatrics; 4) Florida International University, Department of Molecular Genetics; 5) Children's Hospital of Philadelphia, Division of Neurology; 6) Children's Hospital of Philadelphia, Division of Clinical Genetics.

Introduction: Koolen-de Vries syndrome (KDVS), first described in 2006, occurs in 1 in 16,000 births and is caused by the microdeletion or mutation of the *KANSL1* gene located on chromosome 17q21. 3 [Koolen, 2006]. Phenotypic characterization includes epilepsy, cardiac defects, kidney problems, and skeletal anomalies [Koolen, 2006; Koolen, 2008; Tan, 2009]. Developmental delay, mild-to-moderate intellectual disability, a cheerful disposition, hypotonia, and distinctive facial features are also described. Speech and language-based difficulties, graphomotor dysfunction, and slow feeding are not uncommon in the current literature. To our knowledge, this is the first case of a child with *KANSL1* mutation with normal IQ and Childhood Apraxia of Speech (CAS). She has also been diagnosed with ADHD, and graphomotor dysfunction which is associated with Developmental Dyspraxia (Dev Dys). Methods: Comprehensive neurodevelopmental assessments and parent behavioral questionnaires were administered. All neurodevelopmental domains were probed including neuromotor, intelligence, speech and language, and executive function. All assessments were standardized on large normative samples in the United States. Results: Formal assessment indicated a low-normal IQ (VIQ=83) and several subtest scores within normal limits on the WISC-IV. She has a scaled score of 7 on similarities, comprehension and word reasoning. CAS was diagnosed early, characterized by hypotonia, slow feeding as a newborn, and speech delay. Dysarthria was apparent when longer speech patterns developed. She had below average performance on the BOT-2 in balance and strength, a reflection of truncal hypotonia. She also had below average performance on fine motor function supporting dysgraphia with graphomotor dysfunction. Conclusion: To our knowledge, this is the first reported case of normal IQ, Dev Dys, and CAS in KDVS. Dysgraphia and graphomotor dysfunction are further documentation of Dev Dys. In our patient, delayed speech, feeding issues, truncal hypotnoia are reflective of CAS, dysarthria and Dev Dys. This case expands the mild end of the developmental spectrum seen in children with KDVS and *KANSL1* mutation.

2348T

An 8. 3Mb 19p13. 2p13. 3 duplication associated with duodenal atresia and left ventricular noncompaction. *Y. Dowa[1,2], I. Imoto[3], M. Kawai[1], T. Heike[1].* 1) Department of Pediatric Neurology, Gunma Children's Medical Center, Shibukawa, Gunma, Japan; 2) Department of Neonatal Intensive Care Unit, Kyoto University Hospital, Kyoto, Kyoto, Japan; 3) Department of Human Genetics, Institute of Biomedical Sciences, Tokushima University Graduate School.

We report a new case of duplication of 19p13. A preterm baby admitted our neonatal intensive care unit because of very low birth weight, respiratory distress and suspicion of duodenal atresia. She was the first child of healthy non consanguineous parents. She was born at 35 weeks and 1day of gestation by caesarean section because her mother suffered from intrauterine infection and her cardiotocograph indicated non-reassuring fetal status. Her birth weight was 1321g (-3. 0 SD), height was 36cm (-3. 2 SD) and occipitofrontal circumference was 23. 5cm (-4. 4 SD). She presented severe intrauterine growth retardation, microcephaly, sparse hair, sparse eyebrows, epicanthal folds, flat philtrum, thin upper lip, microstomia, accessory ears, hypoplastic fourth toes and nails. The X-ray images revealed duodenal atresia. The blood cell count revealed severe thrombocytopenia and cardiac ultrasonography showed left ventricular noncompaction. She had also congenital stridor and feeding difficulty. G-banded chromosomal test and subtelomere FISH revealed direct duplication of 19p13. Her karyotype was 46,XX,dup(19)(p13. 2p13. 3). Further, we performed array-based copy number analysis (Affymetrix CytoScan HD). It showed a 19p13. 3 duplication of approximately 8. 3Mb which was consistent with the FISH results, a 5q35. 3 duplication of approximately 0. 2Mb and 11q11 deletion of approximately 0. 3Mb. As both 5p35. 3 duplication and 11q11 deletion were very small, they regarded asymptomatic changes. On the other hand, her facial appearance and the characteristic toes were compatible to previous reported duplication of 19p. But the complications of duodenal atresia and left ventricle noncompaction did not report yet. Our findings with a review of literatures allow clarification of a more precise and comprehensive phenotype-genotype correlation for 19p duplication.

2349F

Pallister–Killian Syndrome: Clinical and Cytogenetics Variability of five Egyptian patients. *M. M. Eid[1], O. M. Eid[1], S. Abdel Hadi[2], N. Farouk[3], G. El Kamah[4], H. H. Afifi[4], A. Median[1], G. M. H. Abdel Salam[4].* 1) Human Cytogenetics, National research center, Cairo, Egypt; 2) Pediatric Department, Cairo University, Cairo, Egypt; 3) Orodental Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 4) Clinical Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt.

Background: Pallister–Killian syndrome (PKS) is a rare sporadic genetic disorder caused by a mosaic tetrasomy of chromosome 12p, which manifests with characteristic facial features, intellectual disabilities, skin pigmentation abnormalities and epilepsy. The diagnosis of PKS can be complicated due to the phenotypic variation and the overlap with other syndromes that makes the molecular cytogenetic test necessary to confirm the diagnosis. **Method:**Five patients clinically suspected to have the characteristic facial feature for PK were included in this study. Pedigree construction, thorough clinical examination, radiological investigation and EEG. Heparinized blood sample for karyotyping and buccal samples or skin biopsy for FISH analysis were collected. **Results:**The ages of our patients ranged from 10 months to 2 years. All the patients have the characteristic clinical findings that present in PK patients in form of bitemporal alopecia, hypertelorism, and abnormal ears. Further, all patients had pigmentary skin anomalies, and hypotonia. Although seizures and epilepsy are of common features in PKS and some may consider it part of the triad for the diagnosis that include also characteristic facial feature, skin pigmentation abnormalities, non of our patients exhibited any of them and their EEG examinations were normal. Also, another interesting finding in our patients is the presence of hypogenesis or very thin corpus callosum in all patients. No major organ was affected. FISH analysis using sub telomere 12p probe on skin fibroblast or buccal samples could clearly confirm the diagnosis by the presence of 4signals of the probe instead of normal 2. **Conclusion:**The patients included in this study have shared the characteristic features those previously reported for PKS, however they differed in some clinical aspects. The percentage of the tetrasomy 12p might explain the variability in the severity of the clinical condition that could be attributed to the gene dose that present in the supernumerary chromosome.

2350W

Ring chromosome 15: expanding the phenotype. *H. El-Bassyouni[1], M. Eid[2], O. Eid[2], S. Hammad[2], A. El-Gerzawy[2], M. Zaki[1], M. El-Ruby[1].* 1) Clinical Genetics, National Research Centre, Cairo, Egypt; 2) Cytogenetics Department, National Research Centre, Cairo, Egypt.

Ring chromosome 15 is a rare disorder, with less than 50 cases reported in the literature to date. We report the **c**linical and cytogenetic evaluation of a patient with ring chromosome 15. Diagnostic tests including echocardiography, abdominal ultrasound, brain computerized tomography (CT), magnetic resonance imaging (MRI) and electroencephalogram (EEG) were done. Clinical examination of the patient revealed the characteristic features of ring chromosome 15, such as growth retardation, hypertelorism, frontal bossing, a highly arched palate, small hands and feet and café-au-lait spots. In addition, the patient presented with a mild intellectual disability, a congenital atrial septal heart defect, and abnormal EEG records. We also report 2 novel findings, which to our knowledge; have not been reported before in ring chromosome 15 patients: large areas of hyperpigmentation on the front of both legs and feet and hypogenesis of the corpus callosum. Cytogenetic studies using both conventional G-banding and fluorescence in situ hybridization (FISH) with a Sub Tel 15q probe confirmed the diagnosis of ring chromosome 15. .

Puberty evolution in Jacobsen Syndrome. *C. M. Jurca[1,2], K. Kozma[1,2], O. Iuhas[1], A. Jurca[2], C. Cladovan[1,2], M. Bembea[1,2].* 1) Genetics Department, Municipal Clinical Hospital dr. Gavril Curteanu Oradea, Oradea, Bihor, Romania; 2) Faculty of Medicine and Pharmacy, Oradea.

BACKGROUND: Jacobsen Syndrome (JS) is a contiguous gene syndrome caused by partial deletion of the long arm of chromosome 11. It is a rare syndrome, first described in 1973 by Jacobsen. About 200 cases have been reported thus far. The incidence is about 1/100,000 newborns, with a female/male ratio of 2:1. The key features of the syndrome are prenatal and postnatal growth failure, mental retardation, craniofacial dysmorphism, and thrombocytopenia. Approximately a quarter of children with JS die in infancy. There are very few observations regarding the pubertal period of patients with JS. OBJECTIVES: Identify, describe and monitor pubertal characteristics of patients with JS. CASE REPORT: We present the case of a patient, now a 22 year-old female, who has been monitored in our Genetics Department since the age of 3 months. She had intrauterine growth retardation, failure to thrive, and feeding difficulties. Phenotypically she shows short stature, severe mental retardation, and characteristic craniofacial dysmorphism suggesting JS: microcephaly, trigonocephaly, hypertelorism, bilateral iris coloboma, down-slanting palpebral fissures, palpebral ptosis, strabismus, epicanthic folds, small nose, depressed nasal bridge, thin upper lip, large mouth, small lower jaw, and low set ears. Bilateral clynodactyly, camptodactyly and simian creases are present. She learned to walk at the age of 4 years; she shows spasticity and has profound delay in gross and fine motor skills. She has severe learning difficulties, communicates non-verbally, and displays heteroaggressive and autoaggressive behavior, which have been more pronounced after puberty. She has a mild hemorrhagic tendency. Primary amenorrhea and genital infantilism are evident. Hematological (pancytopenia) and immunological (IgM deficiency) anomalies, absent in infancy, became apparent at puberty. Karyotype: 46, XX del (11) (q23. 3-qter). DISCUSSION: This is an unusual case of JS by rare frequency and uncommon survival. We identified evolution through puberty, with hematologic and immunologic changes, primary amenorrhea, genital infantilism and aggressive behavior. CONCLUSIONS: Patients with JS need special monitoring during puberty. KEY WORDS: Jacobsen Syndrome, mental retardation, craniofacial dysmorphism, thrombocytopenia, puberty.

2352F

A rare case with chromosome 10p15. 1p11. 22 duplication. *E. Kirat, H. Ulucan, G. Guven, A. Koparir, N. Bilge, M. Seven.* Istanbul University Cerrahpasa Medical faculty, Istanbul, Turkey.

Trisomy 10p is a rare chromosomal abnormality which is characterized by severe growth and mental retardation, craniofacial anomalies including dolichocephaly, delayed closure of fontanels, frontal bossing, hypertelorism, up-slanting palpebral fissures, broad nasal root, distinctive mouth, and high arched and cleft palate, camptodactyly, club foot and congenital heart defects. Clinic features vary according to part of trisomic chromosomal region. Here we present a 6-year-old boy with partial trisomy 10p. He was referred to our clinic for developmental delay and dysmorphic features such as dolichocephaly, slanting palpebral fissures, broad nasal root, and micro/ retrognathia. He also had bilateral camptodactyly and club foot. Chromosome analysis showed 46,XY-,der(19)ins(19;10)(q13. 1;p15p11. 2). We analyzed this trisomic region in detail by SNP array as arr[hg19] 10p15. 1p11. 22(5,537,569-33,489,889) x3. This rearrangement with the specific phenotype is discussed reviewing the literature.

2353W

An extremely rare case of trisomy 8 and trisomy 21 mosaicism. *K. Kozma[1,2], O. Iuhas[1], C. M. Jurca[1,2], V. Filip[2], C. Nagy[1], M. Bembea[1,2].* 1) Genetics Department, Municipal Clinical Hospital dr. Gavril Curteanu Oradea, Oradea, Bihor, Romania; 2) Faculty of Medicine and Pharmacy Oradea.

BACKGROUND: Trisomy 8 mosaicism (T8M), also known as Warkany syndrome 2, is a very rare chromosomal abnormality (1:25,000 – 1:50,000 live births) defined by the presence of three copies of chromosome 8 in some cells of the organism (46/47+8). Mosaicism of trisomy 8 and another autosome is extremely rare in live births but was described in some miscarriages and in chronic myeloid leukemia. CASE REPORT: We report the case of a 2 week old baby boy evaluated for craniofacial dysmorphism. He shows a square face, frontal bossing, large anterior fontanel, hypertelorism, deep set eyes, broad nasal bridge, broad/bulbous nose, upturned nostrils, macrostomia, everted lips, micrognathia, high vaulted palate, frenulum of the superior lip adherent to the midline of gingiva, uncommon hypertrophy of the gum at the level of the superior central incisors teeth, dysplastic ears with partial absence of the helix, prominent antihelix, and large lobules. Other traits: deep palmar and plantar creases, abnormal dermatoglyphics, broad toes, prominent calcaneus, short neck with extra skin fold, narrow shoulder, elongated trunk, large mongolian spot of the back, bilateral hydrocele. Radiological findings: hypoplasia of viscerocranium, wormian bones of posterior fontanel and occiput, blurred cranial sutures, sclerosis of orbits and base of skull, large, curved ribs, vertebral anomalies. Organ anomalies: ventricular and atrial septal defect, agenesis of the corpus callosum, agenesis of right kidney, left hydronephrosis. Karyotype: 47,XY,+8(43)/47,XY,+21(10). DISCUSSION: To our knowledge no kindred have been presented with this type of mosaicism in the literature. We discuss the mechanism of the anomaly, the impact for prenatal diagnosis, as well as the need for early postnatal diagnosis, and better management. CONCLUSIONS: This unique case is a challenge in diagnosis and management of a rare trisomic mosaicism. KEY WORDS: chromosomial mosaicism, trisomy 8, trisomy 21, craniofacial dysmorphism.

2354T

Genotype-phenotype correlation of an 8p complex rearrangement. *L. Martelli[1,2], C. H. P. GRANGEIRO[1,2], A. G. GOMES[1], T. M. JOAQUIM[1], L. A. F. LAUREANO[2], J. D. GRZESIUK[1], F. G. O. GENNARO[1], J. HUBER[2], J. A. SQUIRE[1,3].* 1) Genetics Dept, Ribeirao Preto Medical School, University of Sao Paulo, Ribeirao Preto, SP, Brazil; 2) Medical Genetics Dept, Clinical Hospital, Ribeirao Preto, SP, Brazil; 3) Pathology Dept, Ribeirao Preto Medical School, University of Sao Paulo, Ribeirao Preto, SP, Brazil.

Partial duplication 8p is associated with congenital anomalies and different levels of mental retardation. However, the overall spectrum depends on the size and genomic location of the duplicated region. Inverted duplication 8p associated with 8p deletion is an uncommon complex chromosomal rearrangement, with an incidence of 1 in 10,000–30,000 liveborns. We describe a female child initially evaluated by obstetric ultrasonography with corpus callosum agenesis, single umbilical artery and ureteropelvic junction obstruction. Physical examination showed craniofacial dysmorphisms - macrobrachycephaly, arching eyebrows, upslanting palpebral fissures, small nose with anteverted nares, small mouth, hirsutism - and global hypotonia. Cranial MRI indicated corpus callosum agenesis and reduced white matter. US urinary tract showed marked left pyelocaliceal dilatation secondary to obstructive uropathy and cystourethrography with neurogenic/overreactive bladder. The proband had severe delay in psychomotor development, skeletal deformities (kyphosis, pectus excavatum and planovalgus feet) and recurrent urinary infections. Chromosomal analysis by GTG banding revealed 46,XX,add(8p),inv(9)(p13q13). Her father had the same inversion and maternal karyotype was normal. Evaluation by aCGH (2x400k Agilent®) showed a 3. 7Mb deletion at 8p22. 2-22. 3 and four gains at 8p11, 8p12 and 8p22 (two regions) corresponding to 7Mb. Deletion on 8p22. 2-22. 3 involved the *MIR596, ARHGEF10, KBTBD11, MYOM2* and *CSMD1* genes. Losses in that region have been associated with different phenotypic findings including intellectual disability and autism spectrum. The 2Mb gain at 8p12 includes the genes *NRG1* (neuregulin) and *TTI2,* both associated with cell-cell signaling in growth and development of multiple organ systems. *NRG1* is also related to the recycling and maintenance of urothelium and can be a potential biomarker of overactive bladder. The 1. 8Mb gain in 8p11. 22-p11. 23 includes four genes associated with neurogenesis: *GPR124, DDHD2, ADAM5* and *ADAM18*. The first gain at 8p22 of 1. 7Mb involved the gene *MTMR7*, a member of the myotubularin family of tyrosine/ phosphatases, that interact with *PTEN*. This interaction could explain the macrocephaly. The second gain at 8p22 of 1. 5Mb involved the *TUSC3* gene, also associated with mental disability. Exhaustive clinical evaluation and genomic characterization of the deletion and duplication size were essential for diagnosis and genetic counseling.

2355F

Breakpoint mapping by chromosome microdissection and next generation sequencing in patients with balanced chromosomal rearrangements and correlation to phenotype. *M. I. Melaragno[1], M. Moysés-Oliveira[1], M. A. P. Ramos[1], M. C. P. Cernach[1], M. Z. de Souza[1], N. Kosyakova[2], T. Liehr[2], D. Hardekopf[3], J. Stika[3], R. Plachy[3], T. Jancuskova[3].* 1) Genetics Division, Universidade Federal de Sao Paulo, Sao Paulo, Brazil; 2) Institute of Human Genetics, Jena University Hospital, Friedrich Schiller University, Jena, Germany; 3) synlab genetics s. r. o. , Laboratory synlab genetics s. r. o. , Prague, Czech Republic.

The use of next-generation sequencing (NGS) technology for breakpoint sequencing in patients with balanced chromosome abnormalities (BCA) has proven useful for identifying gene disruptions and novel candidate disease loci. We studied two new patients with balanced rearrangements: (1) a 2 year-old female patient with a pericentric inv(20)(p11. 21q12) showing mild hypotonia, wide forehead and protruding to preach in the glabella, large ears with sharply bended helices, small mouth with high and narrow palate, long and tapered fingers, anteverted nostrils, and mild micro/retrognathia; and (2) a 29 year-old woman with a balanced t(4;7)(q28. 3;p22. 1) with flat face, mild brachycephaly, telecanthus, epicanthus, high myopia, high and narrow palate, micrognathia, mild obesity, and mild intellectual disability. Chromosomal microarray showed no potentially disease-associated copy number variations. Regions around the breakpoints of the rearranged chromosomes (about 20–40 Mb) were microdissected using glass microneedles and DNA was amplified by DOP-PCR. The chromosomal origin of the microdissected segment was assessed by reverse chromosome painting (i. e. , fluorescence in situ hybridization on normal chromosome spreads). The GS Junior platform (Roche) was used for next generation sequencing. Chromosomal breakpoint positions of altered chromosomes were identified with accuracy of ~3kb, and referred according to GRCh38. The patient with t(4;7) showed the breakpoints in 4q28. 3(133,193,610bp), in an intergenic region, and in 7p22. 1(5,326,264) in the *TNRC18* gene (trinucleotide repeat containing 18). The patient with inv(20) showed breakpoints in 20p11. 21(24,813,647) and 20q12(41,844,905), both in intergenic regions. The only disrupted gene was *TNRC18* in patient 1 that codes a protein with unknown function but with a potential transcription regulatory region sequence-specific DNA binding. No phenotypic alteration was reported associated to this gene. DECIPHER shows some deletions involving *TNRC18* gene and several other genes in patients, some whom have brachycephaly and high palate. Thus, our data indicate no definitive candidate gene for the disease in the patients. We concluded that phenotype in our patients may underlie more complex pathogenic mechanisms than interruption of specific candidate genes, such as position effect flanking genes near the breakpoints, or other genetic alterations unrelated to the balanced rearrangement. Financial support: FAPESP, Brazil.

2356W

Natural history of patients with trisomy 13 receiving pediatric intensive management. *E. Nishi[1,2], M. Takasugi[3], T. Hlroma[3], M. Arakawa[1], T. Nakamura[3], Y. Fukushima[2], T. Kosho[1,2].* 1) Division of Medical Genetics, Nagano Children's Hospital, Azumino, Japan; 2) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 3) Department of Neonatology, Nagano Children's Hospital, Azumino, Japan.

Trisomy 13 (T13) is a most common autosomal trisomy syndrome, characterized by multiple congenital anomalies, severe developmental delay, and a short life span with the 1-year survival rate as 5–10 % and the median survival time as 7 days according to a large-scale population-based study. Management of neonates with T13 is controversial, palliative care or intensive care, supposedly due to the lack of precise clinical information of the natural history, especially on efficacy of treatment. To delineate natural history of T13 managed under intensive treatment, we reviewed detailed clinical data of 24 patients with full T13 admitted to Nagano Children's Hospital, providing pediatric intensive treatment to those with T13, from 1994 to 2014. Thirteen patients (54%) were found to have fetal ultrasonographic abnormalities, and five were diagnosed with T13 karyotypically. Eight patients were born by cesarean section, which was selective in one and emergent in seven. The most common indication for emergent cesarean section was fetal distress. All patients needed resuscitatation, intubation in 20, and had respiratory and cardiovascular stabilization. Mechanical ventilation was required by 21, six of whom were extubated and 12 of whom needed tracheostomy. Mean birth weight was 2273 g (range, 690 to 3758). Major complications included congenital heart defects (92%), cleft lip or cleft palate (67%), polydactyly (63%), and cryptorchidism (53% of male). Surgical operations were performed on 16 patients (67%), including tracheostomy, ileostomy, hepatic portenterostomy, lens removal for cataract, and correction of umbilical hernia, cleft lip, and polydactyly. Survival rates at age 1 week, 1 month, 1 year, 2 year, and 5 year were 100%, 96%, 46%, 25% , and 17% respectively. Median survival time for both sexes was 335. 5 days, (range, 22 to 3987). It was longer for boys (443 days) than for girls (181 days). Nine patients (38%) were discharged home. Twenty-one patients (88%) were fed enterally, including five having blender food through gastrostomy, eight using ED tube for gastroesophageal reflux, and five fed orally. In conclusion, the current study, though the sample size is small, would demonstrate much longer survival in patients with T13 having pediatric intensive management than in the cohorts described in previous population-based studies. The evidence is helpful for clinicians to offer the best information on treatment options to families of patients with T13.

2357T

Down Syndrome Resources for Clinicians and Investigators: The DS-Connect® Registry Professional Portal and an Updated NIH Research Plan. *M. Parisi[1], S. Bardhan[1], D. Jae[2], L. Kaeser[1], V. Rangel Miller[2].* 1) IDD Branch, NICHD, NIH, Bethesda, MD; 2) PatientCrossroads, San Mateo, CA.

Down syndrome (DS) is the most common genetic cause of intellectual disability. The National Institutes of Health (NIH) has supported research in DS to better understand and to develop effective treatments for those with this chromosomal disorder. As one effort to develop research resources, the *Eunice Kennedy Shriver* National Institute of Child Health and Human Development (NICHD), NIH, launched *DS-Connect®: The Down Syndrome Registry* (http://DSConnect. nih. gov) in 2013 to facilitate information sharing among persons with DS, families, and researchers. The Registry has been supported by the Down Syndrome Consortium, a public-private partnership composed of self-advocates and family members, DS researchers, leaders of professional DS organizations and foundations, and members of the Trans-NIH Down Syndrome Working Group (DSWG). As of June 2015, the registry had nearly 3000 participants. Individuals with DS and family members enter demographic and health information into the online, secure, confidential *DS-Connect®* database. Registry participants can answer surveys, see graphs of their child's height and weight, look up local health care providers, and view aggregate de-identified data from all participants. A professional portal was launched in December 2014 for clinicians and researchers with 3 levels of access depending on their needs: Level 1 users can view the de-identified data and perform detailed searches; Level 2 users can perform more complex searches and review individual-level data; and Level 3 users can post a study notice, work with a Registry Coordinator to recruit for a study, or develop a commercial application. A Research Review Committee reviews all Level 3 requests to ensure that they are scientifically sound. Examples of Registry-supported studies will be presented. A Spanish language version and mobile-device interface are planned for 2015. In addition, the DSWG has developed objectives for DS research across NIH and published *Down Syndrome Directions: The NIH Research Plan on Down Syndrome*, a 2014 update to the first plan developed in 2007. The new research plan demonstrates progress in all the research domains, but gaps remain in several longer-term objectives. The plan provides goals for the new category of "DS and Aging" in recognition of the high prevalence of Alzheimer's disease in aging individuals with DS. The updated research plan is available at [https://www.nichd. nih. gov/publications/Pages/pubs_details. aspx?pubs_id=5865].

2358F

A possible chromosome 9 new heteromorphic variant in a patient with phenotypic alterations. *A. Perez[1,2], M. E. S. Colovati[2], N. Kosyakova[3], T. Liehr[3], A. B. Hamid[3], M. I. Melaragno[2], A. C. M. Malinverni[2].* 1) Medical Genetic Center, Universidade Federal de São Paulo, São Paulo, Brazil; 2) Genetics Division, Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, Brazil; 3) Institut fur Humangenetik , Universitatsklinikum Jena, Jena , Germany.

Several alterations involving chromosome 9 are considered normal population variants. These variants include 9qh+, 9cenh+, 9ph+, 9phand inv(9)(p11q13). The frequency of these variants is approximately 1. 5% in the general population and they are referred to as heterochromatic variants or heteromorphisms, commonly found in routine cytogenetics. Studies with fluorescence in situ hybridization (FISH) using different probes have classified heterochromatic variants in different pattern types (Kosyakova et al, 2013). On the other hand, some studies have associated these heteromorphisms with several clinical disorders such as intellectual disability, congenital malformations and infertility. We report on a 15 year-old female patient who presented with intellectual disability delayed, language and neurodevelopment delay and facial dysmorphism. Her karyotype using GTG-banding in 20 metaphases revealed a pericentric chromosome 9 inversion: 46,XX,inv(9)(p12q13). The SurePrint G3 Human SNP+CGH Microarray, 4x180K (Agilent®) revealed a duplication of approximately 6 Mb, including 22 genes: arr[hg 19]9p13. 1p11. 2(38,869,901-44,870,714)x3. FISH was performed with pericentromeric 9 mix probes and with several chromosome 9 probes: RP11-397D12 (9p13. 2), RP11-246P17 (9p13. 1), RP11-138L21 (9p13. 1), RP11-448C16 (9p12), and RP11-138K6 (9p11. 2). An unusual rearranged chromosome was found: 46,XX,der(9)(pter→p11. 2::q21. 11→q12::p11. 2→p13. 2::q12→p11. 2::q21. 11→qter). Since this chromosome 9 pattern has not been described before, this rearrangement was considered molecular cytogenetically unbalanced. However, patient´s father´s karyotype showed a similar chromosome 9 possibly indicating a variant not described to date. Thus, chromosome 9 variants may be more complex than previously thought, and their precise characterization using a combination of different techniques (G- and C-banding, genomic array and FISH with different probes) is essential for a better knowledge of this intriguing chromosome region. Financial support: FAPESP.

Perspective of Mosaic Patau Syndrome. *J. Roy.* Amity Institute of Biotechnology, Noida, India.

Abstract: Trisomy 13 is one of the most common autosomal disorders in newborns. Popularly known as Patau Syndrome, the disorder is seen in 1 out of every 10,000 live births, out of which 5% are a result of mosaicism. Mosaicism is a condition where an extra chromosome 13 is present only in some of the person's cells. It is not inherited. With postfertilization nondisjunction, a random misdivision occurs in the cell's early mitotic stages. As a result, the infant has two different cell lines: cells with a normal complement of 46 chromosomes and cells with 47 chromosomes. This mixture of cells is referred to as mosaicism. The excess genetic material in each cell is disruptive to their course of development, leading to the characteristic features of Patau syndrome. The physical features of people with mosaic Patau syndrome are many times milder than persons with full Patau syndrome as all the cells do not have an extra copy of chromosome 13. Therefore, they have normal development in some cases with mild dysmorphic features. Few of them also turn out to have a better life expectancy than people with full Patau syndrome. Although, the phenotype and clinical outcome vary greatly in mosaic trisomy 13 often resulting in early death from major malformations. Many live born infants with mosaicism even die within the first month. Mosaic Patau syndrome causes serious physical and mental abnormalities, including heart defects, unusual facial features such as a sloping forehead, a smaller than average head (microcephaly), small or missing eyes (microphthalmia),cleft palateor extra fingers and toes (polydactyly), abnormal genitalia andmental retardation. Since it cannot be cured, genetic counselling is highly encouraged for knowing the chances of other babies being affected, as well as understanding the diagnosis options for identification at foetal stage. Genotypes and copy number information provided by Single-nucleotide polymorphism (SNP) array allow determination of parental origin and uniparental disomy status and direct quantification of mosaicism. Such information may lead to a better understanding of mechanisms of mosaicism, the observed phenotypic variability and better prediction of recurrent risk. **Key words**: Patau Syndrome, mosaicism, SNP array, uniparental disomy.

2360T

The Impact of Early Hormonal Therapy (EHT) on Anthropomorphic Measurements in 47, XXY from 4 to 96 months of age. *C. Samango-Sprouse[1, 2, 3, 4], C. Keen[2], C. Sprouse[5], T. Sadeghin[1, 2], S. Powell[6], A. Gropman[7].* 1) Neurodevelopmental Diagnostic Center, Davidsonville, MD; 2) The Focus Foundation, Crofton, MD; 3) George Washington University, Department of Pediatrics; 4) Florida International University, Department of Molecular Genetics; 5) Georgetown University, Department of Neuroscience; 6) George Washington University; 7) Children's National Medical Center, Division of Neurodevelopmental Disabilities and Neurogenetics.

Introduction: 47, XXY (Klinefelter's Syndrome) is the most commonly occurring chromosomal aneuploidy (1:650) [Chang et al. , 2015]. Though the phenotype varies substantially among those effected, it is clinically defined by small testes, hypogonadism, and neurodevelopmental dysfunction [Skakkebaek et al. , 2015]. These common features are thought to result from a decrease in testosterone levels caused by the extra X. Testosterone replacement therapies have been found to remedy many consequences associated with androgen deficiency [Samango-Sprouse et al. , 2015]. While these findings are well known, the impact of EHT on the physical growth in XXY is not well understood. It has been postulated that EHT may alter growth patterns of boys with XXY but this has not been well investigated. This study investigated the effects of EHT on head circumference (HC), height (HT), and weight (WT) in boys with XXY at 36, 72, and 96 months of age. Methods: As part of the continuing assessment and follow up at the Neurodevelopmental Diagnostic Center, anthropomorphic measurements were taken and recorded by a nurse blinded to each child's course of treatment (n=158). 59 boys were evaluated at 4-36 months; 22 had received EHT, 37 had no EHT. 68 boys were evaluated at 37-72 months; 34 had received EHT, 34 had no EHT. 31 boys were evaluated at 73-96 months; 19 had received EHT, 21 had no EHT. To maintain fidelity of all data, data was calculated and entered by someone blinded to the study. Appropriate biostatistics were completed on the anthropomorphic measurements to determine if EHT had impact between 4 and 96 months of age. Results: Findings indicate EHT does not significantly alter HC, or HT from 4-96 months in XXY boys. There was a significant difference in WT between treated and untreated boys at 73-96 months (p=. 025). Boys who had received EHT weighed 2. 3kg more than boys who received no EHT. Discussion: XXY boys have an androgen deficiency that may begin prenatally to have long-term effects on multiple areas of neurological function. To our knowledge, this is the first study demonstrating no deleterious effects of EHT on anthropomorphic measures for XXY boys from 4-96 months of age. Muscle tone improved in the EHT group, as demonstrated through the BOT-2, possibly explaining the significant difference between the two groups at 73-96 month. This suggests positive effects of EHT on selective aspects of growth and development.

Towards the identification of 9p21. 1 deletion genesis in a family with development delay. *F. J Sheth[1], J. Andrieux[2], T. Liehr[3], K. Shah[1], S. Trivedi[1], M. Desai[1], A. Shah[1], B. Patel[1], JJ. Sheth[1].* 1) Cytogenetic and Molecular Cytogenetic, FRIGE's Institute of Human Genetics, Ahmedabad, Gujarat, India; 2) Laboratory of Medical Genetics, Jeanne de Flandre Hospital CHRU de Lille, Lille Cedex, France; 3) Jena University Hospital, Friedrich Schiller University, Institute of Human Genetics, Kollegiengasse 10, 07743 Jena, Germany.

Statement of purpose Advancement in various cytogenetic diagnostic techniques has helped in detection of more cryptic segmental aneuploidies in cases with multiple congenital anomalies/dysmorphism with or without mental retardation. We report here a family; a young non-consanguineous couple reported with two spontaneous first trimester miscarriages followed by birth of two female children with unexplained mental retardation, associated dysmorphism and global developmental delay especially motor delay, absence of speech and recognition at the age of 7 and 5 years. The mother at 5thgravida was referred for further work up and advice. The family was investigated to uncover the underlying causes and remedies thereof. **Methods used**The family members (mother, father, two alive daughters) and the amniotic fluid culture cells from the gravid mother underwent conventional cytogenetics, aCGH and qPCR as a part of investigative effort. **Summary of results and discussion**Cytogenetic banding study was apparently normal [46,XX] at 550-band resolution. Oligonucleotide arrayCGH using 44K exhibited 151-283Kb deletion at 9p21. 1 [arr 9p21. 1 (28,519,569-28,670,535)x1] involving *LINGO-2 (LRRN6C)* gene. *LINGO-2 (LRRN6C)* is expressed in cortical neurons, dorsal root ganglion neurons and negatively regulates motor neuron survival and axonal length. This deletion is also reported to be associated with the expressivity of tremors and autism. Paternal inheritance was confirmed by qPCR. The deletion might be polymorphic as it was inherited from phenotypically normal father. During 5th gravida, prenatal diagnosis was carried out from amniotic fluid culture at 16 weeks showed rob(13;14)(q10;q10)pat and 151-283Kb deletion at 9p21. 1 {arr 9p21. 1(28,519,569-28,670,535)[hg19]x1} in the fetus. Looking to the clinical presentation of both the children, paternal UPD14 was suspected. Later, it was ruled out after analyzing five different STR loci. Since both the alterations were inherited from the phenotypically and mentally normal father and no rearrangements were detected in the mother; it is highly likely that the when the child inherit deletion encompassing 9p21. 1 along with homozygous deleterious mutation/s in the LINGO2 (LRRN6C) gene, may give rise to the phenotypic expression of facial dysmorphism, global developmental and motor delay, absence of speech and recognition.

2362W

A Predictive Model for Obstructive Sleep Apnea in Patients with Down Syndrome. *B. G. Skotko[1,2], E. A. Macklin[3], M. Muselli[4,5], L. Voelz[6], M. E. McDonough[1], E. Davidson[2,6], V. Allareddy[7], Y. S. N. Jayaratne[8], R. Bruun[9], N. Ching[10], G. Weintraub[11], L. Albers Prock[2,6], D. Gozal[12], D. Rosen[2,13].* 1) Down Syndrome Program, Division of Medical Genetics, Department of Pediatrics, Massachusetts General Hospital, Boston, Massachusetts; 2) Department of Pediatrics, Harvard Medical School, Boston, Massachusetts; 3) Biostatistics Center, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts; 4) Rulex, Inc. , Boston, Massachusetts; 5) Institute of Electronics, Computer, and Telecommunication Engineering, Italian National Research Council, Genoa, Italy; 6) Down Syndrome Program, Division of Developmental Medicine, Department of Medicine, Boston Children's Hospital, Boston, Massachusetts; 7) Department of Orthodontics, The University of Iowa College of Dentistry and Dental Clinics, Iowa City, Iowa; 8) Division of Orthodontics, Department of Craniofacial Sciences, University of Connecticut School of Dental Medicine, Farmington, Connecticut; 9) Department of Dentistry, Boston Children's Hospital, Boston, Massachusetts; 10) Children's Dentistry, El Cerrito, California; 11) David Geffen School of Medicine at University of California, Los Angeles, California; 12) Department of Pediatrics, The University of Chicago, Chicago, Illinois; 13) Division of Respiratory Diseases, Department of Medicine, Boston Children's Hospital, Boston, Massachusetts.

Obstructive sleep apnea (OSA) is a frequent condition in Down syndrome (DS) with prevalence ranging of 55–97% vs. 1–4% in the general pediatric population. OSA is associated with significant morbidity. Sleep studies, the gold standard for diagnosing OSA, are noninvasive, but, they are costly and often poorly tolerated by individuals with DS. Our objective was to construct a clinically useful predictive model to screen for OSA in patients with DS using a combination of signs, symptoms, craniofacial anatomy, and metabolic markers. We enrolled 130 patients with DS, ages 3–21 yrs, for an observational, prospective cohort study. Exclusion criteria included previous adenoid or tonsil removal, a recent sleep study, or treatment for OSA. This study included a physical examination/medical history, lateral cephalogram, 3-D photography, validated sleep-related questionnaires, an overnight sleep study, and night and morning urine samples. Data were used to construct a statistical predictive model using the Logic Learning Machine technique. This model predicts three levels of OSA severity based on apnea-hypopnea index (AHI) (none: AHI $\leq$ 1/hour total sleep time (hrTST); mild: 1 < AHI $\leq$ 5/hrTST; moderate to severe: AHI > 5/hrTST). The best model had a PPV by cross validation of 55% for an AHI > 1/hrTST and 25% for AHI > 5/hrTST; the cross-validated NPV were 73% and 90% respectively. In our random clinical sample, the model predicted no or mild OSA in 39% and 50% of participants, respectively. The model included survey questions, medication history, anthropometric measurements, vital signs, patient's age, and physical examination findings. Data from the study suggests that a negative finding by our model would predict with 90% accuracy that a given individual truly did not suffer from moderate to severe OSA. Positive results would need to be confirmed with a sleep study given the relatively high false positive rate. Nevertheless, using simple procedures that can be collected at minimal cost in a primary care setting, the proposed model predicts when patients with DS are unlikely to have moderate to severe OSA, obviating the need for many sleep studies. With half of patients with DS predicted to be free of moderate to severe OSA and 90% accuracy of those predictions, the model could have broad clinical application. We are currently launching a validation study to confirm the performance of the model prior to clinical implementation.

A girl with recombinant X chromosome and Turner like stigmata: report of clinical and cytogenetic findings and review of the literature. *N. Yachelevich[1], M. Regelmann[2], A. Babu[3], J. Reiner[3], S. Scott[3], L. Edelmann[3], N. Cohen[3].* 1) Clinical Genetics Services, Department of Pediatrics, New York University School of Medicine, New York, NY; 2) Division of Pediatric Endocrinology and Diabetes, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Mount Sinai Genetic Testing Laboratory, Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY.

The patient was a product of an IVF pregnancy with donor gametes delivered at 35 weeks. In infancy she had gastro esophageal reflux. She had recurrent urinary tract infections and was found to have horseshoe kidney and vesico-ureteral reflux which was surgically repaired. Soft tissue cervical mass has been stable in size. Cardiac evaluation for murmur showed mildly dilated ascending aorta (Z score 2. 59). Blood pressure was normal. Her height was close to the 10th percentile until her fifth birthday, after which she was noted to have a deceleration in height velocity. Her height at 9 years 5 months was -3. 19 SD, which was the reason for referral. She has ADHD treated with dexmethylphenidate, starting at age 8 years. She receives regular education. Physical exam is notable for short stature, palpable soft tissue lateral cervical mass, minimally increased carrying angle of forearms, posteriorly rotated ears, mild right eye ptosis, and mild neck webbing. Ovaries were not visible on pelvic ultrasound at age 9. 5 years. Low anti Mullerian hormone level was concerning for gonadal dysfunction. Celiac screen was negative and thyroid antibodies negative. IGF-I, thyroid function tests, sedimentation rate, complete metabolic panel and complete blood count were normal. Peripheral blood chromosome analysis revealed a recombinant chromosome X with karyotype 46,X,rec(X)dup(Xp)inv(X)(p11. 3q21. 1), which results in partial trisomy and partial monosomy of the short and long arms of the X chromosome, respectively. The banding pattern of the recombinant X chromosome suggests it was derived from an X chromosome with a pericentric inversion with likely breakpoints at Xp11. 3 and Xq21. 1. Array comparative genomic hybridization (180K CGH+SNP, Agilent Technologies, hg19) confirmed a duplication of 43. 0 Mb on chromosome Xp22. 33-p11. 11. 3 between breakpoints 169,796-43,251,684 and a deletion of 78. 8 Mb on chromosome Xq21. 1-q28 between breakpoints 76,124,793-155,208,244. Interestingly, the recombinant X chromosome resulted in total three copies of the *SHOX* gene despite her short stature. *DIAPH2* gene, which increases the likelihood of gonadal dysfunction/ovarian insufficiency was deleted. The XIST gene at the X inactivation center (XIC) on Xq13. 2 was not altered. Recombinant X chromosomes are rare and patients vary in regards to their adult stature, gonadal function and external stigmata. We review published cases. The patient's initial response to growth hormone therapy is reported.

Blood Count Alterations in Newborns with Down Syndrome: A Case-Control Study. *FJ. Martínez Macías[1], MJ. González-Cruz[3], C. Peña-Padilla[1], EL. Mellín-Sánchez[1], E. Zapata-Aldana[1], L. Bobadilla-Morales[1,2], JR. Corona-Rivera[2].* 1) Research and Registration Center of Congenital Anomalies, Clinical Genetics, Hospital Civil de Guadalajara "Dr. Juan I. Menchaca", Guadalajara, Mexico; 2) Instituto de Genética Humana "Dr. Enrique Corona Rivera", CUCS-Universidad de Guadalajara; 3) Neonatology, Hospital Civil de Guadalajara "Dr. Juan I. Menchaca".

Introduction: Down Syndrome (DS) is the most frequent chromosopathy in living newborns. The principal complications in DS are those that alter blood tissues, and the most frequent findings are: thrombocytosis, thrombocytopenia (TP), polycytemia, neutrophilia, transitory myeloproliferative disorder, and congenital leukemia. These alterations endanger the stability and considerably reduce life expectancy. Consequently this study was executed at Hospital Civil de Guadalajara "Juan I. Menchaca" to determine the frequency of these alterations within the population of western Mexico, and with it to create awareness of the necessity of dealing with blood count in patients with DS as soon as possible. **Objective:** To describe the principal alterations in blood counts during the hebdomadarian period in children with DS born in our Hospital. **Methods and materials:** After a clinical diagnosis (later confirmed cytogenetically) of DS, a blood count was taken during the first days of life, both of the patients and of the healthy controls. A non-coupled case control study was performed, based at the hospital, retrospective analytic at the Hospital Civil de Guadalajara "Dr. Juan I. Menchaca", Guadalajara, México during the period betweenJanuary the 1st of 2009- Decemberthe 31stof 2014. The proportion and frequency of the categorical values were analyzed, and averages and standard deviations of quantitative variables were found. Chi squared test and the fisher exact were used, the quantitative variables were compared with a *t* student test for two independent samples. The association between alterations in blood count and DSe was measured with the Odds ratio (OR). **Results:**TP was the most common hematological anomaly detected in 67/108 cases (62. 03%), followed by high CHCM 36/108, anisocytosis 38/108, monocytosis 26/108, and limphocytosis 26/108. The hematological alterations that were associated to DS, comparing with controls: TP (OR 30. 50). The severity was: mild TP (OR 9. 81) and moderate TP (OR 8. 06); anisocytosis (OR 19. 78), linfocytosis (OR 23. 84), leucemode reaction >30,000 leu (OR 10. 43), leucemoide reaction >35,000 leu (OR 17. 7) and policytemia (OR 15. 88). **Discussion:** The hematological alterations are vital to patients with DS, which is why a complete blood count is suggested during initial hospital stay. As it is taking a smear of peripheral blood in patients who require it. These actions will lead to early detection and a timely treatment of these alterations.

2365W

Hexasomy for Chromosome 15q11. 2q13. 1. *a. Tsai.* pediatrics, University of Colorado , Aurora, CO.

Duplications of chromosome 15q11-13, both interstitial and as a supernumerary marker chromosome, are common with well-known clinical features. However, higher order duplications are considerably rarer. We describe an 8-month-old girl with a hexasomy (6 copies) of 15q11. 2q13. 1 and tetrasomy (4 copies) of 15q13. 2q13. 3 on an isodicentric marker chromosome. The patient has infantile epilepsy, cortical visual impairment, dysphagia, and global developmental delay.

2366T

Aarskog-scott(saa) with cleft lip and palate in patients from operation smile colombia; clinical description. *I. Briceno[1], j. Martinez[1], A. Collins[2], A. Zarate[1], L. Arias[1], I. Briceno[3].* 1) Bioscience, U Niversidad de La Sabana, Chia, Colombia; 2) University of Southampton, UK; 3) Pontificia universidad Javeriana, Colombia.

AARSKOG-SCOTT(SAA) WITH CLEFT LIP AND PALATE IN PATIENTS FROM OPERATION SMILE COLOMBIA; CLINICAL DESCRIPTION.

Briceño, Ignacio. Martínez, Julio Cesar. Collins, Andres. Zarate, Andrés Arias Liliana, Briceño Ignacio.

Aarskog-Scott syndrome (ASS), is a rare disease characterized by short stature, hypertelorism, shawl scrotum, and brachydactyly, there can be a wide phenotypic variability including other features as neurobehavioral disorders, short nose, widow's peak, and inguinal hernia. Although the presence of cleft lip and palate (CLP) has been described in patients with ASS, it is of rare occurrence. During the clinical genetics examination of a population of 1350 patients from "Operation Smile Colombia" 25 patients have been found with ASS and CLP. After signing the informed consent, the patients were examined and blood samples for DNA extraction was obtained and molecular genetic analyses were performed. The clinical signs are described and the phenotype–genotype correlation is analysed.

2367F

Clinical Face Phenotype Space: dysmorphology photographs to aid diagnosis of genetic syndromes. *C. Nellaker[1], M. Alvi[1], Q. Ferry[1], J. Steinberg[1], C. Webber[1], D. R. FitzPatrick[2], C. P. Ponting[1], A. Zisserman[1].* 1) University of Oxford, Oxford, United Kingdom; 2) MRC Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh, United Kingdom.

Clinical dysmorphologists require an enormous breadth of experience to correctly classify and diagnose ultra-rare diseases. Developments in computer vision research now enable computational phenotyping based on ordinary photographs. Computational phenotyping tools are poised to become a transformative technology in healthcare, bringing objective quantification and learned models to help clinicians diagnose, prioritise interventions, and monitor outcomes. We recently introduced Clinical Face Phenotype Space (CFPS), which locates patients in the context of known syndromes, and thus can help to generate disease hypotheses. Moreover, CFPS improved the clustering of patients by phenotype by 27 fold over random chance, even when no known syndrome diagnosis exists. This holds promise as an impartial means by which to narrow the search space for suspected rare diseases, and could augment the prioritisation of testing in clinical investigations. The CFPS algorithm automatically detects faces in photographs, annotates locations of key anatomical parts, and extracts machine readable feature descriptions of the facial gestalt. From a proof-of-principle CFPS we have further improved the face detection, feature point annotation and feature descriptors. We increase accuracies of facial phenotype representations and test how novel models of phenotype variation can aid narrowing the search space to diagnoses. More precise face detections and feature point annotations improve the fidelity of the phenotypes captured in photographs, which can be used to generate life-like representations of syndrome characteristics useful for training. Furthermore we show how the choice of feature descriptor has a large impact on CFPS modelling. Three critical criteria must be met to bring these promising technologies to clinical utility: 1. The ethical and legal framework for working with inherently identifiable medical data across international systems, 2. Training the models on all possible patient examples with molecular validation, and 3. The means for clinician researchers to extract clinically relevant data from the phenotype models. Importantly we are launching the CFPS Consortium for clinical collaborations. We have established a legal, ethical and secure framework for clinical collaborations which safeguards the interests of institutions, clinician researchers and patients. Together we will bring computational phenotyping to clinical utility.

2368W

Delayed diagnosis in turner syndrome is associated with social anxiety. *C. McDougall[1], L. Conway[1], D. Bousquet Moore[2].* 1) Arcadia University, 450 S Easton Rd, Glenside, PA 19038; 2) Turner Syndrome Foundation, PO Box 726, Holmdel, NJ 07733.

Previous studies have indicated that women and children with Turner syndrome may experience psychosocial and behavioral challenges, such as anxiety, depression and decreased self-esteem. This study surveyed women over 18 years of age with Turner syndrome to assess the prevalence of social anxiety and whether there is an association between social anxiety and either current height or age at diagnosis. A link to an online survey was posted to the Turner Syndrome Foundation's (TSF) webpage and the TSF Facebook page. One hundred twenty-one women over 18 years of age responded and eighty-six submitted a complete survey between July 2014 and June 2015. The Liebowitz Social Anxiety Scale—Self Report (LSAS-SR) was used to assess social anxiety. We found that 76% of the participants are classified as having social anxiety disorder. Twenty-six women (30%) had scores between 30 and 60 indicating a non-generalized, or subtype of, social anxiety disorder and 40 women (46%) had scores >60 indicating a diagnosis of generalized social anxiety disorder. The Mantel-Haenszel chi-square test was used to assess the correlations. There was no correlation between current height and social anxiety (p=0. 985). There was a significant association between age at diagnosis and level of social anxiety (p=0. 043), with a higher prevalence of social anxiety in women diagnosed at older ages. This study provides further evidence that social anxiety is a common psychosocial difficulty for women with Turner syndrome. Recognition of social anxiety as a feature associated with Turner syndrome may help healthcare providers give appropriate guidance and services to individuals with Turner syndrome and their families. The increased risk of social anxiety associated with delayed diagnosis provides evidence that early diagnosis may lead to improved psychosocial outcomes in individuals with Turner syndrome.

2369T

An adult with intellectual disability, ADHD, autistic featrues, and an interstitial microdeletion involving CNTN4. *E. Chow[1,2,3], P. Desarkar[3,4].* 1) Clinical Genetics Service, CAMH, Toronto, ON, Canada; 2) Campbell Family Mental Health Research Institute, CAMH, Toronto, ON, Canada; 3) Department of Psychiatry, University of Toronto, Toronto, ON, Canada; 4) Dual Diagnosis Service, CAMH, Toronto, ON, Canada.

Contactin 4 (CNTN4) is one of theaxon-associated cell adhesion molecules of the immunoglobulin superfamily that play important roles in the formationof neuronal networks. CNTN4 hasbeen considered as acandidate geneforautism and developmentaldelays, based on its functions and case reports of individuals with interstitial or terminal 3p26 deletions. Most individuals affected by 3p26 deletions reported in the literature are children. We present the case of a45-year-old womanfound to have a microdeletion involving CNTN4to add to the literature on CNTN4 and 3p26 microdeletions. The proband was referred to a psychiatric genetics clinicby her dual diagnosis psychiatrist for genetic investigations of her mild intellectual disability. She was of Chinese ethnic origin and her family history was negative for autism, intellectual disabilities, and ADHD. She was the first child of her middle-class parents and was born after an uneventful pregnancy, laborand delivery. She was of average birth weight and had no obvious birth defects. Early developmental milestones were reportedlymet, but her development slowed down after the first year. She began to haverecurrent febrile and non-febrile seizures from age 4 on. Sheshowed hyperactivity, problems with expressive language, poor impulse control, and socially inappropriateand repetitive behaviors when she started school. She wasdiagnosed withmild intellectual disability in grade school, and ADHD as a young adult. As an adult, she was treated forhypertension and hypercholesterolemia. On examination as an adult,she had short stature (148 cm) and had relative microcephaly (51. 3 cm, ~3% tile for height). Her BMI was 18. 4. She had a small uvula and a thickened left pinna, but otherwise was not dysmorphic. She did not have other typical features of3pdeletion syndrome. Results: Fragile X Syndrome and Rett Syndrome testing were negative. Clinical microarrayidentified a very smallheterozygous deletion at 3p26. 2 (3,0983,55-3,120,958) involving the proximal end of CNTN4gene. Genetic testing of her family members is being pursued. Conclusions: While it cannot be definitely concluded that CNTN4 disruption by microdeletion was casually related to this patient's presentation,itlikelycontributed to herneurodevelopmental phenotype.

2370F

Expanding the clinical spectrum for 10q26. 2q26. 3 deletion. *V. Fairchild[1], A. Shrimpton[2], C. Stein[2], K. Werner[3], R. R. Lebel[1].* 1) Section of Medical Genetics, SUNY Upstate Medical University, Syracuse, NY; 2) Department of Pathology, SUNY Upstate Medical University, Syracuse, NY; 3) Department of Neurology, SUNY Upstate Medical University, Syracuse, NY.

This female was born to a 24 year old primigravid woman by emergency cesarean route at 28 weeks following a pregnancy complicated by infections. The neonatal period was significant for low Apgar scores, poor suck, episodic bradycardia, hyperbilirubinemia, and anemia. At age 9 years 4 months her course is significant for ADHD, autism spectrum disorder, developmental coordination disorder, impulsivity, central auditory processing disorder, spastic diplegia, seizures, cerebral palsy, scoliosis, high frequency hearing loss in the right ear, and encopresis. We also noted slender body habitus, long narrow face, prominent eyebrows and eyelashes, small flat feet, and scoliosis. Family history is significant for seizures and learning disability in her maternal uncle's daughter. Microarray analysis revealed a 5. 26 million base pair deletion at 10q26. 2q26. 3 (130,163,870-135,427,143) encompassing 41 genes, 19 of which are annotated in OMIM. The 10q26 deletion syndrome as a broad entity is well established in the literature, however there have been few reports describing 10q26. 2q26. 3 deletion specifically. We believe the present case will serve to further define the phenotype.

2371W

11q13. 4 deletion disrupting SHANK2 gene in a male with ASD and moderate ID. *M. Grisolia[1], F. Scionti[1], E. Elisa[1], S. Ferraro[1], S. Sestito[1], A. Novelli[2], D. Concolino[1].* 1) Department of Pediatrics, University Magna Graecia, Catanzaro, Italy; 2) Department of Medical Genetics, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.

SHANK2 (MIM 603290) is a member of a family of scaffold proteins that localize to the postsynaptic site of excitatory synapses in the central nervous system. Mutations and copy number variations in *SHANK2* gene have been reported in individuals with autism spectrum disorders (ASDs [MIM 209850]) and intellectual disability (ID). Here we report on a male patient arrived to our attention at age 11 years for ASD and moderate ID. The proband is the second-born child of healthy consanguineous parents. Family history was unremarkable. He was born at full term after an uneventful pregnancy with a normal neonatal period. Developmental milestones were delayed: he walked unsupported at age 2 years. He showed speech delay and used gestures associated with vocalization to indicate and formulate questions. His behaviour was friendly and sociable. The physical examination showed a mild obesity (BMI=35). No dysmorphic features were observed except synophrys. No history of other relevant health problems were reported. The same phenotype was observed in his sister. Array-CGH analysis identified an interstitial deletion of 11q13. 4 [arr 11q13. 4(70,505,060-70,588,559)x1 pat; assembly hg19] disrupting *SHANK2* gene as confirmed by qPCR. Parental chromosome analysis revealed the paternal inheritance of the deletion. Sister has not yet been analyzed. Despite the paternal origin of 11q13. 4 deletion described in our patient, previous functional studies have shown that inherited variants in *SHANK2* are associated with a statistically significant reduction in the density of synapses, although not as severe as the reduction caused by the *de novo* or truncating mutations. Genetic and functional data suggest that, although present in healthy parents, some inherited *SHANK2* mutations might contribute to the development of ASD. There are also evidences that additional genetic/epigenetic factors might be necessary to develop ASD. It's not excluded that other genes involved in the *SHANK2* synaptic pathway, such as neurexin and neuroligin genes, can contribute to the phenotype observed in our patient.

Further delineation of the phenotypic spectrum of *ZBTB18* mutations. *S. A. de Munnik[1], M. W. Elting[2], S. García-Miñaúr[3], J. Schoots[1], E. A. Sistermans[2], M. M. Weiss[2], N. V. A. M. Knoers[4], H. G. Brunner[1], E. M. H. F. Bongers[1].* 1) Department of Human Genetics, Radboud University Medical Centre, Nijmegen, Netherlands; 2) Department of Clinical Genetics, VU University Medical Centre, Amsterdam, Netherlands; 3) Department of Clinical Genetics, Hospital Universitario La Paz, Universidad Autónoma de Madrid, Madrid, Spain; 4) Department of Medical Genetics, University Medical Centre Utrecht, Utrecht, Netherlands.

ZBTB18 haploinsufficiency was proposed to contribute to some of the key features of the 1q43q44 microdeletion syndrome, encompassing intellectual disability with speech delay, microcephaly and short stature. This hypothesis was based on the first publication in 2014 of a female with a global developmental delay, short stature, microcephaly, dysmorphic facial features, and a *de novo* nonsense mutation in *ZBTB18*, a gene located in the 1q43q44 microdeletion region. Here, we present a second individual with a *de novo* missense mutation in *ZBTB18*. This 15 year old boy has a severe developmental delay, seizures in infancy, and facial dysmorphic features. These two individuals both have a severe developmental delay with marked speech delay, supporting our proposition that *ZBTB18* plays an important role in the intellectual development present in the 1q43q44 microdeletion syndrome. Both individuals lack corpus callosum abnormalities on brain MRI, whereas agenesis or hypogenesis of the corpus callosum is seen in approximately 80% of individuals with a 1q43q44 microdeletion. We hypothesize that haploinsufficiency of other genes in the 1q43q44 microdeletion region contribute to these corpus callosum abnormalities. Overlapping facial characteristics include arched eyebrows, a full nasal tip, and a pointed chin. The first individual had a short stature and microcephaly, while the second individual had a normal height (-1 SD) and borderline headcircumference (-2 SD). In conclusion, the phenotype of these individuals with *ZBTB18* mutations comprises intellectual disability with profound speech delay, and overlapping facial characteristics. To further delineate the phenotypic spectrum and variability of *ZBTB18* mutations, the collection of clinical data of additional individuals with *ZBTB18* mutations is mandatory. Furthermore, functional studies are necessary to determine the specific effects of missense and nonsense mutations on protein formation.

2373F

A Novel 17q24. 2 Microdeletion Localized to the PRKCA Gene. *B. Shayota, P. Gupta.* St Joseph's Medical Center, Paterson, NJ.

Introduction: Several chromosome 17 deletions and duplication syndromes have been described in the current literature, including the rare 17q24. 2 microdeletion. Of those 17q24. 2 microdeletions reported, all have had multiple genes affected at once, making it difficult to determine the relationship of each feature with a specific gene. One study of 17q24. 2 microdeletions reported 4 unrelated cases of various deletions and clinical features including intellectual disability, speech delay, and truncal obesity. The affected genes included some with known significance like CACNG causing seizures and PRKAR1A causing the Carney Complex, while others like PRKCA have unknown significance. This has created a complex array of phenotypic features in previously reported patients. As such, it becomes increasingly important to understand the function of each individual gene and its contribution to complex clinical presentations. Therefore, we present a case of a 17q24. 2 microdeletion localized to the PRKCA gene only. Clinical Description: The patient was referred for genetic evaluation at 2 years of age for macrocephaly and significant speech and motor delays. The patient was born at 30 weeks from an otherwise uncomplicated non-consanguineous pregnancy. The patient weighed 2. 225 kg at birth and required respiratory support only. The patient has since developed autism spectrum disorder and developmental delays. On physical examination the patient has obesity (>97%), macrocephaly (>97%), 2 hair whorls, prognanthia, and bilateral pes planus. In addition, MRI revealed delayed myelination of the periventricular white matter. Molecular Analysis: Genetic analysis was performed with SNP microarray on lymphocyte extracted DNA. The results included a 239 Kb 17q24. 2 deletion involving the PRKCA gene and a 862 Kb 2q13 duplication. Follow-up genetic testing on both parents showed that the mother, without any phenotypic abnormalities, also has the 2q13 duplication. Discussion: To the author's knowledge, no other patient with a similar 17q24. 2 microdeletion has been described before. This provides great insight to the function of PRKCA gene and phenotypic presentation when deleted. While it cannot be excluded that some of the patient's features may be due to the 2q13 duplication, it is less likely since the mother carries the same duplication without symptoms. Additionally, a previous study had shown that 1 in 876 normal controls carry the 2q13 duplication.

2374W

Primary microcephaly in a child with an increased number of prophase-like cells without MCPH1 gene mutation. *S. Lala[1], S. Ursin[1, 2], H. Chen[1, 2], L. Prouty[1, 2, 3].* 1) Department of Pediatrics, Louisiana State University - Shreveport, Shreveport, LA; 2) Department of Genetics, Louisiana State University - Shreveport, Shreveport, LA; 3) Department of Clinical Pathology, Louisiana State University - Shreveport, Shreveport, LA.

Microcephalia vera, also known as autosomal recessiveprimarymicrocephaly(MCPH), is a rare, genetically and clinically heterogeneous disorder of neurogenesis within the neurogenic epithelium, leading to a decrease in neuron number and brain size. Patients with MCPH typically exhibit microcephaly at birth (greater than three standard deviations below normal) and a degree of non-progressive mental retardation, usually without other neurological findings or malformations. This is largely due to a reduction in gray matter and subsequent brain volume, primarily affecting the cortex. There are 11 subtypes of MCPH with at least eight loci and six different genes implicated in this disorder, including autosomal recessive primary microcephaly 1 (MCPH1), abnormal spindle-like, microcephaly associated (ASPM), cyclin-dependent kinase 5 regulatory subunit-associated protein 2 (CDK5RAP2) and centromere protein J (CENPJ). A defect in the ASPM gene is the most common cause of MCPH in reported families, however MCPH1 is increasingly becoming diagnosed by finding increased numbers of "prophase-like cells" on routine cytogenetic investigation. Here, we provide, to our knowledge, the first instance in the literature of a patient with increased prophase-like cells without a pathological sequence change, deletion or duplication in the MCPH1 and ASPM genes. We conclude with a brief clinical overview of primary microcephaly.

2375T

Classical microdeletion syndromes due to chromosomal rearrangements. *S. R. Menon, D. K Das, P. M. Tamhankar.* Genetic Research Center, National Institute for Research in Reproductive Health, Mumbai, Maharashtra, India.

Classical microdeletion syndromes such as Prader Willi syndrome and Wolff Hirschhorn syndrome occur usually de novo. However, in in 5 to 10 percent cases, these could due to parental balanced translocations leading to unbalanced deletion/duplication syndromes. We report a 6 months old female child with Prader Willi syndrome due to t(X;15) and another 4 months old boy with Wolff Hirschorrn syndrome with proximal 4p duplication and distal 4pter deletion. Their clinical phenotypes and molecular findings are discussed.

2376F

Developmental Delay and Skeletal Dysplasia associated with a Maternally Inherited Deletion of 3p26. 3 with a phenotypically Normal Mother. *A. S. Angulo, E. R. Elias.* Developmental-Behavioral Pediatrics, Children's Hospital Colorado, Aurora, CO.

Introduction: Children with phenotypic abnormalities often undergo genetic testing with microarray. If a subtle abnormality is found, parents may be tested. If a parent has the same abnormality, but doesn't share the child's phenotype, the clinical significance of the genetic change becomes more difficult to interpret. **Case report:** A 30-month old female with skeletal abnormalities and unusual features presented for genetic evaluation. Her past medical history was notable for slow growth and developmental delay. On exam, she had mildly dysmorphic features including hypertelorism, low set pinnae, small pursed mouth, long philtrum, and small chin. She had global developmental delay with skills at an 18 month old level. Skeletal films were significant for short extremities, genu valgus and tibial bowing, irregular pelvis, and J-shaped sella. Family history revealed healthy parents without consanguinity. The maternal aunt and mother have both had difficulty conceiving. The mother had two miscarriages. **Genetic testing:** An 849 kb loss in 3p26. 3 (1,247,015-2,095,542) was revealed by CytoSNP-850K bead array. This loss coordinates with the CNTN6 (contactin 6) gene, which encodes a protein that is part of the NOTCH signaling pathway. This protein is involved in cell adhesion and contributes to neurogenesis and axonal formation. The deletion was confirmed by FISH studies. The mother also carries the same deletion, while the father's FISH was normal. Previous patients reported with this deletion include a child with cognitive impairment who inherited the deletion from a normal parent without mention of skeletal dysplasia. Other reports of microdeletions of the CNTN6 gene are associated with intellectual disability or autism. As the patient's features suggested Freeman-Sheldon syndrome, sequencing of MYH3 was done and was normal. **Conclusion:** The patient described in this report does not fit the phenotype of previously reported patients with 3p26. 3 deletions, other than her developmental lag. Since this patient's mother has the same deletion but neither skeletal dysplasia nor developmental delay, it is difficult to know whether this chromosomal change is clinically significant or a benign familial variant. It is also unclear whether this deletion is linked with the mother's history of infertility and fetal loss. This report of a subtle deletion in 3p26. 3 helps expand the phenotype of this rare chromosome abnormality.

2377W

Auditory phenotype of Smith-Magenis syndrome. *M. Brendal[1], K. King[1], C. Zalewski[1], B. Finucane[2], W. Introne[3], C. Brewer[1], A. CM Smith[3].* 1) Otolaryngology Branch, NIDCD/NIH , Bethesda, MD; 2) Geisinger Autism & Developmental Medicine Institute. Lewisburg, PA; 3) Office of the Clinical Director, NHGRI/NIH, Bethesda, MD.

Introduction: Smith-Magenis syndrome (SMS) is a rare disorder commonly caused by a microdeletion of chromosome region 17p11. 2, or less frequently from the mutation of *RAI1*, a gene mapped to 17p11. 2. SMS is characterized by physical anomalies, developmental delay, sleep disturbances, and a distinct behavioral phenotype. Clinical recognition typically leads to diagnosis, but genetic testing is required for confirmation. Hearing loss (HL) has been reported in the SMS population, but a comprehensive characterization of the auditory phenotype does not exist. We present a thorough examination of the auditory phenotype within a large (n=76) SMS patient population aged 1-49 years. Methods: Standard, age-appropriate hearing evaluations were analyzed for the 4-frequency (. 5,1,2,4k Hz) air-conduction pure-tone average (4F-PTA), 3-frequency (. 5,1,2k Hz) PTA for air- and bone-conduction, and tympanometry. 4F-PTA determined HL degree while 3F-PTA of air and bone conduction determined HL type. Tympanometry was used to evaluate middle ear (ME) function. Categorical and descriptive analyses of HL (degree and type) and ME function were grouped by age (0-5, 6-10, 11-20, 21-49 years) and classified according to previously published criteria. Results: Of 97 diagnostically confirmed SMS patients with audiological data, 76 (deletion: 72; *RAI1* mutation: 4) individuals (F:44; M:32), aged 1-49 years, (mean: 11. 5), provided evaluable data for cross-sectional analyses. HL occurred in 72% of ears (n=133). Mild HL most affected ears under 5 years. Hearing appeared to improve for 6-10 y/o, with more normal hearing and slight HL, before declining back to the mild range for 11-20 y/o. Ears with HL and evaluable air-bone gaps (n=54) revealed conductive HL was most endemic of 0-10 y/o. For 11-49 y/o, however, 66% of HL was sensorineural (SNHL), followed by mixed HL. Tympanometry results were reflective of the HL type, with a majority of 0-10 y/o exhibiting ME dysfunction and 11-49 y/o presenting normal ME function, typical of SNHL. Conclusion: Mild HL is most probable in the SMS population with a variable HL type. Identification of the SMS auditory phenotype is critical for effective patient management, early intervention, and patient education. Future identification of genotype-phenotype correlations may lead to a better understanding of genetic pathways involved in SMS and their influence on the auditory system.

2378T

Agenesis of the corpus callosum, developmental delay and Posterior polymorphous corneal dystrophy associated with ZEB1 gene deletion. *A. Chaudhry[1], B. Chung Hon-Yin[2], DJ. Stavropoulo[3], M. Perez Araya[4], E. Heon[4], D. Chitayat[1].* 1) Division of Clinical and Metabolic Genetics. , The Hospital for Sick Children. University of Toronto. , Toronto, Ontario, Canada; 2) Department of Paediatric and Adolescent Medicine, University of Hong Kong; 3) Department of Paediatric Laboratory Medicine, Division of Genome Diagnostics, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 4) Department of Pediatrics, Division of Ophthalmology and Vision Sciences, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada.

Agenesis of corpus callosum (ACC) is one of the most common brain abnormalities with a prevalence of 0. 5 per 10,000 in the general population and 230-600 per 10,000 in children with neurodevelopmental disability. Etiologically, the condition is heterogeneous and in a Californian birth prevalence study, chromosomal abnormalities were detected in 17. 8% of the children with ACC. We report on a girl diagnosed antenatally with ACC on fetal ultrasound and MRI. On postnatal follow-up she was noted to have developmental delay, facial dysmorphism, autism spectrum disorder and posterior polymorphous corneal dystrophy. There was no keratoconus. Array-CGH showed a 2. 05 Mb de novo interstitial deletion in chromosome 10p11. 23p11. 22. The deleted region overlaps 1 OMIM Morbid Map gene, ZEB1 (the zinc finger E-box binding homeobox transcription factor 1), in which mutations are found to cause posterior polymorphous corneal dystrophy (PPCD). Recently Jang *et al.* (2014) reported 2 unrelated individuals with agenesis/hypoplasia of corpus callosum as well as posterior polymorphous corneal dystrophy (PPCD3). Both of these individuals were found to have frameshift mutations in ZEB1 gene. We provide the first phenotype correlation to a whole gene deletion. Gene expression arrays have shown that *ZEB1* is expressed in many tissues in vertebrates including brain. ZEB1-null mice showed mesenchymal-epithelial transition, which is associated with diminished proliferation of progenitor cells in the central nervous system. Haplo-insufficiency of *ZEB1* is likely related to the phenotype of our patient. Further studies are needed to elucidate the role of *ZEB1* our patient's phenotypic findings.

2379F

Behavioral features within adaptive behavior profiles: VABS Subdomain profiles in subtelomeric disorders. *G. Fisch[1], A. Battaglia[2], J. Carey[3], R. Falk[4], R. Simensen[5], J. Youngblom[6].* 1) Statistics and CIS, CUNY / Baruch College, New York, NY; 2) Stella Maris Clinical Research, Calambrone, Italy; 3) University of Utah, Salt Lake City, UT; 4) Cedars Sinai Hospital, LA, CA; 5) Greenwood Genetic Center, Greenwood, SC; 6) CSU, Turlock, CA.

Background: Previously, we found significant differences in both cognitive- and adaptive behavior profiles in children with subtelomeric deletions: 2q37, 8p21invdupdel, Wolf-Hirschhorn Syndrome [WHS] and Jacobsen Syndrome [JBS]. Thus the aim of this study was to determine if there were significant profile differences among these subtelomeric disorders within the subdomains of the Vineland Adaptive Behavior Scale: Communication, Daily Living Skills [DLS], and Socialization. **Method**: Forty-nine children diagnosed with WHS [n=22], JBS [n=10], 2q37 [n=9] or 8p21invdupdel [n=8] most of whom were recruited previously were assessed with the VABS. Ages at testing ranged 4 – 20 years. M:F ratio was ~ 1:1 (25:24). Children were assessed for cognitive ability [IQ] with the SBFE and adaptive behavior with the VABS [Domains and Subdomains]. **Results:** As noted previously, mean IQs differ significantly from among the several subtelomeric deletion disorders. To examine Domain profiles, raw scores were converted into Age-Equivalent [AE] years. Despite their lower raw score numbers, AEs in the Written subdomain were markedly higher than Receptive or Expressive subdomain AEs in the Communication Domain. Community subdomain AEs from the DLS were somewhat higher than Personal or Domestic subdomains, but subdomain AEs in the Socialization Domain did not differ noticeably from one another. A MANOVA of the 3 Domain AEs as a function of Genetic Disorder and Gender showed significant differences in AEs for Communication and DLS as a function of Genetic Disorder but not Gender. Neither predictor variable had a significant effect on Socialization AE. Not surprisingly, given their respective IQ scores, highest AEs were recorded among children with JBS; lowest among children with WHS (Scheffe corrected $p<0.05$). To correct for the effect of IQ, AEs for the 4 genotypes were analyzed using an ANCOVA model with IQ as covariate. As expected, IQ contributed significantly to AEs in all 3 adaptive behavior Domains ($p<0.03$). Interestingly, when AE was adjusted for by IQ, genotype did not contribute significantly to AE in any adaptive behavior domain. **Conclusion:** Although it has been well documented that IQ is strongly correlated DQ, the extent to which IQ accounts for various activities associated with adaptive behavior in genetic disorders that produce ID should probably be reconsidered.

2380W

Microdeletion at Xq13. 1 causing loss-of-function of CITED1 gene in a male newborn with multicystic dysplastic kidney disease (MCDK). *L. Mao[1], Y. Li[1,2], I. Yosypiv[2], S. Rito[2], A. Janssen[1], E. Morava[1,2], T. -J. Chen[1,2].* 1) Hayward Genetics Center, Tulane University School of Medicine, New Orleans, LA; 2) Dept. of Pediatrics, Tulane University School of Medicine, New Orleans, LA.

Genetic factors have been previously demonstrated to play a role in the etiology of multicystic dysplastic kidney disease (MCDK). However, the etiology of the majority of MCDK cases remains unknown. Here we report a case of MCDK diagnosed prenatally in a male fetus with right-sided multicystic kidney at the 24-weeks gestation by ultrasound. The infant was delivered via Cesarean-section at 35 weeks due to fetal distress. Postnatal renal ultrasound confirmed the diagnosis of right-sided MCDK and revealed mild hydronephrosis in the left kidney with no cysts. MAG3 renal scan demonstrated no function of the right kidney and normal function of left kidney. No facial dysmorphology, cardiac or hepatic defect was noted. At 40-day postnatal checkup, the patient showed normal growth and development. Biochemical profile indicated that he had mildly elevated of potassium, glucose and blood urea nitrogen, and was normal on sodium, creatine and AST/ALT levels. A 79 Kb microdeletion at Xq13. 1was identified by arrayCGH. This alteration results in full deletion of four genes (PIN4, RPS4X, CITED1 and HDAC8) in this patient. PIN4 encodes a peptidyl-prolyl cis/trans isomerase and has been suggested to play a role in the cell cycle. RPS4X encodes for the ribosomal protein S4, a component of the 40S subunit. HDAC8 belongs to the class I of the histone deacetylase family that is involved in DNA methylation and transcriptional regulation. These three genes may play a role in kidney development although there is no direct evidence so far. It is worth to note that expression of CITED1 is a well-known marker for renal progenitor cells, and the function of CITED1 has been previously implicated in fetal kidney development. In CITED1 mutant mice, renal medullary dysplasia was found to be a direct consequence of placental insufficiency resulting from the loss function of CITED1. Mutations in CITED1 have never been reported in humans, and have not been associated with any clinical phenotype, including MCDK. This is the first case to link the function of CITED1 and other gene(s) within the Xq13. 1 to MCDK. Thus, further investigation on the functions of these genes should be conducted for better understanding of the molecular etiology of MCDK.

2381T

Increased Prevalence of Malignancy in Twins with 22q11. 2 Deletion Syndrome. *A. R. Schott[1], K. D. Valverde[1], J. M. Kalish[2,3], M. P. Lambert[2,3], J. J. D. Morrissette[2,3], B. S. Emanuel[2,3], E. H. Zackai[2,3], D. M. McDonald-McGinn[2,3].* 1) Arcadia University, Philadelphia, PA; 2) Children's Hospital of Philadelphia, Philadelphia, PA; 3) The Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA.

Background: Various malignancies have been reported in association with the 22q11. 2 microdeletion syndrome (22q11. 2DS), albeit rarely, with hepatoblastoma being the most common. Associated immunodeficiency has been postulated as a possible etiology. Previous studies report that the incidence of malignancy is the same for both singleton and twin pairs but epigenetic discordance has been reported within the twin population. Both the *DGCR8* and *COMT* genes found within the deleted region of chromosome 22 have been identified as areas with DNA methylation differences in twins. A better-defined risk of malignancy within this deletion syndrome allows for more appropriate patient management and potential implementation of tumor screening. **Methods:** Records from 1232 patients with a 22q11. 2DS evaluated at the 22q and You Center at the Children's Hospital of Philadelphia (CHOP) were reviewed for evidence of malignancy. This included oncologic pathology reports. **Results:** Four cases of malignancy not previously reported as case studies in the literature were identified including: a Caucasian 29 year old with cancer of the mouth; a Caucasian 10 year old with papillary thyroid carcinoma; an African American 9 year old with labial melanoma; and a Caucasian 18 year old with B-cell acute lymphoblastic leukemia. Of note, 3 out of these 4 patients were members of a twin pair. In addition, we previously reported hepatoblastoma in a twin pair seen at CHOP. The CHOP cohort includes 21 pairs of dizygotic and 7 pairs of monozygotic twins, to date three different members of monozygotic twin sets and one member of a dizygotic twin set have been affected by malignancy. **Discussion:** Based on these cases, the prevalence of malignancy in twins in our cohort was 14% (4/28), making it 15 times higher than the prevalence of malignancy found in twin studies in the general population. Moreover, the overall prevalence of malignancy within our cohort, inclusive of our previous reported cases, was 0. 6%, which is greater than the 0. 0867% (age 0-9) and 0. 187% (age 10-19) reported 2011 prevalence percentage SEER data. These findings support further study directed at both epigenetic differences and gene functions that could lead to the increase risk for malignancy in the 22q11. 2DS patient population, specifically within the subset of affected twins.

2382F

Neonatal hemolytic anemia and multiple congenital anomalies due to deletions of 5q33, 6q24, and 14q23. *Y. Watanabe[1,2], M. Unno[1], M. Mitsuo[1], S. Nakagawa[1], S. Ozono[1], K. Ueda[1], Y. Yoshino[1], N. Harada[1], K. Fukui[1], S. Yano[3].* 1) Dept Pediatrics and Child Health, Kurume Univ, Kurume, Fukuoka, Japan; 2) Research Institute of GC/MS, Kurume Univ, Kurume, Fukuoka, Japan; 3) Genetics Division, Dept Pediatrics, LAC+USC Medical Center, Univ of Southern California, Los Angeles, CA, USA.

Background :Chromosomal microdeletions have been associated with many syndromes with variable clinical findings, and make up a fraction of copy-number variants (CNVs). Recurrent CNVs generally arise by nonallelic homologous recombination (NAHR) during meiosis. NAHR mediated rearrangement often involves local architectures, i. e. , segmental duplications or low-copy repeats. Many disease associated NAHR hot spots have been reported including chromosome 5q and 14q. **Case Report**:A 3-month-old girl was hospitalized due to failure to thrive and chronic anemia. She was a product of a healthy Japanese mother and a non-consanguineous healthy father. The pregnancy history was unremarkable. She was a term baby: birth weight 2135 g (SFD -1. 3SD) and the Apgar scores were 71/85. She was noted to have bilateral cleft lip/palate, patent ductus arteriosus, bilateral hearing loss, unilateral branchial fistula and sacral dimple. Jaundice and microcytic hemolytic anemia was diagnosed at 1 day of age. Chromosome studies showed the abnormal karyotype with 46,XX,del(5)(q33. 1q33. 3). Since the deletion of 5q31-q33, which is close to the deleted region, is known to be associated with myelodysplastic syndrome, bone marrow biopsy was performed at 3 months of age. It demonstrated mild hypocellularity with decreased erythroid colonies, suggestive of pure red cell aplasia. A SNP microarray study detected multiple chromosomal deletions at 5q33. 2q34 (6. 1 Mb), 6q24. 1 (423Kb), and 14q23. 1q23. 3 (5. 8Mb**). Discussion**: The deleted region of chromosome 5q was distal to the ribosomal protein S14 gene which is defective in a myelodysplastic syndrome. The deleted regions of the chromosome 5q33. 2-q34 and 14q23. 1-q23. 3 involve the following genes: *SGCD, HAVCR1, ITK, NIPAL4, and IL12B* for 5q *and SIX6, SIX1, PRKCH, SYNE2, MTHFD, SPTB, and MAX* for 14q. There are no known genes responsible for human disorders in the deleted region of chromosome 6q. A deletion of *SPTB* is known to cause spherocytosis and hemolytic anemia in infant. *SIX1* mutations are reported in Branchio-Oto-Renal syndrome. The other genes on the deleted regions are also likely contributing her clinical findings with multiple anomalies. Parental chromosome studies including microarray studies will be performed to investigate the cause of multiple chromosomal involvement. .

2383W

Prenatal Detection By Array CGH Of *GPC3* Intragenic Duplications Causing Simpson-Golabi-Behmel Type 1: Study Of Two Cases And Literature Review. *C. Maftei[1,2], M-A. Delrue[2], V. Desilets[2], A. Fortier[1], S. Wavrant[3], F. Rypens[4], G. Mathonnet[1], S. Nizard[1,2], F. Tihy[1], G. Maire[1], E. Lemyre[1,2].* 1) Cytogenetic Laboratory, CHU Ste-Justine, Montreal, Quebec, Canada; 2) Medical Genetics Division, CHU Ste-Justine, Montréal, Canada; 3) Obstetric Department, CHU Ste-Justine, Montréal, Canada; 4) Imaging Department, CHU Ste-Justine, Montréal, Canada.

ObjectiveWe report the first two patients diagnosed by prenatal array CGH with Simpson-Golabi-Behmel type 1 (SGBS1) syndrome caused by intragenic duplications in the *GPC3* gene, and we review the literature. **Case report**The first patient, a male foetus, was investigated at 22 weeks of gestation for foetal sexual ambiguity and ventriculomegaly. Array CGH analysis revealed a duplication encompassing exon 3 to 7 of *GPC3*. The 24 weeks ultrasound showed macrosomia, nephromegaly and hypogenitalism, which were confirmed at autopsy. The second patient presented with polyhydramnios, macrosomia, pyelectasy and suspicion of polydactily, at 28 weeks of gestation. Array CGH analysis revealed a *GPC3* duplication of exon 7 in this male foetus. The postnatal evaluation found facial dysmorphia, diastasis recti, nephromegaly and vertebral anomalies. Maternal transmission was confirmed in both cases by array CGH. **Literature review**Only two intragenic duplications in the *GPC3* gene are reported in the literature: exons 2 to 4 in one patient, and exon 2 in two siblings. These patients were diagnosed in the postnatal period by MLPA, having a classical SGBS1 phenotype. Our patients are the first to be identified in the prenatal period, and by array CGH. The pathogenicity of these duplications is supported by the clinical presentation. **Conclusion**Our cases expand the mutation spectrum associated with SGBS1 and illustrate the point that array CGH interpretation of intragenic duplications can be difficult, especially in the prenatal period.

2384T

5q12. 1 Deletion – First Report of Transmission and Adult Phenotype. *C. Bupp, A. Thompson, T. Drumheller.* Spectrum Health, Grand Rapids, MI.

Microdeletion at 5q12. 1 is a rarely reported finding with common phenotypic features of intellectual disability and ocular defects. We present two additional cases of a father and son with 5q12. 1 deletion which represent the first examples of transmission of the deletion and of the adult evolution of the phenotype. Patient 1 is a 6-year-old male with developmental delay, mild intellectual disability, hypotonia, and ocular findings of esotropia, amblyopia, and hyperopic astigmatism. Other notable findings include cryptorchidism and ventricular septal defect. Patient 2 is his father, a 43-year-old male who had mild developmental delay, has difficulty with anxiety, agorophobia, short-term memory, and also has restless leg syndrome. He completed 12 years of schooling and is actively employed. Glasses are worn for hypermetropia. Patient 2 has three additional female children, all with learning difficulties, but none have had genetic testing. Both patients presented have migraine headaches beginning in childhood. Facial features are not consistent between the two or in close approximation to features previously described in the literature (broad forehead, thin upper lip, coarseness). Deletions are sized at 4. 12Mb at 5q12. 1q12. 3 (hg18 – chr5:60945135-65063168; hg19 - 60909378-65027412) which is intermediate in size to other reports (0. 98-17. 3Mb). In our review, *C5orf64* is identified as a potential candidate gene for eye movement and vision abnormalities as it is deleted in all cases of deletion that had ocular defects as a feature. Previously, the adjacent gene *KIF2A* has been suggested as the phenotypic candidate. When factoring in other cases with larger deletions, we identified a deletion that includes *C5orf64,* but not *KIF2A,* in which there are ocular defects. This suggests *C5orf64* may be more responsible for ocular findings than *KIF2A*. These reported clinical findings show some agreement with previously published phenotype, especially in developmental delay and ocular defects, yet suggest inconsistency in facial morphology. This first adult case appears to have the most mild presentation of all those reported with 5q12. 1 deletion which may be due to ascertainment bias; it should be used cautiously in predicting future outcomes. Candidate genes for the ocular findings commonly seen in 15q12. 1 deletion should now include *C5orf64*.

2385F

Developmental Delay and Characteristic Facial Features in a Novel 7p22. 3p22. 2 Microdeletion Syndrome. *A. C. Yu[1], R. M. Zambrano[2], I. Cristian[3], C. Armour[1,4].* 1) Department of Genetics, Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 2) Division of Clinical Genetics, Department of Pediatrics, Louisiana State University Health Science Center, New Orleans, Louisiana, USA; 3) Nemours Children's Hospital Orlando, Orlando, Florida, USA; 4) Children's Hospital of Eastern Ontario Research Institute, Ottawa, Canada.

The clinical use of genomic microarrays in the evaluation of patients with developmental delay has led to the discovery of many novel microdeletion and microduplication syndromes. However, there are still a number of areas in the genome where the genotype-phenotype correlation is not well described. A search of the literature reveals that there are very few reported cases of patients with a deletion in 7p22. 3p22. 2 and only one case in which the deletion was isolated. Here we describe 3 female patients with overlapping *de novo* microdeletions of 7p22. 3p22. 2. The clinical features observed in these patients included characteristic facial features, variable developmental delays, and minor brain MRI findings. Although the deletions varied in size, there was a 0. 47 Mb common region of overlap which contained the genes: *EIP3B, CHST12, LFNG, BRAT1, TTYH3, AMZ1,* and *GNA12*. We propose that these patients represent a novel and distinctive microdeletion syndrome characterized by distinctive facial features and variable developmental delay.

2386W

A case of 2q33. 1 microdeletion syndrome resulting from a *de novo* reciprocal translocation t(2;11)(q32;q13). *F. Falvo[1], F. Scionti[1], I. Mascaro[1], A. Nicoletti[1], F. Ceravolo[1], A. Novelli[2], D. Concolino[1].* 1) Department of Pediatrics, University Magna Graecia, Catanzaro, Italy; 2) Department of Medical Genetics, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.

Interstitial deletions of 2q involving the 2q31q33 region are associated to 2q33. 1 microdeletion syndrome [MIM 612313]. Clinical features include severe mental retardation, developmental delay, dysmorphic features, failure to thrive, thin and sparse hair, cleft or high palate and behavioral disturbances. Haploinsufficiency of one gene within the deleted region, *SATB2* [MIM 608148], has been suggested to be responsible for most of the features of the syndrome. We describe a male patient with a *de novo* deletion spanning the 2q32. 2q33. 3 region due to reciprocal translocation t(2;11)(q32;q13), whose phenotype is consistentwith 2q33. 1 microdeletion syndrome. Clinical manifestations included intellectual disability, speech delay, short stature, microcephaly, cryptorchidism, anterior muscular ventricular septa defect and an aggressive behaviour. Facial dysmorphisms included long face, frontal bossing, downslanting palpebral fissures, low-set ears, blue sclerae, cleft palade, micrognathia. Brain MRI did not reveal any abnormality. Conventional karyotype detected a reciprocal translocation between chromosome 2 and 11 involving respectively 2q32 region and 11q13 region. Parental karyotypes resulted normal. Further characterization by array-CGH analysis revealed a 15 Mb deletion on chromosome 2 [arr 2q32. 2q33. 3(190,458,579-205,973,945)x1 dn; assembly hg19] as confirmed by FISH. These genetic data demonstrate the importance and diagnostic complementarity between karyotype and array-CGH for a complete molecular characterization of non-pure rearrangements. Clinical and molecular findings are consistentwith 2q33. 1 microdeletion syndrome and support the hypothesis that the 11q breakpoint don't contribute to pathological phenotype observed in our patient.

2387T

Inherited intrachromosomal Xq28 deletion involving *MECP2* and Xp22. 33 duplication in a patient with Rett-like phenotype. *A. Nicoletti[1], F. Scionti[1], S. Sestito[1], E. Pascale[1], F. Falvo[1], M. Grisolia[1], A. Novelli[2], D. Concolino[1].* 1) Department of Pediatrics, University Magna Graecia, Catanzaro, Italy; 2) Department of Medical Genetics, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy.

Xq28 deletion encompassing the *MECP2* [MIM 300005] gene were described in affected femals with Rett-like phenotype characterized by idiopathic intellectual disability, autism, epilepsy, late regression age, intact ability to walk and mild dyspraxia of hand movement, congenital malformations and facial dysmorphisms. Genomic rearrangements involving terminal deletion of Xq28 and terminal duplication of Xp22. 33 are rarely reported in literature. These cases are presumed to be the result of either a recombination event in a parent carrying a pericentric inversion or inherited from a phenotypically normal mother carrying the abnormal X. We report on 5-years-old female carrying an intrachromosomal Xq28 deletion encompassing the *MECP2* gene and an Xp22. 33 duplication. Her phenotype included short stature, speech and developmental delay, hypotonia, cerebellar vermis hypoplasia, thinning of corpus callosum, seizures, bilateral hypoacusis, patent ductus arteriosus, areas of hypopigmentation in legs and skeletal malformations (scoliosis, clinodactyly, syndactyly). Facial features were hypertelorism, epicanthus, micrognathia, low-set ears and cleft palate. Conventional karyotype revealed a partial deletion of the long arm of X chromosome. Further array-CGH analysis confirmed a deletion of Xq28 and also identified a duplication of Xp22. 33, spanning respectively 6 Mb and 2. 4 Mb [arr Xq28(149,116,213-155,190,024)x1 mat, arr Xp22. 33(61,091-2,651,980)x3 mat; assembly hg19]. Maternal chromosome analysis, performed with FISH, detected the same abnormal X chromosome. X-chromosome inactivation (XCI) analysis, performed on peripheral blood lymphocytes, revealed a skewed pattern of XCI in the patient, along with the findings of an active derivative X chromosome and an inactive normal X, while the maternal pattern of XCI resulted random. Clinical manifestations in our case are consistentwith RTT subtype. The proband also exhibited short stature and several skeletal anomalies that we suggest are probably due to the Xp22. 33 duplication including *SHOX* [MIM 213865] gene. However X-chromosome inactivation studies in other tissues may provide a better explanation for the difference in phenotypes and X-inactivation patterns between proband and her mother.

2388F

An interstitial 2q22. 3q23. 2 deletion not involving *ZEB2* gene in a male with Mowat-Wilson syndrome-like phenotype. *F. Scionti[1], A. Novelli[2], R. Apa[1], M. T. Moricca[1], G. Bonapace[1], V. Salpietro[3], P. Strisciuglio[4], D. Concolino[1].* 1) Department of Pediatrics, University Magna Graecia, Catanzaro, Italy; 2) Department of Medical Genetics, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy; 3) Department of Pediatrics, University of Messina, Messina, Italy; 4) Department of Pediatrics, University Federico II, Naples, Italy.

Mowat-Wilson syndrome (MWS [MIM 235730]) is a rare genetic disorder caused by heterozygous mutations or deletions of the *ZEB2* [MIM 605802] gene. The major symptoms include characteristic facial features, usually severe intellectual disability, epilepsy, Hirschsprung disease (HSCR), and multiple congenital malformations, including genital anomalies, congenital heart defects, agenesis of the corpus callosum, and eye defects. We report on 36-years-old male patient with an interstitial deletion of the long arm of chromosome 2 involving the 2q22. 3q23. 2 region but not *ZEB2* gene and with a phenotype consistent with MWS. The proband exhibited postnatal growth retardation, severe developmental delay, hypotonia, speech delay, seizures and behavioral problems. The physical examination showed microcephaly, frontal bossing, large and deep-set eyes, hypertelorism, broad nasal bridge, open mouth, with M-shaped upper lip, frequent smiling, prominent pointed chin and low-set ears. Additional clinical manifestations included constipation and a severe immunoglobulins deficiency. Array-CGH analysis revealed a 4. 6 Mb deletion on chromosome 2 [arr 2q22. 3q23. 2(145,664,976-150,357,530) x1; assembly hg19] as confirmed by FISH. Maternal chromosome analysis resulted normal. Father was not investigated. The deletion detected in our patient doesn't involve *ZEB2* gene but his phenotype is suggestive of MWS. However several studies have identified deletions that encompass enhancer elements, resulting in loss or gain of expression of nearby genes. Upstream of the *ZEB2* promoter is reported a regulatory region, at positions chr2:146,509,221–146,510,330 (hg19) that results deleted in our patient, so we hypothesize a positional effect of 2q22. 3 deletion. Interestingly, our patient showes immunoglobulins deficiency that have not been reported previously and is possibly an additional feature of this syndrome.

2389W

Chromosomal microarray testing identifies trichorhinophalangeal syndrome type I with cognitive developmental delay. *J. Gilman[1], C. Stein[2], K. Palomino[3], RR. Lebel[1].* 1) Section of Medical Genetics, SUNY Upstate Medical University, Syracuse, NY; 2) Department of Clinical Pathology-Cytogenetics, SUNY Upstate Medical University, Syracuse, NY; 3) Department of Orthopedic Surgery, SUNY Upstate Medical University, Syracuse, NY.

This male was born to a 20 year old G4P3>4 woman with an uncomplicated pregnancy and delivery. There were no suspected teratogen exposures and the union is not known to be consanguineous. He had significant developmental delays, walking at 3 years and speaking his first words at 4 years, but he made significant improvements with the aid of special education. Radiographs and MRI demonstrated avascular necrosis of the left femoral head, but no exostoses. At age 10, the patient was diagnosed with Osteochondrosis/Legg-Calve-Perthes disease of the left hip. He underwent left hip arthrodesis and spica casting surgery at age 13. He rapidly gained 120 pounds while immobile during post-recovery, and remained hyperphagic thereafter. The patient presents with short stature (1st percentile for height), obesity (96th percentile for weight), large tongue with prominent taste buds, high arched palate, hyperextensible joints, mild scoliosis, and a bulbous nasal tip. He has short hands and feet, brachydactyly, hypoplastic toenails and a small penis. The patient's father was reported to also be affected by short stature, early baldness, irregularly short digits, and a bulbous nasal tip.

Microarray analysis identified a 198 kbp deletion at 14q32. 11 and a 3. 08 Mbp interstitial deletion at 8q23. 3. The deletion at 8q23. 3 includes only two annotated genes. *TRPS1*, which codes for a zinc-finger protein that acts as a transcriptional repressor of GATA-regulated genes. The *TRPS1* gene is associated with trichorhinophalangeal syndrome type I (TRP1), which is inherited as a dominant trait, supported in this patient by the father's history. The lack of exostoses and the location of the deletion both indicate type I as opposed to type II, although intellectual disability and hyperextensible joints are typically features of type II. The 8q23. 3 deletion also includes the *CSMD3* gene, which is associated with changes in brain activity, but loss of one copy is of uncertain significance. The deletion at 14q32. 11 includes only the genes *TDP1* and *EFCAB1.* Loss of one copy of each is considered a variant of uncertain significance. The current literature includes three reports of TRP1 with intellectual disability; all the authors conclude that the size of the deletion is proportional to the degree of intellectual disability. We propose that our patient's 3. 08 Mbp deletion 8q23. 3 is the etiology for TRP1 with intellectual disability and hyperextensible joints in him.

2390T

Deletion of KIRREL3 causes intellectual disability in Jacobsen syndrome. *C. Hatano[1], T. Yokoi[1], Y. Enomoto[1], T. Saito[2], J. Nagai[2], K. Kurosawa[1].* 1) Genetiscs, Kanagawa Children's Medical Center, Yokohama, Japan; 2) Department of Clinical Laboratory, Kanagawa Children's Medical Center, Yokohama, Japan.

Jacobsen syndrome is a rare contiguous gene disorder associated with multiple congenital anomalies. The major symptoms include growth retardation, developmental delay, congenital heart defects, and thrombocytopenia. The degree of intellectual disability in the patients varies widely. We report on a female patient of Jacobsen syndrome caused by a deletion of terminal 6. 5 Mb in 11q24. 3q25 representing normal development. She was born to nonconsanguineous parents at 38 weeks of gestation. Her birth weight was 2660g (-0. 7SD), length 47cm (-0. 8SD), and the head circumference 32. 5cm (-0. 5SD). She had coarctation of the aorta and was repaired at 2 months old. At 3 years old, her weight was 13. 5kg (-0. 9SD), length 81. 7cm (-3. 0SD), head circumference 47. 6cm (-0. 6SD). She also had mild thrombocytopenia. She was able to walk with support at 13 months old and without support at 15 months old. Her developmental milestones were normal. She spoke at 13 months old and two-word sentence at 18 months old. She goes to kindergarten without any support. The standard karyotyping revealed normal, 46,XX. We performed cytogenetic microarray analysis, which revealed a 6. 5Mb terminal deletion at 11q24. 3q25, extending from position128, 350,397-134,868,407 (hg19). The genotype-phenotype correlation has been established on the distinctive features in Jacobsen syndrome. The deletion of JAM3 and ETS1 cause cardiovascular complication, and the deletion of FLI1 and NFRKB cause thrombocytopenia, respectively. Although she had 6. 5 Mb deletion encompassing several genes, likely responsible for intellectual disability in Jacobsen syndrome, her development milestones are within normal range. KIRREL3, associated with neural development, is retained in her der(11), but deleted in most of the previously reported patients with severe intellectual disability. These results indicate that KIRREL3 is a candidate gene responsible for intellectual disability in Jacobsen syndrome.

2391F

Submicroscopic Deletions at 13q32. 1Cause Congenital Microcoria. *L. Fares Taie[1], S. Gerber[1], A. Tawara[2], A. Ramirez-Miranda[3], JY. Douet[4], H. Verdin[5], A. Guilloux[1], JC. Zenteno[6], H. Kondo[2], H. Moisset[1], B. Passet[7], K. Yamamoto[8], M. Iwai[9], T. Tanaka[10], Y. Nakamura[11], W. Kimura[12], Ch. Bole-Feysot[13], M. Vilotte[7], O. Odent[14], JL. Vilotte[7], A. Munnich[1], A. Regnier[4], N. Chassaing[15], E. De Baere[5], I. Raymond-Letron[4], J. Kaplan[1], P. Calvas[15], O. Roche[16], JM. Rozet[1].* 1) Imagine - Institute of Genetic Diseases, Paris Descartes University, 75015 Paris, France; 2) University of Occupational & Environmental Health, Kitakyushu, Japan; 3) Instituto de Oftalmologia "Conde de Valenciana". Congenital microcoria (MCOR) is a rare autosomal dominant disorder characterized by inability of the iris to dilate owing to absence of dilator pupillae muscle. So far, a dozen MCOR families are reported worldwide. By using whole-genome oligonucleotide array CGH, we have identified deletions at 13q32. 1 segregating with MCOR in six families originating from France, Japan and Mexico. Breakpoint sequence analyses showed nonrecurrent deletions in 5/6 families. The deletions varied from 35 Kbp to 80 Kbp in size, but invariably encompassed or interrupted only two genes: *TGDS* **encoding the TDP-glucose 4,6-dehydratase and** *GPR180* **encoding the G protein-coupled receptor 180, also known as intimal thickness-related receptor (ITR). Unlike TGDS which has no known function in muscle cells, GPR180 is involved in the regulation of smooth muscle cell growth. The identification of a null** *GPR180* **mutation segregating over two generations with iridocorneal angle dysgenesis which can be regarded as a MCOR endophenotype is consistent with the view that deletions of this gene, with or without the loss of elements regulating the expression of neighboring genes, are the cause of MCOR.** .

2392W

Genetic analysis of autism spectrum disorder (ASD) based on developed diagnostic flows using next-generation sequencing (NGS). *Y. Enomoto[1], T. Yokoi[2], C. Hatano[2], I. Ohashi[2], Y. Kuroda[2], K. Ida[2], T. Naruto[1], K. Kurosawa[2].* 1) Clinical Research Institute, Kanagawa Children's Medical Center, Yokohama, Japan; 2) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Japan.

Next generation sequencing (NGS) is a new technology for detecting mutations comprehensively. NGS has a basically broad impact on many facets of biological and clinical research. We introduced NGS technology since 4 years ago and developed diagnostic flows of molecular diagnosis using NGS to identify mutations in genetic disorders and birth defects in KCMC. Autism spectrum disorder (ASD) is classified into brain dysfunction. ASD is characterized by impaired social interaction, communication disorder, stereotyped behavior and hyperactivity, etc. Division of Medical Genetics in Kanagawa Children's Medical Center (KCMC) has about 50 patients of ASD annually. The majority of ASD patients in KCMC have severe symptoms. ASD is considered to be a polygenic disease, which is influenced by many genes. 904 genes related to ASD are registered in The Human Gene Mutation Database (HGMD) as of June 2015. Their relationship is not sufficiently clear yet and pathogenic mechanism of ASD remains unclear. We infer severe ASD patients have mutations in genes related to ASD. Thus, we performed NGS analysis of severe ASD patients based on developed diagnostic flows, using exon sequencing of Mendelian disorders (TruSight One) or whole exon sequencing. We identified causative mutations in some patients, including two patients of severe ASD have mutations in CHD8 gene. We report about some causative mutations identified in this analysis and clinical feature of ASD patients.

2393T

Oro-facial-digital syndrome. (ofd), in a population from operation smile foundation in colombia. clinical, molecular and genetic characterization. *j. martinez[1], i. Briceno[1], a. Zarate[1], j. Becerra[1], s. Serrano[1], s. Idarraga[1], a. Collins[2], e. Soracipa[3].* 1) Medicine, Universidad de La Sabana, Bogota, bogota, Colombia; 2) University of Southampton. UK; 3) Colegio mayor de Cundinamarca. Bogota. Colombia.

Oro-facial-digital-syndrome. (ofd) is a ciliopathy causing phenotypic alterations such as cleft lip and palate, polydactyly, lobulated tongue, telecanthus, delayed psycomotor development and even death. SOFD has been classified in 14 different variants taking into account the clinical characteristics of the patients and some molecular findings. The actual incidence and the molecular and genetics features involved in this disease is currently unknown, therefore the goal of the project was to describe the clinical molecular and genetics characteristics present in the syndrome oro-facial-digital in patients attending the foundation “operation Smile” in Colombia. by genomic analysis. After informed consent was obtained, DNA extraction was performed. OFD! candidate genes C2Cd#, C5orf42 and TCTN3 were evaluated exome sequencing was performed and analyzed in the laboratory of genetics from “The university of Southampton”. The results show the posibility of a new variant of SOFD and genetic heterogeneity was observed.

2394F

Clinical and Molecular study of a series of 31 patients with chondrodysplasia with multiple dislocations. *E. Ranza[1,17], C. Huber[1], N. Levin[1], G. Baujat[1], Y. Alanay[2], L. Al Gazali[3], P. Cormier-Daire[1].* 1) Department of Genetics, INSERM UMR 1163, Université Paris Descartes- Sorbonne Paris Cité, Institut Imagine, Hôpital Necker Enfants Malades , Paris, 75015, France; 2) Acibadem University, School of Medicine, Department of Pediatrics, Pediatric Genetics Unit, Istanbul, Turkey; 3) Department of Pediatrics, College of Medicine and Health Sciences, UAE University, Al Ain, United Arab Emirates; 4) Génétique Médicale, Hôpital Jean Verdier, Bondy, France; 5) Génétique Clinique, Hôpital Jeanne de Flandre, Lille, France; 6) Département de Génétique Médicale, Hôpital Arnaud de Villeneuve, Montpellier, France; 7) Department of pediatrics-genetics, Marmara university medical school, Istanbul, Turkey; 8) Centre de Génétique, Hôpital d’Enfants,Dijon, France; 9) Sheffield Clinical Genetics Service, Sheffield Children’s hospital, Sheffield, UK; 10) Center of Medical Genetics, Sir Ganga Ram hospital, New Delhi, India; 11) Medical Genetics , St George’s Healthcare NHS Trust, London United Kingdom; 12) Akdeniz University School of Medicine, Division of Pediatric Genetics, Antalya, Turkey; 13) Unité de Génétique Clinique , Hopital Robert Debré, Paris, France; 14) Génétique Médicale, Hôpital Sud, Rennes, France; 15) Wilhelmina Childrens hospital, Lundlaan 6 3584 EA AB, Utrecht, the Netherlands; 16) Istanbul University, , Dept of Pediatric Genetics, Cerrahpasa Medical Faculty, Istanbul, Turkey; 17) Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland.

The group of chondrodysplasia with multiple conditions includes 7 distinct entities all characterized by short stature, dislocation of large joints, hand anomalies and/or vertebral anomalies. Facial features, and cleft palate are also often reported. Among them, Larsen syndrome is the only one with an autosomal dominant inheritance and due to *FLNB* mutations while the 6 other recessive disorders, namely Desbuquois dysplasia (DD) type 1/Kim type and type 2, Spondylo-Epiphyseal Dysplasia with dislocations, chondrodysplasia with luxations, Larsen Like and Larsen of Reunion island syndromes are due respectively to *CANT1, XYLT1, CHST3, IMPAD1, B3GAT3,* and *B4GALT7* mutations. The aim of our study was to identify the molecular basis of a series of 31 patients presenting with these conditions. The series included 15 females and 16 males, originating from Algeria, France, India, Morocco, Netherlands, Turkey, UK and UAE. Consanguinity was reported in 20 families. 6 were fetuses and 25 were postnatal cases ranging in age from 1 to 30 years of age. Criteria for inclusion in the study were 1) Short stature < -2. 5 SD 2) Dislocation of at least one large joint 3) Hand anomalies and/or Vertebral anomalies. Referring diagnosis were DD type 1 (3), DD type 2 (6), Larsen syndrome (4), Larsen of Reunion Island (1), Catel Manzke syndrome (2) and unclassified (15). We performed exome sequencing. Our first analysis focused on the 7 known genes involved in this group but also on *B3GALT6, CHSY1, DSE, CHST14, SLC26A2* and *TGDS* involved in related conditions. All mutations were confirmed by Sanger sequencing. We identified mutations in 16/31 cases including *FLNB* (1) *CANT1* (3), *XYLT1* (2), *CHST3* (1), *B3GAT3* (3), *B4GALT7* (1), *B3GALT6* (1), *TGDS* (1), *CHSY1* (1), *DSE* (1) and *SLC26A2* (1). A complete deletion of *IMPAD1* was also observed at the homozygote state in one case. The initial diagnosis was accurate in 11/17 cases. Characteristic hand anomalies were consistently observed in patients with mutations in *CANT1, IMPAD1, CHSY1,* and *TGDS.* Intellectual disability and obesity were often observed in the course of the disease. Our study further expands the clinical spectrum of this group of conditions and also emphasizes proteoglycan synthesis impairment in recessive chondrodysplasia with dislocations. Finally, exome sequencing analysis is currently in progress for the remaining 14 cases.

2395W

A new multiple congenital anomaly syndrome due to a de novo variant in the ATP binding domain of FGFR2 detected by trio-based whole-genome sequencing. *T. Vilboux[1], D. L. Bodian[1], A. Khromykh[1], P. F. Cherukuri[1], S. Garcia[2], D. Glazer[2], R. Baveja[3], B. D. Solomon[1], J. Vockley[1], J. E. Niederhuber[1].* 1) Division of Medical Genomics, Inova Translational Medicine Institute, Falls Church, VA; 2) Personalis, Inc. 1350 Willow Rd Menlo Park, CA; 3) Fairfax Neonatal Associates - IFH, Inova Health System, Falls Church, VA.

We report a newborn with a previously undescribed severe, perinatally lethal disorder. The child presented with notable dysmorphic features (microtia, mild scaphocephaly, upslanting palpebral fissures), and other major anomalies including severe radial hypoplasia, short ulna, unilateral renal agenesis with cystic hypodysplasia. Research-based trio whole-genome sequencing identified a *de novo* variant in *Fibroblast Growth Factor Receptor 2* (*FGFR2*). Although heterozygous mutations in *FGFR2* have been reported to cause craniosynostosis syndromes such as Apert syndrome, Crouzon syndrome, Jackson-Weiss syndrome and Pfeiffer syndrome as well as Lacrimoauriculodentodigital (LADD) syndrome and Bent bone dysplasia syndrome (BBDS), the patient's phenotype appears to represent a distinct condition. Further analysis of all the previously reported variants revealed that this new variant is the first one described in the ATP binding region of FGFR2. Computational variant effect prediction tools suggest a severe consequence of this variant that would lead to a loss of function of FGFR2. Craniosynostosis syndromes are due to a gain of function whereas LADD is due to a decrease function of FGFR2 and BBDS to a more complex gain/loss of function. This new disorder is distinct from all the previously described *FGRF2* related disorders likely due to the specific functional domain in which the variant occurred and the degree to which the it is damaging.

2396T

A Three-Year-Old with ALVES syndrome: Case Review with Further Delineation of Phenotype and Inheritance. *M. Crenshaw.* Division of Genetics and Metabolism, All Children's Hospital/ Johns Hopkins Medicine, St. Petersburg, FL.

Alves syndrome (Tricho-Oculo-Dermo-Vertebral) Syndrome is characterized by ectodermal dysplasia with hypohydrosis in the setting of congenital arthrogryposis. There are fewer than five cases reported in the literature, and no causative gene is yet identified. Here I review a 3-year, 4-month-old you lady presenting at birth with distal arthrogryposis with camptodactyly. This is accompanied by mild dysmorphisms including ear anomalies and micrognathia with relative microcephaly. At 3-years of age, she has developed hypohydrosis and hyperkeratosis. Her genetic evaluation has included a chromosome microarray, serum amino acid and urine organic acid analyses, long chain fatty acid analysis, and carbohydrate deficient transferrin, which are normal. Mitochondrial DNA sequencing and deletion testing was normal. Testing for spinal muscular atrophy type 1 did not reveal a mutation. Sequencing of the genes *TNNI2, TNNT3*, *MYH3,* and *TPM2* associated with distal arthrogryposis showed no mutation in these genes. A brain MRI indicated some mild, nonspecific prominence of the ventricles. She is the product of a consanguineous union with no history of affected individuals in the family. This pattern is consistent with the proposed autosomal recessive inheritance of other described cases. Further evaluation by whole exome sequencing may be helpful in further evaluation for the causative gene and is planned.

2397F

Reverse phenotyping of a patient with *CRIPT* gene mutation and further delination of the associated phenotype. *B. Demeer[1,9], A. DADBAN[2], P. VABRES[3, 4], G. MORIN[1], B. ARAL[3,5], A. VARENTERGHEM[7], J. THEVENON[3,6], D. BREMOND-GIGNAC[8], J. St ONGE[3,5], J. RIVIERE[3,5], J. COURCET[3], C. THAUVIN[3,7], L. FAIVRE[3,7].* 1) Genetics department, Amiens-Picardie University hospital, Amiens cedex, France; 2) dermatology departement, Amiens-Picardie University hospital, Amiens cedex, France; 3) Equipe d'Accueil 4271 Génétique des Anomalies du Développement, Fédération Hospitalo-Universitaire, Université de Bourgogne, Dijon, France,; 4) Service de Dermatologie, CHU Le Bocage, Dijon, France; 5) Génétique des Anomalies du Développement, Fédération Hospitalo-Universitaire, Université de Bourgogne, Dijon, France. Laboratoire de Génétique Moléculaire, FHU-TRANSLAD, Plateau technique de Biologie, CHU, Dijon, France; 6) Centre de Référence Maladies Rares ;Anomalies du Développement et Syndromes Malformatifs; de l'Est, Centre de Génétique et Pédiatrie 1, Hôpital d'Enfants, Dijon, FranceGénétique des Anomalies du Développement, Fédération Hospitalo-Universitaire, Université de Bourgogne, Dijon, France; 7) Pediatrics department, CHU Amiens-Picardie, amiens, France,; 8) Ophtalmology department, CHU Amiens-Picardie, amiens, France,; 9) EA 4666, Université de Picardie Jules Verne, Amiens, France.

We report on a 3 ½ year old boy, with prenatal onset growth deficiency (height:-4SD), microcephaly (OFC:-3. 5 SD), transient neonatal pancytopenia, facial dysmorphism, feeding difficulties, developmental and speech delay, global hyperlaxity, significant sleep disturbance, and genital, ocular and extremities anomalies. He also presents with generalized pigmentation anomalies, and signs of ectodermal dysplasia. Array CGH (Agilent 60k), cytogenetic diagnosis of chromosomal breakage syndrome and metabolic screening are negative. The whole exome sequencing performed revealed a homozygous frame-shift mutation of the *CRIPT* gene, recently described as a novel primordial dwarfism gene (Shaheen et al, 2014). The mutation (c. 132delA), described as probably pathogenic, was confirmed in the homozygous state by Sanger sequencing. Both healthy consanguineous parents were proven to be carrier in the heterozygous state. Few available clinical data of the 2 described patients show very similar clinical appearance with strikingly facial dysmorphism, growth deficiency, microcephaly, psychomotor delay, and ocular and extremities anomalies. Mottled hypopigmentation is also described in the older patient. This report is an example of "reverse phenotyping". The first description of the *CRIPT* gene by Shaheen et al helped us to reach a diagnosis in our patient. Nevertheless the term of primordial dwarfism and its broad definition used by the authors can be confusing; and can prevent some clinicians from suggesting this diagnosis. Cutaneous signs seem also to be very specific, and need to be precisely looked at in additional patients presenting with this unique syndrome.

2398W

Whole Genome Sequencing Identifies Multiple Pathogenic Mutations in a Patient With Recurrent Infections and Multiple Congenital Anomalies. *A. Fadda[1], F. Butt[2], S. Tomai[1], A. Robay[3], S. Deola[1], R. Crystal[3], E. Wang[1], K. Fakhro[1,3], C. Cugno[1].* 1) Biomedical research, Sidra Medical and Research Center, Doha, Qatar; 2) Hamad Medical Corporation, Doha, Qatar; 3) Weill Cornell Medical College in Qatar, Doha, Qatar.

A consanguineous family of Arab ethnic origin with two unaffected siblings and a 7-year-old female child affected by recurrent infections and multiple congenital anomalies was screened by Whole Genome Sequencing (WGS) to identify the offending mutations. The disorder is marked by pan-leukopenia, recurrent severe infections since birth including pneumonia, bronchitis, pyelonephritis, urinary tract infections leading to hypoplasia and functional impairment of the left kidney, and otitis media. She is developmentally delayed with stunted growth and learning difficulties. There is microcephaly, thin hair, triangular face, small eyes, low-set ears, finger and toe clubbing, dry skin, vesicoureteral reflux and skeletal abnormalities including 11 pairs of ribs. Family history is marked by three first cousins (two males and one female, also products of consanguineous marriages) that died in early childhood from severe infections. WGS was performed for the patient, two unaffected siblings, and mother. The data was mined for homozygous damaging variants conforming to autosomal recessive inheritance. A novel *LIG4* (DNA ligase) homozygous nonsense c. T1312C/p. Y438H mutation was detected. *LIG4* pathogenic mutations cause immunodeficiency, growth and developmental delay, unusual facial features and microcephaly, justifying the clinical presentation. Two additional pathogenic mutations were detected. A *LRIG2* homozygous nonsense c. C2125T/p. R709X mutation previously reported to cause Uro-facial syndrome characterized by congenital urinary bladder dysfunction and inverted smile that are not apparent in the patient; an *LFNG* (lunatic fringe involved in Notch signaling pathways) homozygous frameshift c. 163-166dupGATG/p. E56fs*2 absent in 1000 Genomes and ESP databases. *LFNG* mutations cause spondylocostal dysostosis. The patient is being investigated for congenital vertebral anomalies. The identification of multiple pathogenic mutations by WGS might indicate the presence of multiple autosomal recessive conditions due to the extensive consanguinity, resulting in complex clinical presentation. But it clearly demonstrates that when applying WGS data to clinical diagnoses, all significant variants should be considered and scrutinized for their clinical impact, irrespective of the observed clinical symptomatology.

2399T

***PTCH* gene deletion in a individual presenting holoprosencephaly associated to bilateral anophthalmia and orbital cyst.** *L. Bicudo[1,2], B. Gamba[2], J. Arruda[1], B. Maranhão[1], A. Costa[3].* 1) Genetics, Bioscience Institute, Federal University of Goias, Goiania, Brazil; 2) Genetics, Bioscience Institute, Sao Paulo State University, Botucatu, Brazil; 3) Genetics, Sao Paulo University, Bauru, Brazil.

The SHH-PTCH pathway is a dosage-sensitive signalling network which is particularly critical in cellular growth and development during embryonic development. Inherited and sporadic mutations in genes in this pathway have been implicated in a number of human birth defects and adult cancers . PTCH haploinsufficiency in humans has been postulated to interact with the expression of other genes resulting in anomalies of the eye, brain and digits, or to explain microphthalmia and orbital cysts which are functionally active during neurulation. Human *PTCH* mutations commonly cause sporadic and hereditary NBCS; however, primary eye involvement and/or holoprosencephaly due to *PTCH* mutations are uncommon. Holoprosencephaly (HPE) is a malformation sequence where the cerebral hemispheres fail to separate into distinct left and right halves. It can be associated with midline structural anomalies of the central nervous system and/or face. *SHH* is the major gene implicated in HPE and it plays a critical role in early forebrain and central nervous system development. Eye anomalies are part of the clinical spectrum of the HPE, ranging from cyclopia to variable structural eye defects with the most extreme variant represented by bilateral anophthalmia. Eye anomalies mainly represented by microphthalmia and orbital cyst was reported in a girl with NBCS who presented a mutation in the *PTCH* gene. Here we report a patient with HPE associated to bilateral anophthalmia and orbital cyst who presented a deletion showed by MLPA analysis in *PTCH1* gene. This is the third variation in *PTCH1* gene identified in patients with ano/microphthalmia and orbital cysts. The occurrence of severe eye involvement in these patients as well as the presence of HPE in two of them and BCNS in the other, make obvious the spectrum of manifestations occurring in mutations of the *PTCH* gene that includes tumorigenesis, ocular anomalies, and HPE.

2400F

Male Newborn Presented With Hyponatremia Who Has 21-Hydroxylase Deficiency. *A. Ecevit[1], H. Verdi[2], FB. Atac[2], S. Tulgar Kinik[3], HI. Ruhi[4], FA. Tukun[4].* 1) Department of Pediatrics, Division of Neonatology, Baskent University Shool of Medicine , Ankara, Turkey; 2) Baskent University Shool of Medicine Department of Medical Biology, Ankara, Turkey; 3) Baskent University Faculty of Medicine, Division of Pediatric Endocrinology, Ankara, Turkey; 4) Ankara University School Of Medicine Department Of Medical Genetics.

One of the most common inherited metabolic disorders is congenital adrenal hyperplasia (CAH). The commonest form of CAH is steroid 21-hydroxylase deficiency (21OHD, MIM +201910) caused by sequence variants in the 21-hydroxylase gene (CYP21A2, GeneID 1589) that accounts for 90–95% of cases. The clinical features reflect the magnitude of the loss of function mutations that range from complete loss of enzyme function to partial enzyme activity. The two types of the disease are classic forms, known as the salt-wasting and simple virilizing types while the third type is called the non-classic type. Newborns with salt-wasting 21-OHD CAH are at risk for salt-wasting crises. Females are frequently diagnosed at birth because of ambigious genitalia but male newborns are undiagnosed. Females with the non-classic type of 21-hydroxylase deficiency may experience hirsutism, male pattern baldness, irregular menstruation, and decreased fertility. However some individuals have no symptoms of the disorder. Here we present a case with severe hyponatremia who was compound heterozygote for 21-hydroxylase deficiency. **Case:** One- month old baby boy presented with the vomiting and failure to weight gain. Physical examination was normal except penile length 4. 5 cm and mild hyperpigmentation. The parents were not relative. Mother and father were healthy and no remarkable family history. Laboratory findings: serum Na<100 mmol/L K:5. 7 mmol/L urinary sodium:33 mmol/L plasma renin activity:22 ng/mL/hour (0. 51-2. 64)ACTH:192 ng/mL (<46) Cortisol:5. 1 mcg/dL aldosterone:1357 pg/L (50-900)DHEAS:4074 mcg/dL (31-214) testosterone:1004 ng/dL (142-923) androstenedione:65 ng/mL (006-0. 68)17OH progesterone:815 ng/mLHe was diagnosed as congenital adrenal hyperplasia. Molecular analysis revealed that: Proband was compound heterozygote for I2A/C656G and Q318X. Mother was homozygote for I2A/C656G mutation and Father was heterozygote for Q318X. With the treatment of hydrocortisone, fludrocortisone and salt replacement, he is going well. As a result, due to lack of ambigious genitalia in male newborns with salt-wasting CAH are generally undiagnosed at birth and come to medical attention with salt losing crisis. Although the mother is homozygote for I2A/C656G, she is healthy without hirsutism, infertility or menstrual irregulatory. That case impresses the probability of discordance between genotype and phenotype in cases with CAH.

2401W

Concomitant *de novo NFIX* heterozygous deletion and truncating *EVC* mutation escaping nonsense-mediated mRNA decay in a subject with severe intellectual disability and postnatal growth delay. *D. Uehara[1], S. Hayashi[1,2,3], K. Tanimoto[1], S. Mizuno[4], J. Inazawa[1,2,5].* 1) Department of Molecular Cytogenetics, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Tokyo, Japan; 2) Hard Tissue Genome Center, Tokyo Medical and Dental University, Tokyo, Japan; 3) Department of Neurobiology, Yale University School of Medicine, CT; 4) Department of Pediatrics, Central Hospital, Aichi Human Service Center, Kasugai, Japan; 5) Bioresource Research Center, Tokyo Medical and Dental University, Tokyo, Japan.

NFIX heterozygous aberrations at 19p13. 2, namely whole-gene deletions and point mutations affecting its DNA-binding domain, have been described in subjects whose common features include intellectual disability (ID), overgrowth and macrocephaly. These features are now referred to as Sotos syndrome 2 or Malan syndrome. Among our screening of 645 Japanese subjects with ID and multiple congenital anomalies of unknown etiology, we report on a female subject with a 393-kb *de novo* deletion at 19p13. 2 encompassing *NFIX*, detected by SNP arrays. Clinical features included severe ID, hypotonia, small intestinal atresia and mesenteric malformation, low stature (-3. 5 SD) and weight (-2. 5 SD), along with a relative macrocephaly (-0. 7 SD) at the age of seven years old. Her birth size was normal. In order to identify other variants that could explain her postnatal growth delay, we performed a complementary investigation with whole-exome sequencing, which revealed a novel nonsense mutation (c. 1273C>T or Q425X) in the *EVC* gene, inherited from the mother. RT-PCR followed by Sanger sequencing in lymphoblastoid cell lines revealed that, as expected, the mutant allele in the mother was degraded by nonsense-mediated mRNA decay (NMD). However, the same mutant allele escaped from NMD in the proband. *EVC* is the causative gene of the autosomal recessive Ellis-van Creveld syndrome, characterized by short stature, postaxial polydactyly, dysplastic nails and teeth, and cardiac defects in 60% of the cases. Unlike the previous reports of *NFIX* haploinsufficiency leading to overgrowth, our case presents short stature that might be explained as a result of a dominant-negative effect exerted by the mutant *EVC* protein. The reason why the mutant allele escaped only in the proband remains unclear.

2402T

Macrothrombocytopenia and Developmental Delay with a *de novo CDC42* Mutation: Yet Another Locus for Thrombocytopenia and Developmental Delay. *K. Kosaki[1], T. Takenouchi[1], T. Uehara[1], R. Kosaki[2].* 1) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan; 2) Division of Medical Genetics, National Center for Child Health and Development.

Isolated thrombocytopenia combined with a developmental delay classically suggests a chromosome 11q deletion including the *FLI1* locus, a transcription factor that is essential for megakaryopoiesis (Jacobsen syndrome) or a 21q22 microdeletion that includes the *RUNX1* locus. Here, we report a female patient who presented with macrothrombocytopenia (64,000 μ/L)and a developmental delay. The observation suggests presence of yet another locus, *CDC42*, for thrombocytopenia with developmental delay. Thepatient hadmidfacial hypoplasia, synophrys, mild ptosis, eversion of the lateral portion of the lower eyelid, exotropia, short philtrum, thin upper lip and generalized eczema without petechia. She also hadlymphedema in her legs. At age18 years,she was unable to climb stairs without support andcommunicated with simple words. A complete blood count showed a platelet count of as low as 52,000 μ/L and normal white blood cell count of 3,000 μ/L and normal hemoglobin level. A peripheral blood smear revealed enlarged platelets. Whole exome sequencing identified a *de novo* mutation in the GTPase *CDC42*c. 191A>G, p. Tyr64Cys as the sole candidate in an autosomal dominant de novo or recessive model. The mutation was confirmed using Sanger sequencing. The strong degree of similarity between the phenotype of the proposita and that of mice lacking *Cdc42* suggests a probable causal relationship. The conditional homozygous knock-out of *Cdc42* in mice results in mild thrombocytopenia and an increase in platelet size, i. e. , macrothrombocytopenia. Phenotypes other than the macrothrombocytopenia observed in the proposita could also be ascribed to the defect in *CDC42.* First, the developmental delay could be explained by the *CDC42* mutation, since Cdc42 plays a critical role in the proliferation of neuronal progenitor cells. Second, the lymphedema could be ascribed to the *CDC42* mutation, since Cdc42 directly interacts with Rac1, the defect of which leads to lymphedema in mice. Third, the severe eczema could also be explained by the *CDC42* mutation, since CDC42 directly interacts with WASP, the defect of which leads to Wiskott-Aldrich syndrome, which is characterized by eczema accompanied with thrombocytopenia. Apparent phenotypic similarity between WAS and the proposita may reflect combinatory role of WASP and CDC42 in cytoskeletal actin polymerization in various biological processes including platelet genesis.

2403F

Holoprocencephaly and Neural tube defects: Strange bedfellows: Is there a third and even stranger bedfellow-Heterotaxy? *S. Krishnamurthi, T. Sadler, R. Stevenson.* Genetics, Greenwood Genetic Center, Greenwood, SC.

Holoprosencephaly (HPE) and neural tube defects (NTDs) are both midline defects with an embryological basis in the closely intertwined dynamic processes of gastrulation and neurulation. Coincidental occurrence of these two conditions is approximately 1:16,000,000. We report a series of 5 cases of HPE with associated NTDs and laterality defects over a 23 year period (1,284,000 births, 1992-2015), which represents a 50-fold increase over the expected combined prevalence. Six additional cases with NTDs had facial findings suggestive of HPE but insufficient information to be conclusive. Some of our cases of HPE and NTDs also exhibited laterality defects. Thus we hypothesize that the etiology of HPE, NTDs and heterotaxy may be related, possibly involving genes that regulate patterning the body by early in the third week of embryonic development. Both HPE and NTDs exhibit phenotypic variability that appear to be chronologically and topographically related to alterations in genetic determinants in highly conserved regulatory pathways, notably the Sonic Hedgehog signalling pathway. Decreased expression of *sonic hedgehog* (*SHH*) has been associated with HPE, whereas in cases of NTD, expression is increased. Of the 4 major HPE associated genes, *SHH, ZIC2* and *SIX3* are all linked to the SHH pathway. *TGIF* encodes a co-repressor for the TGFb/Nodal signaling and appears to function as a key regulator of SHH signaling. Reduced expression of *Zic2* in knockdown models results in HPE and NTD. Both defects also appear to be more frequent with *TGIF* mutations. Loss of function of *TGIF* has been implicated in failure of gastrulation. Genes in these pathways have also been implicated in establishing the left-right (L-R) axis. Mutations involving genes responsible for neural patterning and left-right asymmetry have been demonstrated to produce midline and laterality defects in knockout animal models. SHH is also a key gene involved with *NODAL* in establishing the left-right (L-R) axis. Both genes are expressed asymmetrically in the primitive node to regulate *PITX2* expression on the left side that then establishes the L-R axis. Both *SHH* and *NODAL* knockouts have cyclopia and heterotaxy, while *STIL* knockouts have decreased expression of *SHH*, bilateral expression of *NODAL* and *PITX2*, cyclopia, NTD, and heterotaxy. We hope to establish a common genetic basis for these defects by examining genes in this pathway and other regulatory contributors through whole genome sequencing.

2404W

Whole Exome Sequencing of a Syrian Family with Oral Cleft and Split Hand/Foot Syndrome Reveals Novel *de novo* Mutation in *TP63*. *C. L. Simpson[1], D. C. Kimble[2], S. C. Chandrasekharappa[2], N. I. S. C. Comparative Sequencing Program[3], K. Alqosayer[4], H. Albacha-Hejazi[5], J. E. Bailey-Wilson[1].* 1) Computational and Statistical Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Baltimore MD 21224; 2) Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda MD 20814; 3) NIH Intramural Sequencing Center, National Human Genome Research Institute, National Institutes of Health, Bethesda MD 20814; 4) Prime Health Clinic, Jeddah, Riyadh 21511, Saudi Arabia; 5) Hejazi Clinic, P. O. Box 2519, Riyadh 11461, Saudi Arabia.

Oral clefts are a common, heterogeneous birth defect affecting 1 in 750 live births in the US, typically present as cleft lip with or without cleft palate. Split hand/foot malformations are a less common heterogeneous birth defect with 1 in 8,500 to 25,000 live births affected. Here we present results of whole exome sequencing (WES) analysis in a Syrian family with an affected proband who presented with both orofacial clefting and split hand/foot. An additional family member affected with an oral cleft but without limb abnormalities died at birth and was unavailable for analysis. We performed WES in the proband, both parents and two unaffected siblings. Quality control was performed in Golden Helix SVS and PLINK. Variant annotation, Mendelian inconsistencies and novel variants in known cleft genes were examined. Candidate variants were validated using Sanger sequencing. 185,474 SNVs and 18,058 INDELs were released by the sequencing center. Genotypes were dropped for depth < 10, quality score < 10 or genotype quality to depth ratio of < 0. 5. Variants monomorphic after filtering were dropped. There were 11,905 INDELS and 137,989 SNVs available for analysis after all filtering steps. Examining Mendelian errors revealed 35 candidate *de novo* events of which 1 was in a known oral cleft and split hand/foot gene, TP63 (c. 956G>T, p. Arg319Leu) and confirmed by Sanger sequencing. A tri-allelic SNV was also found in HLA-DRB5, which is similar to and overlaps with the known oral cleft gene HLA-DRB1. Mutations in*TP63*are associated with multiple disorders which include oral clefts and limb malformations, including Ectrodactyly, Ectodermal Dysplasia and Cleft Lip/Palate Syndrome 3 (EEC3), Split Hand/Foot Malformation 4 (SHFM4), Hay-Wells Syndrome and acro-dermato-ungual-lacrimal-tooth (ADULT) syndrome, and most mutations are dominant. The mutation presented here is a *de novo* event but is also a novel mutation. However, another known mutation 1bp upstream (rs121908839, c. 955C>T, p. Arg319Cys) affects the same codon but produces a different amino acid (AA) change and provides strong evidence that mutating this AA is deleterious. However, it is not clear whether this mutation is only responsible for the split hand/foot or whether it is also causing oral cleft. The p. Arg319Cys mutation is known only to cause split hand/foot, and not oral clefts. Further functional analysis is needed to see if this mutation is the cause of the entire phenotype or only the limb malformation.

2405T

Biallelic *SZT2* mutations in a case with early infantile epileptic encephalopathy. *A. Miyauchi[1], H. OSAKA[1], N. SHIMOZAWA[2], N. MATSUMOTO[3], H. SAITSU[3], T. YAMAGATA[1].* 1) Pediatrics, Jichi Medical University, Shimotsuke-shi, Tochigi, Japan; 2) Division of Genomics Research, Life Science Research Center, Gifu University, Gifu, Japan; 3) Department of Human Genetics, Yokohama City University Graduate School of Me dicine, Kanagawa, Japan.

(Introduction) Biallelic mutations in*SZT2*have been recently reported in patients with infantile encephalopathy, who showed severe development delay, intractable epilepsy, as well as thick and short corpus callosum and persistent cavum septum pellucidum on brain MRI. We report a fourth case with biallelic*SZT2*mutations. (Case Report) Patient is a 3-year-old-girl who is the third child of healthy nonconsanguineous parents. An elder sister, showing severe developmental delay and intractable epilepsy, died at age of 2 with acute encephalopathy. An elder brother was born at 23 weeks gestation and died soon after birth. She was born at 1,398 g for 32 wks. She had facial dysmorphic features included a high forehead and bilateral ptosis. Symptoms include severe developmental delay with hypotonia, failure to thrive, and intractable epilepsy. At the age of 2 mos, complex partial seizures and secondary generalized seizures began, which were refractory to multiple antiepileptic drugs. Interictal EEG showed bilateral frontal dominant spike-and-waves. Brain MRI showed a short and thick corpus callosum. She developed thrombocytopenia (~3,000 to 200,000 /μl) since 2 yrs and 6 mos. She did not respond to discontinuation of suspicious drugs and needed platelet transfusions. A G-banding and array CGH revealed no abnormal findings. By whole-exome sequencing and subsequent Sanger sequencing, we identified compound heterozygous frameshift mutations in *SZT2*, in which c. 3700_3716del and c. 5482del were transmitted from her father and mother, respectively. (Discussion) To date, only three families with *SZT2* mutations have been reported including our family. Clinical features of previous two families were similar with those of our case except for thrombocytopenia which is uniquely observed in our case. Expression of *SZT2* is reported to be increased by glutamic neurotoxic stimulation and co-localize with catalase at the peroxisome. In mice, *Szt2* has been reported to regulate seizure threshold and influence epileptogenesis. Association of SZT2 to epileptogenicity and thrombocytopenia will be a target for future investigation.

2406F

Analysis of the planar cell polarity regulator gene *PTK7* in neural tube defects. *Y. Lei[1], H. Zhu[1], G. Shaw[2], E. Ross[3], R. Finnell[1].* 1) Dell Pediatric Research Institute, Department of Nutritional Sciences, The University of Texas at Austin, Austin, Texas; 2) Department of Pediatrics, Division of Neonatology, Stanford University School of Medicine, Stanford, CA; 3) Center for Neurogenetics, Brain and Mind Research Institute, Weill Cornell Medical College, New York, NY.

Neural tube defects (NTDs), including anencephaly, spina bifida and craniorachischisis, are severe birth defects that affect 0. 5-1 in 1000 births. Recently, mutations in planar cell polarity (PCP) pathway genes were implicated in the pathogenesis of NTDs in both the mouse model and in human cohorts. Mouse models indicate that the homogenous disruption of *Ptk7* gene, a PCP regulator, results in craniorachischisis, while embryos that are double heterozygous for *Ptk7* and *Vangl2* Lp mutations result in spina bifida. In this study, we sequenced exons of the human *PTK7* gene in 192 spina bifida patients and 190 controls from a California population. Included were live-born cases with spina bifida. Controls were randomly selected among all liveborn infants corresponding to the same geographic area and birth time periods as cases. DNA for genotyping was obtained from newborn bloodspots. We identified three rare (MAF < 0. 01) missense heterozygous *PTK7* mutations (p. Thr186Met, p. Arg630Ser and p. Tyr725Phe) in spina bifida cases. Two of the variants (p. Arg630Ser and p. Tyr725Phe) which were predicted to be damaging by PolyPhen, were absent in well-matchedall controls, as well as in ExAC control database. No novel damaging missense *PTK7* mutation was identified in control subjects. Our study suggests that missense mutations in *PTK7* appear to contribute to the genetic risk of spina bifida in the studied population.

2407W

A six-year-old boy with compound heterozygote mutations of *ERCC6* and a splice site mutation of *ATRX*. *K. Kojima[1], A. Miyauchi[1], N. Ikeda[1], M. Yamazaki[1], Y. Monden[1], H. Osaka[1], H. Shimbo[2], T. Wada[3], H. Saitsu[4], N. Matsumoto[4], T. Yamagata[1].* 1) Pediatrics, Jichi Medial University, Shimotsuke-shi, Tochigi, Japan; 2) Department of Neurology, Kanagawa Children's Medical Center; 3) Depatment of Medical Ethics, Kyoto University Graduate School of Medicine; 4) Depatment of Human Genetics, Yokohama City University Graduate School of Medicine.

(Introduction)Cockayne syndrome (CS) is an autosomal recessive disorder, showingcachectic dwarfism, severe intellectual disability (ID),progeroid appearance,sensorineural hearing loss, intracranial calcification, etc. The responsible gene is*Excision repair cross-complementation group 6 (ERCC6)*and*ERCC8.* Alpha thalassemia X-linked intellectual disability (ATRX) syndrome is characterized byID, characteristic facial features, the genitourinary tractabnormalitiesand alpha thalassemia, caused by the defect of*ATRX*. We report a boy withmutations in two genes that werecompound hererozygote mutation of*ERCC6*and alsosplice site mutationof*ATRX*.

(Patient) Patient was a 6year-old boyborn from non-consanguineous parents with uneventful delivery. Hisbirth weight was 3. 36kg (0. 2SD). At 5 year-old, his height was 91cm (-4. 3SD) and weight 14. 7kg(-1. 4SD). He hadbird like appearance, andmoderate ID with several meaningful single words. He also hadspastic diplegiawith knee and ankle joint contracture, and could walk several steps. He did not have hearing loss and genital abnormality. His cranial CT showed calcification on basal gangliaand MRI showed mild cerebellar atrophy. His blood analysis showed no thalassemia.

(Methods and Results)Genomic DNA was obtained from this patient and hismother after the informed consent. By whole exomesequencing, we detectedcompound heterozygousmutationsin*ERCC6*; c. 1936del (p. Asp646Thrfs*52) that wasalsodetected in his mother, and c. 1627A>T (p. Ile543Phe)that was supposed to be inherited from his father. In addition,a splice site mutationin*ATRX*(c. 21-G>A)was detected. RT-PCR analysisfor*ATRX*detected the mRNA that was spliced from exon 1 to 3 with exon 2 skipping. Immunostaining of patient's fibroblastsusing rabbit polyclonal antibody for C terminal region of ATRX detected the expression of ATRX in nuclei.

(Discussion)This patient had spastic diplegia and some features of Cockayne syndromealthoughthey were mild, buthadunremarkablephenotypes of ATRX syndrome. The product of splicing variant skipping exon 2 induced by c. 21-G>A in*ATRX*was supposed to terminate early. A male patient who also had exon 2 skipping mutation of*ATRX*was reported to haveChudley–Lowry syndrome. To elucidate the reason for milder phenotype in this patient, the interference of these two genes should be examined.

2408T

Identification of a new mutation in *C2CD3* by whole exome sequencing in an oral-facial-digital syndrome family with intrafamilial variability. *S. Scheidecker[1], Y. Perdomo[2], V. Geoffroy[1], D. Chaigne[3], M. Koob[4], C. Stoetzel[1], H. Dollfus[1,2].* 1) Laboratoire de Génétique Médicale, INSERM U1112, IGMA, Faculté de Médecine, UDS, Strasbourg, France; 2) Centre de Référence pour les affections rares en Génétique ophtalmologique, CARGO, HUS, Strasbourg, France; 3) Service de Pédiatrie, HUS, Strasbourg, France; 4) Service de RadioPédiatrie/Imagerie 2, HUS, Laboratoire ICube, UMR 7357/FMTS/UDS-CNRS, Strasbourg, France.

The oral-facial-digital (OFD) syndrome is a heterogeneous group of disorders that affect almost invariably the oral cavity, the face and the digits. To date, more than 13 types have been distinguished based on characteristic clinical manifestations with other organ systems involved. Extensive overlap in the phenotype exists between the various forms with different inheritances. Recently, *C2CD3* gene was reported to be associated with an autosomal recessive OFD syndrome in a child with severe microcephaly, micropenis, severe intellectual disability, retinopathy, and cerebral MRI scan anomalies, and a fetus male with oral anomalies, polydactyly and cerebral malformations (Thauvin-Robinet, et *al*. 2014). *C2CD3* encodes a protein colocalizing with OFD1 and having an essential role in the assembly of centriolar distal appendages. We report a new *C2CD3* variant in a family with two affected siblings with a phenotype of OFD spectrum. The propositus was the second child of related healthy parents. The girl was born with hypotonia and microcephaly. Were also noted hyperplastic oral frenula, hamartomas of the tongue and partial choanal atresia. She had breath difficulties with episodes of apnea in the first days of life. She developed retinopathy and mild ataxia and had learning difficulties. Cerebral MRI scan showed cerebellar anomalies associated with neuronal migration defect. Clinical examination revealed mild dysmorphism features. Her younger brother had also microcephaly at birth with hypotonia. He developed a retinopathy without other anomalies at the age of 12 months. Whole exome sequencing performed on the family trio (the affected propositus and the healthy parents) revealed a rare variant (c. 4922T>C; p. Val1641Ala) at homozygous state in the affected child. The variant was also detected by Sanger sequencing in the younger affected brother at homozygous state. The identification of new individuals carrying *C2CD3* mutation highlights the interest to look at variants in this gene very recently described in autosomal recessive form of oral-facial-digital syndrome. Description of more C2CD3 cases could help to delineate a new subtype of OFD.

2409F

Associated non diaphragmatic anomalies among cases with congenital diaphragmatic hernia. *C. Stoll, Y. Alembik, B. Dott, MP. Roth.* Genetique Medicale,Faculte de Medecine, Strasbourg, France.

The etiology of congenital diaphragmatic hernia (CDH) is unclear and its pathogenesis is controversial. Because previous reports have inconsistently noted the type and frequency of malformations associated with CDH, we assessed these associated malformations ascertained between 1979 and 2007 in 386,022 consecutive births of known outcome. Of the 139 patients with CDH, 85 (61. 2%) had associated anomalies. These malformations included: chromosomal abnormalities (n=25, 18. 0%); recognized conditions non-chromosomal (n = 24, 17. 3 %): syndromes (Fryns syndrome, fetal alcohol syndrome, De Lange syndrome, CHARGE syndrome, Fraser syndrome, Goldenhar syndrome, Smith-Lemli-Opitz syndrome, multiple pterygium syndrome, Noonan syndrome, spondylocostal dysostosis, and Beckwith-Wiedemann syndrome), malformation sequences (laterality sequence, ectopia cordis), malformation complexes (limb body wall complex), and non syndromic multiple congenital anomalies (MCA) (n=36, 25. 9%). Malformations of the cardiovascular system (n=53, 27. 5%), urogenital system (n=34, 17. 6%), musculoskeletal system (n=29, 15. 0%), and central nervous system (n=19, 9. 8%) were the most common other congenital malformations. We observed specific patterns of malformations associated with CDH which emphasizes the need to evaluate all patients with CDH for possible associated anomalies. One should be aware that the anomalies associated with CDH can often be classified into a recognizable malformation syndrome or pattern, in 57. 6% of the cases.

2410W

An aberrant splice acceptor site due to a novel intronic nucleotide substitution in MSX1 gene is the cause of congenital tooth agenesis in a Japanese family. *T. Tadashi[1], K. Masashi[1,2,7], N. Mitsuko[3], M. Junichiro[1,4], Y. Seishi[1,5], S. Akio[1,2,7], G. Hiroki[1,7], N. Atsuo[6], H. Yujiro[7], M. Hitoshi[1], S. Kazuo[1], M. Naomichi[3], T. Yoshihito[7].* 1) Maxillofacial Surgery, Aichi-Gakuin University School of Dentistry, Chikusa-ku, Nagoya , Japan; 2) Dentistry Oral and Maxillofacial Surgery, Ogaki Municipal Hospital, Ogaki, japan; 3) Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 4) Oral and Maxillofacial Surgery, Toyota Memorial Hospital, Toyota, Japan; 5) Dentistry and Oral Surgery, Aichi Children's Health and Medical Center, Obu, Japan; 6) Embryology, Institute for Developmental Research, Aichi-Human Service Center, Kasugai, Japan; 7) Perinatology, Institute for Developmental Research, Aichi-Human Service Center, Kasugai, Japan.

Congenital tooth agenesis is caused by mutations in the MSX1, PAX9, WNT10A, or AXIN2 genes. Here, we report a Japanese family with nonsyndromic tooth agenesis caused by a novel nucleotide substitution in the intronic region between exons 1 and 2 of the MSX1 gene. Because the mutation is located 9 bp before exon 2 (c. 452-9G>A), we speculated that the nucleotide substitution would generate an abnormal splice site. Using cDNA analysis of an immortalized patient blood cell, we confirmed that an additional 7-nucleotide sequence was inserted at the splice junction between exons 1 and 2 (c. 451_452insCCCTCAG). The consequent frameshift generated a homeodomain-truncated MSX1 (p. R151fsX20). We then studied the subcellularlocalization of truncated MSX1 protein in COS cells, and observed that it had a whole cell distribution more than a nuclear localization, compared to that of wild-type protein. This result suggests a deletion of the nuclear localization signal, which is mapped to the MSX1 homeodomain. These results indicate that this novel intronic nucleotide substitution is the cause of tooth agenesis in this family. To date, most MSX1 variants isolated from patients with tooth agenesis involve single amino acid substitutions in the highly conserved homeodomain or deletion mutants caused by frameshift or nonsense mutations. We here report a rare case of an intronic mutation of the MSX1 gene responsible for human tooth agenesis. In addition, the missing tooth patterns were slightly but significantly different between an affected monozygotic twin pair of this family, showing that epigenetic or environmental factors also affect the phenotypic variations of missing teeth among patients with nonsyndromic tooth agenesis caused by an MSX1 haploinsufficiency.

2411T

The Etiological Exploration of PHACE Syndrome. *K. F. Schilter[1], D. W. Metry[2], I. J. Frieden[3], W. B. Dobyns[4], E. A. Worthy[5], B. A. Drolet[1], D. H. Siegel[1].* 1) Departments of Dermatology and Pediatrics, Medical College Wisconsin, Milwaukee, WI; 2) Department of Dermatology, Baylor College of Medicine, Houston, TX; 3) Departments of Dermatology and Pediatrics, University of California San Francisco, San Francisco, California; 4) Departments of Pediatrics and Neurology, University of Washington, Seattle Washington; 5) Departments of Pediatrics and Human and Molecular Genetics Center, Medical College of Wisconsin, Milwaukee, WI.

PHACE syndrome is an uncommon neurocutaneous syndrome consisting of features including Posterior fossa malformations, Hemangiomas, Arterial anomalies, Cardiac defects, and/or anomalies of the Eye (OMIM #606519). The exact etiology and pathogenesis of PHACE syndrome and the associated features are not yet known. One of the most frequently associated features of PHACE syndrome are the cerebrovascular anomalies present in 84%. In a cohort of 70 PHACE patients with known cerebrovascular anomalies, 56% were further described as having arterial dysgenesis, and another 47% having anomalous course and/or origin of the arteries. It was also noted that in all but one case, the associated features of arterial and brain anomalies are found ipsilateral to the hemangioma, suggesting factors early in development. Furthermore, the effect of the anterior rather than posterior circulation suggests involvement of neural crest lineage. Based on current knowledge of the syndrome, it is hypothesized that there is a mosaic genetic component contributing to the development of multiple congenital anomalies, most notably the cerebrovascular anomalies. The PHACE Syndrome International Clinical Registry and Genetic Repository was established in 2006, and currently has approximately 210 patients enrolled. To date, genetic studies conducted through the PHACE syndrome registry, including X-inactivation analysis, copy number variation analysis, and candidate locus analysis, have not identified a genetic etiology. While these studies did not reveal any specific genetic variant or copy number change, their findings may provide information in the future about modifying or susceptibility factors in PHACE syndrome which may account for the variability in the phenotype. Current genetic analyses include whole exome and whole genome sequencing to further investigate genetic involvement in PHACE syndrome. Analyses are being directed with somatic mosaicism as the hypothesis of the etiology.

2412F

Novel heterogenous mutation in *DYNC1H1* gene in a boy with arthrogryposis and motor neuropathy. *H. Alsharhan, A. Rajadhyaksha.* Pediatrics, Miami Children's Hospital, Miami, FL.

We present a three-year old boy, currently wheelchair bound, who was born at 35 weeks gestation, via caesarian section due to breech presentation, found to have arthrogryposis, severe clubfeet, bilateral femur fractures and hip dislocation at birth. Prenatal period was significant for for decreased fetal movements, and highly suspected arthrogryposis in fetal ultrasonography. Later, he developed knee contrctures, hypotonia, and found to have global developmental delay with further femur fractures, requiring multiple orthopedic interventions. Extensive workup was conducted, which yielded normal results. His newborn screen was normal along with his karyotype (XY). Arthrogryposis panel was negative as well. His brain magnetic resonance imaging (MRI) showed mild enlarged ventricles, but spine MRI was unremarkable. His cardiac evaluation, hearing and vision were all within normal limits. Muscle biopsy was non contributory. At age of 2 years, whole exome sequencing was performed, which identified a novel de novo heterozygous mutation in dynein heavy chain1*DYNC1H1,c. 3623G>Tp. W1208L. DYNC1H1*gene encodes for a cytoplasmic dynein heavy chain, which is a motor protein complex, presents in muscles, nerves, bones and other tissues. Cytoplasmic dyneins, large mechanochemical motor compromising heavy, intermediate, and light chains, are implicated in intracellualr motility, including retrograde axonal transport, neuronal migration, spindle dynamics and other intracellular motility functions. Mutations of*DYNC1H1*gene have been associated with autosomal dominant Charcot-Marie-Tooth type, distal spinal muscular atrophy (SMA), predominantely affecting the legs (SMA-LED), and mental retardation, indicating that dynein dysfunction is associated with a range of phenotypes in humans involving neuronal development and maintenance. Here we report the first patient with this mutation who manifested with both bone and neurological manifestations. This case further expands the set of pathological mutations of*DYNC1H1*gene and thus reinforce role of cytoplasmic dynein in both motor neuropathies and bone disorders.

2413W

The analysis of *IL36RN* mutations in subtypes of pustular psoriasis. *J. Hong[1,2], T. Wang[2], T. Tsai[2].* 1) The Graduate Institute of Medical Genomics and Proteomics, National Taiwan University Hospital and College of medicine, Taipei, Taiwan; 2) Department of Dermatology, National Taiwan University Hospital and College of medicine, Taipei, Taiwan.

Pustular psoriasis is a special form of psoriasis characterized by the occurrence of sterile pustules on normal-appearing or inflamed erythematous skin. It can be further classified into several clinical features depending on the clinical course and location: generalized pustular psoriasis (GPP), annular pustular psoriasis (APP), plaque-type psoriasis with pustules (PsOp), impetigo herpetiformis (IH), erythrodermic psoriasis (EP) and localized pustular psoriasis—palmoplantar pustulosis (PPP), and acrodermatitis continua of Hallopeau (ACH). The previous studies showed that GPP is linked to *IL36RN* mutation. However, the percentage of pustular psoriasis patients with *IL36RN* mutation vary among different studies. The variation of mutation frequency might be related to the classification of subtypes of psoriasis. To investigate the frequency of *IL36RN* mutation in different subtypes of pustular psoriasis, we enrolled 57 Han Chinese patients with pustular psoriasis, including 10 ACH and 17 GPP patients. The blood samples were collected and genomic DNA was extracted from leukocytes, and the PCR-based Sanger sequencing was used to analyze the coding exons and flanking introns of the *IL36RN* gene. The results revealed that patients with ACH and GPP had the highest mutation rates of *IL36RN*, which were about 90. 0% and 76. 5% respectively. The splicing mutation, c. 115+6T>C, was the most common variant in ACH and GPP patients with *IL36RN* mutations. For APP, the mutation rate was 40%. In comparison, the *IL36RN* mutation rates of PPP, PsOP, and EP were only about 22%, 14%, and 0% respectively. In summary, a much higher *IL36RN* mutation rate was found in some particular types of pustular psoriasis, ACH and GPP. In view of the rarity of pustular psoriasis, cooperative studies will be needed to screen for other mutations for pustular psoriasis patients without *IL36RN* mutation.

2414T

Identification of a heterozygous stop-gain mutation in *ASXL3* refines autism spectrum disorder diagnosis to Bainbridge-Ropers syndrome. *J. C. Jacobsen[1], B. Swan[1], J. Taylor[2], R. Hill[2], K. Lehnert[1], R. Snell[1].* 1) The University of Auckland, Auckland 1010, New Zealand; 2) Auckland City Hospital, Auckland 1142, New Zealand.

We have identified a cohort of New Zealand females with apparently sporadic Autism Spectrum Disorder (ASD) from the Minds for Minds database#. Exome sequencing of 6 trios from this cohort was performed in order toestablishetiologic genetic variations. In one trio we identified a *de novo* heterozygous four base-pair duplication (c. 1490_1493dup). This results in a frameshift, inducing a premature stop codon (p. NL498K*) in the gene *ASXL3* (Additional Sex Combs Like 3). Five previous observations of heterozygous stop-gain mutations in *ASXL3* have been associated with Bainbridge-Ropers syndrome (BRS). These mutations occur in a disease-causing mutation hotspot in the 5' end of exon 11. The clinical features of BRS include global developmental delay, intellectual impairment, feeding difficulties in infancy, growth retardation and craniofacial abnormalities, such as highly arched eyebrows, anteverted nares, high arched palate and abnormal position of the hands with ulnar deviation. The female proband in our cohort had many of these features including global developmental delay, feeding difficulties, growth retardation and similar craniofacial features, although she lacked ulnar deviation of the hands. The ASXL genes are putative polycomb-group proteins involved in transcriptional regulation during development. Additional *ASXL3* truncating variations have been observed in the population, suggesting that the condition may be caused by dominant gain of function rather than hemizygosity. The mechanism of *ASXL3* truncation mutations in BRS has yet to be established and is the focus of ongoing work. This research has utilized whole-exome sequencing to refine a diagnosis of ASD to BRS, vouching for the use of next generation sequencing for the diagnosis of neurodevelopmental disorders. #Minds for Minds is a New Zealand based organization focused on researching ASD and other neurodevelopmental disorders. We currently have a database of more than 1200 individuals, including 700 New Zealanders diagnosed with ASD. The database reflects the male:female bias in ASD, and the self-attributed ethnic background reflects New Zealand's population.

2415F

Focusing from Chronic Kidney Disease to Cystinosis: Discrepancy Between the Clinical Incidence of Cystinosis and Estimates Based on 1000 Genomes. *W. Wu, L. Stark.* Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT.

Background: Chronic Kidney Disease (CKD) is a complex trait with many contributory causes of which cystinosis is one. Cystinosis is an autosomal recessive metabolic disease characterized by accumulation of cystine. The primary type is the nephropathic form. Patients typically suffer from proximal tubule dysfunction which leads to glycosuria, phosphaturia, aminoaciduria, sodium wasting, polyuria and metabolic acidosis. These may result in growth retardation with rickets, and acute dehydration episodes. The glomerular filtration rate declines gradually and eventually progresses to end-stage renal disease. Extra-renal manifestations are commonly seen in other organs, too. The causative gene of cystinosis has been mapped to CTNS, a gene located on chromosome 17p13. CTNS encodes cystinosin, which is a lysosomal membrane protein responsible for cystine transport. This study explored the allele frequency and estimated the affected and carrier rate of cystinosis in the general population. **Methods:**To identify pathogenic variants, we parsed the Human Gene Mutation Database (HGMD; a manually-curated database) to collect confirmed disease-causing mutations. For identification of variants in the healthy general population, we parsed the 1000 Genomes database (1KG). CTNS variants procured from both databases were intersected and allele frequency was calculated based on the 1KG. Carrier rate (heterozygotes with a pathogenic variant) and affected rate (homozygotes or compound heterozygotes with pathogenic variants) were estimated based on Hardy-Weinberg equilibrium. **Results:**There are 75 pathogenic CTNS variants in the HGMD. These variants include missense mutations, nonsense mutations, insertions, deletions, and complex substitutions. Healthy individuals in the 1KG carry 444 CTNS variants. When we intersected the two databases, we found 36 people in the 1KG who carry pathogenic CTNS variants in a heterozygote state. From these data we calculated a frequency of 0. 016 for all disease-causing alleles. Therefore, the predicted affected rate would be 0. 00027 (approximately 1:3680), and the predicted carrier rate would be 0. 032 (approximately 1:30). **Discussion:**The clinical incidence of cystinosis is nearly 6 per 100,000. However, our estimate based on 1KG is approximately 24 times higher. Possible explanations for this large difference include under-diagnosis of cystinosis, or low penetrance of CTNS variants. Distinguishing between the two will require further investigation.

2416W

Phenotype of a 23 year old male with *FAM111B* mutation: poikiloderma, myopathy, joint contractures, and lymphedema. *M. Ganapathi[1], PL. Nagy[1], C. Ulane[2], U. Agbim[3], J. Odel[4], JB. Sampson[2].* 1) Pathology & Cell Biology, Personalized Genomic Medicine, Columbia University Medical Center, New York, NY; 2) Department of Neurology, Columbia University Medical Center, New York, NY; 3) Department of Medicine, Columbia University Medical Center, New York, NY; 4) Department of Ophthalmology, Columbia University Medical Center, New York, NY.

FAM111B mutations were first described in 8 individuals with autosomal dominant hereditary fibrosing poikiloderma with tendon contracture, myopathy, and pulmonary fibrosis (Am J Hum Genet. 93 (6):1100-7, 2013). This case broadens the phenotype previously described. Clinical presentation: At age 6 months, the patient developed skin rash and hair loss. His walking milestones were normal and comparable to his fraternal twin, but he was noted to have abnormal gait starting at that time. He is ambulatory, but his proximal and distal weakness has been progressive. Pancreatic insufficiency was diagnosed at age 14yrs. He is cognitively normal. At age 23 he presented to our institution. He has poikiloderma on the face,and sun exposed areas, lymphedema in the limbs, hypohidrosis, hypotrichosis, alopecia and nail dysplasia. Muscle strength is reduced in the biceps (3/5 MRC scale), triceps (3/5), wrist extension (4/5) and hip flexor muscles (4/5). He has bilateral elbow contractures and dysphagia. Ophthalmologic examination showed shallow orbits with mild restriction of medial rectus action OU and right macular pigmentary changes. Serum creatine kinase levels were elevated (312-372 U/L). EMG studies revealed normal nerve conductions and absence of myotonic or myopathic changes. Muscle biopsy showed dystrophic changes, with both atrophic and hypertrophic fibers, central nuclei, endomysial fibrosis and fibroadipose replacement. Abdominal CT showed atrophy of paraspinal muscles, rectus abdominis muscles, and pancreatic atrophy but no fibrosis. Liver function tests showed elevated SGOT (26-100 U/L), SGPT (25-132 U/L), alkaline phosphatase (79-129 U/L) and gamma glutamyl transferase (106 U/L), however these resolved. Pulmonary forced vital capacity testing was 64% of predicted but CT scans show no evidence of pulmonary fibrosis. The patient was originally diagnosed in childhood with Rothmund Thompson syndrome, a close mimic of FAM111B. RECQL4 sequencing at that time failed to detect pathogenic variants. Whole exome sequencing on the proband and parents revealed a heterozygous de novo missense variant (c. 1883G>A; p. S628N) in the *FAM111B* gene. This mutation (p. S628N) was previously reported in 1 patient presenting with congenital poikiloderma of the face and extremities, diffuse alopecia, anhidrosis, lymphedema of the extremities and progressive muscle weakness (Am J Hum Genet. 93(6):1100-7, 2013). This individual consented to photography under our IRB-approved protocol AAAK2000.

2417T

Diagnostic difficulties in a newborn with rhizomelic dwarfism, multiple intrauterine fractures and dysmorphic features due to mucolipidosis type II (MLD II) due to compound heterozygote *GNPTAB* mutations and an unreported heterozygote change in the *SERPINF1* gene. *Y. Lacassie[1], K. Wood[2], R. M. Zambrano[1], B. J. Cheek[3], C. Arcement[4], M. Haymon[4], J. Steinkampf[1], S. Sampath[5], J. C. Hyland[6].* 1) Department of Pediatrics, LSUHSC and Children's Hospital, New Orleans, LA; 2) Department of Genetics, LSUHSC New Orleans, LA; 3) Department of Pathology, LSUHSC New Orleans, LA; 4) Department of Radiology, Children's Hospital New Orleans, LA; 5) Prevention Genetics, Marshfield, WI; 6) Connective Tissue Gene Tests, Allentown, PA.

We report a NB with a history of polyhydramnios, severe IUGR and rhizomelic dwarfism with bowed femurs and poorly calcified fibulas. Rhizomelic Chondrodysplasia Punctata Type I was suspected by MFM; however aCGH and mutation analysis for *PEX7* were normal. Hypotonia, weak cry, hypertelorism, rotated ears and rhizomelic limbs with camptodactyly were noticed at birth. Babygram showed possible fractures raising diagnosis of OI. Genetics ruled out any of the classical types of OI, but the possibility of OI type VII was mentioned. Family evaluation revealed that the 37yo AA father is tall, macrocephalic, has telecanthus and thumb subluxation. The mother is a non-consanguineous, G5P4L3, 31yo AA with a history of ovarian cysts, hypertelorism and long fingers with extra ffc. The proband was born via vaginal induction at 366/7 WGA. BW and BL at 3rd centile, HC at 10th centile. Telecanthus, anteverted nostrils, short columella, micrognathia, long fingers and toes with clinodactyly, camptodactyly and overriding fingers, extra crease R2-3F, prominent left interdigital areas and vertical main line A at left were observed. NGS panel for AR OI was requested. However, scannogram showed marked coarsening of trabecula with periosteal cloaking, metaphyseal cupping, flaring and irregularity with bending metaphyseal fractures, diaphyseal expansion in the bones of the hand with proximal and distal constriction, calcific stippling of both calcaneus and other skeletal abnormalities suggestive of dysostosis multiplex, specifically MLD type II (I-Cell Disease). Blood smear and MLD II/III plasma screen were consistent. *GNPTAB* gene sequencing showed compound heterozygosity for a pathogenic sequence variant (c. 1399delG; p. Asp467Ilefs*33) reported in MLD II, and also for an unreported but expected pathogenic sequence variant (c. 1905_1908delAAGG; p. Glu637Aspfs*4.). Both variants are predicted to result in a frameshift and premature termination of the protein N-acetylglucosamine-1-phosphotransferase subunits alpha/beta. MLD II is a rare AR disorder with a phenotype resembling Hurler syndrome and usually appearing after 6-12 months of age. Interestingly, the NGS panel for recessive OI revealed an extremely rare heterozygote variant (c. 1004A>G transition) in exon 8 of the *SERPINF1* gene. Parents are planning to be tested to determine the role of these variants. Complex interactions between different genes might explain the unusual and severe phenotype observed in this newborn.

2418F

Clinical heterogeneity of genetically confirmed six patients with Vici syndrome. *I. Hori[1], F. Miya[2], M. Nakashima[3], Y. Negishi[1], H. Shiraishi[4], Y. Nonoda[5], J. Tohyama[6], N. Okamoto[7], A. Hattori[1], N. Ando[1], M. Kato[8], T. Tsunoda[2], I. Nishino[9], H. Saitsu[3], Y. Kanemura[10], N. Matsumoto[3], K. Kosaki[11], S. Saitoh[1].* 1) Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2) Center for Integrative Medical Sciences, RIKEN, Yokohama, Japan; 3) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 4) Department of Pediatrics, Hokkaido University Graduate School of Medicine, Sapporo, Japan; 5) Department of Pediatrics, Kitasato University School of Medicine, Sagamihara, Japan; 6) Department of Pediatrics, Epilepsy Center, Nishi-Niigata Chuo National Hospital, Niigata Japan; 7) Department of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan; 8) Department of Pediatrics Showa University School of Medicine, Tokyo, Japan; 9) Department of Neuromuscular Research, National Institute of Neuroscience, National Center of Neurology and Psychiatry, Tokyo, Japan; 10) Division of Regenerative Medicine, Institute for Clinical Research, Osaka National Hospital, National Hospital Organization, Osaka, Japan; 11) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan.

Vici syndrome (OMIM #242840) is a rare autosomal recessively inherited multisystem disorder characterized by agenesis of the corpus callosum, cataracts, cardiomyopathy, combined immunodeficiency, psychomotor delay, and hypopigmentation. Mutations in the gene *EPG5* gene in chromosome 18q12. 3 were recently shown to be causative for Vici syndrome. *EPG5* is the human homolog of the metazoan-specific autophagy gene epg-5, encoding a key autophagy regulator (ectopic P-granules autophagy protein 5) implicated in the formation of autolysosomes. To better delineate the clinicopathological features of Vici syndrome, we studied 6 patients from 4 families with genetically confirmed Vici syndrome. Three patients were male. All parents were non-consanguineous. Muscle biopsy was performed in 4 patients. We performed whole exome sequencing to four probands from respective families, and identified mutations were validated in all six patients as well as their parents by Sanger sequencing. Compound heterozygous truncating mutations were confirmed in all six patients, and parents were revealed to be carriers. Common features of six patients included developmental delay, hypotonia, seizures, recurrent infection, agenesis of the corpus callosum, and elevated liver enzyme. No patients had cataracts. Only two patients had cardiomyopathy based on the specific findings on cardiac ultrasonography. Although all patients had the suspicion of an associated immunodeficiency based on clinical findings of an increased number of infection, there were few immunological abnormalities, which are consistent with previous reports. Additional central nervous system abnormalities included polymicrogyria, cortical developmental malformation, paucity of white matter, irregularity of ventricular wall, ventricular dilation, and delayed myelination. Pathologic findings in muscle revealed no specific features. It is likely that the incidence of cataracts and cardiomyopathy would be low in early course of Vici syndrome. When patients have agenesis of the corpus callosum and severe developmental delay of unknown etiology, we need to consider the possibility of Vici syndrome and the molecular test should be applied even full-blown clinical features are not present.

2419W

Juvenile Xanthogranuloma in Noonan Syndrome. *M. M. Ali[1], A. E. Gilliam[2], A. C. Gilliam[3], K. A. Rauen[4].* 1) Pediatrics, UCSF, San Francisco, CA; 2) Dermatology, UCSF, San Francisco, CA; 3) Dermatology, Stanford University, Palo Alto, CA; 4) Pediatrics, UC Davis, Sacramento, CA.

Noonan syndrome (NS) is an autosomal dominant RASopathy that affects approximately 1 in 1,000-2,000 individuals. NS exhibits a widely variable clinical phenotype, however, it is characterized by distinctive craniofacial features, congenital cardiac defects, reduced growth, bleeding disorders and a variable degree of neurocognitive delay. One other phenotypic feature which assists in the clinical diagnosis of NS is its cutaneous manifestations whereby individuals may have scattered café au lait macules, junctional nevi, lentigines and keratosis pilaris. We describe a 10 month old female with the clinical diagnosis of NS who was confirmed molecularly by the identification of a heterozygous SHP2 p. Y62D missense mutation [*PTPN11* gene]. Physical exam was consistent with features of NS, but dermatologic evaluation revealed yellowish-red nodules consistent with juvenile xanthogranuloma (JXG). Biopsy with histopathologic evaluation confirmed the diagnosis of JXG. A RASopathy that is known to be associated with JXG is Neurofibromatosis Type 1 (NF1). NF1 individuals who are diagnosed with JXGs are thought to have an elevated risk of juvenile myelomonocytic leukemia (JMML). JMML is a myelodysplastic and myeloproliferative disorder that accounts for 1–2% of childhood leukemias in the United States. A JMML-like phenotype with spontaneous regression in infants with NS has been previously reported, with an estimate of the incidence being approximately 10% in patients with NS. The association of JXG, JMML and NF1 has been described before, however, this association is still controversial. Children with both NF1 and JXG have been estimated to have a 20–32 times higher risk of developing JMML than do those with NF1 alone. In understanding the common underlying pathogenetic dysregulation of the Ras/MAPK pathway in both NS and NF1, there may be a possible similar relationship between patients with NS and JXG. To our knowledge, this report represents the first case describing a NS individual with JXG, highlighting the importance of carefully examining all RASopathy individuals for these skin lesions.

2420T

GNE Myopathy in the Non-Jewish Population, a Genotype-Phenotype Correlation Study. *A. Haghighi[1], S. Nafissi[2], A. Qurashi[3], Z. Tan[3], H. Shamshiri[2], Y. Nilipour[4], A. Haghighi[5], R. J. Desnick[3], R. Kornreich[3].* 1) Harvard Medical School, Boston, MA; 2) Department of Neurology, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran; 3) 4 Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, New York, USA; 4) Department of Pathology, Pediatric Pathology Research Center, Mofid Children Hospital, Shahid Beheshti Medical University, Tehran, Iran; 5) Toronto General Hospital, University of Toronto, Toronto, Canada.

GNE myopathy, also known as hereditary inclusion body myopathy, is characterized by progressive muscle atrophy and weakness, initially involving the distal muscles. The disease usually spares the quadriceps muscles. This autosomal recessive disease is caused by mutations in *GNE* gene. In this study, 18 non-Jewish patients from 11 Iranian families were comprehensively investigated. Genetic analysis identified three homozygous *GNE* mutations: c. 2228T>C (p. M743T) in 7, c. 830G>A (p. R277Q) in 2, and one novel variation (c. 804G>A) in 2 families. The latter is a novel mutation that results in a synonymous codon change (p. L268=) and is predicted to cause abnormal splicing. The youngest patient was an 18-year-old girl (with c. 830G>A, p. R277Q), whereas the oldest onset age (31 years) was seen in a male patient with c. 804G>A (p. L268=). Three of our p. M743T patients who were more than 6 years after the onset used wheelchairs, but none of them was wheelchair bound, even 17 years after the GNE myopathy onset. Our results confirmed that, however, p. M743T, in the kinase domain, is the most common disease causing variant in non-Jewish Iranian patients, other mutations, epimerase domain, can also cause the disease in this population. This study expands the knowledge on the phenotype and molecular genetic heterogeneity of the GNE myopathy.

2421F

A novel IRF6 mutation in female affected members of an Asian family with Van der Woude syndrome. *E. C. Tan[1], E. C. P. Lim[1], H. W. Lim[1], S. T. Lee[2].* 1) Research Laboratory, KK Women's & Children's Hospital, Singapore; 2) 3Department of Plastic, Reconstructive & Aesthetic Surgery, Singapore General Hospital, Singapore.

We describe a previously unreported IRF6 variant found in a pedigree that has five members with Van der Woude syndrome, the most common among syndromes which include cleft lip and/or cleft palate as one of the presentations. Mutations in the interferon regulatory factor 6 (IRF6) gene which encodes a transcription factor with a DNA-binding domain and a protein-binding domain have been identified in many VWS patients. The gene is thought to play a key role in regulating proliferation and differentiation during epidermal development. The proband is an 19-year old girl with bilateral cleft lip and palate and lip pits. She is the eldest child of non-consanguineous parents. Her mother is of Malay ancestry while her father was from Bangladesh in the Indian subcontinent. Her mother also presents with bilateral cleft lip and palate and lip pits. She has 2 affected sisters and an unaffected brother. The only other affected family member is a maternal aunt. None of the male members of the pedigree has the VWS phenotype. Peripheral blood was obtained from the proband, the parents and one of the affected sisters. Sequence analysis targeting coding exons of IRF6 uncovered a single nucleotide variant in Exon 3, which changes the amino acid encoded from an isoleucine to a threonine. This variant has not been reported and is not in any database. As the missense substitution occurs in the DNA-binding domain, it is likely to affect its binding with its target DNA site. Targeted testing performed on the family samples revealed the presence of the same variant in her affected mother and her affected sister but not in her unaffected father. Testing on saliva DNA of her other affected sister and her unaffected brother showed complete co-segregation of the mutation with the VWS phenotype. The evidence is strong that the identified mutation is causative of the phenotype in this pedigree given the variant's segregation with the VWS phenotype, and the substitution of a hydrophobic by a polar residue in the DNA-binding domain. One interesting feature is that none of the male members of the pedigree has the VWS phenotype.

2422W

Sengers syndrome: clinical investogation and identifying novel *AGK* mutations. *H. Haghighi-Kakhki[1], A. Haghighi[2], T. B. Haack[3], M. Atiq[4], H. Mottaghi[5], R. A. Bashir[6], U. Ahting[3], R. Taylor[14], H. Prokisch[3].* 1) School of Medicine, Mashhad Azad Unievrsity, Mashhad, Iran; 2) Department of Genetics, Harvard Medical School, Boston, MA, USA; 3) Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, München, Germany; 4) Department of Pediatrics, Aga Khan University, Karachi, Pakistan; 5) Department of Pediatrics, Imam Reza Hospital, Mashhad University of Medical Sciences, Mashhad, Iran; 6) Department of Paediatrics and Neonatology, Ahmadi Hospital, Kuwait Oil Company, Al Ahmadi, Kuwait; 7) Department of Paediatrics, Paracelsus Medical University, Salzburg, Austria; 8) Inserm UMR 1163, Imagine Institute, Paris Descartes University, Paris France; 9) Department of Neurology, Friedrich-Baur-Institute, Ludwig-Maximilians-Universitét München, Munich, Germany; 10) Department of Pediatric Cardiology, University Hospital, Aachen University of Technology, Aachen, Germany; 11) Pediatric Department, Hospital Dr. Gustavo Fricke, Viña del Mar, Chile; 12) Deptartment of Genetics, Medical School, Kerman University of Medical Sciences, Kerman, Iran; 13) Wellcome Trust Centre for Mitochondrial Research, Institute of Genetic Medicine, Newcastle University, Newcastle upon Tyne, UK; 14) Wellcome Trust Centre for Mitochondrial Research, Institute of Ageing and Health, Newcastle University, Newcastle upon Tyne, UK.

Sengers syndrome is a rare autosomal recessive disease. The patients have characterized congenital cataract, cardiomyopathy, skeletal myopathy and lactic acidosis. Mutations in the acylglycerol kinase (*AGK*) gene can cause Sengers syndrome. We studied the clinical features of the disease and genetic variants of *AGK* in seven new families with Sengers syndrome from around the world. Congenital cataract and cardiomyopathy were found d in all patients. Lactic acidosis and tachydyspnoea were the other common findings in the patients. Mutational analysis identified disease-causing *AGK* mutations in all patients, including six novel variants: homozygous c. 523_524delAT (p. Ile175Tyrfs*2), c. 424-1G>A (splice site), c. 409C>T (p. Arg137*) and c. 877+3G>T (splice site), and compound heterozygous c. 871C>T (p. Gln291*) and c. 1035dup (p. Ile346Tyrfs*39). The findings of our study expand the knowledge on genotype-phenotype correlations in Sengers syndrome and will have important implications for genetic screening and diagnosis.

2423T

Primordial Dwarfism associated novel *POC1A* mutation reveals new insights for centriole biogenesis. *M. Ozen[1,2,3], A. Koparir[1], O. F. Karatas[4], A. Gezdirici[5], B. Yuceturk[6], B. Yuksel[7], A. O. Bayrak[6], O. F. Gerdan[6], M. S. Sagiroglu[6], K. Kirimtay[8], E. Selcuk[8], A. Karabay[8], C. J. Creighton[9], A. Yuksel[3].* 1) Department of Medical Genetics, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey; 2) Department of Pathology & Immunology, Baylor College of Medicine, Houston, TX, 77030, USA; 3) Biruni University, Department of Molecular Biology and Genetics, Topkapi, Istanbul, Turkey; 4) Molecular Biology and Genetics Department, Erzurum Technical University, Erzurum, Turkey; 5) Department of Medical Genetics, Kanuni Sultan Suleyman Training and Research Hospital, 34303, Istanbul, TURKEY; 6) Advanced Genomics and Bioinformatics Research Center (IGBAM), BÝLGEM, TUBITAK, Kocaeli, Turkey; 7) Genetic Engineering and Biotechnology Institute, TUBITAK Marmara Research Center, Kocaeli, Turkey; 8) Department of Molecular Biology and Genetics, Istanbul Technical University, Istanbul, Turkey; 9) Department of Medicine and Dan L Duncan Cancer Center, Division of Biostatistics Baylor College of Medicine, Houston, TX, 77030, USA.

POC1A encodes a WD repeat protein localizing to centrioles and spindle poles and is associated with short stature, onychodysplasia, facial dysmorphism and hypotrichosis (SOFT) syndrome. These main features are related with the defect in cell proliferation of chondrocytes in growth plate, which were observed in a mouse model in recent study. In the current study, we report two patients with primordial dwarfism (PD) in a single family. We utilized Whole Exome Sequencing (WES) in the patients. A novel homozygous p. T120A missense mutation was detected in *POC1A* in both patients, a known causative gene of SOFT syndrome, and confirmed using Sanger sequencing. To confirm the pathogenicity of the detected mutation, primary fibroblast cultures obtained from the patients and a control individual were used. To further evaluate the global gene expression profile of cells carrying p. T120A mutation in *POC1A*, we performed gene expression array analysis which showed that 4800 transcript probes were significantly deregulated in cells with p. T120A mutation in comparison to the control. GO term association results showed that deregulated genes are mostly involved in extracellular matrix and cytoskeleton. Furthermore, the p. T120A missense mutation in *POC1A* caused formation of abnormal mitotic spindle structure, including supernumerary centrosomes, and changes in POC1A was accompanied by alterations in another centrosome associated WD repeat protein p80-katanin. As mutations in p80-katanin gene have been previously reported, which also can cause mitotic spindle abnormalities similar to those we associate with POC1A p. T120A mutation, further studies into the functional relationships involving POC1A and p80-katanin are warranted.

2424F

Rare familial *TSC2* gene mutation associated with atypical phenotype of tuberous sclerosis complex. *S. Ben-Shachar[1, 2], J. Fox[2], S. Oliel[1,2], R. Svirski[1,2], H. Saitsu[3], N. Matsumoto[3], A. Fattal-Valevski[1,2].* 1) Tel-Aviv Medical Center, Tel-Aviv, Israel; 2) Sackler Faculty of Medicine, Tel-Aviv University, Tel Aviv Israel; 3) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Tuberous sclerosis complex (TSC) is a neurocutaneous disorder that results from mutations of either the *TSC1* gene or the *TSC2* gene. Diagnosis is based on well-established clinical criteria or molecular analysis. We describe an 18-month-old boy with seizures and a single hypopigmented macule which did not meet consensus criteria for the diagnosis of TSC. Whole exome sequencing revealed a heterozygous *TSC2* mutation (c. 5138G>A (p. Arg1713His)) in the patient, his mother as well as several other family members on the maternal side. The mother and other family members with the mutation were asymptomatic except for the presence of hypomelanotic macules. The phenotypic characteristics of the individuals in this family were not indicative of a *TSC2* mutation since none satisfied the criteria for even suggesting a diagnosis of possible TSC. This case provides evidence of a unique *TSC2* mutation that resulted in an atypical clinical presentation and indicates potential shortcomings of the current diagnostic criteria for TSC. These findings may have implications for genetic counseling and screening.

2425W

X-Linked Congenital Disorder of Glycosylation in a female infant due to *SLC35A2* gene mutation - Expanding the clinical phenotype. *A. Pandya[1], B. Lincoln-Boyea[1], R. S. Greenwood[2].* 1) Pediatric Genetics and Metabolism, University of North Carolina, Chapel Hill, CHAPEL HILL, NC; 2) Child Neurology, Department of Neurology, UNC, Chapel Hill,.

Congenital Disorders of Glycosylation (CDG) are a heterogeneous group of neurometabolic diseases, caused mainly due to defects in N-linked glycosylation. Although the majority of these are inherited as autosomal recessive disorders, several X-linked forms of CDG have been identified recently. Since 2013, mutations in three genes, *ALG13, SLC35A2* and *SSR4* have been reported to cause X- Linked form of CDG. The *SLC35A2* gene encodes the only known Golgi localized UDP-galactose transporter, mutations in which decrease the UDP-galactose transport, causing galactose deficient glycoproteins. Interestingly, of the six patients identified with mutations in *SLC35A2,* four were female patients, and two males, the latter demonstrating somatic mosaicism. We report a female infant who presented with hypotonia, motor delay and distinct facial features. The MRI was notable for diffuse atrophy and decreased white matter. At age nine months she had an abnormal transferrin isoelectric study highly suggestive of CDG, based on unusual transferrin glycated variants, reflecting a loss of sialic and galactose moieties. Testing of *SLC35A2* gene was positive for a heterozygous c. 991 G > A (V331I) variant in exon 4, determined to be pathogenic. The child has distinct facial features, no seizures and unique skin pigmentary changes following the lines of Blaschko. This is the first report of pigmentary changes noted in a patient with *SLC35A4* mutation, which can be used as an indicator for the presence of genetic mosaicism. This observation provides an opportunity to expand the clinical phenotype of this recently identified X- linked form of CDG.

2426T

Evaluation of Growth Parameters in the LCRC Dataset Demonstrates Differences Based on Osteogenesis Imperfecta Subtype for All Age Groups. *A. Tam[1], M. Jain[1], D. Cuthbertson[2], J. R. Shapiro[3], R. D. Steiner[4, 5], P. A. Smith[6], M. B. Bober[7], T. Hart[8], J. Krischer[2], P. H. Byers[9], M. Pepin[9], M. Durigova[10], F. H. Glorieux[10], F. Rauch[10], B. Lee[1], V. R. Sutton[1], S. C. S. Nagamani[1].* 1) Baylor College of Medicine, Houston, TX, USA; 2) University of South Florida, Tampa, FL, USA; 3) Kennedy Krieger Institute, Baltimore, MD, USA; 4) Oregon Health & Science University, Portland, OR, USA; 5) University of Wisconsin, Marshfield, WI, USA; 6) Shriners Hospitals for Children, Chicago, IL, USA; 7) Alfred I. DuPont Hospital for Children, Wilmington, DE, USA; 8) OI foundation, Gaithersburg, MD, USA; 9) University of Washington, Seattle, WA, USA; 10) Shriners Hospital for Children and McGill University, Montreal, QC, Canada.

Osteogenesis imperfecta (OI) predisposes to recurrent fractures and bone deformities, factors that affect bone growth. There is a lack of large-scale studies that investigate growth parameters, including height and weight in patients with OI. The Linked Clinical Research Centers (LCRC) is a network of five centers established to foster clinical research and advance the care of patients with OI across North America. Using data from the LCRC, we analyzed height, weight, and arm-span to height ratio in 552 individuals with OI (type I n=244; Type III OI n=110; type IV OI n=150). Chi square analysis was used to analyze for differences in proportion of individuals below the third percentile of CDC growth curves and unpaired t-test was used to compare growth parameters as continuous variables. As expected, subjects with type III OI had an increased probability of being below the third percentile for height and weight as compared to those with type I, and IV OI ($p<0.0001$). Whereas the arm-span to height ratio was not different between the various subtypes prior to age 10, increased ratio was observed in subjects with OI type III compared to OI type I older than 10 years ($p<0.05$). The final adult height, as expected was in the order OI type I >OI type IV> OI type III. As many factors contribute to adult height including familial stature, we further examined individuals without a parental history of OI by calculating mid-parental height, and compared this to the actual adult height. Our results suggest that final adult height is affected across OI subtypes, with 48% of individuals with type I OI, 58% of type IV OI and 100% of type III OI being below the predicted third percentile for mid-parental height (OI type III vs type I, $p<0.0005$; OI type IV vs type I, $p<0.01$). Our data support expected growth patterns for OI subtypes and will be utilized to examine growth over time in a longitudinal fashion, with the hopes of defining age-expected distributions for height and weight for OI subtypes. Characterization of growth patterns in OI subtypes will help clinicians determine whether patients with OI are following expected growth based on their OI subtype.

2427F

Behavioral Phenotype of Muenke Syndrome (FGFR3-Related Craniosynostosis). *Y. Addissie, C. Yarnell, P. Kruszka, M. Guillen, R. Hart, N. Agochukwu, E. Wiggs, D. Hadley, M. Muenke.* Medical Genetics Branch, National Human Genome Research Institute, Bethesda, MD.

Background: Muenke syndrome is the most common craniosynostosis syndrome defined by the presence of the p. Pro250Arg mutation in the *FGFR3* gene and is clinically characterized by craniosynostosis, hearing loss, developmental delay, and carpal and tarsal fusions. Previous research suggests that children with craniosynostosis syndromes have an increased risk of developing behavioral problems, yet there has been no research to date focusing solely on individuals with Muenke syndrome. This study investigates executive function and adaptive behavior in persons with Muenke syndrome using validated instruments with a normative population and unaffected siblings as controls. **Study Design:** Participants in a cross sectional study included individuals with Muenke syndrome (P250R mutation in *FGFR3*) and their mutation negative siblings. Participants completed validated assessments of executive functioning (Behavior Rating Inventory of Executive Function; BRIEF) and adaptive behavior skills (Adaptive Behavior Assessment System; ABAS-II). **Results:** Forty-four *FGFR3* mutation positive individuals, median age 9 years, range 7 months to 52 years were enrolled. Additionally, 10 unaffected siblings were used as controls (5 males, 5 females, median age of 13 years, range 3 to 18 years). For the General Executive Composite scale of the BRIEF, 32. 1% of the cohort had scores greater than +1. 5 SD, signifying "Potential Clinical Significance. " For the General Adaptive Composite of the ABAS-II, 28. 2% of affected individuals scored in the 3rd -8th percentile of the normative population and 56. 4% were below the "Average" category (less than the 25th percentile). Multiple regression analysis showed that craniosynostosis was not a predictor of BRIEF (P = 0. 7) and ABAS-II scores (P = 0. 7). Other factors includingsurgery for craniosynostosis, hearing loss, and history of seizureswere also not predictive. In the sibling pair analysis, affected siblings performed significantly poorer in the BRIEF General Executive Composited and the ABAS-II General Adaptive Composite. **Conclusion:** Individuals with Muenke syndrome are at an increased risk for developing adaptive and executive function behavioral changes when compared to a normative population and unaffected siblings, regardless of whether craniosynostosis is present.

2428W

Böök syndrome (Premolar aplasia, Hyperhidrosis, and Canities prematura) is an Autosomal Dominant Ectodermal Dysplasia with Variable Expression. *M. Hajianpour, C. Evers, p. Trapane.* Pediatrics/ Medical Genetics, University of Iowa, Iowa City, IA.

Proband is a Three-year-old female with a history of **slow hair growth**, and severe **dental caries**. She has excessive sweating (**hyperhidrosis**). Her height and weight are just above97th percentile, and herhead size isat 70thpercentile for age (parents and sibling have large built). Her development is normal. **Proband's mother**has a history of **slow hair growth**with **premature hair graying** at age 15 years and **hyperhidrosis**. Maternal grandfather and his mother, and maternaluncle alsohad premature hair graying. Maternal grandfather and his motherhaddental caries. A maternal first cousin,and several of mother's second cousins have **missing teeth** (more than six). It is not clear which teeth are missing. Böök (1950) reported 25 persons in 4 generations of a Swedish family with **P**remolar aplasia, **H**yperhidrosis, and **C**anities prematura (premature graying of hair), anddesignated the disorder**"PHC"** syndrome. Inheritance of the disorder in this family was clearly **autosomal dominant** with high penetrance. Salinas et al. (1992) described "**a new ectodermal dysplasia syndrome**" in an 18-year-old Caucasian woman with congenitally missing premolars, narrow palate, severe functional hyperhidrosis of the hands and feet, small hands,hypoplastic nails, disorganized eyebrows, unilateral simian creases,and poorly formed dermatoglyphicsincludingdistal digital creases. The authors suggested that this may be a new case of **Böök** syndrome. However, the patient **lacked premature graying of hair. Ectodermal Dysplasia,**is a group of disorders characterized by abnormal development in two or more ectodermal structures(hair, teeth, nails and sweatglands),with or withoutother systemic findings. Therefore,based on this definition,**Böök syndrome,**is an **ectodermal dysplasia** by involving teeth, hair and sweat glands. Our patient shows severe dental caries, hyperhidrosis, no dental aplasia at age three years, and no canities prematura, which is often seen in teenage period. However, her mother had premature graying of hair and hyperhidrosis, and some other relatives had dental aplasia and canities prematura in three generations, presenting an **autosomal dominant** mode of inheritance with **variable expressivity**. We agree with Salinas et al. (1992) who suggested that "the lack of other reports of Böök syndrome may result from the clinical features being of relatively little consequence to most affected individuals or from symptoms being treated as separate entities by different specialists. ".

2429T

Clinical and molecular spectrum of Noonan syndrome and other RASopathies. *J. Kim[1], G-H. Kim[1], B. Lee[1,2], J-H. Choi[1,2], H-W. Yoo[1,2].* 1) Medical Genetics Center, Asan Medical Center, Seoul, South Korea; 2) Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, South Korea.

Background: Noonan syndrome (NS) and NS-related disorders (cardiofaciocutaneous [CFC], Costello, Legius syndromes, and Noonan syndrome with multiple lentigines [NSML]) share common clinical features characterized by unique facial features, postnatal growth failure, psychomotor retardation, ectodermal abnormalities, congenital heart diseases, chest and skeletal deformities, and delayed puberty. To date, this group of disorders has been known to be caused by germ-line mutations of at least 13 genes of the Ras-mitogen-activated protein kinase pathway (*PTPN11, SOS1, RAF1, SHOC2, BRAF, KRAS, NRAS, CBL, HRAS, MEK1, MEK2, SPRED1*, and *RIT1*), mostly with gain of function. **Purpose:** This study was performed to investigate mutation spectrum and phenotype of Noonan syndrome and its related disorders. **Methods:** Clinical characteristics and genotypes of 10 previously known (*PTPN11, SOS1, RAF1, SHOC2, BRAF, KRAS, NRAS, HRAS, MEK1, MEK2*) and two candidate genes, *SPRY1-4* and *SPRED1*, were investigated in 175 patients with NS, 25 with CFC syndrome, 12 with Costello syndrome (CS), and 7 with NSML. **Results:** *PTPN11* (41. 1%), *SOS1* (13. 1%), *RAF1* (6. 3%), *BRAF* (3. 4%),*KRAS* (2. 9%), *SHOC2* (1. 1%), and *MEK1* (0. 6%) mutations were identified in NS; *BRAF* (48%), *SHOC2* (24%), and *MEK1* (8%) mutations in CFC; and *HRAS* and *PTPN11* mutations in CS and NSML, respectively. Normal stature was frequently observed in individuals with *SOS1* mutations, hypertrophic cardiomyopathy in *RAF1*and *HRAS*, pulmonic stenosis in *SOS1* and developmental delay in *RAF1*, *BRAF* or *SHOC2* mutations. Cardiac hypertrophy should be carefully evaluated in patients with *RAF1* and *HRAS* mutations. Tumor surveillance is recommended for subjects with *HRAS* mutations. Mutation was not identified in 29. 7% of NS and 20% of CFC syndrome. Whole exome sequencing analysis and array comparative genomic hybridization were selectively performed in patients without mutations by Sanger sequencing of the candidate genes. Novel sequence variants were found in *RUVBL2* and *MYH11*, and haploinsufficiency of *ARID2* was identified. **Conclusions:** This study described the mutation spectrum and identified new candidate genes for RASopathies. Functional studies are needed to verify the impact of sequence variants of novel genes on patients' phenotypes. Molecular genetic testing have a role in the process of differential diagnosis of NS and NS-related disorders because of the constellation of overlapping clinical features of RASopathies.

2430F

Congenital nephrosis, cerebral ventriculomegaly and heterotopias – expanding the phenotype associated with *CRB2* mutations. *A. Slavotinek[1], K. Gray[2], L. Rodan[2], B. P. Chaudhari[3], A. Rajkovic[3], D. Steele[3], R. Vanderwall[3], K. Owens[4], M. Hannibal[4], W-H. Tan[2].* 1) University of California, San Francisco, San Francisco, CA; 2) Boston Children's Hospital, Boston, MA; 3) Center for Medical Genetics and Genomics, Magee-Womens Hospital of University of Pittsburgh Medical Center, Pittsburgh PA; 4) Pediatrics and Communicable Diseases, University of Michigan Medical School, Ann Arbor, MI.

We recently reported five fetuses and a child with a novel phenotype comprising cerebral ventriculomegaly, echogenic kidneys and greatly elevated maternal serum alpha-fetoprotein (MSAFP) and amniotic fluid alpha-fetoprotein (AFAFP; CRB2 syndrome). Renal findings included tubular cysts at the corticomedullary junction, diffuse effacement of the epithelial foot processes and microvillous transformation of the renal podocytes similar to congenital nephrotic syndrome, Finnish type. All cases had deleterious mutations in *CRB2*. Studies in *Danio rerio* have shown that reduced *crb2b* function results in loss of the slit diaphragms of the podocytes. We now provide a further 12 cases with similar findings and an additional child with a single *CRB2* mutation. A 5-day old female had nephrotic syndrome with renal microcysts, massive hydrocephalus, a large atrial septal defect, probable Scimitar syndrome and a Muellerian duct anomaly. A fetus with ventriculomegaly had elevated MSAFP and AFAFP. Testing for *CRB2* mutations in these two cases is pending. Clinical exome sequencing in a 2-year old male with hypotonia, developmental delays, an absent left kidney and a smaller right kidney had a single *CRB2* mutation, p. Arg633Trp that was paternally inherited; coverage of the coding region was high and array showed no deletions in the *CRB2* gene region. We found 10 reported cases consistent with CRB2 syndrome (Reuss et al. , 1989; Jolly et al. , 2003), with additional findings of pericardial effusion (2/10), postaxial polydactyly (1/10), choroid plexus hyperplasia (1/10), duplication of the right kidney/ureter (1/10) and absent lung fissure with incomplete intestinal rotation (1/10). Gray matter heterotopias were prominent in one of the first reported children with *CRB2* mutations. This feature overlaps with Galloway-Mowat syndrome (GMS), characterized by microcephaly, hiatal hernia and nephrotic syndrome, in which heterotopias were described. We found one reported child with periventricular nodular heterotopias, a raised AFAFP and renal echogenicity that was reported as GMS, but probably had CRB2 syndrome (Palm et al. , 1986). We conclude that the phenotype associated with CRB2 mutations overlaps with other conditions with early-onset nephrosis and cerebral malformations, such as GMS. The high AFP measurements and the renal histology may help clinical distinction. Jolly et al. Prenat Diag 2003;23:48; Palm et al. Arch Dis Child 1986;61:545; Reuss et al. , Am J Med Genet 1989;33:385.

Pseudoarthrosis of the tibia and retroperitoneal neurofibroma in NF1: case report and 4-year follow-up. *M. Aceves-Aceves[1], I. M. Salazar-Dávalos[1], S. A. Alonso-Barragán[2], A. Marín-Medina[2], D. García-Cruz[1,2], N. O. Dávalos[1,2], G. Chiapa[3], M. Puebla-Mora[4], M. Salazar-Páramo[5], I. P. Dávalos[1,2].* 1) Instituto de Genética Humana, DGH, CUCS, Universidad de Guadalajara, Guadalajara, México; 2) Doctorado Genética Humana (DGH), CUCS, Universidad de Guadalajara, CIBO, IMSS, Guadalajara, México; 3) Servicio de Ortopedia y Traumatología, UMAE, HP, CMNO, IMSS, Guadalajara, México; 4) Servicio de Anatomía Patológica, UMAE, HP, CMNO, IMSS, Guadalajara, México; 5) Depto. de Fisiología, CUCS, Universidad de Guadalajara, Div. Investigación, UMAE, HE, CMNO, IMSS, Guadalajara, México.

Introduction: Neurofibromatosis type 1 (NF1), MIM #162200, is an autosomal dominant disorder with an incidence of 1 in 3000 live births. NF1 is caused by mutation in the *NF1* gene on chromosome 17q11. 2, characterised by café-au-lait spots, Lisch nodules, fibromatous tumors of the skin and benign and malignant tumors. Pseudoarthrosis of the tibia (PT) is associated with NF1, 55% of the patients with PT presented NF1 and 6% of NF1 patients develop tibial dysplasia. The affected bone shows insufficient mechanical strength, excessive bone resorption, impaired vascularization and decreasing osteogenic capability. **Objective:**To present a case with NF1 with congenital pseudoarthrosis of the tibia and retroperitoneal neurofibroma. **Case Report:** The *propositus* a boy aged 9 year-old, father (52 years) and sister (17 years) had NF1 with no pseudoarthrosis. Mother (42 years) and a healthy sister (16 years). At physical examination: weight 24. 4 kg (pc 10), height 130 cm (pc 10), head circumference 54 cm (pc 10), thorax with café-au-lait spots (>30), axillary freckling, post surgical scars on right costal region (plexiform neurofibroma), retroperitoneal intraneural neurofibroma and tibial pseudoarthrosis. At 3 months he presented anterolateral deformity of the left tibia, at 4 year-old was resected a plexiform neurofibroma on right costal region, next year presented a fracture of the left tibia secondary to trauma and was surgically treated with transcalcaneal intramedullary nail fixation, with inadequate fracture consolidation. Two years later intramedullary nail was replaced and bone graft was added. At 8 year-old abdominal ultrasonography revealed retroperitoneal mass, confirmed by CT as a solid lobulated mass, from upper border of the pancreas extending to retroperitoneum, histopathological study reported intraneural neurofibroma. At 9 year-old remains refractory to surgical treatment. **Conclusions:** We present a patient with NF1 diagnosis (NIH Consensus Development Conference criteria); he presented pseudoarthrosis of left tibia and retroperitoneal intraneural neurofibroma. PT is an incapacitating condition with lack of normal bone formation. Pseudoarthrosis treatment is complex. NF1 disorder requires a periodical clinical evaluation, imaging studies and multidisciplinary approach to allow an opportune detection and treatment of complications.

2432T

A family with Novel *MED12* Mutation Substantiates the Existence of a Fourth Recognizable Clinical Phenotype. *V. Ottaviani[1], D. Rogaia[2], I. Isidori[2], A. Mencarelli[2], G. Merla[1], P. Prontera[2].* 1) Medical GenMedical Genetics Unit, IRCCS Casa Sollievo della Sofferenza Hospital, San Giovanni Rotondo, Foggia, Italy; 2) Medical Genetics Unit, University and Hospital of Perugia, Perugia, Italy.

Different missense mutations in the *MED12* gene have been described in patients with Optiz-Kaveggia Syndrome, Lujan-Fryns Syndrome, or X-linked Ohdo Syndrome. Recently, a different phenotype, characterized by dysmorphisms of the face, severe intellectual disability (ID), absent language and friendly personality, was reported in a family carrying a frameshift *MED12* mutation (c. 5898dupC). This phenotype is clinically distinguishable from the other *MED12*-related disorder, supporting the presence of a fourth clinically recognizable *MED12* syndrome. Here we report a family, including two males and one females, affected with moderate to profound ID, in which targeted next-generation sequencing disclosed a novel c. 2312T>C (p. Ile77Ther) *MED12* mutation. This highly conserved variant segregates with the disease and is predicted to be deleterious by different mutation prediction tools; moreover it was not found in healthy first-degree male relative as well as in the SNP-database. The phenotype of male patients clearly overlap to those described in the patients carrying the frameshift mutations thus indicating the existence of a fourth, clinically recognizable *MED12*- related disorder.

2433F

Intragenic *CFTR* micro-duplication and 5T/12TG track in a patient with non-classical cystic fibrosis. *P. B. S. Celestino-Soper[1], E. Simpson[1], S. Dlouhy[1], M. Vatta[1, 2], J. Yeley[3], C. Brown[3], S. Bai[1].* 1) Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA; 2) Krannert Institute of Cardiology, Division of Cardiology, Department of Medicine, Indiana University School of Medicine, Indianapolis, IN, USA; 3) Division of Pulmonary, Allergy, Critical Care, Occupational, and Sleep Medicine, Indiana University, Indianapolis, IN, USA.

Cystic fibrosis (CF [MIM 219700]) is an autosomal recessive disorder characterized by the accumulation of sticky and heavy mucus that can damage several organs. The disorder shows variable expressivity in different affected individuals, but it typically causes respiratory and digestive system complications as well as reproductive system problems in males. Individuals with the classical form of CF usually have two classic mutations in the cystic fibrosis transmembrane conductance regulator gene (*CFTR* [MIM 602421)] such as c. 1521-1523-delCTT (p. F508del). Individuals with other variants, including a CF disease-causing mutation in *cis* with a short 5T nucleotide track and extended 12TG or 13TG di-nucleotide track in intron 8 of *CFTR* may present with classic, non-classic or milder forms of CF due to possible resulting lower levels of functional CFTR protein. In this case report, a female patient presents with chronic daily cough and sputum production, chronic sinusitis, mild reversible airflow obstruction, minimal bronchiectasis, and intermediate sweat chloride level (51mmol/L), but no pancreatic insufficiency. Clinically, the patient was classified to have features of asthma and mild or non-classic CF. We performed *CFTR* sequence analysis and deletion/duplication analysis by multiplex ligation-dependent probe amplification (MLPA). BigDye terminator *CFTR* sequence analysis demonstrated that she is a carrier for the 5T/12TG variant. Deletion/duplication analysis showed the presence of an intragenic duplication involving exons 7-11 of the *CFTR* gene. This large duplication is predicted to result in the production of a truncated CFTR protein lacking the terminal part of NBD1 domain and thus can be considered a null allele. Therefore, the combination of this large intragenic duplication and 5T/12TG probably causes the mild or non-classic CF features in this individual.

2434W

Mutation in *NRAS* in familial Noonan syndrome: A case report. *M. Wilbe[1], S. Ekvall[1], J. Dahlgren[2], E. Legius[3], A. van Haeringen[4], O. Westphal[2], G. Annerén[1], M. L. Bondeson[1].* 1) Immunology, Genetics and Pathology, Science for Life Laboratory, Uppsala, Sweden; 2) Department of Paediatrics, the Sahlgrenska Academy, Gothenburg University, Sweden; 3) Department of Human Genetics, KU Leuven, Leuven, Belgium; 4) Department of Clinical Genetics, Leiden University Medical Center, Leiden, the Netherlands.

Noonan syndrome (NS) is a heterogeneous developmental disorder associated with variable clinical expression including short stature, congenital heart defect, unusual pectus deformity and typical facial features. It is caused by activating mutations in genes involved in the RAS-MAPK signaling pathway. We present a clinical and molecular characterization of a small family with Noonan syndrome. Comprehensive mutation analysis of *NF1, PTPN11, SOS1, CBL, BRAF, RAF1, SHOC2, MAP2K2, MAP2K1, SPRED1, NRAS, HRAS* and *KRAS* was performed using targeted next-generation sequencing. The result revealed a recurrent mutation in *NRAS*, c. 179G>A (p. G60E), in the index patient. This mutation was inherited from the index patient's father, which also showed signs of NS. We describe clinical features in this family and review the literature for genotype-phenotype correlations for NS patients with mutations in *NRAS*. Neither of the affected individuals in this family presented with juvenile myelomonocytic leukemia (JMML), which together with previously published results suggest that the risk for NS individuals with a germline *NRAS* developing JMML is not different from the proportion seen in other NS cases. Interestingly, 50% of NS individuals with an *NRAS* mutation (including our family) present with lentigines and/or Café-au-lait spots. This demonstrates a predisposition to hyperpigmented lesions in *NRAS*-positive NS individuals. In addition, the affected father in our family presented with a hearing deficit since birth, which together with lentigines are two characteristics of NS with multiple lentigines (previously LEOPARD syndrome), supporting the difficulties in diagnosing individuals with RASopathies correctly. The clinical and genetic heterogeneity observed in RASopathies is a challenge for genetic testing. However, using the advent of next-generation sequencing, which allows screening of a large number of genes simultaneously, will have an important impact on the correct diagnosis as well as prognosis and treatment of these patients in the future.

2435T

Complex Inheritance of *ABCA4* Disease: Four Mutations in a Family with Multiple Macular Phenotypes. *W. Lee[1], Y. Xie[1], J. Zernant[1], B. Yuan[2], S. Bearelly[1], S. H. Tsang[1, 3], J. R. Lupski[2], R. Allikmets[1, 3].* 1) Department of Ophthalmology, Columbia University, New York, NY; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Department of Pathology and Cell Biology, Columbia University, New York, NY.

Over 800 mutations in the *ABCA4* gene cause autosomal recessive Stargardt disease. Due to extensive genetic heterogeneity, observed variant-associated phenotypes can manifest extensive variability of expression. In addition, high carrier frequency of pathogenic *ABCA4* alleles in the general population (~1:20) often results in a pseudo-dominant inheritance pattern. Here we describe a genotype/phenotype analysis of a two-generation family with multiple macular disease phenotypes segregating four *ABCA4* mutant alleles. Complete sequencing of the *ABCA4* gene discovered 2 known missense mutations, p. C54Y and p. G1961E. Array comparative genomic hybridization revealed a large novel deletion combined with a small insertion, c. 6148-698_c. 6670del/insTGTGCACCTCCCTAG, and complete sequencing of the entire *ABCA4* genomic locus uncovered a complex allele with two new deep intronic variants, c. 302+68C>T. Patients with the p. G1961E mutation had the mildest, confined maculopathy phenotype with peripheral flecks while those with all other combinations of mutant variant alleles exhibited a more advanced stage of generalized retinal and choriocapillaris atrophy. This family epitomizes the complexity of the analysis of *ABCA4*-associated diseases. It contained variants from all classes of mutations, in the coding region, deep intronic, both SNV and CNV, and suggested dominant inheritance. Unequivocally defining disease-associated alleles in the *ABCA4* locus requires extensive analyses by a combination of mutation detection approaches.

2436F

A BOY WITH GNAS MUTATION. *S. Tulgar Kinik[1], NM. Sahin[2], FB. Atac[3], H. Verdi[3], S. Thiele[4].* 1) Pediatric Endocrinology, Baskent University Faculty of Medicine, Ankara, Turkey; 2) Dr. Sami Ulus Obstetrics, Children Health and Diseases Training and Research Hospital, Ankara, Turkey; 3) Baskent University Faculty of Medicine, Department of Medical Biology, Ankara, Turkey; 4) Division of Experimental Paediatric Endocrinology and Diabetes, Department of Paediatrics, University of Lübeck Lübeck, Germany.

Pseudohypoparathyroidism (PHP) is a disorder of end-organ resistance primarily affecting the actions of parathyroid hormone (PTH). Parental imprinting and the type of the genetic alteration play a determinant role in the phenotype expression of GNAS locus associated with pseudohypoparathyroidism (PHP). GNAS locus gives rise to several different messenger RNA transcripts that are derived from the paternal allele, the maternal allele, or both and can be either coding or non-coding. As a consequence, GNAS mutations lead to a wide spectrum of phenotypes. Here we present a boy with GNAS mutation. Case:12. 2 years old boy admitted to our center with the history of congenital ptosis,osteoma cutis and primary hypothyroidism. His laboratory findings revealed mild hypocalcemia, hyperphospatemia, elevated PTH level with the normal vitamin D and magnesium level. He has Albrigth Hereditary Osteodistrophy (AHO) features, mild mental retardation with the normal height and appropriate pubertal stage (Tanner stage III). He was born term and low birth weight. The parents werenon-consanguineous. His mother, fatherand sister laboratory findings were normal and they have not AHO features. In the mother osteoma cutis was detected. The Gsα enzyme activity was low in proband (%53,8/55); while %85,7/82,1 and :%96,2 in mother and father respectively. The molecular data has revealed c. 936_946dup CTTTCCAGAAT in exon 11. No mutation was determined neither mother nor father. All the findings of the proband implies to PHP type1a. However the lack of mutation, normal Gsα enzyme activity and the existence of osteoma cutis in mother were the findings that differ from the previous reports. In addition the coexistance of PHP-congenitalptosis was defined as PHPtype 1b, that clinical presentation may points out mild methylation defects or other epigenetic variations.

2437W

Novel *SOX10* variant causing Waardenburg syndrome without cutaneous pigmentary changes. *C. J. Adams[1], K. Chao[1], L. A. Wolfe[1,2], B. Brooks[3], W. A. Gahl[1,2], C. Toro[1], D. R. Adams[1,2].* 1) Undiagnosed Diseases Program, National Human Genome Research Institute, Bethesda, MD; 2) Office of the Clinical Director, National Human Genome Research Institute, Bethesda, MD; 3) National Eye Institute, Bethesda, MD.

We present an 11 year, 10 month old Northern European and Ashkenazi Jewish male who was diagnosed with SOX10-associated Waardenburg syndrome during an evaluation by the NIH Undiagnosed Diseases Program. Extensive phenotyping highlights typical and atypical features of this rare syndrome. Early disease manifestations included sensori-neuro hearing loss, first identified at 8 weeks of age. Nystagmus with left eyelid ptosis and cortical visual impairment associated with hypotonia were diagnosed soon after the hearing loss. A head CT scan demonstrated vestibular hypoplasia and a cochlear implant was placed at 1 year of age. Other findings included short stature, growth hormone deficiency, attention deficit hyperactivity disorder, neurogenic bladder, and a combination of spastic diplegia and peripheral neuropathy requiring a wheelchair. His NIH evaluation confirmed a prior diagnosis of attention deficit disorder and determined his total IQ, off medications, to be 83. Ophthalmological evaluation identified nystagmus, asymmetric, segmental choroidal hyperpigmentation, mild optic pallor, and myopia. Dental evaluation found no evidence of ectodermal dysplasia. Dermatologic evaluation concluded that the hypo-pigmented areas were not related to an overall syndrome and were most consistent with healing scratches from his dry skin. Clinical sequencing identified a novel *SOX10* frameshift mutation c. 1107delC in exon 4. Similar mutations have been reported in both Type 2 & Type 4 Waardenburg syndrome. This syndrome has been reported as both an autosomal dominant disorder with variable penetrance as well as sporadic. Neither parent carried this variant. Up to 90% of those affected with Type 2 Waardenburg syndrome have sensori-neural hearing loss and many have inner ear malformations such as those identified in our patient. Demyelinating neuropathy, leukodystrophy with spasticity, various degrees of intellectual disability and seizures have all been reported in both Type 2 and 4 Waardenburg syndrome. Retinal and skin pigmentary changes are highly variable among Waardenburg patients, although our patient had much more significant retinal pigmentary changes than has previously been described.

2438T

Desmosomal diseases: the key role of dermatological features for the detection of severe subclinical cardiac involvement and for the phenotype to genotype correlation : Proposition of an algorithm. *L. Polivka[1, 2], C. Bodemer[1, 2], S. Hadj-Rabia[1, 2].* 1) Dermatology, Necker-Enfants Malades Hospital, AP-HP, Paris, France; 2) Inserm U1163, Institut Imagine, Université Paris Descartes.

Inherited desmosomal diseases are characterized by skin and/or cardiac features. The dermatological features might be a clue in the determination of the underlying life-threatening cardiac disease. After systematic review of published articles (1997-2015), we propose a clinical dermatological algorithm in order to identify as soon as possible the patients at high risk of cardiac involvement and to orientate gene sequencing. The inclusion criteria were: 1) At least one identified mutation in the following desmosomal genes: *JUP*; *PKP1, PKP2*, *DSP*, *DSG1* to *4*, *DSC1-3* and *CDSN*; 2) Description of the cutaneous phenotype. Articles focusing on extra-cutaneous manifestations and/or cardiac involvement only and redundant articles were excluded. Sequence variations were checked and actualized using ENSEMBL software. A total of 78 articles fulfilled the inclusion criteria. They reported 458 patients carrying at least one mutation in one of the eight genes encoding proteins of the epidermal desmosome. Palmoplantar keratoderma (PPK), hair shaft anomalies (HSA), and skin fragility were the major features of cutaneous desmosome diseases. Isolated PPK or isolated HSA are associated to a desmosomal disease limited to skin. The combination of PPK and HSA was recorded in 161 patients, and this association is at high risk of cardiac disease (129/161 patients, 80. 1%). In all the 129 reported patients, dermatological features occurred before cardiac manifestations i. e. HSA since birth, PPK around one year. However, they had led to cardiac monitoring in only 2. 3% of those patients. Therefore regular cardiac monitoring, including cardiac ultrasound and electrocardiogram, is mandatory in all patients presenting with both PPK and HSA, even in the absence of clinical signs of cardiac involvement. Taking PPK, HSA and skin fragility into account, we delineated three major phenotypes: 1) the PPK-HSA-non fragile skin subtype (77%, 124/161), always associated to cardiac involvement; 2) the PPK-HSA-skin fragility-normal cardiac function subtype (19. 9%, 32/161) frequently associated to *PKP1* anomalies (*PKP1* is not expressed in the heart); 3) the PPK-HSA-skin fragility-cardiac involvement subtype (3. 1%, 5/161) always due to *DSP* mutations. Three mutation hotspots in *DSP* and *JUP* account for 90. 8% of the patients with cardiac involvement. The combination of PPK and HSA justify long-term cardiac monitoring unless *PKP1* mutation is identified.

2439F

Two Siblings With Conjenital Hyperinsulinism. *N. Muratoglu Sahin[1], H. Verdi[2], FB. Atac[2], S. Tulgar Kinik[3], SE. Flanagan[4], H. Khalid[5].* 1) Division of Pediatric Endocrinology, Dr . Sami Ulus Obstetrics, Children Health and Diseases Training and Research, Ankara, Turkey; 2) Baskent University Faculty of Medicine, Department of Medical Biology, Ankara, Turkey; 3) Baskent University Faculty of Medicine, Division of Pediatric Endocrinology, Ankara, Turkey; 4) Institute of Biomedicaland Clinical Science, University of Exeter Medical School, UK; 5) Departments of Pediatric Endocrinology, Great Ormond Street Hospital for Children NHS Trust, London, UK.

Congenital hyperinsulinism (CHI) is a complex heterogeneous disorder characterizedby dysregulated insulin secretion from pancreatic β-cells causes. The molecular basis of CHI involves perturbations in the key genes involved in controlling insulin secretion. One of the known etiologies includes inactivating mutations of the KATP channel genes. Autosomal recessive and dominant mutations in ABCC8/KCNJ11 are the commonest cause of medically unresponsive CHI. In addition the focal form appears to be higher in Asian countries; therefore, the establishment of treatment systems should be considered. Here, we report two siblings diagnosed with CHI, due to a novel mutation (p. Q392H) in the *ABCC8* gene. Case1: A male newborn (no problem in pregnancy and delivery) was admitted to hospital suffering from hypoglycemic seizure started in the first day. The parents were first cousins. During hypoglycemia, blood ketone was negative, insulin was 400 uIU/mL (5–25), c-peptide was 26. 5 ng/mL (0. 9–7. 1), the infant was diagnosed as CHI. During follow-up, with the intensive medical therapy (diazoxide, somatostatin, nifedipine, and intensive feeding), his blood glucose levels were normal. Although hypoglycemia was seldom detected, his neurological status never improved. He was died in two months. The sequencing analysis revealed a novel p. Q392H mutation in ABCC8 gene. Both parents were found to be heterozygote carriers of the same mutation. Case 2: Corion villus sampling was performed for the second baby. The molecular analyses have revealed that the baby girl was heterozygote for the same mutation. She was born from uneven fulpregnancy and delivery. In the postnatal second hour, hypoglycemia was detected. She was diagnosed CHI as well. With the treatment of octreotide, normoglycemia was maintained and the treatment was ceased at the first age. With the further molecular analysis, the paternal inheritance of mutant allele was determined. We were unable to perform a DOPA-PET scan in our case. Finally, it maybe autosomal dominant diffuse CHI. The difference in the severity of the disease may be due to homo and heterozygosity of the mutation in siblings. Moreover, paternally inherited allele as in the second baby might cause focal hyperinsulinism.

2440W

Mutational analysis of an adult with an RNU4ATAC associated primordial dwarfism: expanding the phenotype. *S. M. Kirwin[1], I. L. Gonzalez[1], R. L Smith[3], M. B. Bober[2], E. T. Rush[3, 4], V. L. Funanage[1].* 1) Molecular Diagnostics Laboratory, Nemours/A. I. duPont Hospital for Children, Wilmington, DE; 2) Division of Orthopaedics, Nemours/A. I. duPont Hospital for Children, Wilmington, DE; 3) Munroe-Meyer Institute for Genetics and Rehabilitation, University of Nebraska Medical Center, Omaha, NE; 4) Departments of Pediatrics, Internal Medicine, and Orthopaedic Surgery, University of Nebraska Medical Center, Omaha, NE.

Microcephalic osteodysplastic primordial dysplasia (MOPD I; OMIM 210710) is a rare autosomal recessive disorder characterized by intrauterine as well as postnatal growth delay, severe microcephaly, distinct brain malformations (pachygyria or agyria); short bowed long bones, broad metaphyses, dry skin, and sparse hair and eyebrows. Facial characteristics may include a sloping forehead; protruding eyes; a prominent nose with a flat nasal bridge; and micrognathia. Mutations in the *RNU4ATAC* small nuclear RNA have been linked to this disorder. This snRNA is mapped to intron 2 of the *CLASP1* gene on chromosome 2, (2q14. 2), and is a component of the minor U12-dependent spliceosome. Eleven different variants in *RNU4ATAC* have been reported and lead to a spectrum of severity within the MOPD I phenotype. One recurrent variant, n. 51G>A has been reported across differing ethnic backgrounds. We report here on a now 22 year old patient with microcephaly (-8-10 SD), lissencephaly, agenesis of the corpus callosum and dwarfism with a height of 132cm. He presented to hospital with new onset of type II diabetes. He was dysmorphic with sloping hairline and prominent supraorbital ridges with lateral periorbital fullness. He has sparse eyebrows, and palpebral fissures are narrow with hooded eyelids and a left Horner syndrome. His nose has high and tubular nasal bridge with broad tip and depression between the nasal tip and the alae nasi. He has macrostomia and fleshy lips. Hands are small compared with the rest of the body, skin appears loose and wrinkled. Terminal phalanges and fingernails are hypoplastic. Feet are edematous which is non-pitting. The patient has continued to have a progressive clinical course with onset of anemia over the past 15 months. He also has developed stage V chronic kidney disease and at the time of most recent evaluation, had a glomerular filtration rate of 11 mL/min. Sanger sequencing of the *RNU4ATAC* region identified two novel variants: a n. 46G>C within the 5' stem loop region, and n. 118T>C, in the Sm protein binding domain. The pathogenicity of n. 118T>C is supported by a previous study that mutations in the 3' end of the stem loop disrupts the normal spliceosomal complex. Our patient, who is likely a compound heterozygote, may be the longest surviving patient with MOPD I that we are presently aware of. Our findings may provide insight into the molecular basis of an MOPD I patient who demonstrates a phenotype unlike those previously reported.

2441T

Genetic Analysis in Beta Thalassemia Minors in Certain Communities of Gujarati Population. *M. V. Rao[1], S. R. SHAH[1], A. P. PATEL[2].* 1) Department of Zoology, BMTC & Human Genetics, School of Sciences, Ahmedabad-380009, Gujarat, India; 2) 2, Saumrut Laboratory, 402, Narayan Complex, Navarangpura, Ahmedabad-380009.

Thalassemia is one of the hemoglobinopathies which belongs to a class of genetic disorders. Beta thalassemia is an inheritable genetic anomaly whose gene belongs to chromosome 11. The genetic mutation in that chromosome leads to the abnormal synthesis of β-globin chain of the hemoglobin molecule. More than 300 mutations are noted for this gene and this disease occupies one of the most important genetic disorders in global populatio. In India, patients are identified by characterization of common mutation in them, where IVS 1-5 is predominant. In Gujarati Population of our study, a total number of 108 patients' DNA was analyzed for five common mutations using molecular biological methods. These include IVS 1-5 (G>C), -619 bp deletion, IVS 1-1 (G>T), CD 8/9(+G) also known as FS 8/9 along with CD 41/42 respectively. The results showed that IVS 1-5 mutation was found to be dominant (70%) followed by 11% of -619 bp deletion. All patients in this study consisted of Prajapatis (39), Muslims (32), Sindhis (14), Patels (8) and others (15) (Rajput, Lohanas, etc.). All these ethenic groups had also the predominance of IVS 1-5 followed by -619 bp deletion. However in Muslim community, second highest mutation was of IVS 1-1 and in Sindhis, -619 bp deletion was seen high followed by IVS 1-5 and CD 8/9, though this community had less in number in this study. Similarly other community populations showed variations in these mutations analyzed. These mutational variances are due to many factors like migration, natural selection, ethical issues and other factors and thus signifies the importance of community based studies in relation to mutational variations of thalassemia patients.

2442F

Hemoglobin beta chain -619 base pair deletion screening of patients with high HbA2 Level. *R. J. Raval[1], N. Shah[2], P. S. Shah[2], M. V RAO[1].* 1) Gujarat Genetic Diagnostic Center (GenDiCe), Department of Zoology, BMTC and Human Genetics, Ahmedabad, India; 2) Supratech Laboratory and Research Institute, Off C G Road, Opposite Krupa Petrol Pump, Parimal Garden, Ahmedabad, Gujarat 380006, India.

Introduction: Beta thalassemia is a blood disorder that affects the production of abnormal hemoglobin. Low levels of hemoglobin leads to a lack of oxygen in the body. Affected individuals also have a shortage of red blood cells (anemia), which can cause pale skin, weakness, fatigue, and more serious complications. Patients with beta thalassemia are at an increased risk of developing abnormal blood clots. Beta thalassemia is classified into two types depending on the severity of symptoms: thalassemia major (Cooley's anemia) and thalassemia intermediate (Minor). Thalassemia major is more severe. **Methods:**Whole Blood samples were collected from patients (n=107) with complain of high HbA 2 level. HbA 2 levels were evaluated. Genomic DNA was isolated from peripheral blood and its quality and quantity were checked. With help of Polymerase Chain Reaction (PCR) amplification of the exon of genes HBB was carried out. PCR products were checked by 2. 5 % Agarose Gel Electrophoresis. **Results**:In Beta Thalassemia, out of 107 patients 13 revealed -619 base pair deletion with heterozygous condition, hence declared as Thalassemia minor. No further mutations were seen in this study. **Conclusion**:In Asian population, Beta Thalassemia patients exhibited alterations in 619 base pair deletion only. However, further studies are necessary.

2443W

Next-generation sequencing uncovered unexpectedly high prevalence of neonatal Dubin-Johnson syndrome. *T. Togawa[1], T. Sugiura[1], K. Ito[1], T. Endo[1], A. Kikuchi[2], N. Ichinoi[2], S. Kure[2], S. Saitoh[1].* 1) Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2) Department of Pediatrics, Tohoku University School of Medicine, Sendai, Japan.

Neonatal cholestasis results from impaired bile formation by hepatocytes or from obstruction of bile flow. The incidence of neonatal cholestatic jaundice varies between 1:2,500 and 1:5,000 newborns. The etiology is highly variable. Thanks to advances in the understanding of the molecular basis of neonatal/infantile intrahepatic cholestasis (NIIC), diagnostic methods taking into account the genetic make-up have developed. Several disorders have been divided from idiopathic neonatal hepatitis in the 1970s to 2000s. The Dubin-Johnson syndrome (DJS, [MIM: 237500]) phenotype results from mutations in the protein encoded by *ABCC2* [MIM: 601107], which is a member of the large ABC transporter family. DJS was rarely diagnosed in the neonatal period and thus far only five neonatal DJS cases have undergone molecular analysis. We developed a diagnostic custom panel of causative 18 genes (NIIC gene panel), included *ABCC2*, using the AmpliSeq (Life Technologies). From June 2013 to May 2015, we sequenced 134 patients with NIIC using Ion PGM system (Life Technologies) and analyzed with bioinformatics. We diagnosed six neonatal DJS cases (including 2 siblings) with the molecular analysis. Two patients had clinical diagnosis with the black liver. Other four had no definitive diagnosis before analysis. Five of 6 patients were Japanese patients and the other one was Chinese. Eight heterozygous pathogenic mutations were identified, those included 1 nonsense mutation, 4 splice site mutations, 2 missense mutations, and 1 small deletion. All patients had compound heterozygous mutations, including predicted truncating mutations or exon skipping at least in one allele. We suspected the presence of hot spots in *ABCC2* for neonatal DJS in Japanese population, because three Japanese patients had p. R768W. We have calculated the cumulative carrier rate of our identified mutations in Japanese population thanks to Human Genetic Variation Browser (URL: http://www. genome. med. kyoto-u. ac. jp/SnpDB), and the rate was predicted approximately 1/54. Based on the carrier rate, estimated incidence of the affected patients was calculated approximately 1/12,000, and we speculated that neonatal DJS would be more frequent in Japanese. In conclusion, NGS and bioinformatics with NIIC gene panel are clinically useful to uncover neonatal DJS. Neonatal DJS would be more frequent in Japanese population.

2444T

An unusual presentation of Schimke Immunoosseous Dysplasia. *M. AlAmr[1], A. Torkamani[2], L. M. Bird[3].* 1) Health Science International, University of California, San Diego, San Diego, CA; 2) Scripps Translational Science Institute, La Jolla, CA, United States; 3) Department of Pediatrics, University of California, San Diego, CA, and Rady Children's Specialists of San Diego, Division of Dysmorphology/Genetics, San Diego, CA, United States.

A Middle Eastern male was born to second-cousin parents at 35 weeks of gestation following premature rupture of membranes at 25 weeks. He was delivered by Cesarean section weighing 1. 7 kg. Bilateral cataracts were removed at 2 years of age. He had delayed tooth eruption and mild gross motor delay. Short stature became concerning around two years of age, and he was treated with an unknown injectable medication. Esotropia was surgically corrected. Pectus carinatum developed around age 5 years and hyperpigmented macules appeared at 6 years. He exhibited flesh colored papules on his neck consistent with flat warts; biopsy showed features of epidermodysplasia verruciformis. He gradually developed disproportionate short stature and lordosis. No specific diagnosis was suggested upon review of radiographs (taken at age of 5 years) at the International Skeletal Dysplasia Registry. Past work up included karyotype (46XY), lysosomal enzyme panel (normal) and microarray (no copy number variations, 216. 5 Mb of homozygosity consistent with stated consanguinity). At the age of 7 years, his evaluation showed microcephaly and short stature (- 7. 9 SDs) with arm span 14% greater than height and normal upper/lower segment ratio. He had a short trunk, pectus carinatum and dramatic lordosis. There were numerous tan macules scattered on trunk. Radiographs from age 7 years showed platyspondyly, decreased bone mineralization, dysplastic acetabulae, small irregular dislocated femoral heads, osteopenia and lacy ossification of the humeral head, relatively normal epiphyses at the knees and elbows, and metacarpal shortening. Again no specific diagnosis was made. Whole genome sequencing revealed a homozygous nonsense mutation in SMARCAL1 (chr2:217288391 snp G>T), p. E378X). The same mutation was reported previously in a Middle Eastern girl with Schimke Immunoosseous Dysplasia (SIOD). SIOD is an autosomal recessive progressive multisystem disorder causing skeletal, renal and immunologic dysfunction. The most consistent presentation is decreased postnatal growth rate and nephropathy in addition to skin pigmentation beginning in childhood. Cataracts have been described but are uncommon. Radiographs were re-reviewed in light of the mutation results, and were felt to be atypical and more severe than usually seen in SIOD. The lack of clinical immunodeficiency, lack of clinical renal disease, presence of cataracts and atypically severe skeletal findings make this case noteworthy.

2445F

A novel, SF3B4 missense mutation, as a possible cause for Nager syndrome. *C. K. Dzolang[1], J. S. Bamforth[1], K. Atta[2], E. Garside[2], A. MacMillan[2], O. Caluseriu[1].* 1) Medical Genetics, University of Alberta, Edmonton, Canada; 2) Biochemistry, University of Alberta, Edmonton, Canada.

Nager syndrome (NS; OMIM 154400) is the prototype for a group of disorders called acrofacial dysostoses characterized by mandibulofacial and limb anomalies. NS is an autosomal dominant genetic disorder with a variable, multisystemic involvement but hallmarks of the condition are a recognizable facial gestalt including downslanted palpebral fissures, malar hypoplasia, and micrognathia, and most commonly preaxial, predominantly upper limb anomalies including aplasia/hypoplasia of the thumb and radioulnar synotosis. In 2012, Bernier et al, have hypothesized that haploinsufficiency of SF3B4 is the cause of 61% of the individuals clinically diagnosed with Nager syndrome in their cohort. Further studies support this initial finding (Czeschik et al, 2013; Petit et al, 2014). Published pathogenic mutations associated with Nager syndrome include a specific missense in the initiator Met, nonsense, frameshift, and splicing mutations. To our knowledge, no other pathogenic NS missense mutations have been published to date. SF3B4 encodes SAP49, a highly conserved spliceosomal protein, with two RNA recognition motifs (RRMs) followed by a proline-glycine rich domain. During assembly of the U2SNP prespliceosomal complex, SAP49 binds to the pre-mRNA just upstream of the branch point sequence and is believed to play a crucial role in tethering the U2 snRNP to the branch site. This report brings preliminary evidence for the first SF3B4 missense mutation outside the initiator Met in a patient with a clinical diagnosis of Nager Syndrome. Our patient, a 12 years old boy, presented with a constellation of features including relative macrocephaly, downslanted palpebral fissures, zygomatic hypoplasia, micrognathia, bilateral hypoplastic thumbs, conductive hearing loss, and speech delay. Sanger sequencing of SF3B4 in our patient revealed a novel variant (c. 251T>G) in exon 3, a replacement of an isoleucine (hydrophobic amino acid) by an arginine (basic amino acid). In silico analysis (SIFT, Mutation Taster and Polyphen) indicate that this change is deleterious/ disease-causing. This mutation is situated in the first RRM of SF3B4, and protein homology and conformation study indicate severe disruption of Sap49 at an essential site. Further functional studies are under way to confirm pathogenicity. We are reporting, to our knowledge, the first patient with a clinical diagnosis of NS and a rare missense mutation likely pathogenic in the functionally essential SF3B4 RRM1 domain.

2446W

A novel SOX9 mutation with normal male genitalia and otherwise classic campomelic dysplasia. *G. C. Gowans, M. J. Curtin, K. R. Kerr, E. K. Schmitt, L. A. Autullo, P. L. Brock, K. E. Jackson, K. C. Platky Warren, K. L. Stoate, K. M. Goodin, J. H. Hersh, A. Asamoah.* Pediatrics, University of Louisville, Louisville, KY.

A21 month old male has campomelic dysplasia (CD), normal male genitalia, and de novo SOX9 mutation. The child was born after prenatal diagnosis of skeletal abnormalities and hydronephrosis. Complications in the newborn period were related to congenital abnormalities and included respiratory distress and feeding difficulties. The patient has a variety of congenital abnormalities including tracheomalacia, cardiac anomalies, conductive hearing loss, bilateral hydronephrosis, and low lying conus. The skeletal anomalies included hip dislocation, 11 pairs of ribs, rhizomelic extremities, bowed lower extremities with pretibial dimples in the skin, malformed tibia/fibula, and talipes equinovarus with wide spacing between the hallux and 2nd toes. Facial features are typical of CD, including relative macrocephaly, flat face, hypertelorism, upturned nose, long philtrum, and micrognathia with cleft palate. External genitalia were phenotypically male. The family history is negative for consanguinity, genetic conditions, birth defects, recurrent pregnancy loss, or ID. CD particularly impacts the skeletal, respiratory, and reproductive systems. Skeletal findings typically include bowing of the long bones of the lower extremities and less frequently the upper extremities as well that causes characteristic skin dimples over the curved bone(s). Shortened limbs, dislocated hips, underdeveloped shoulder blades, 11 pairs of ribs, cervical spine abnormalities, and talipes equinovarus are common. Reproductive findings include various levels of both external and internal genital defects, most commonly manifesting as ambiguous genitalia or sex reversal. Almost 75% of affected males have a 46,XY genotype with either ambiguous genitalia or normal female external genitalia. Internal genitalia are variable. The SOX9 gene on 17q24. 3 is the only gene known to be associated with CD. Following gene sequencing of SOX9, also known as SRY (sex-determining region Y)-box 9 protein, a c. 349C>G (Gln117Glu) variant of uncertain significance was found. This had not been reported previously. This c. 349C>G transversion in exon 1 converts a codon from glutamine (CAG) to glutamic acid (GAG). Parental testing revealed neither parent has the mutation, consistent with a de novo mutation pattern. This particular SOX9 variant may explain the normal male phenotype of this patient. We will compare our patient to some relevant previously reported SOX9 genotypes with their resulting CD phenotypes.

2447T

A novel mutation of *OTX2* contributing to a case of otocephaly initially diagnosed by prenatal ultrasound in the first trimester. *M. K. Jones[1], J. Chung[1], V. Kimonis[1], JA. Gold[1, 2].* 1) Pediatrics, University of California, Irvine, Orange, CA; 2) Loma Linda University Health, Loma Linda, CA.

We report a prenatal case of an unspecified facial defect first identified early in pregnancy during a routine first trimester ultrasound. CVS was subsequently performed with a normal female karyotype 46,XX and SNP-microarray. The patient is a 37-year-old G3 P0 TAB1 Hispanic female. With a previous partner, the patient had infertility with two unsuccessful intrauterine insemination (IUI) attempts and one unsuccessful *in vitro* fertilization (IVF) cycle. With the current partner, the patient had a previous pregnancy with trisomy 21, which she terminated. Family history was otherwise unremarkable. Detailed ultrasound in the second trimester revealed: agnathia, low set ears (otocephaly), aglossia, and microstomia. A dandy-walker variant was also suspected, although a subsequent fetal MRI did not confirm this finding, with brain anatomy appearing within normal limits. The rare, lethal agnathia-otocephaly phenotype was suspected. The patient was counseled regarding her options and elected continuation of the pregnancy with nonintervention at the time of delivery. The pregnancy was complicated by severe polyhydramnios requiring multiple amnioreductions for symptomatic relief. Birth was at 38. 5 weeks gestation after spontaneous labor; she was a stillborn female with confirmed otocephaly on physical examination by geneticist and on autopsy. Tissue was sent for DNA analysis of *OTX2* and *PRRX1*. Recently mutations in two genes, orthodenticle homeobox 2 (*OTX2*) and paired-related homeobox 1 (*PRRX1*), have been found to be associated with some cases of otocephaly. DNA analysis of *OTX2* and *PRRX1* in our case revealed a novel heterozygous nonsense mutation in *OTX2*. Specifically, the mutation found was c. 534C>A p. CYS178* (C178X) in exon 3 of the *OTX2* gene. DNA analysis of *PRRX1* was negative for sequence alterations and deletions/duplications within the gene. Other cases presumed to be caused by mutations in *OTX2* have been reported in the literature; still, many cases have no identifiable genetic etiology. There is one report of autosomal dominant transmission and presumed gonadal mosaicism. Parental testing is pending for the familial mutation to determine ifit is*de novo.* These findings could suggest that mutations in *OTX2* contribute; but, may not be the only genetic factor related to the overall phenotype. Additional studies might include DNA analysis of *SOX9*previously implicated in Pierre-Robin sequence, a less severe mandibular phenotype.

2448F

A novel mutation of the *TWIST1* gene in a family with Baller-Gerold syndrome without poikiloderma. *T. Kaname[1,2], K. Sameshima[3], K. Yanagi[1], Y. Kuroki[1], G. Nishimura[4], K. Naritomi[2], Y. Matsubara[5].* 1) Dept Gen Med, Natl Ctr Child Hlth Dev (NCCHD), Tokyo, Tokyo, Japan; 2) Dept Med Gen, Univ Ryukyu Grad Schl Med, Nishihara, Okinawa, Japan; 3) Div Med Gen, Gunma Child Med Ctr, Gunma, Japan; 4) Dept Ped Imag, Tokyo Mtrpltn Child Med Ctr, Tokyo, Japan; 5) Natl Res Inst Child Hlth Dev, Tokyo, Japan.

Baller-Gerold syndrome (BGS) is characterized by craniosynostosis, paraxial upper limb malformations, and growth retardation, and sometimes by poikiloderma. Although many patients with BGS are caused by mutations in the *RECQL4* gene, BGS is known to be of heterogeneous cause. In fact, three BGS patients with mutations in the *TWIST1* gene were reported to date. We met a family with clinically diagnosed with mild BGS without poikilodermic skin changes. The boys were the second and third children born to nonconsanguineous parents. There was no prenatal exposure to medications. They had bilateral coronal craniosynostosis with prominent forehead, dysmorphic facial appearance with left ptosis, and mild radial ray hypoplasia with abnormal thumb. Chromosome analysis showed a normal karyotype in each patient. To elucidate the cause of mutation in the patients, we performed a targeted resequencing analysis by next-generation sequencer (NGS) with a custom-made panel for genes related to craniosynostosis, including *RECQL4, TWIST1, FGFR1, FGFR2*, and *FGFR3*. Then, whilst no pathogenic mutations were detected by NGS data analysis, coverage at a part of exon 1 in the *TWIST1* gene was reduced compared to control individuals. Thus, we confirmed the sequence in *TWIST1* and plus *RECQL4* in the patient by conventional Sanger sequencing. Finally, although pathogenic mutations were not found in the *RECQL4* gene including promoter region, a 21 bp insertion at exon 1 of the *TWIST1* gene was found in the patients. The insertion is located at the coding region of basic helix-loop-helix domain, which may affect the activity of TWIST protein. Our result and previous reports of *TWIST1* mutations in patients with BGS may suggest a subtype of BGS without poikiloderma.

2449W

TWIST2 is the cause of Ablepharon Macrostomia and Barber Say Syndromes: Reascertainment of two cases lost to follow-up as keys to solving these conditions. *T. Markelllo[1], S. Marchegiani[2], T. Davis[1], F. Tessadori[3], G. van Haaften[4], F. Brancati[5], B. Pusey[1], L. Wolfe[1], C. Tifft[1], V. Ferraz[6], N. Roche[7], F. Ramos[8], M. Malicdan[1], C. Boerkoel[1], W. A. Gahl[1], B. de Vries[9], M. van Haelst[4], M. Zenker[10], special acknowledgement by the authors to F. Greenberg posthumously.* 1) NHGRI/NIH, Bethesda, MD; 2) WalterReed National Millitary Medical Center, Bethesda, MD; 3) Hubrect Institute-KNAW, CT Utrecht, The Netherlands; 4) University Medical Center Utrecht, The Netherlands; 5) University of G. d' Annunzio Chieti and Pescara, Chieti, Italy; 6) Universidade de Sao Paulo, Brazil; 7) University Hospital of Ghent, Ghent, Belgium; 8) Universidad de Zaragoza, E-50009 Zaragoza, Spain; 9) Radboud University Medical Center, Nijmegen, Netherlands; 10) Institute of Human Genetics, Magdeburg, Germany.

We recently published TWIST2 as the genetic locus of ablepharon macrostomia (AMS) and Barber-Say Syndrome (BSS). In several independent cases they are caused by a single base, changed into one of two different alternative alleles (Marchegiani et al. "Recurrent mutations in the basic domain of TWIST2 cause Ablepharon macrostomia and Barber-Say syndromes", AJHG in press). During ascertainment we discovered that the index case's father underwent mosaicism karyotype analysis at birth and due to fortuitous circumstances we were able to obtain the birth records from copies maintained by the grandmother and from photographs saved by Dr. F. Greenberg then inherited by Ms. Ann Smith after his death. Records and photographs were rediscovered after the molecular biological work was begun. Additional information from a second historical case reported one decade previous was re-ascertained by our Italian coauthor. The participation of that person facilitated understanding of the mosaic presentation in these unique two cases of AMS. The re-ascertainment of another cryptic genetic condition, previously studied then lost to follow-up has been described: Case 11-2005 — A 32-Year-Old Pregnant Woman with an Abnormal Fetal Karyotype. Holmes et al. N Engl J Med 2005; 352:1579-1587. These examples of two different genetic conditions that were lost to followup for an entire generation illustrate the importance of preserving and archiving data and photographs from old genetic cases, both unsolved or solved. The first example shows the benefit of preserving old photographs that require digitizing. This opportunity only exists prior to the medical-legal dates for destruction of hospital records, and prior to the retirement or death of senior genetic investigators.

2450T

Hutchinson-Gilford progeria syndrome: clinical and molecular characterization. *H. Pachajoa[1, 2], AF. Ramirez[1], X. García[1], LJ. Posso[1], F. Ruiz[1].* 1) Universidad Icesi, Cali, Colombia; 2) Fundación Clínica Valle del Lili, Cali, colombia.

Hutchinson-Gilford progeria syndrome (HGPS, MIM 176670) is a rare congenital disease secondary to mutations in the LMNA gene. It is characterized by lipodystrophy, short stature, low body weight, scleroderma, decreased joint mobility, osteolysis and senile facial features. Patients have a life expectancy of 13. 4 years and cardiovascular compromise is usually the cause of death. **Case report:** This is the case of a 14 year old female patient with scarse hair, dysmorphic features, short stature, senile appearance and congestive heart failure. LMNA sequencing detected a mutation a heterozygous mutation c. 1824C>T (p. Gly608Gly) which confirms a diagnosis of HGPS. **Conclusions:** The "classical" phenotype of HGPS is secondary to the mutation in LMNA gene c. 1824C>T (p. Gly608Gly), which leads to the formation of an aberrant farnesylated protein, progerin. There is an ongoing clinical trial in phase II which combines the use of farnesyltransferase inhibitor (lonafarmib), statins (pravastatin) and bisphosphonate (zoledronate) that has demonstrated an increase in mean survival by 1. 6 years. This is the first evidence of treatments improving survival for this fatal disease.

2451F

A pathogenic variant in *BMPR1A* results in craniofacial dysmorphism, Robin sequence, and juvenile polyposis syndrome. *W. H. Tan[1], A. H. O'Donnell Luria[1], V. L. Fox[2], J. B. Mulliken[3].* 1) Division of Genetics, Boston Children's Hospital, Boston, MA; 2) Division of Gastroenterology, Boston Children's Hospital, Boston, MA; 3) Department of Plastic and Oral Surgery, Boston Children's Hospital, Boston, MA.

Loss-of-function mutations in *BMPR1A* are found in 20 – 25% of individuals with juvenile polyposis syndrome (JPS). Facial dysmorphism and cleft palate have not been described in patients with JPS, although cleft palate has been reported in a child with a chromosome 10q22. 3-q23. 2 microdeletion that includes *BMPR1A* along with other genes [Petrova E. *Mol Syndromol*. 2014; 5:19-24]. Murine studies have shown that *Bmpr1a* is expressed in the developing primary and secondary palate, and knockout of *Bmpr1a* in palatal mesenchyme resulted in clefting of the anterior palate [Baek JA. *Dev Biol*. 2011; 350:520-31]. A more recent study revealed that the mandibular condyle was smaller in cartilage-specific *Bmpr1a* knockout mice, putatively due to down-regulation of Sox9, which controls the differentiation of chondrocytes [Jing J. *Connect Tissue Res.* 2014; 55 Suppl 1:73-8]. Herein we present a boy with facial dysmorphism, Robin sequence, and JPS due to a heterozygous mutation in *BMPR1A*. A 13 year-old boy first presented with gastrointestinal bleeding at the age of 6 years, and colonoscopy revealed multiple juvenile polyps throughout the colon and rectum. He was born with a complete cleft of the secondary palate that was repaired in late infancy. He had respiratory and feeding difficulties as a neonate, requiring treatment with continuous positive airway pressure and a feeding tube for about 5 weeks. He had minor gross motor delay in infancy, which he has since overcome; his cognitive development has always been normal. Physical examination at age 12 was significant for macrocephaly, a long and narrow face, long ears, retrognathia, and severe dental crowding with class II malocclusion. He had hyperconvex finger and toe nails; his limbs were otherwise normal. He had epispadias. Brain MRI and echocardiogram were both normal. Sequencing of *SMAD4* and *BMPR1A* revealed a *de novo* heterozygous nonsense mutation in *BMPR1A* (c. 1480C>T (p. R494X)). This mutation has previously been reported in at least two individuals who both had juvenile and hamartomatous intestinal polyps. SNP-based chromosomal microarray identified a maternally-inherited 128 – 217 kb gain on chromosome 5p15. 33 that does not encompass any protein-coding genes, although there are 2 microRNAs of unknown function. We hypothesize that heterozygous loss-of-function mutations in *BMPR1A* can be associated with syndromic Robin sequence in addition to juvenile polyposis.

2452W

A new case of Kenny-Caffey syndrome type 2 with molecular confirmation. *A. Wadley, F. Ramji, E. Kalaitzoglou, S. Krishnan, B. Drabu, C. Kesserwan.* Department of Pediatrics, University of Oklahoma Health Science Center, Oklahoma City, OK.

Background: Kenny-Caffey syndrome (KCS) type 2 is a rare genetic condition characterized by impaired skeletal development, hypoparathyroidism, hypocalcemia and distinct facial features. A perinatal lethal form of the syndrome is known as Osteocraniostenosis (OCS). KCS type 2 and OCS are allelic disorders caused by germline mutations in *FAM111A.* We describe here phenotypic and molecular findings in an infant with clinical presentation consistent with KCS type 2. **Case report:** The patient was born at 37 weeks gestational age to healthy non-consanguineous parents. Prenatal ultrasound showed intrauterine growth retardation, cloverleaf skull and shortened long bones. At birth the patient had a large anterior fontanelle, small palpebral fissures, bitemporal narrowing and supra-auricular bulging. Growth parameters were greater than 2 standard deviations below the mean. The patient's skeletal survey showed hypomineralization of calvarium but normal density of the long bones. At one month of age he developed hypocalcemia-induced seizures and was diagnosed with primary hypoparathyroidism and anemia. He responded well to calcium replacement. KCS type 2 was clinically suspected and DNA was sent for *FAM111A* mutation testing. **Results:** Sanger sequencing in a CLIA-approved lab returned a c. 1012A>G transition in exon 6 of the *FAM111A* gene (NM_001142520). Parental testing showed wild type alleles for the *FAM111A* gene. This change has been previously reported as a *de novo* mutation in one individual with OCS who died at 2 months of age. The *de novo* occurrence of this change in an affected individual suggests that this change is likely pathogenic. The patient is currently 6 months and his developmental milestones are appropriate for his age. Since the hospitalization at one month old he has had one other occurrence of hypocalcemia and seizure activity in the setting of a parainfluenza viral infection. He had a full recovery with no sequelae. He continues to have poor growth parameters and remains on calcium and activated vitamin D replacements. **Conclusion:** The clinical and radiological features in this patient are consistent with KCS type 2 rather than with OCS. We conclude that studying additional patients with the condition is needed to better address genotype-phenotype correlation.

2453T

Subtle Facial Dysmorphism, a Variable Phenotype and Negative 4 Gene Testing in Young Adults with Holoprosencephaly. *K. Weiss, M. Guillen Sacoto, C. Hadsall, R. Hart, E. Roessler, P. Kruszka, M. Muenke.* Medical Genetics, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA.

Background Holoprosencephaly (HPE) is a structural anomaly of the brain in which there is failed or incomplete separation of the forebrain, caused by chromosomal anomalies, teratogenic exposure, part of a syndrome, or due to mutations in more than 12 known HPE-associated genes of which 4 genes (*SHH*,*ZIC2*,*SIX3*, and*TGIF*) are seen most frequently (Solomon, 2010) . The common facial features include hypotelorism, midface hypoplasia, cleft lip and/or palate, and a single maxillary central incisor. HPE occurs in up to 1 in 250 conceptions, but in only approximately 1 in 10,000 liveborn infants (Leoncini, 2008). It is extremely rare that individuals with HPE will survive into adulthood and little is known about the phenotypic characteristics of these older patients. The aim of this study is to evaluate the phenotype and genotype of adolescents and adults with HPE. MethodsWe evaluated 7 families of individuals with HPE, above the age of 16 years ascertained through the international registry of HPE. All patients were consented to our institutional review board approved protocols for clinical and genetic evaluation at the National Institutes of Health Clinical Center. All patients underwent physical exams, labs, neuropsychological evaluations, ophthalmic evaluations, brain MRI and genetic testing for the 4 most common HPE genes. Results8 individuals from 7 families were evaluated, 3 males, 5 females, aged 16-33 years (mean 21). All had negative 4 gene testing. The MRI scans showed semilobar HPE in 6 of the patients and lobar HPE in 2. All had only subtle dysmorphic features and none of the hallmark facial features of HPE. The neuropsychological development was variable: one individual walks independently and communicates verbally, one is non-ambulatory and communicates verbally and 6 are non-verbal and non-ambulatory. 4 patients had recurrent seizures, 3 patients are G-tube fed due to recurrent aspiration and all of the patients had scoliosis. Only one patient had overt diabetes insipidus. The most common ophthalmologic findings were optic nerve abnormalities and cortical visual impairment. ConclusionsWe evaluated a unique and rare group of young adult with HPE. The phenotype of adults with HPE supports the negative correlation between severe facial findings and survival but do not correlate with the HPE type on imaging. The patients we evaluated had negative 4 gene testing and we speculate that patients who survive into adulthood have a different etiology.

2454F

CASK mutation identified by whole exome sequencing in a patient that expands the clinical spectrum for MICPCH syndrome. *J. Zhao[1], S. Tang[2], D. Schuessler[3], N. Dosa[1], RR. Lebel[1].* 1) Center for Development, Behavior and Genetics, SUNY Upstate Medical University, Syracuse, NY; 2) Ambry Genetics, Aliso Viejo, CA; 3) Community Health Center, Gouverneur, NY.

A 23-year-old mixed-European female with no family history of intellectual disability presented with multiple malformations and developmental delays. She exhibits microcephaly, severe intellectual disability, dyspraxia, congenital quadriplegia, dystonia of the upper extremities, spasticity, and scoliosis. Brain imaging revealed pontine and cerebellar hypoplasia with intact corpus callosum. We noted down-slanting palpebral fissures, midface hypoplasia, high-arched palate, dental crowding, large tongue, and long narrow asymmetric face. Chromosome analysis, metabolic testing, and microarray all revealed no abnormalities. Whole exome sequencing revealed c. 2065A>T, a single nucleotide change in the *CASK* gene, which is located on chromosome Xp11. 4 and encodes for a calcium/calmodulin-dependent serine protein kinase. This protein is essential in synaptic function and brain development. The *de novo* nonsense mutation truncates the CASK protein, which is likely the etiology of the patient's adverse phenotype. The major features in our patient resemble those reported in MICPCH syndrome (microcephaly with pontine and cerebellar hypoplasia). Since MICPCH syndrome is a rare X-lined dominant disorder (OMIM #300749) associated with mutations in the *CASK* gene, we believe our patient expands the phenotypic profile of *CASK* mutations.

***PNPLA6* mutations – a rare genetic cause of syndromic hypogonadotrophic hypogonadism.** *A. L. Frederiksen[1], J. H. Langdahl[1, 2], K. Brusgaard[1], N. Nguyen[3], C. B. Juhl[2].* 1) Dept. of Clinical Genetics, Odense University Hospital, Odense C, Denmark; 2) Dept. of Endocrinology, Hospital of South West, Esbjerg, Denmark; 3) Dept. of Radiology, Odense University Hospital, Odense C, Denmark.

Background: Congenital hypogonadotrophic hypogonadism (HH) includes clinically and genetically heterogeneous conditions including both syndromic and non-syndromic forms. A growing number of genes are recognized as responsible of HH though, the individual genetic abnormalities are infrequent. Boucher-Neuhäuser syndrome (BNS) which describes the clinical triade of early-onset ataxia, hypogonadotropic hypogonadism and chorioretinal dystrophy has just recently been linked to autosomal recessive *PLPNA6.* However, complicated spastic paraplegia, type 39 (SPG39) was until now considered to be the prominent phenotype of mutations in *PLPNA6.* **Case**: We describe two siblings a male and female clinically diagnosed with BNS at age 56 and 64 carrying a known*PNPLA6* mutation and a novelvariantThe index patient a male age 56 was diagnosed with osteoporosis and refereed to the department of endocrinology. The previous medical history exposed that he had been diagnosed with HH at age 17 years and treated with testosterone replacement therapy. On clinical examination he presented with ataxic gait, dysarthria and nystagmus. A detailed family history was recorded. The patient was number 4 of 7 siblings. The oldest age sister age 64 did not have any children and was reported with osteoporosis and ataxic gait while the remaining five siblings, who all had children, were without any symptoms. The oldest sister was then referred for clinical evaluation. She reported a tendency to fall since childhood and had been diagnosed with ataxia. Due to primary amenorrhea she was diagnosed with HH at age 25 and treated with hormone substitution however, she discontinued due to side effects. Age 58 she had been diagnosed with osteoporosis. A subsequent ophthalmological evaluation exposed both patients with chorioretinal dystrophy and thus both fulfilled the criteria for BNS. **Result:** A genetic screening identified two heterozygous variants *PNPLA6*, c. 2944_2947dup, (p. Arg983fs), and c. 3932G>A, (p. Arg1311Gln) in both patients. The c. 3932G>A has not previously been reported. To support a potential significance of the mutations their five asymptomatic siblings were subsequently tested. All five were either non-carriers or heterozygous carriers of only one of the variants. The results indicate the mutations to be pathogenic. **Conclusion:** This case illustrates *PLPN6* mutations as a rare genetic cause of HH syndrome and to the best of our knowledge presents a novel *PLPLN6* mutation.

2456T

Point mutation in the proline dehydrogenase gene (*PRODH)* plus a microdeletion in the proximal part of DiGeorge syndrome chromosomal region (DGCR) in juvenile onset epileptic encephalopathy – a case report. *C. Lau, G. Golas, B. Pusey, W. Bone, E. Valkanes, T. Markello, D. Adams, W. Gahl.* NIH Undiagnosed Disease Program, National Institutes of Health, Bethesda, MD.

Introduction: Epileptic encephalopathies are severe brain disorders involving epileptic electrical discharges that contribute to progressive psychomotor dysfunction. Clinical manifestation often includes multiform and intractable seizures, behavioral and neurological impairments and sometimes early death. **Case Presentation:** The proband is a 22-year-old (y/o) male who was born via induced vaginal delivery from non-consanguineous parents with normal early developmental milestones. His first presenting symptoms occurred at age 7 y/o with attention difficulties, anxiety, hyperactivity and oppositional-defiant behaviors. Subsequently tonic clonic seizures (1-2/month) started, followed by progressive neurocognitive decline, progressive motor apraxia and retinopathy. Poor appetite led to failure to thrive. Neuroimaging detected cerebral and cerebellar atrophy. Exome sequencing detected a p. L289M variant in *PRODH* and SNP microarray analysis uncovered an approximately 100 kb microdeletion in the proximal part of DGCR, harboring *PRODH*, *DGCR2*, *DGCR5* and *DGCR6*. Subsequently, heightened proline and glutamine levels in CSF were found. In addition, two deleterious appearing compound heterozygous alleles in *PDE6B* (c. 1401+5G>A and c. 2470_2478del9) were detected. **Discussion:** Homozygous or compound heterozygous variants in *PRODH* have been shown to cause hyperprolinemia type 1 (HP1). However, clinical relevance of HP1 has been unclear since the clinical manifestations reported ranges from increased proline level with no other physical findings to severe neurologic manifestations including epilepsy and mental retardation. This specific p. L289M variant that moderately decrease PRODH activity (<30%) was identified in 2 of 63 unrelated patients with schizophrenia. In our patient and his affected brother, it is in trans with the deletion of *PRODH*. We believe this resulted in the heightened proline and glutamine levels, the contributing cause of the epileptic encephalopathy observed, and additionally the variants in *PDE6B* led to the retinopathy finding. **Conclusion:** We propose that a combination of the previously-reported *PRODH* mutation (p. L289M) plus a hemizygous deletion of *PRODH* contribute to and/or cause the epileptic encephalopathy and separately the *PDE6B* deleterious variants contributed to the retinopathy observed in these brothers. Cases such as this may shed light on modifiers that contribute to the wide spectrum of epileptic encephalopathies.

2457F

Mutation in *TWIST2* gene and its relation to a new clinical finding - lipodystrophyc habitus - in Ablepharon Macrostomia Syndrome. *E. M. S. M. M. Souza[1, 3, 4], K. C. Peronni[3, 4], J. R. Plaça[3, 4], G. A. Molfetta[1, 3, 4], S. C. S Carvalho[1, 3, 4], A. A. Marques[3, 4], L. F. Araújo[1, 3, 4], W. A. Silva-Jr[1, 3, 4], V. E. F. Ferraz[1, 2].* 1) Department of Genetics, Ribeirao Preto Medical School, University of Sao Paulo, Ribeirao Preto, Sao Paulo, Brazil; 2) Department of Medical Genetics, Clinics Hospital of the Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, São Paulo, Brazil; 3) Center for Cell-Based Therapy (CEPID/FAPESP); National institute of Science and Technology in Stem Cell and Cell Therapy (INCTC/CNPq), Regional Blood Center of Ribeirão Preto, Ribeirão Preto, Sao Paulo, Brazil; 4) Center for Medical Genomics (HCFMRP/USP); Center for Integrative Systems Biology (CISBi - NAP/USP), Ribeirao Preto, Sao Paulo, Brazil.

Ablepharon Macrostomia Syndrome (AMS) is a rare condition mainly characterized by absent or hypoplastic eyelids, absent eyebrows and eyelashes, and macrostomia. Only 17 cases of the syndrome have been reported since its first description and all the cases are sporadic except for two reports of familial recurrence. The aim of this study was to clinically reevaluate one family, consisting of recurrence among sisters and a father with mild phenotype, and to identify the gene mutation responsible for the syndrome in these patients. To achieve this goal exome sequencing was performed in five members of this family (father, mother, two affected sisters, and one unaffected sister) and all mutations in the protein-coding portions of the genome were identified. The mutations were filtered and evaluated by inheritance, pathogenicity, relevance to the AMS phenotype and by gene function. The mutation c. 223G>A (p. E75K) on the *TWIST2* gene was the only one segregating among the affected members, which encoded a transcription factor with regulatory function on dermal development. This mutation was validated by Sanger Sequencing and is predicted as pathogenic, causing the change of glutamic acid, a small and negatively charged amino-acid, to lysine, a larger and positively charged amino-acid. This change happens in position 75 of the protein, inside the basic Helix-Loop-Helix domain, which could disrupt dimerization and DNA binding. Additionally, we report the presence of a new feature in the two sisters with AMS – the loss of adipose tissue and fat accumulation in the lower back, common features in lipodystrophy. *TWIST2* mutations have already been associated with Familial Partial Lipodystrophy in mouse knockout studies, suggesting that *TWIST2* may play a role in the lipodystrophic features observed in affected sisters. Finally, we suggest that the phenotype heterogeneity associated with mutations in *TWIST2* can occur due to the wide regulatory function of this transcription factor in several developmental genes.

Autosomal recessive truncating mutations of *KLHL7* cause a Bohring-Opitz like syndrome. *J. Thevenon[1,2], S. Bigoni[3], J. St-Onge[1,2], G. Parmeggiani[3], A. Ferlini[3], G. Garani[4], E. Ballardini[4], C. Gilissen[5], B. van Bon[5], R. Acuna-Hidalgo[5], C. Thauvin-Robinet[1,2], A. Bohring[6], J. B Rivière[1,2], H. G Brunner[5], L. Faivre[1,2], A. Hoischen[5].* 1) FHU-TRANSLAD, Université de Bourgogne/CHU Dijon, Dijon, France; 2) Équipe EA42271 GAD, Université de Bourgogne, Dijon, France; 3) UOL of Medical Genetics, Department of Reproduction and Growth and Department of Medical Science, University-Hospital S'Anna, Ferrara, Italy; 4) Neonatal Intensive Care Unit, Department of Reproduction and Growth, University-Hospital S'Anna, Ferrara, Italy; 5) Radboud University Medical Center, Department of Human Genetics, Nijmegen, The Netherlands; 6) Department of Pediatrics, Ostholstein Kliniken, Eutin, Germany.

Bohring-Opitz syndrome (BOS) is characterized by distinctive craniofacial features, distal joint contractures, pre- and post-natal growth retardation, failure to thrive, severe developmental delay, brain malformations. Most typical cases are caused by *ASXL1 de novo* mutations. BOS-like was also described in cases with heterozygous *ASXL3* truncating mutations, suggesting genetic heterogeneity. We identified a case born from non-consanguineous parents, with a personal history of prenatal growth retardation and hydramnions. At birth, global hypotonia with poor mobility, reducible distal and proximal joint contractures suggesting the BOS posture were noted. Main facial dysmorphism were broad forehead with nevus flammeus, hypertelorism, prominent eyes, anteverted nares, micro-retrognathia. Evolution was marked by severe feeding problems, seizures, perceptive deafness, recurrent pulmonary infections. Brain MRI showed dysmyelination and a thin corpus callosum. The patient was negative for *ASXL1* mutation screening. Whole-exome sequencing detected a candidate homozygous non-sense change of *KLHL7*. International data-sharing identified an additional family carrying a homozygous splice-site mutation of *KLHL7*. In this family, two siblings were affected by a previously undiagnosed condition. Phenotypic manifestations included pre-natal growth retardation, hydramnios, distal joint contractures, severe epileptic disease, failure to thrive and feeding problems, recurrent pulmonary infections, hypertrichosis. Facial dysmorphism was very similar to patient from family one. Brain MRI revealed agenesis of corpus callosum, fusion of thalami and frontal region in both children. Additionally, sibling one had a left temporal cortical dysplasia and sibling two had a cleft palate and an atrio-septal defect. Both children died from acute respiratory distress in their second year. *KLHL7* encodes a BTB-kelch protein implicated in cellular cycle and ubiquitin pathway. Rare families with heterozygous missense changes in a specific domain of KLHL7 were associated with an autosomal dominant retinis pigmentosa (RP), with a suspected dominant negative mechanism. Conversely, none of the reported patients with truncating variant had signs of RP. Truncating events in *KLHL7* are rare in ExAC databases (0. 02%), with no homozygous individual reported suggesting a dosage-sensitivity. In conclusion, we suggest that autosomal recessive truncating mutations of *KLHL7* can cause BOS-like.

2459T

Identification of Mutation in Kelch-Like Family Member 15 Gene in a Patient with Abnormal Cortical Development and Hypergonadotrophic Hypogonadism. *G. Yesil[1], E. KARACA[2], Y. BAYRAM[2], T. GURAN[3], D. PEHLIVAN[2], Z. COBAN AKDEMIR[2], T. GAMBIN[2], S. JHANGIANI[4], D. MUZNY[4], R. GIBBS[4], J. R. LUPSKI[2,4,5,6], The Baylor-Hopkins Center for Mendelian Genetics.* 1) Department of Medical Genetics, Bezmialem University, Istanbul, Turkey; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA; 3) Department of Pediatric Endocrinology, Marmara University, Istanbul, Turkey; 4) Human Genome Sequencing Center, Baylor College of Medicine, Houston TX, USA; 5) Department of Pediatrics, Baylor College of Medicine, Houston, TX, USA; 6) Texas Children's Hospital, Houston, TX, USA.

Whole-exome sequencing (WES) is a new groundbreaking technology that has changed the course of clinical/human genetics. As a more efficient and cost effective method, WES is now widely used as a diagnostic tool for identifying challenging genetic syndromes. Here we report a female patient with clinical diagnosis of Aicardi syndrome (MIM#304050) whom we identified heterozygous missense mutation in Kelch-Like Family Member 15 (*KLHL15*) gene by using WES. Mutations in *KLHL15* were shown in patients with either isolated intellectual disability (ID) or ID together with structural brain malformations and epilepsy. The present case had some features of Aicardi syndrome such as microcephaly, optic atrophy, convulsions, diffuse cerebral atrophy, agenesis of corpus callosum and facial dysmorhism with an upturned nose and hypertelorism. Hypergonadotrophic hypogonadism and thyroid hypoplasia were additional features. *KLHL15* is located on chromosome Xp22. 11, within the candidate locus for Aicardi syndrome. In conclusion, our clinical and genomic findings, together with previous clinical data in the literature, suggest that mutations of *KLHL15* might be associated with Aicardi syndrome, or a new neuroendocrine syndrome. Additional reports of individuals with a similar phenotype and animal studies will be crucial to clarify the potential role of *KLHL15* gene.

2460F

Clinical characteristics of fragile X syndrome for genetic counseling: First reported in Thai patients. *C. Charalsawadi[1], S. Jaruratanasirikul[2], J. Worachotekamjorn[2], P. Limprasert[1].* 1) Department of Pathology, Faculty of Medicine, Prince of Songkla University, Hat Yai, Songkhla, Thailand; 2) Department of Pediatrics, Faculty of Medicine, Prince of Songkla University, Hat Yai, Songkhla, Thailand.

Fragile X syndrome (FXS) is the most common inherited mental retardation, caused by CGG trinucleotide repeat expansion in the *FMR1* gene on chromosome Xq27. 3. About 7% of Thai boys with developmental delay are affected with FXS. This is the first systematic study in Thailand. We reviewed a retrospective cohort of Thai patients with FXS between the years of 1993 through till the year 2015. A total of 128 patients (104 males and 24 females) were diagnosed with FXS, using standard molecular methods. To determine frequencies of common clinical characteristics, based on the 5-item clinical checklist developed by Limprasert et al (J Med Assoc Thai. 2000;83:1260-6), 56 prepubertal and 3 post pubertal boys with FXS, who were the first affected persons in their families, were evaluated. Age at diagnosis ranged between 18 and 166 months of age (mean 80, SD 40). The majority of patients were diagnosed between the ages of 5 and 10 (48%) and under 5 years old (32%). The most common referral reason was developmental delay. The average age of first understandable word and unassisted walking were 31 months (SD 11) and 21 months (SD 6), respectively. X-linked inheritance pattern was observed in 14% of the 57 families. Out of 26 patients, IQ ranged between 30 and 64 (mean 44, SD 9). About 69% of the patients had an IQ within a moderate range. For prepubertal boys, attention deficit and/or hyperactivity were the most common clinical characteristics (96%). Prominent ears as well as elongated face were observed in 78% and 48%, respectively. About 52% of prepubertal boys had macroorchidism. Other common characteristics e. g. hyperextensible MP joint (n=22), autistic features (n=15), social anxiety/ shyness (n=13), flat feet (n=13), aggressive/ self injury (n=12), and high-arched palate (n=11) were observed. To identify rare characteristics, we examined 70 males and 7 females with available medical records. Rare characteristics e. g. seizure (n=5), Prader-Willi-like phenotype (n=3), Sotos-like phenotype (n=2), strabismus (n=2), astigmatism and hypermetropia (n=1), bilateral ptosis (n=1), cleft palate (n=1), bilateral conductive hearing loss (n=1), tetralogy of Fallot (n=1), medulloblastoma (n=1), unilateral macroorchidism (n=1), precocious puberty (n=1), primary amenorrhea (n=1), and hypothyroidism (n=1) were recognized. In conclusion, our study provides insight into clinical characteristics of FXS in Thai patients, which is necessary for genetic counseling in Asian ethnicities.

2461W

Mutations in the PI4KA-TTC7A-EFR3B Signaling Pathway Result in a Progressive Lethal Syndrome. *R. C. Lombardo, L. Wung, S. A. Kocoshis, A. H. Filipovich, C. A. Valencia, R. L. McMasters, K. Zhang, T. A. Kalfa, K. Risma, R. J. Hopkin.* Cincinnati Children's Hospital and Medical Center, Cincinnati, OH.

The PI4KA-TTC7A-EFR3B pathway plays a key role in critical intracellular functions and has recently emerged as a cause of human disease. We describe a fatal clinical outcome believed to be secondary to mutation in a gene affecting this pathway. Patient was a female infant, prenatal testing identified a single umbilical artery, symmetric IUGR, and complex congenital cardiovascular abnormalities. Clinical course was marked by progressive multiple organ failure with development of a dyserythropoietic anemia and immunologic abnormalities. Gastrointestinal evaluation revealed eosinophilic enterocolitis with prominent epithelial apoptosis, limited clinical response to oral corticosteroids, and progression to intestinal failure. Microarray and metabolic studies were normal, whole exome sequencing identified heterozygous mutations in *PI4KA*. At 10 months of age, she succumbed to a culture negative sepsis- like inflammatory cascade and died of multiple organ failure. Prior studies have demonstrated that genes contributing to the PI4KA-TTC7A-EFR3B pathway are critical to intracellular function and highly conserved among vertebrate species. Cellular models suggest EFR3B tethers TTC7A to the plasma membrane which in turn, plays a primary role in proper localization of phosphatidylinositol 4-phosphate (PtdIns4P). Alteration of this complex results in loss of plasma membrane integrity, cell polarity, and interferes with normal vesicular trafficking, cellular adhesion, RhoA-mediated cytoskeletal organization, and phosphatidylinositol signaling. Previous reports have described a small number of patients with TTC7A mutations with severe gastrointestinal manifestations, variable immunodeficiency, and death in early infancy1. Animal models exhibit small head size, decreased cerebral volume, and cardiovascular developmental abnormalities2 and conditional knock out mice develop intestinal failure, diffuse systemic inflammation, and cardiovascular collapse following pathway inhibition3. We propose that alterations of PtdIns4P signaling results in a recognizable syndrome characterized by congenital heart defects, failure to thrive, very early onset intestinal failure, severe immunodeficiency, and progressive multiple organ failure with lethal outcome. 1. 2462T

Mutations in SEC61A1 cause autosomal dominant interstitial kidney disorder associated with anemiaand growth retardation. *C. Golzio[1], N. Bolar[2], C. Van Hemelrijk[4], A. Hoischen[3], J. Huyghe[2], A. Raes[4], E. Matthys[5], E. Sys[6], M. Gubler[7], C. Antignac[7], M. Azou[8], G. Van Camp[2], S. Kmoch[9], A. Bleyer[10], J. Vande Walle[4], G. Mortier[2], H. Brunner[3], L. Van Laer[2], N. Katsanis[1], B. Loeys[2,3].* 1) Center For Human Disease Modeling Duke Univ Medical Center, Durham, NC; 2) University of Antwerp, Antwerp, Belgium; 3) Radboud University Medical Center, Nijmegen, Netherlands; 4) University of Ghent, Ghent, Belgium; 5) Sint-Jan Hospital, Brugge, Belgium; 6) Sint-Lucas Hospital, Brugge, Belgium; 7) Inserm U983, Paris, France; 8) Damian Hospital,Ostend, Belgium; 9) Charles University, Prague, Czech Republic; 10) Wake Forest School of Medicine, Winston-Salem, NC, United States.

Autosomal dominant tubulo-interstitial kidney disease refers to a group of disorders characterized by progressive loss of kidney function and the eventual need for dialysis and kidney transplantation. While mutations in the *UMOD*, *MUC1*, and *REN* genes have been identified as the primary causes of this disorder, there remain a number of families in whom the genetic cause has not been identified. Here were report a three-generation family with autosomal dominant progressive chronic kidney disease associated with congenital anemia and intrauterine growth retardation. Ultrasound examinations revealed small dysplastic kidneys without cysts, and a kidney biopsy revealed tubular atrophy with secondary glomerular sclerosis. We performed genome-wide linkage analysis and identified a candidate region with a maximum LOD-score of 2. 7 on chromosome 3q. Combining whole exome sequencing data with our critical interval, we identified a variant p. Thr185Ala change in *SEC61A1*. *SEC61A1* encodes the alpha-subunit of the SEC61 complex, responsible for the translocation of proteins across the endoplasmic reticulum membrane. Suppression of sec61a1 in zebrafish embryos led to an absence of convolution of the pronephric tubules, whereas the pronephric ducts were unaffected, a phenotype similar to the tubular atrophy seen in our patients. This phenotype could be rescued by wild type *SEC61A1* mRNA, but not with mRNA encoded from the p. Thr185Ala allele, suggesting that the variant is a loss of function. In addition, we identified another variant in*SEC61A1*(p. Val67Gly) in a second family with similar phenotypes; the p. Val67Gly allele also appeared to be pathogenic in ourin vivocomplementation assay. Taken together, our genetic findings and the functional studies support *SEC61A1* as a causal gene for a novel, dominant syndromic form of progressive chronic kidney disease with tubular atrophy.

Siblings with Harderophorpheria: Early signs mimic infantile osteopetrosis. Revisiting a clinical diagnosis 15 years later with the aid of whole exome sequencing. *L. Dupuis[1], E. Bareke[2], T. Hartley[3], P. Kannu[1], K. Boycott[3], M. Yasuda[4], R. J. Desnick[4], D. O. Doheny[4], R. Mendoza-Londono[1], Care for Rare Consortium.* 1) Division of Clinical and Metabolic Genetics, The Hospital for Sick Children and University of Toronto, Toronto, Ontario, Canada; 2) Department of Human Genetics, McGill University and Génome Québec Innovation Centre, Montréal, Quebec, Canada; 3) Children's Hospital of Eastern Ontario Research Institute, University of Ottawa, Ottawa, Ontario, Canada; 4) 4Icahn School of Medicine at Mount Sinai, Department of Genetics & Genomic Sciences, New York, NY, United States of America.

The advent of whole exome sequencing (WES) has revolutionized gene discovery and led to the identification of atypical phenotypes for well known syndromes. Our case illustrates the phenotypic overlap between very different syndromes, harderoporpheria and infantile osteopetrosis, which was only resolved by WES. We report two siblings, both born with severe hepatosplenomegaly, jaundice, thrombocytopenia and anemia. The eldest sibling had increased bone density on radiographs and was diagnosed with infantile osteopetrosis. Both children responded well to bone marrow transplant (BMT). Molecular testing was negative for genes involved in infantile osteopetrosis*: CLCN7, TCIRG1, OSTM1, TNFSF11A* and *PLEKHMI1*. Many years later, the family was offered whole exome sequencing to clarify the underlying molecular etiology. The siblings were found to harbor a homozygous mutation (p. K404E) in the *CPOX* gene confirming a diagnosis harderoporphyria. No mutations were found in any known genes causing infantile osteopetrosis. Defects of heme biosynthesis enzymes result in porphyrias. Harderoporphyria is caused by homozygous mutations in the *CPOX* gene which encodes coproporphyrinogen oxidase. Individuals with harderoporphyria exhibit neonatal hyperbilirubinemia, hemolytic anemia, hepatosplenomegaly and photosensitivity. Infantile osteopetrosis presents with increased bone density, reduction of bone marrow spaces leading to anemia, hepatosplenomegaly, cranial nerves compression and severe growth failure. It is a lethal condition, but responds well to BMT. Given that both children had undergone BMT, their own hematopoietic precursors would have been replaced by those of the donor. Thus, they would not be expected to manifest a harderoporphyria phenotype. To our knowledge, there have been no reports of increased bone mineral density in patients with harderoporphyria. An initial clinical presentation suggesting a diagnosis infantile osteopetrosis was only challenged after the WES data returned. Since the siblings received BMT in the first year of life, it remains unknown whether increased bone density was a persistent finding. This case report illustrates the clinical utility of WES and the importance of establishing a definitive molecular diagnosis for appropriate genetic counselling and medical management.

Improved detection of FLCN mutations in patients with BHDS. *J. R. Toro[1, 2], B. Friedman[3], S. Bale[3].* 1) National Cancer Institute, Maryland, MD; 2) Dermatology Department, Veterans Affairs Medical Center, Washington, DC, USA; 3) GeneDx, BioReference Laboratories, Inc. , Gaithersburg, MD Maryland, USA.

Birt-Hogg-Dubé syndrome (BHDS) (MIM 135150) is an autosomal dominant predisposition to the development of follicular hamartomas (fibrofolliculomas), lung cysts, spontaneous pneumothorax, and kidney neoplasms. Germline mutations in FLCN are associated with the susceptibility for BHDS. To date 153 FLCN germline mutations have been reported in the online Folliculin sequence variation database. Objective: To characterize methods for improved FLCN mutation detection and novel mutations. Methods: Initial screening was conducted with direct bidirectional DNA sequencing of the coding regions and splice sites of exons 4-14 of FLCN. If no mutation was identified by sequencing analysis, large intragenic insertion and deletion mutations were screened by RQ-PCR and targeted arrays comparative genomic hybridization with exon-level resolution. Results: The FLCN mutation detection rate by direct sequencing was 89 percent. We detected 56 unique novel FLCN germline mutations: 22 deletions, 11 insertions, 13 missense,7 nonsense, 2 splice site and 1 deletion/insertion. To date only eight large unique intragenic mutations have been reported. We identified one whole gene FLCN deletion and eleven unique large FLCN intragenic deletions: four involving exon 1, one in exon 6 and six encompassing: exons 1-6, exons 2-5, exons 2-13, exons 6-14, exons 7-8 and exons 10-14. Including this report, to date there are 214 unique FLCN mutations identified: 76 deletions, 32 insertions, 99 substitutions and 7 deletion/insertion. A comprehensive worldwide review of published FLCN mutations and current ongoing efforts to detect novel BHDS causing mutations will be discussed. Conclusion: A systematic approach combining accurate and sensitive methods to detect FLCN mutations provides evidence that most patients with BHDS have mutations in FLCN.

2465T

A compound-heterozygous mutations in patients with autosomal-dominant Marfan syndrome. *P. Cibulkova[1,2], R. Richterova[1,2], M. Dvorakova[1,2], R. Krenkova[1,2], E. Augste[1,2].* 1) Laboratories AGEL, Novy Jicin, Czech Republic; 2) Education and Research Institute AGEL, Prostejov, Czech Republic.

Objectives: Marfan syndrome (MFS) is known as an autosomal dominant genetic disorder caused by mutation in *FBN1* gene, resulting in defective glycoprotein fibrillin-1. It is a multisystem connective tissue disease, mainly involving the cardiovascular, ocular and skeletal systems. We describe four cases of rare compound-heterozygous MFS patients. Three probands were from families where only one of the parent was affected and the second mutation was *de novo*, in two cases we did not have enough information if mutations are in cis or trans position. The last reported case of two mutations in the *FBN1* gene is from family where both mutations are in one *FBN1* allele that was inherited across three generations. **Methods:** We performed molecular analysis of all exons of *FBN1* gene to identify pathogenic mutations in unrelated patients with clinical diagnosis of MFS. DNA was isolated from peripheral blood. 750 patients were analyzed by SSCP method and 350 by NGS (Junior 454, Roche). MLPA analysis was also performed. All detected sequence variants were tested by *in silico* prediction tools for its effect on protein function. **Results:** We identified 129 mutations by SSCP and 81 by NGS in *FBN1* gene, some of them have already been published. Reported four cases of compound-heterozygous MFS demonstrate incomplete dominance of detected *FBN1* mutations. The phenotypes of proband´s heterozygous family members were mild, did not cause the comlpete MFS and they do not meet the Ghent clinical criteria for MFS. They have not been previously tested or suspected for MFS. The phenotypes of the compound-heterozygous probands were much more severe and had required cardiovascular, surgical or ophthalmological solution early in childhood, but did not lead to lethally affected individual. **Conclusion:** Genetic counselling in affected families is complicated after discovery of compound-heterozygous MFS due to autosomal-dominant heredity of MFS and intrafamilial variable phenotype manifestation. The fact that compound-heterozygous MFS patients had not fatal clinical manifestations after birth signify, that some mutations behave semi-dominantly rather than purely dominantly. However they are more severely affected than their simple heterozygote parents or relatives.

2466F

GenIDA: an international registry of individuals affected by monogenic forms of intellectual disability or autism and a families and professionals social network, to collect medically relevant information and gene specific natural histories. *J. -L. Mandel[1,2,3], F. Colin[1], T. Mazzucotelli[4], P. Parrend[4,5], A. Deruyver[4], T. Kleefstra[6], D. Koolen[6].* 1) Translational medicine and neurogenetics dept. , Institut de Génétique et de biologie Moléculaire et cellulaire (IGBMC) - INSERM U964 - CNRS UMR7104 - University of Strasbourg, Illkirch, France. (jlmandel@igbmc. fr and colin@igbmc. fr); 2) Genetic diagnostic laboratory, CHU Strasbourg, France; 3) Collège de France, Chaire de Génétique humaine, Paris, France; 4) Engineering, informatics and imaging sciences laboratory (ICube) - CNRS UMR 7357 - ENGEES - INSA of Strasbourg, Illkirch, France; 5) ECAM, Strasbourg-Europe, Schiltigheim, France; 6) Department of Human Genetics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.

Intellectual disability (ID) and autism spectrum disorders (ASD) are overlapping disorders that constitute a major public health, social and educational problem because of their cumulated frequency (about 2. 5%), and constitute a great burden for affected individuals and families. ID/ASD are characterized by a striking genetic heterogeneity that underlies a phenotypic heterogeneity in severity and in associated medical problems. Progress in genome analysis has allowed the identification of many recurrent CNVs and of more than 600 genes implicated in monogenic forms of ID/ASD. An increasing number of genetic diagnoses are made in individuals with ID/ASD but the genetic heterogeneity renders extremely difficult the determination of genotype-phenotype correlations and natural history. Symptomatic treatments for comorbidities are proposed with limited opportunities to assess their efficacies or potential adverse effects. We have initiated the development of an alternative database model for specific genetic causes of ID/ASD, organized in a social network format whereby most clinical information (HPO-compatible) is entered and updated by the family of the affected individual based on wide range of structured questionnaires translated in different languages. We have recently merged our questionnaire with the one of a similar project, Syndrome Monitor, initiated at Radboud U. Nijmegen. Contacts between families affected by the same genetic cause will be possible if they wish so, creating gene or CNV specific social networks to which interested professionals could be associated, akin to disease specific patients associations. Anonymized summary data will be accessible to families and to professionals. Interested professionals will be able to submit specific questionnaires or recruit patients for clinical studies. Such proposals will be screened by a steering committee (professionals and patients representatives) that will control medical interest, feasibility and respect of ethical rules. We will present the structure and features of the GenIDA project (genida. unistra. fr) that is currently in its beta testing phase. This strategy aim is to collect information on natural history and comorbidities of rare monogenic forms of ID/ASD, including potential mutated-gene specific adverse effects of symptomatic drugs. It will promote families' empowerment and hopefully impact patients' care. The setting up of patient e-cohorts should favor international clinical studies.

2467W

Case report of family with Christianson syndrome and apparently novel pathogenic variant in the *SLC9A6* gene. *J. Moeschler[1], J. Filiano[2], S. Upton[1].* 1) Section of Medical Genetics, Geisel School of Medicine, Dartmouth-Hitchcock Med Ctr, Lebanon, NH; 2) Section of Child Neurology, Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Christianson syndrome (OMIM#300243) is a rare X-linked intellectual disability syndrome with features similar to those seen in Angelman syndrome. First described in 1999 by Christianson AL, Stevenson RE, et al in a large South African family, there are approximately 30 patients reported in the literature. Microcephaly, impaired ocular movements, severe global developmental delay, developmental regression, hypotonia, abnormal movements, and early-onset seizures of variable types characterize the syndrome. Gilfillan GD, Selmer KK et al (2008) identified *SLC9A6* gene mutations as the cause of this XLID syndrome. The *SLC9A6* gene encodes the Na(+)/H(+) exchanger NHE6. Pescosolido MF, Stein DM (2014) described the phenotype to include early-childhood onset in boys, nonverbal status, moderate to severe intellectual disability, epilepsy, truncal ataxia, postnatal microcephaly and/or attenuation in growth of head circumference, and hyperkinetic behavior. Fewer patients are reported to develop eye movement abnormalities, developmental regression, particularly loss of independent ambulation after 10 years of age, low weight for age, and cerebellar vermis atrophy, particularly after 10 years of age. We describe a family with three affected males and two unaffected carrier females with a novel pathogenic variant in the *SLC9A6* gene. The proband was a 16-year old boy who presented to our medical center with the clinical diagnosis of Angelman syndrome. He presented with microcephaly, intellectual disability, no speech, epilepsy (staring spells and tonic-clonic seizures) and self-injurious behavior. He has one older and one younger affected brother with similar clinical presentation. All three have severe cognitive disability, seizure disorder, lack of speech. Family history describes one sister and one brother who are both unaffected. Mother is unaffected and the family history is otherwise negative. A hemizygous insertion variant was detected in exon 4 of the *SLC9A6* gene: c. 630_631insT (p. Ile211Tyrfs*53). The variant is predicted to result in reading frame shift leading to an early termination of the encoded protein. This is interpreted as a pathogenic variant. To our knowledge this variant has not been reported in the literature. The mechanism for the clinical phenotype is not yet clear. Treatment remains symptom-based.

2468T

Abnormal primary dentition : a clue for the diagnosis of the SATB2-associated syndrome. *M. Rio[1], A. Elmorjani[1], B. Kverneland[2], G. Barcia[1], A. Munnich[1], JP. Bonnefont[1], S. Hanein[1].* 1) Département de Génétique, Université Paris Descartes, Sorbonne Paris Cité, Institut Imagine, Hôpital Necker-Enfants Malades, Paris, France; 2) Service de stomatologie, Hôpital Necker-Enfants Malades, Paris, France.

The *SATB2*-associated syndrome (SAS) has been recently proposed as a new clinically recognizable syndrome that results from deleterious alterations of the *SATB2* gene in humans. We report the clinical characterization of 3 patients in whom targeted high-throughput sequencing for the diagnosis of intellectual disability identified a *de novo* mutation in the *SATB2* gene for all three patients. Patient 1 is a 8-year-old boy with intellectual deficiency and hyperactivity. He walked at 2 years. He was toilet trained at 5 years. He had delayed primary dentition. He fractured his humerus at 7 years. At examination, speech was severely impaired: he was able to speak single words but did not put words together. Nevertheless he used more than 25 signs to communicate. He had a pre auricular tag, smooth philtrum, and hirsutism. He had macrodontia and irregular shape of the primary teeth, narrow palate and dental crowding. Patient 2 is a 5-year-old boy with psychomotor delay and hyperactivity. He walked at 22 months. At examination, he had no speech and was not toilet trained. Dysmorphic features included a class II malocclusion with smooth philtrum and thin upper lip. He had narrow palate, dental crowding and irregular shape of the primary teeth. Patient 3 is a 7-year-old girl. Cleft palate was diagnosed at birth and was surgically corrected at 4 months. She walked at 21 months of age. At 2 years, she fractured her tibia. She had two febrile seizures. At 7 years, she could speak few single words and was able to use 5 signs to communicate. She had macrodontia, no permanent teeth and smooth philtrum. The 3 patients had overlapping features that support the diagnosis of the SAS: intellectual disability with limited speech development, palate abnormalities, dysmorphic features and dental abnormalities. Interestingly, anomaly of the primary teeth is a consistent finding detected in the 3 patients and a good handle for early diagnosis of SAS.

2469F

Somatic Mosaic *PIK3CA* Mutations in Chinese Patients with *PIK-3CA*-Related Overgrowth Spectrum from Hong Kong. *B. Chung[1], K. S. Yeung[1], G. Leung[1], W. L. Wong[1], C. H. Li[2], K. Y. Choi[3], E. Kuong[4], W. Chow[4], M. To[4], J. Ip[5], P. Beh[6], G. C. F. Chan[1].* 1) Paediatrics & Adol Med, The University of Hong Kong, Hong Kong, N/A, Hong Kong; 2) Paediatrics & Adol Med, Tuen Mun Hospital, Hong Kong; 3) Orthopaedics & Traumatology, Yuen Mun Hospital, Hong Kong; 4) Orthopaedics & Traumatology, Queen Mary Hospital, Hong Kong; 5) Radiology, Queen Mary Hospital, Hong Kong; 6) Pathology, The University of Hong Kong, Hong Kong,.

Somatic mosaicism of phosphatidylinositol-4,5-bisphosphate 3-kinase (*PIK3CA*) mutation, one of the genes involved in the PI3K/AKT/mTOR pathway, is associated with a group of rare asymmetrical overgrowth syndrome that is collectively named as *PIK3CA*-Related Overgrowth Spectrum (PROS). We identified six suspected patients of PROS, including two suspected cases of CLOVES Syndrome [MIM 612918], one with Cystic Hygroma, one with Klippel-Trenaunay Syndrome [MIM 149000], one with isolated macrodactyly, and one with multiple lipomatosis. We had the fresh surgical tissues from 3 patients; while for the others we had their formalin-fixed, paraffin-embedded (FFPE) tissues only. We aim to identify the mutations of *PIK3CA* in each patient. Since there are five recurrent *PIK3CA* mutations that are known to account for about 80% of PROS, droplet digital PCR was used to target these recurrent mutations in each patient. We identified three patients with p. Glu542Lys (*PIK3CA*: NM_006218. 2: c. G1624A); while the remaining had p. His1047Arg (*PIK3CA*: NM_006218. 2: c. A3140G). The percentage of mutant ranged from 3. 3% to 31. 6%. Our findings suggested that droplet digital PCR is useful in identifying mutations in PROS. Surgical debulking is now the r treatment of choice for PROS, inhibitors of PI3K/AKT/mTOR pathway may be used in controlling the progressive overgrowth in patients with the molecular confirmation of *PIK3CA* mutations in the affected tissue.

2470W

A novel *PITX1* mutation segregating with familial tibial hemimelia. *D. Ortiz[1], L. Karger[1], C. Jalas[2], J. Neidich[3], J. Juusola[3], S. Bale[3], J. E. Herzenberg[4], B. D. Webb[1].* 1) Dept. of Genetics & Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Bonei Olam, Brooklyn, NY; 3) GeneDx, Gaithersburg, MD; 4) Rubin Institute for Advanced Orthopedics, Sinai Hospital of Baltimore, Baltimore, MD.

Tibial hemimelia (MIM 275220) is a rare congenital limb abnormality that occurs as an isolated anomaly in an estimated 1 in 1 million live births. Rare cases of familial tibial hemimelia have been reported with autosomal recessive or autosomal dominant inheritance. *PITX1* is a transcription factor that is known to have a critical function in hindlimb morphology, and *PITX1* haploinsufficiency has been implicated in congenital talipes equinovarus, polydactyly and additional lower limb malformations, including two cases of tibial hemimelia. We present a family with a spectrum of lower limb anomalies and a novel *PITX1* pathogenic variant (c. 442_443delGAinsCACT, p. E148HfsX21) identified via whole exome sequencing. The proband has congenital bilateral tibial hemimelia, with the right lower limb more severely affected than the left, left talipes equinovarus, congenital hip dysplasia, and bilateral pre-axial polydactyly of the feet. He was treated with serial casting and Achilles tenotomy for the left clubfoot and right knee disarticulation. Family history was significant for a younger male sibling with a nearly identical phenotype, including high grade congenital bilateral tibial hemimelia and bilateral pre-axial polydactyly of the feet, father with bilateral femoral anteversion, and a paternal male first cousin with congenital talipes equinovarus. The heterozygous p. E148HfsX21 *PITX1* pathogenic variant was identified in the proband, father, and an affected sibling. A 2 month old sibling without talipes equinovarus or tibial hemimelia was also noted to have the variant. This finding highlights the variable clinical phenotypic spectrum and incomplete penetrance of *PITX1* within families, and emphasizes its crucial role in tibial hemimelia. This case study strengthens the evidence that *PITX1* haploinsufficiency has a critical role in a variety of lower limb malformations, especially tibial hemimelia, and suggests that additional contributory factors of limb formation and development remain to be identified.

2471T

Delivery by Cesarean Section is not Associated With Decreased at-Birth Fracture Rates in Osteogenesis Imperfecta. *M. Jain[1,12], S. Bellur[1], D. Cuthbertson[2], D. Krakow[3], J. R. Shapiro[4], R. D. Steiner[5,6], P. A. Smith[7], M. B. Bober[8], T. Hart[9], J. Krischer[2], M. Mullins[1], P. H. Byers[10], M. Pepin[10], M. Durigova[11], F. H. Glorieuz[11], F. Rauch[11], V. R. Sutton[1,12], B. Lee[1,12], S. C. Nagamani[1,12], Members of the BBD Consortium.* 1) Human & Molecular Gen, Baylor college Medicine/Texas Children's Hosp, Houston, TX; 2) College of Medicine, University of South Florida, Tampa, FL, USA; 3) Departments of Orthopedic Surgery, Human Genetics, and Obstetrics and Gynecology, University of California, Los Angeles, CA, USA; 4) Department of Bone and Osteogenesis Imperfecta, Kennedy Krieger Institute, Baltimore, MD, USA; 5) Departments of Pediatrics and Molecular and Medical Genetics, Oregon Health & Science University, Portland, OR, USA; 6) Marshfield Clinic Research Foundation and University of Wisconsin, Marshfield and Madison, WI, USA; 7) Shriners Hospitals for Children, Chicago, IL, USA; 8) Division of Medical Genetics, Alfred I. DuPont Hospital for Children, Wilmington, DE, USA; 9) Osteogenesis Imperfecta Foundation, Gaithersburg, MD, USA; 10) Departments of Medicine and Pathology, Division of Medical Genetics, University of Washington, Seattle, WA, USA; 11) Department of Orthopedic surgery, Shriners Hospital for Children and McGill University, Montreal, QC, Canada; 12) Texas Children's Hospital, Houston, Texas, USA.

Osteogenesis imperfecta (OI) predisposes to recurrent fractures. The moderate-to-severe forms of OI present with antenatal fractures and the mode of delivery that would be safest for the fetus is not known. We conducted systematic analyses on the largest cohort of individuals (n=540) with OI enrolled to-date in the OI Linked Clinical Research Centers. Self-reported at-birth fracture rates were compared in individuals with OI types I, III, and IV. Multivariate analyses utilizing generalized linear modeling and backward elimination model-building were performed to assess the effect of multiple covariates including method of delivery on fracture-related outcomes. When accounting for other covariates, at-birth fracture rates did not differ based on whether delivery was by vaginal route or by cesarean section (CS). Increased birth weight conferred higher risk for fractures irrespective of the delivery method. *In utero* fracture, maternal history of OI, and breech presentation were strong predictors for choosing CS for delivery. Our study, the largest to analyze the effect of various factors on at-birth fracture rates in OI shows that CS is not associated with decreased fracture rate. With the limitation that the fracture data were self-reported, these results suggest that CS should be performed only for other maternal or fetal indications, but not for the sole purpose of fracture prevention in OI.

2472F

Congenital central hypoventilation syndrome mimicking mitochondrial disease. *K. Rojnueangnit[1,2], M. Descartes[2,3].* 1) Department of Pediatrics, Faculty of Medicine, Thammasat University, Thailand; 2) Department of Genetics, University of Alabama at Birmingham, Alabama, USA; 3) Department of Pediatrics, University of Alabama at Birmingham, Alabama, USA.

Congenital central hypoventilation syndrome (CCHS: MIM 209880) is a rare unique respiratory center defect cause hypoventilation mainly during sleep but in neonate and/or severe type presents during sleep and waking. Late-onset has been reported but is uncommon. Mutation in *PHOX2B* (paired-like homeobox) is a causative gene. Our patient is a previously healthy 18 months old who one week after routine immunization developed generalized muscle weakness, cardiomegaly, hepatomegaly, pleural effusion, and ascites. She developed acute respiratory failure requiring intubation. Her clinical symptoms improved and extubation was done at day 5. She recovered completely within 2 weeks. At that time, viral infection was suspected without any confirmation tests. Three months later, she developed a second episode of acute respiratory and cardiac failure with pulmonary hypertension. Echocardiogram showed the right ventricular hypertrophy and atrium enlargement. Intubation was required for a week. As in the first episode, she recovered within a couple weeks. Variety of tests were performed, mitochondrial disease was suspected given she had multiple organ involvement, low oxidative phosphorylation in complex I (3%) from muscle biopsy and microdeletion 270 kb of the short arm of chromosome 6 (6p25. 1), involved in *FARS2*, a nuclear mitochondrial gene. Therefore, we intensively investigated for *FARS2* mutation which was negative by sequencing the entire gene and a functional enzyme test confirmed happloinsufficiency the FARS2 protein as predicted. As polysomnography showed hypoxia, hypoventilation with hypercapnia (pCO2 range from 44 to 62 mmHg), sleep apnea could not be ruled out, therefore she was treated by noninvasive respiratory support during sleep. Her clinical symptoms, and polysomnography improved, cardiac impairment was resolved. We monitored her as a mitochondrial disease patient with a doubtful diagnosis. After several further tests, *PHOX2B* was tested for CCHS, revealing heterozygous expansion of the polyalanine to 25 repeats (p. Ala256_Ala260dup). A late-onset CCHS presented with an episodic respiratory failure was the final diagnosis. Therefore, CCHS should be included in the differential diagnosis of mitochondrial disease.

2473W

Autosomal recessive Usher Syndrome and autosomal dominant retinitis pigmentosa in a Louisiana Acadian Family. *A. Umrigar[1], A. Musso[1,2], A. Hurley[2], F. Tsien[1].* 1) Department of Genetics, LSU Health Sciences Center, New Orleans, LA; 2) Department of Audiology, LSU Health Sciences Center, New Orleans, LA.

Usher Syndrome accounts for greater than 50% of patients with combined deafness and blindness. Usher Syndrome Type 1 is inherited in an autosomal recessive manner and is characterized by congenital deafness followed by retinitis pigmentosa (RP) later in life. The most common mutation observed in the Acadian population is a G to A mutation in the USH1C gene. Isolated RP can be caused by a number of gene mutations and can follow an autosomal dominant, autosomal recessive, or X-linked pattern of inheritance. We present a Louisiana Acadian family affected by both autosomal recessive Usher Syndrome and autosomal dominant isolated RP. The proband is clinically diagnosed with isolated RP and is a heterozygous carrier for the common USH1C mutation. The proband's brother is also affected with isolated RP with no common USH1C mutations detected. The proband's two maternal half-brothers are homozygous for the USH1C G-A mutation. An extensive family history spanning five generations revealed eight (8) Usher Syndrome 1C affected individuals on the maternal side of the family, while most members of the paternal side of the family were clinically diagnosed with isolated RP. We performed exome sequencing to determine the mutation(s) responsible for the isolated RP and aid in the diagnosis, prognosis and genetic counseling of family members.

2474T

Parental Mosaicism in Type II Collagenopathies. *N. Beck[1], K. Seifert[2], A. Kumar[2], J. Hoover-Fong[1].* 1) Greenberg Center for Skeletal Dysplasias, McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 2) Department of Plastic and Reconstructive Surgery, Johns Hopkins Hospital, Baltimore, MD.

COL2A1 (OMIM #120140) encodes the pro-alpha-1 (II) chain of type II collagen. Mutations in *COL2A1* are associated with multiple syndromes such as spondyloepiphyseal dysplasia congenital, Kneist syndrome, Stickler syndrome and others. Stickler syndrome is due to mutations in *COL2A1/COL11A1/COL11A2* (dominant forms) or *COL9A1/COL9A2* (recessive forms). The type II collagenopathies have pleiotropic manifestations in skeletal, ocular, orofacial and auditory systems, necessitating multidisciplinary evaluation and care. Inter- and intrafamilial variability and phenotypic overlap among the type II collagenopathies makes clinical diagnoses challenging. We report a young male with Pierre Robin sequence (PRS) who transferred care to our multidisciplinary Cleft Lip & Palate Clinic at 21 months of age without any prior genetics work up. He had normal global development, malar flattening, mild joint hypermobility and normal hearing, but vision had never been formally assessed. His father had joint hypermobility and extreme deficiency of cartilaginous tissue in his nasal tip and pinnae and no vision or hearing concerns. We referred our patient to ophthalmology where myopia was detected and close follow-up was recommended due to the risk of retinal detachment. With our clinical suspicion of autosomal dominant Stickler syndrome, molecular analysis of the *COL2A1/COL11A1/ COL11A2* genes was pursued and revealed a previously reported pathogenic variant in *COL2A1* (c. 3597+1G>C), a transversion in IVS50 at an invariant position of the donor splice site, resulting in aberrant mRNA processing. Genetic counseling was provided to the patient's parents and the father was found to share the same COL2A1 mutation in 10% of his peripheral blood sample; mother was negative. *COL2A1* mosaicism has been reported in three unrelated families with both Kneist and Stickler phenotypes by Winterpacht et al (1993) and Spranger et al (1994) and in five unrelated families with varying type II collagenopathies by Nagendran et al (2012). The somatic mosaic parent in these publications was paternal in 5/8 (4/8 molecularly confirmed). Our case highlights the importance of a comprehensive genetic medicine work up for patients with features of any of the type II collagenopathies to direct diagnosis-specific care and allow for familial testing. For this case, a confirmed diagnosis has provided our family specific recurrence risks and has allowed for directed medical care for the mosaic parent.

2475F

Mitotic Intragenic Recombination: A Mechanism of Survival for Several Congenital Disorders of Glycosylation. *M. S. Kane[1,2], M. Davids[1,2], C. Adams[1,2], L. A. Wolfe[1,2], H. Cheung[1,2], A. Gropman[1,3], V. Konasani[4], B. Ng[5], C. Scaman[4], H. Freeze[5], D. R. Adams[1,2], W. A. Gahl[1,2], C. F. Boerkoel[4].* 1) NIH Undiagnosed Diseases Program, Common Fund, Office of the Director, National Institutes of Health, Bethesda, MD; 2) National Human Genome Research Institute, Bethesda, MD; 3) Department of Neurology, Children's National Medical Center, Washington, DC; 4) University of British Columbia, Vancouver, Canada; 5) Sanford-Burnham Medical Research Institute, La Jolla, CA.

Congenital disorders of glycosylation (CDG) are disorders of protein glycosylation that affect multiple organ systems. Since most CDGs occur in only a few individuals, we have limited understanding of the associated phenotypes and the mechanisms of patient survival. We investigated two siblings, aged 6 and 11 years, with MOGS-CDG (previously referred to as CDG-IIb) and biallelic *MOGS* mutations (*NM_006302. 2:c. [65C>A; 329G>A];[370C>T]*), who survived much longer than the only other reported MOGS-CDG patient, a child who died at 74 days of age. In these two siblings, we detected multiple *MOGS* genotypes including wild type alleles in the DNA of their peripheral blood and cultured fibroblasts. Analysis of DNA from cultured fibroblasts of six individuals with compound heterozygous mutations of PMM2-, MPI-, ALG3-, ALG12-, DPAGT1-, and ALG1-CDG also revealed multiple genotypes including wild type alleles in each case. Droplet digital PCR showed a ratio of nearly 1:1 wild type to mutant alleles for most, but not all, mutations. This suggests that selection for cells carrying wild type alleles arising from mitotic recombination contributes to the survival and the variable expressivity of individuals with compound heterozygous CDGs. Our findings also provide an explanation for prior observations of a reduced frequency of homozygous mutations and the higher than expected residual enzyme activity in cultured fibroblasts of patients with CDGs.

2476W

Tuberous sclerosis complex-causing mutations analyzed in a cohort of 41 Brazilian patients. *L. Almeida[1], J. P. G Almeida[2], L. Masulk[3], M. Richartz[3], N. Miranda[3], S. A Antoniuk[3], S. Rosemberg[2], L. A Rosemberg[1].* 1) Department of Genetic and Evolutionary Biology, Universitade de Sao Paulo, Sao Paulo, SP, Brazil; 2) Department of Pediatrics, Division of Child Neurology, Faculdade de Medicina da Santa Casa de São Paulo, Sao Paulo, Brazil; 3) Department of Pediatrics, Universidade Federal do Parana, Curitiba, Brazil.

Tuberous sclerosis complex (TSC) is an autosomal dominant hamartomatosis with variable expression, affecting one out of 10,000 newborns. Hamartomas may develop notably in the brain, kidneys, heart, skin, lungs, and retina. Mutations in either tumor suppressor gene *TSC1* or *TSC2* are responsible for TSC. The proteins expressed by those genes, respectively hamartin and tuberin, form a heterodimer that inhibits the mammalian target of rapamycin complex 1 (mTORC1), controlling cell growth and proliferation. Comprehensive screens for *TSC1* and *TSC2* mutations are well established, disclosing approximately 70% of mutations in the *TSC2* gene and 30% in the *TSC1* gene. Even with the most current techniques, nearly 10% of the patients have no mutation identified (NMI). We aimed to search for TSC-causing mutations by standardizing different techniques to evaluate the *TSC1* and *TSC2* sequences. Here we present the first thorough molecular analysis of the *TSC1* and *TSC2* genes conducted in a cohort of patients from Brazil having definite clinical diagnosis of TSC. We examined leukocyte DNA from the first 41 patients referred to our laboratory from two collaborating clinical services. Each sample was evaluated by *TSC1* then *TSC2* Sanger sequencing, followed by multiplex ligation-dependent probe amplification (MLPA) and quantitative PCR analysis for both genes for every negative result. The full protocol has been employed so far for 37 patients. Other four patients have been enrolled but the analysis is not yet concluded. We detected 36 pathogenic mutations (36/37, 97. 3%) of which 11 (29. 7%) and 25 (67. 6%) distributed respectively to the *TSC1* and *TSC2* genes. The NMI patient presented an exonic DNA variant in the *TSC2* gene that may potentially impair pre-mRNA splicing. For the four patients whose molecular analyses have not been concluded, two may have splicing mutations in the *TSC2* gene, and molecular confirmation is underway. One additional patient has a DNA variant within a predicted intronic splicing-regulating element. The NMI rate for this study is anticipated to be between 2. 4% (1/41) and 12. 2% (5/41), lying within the range observed by other studies. Preliminary results indicating two additional splicing mutations suggest that the NMI rate may be not more than 7. 3% (3/41). By the end of the analysis, DNA from all NMI patients will be submitted to next-generation sequencing targeting the *TSC1* and *TSC2* genes.

2477T

Gynecologic and Obstetric Issues in a Large Cohort of Patients with Hermansky-Pudlak Syndrome. *M. Merideth[1], K. O'Brien[2], T. Markello[2], W. Gahl[1, 2].* 1) Medical Genetics Branch, NHGRI, NIH, Bethesda, MD; 2) Office of the Clinical Director, NHGRI, NIH, Bethesda, MD.

Objective: To evaluate the obstetric/gynecologic health in women with Hermansky-Pudlak syndrome (HPS)**Background:** HPS is a rare autosomal recessive disorder characterized by defective biogenesis of lysosome-related organelles. There are 9 known subtypes of HPS caused by mutations in 9 genes involved with intracellular vesicle formation and trafficking. Clinical manifestations include oculocutaneous albinism, a bleeding disorder, and, in some patients, granulomatous colitis and/or a fatal pulmonary fibrosis. The bleeding disorder in HPS is related to an absence of platelet dense bodies, which are lysosome-related organelles. Women with HPS often have problems with heavy menstrual periods and excess bleeding during deliveries, yet very little information has been published on the gynecologic/obstetric issues in HPS. **Methods:** Ninety-eight females with HPS were surveyed under an NIH IRB-approved protocol from 2007 to 2015. **Results:** The patients ranged in age from 12-67y with a median of 35y, and were diagnosed with HPS at a median age of 21y; median age at menarche was 12y (range 8-17). Eighty-two of the 98 patients (84%) report a history of heavy menstrual periods; 56 were treated with oral contraceptive pills to manage heavy menses, and 47 of 56 reported improvement. Six of 8 patients had improvement of heavy menses after insertion of a Mirena progesterone IUD; 4 had improvement with Depo Provera. Seven patients underwent hysterectomy for heavy menses at a median age of 38y. Forty-nine patients have been pregnant with a median of 2 pregnancies (range 1-5). Fifteen of 49 patients had problems with bleeding during pregnancy. Bleeding problems were reported in 15 deliveries, requiring platelets, blood transfusion or ddAVP in 6. Prophylactic platelet transfusion or ddAVP was given prior to 19 deliveries, with no subsequent bleeding problems reported. Postpartum bleeding problems occurred in 28 deliveries: treatment by surgery, transfusion of platelets or medication was required in 14. **Conclusions:** Women with HPS can have significant problems with vaginal bleeding leading to multiple interventions. Obstetrician/Gynecologists have an opportunity to assist in the diagnosis of HPS patients, particularly since a majority of patients surveyed were diagnosed many years after the onset of menses. The history of a menstrual bleeding disorder, combined with some degree of hypopigmentation, should prompt investigation into the diagnosis of HPS.

2478F

Novel *RAF1* mutation in a newborn with Noonan syndrome phenotype. *R. Zambrano[1], J. Patrick[2], J. Surcouf[2].* 1) Pediatrics, Clinical Genetics, Louisiana State University Health Science Center, New Orleans, LA; 2) Pediatrics, Neonatology, Louisiana State University Health Science Center, New Orleans, LA.

Noonan Syndrome (NS) is a dominant disorder characterized by distinctive facial features, short neck, short stature, congenital heart defects, pectus deformities and variable developmental delays. NS is genetically heterogeneous as mutations in several genes involved in the Ras/MAPK (mitogen-activated protein kinase) pathway have been associated with a NS phenotype. 50 % of patients harbor mutations in *PTPN11*, 3-17 % of patients have mutations in *RAF1.* We present a 32 3/7 week gestational age male infant born vaginally to a 24 year old G2P1 mother. Prenatal ultrasounds revealed polyhydramnios, hydrops fetalis with pericardial effusion and cardiac arrhythmias. Dysmorphic features at delivery included: Short neck; dysplastic, low set and posteriorly rotated ears; down-slanting palpebral fissures; short nose with anteverted nares and minor micrognathia. His prolonged and complicated NICU course included severe obstructive hypertrophic cardiomyopathy (HCM) , dysplastic mitral valve, atrial septal defect, severe pulmonary hypertension and arrhythmias. Cardiac failure developed, and despite aggressive medical management, it resulted in death at DOL#73. NS was suspected and molecular testing revealed a novel missense mutation of a highly conserved residue in *RAF1* (p. Pro261Arg: c782 C>G). *RAF1* encodes a downstream effector of RAS signaling in the MAPK pathway. It has three domains: CR1 (residues 61–192) contains a Ras-binding domain, CR2 (residues 251–266) is a site of regulatory phosphorylation and association with the 14-3-3 protein and CR3 (residues 333–625) also interacts with the 14-3-3 protein. In the literature, *RAF1* mutations have been associated with HCM in NS; 4 published patients were found to have a single nucleotide change at nucleotide 781 resulting in Pro261Ser (3) and Pro261Ala (1) substitutions , they all had non lethal HCM and septal defects. Our novel mutation was reported in ClinVar with conflicting interpretations of pathogenicity. This case clearly illustrates this mutation is responsible for our patient's NS phenotype, further supporting its classification as a pathogenic variant. .

2479W

Unusual Frequency of MPS IIIC on central Colombia: probable genetic cluster? *H. M. Velasco[1], Y. Sanchez[2], A. Martin[1], J. Galvis[1], L. A. Umaña[1].* 1) Unidad de Genética Humana, Universidad Nacional de Colombia, Bogotá Colombia; 2) Universidad Pedagógica y Tecnológica de Colombia, Túnja, Colombia.

There are several reports of an increased burden of genetic disease in several regions of Colombia; likely due to multifounder effect as wel as for endogamy and consanguinity. Using a community health approach, a group of geneticists and a pediatric neurologist explored the Boyaca region in central Colombia. We identified in a village of 2500 inhabitants a cluster of 11 patients with mucopolysaccharidosis type IIIC; Pedigree revealed that most members of the hamlet where all of the patients were found had an origin in 4 ancestral families and there were several instances of consanguinity; molecular analysis of *HGSNAT*identified a novel c. 1360C>T mutation which leads to an early termination codon. The estimated incidence for this region is 1:228 which is significantly higher than reported in the literature and might account for the first population cluster for Mucopolysaccharidosis type IIIC.

2480T

Medical complications and functional issues in 122 pediatric patients with non-vascular Ehlers-Danlos syndrome. *A. D. Kline, M. Ferguson, A. Kimball, C. Haakonsen, C. Francomano.* Harvey Inst for Human Genetics, Greater Baltimore Med Ctr, Baltimore, MD.

The Ehlers-Danlos syndromes (EDS) form a group of connective tissue disorders, most of which are autosomal dominant and due to mutations in genes coding for collagen (e. g. types III and V). Although numerous reports exist describing some of the clinical course, there has not been a comprehensive review of patients in the pediatric population to date. We describe an active cohort of 122 patients with non-vascular EDS in terms of specific type, inheritance within family, and involvement of the skin, joint, GI, cardiac, neurologic and neurodevelopmental systems. The majority of the patients (73%) have hypermobile EDS and the rest have classical EDS (15%, clinically diagnosed) and unclear or overlapping type (8%). Nearly 80% are familial cases, mostly maternal, although some additional family members could be very mildly affected and unaware of the diagnosis. Medical complications involve the musculoskeletal, skin, GI, cardiovascular and neurologic systems. Hypotonia was noted in 23%. Previously unreported or single case reports in the pediatric population with EDS have described some rare accompanying findings. In our cohort, these include migraines and headaches in 19%, postural orthostatic tachycardia syndrome in 6%, functional GI complications in 18% (e. g. motility problems, gastroesophageal reflux, irritable bowel syndrome) and Chiari malformation and/or craniocervical junction abnormality in 3%. In addition, we noted accompanying intellectual disability or autism in 15%, learning disability in 11%, ADHD in 14%, and significant behavioral issues, including anxiety or depression, in 12%. Medical work-up and management issues will be discussed.

2481F

Novel compound heterozygous STRA6 mutations in a case of isolated anophthalmia. *H. Chapman[1], A. Schneider[2], T. Glaser[1].* 1) Department of Cell Biology and Human Anatomy, Congenital Eye Study Group, University of California, Davis School of Medicine, Davis, CA; 2) Division of Genetics, Einstein Medical Center, Philadelphia, PA.

Microphthalmia, anophthalmia, and coloboma (MAC) are a spectrum of developmental eye disorders, which often occur together with multisystem defects. Mutations in STRA6 (stimulated by retinoic acid), the polytopic transmembrane (TM) receptor for retinol (vitamin A) binding protein, cause Matthew-Woods syndrome, characterized by anophthalmia, lung hypoplasia, diaphragmatic hernia, congenital heart defects and mental retardation. Few STRA6 variants have been identified in cases with isolated ocular malformations. Here we report novel STRA6 mutations in a compound heterozygous child with bilateral anophthalmia and no other clinical abnormalities. One mutation disrupts a splice acceptor, which is likely to trigger nonsense-mediated decay of the STRA6 transcript, resulting in a null allele. The second mutation changes a conserved aromatic amino acid in the first intracellular loop to an aliphatic residue. Aromatic side groups, especially near the ends of TM segments, are known to mediate protein-protein interactions, ligand binding, and lateral contacts between TM domains. In contrast to previous clinical mutations, which impair surface expression and affect STRA6 globally, this unique hypomorphic allele may be particularly informative, by disrupting a subset of STRA6 functions. We are currently applying a panel of molecular assays to reveal the specific role of this intracellular domain in vitamin A transport.

2482W

***HS6ST2* is mutated in a family with Brooks-Wisniewski-Brown syndrome.** *M. Miozzo[1], L. Paganini[1], L. Pezzani[1], D. Rovina[2], E. Bonaparte[1], L. Fontana[1], C. Pesenti[1], N. Carlessi[1], A. Pirelli[1], R. Falcone[1], M. Chetta[3], S. Tabano[1], S. Sirchia[2], D. Milani[4].* 1) Division of Pathology, Fondazione IRCCS Ospedale Maggiore Policlinico; Université degli Studi di Milano, Milano, Italy; 2) Medical Genetics, Dept of Health Sciences, Université degli Studi di Milano, Milano, Italy; 3) GenomiX 4 Life, Université degli Studi di Salerno, Salerno, Italy; 4) Pediatric Highly Intensive Care Unit, Fondazione IRCCS Ospedale Maggiore Policlinico; Université degli Studi di Milano, Milano, Italy.

Brooks-Wisniewski-Brown syndrome (BWBS, OMIM: 300612) is a very rare genetic disease characterized by severe developmental delay, encephalopathy with atrophic hydrocephalus, microcephaly, progressive spastic diplegia, characteristic facial appearance, optic atrophy, growth retardation and high lactate levels. Based on the male preponderance of BWBS subjects in the two unrelated families studied so far, a recessive X-linked inheritance has been proposed. Furthermore, BWBS overlapping phenotype was described in a XLMR syndrome with severe optical atrophy and decreased vision, whose linkage analysis revealed the involvement of the Xq26 region. A family with clinical diagnosis of BWBS was counseled and studied by NGS-approach in our Institution. It was composed of non-consanguineous healthy parents and three male children: a healthy one and two with BWBS manifestations. We performed the chromosome X exome sequencing by Illumina HiSeq 1500 in the mother and in the three children. Variants annotation was carried out with “Enlis Genome Research” software that identified the single nucleotide unknown variant c. 916G>C within the exon 3 of the Heparan Sulfate 6-O-Sulfotransferase gene (*HS6ST2*). Base change was confirmed by Sanger sequencing and we did not find this variant in more than one-hundred subjects. *HS6ST2* maps in Xq26. In mice model HS6ST2 has a role in retinal neurogenesis, optic fissure closure and optical vesicle development. The 6-O-sulfation enzyme encoded by *HS6ST2* catalyzes the sulfate transfer from 3’-phosphoadenosine 5’-phosphosulfate (PAPS) to position 6 of the N-sulfoglucosamine residue (GlcNS) of the heparan sulfate (HS). HSs are ubiquitous components of the cell surface, extracellular matrix, basement membranes and interact with various ligands to influence cell growth, differentiation, adhesion and migration. The adult *HS6ST2* mutant animals develop optic nerve aplasia/hypoplasia and displayed retinal degeneration. From a preliminary bioinformatics analysis performed by PolyPhen-2, c. 916G>C variant resulted to be deleterious for the HS6ST2 protein structure and function, supporting its role in the onset of optic atrophy associated to BWBS. Our hypothesis requires to be confirmed by *in-vitro* and *in-vivo* functional studies.

2483T

Inherited loss of function mutation in *CASK* causing microcephaly-pontocerebellar hypoplasia: first report. *L. Pisani[1], H. Raynes[2,3], J. Forman[2], S. Desiraju[2], B. Webb[1].* 1) Dept. of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Dept. of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Dept. of Neurology, Icahn School of Medicine at Mount Sinai, New York, NY.

Mental retardation and microcephaly with pontocerebellar hypoplasia (MICPCH, OMIM #300749) is an X-linked disorder caused by heterozygous loss of function mutations or deletions in*CASK*(calcium/calmodulin-dependent serine protein kinase), located on chromosome Xp11. 4. The phenotype includessevere intellectual disability, microcephaly, variable degrees of pontocerebellar hypoplasia (PCH), very poor psychomotor development, absent ambulation or speech, axial hypotonia with or without hypertonia, and seizure disorder. The phenotype is significantly more severe in males, with perinatal lethality, early infantile epileptic encephalopathy (EIEE), opisthotonus, severe failure to thrive, and/or optic nerve hypoplasia. Dysmorphic features include broad nasal bridge and tip, large ears, long philtrum, micrognathia, and hypertelorism. All the cases thus far reported have been caused by *de novo* mutations. We report a 4 month old boy, born to nonconsanguineous Hispanic parents, presenting with microcephaly, infantile spasms unresponsive to topiramate, bilateral optic nerve hypoplasia, “back arching”, and severe failure to thrive. Upon evaluation, opisthotonus, absent tracking, poor head control, and absent social smile were noted. Facial features were notable for oval face, bilateral epicanthal folds, hypertelorism, low-set ears, high-arched palate, and micrognathia. Family history was reportedly unremarkable, but short stature, delayed speech response, slow processing, and possible staring episodes were noted in the mother. Brain MRI revealed pontocerebellar hypoplasia. Testing revealed 46, XY karyotype, and chromosomal microarray was unremarkable for copy number variation. Mutation analysis of*CASK*done as part of a NGS panel revealed a hemizygous p. M1? pathogenic variant in the translation initiation codon, previously reported in one male patient and shown *in vitro* to cause absence of protein expression. Targeted testing of the mother revealed she was heterozygous for the p. M1? pathogenic variant. . Formal neurologic evaluation and brain MRI were recommended for the mother, but have been deferred. Our patient is now 15 months old; he has received ACTH therapy and has received trials of various anti-epileptic drugs with no change in seizure frequency (6-7/day). Recent renal US revealed diffuse bilateral nephrocalcinosis, likely secondary to topiramate therapy. This is the first report of an inherited loss of function mutation in *CASK* causing the MICPCH phenotype.

Mild and Moderate Osteogenesis Imperfecta: A Retrospective Chart Review. *E. Carter, L. Tabanfar, J. Davis, C. Raggio.* Ctr Skeletal Dysplasias, Hosp Special Surgery, New York City, NY.

Background:OI is a heterogeneous genetic disorder characterized by bone and tissue fragility and skeletal deformities. Dominant mutations of the type I procollagen genes cause most cases; less common forms are due to mutation of collagen-interactive proteins. In 1979, Sillence et al classified OI into four types based on phenotype: mild type 1, moderate type 4, severe/progressive type 3, and perinatally lethal type 2. When a severe OI phenotype is present, a qualified physician can diagnose the disease. Milder phenotypes are more difficult to diagnose. We reviewed charts from individuals with mild and moderate OI for major clinical findings and genotype information. Hypothesis:Definitive determination of a diagnosis of mild/moderate OI is by direct genomic sequencing. Methods:Retrospective review of charts from patients diagnosed with mild/moderate forms of OI. Clinical findings (fracture frequency, blue/grey sclera, dentinogenesis imperfecta (DI), hearing loss, short stature, scoliosis, osteopenia/porosis, bone deformity, and ligament laxity) and molecular genetic test results were collected. Results:84 individuals (44 female, 40 male; age range 1 months to 84 years) were identified as having classic OI types 1, 4, or a non-classical mild/moderate type. 35 patientshad genotype information available (41. 67%). 30 haddominant mutation in either *Col1a1/1a2* (85. 7%). 8 had non-classical types (*IFITM5, Wnt1, PPIB*). Fifty-one had type 1 OI; 19 (37. 2%) had documented *Col1a1/1a2* haploinsufficiency mutations. Type 1 OI clinical findings: 71% had blue sclerae, 24% had DI, 27% had hearing loss, 57% had osteopenia/porosis, and 14% had bone deformity. Patients reported 0 to 300 fractures. Twenty-five had type 4 OI; 11 (44%) had documented *Col1a1/1a2* mutation. Type 4 OI clinical findings: 64% with DI, 28% with hearing loss, 35% with bone deformity, 48% with osteopenia/porosis; 36% had blue/gray sclerae, 40% had white sclerae, and 24% reported having blue/gray sclerae during childhood. Patients reported 0 to 200 fractures. Conclusion:The majority of patients clinically diagnosed with mild or moderate OI did not have molecular genetic confirmation. Genotype did not correlate with fracture number. Clinical findings in our cohort were consistent with those reported in other patients with types 1 and 4 OI. Our sample size was too small to draw statistically significant conclusions. We will continue to review phenotype/genotype information from patients with mild/moderate OI.

2485W

Clinical and Molecular Assessment of 78 OculoAuriculoVertebral Spectrum (OAVS [MIM 164210]) patients. *S. Bragagnolo[1], M. E. Colovati[2], M. F. S. Soares[3], C. A. Kim[4], M. I. Melaragno[2], A. B. A. Perez[1],* *Financial support: FAPESP 2013/04623-2.* 1) Genetic Medical Center, UNIFESP, Sao Paulo, Sao Paulo, Brazil; 2) Mophology and Geneic Department, UNIFESP, Sao Paulo, Brazil; 3) Imaging Department ,UNIFESP, Sao Paulo,Brazil; 4) Children Institute, USP, Sao Paulo,Brazil.

Purpose: Clinical characterization and classification of OAVS patients following the minimum criteria from Tasse et al (2007): facial asymmetry with asymmetric and/or preauricular pits or tags. Methods: We assessed 78 patients, 55 male and 24 female, with the protocol based in the Tasse et al. (2007) and Golgoutas e cols. (2005) criteria. Results: 23(28%) cases are familial and the remaining is sporadic (72%). 61 patients performed a craniofacial X ray and 52 (85%) presented with abnormalities. 64 patients performed spinal X ray and 47 (73%) presented with abnormalities. 55 patients performed temporal bones CT scan and 41 (74%) presented with abnormalities. 62 patients performed audiology evaluation and 50 (81%) presented some hearing loss. 45 patients performed a nasofibroscopy and 28 (62%) presented with abnormalities. 54 patients performed ophthalmologic evaluation and 32 (59%) presented with some kind of abnormality: 12 patients (22%) were diagnosed with a epibulbar dermoid. 64 performed an Echocardiogram and 42 (65%) presented with abnormalities. 62 patients performed a renal ultrasound and 26 (41%) presented with abnormalities. 27 (35%) patients were detected with some abnormalities in other systems and organs. 67 patients performed KT analysis and 9 (13%) presented with chromosomal abnormalities. 67 patients performed CMA and 29 (43%) patients presented altered results 16 (19%) variants considered pathogenic 13 (19%) variants of unknown significance. In between the pathogenic 8 (50%) were duplication, 7 (44%) were deletions (44%) and one del/dup (6%). 7 patients (44%) presented with a chromosome 4 alteration, 5 (32%) in the short arm (2 deletions and 3 duplications) and 2 (12,5%) in the long arm (1 duplication and 1 deletion). Discussion: The clinical assessment allowed us to classify these patients within the OAV spectrum and the phenotypic association was compatible with the literature. CMA provided a much more accurate laboratorial diagnose than the KT analysis and we could observe recurrent chromosomal abnormalities especially on regions 4p15. 33, 4p16. 1 (two patients), 4p16. 3p15. 33, 4p16. 3, 8q13. 3 e 22q11. 21. These regions contain genes related to phenotypes associated to OAVS, like: *NKX3-2* (*BAPX1* [MIM 164210]); *HMX1* [MIM 612109]; *EYA1* [MIM 166780]; and *YPEL1* e *MAPK1* (*ERK2)*, in 22q11. 2.

2486T

Performance of Facial Dysmorphology Novel Analysis: comparison to molecular testing-based diagnostics. *L. Basel-Vanagaite[1,2,3], S. Lyonnet[4], V. Cormier-Daire[4], M. Rio[4], J. Amiel[4], L. Wolf[2,3].* 1) Rabin Medical Center, Petah Tikva, Israel; 2) Tel Aviv University, Tel Aviv, Israel; 3) FDNA Ltd. , Herzlyia, Israel; 4) Université Paris Descartes-Sorbonne, Imagine Institute, Hôpital Necker Enfants Malades, Paris, France.

Introduction: Facial Dysmorphology Novel Analysistechnology automatically identifies facial patterns associated with genetic syndromes by analyzing two dimensional facial photos. We evaluated the technology's ability to retrieve a gestalt-based list of syndromes that matches molecularly confirmed diagnoses of individuals. Methods: 130 anatomical points were automatically located on the face and multiple lengths, angles and ratios were computed for each face. Local image information was integrated in order to provide the gestalt description of the face. We analyzed 331 frontal images of Caucasian children with 43 different molecularly confirmed genetic syndromes including chromosomal and monogenic syndromes. The images were submitted by clinical geneticists. Each image received a list of syndromes ranked by gestalt-based similarity. Results: The molecularly confirmed diagnosis was listed in the first 20 matches for 89% of the cases, 10 for 75% of the cases, 5 for 69% of the cases, 2 for 54% of the cases and as the first result for 40% of the cases. Statistically, the chances of obtaining such results are close to zero ($p<1e-100$). However, since some syndromes are more common than others, we ran permutation tests. Mixing the images and the diagnosis randomly, the rank 1 retrieval was less than 5%. For microdeletion syndromes, the best performance was observed for Angelman syndrome (listed in the first 5 matches in 93% of the cases) as compared to Williams syndrome and velo-cardio-facial syndrome (86% and 67%, respectively). For monogenic syndromes, SHORT Syndrome, Kaufman oculocerebrofacial syndrome and auriculo-condylar syndrome were ranked as correct 1st match in all cases. Conclusions: We conclude that a system supported with Facial Dysmorphology Novel Analysistechnology can be useful for medical professionals in diagnosing genetic syndromes. Future applications include: 1) guiding targeted molecular testing; 2) complementing next generation sequencing-based molecular testing by inferring causative genetic variants from sequencing data; 3) assisting in diagnostics in a country where molecular testing resources are poor and clinical diagnosis is therefore important.

Molecular Pathogenesis of Congenital Diaphragmatic Hernia Revealed by Family Based Genetic Strategies, Next Generation Sequencing and Bioinformatics. *H. Shanmugam[1], N. Matsunami[2], L. Baird[2], J. Stevens[2], B. Otterud[2], C. Rau[1], S. Baker[1], N. Bowels[2], M. Leppert[2], L. Brunelli[1].* 1) Department of Pediatrics-Neonatology, University of Utah Health Sciences Center, Salt lake city, UT; 2) Department of Human Genetics, University of Utah Health Sciences Center, Salt Lake City, UT.

Background: Congenital diaphragmatic hernia (CDH) is a severe birth defect with high morbidity and mortality. Despite the clinical significance of CDH, the molecular causes underlying the defect are not completely understood. CDH is considered to be a multifactorial disease, with strong evidence implicating genetic factors. Although aneuploidies and copy number variants are important in CDH, few single genes have been definitively implicated in human CDH. **Aim**: We aim to identify the pathogenic variants leading to syndromic and isolated CDH using family-based genetic strategies and next generation sequencing. **Methods**: After IRB approval, we recruited a syndromic trio with unaffected parents and a daughter with duplication of pituitary gland syndrome and CDH. Additionally, we recruited a highly penetrant three-generation isolated CDH family with an affected grandfather, an affected father, and two affected daughters. Whole exome sequencing was carried out on each blood DNA. DNA sequence was analyzed by BWA/GATK and Novoalign/GATK. Variant filtering, classification and prediction were performed using Golden Helix SNP & Variation Suite. Genetic analysis was carried out using recessive, compound heterozygous, and *de novo* models in the syndromic trio. Dominant model and variant sharing analysis among affected individuals were used for the three-generation isolated CDH family. Finally, we used pVAAST (Hu et. al. , *Nat Biotechnol* 2014) to prioritize variants. Candidate variants were validated by Sanger DNA sequencing. **Results:** In the syndromic CDH trio, we identified two *de novo*missense mutations in *H1ST1HE* and *FILIP1* genes. In the three-generation isolated CDH family, we identified about 50 rare functional variants inherited from the affected grandfather. The best candidates scored by pVAAST analysis include two missense variants in *PPARD* and *CWF19L1* genes, a nonsense variant in *STOX1* gene, and a frame-shift variant in *MYO1C* gene. We are currently testing some of these variants in mice. **Conclusion**: The combination of family based genetic strategy with next generation sequencing and bioinformatics reveal two *de novo* mutations in a syndromic CDH trio and the role of heritability in a three-generation isolated CDH family. By defining the spectrum of genes associated with CDH, we will be able to define common molecular causes of CDH and define the clinical syndromes associated with these genes to inform prognosis and hopefully guide treatment.

2488W

Fragile X syndrome and periventricular heterotopia: one or two syndromes? *A. Lavillaureix[1,8], M. Gerard[2], M. Baulac[3], S. Drunat[1,4,5], C. Beldjord[6,7], A. Verloes[1,4,5], S. Passemard[1,4,5].* 1) Département de Génétique, Hôpital Robert Debré, Paris, France; 2) Département de Génétique, Hôpital de Caen, Caen, France; 3) Department de Neurologie, Hôpital Pitié-Salpêtrière, Paris, France; 4) INSERM U676, Hôpital Robert Debré, Paris, France; 5) Université Paris Diderot, Paris 7, Paris, France; 6) Département de Biologie Moléculaire, Hôpital Cochin, Paris, France; 7) Département de Génétique et Développement, Inserm U1016, Institut Cochin, Paris, France; 8))Université Paris Descartes, Paris 5, Paris, France.

Children carrying Fragile X full mutation exhibit mild to severe intellectual disability, behavioral disorders and a higher risk of seizures. Epilepsy occurs in 12% of Fragile X syndrome patients, beginning between 4 and 10, with a higher prevalence in males than in females. Although evidences suggest that migration disorders may be observed in Fragile X syndrome, the origin of seizures is not systematically sought and brain MRI is rarely performed in these patients. Here we describe periventricular heterotopia (PVH) in two siblings, a male and a female, with Fragile X full mutation. The boy, with intellectual disability, because of abnormal movements during sleep, had investigations that brought out unilateral PVH at age 10. His sister presented late onset, drug resistant epilepsy beginning at age 18, and extensive bilateral laminar and nodular periventricular heterotopia. PVH has been only described in four males with Fragile X syndrome and has never been reported in females. We discuss here the interest of investigating these patients with brain MRI for the developmental and epilepsy follow-up and confirm that PVH may be caused by Fragile X mutation in males and should suggest other etiologies in females, such as FLNA mutation, even in a context of Fragile X full mutation.

-238 Tumor necrosis factor-alpha gene polymorphism in Periodontitis patients. *R. P. Mariaud-Schmidt[1], M. G. Fuentes-Lerma[2], J. R. Gomez-Sandoval[1], V. C. Martinez-Rodriguez[3], I. A. Gutierrez-Hurtado[4], M. P. Gallegos-Arreola[4].* 1) Instituto de Investigación en Odontología, Universidad de Guadalajara, Guadalajara , Mexico; 2) Departamento de Clinicas, Centro Universitario de los Altos, Universidad de Guadalajara, Mexico; 3) Posgrado en Periodoncia, DECOI, Universidad de Guadalajara, Mexico; 4) Laboratorio de Genetica Molecular, CIBO-IMSS, Guadalajara, Mexico.

Abstract*Background.* Periodontal disease is triggered by bacteria, predominantly Gram negative anaerobes, which produce inflammatory mediators leading to the destruction of connective gingival tissue and dental alveolar bone. Cytokines as tumor necrosis factor alpha (TNF-α) induces periodontal disease. TNF-α is a key mediator of the inflammatory process and the same cytokine gene polymorphism has been associated with periodontal disease, although such results remain controversial. The aim of the present study was to evaluate the frequency of –238 TNF-α gene polymorphism in periodontal disease patients. *Material and Methods*. The protocol was approved by the local clinical ethics committee and a written explanation of the purpose of the study was provided for each subject and signed consent according to the Helsinki Declaration was obtained for the genetic analysis. 77 periodontitis patients and 49 control subjects were enrolled in the study. Blood sample were taken from participants and DNA extraction was made by the Miller and Gustincich method and stored frozen at -20°C until use. TNF-alpha SNPs was genotyped by polymerase chain reaction-restriction fragment length polymorphism for all subjects. *Results*. All 77 patients enrolled in the study had clinical and biological features of chronic periodontitis (periodontal disease). 69 (90%) patients had GG genotype, 7 (9%) patients had GA genotype and only one patient (1%) had AA genotype. The control subjects 42 (86%) had GG genotype, 6(12%) had GC genotype and 1 (2%) had AA genotype. Statistical analysis. We used *X2* test for frequencies determination. Non significative difference was observed. *Conclusion.* Genetic polymorphism in the TNF-alpha gene at position-238 could not be identified as susceptibility factor in chronic periodontitis.

Complex chromosome 6 aberration in two sisters with MR and MCA derived from a maternal paracentric inversion. *F. A. T. de Vries[1], G. M. S. Mancini[1], F. Bal-van Breda[1], W. Y. Cheung[1], G. C. B. Bindels-de Heus[2], C. H. Wouters[1].* 1) Department of Clinical Genetics, ErasmusMC, Rotterdam, Netherlands; 2) Department of Pediatrics, ErasmusMC, Sophia Children's Hospital, Rotterdam, Netherlands.

Two sisters aged 5 and 3 with developmental delay, behaviour problems, excessive drooling, short stature, respiratory distress and stridor caused by narrow trachea, strabismus and very similar facial featureswere investigated with SNP array analysis. Besides two losses in the X-chromosome (p22. 33) and in chromosome 7 (p21. 2p21. 1), both inherited from the healthy mother, two duplications were detected in chromosome 6 (q14. 1 and q16. 1) together with a deletion (q23. 3q24. 1). Parental array analysis showed a normal pattern for the chromosomes 6. FISH performed on parental chromosomes showed a paracentric inversion of one of the chromosomes 6 (q14. 1q24. 1) from the mother. A meiotic recombination of the paracentric inversion could not result in the exact same derivative chromosome 6 found in both daughters. Moreover the resolution of the dicentric chromosome after meiotic recombination would result in a derivative chromosome with a single interstitial duplication and a terminal deletion. The only conclusion has to be that the mother is a mosaic, the inv(6) will be present in the mature part of her cells, and the similar der(6) (resulting from a mitotic recombination), as found in her daughters, will be (at least) present in her germ line. This is an unusual case of high recurrence risk for a pathogenic rearrangement in a healthy woman who is carrier of a paracentric inversion, generally considered a low risk chromosome aberration. In the prenatal counseling, this is an apparent exception to the general rule that paracentric inversions should not be offered invasive prenatal diagnosis.

2491F

Formation of triplications by a template switching mechanism can contribute to disease phenotype in humans beyond formation of simple copy-number gain. *C. M. B. C. Fonseca[1], N. A. Hanchard[1], B. Yuan[1], P. Stankiewicz[1], J. W. Belmont[1,2], S. W. Cheung[1], V. R. Sutton[1,3], P. I. Bader[4], J. R. Lupski[1,2,3].* 1) Dept Molecular Human Genetics, Baylor Col Medicine, Houston, TX; 2) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 3) Texas Children's Hospital, Houston, TX; 4) Northeast Indiana Genetics, Fort Wayne, IN.

Segmental triplications (copy number N = 4 in autosomes and N = 3 when on male X-chromosome) can contribute to disease etiology via gene dosage effects, gene disruption, position effects or fusion gene formation. We have recently published five cases for which the triplications were formed in association with a distal absence of heterozygosity (AOH) extending to the telomere on the same chromosome (PMID: 25799105). These regions of AOH ranged in size from 6 Mb to 50. 3 Mb in length. The genomic structure of those post-zygotic complex genomic rearrangements (CGRs) shows a consistent pattern of an inverted triplication flanked by duplications (DUP-TRP/INV-DUP) and is hypothesized to be formed by replication-based mechanisms such as microhomology-mediated break induced replication (MMBIR) and fork stalling and template switching (FoSTeS). We now report a patient who carries a 2. 1 Mb DUP-TRP/INV-DUP followed by 42. 2 Mb of AOH involving chromosome 14 identified by array comparative genomic hybridization and breakpoint junction sequencing. Using SNP array OmniExpress (Illumina) we determined that the segmental AOH occurred on the maternally inherited chromosome and therefore this patient has a high risk to present with clinical features of maternal uniparental isodisomy for chromosome 14 (UPD(14)mat) [MIM#616222] as well as for expression of recessive traits. Infinium Human Methylation450 Beadchip (Illumina) in samples extracted from this patient, unaffected family members and previously known UPD14 patients (both maternal and paternal) revealed that the genomic DNA of this patient shows methylation patterns typical of UPD(14)mat at both known (*MEG3* promoter) and novel (intron 2 of *MEG8*) differentially methylated regions along the *DLK1-DIO3* domain. This data provide experimental evidence that, in humans, triplication generated post-zygotically can lead to segmental UPD. Furthermore, the impact on the disease phenotype resulting from the underlying replication-based mutational mechanism in humans can extend beyond that due to the formation of copy-number variants.

2492F

A case of partial trisomy 21q resulting from meiotic recombination of a maternal pericentric inversion. *S. Jung[1], K. Lee[2], M. Jang[1], C. Chi[1], K. No[1], K. Lee[1].* 1) Molecular Diagnostics Testing Center, Seegene Medical Foundation, Seoul, South Korea; 2) Department of Physics, Kangwon National University, Chuncheon, South Korea.

Down syndrome (DS) is a genetic disorder caused by an extra copy of chromosome 21. In rare cases, DS is associated with a partial trisomy 21 and less than 3% of DS patients have duplication as a result of parental pericentric inversion of chromosome 21. Here we report the case of a two-month-old girl with features of DS but with an atypical karyotype. Initial chromosome analysis of peripheral blood lymphocytes was 46,XX-,21p+. To identify the extra chromosomal material on 46,XX,21p+, parental chromosome study was performed. The results showed a normal paternal karyotype (46, XY) and an abnormal maternal karyotype [46,XX-,inv(21)(p12q22. 1)]. The fluorescence in situ hybridization (FISH) study of the patient was performed. The interphase FISH analysis with Vysis LSI ETV6(TEL)/RUNX1(AML1) ES Dual Color Translocation Probe showed three signals of the probe for 21q22. The metaphase FISH showed two hybridization signals of 21q22 within one chromosome 21 homologue. According to FISH and parental karyotype results, her karyotype was designated as: 46,XX,rec(21)dup(21q)inv(21)(p12q22. 1)mat. ish rec(21)dup(21q)inv(21)(p12q22. 1)(RUNX1++). nuc ish(RUNX1x3). To our knowledge, this is the 1st report in Korea of a DS patient with rec(21)dup(21p).

2493F

Clinical, cytogenetic and molecular evaluation of a phenotipically male patient with a karyotype of 46, XX but bearing an intact SRY loci: a case report. *H. Bagis[1], M. O. CEVIK[1], A. CIFT[2], I. GUNEY[1].* 1) Department of Medical Genetics, Adiyaman University School of Medicine , Adiyaman, Turkey; 2) Adiyaman University School of Medicine Department of Urology, Adiyaman, Turkey.

OBJECTIVE:The objective of this study was to analyze of clinical, cytogenetic and molecular features of a 46,XX phenotypically male SRY positive patient in terms of infertility. METHODS:The clinical features of a phenotypically male patient with 46, XX (SRY positive) were reported. Chromosome analysis showed a 46, XX karyotype and translocation of SRY (testis-determining factor) was detected by fluorescence in situ hybridization (FISH) and molecular analysis of AZF microdeletions on the Y chromosome were performed by multiplex PCRs amplification. The set of PCR primers for the diagnosis of microdeletion of the AZFa, AZFb and AZFc region included: sY81a, sY84, sY86, sY87, sY88, s128a, sY121b, sY124c, sY127, sY128, sY130, sY133, sY134, sY143b, sY145, sY152, sY157, sY158, sY160, sY254, sY255c, SRY and ZFX/ZFY. RESULTS:A 24 year old married man was referred to urology clinic with a 4 year history of infertility due to male partner. No gynaecomastia was noted and his facial, axillary and pubic hair was all of normal density and distribution. Physical examination revealed that his testes were small in volume and soft in texture and has a bilateral varicocele, but his penis phenotype was normal. Semen analyses showed complete azoospermia. All were karyotyped as 46, XX. Molecular analyses display the presence of the SRY gene and absence of AZFa, b and c of the Y chromosome. FISH analysis showed that SRY genes were translocated to X. CONCLUSION:Classical, molecular cytogenetic and molecular genetics tests on 46,XX male syndrome may help to explain its genotype-phenotype relationships. Our laboratory test results suggest that genetic counseling useful information in these infertile men before starting assisted reproductive treatments.

High incidence of CNVs in patients with oculo-auriculo-vertebral spectrum disorders. *S. Oliveira[1 2], P. Costa dos Santos[2], C. Pereira de Oliveira[3], A. Bastos de Oliveira[2], H. Safatle[4], M. Santos Cordoba[4], M. T. Silva Rosa[4], C. Rosenberg[5], E. Freitas[5], E. Ribeiro[6], R. Pogue[7], R. Pereira[7], I. Ferrari[1], H. Mestrinho[1], A. Pic-Taylor[1 2], J. Mazzeu[2 3 8].* 1) Genetica e Morfologia, Universidade de Brasilia, Brasilia, Brasilia (Distrito Federal, Brazil; 2) Programa de Pós-graduação em Ciências da Saúde, Universidade de Brasília, DF, Brazil; 3) Programa de Pós-graduação em Ciências da Médicas, Universidade de Brasília, DF, Brazil; 4) Ambulatório de Genética, Hospital Universitério de Brasília, Universidade de Brasília, DF, Brazil; 5) Departamento de Genética e Biologia Evolutiva, Instituto de BioCiências, Universidade de São Paulo, SP, Brazil; 6) Hospital Infantil Albert Sabin, Genética Médica, Fortaleza, Ceará, Brazil; 7) Programa de Pós-graduação em Ciências Genómicas e Biotecnologia, Universidade Católica de Brasília, DF, Brazil; 8) Área de Clínica Médica, Faculdade de Medicina, Universidade de Brasília.

Oculoauriculovertebral spectrum (OMIM 164210) is characterized as a developmental defect involving the first and second branchial arch derivatives. This spectrum is clinically broad, ranging from isolated microtia to multiple visceral malformations and it includes the Goldenhar Syndrome. Main clinical features include unilateral or bilateral ear anomalies, hemifacial microsomia, ocular defects and vertebral malformations. Other features are cleft lip and/or palate; cardiac, renal, cerebral malformations; and mental retardation. Most cases are sporadic, but there are familial cases that exhibit autosomal inheritance. Genetic, environmental and multifactorial etiology, especially events that occur during the seventh week of pregnancy, were described. Therefore, OAVS is a clinic and genetically heterogeneous disorder that demands a better understanding. This work performed chromosomal microarray analysis in 26 patients with OAVS in order to identify new genomic loci that are potentially involved in disease pathogenesis. This study was approved by the institutional ethics committee and families provided written informed consent. As expected, results showed a large heterogeneous genetic etiology. No chromosomal abnormalities other than already described polymorphic CNVs were found for 53. 8% of the cases. Diagnosis of normal chromosomal microarray was determined as no rearrangements or chromosomal rearrangements that had been described as non-pathogenic CNVs in DGV database. New chromosomal rearrangements were found, as follows: del22q11. 2, del12q24. 21, LOH 3p26. 3-14. 3, del2p25. 3 and dup2p25. 3, dup4q21. 1, dup20p12. 3-12. 2, dup1q31. 1 and dup10q23. 31, dup11p15. 5, LOH 12q15-q22, dup12p12. 1 and dup6q21. Analysis of inheritance showed that three of these rearrangements were *de novo*, one maternally inherited and one paternally inherited. In seven patients the origin of the rearrangements were not determined. The chromosome abnormalities identified are non-recurrent. This is the first time that these CNVs are described, except for the deletion of 22q11. 2 and 20p12. 2 duplication. These results confirm the genetic heterogeneity of the syndrome and describe new genomic regions and genes involved in its etiology. Acknowledgement: FAP-DF; CAPES; CNPQ;PPSuS.

Genome-wide association study of copy number variation in a Thai autism spectrum disorder cohort. *N. Jinawath[1,2], A. Hnoonual[3], W. Thammachote[1], T. Pongrujikorn[1], MS. Shiao[1], P. Phokuanoy[4], T. Tim-Aroon[5], K. Rojnueangnit[6], T. Hansakunachai[6], P. Limprasert[3], N. Ruangdaraganon[7], D. Wattanasirichaigoon[5], B. Suktitipat[8,2].* 1) Research Center, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 2) Integrative Computational Bioscience Center, Mahidol University Salaya Campus, Nakhon Pathom, Thailand; 3) Division of Human Genetics, Department of Pathology, Faculty of Medicine, Prince of Songkla University, Songkla, Thailand; 4) Department of Pathology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 5) Division of Medical Genetics, Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 6) Department of Pediatrics, Faculty of Medicine, Thammasart University, Pathumthani, Thailand; 7) Division of Developmental-Behavioral Pediatrics, Department of Pediatrics, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 8) Department of Biochemistry, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Autism spectrum disorder (ASD) is an array of neurodevelopmental disorders characterized by difficulties in social interaction, verbal and non-verbal communication, and stereotyped behaviors and interests. The cause of ASD is still largely unknown, but there is a strong genetic link. Since 2010, the use of cytogenomics microarray (CMA) for detection of copy number variation (CNV) has been recommended as a first-tier genetic test for individuals with ASD in the US. In Thailand, the incidence of ASD is currently on the rise, with an incidence rate of 9. 9:10,000 in children aged 1-5 years. It is estimated that the average health care costs for individuals with ASD are 4-6 times more than those of general population, emphasizing the socioeconomic importance of ASD in Thailand. In this study, we employed Illumina CytoSNP-850K to detect CNVs in the 55 Thai patients who met the DSM-IV criteria for non-syndromic ASD, had normal karyotype, and a negative Fragile X and *MECP2* testing. CNV locations were identified using BlueFuse Multi, an HMM-based algorithm, to detect CNVs with at least 10 probes coverage. After excluding CNVs that overlapped with pericentromeric regions, we identified a total of 371 CNVs in all patients. The median number of CNVs found was 6 per patient, ranging from 2 to 14. The CNV size ranged from 1,632bp to 4. 5Mb, with a median of 90kb. The overall diagnostic yield of CMA in the Thai ASD cohort was 15%, which is comparable to the reported yield in other studies. ASD-associated pathogenic CNVs that cause 15q13. 3 microdeletion syndrome and 16p13. 11 microduplication syndrome were among the pathogenic CNVs identified in these patients. Furthermore, the genes overlapping with CNVs in ASD cohort were then compared with those of CNVs from the 3,017 general Thai subjects previously reported in the Thai CNV database. Using 50,000 permutation-based association tests, implemented in PLINK, CNVs overlapping with *NOTCH2* (1p12), *HBM* (16p13. 3), and *CYP2A7* (19q13. 2), and *PCDH11X* (Xq21. 31) were significantly associated with ASD (genome-wide corrected p-value < 0. 05). Interestingly, both *NOTCH2* and *PCDH11X* are expressed in the brain, and have been previously linked to developmental delay, as well as dyslexia. In summary, this is the first report of genome-wide association study of CNV in Thai ASD subjects. Our findings may contribute to the identification of novel autism-associated genes and elucidation of the underlying genetic basis of ASD.

***De Novo* Assembly of the Genome-in-a-Bottle Reference Ashkenazi Trio, Structural Variation Discovery and Comparison with Other Individuals by Genome Mapping.** *A. Hastie, E. T. Lam, T. Liang, A. Pang, S. Chan, Z. Džakula, H. Cao.* BioNano Genomics, Inc. , San Diego, CA.

Structural variation analysis (SVA) of human genomes is usually a reference-based process and therefore biased and incomplete. In order to have a comprehensive analysis of structural variation, a *de novo* approach is needed. As a result of the remaining limitations of DNA sequencing and analysis technologies, it is not feasible to create high quality *de novo* assemblies of individuals for detecting and interpreting the many types of structural variation that are refractory to high-throughput or short-read technologies. Using a single-molecule genome analysis system, the Irys® System, we produced high resolution genome maps that were assembled *de novo*. These maps preserve long-range structural information necessary for structural variation detection. The Genome in a Bottle reference trio of Ashkenazi Jewish decent (NA24385, NA24149, NA24143) has been *de novo* assembled by the Irys System. Structural variation analysis reveals insertions, deletions, inversions, including large deletions in the UGT2B17 gene (involved in graft versus host disease, osteopathic health and testosterone and estradiol levels) in the mother and son. We have also investigated the amylase locus in this trio as well as ~ 20 other individuals and have found at least 15 different structural variants. Human amylase genes have variable copy number and this variation is believed to have been evolved to adapt to increase starch intake. We were able to identify multiple copy neutral variants, such as inversions, in these individuals.

Danish Central Cytogenetic Register: Population-based survival analysis of mental disorders among carriers of chromosomal abnormalities. *L. Høffding[1], BB. Trabjerg[2], A. Vangkilde[1], L. Olsen[1], C. Bøcker Pedersen[2], T. Werge[1], W. Mazin[1].* 1) INSTITUTE OF BIOLOGICAL PSYCHIATRY, Mental Health Services of Copenhagen , Copenhagen, Denmark; 2) Centre for Integrated Register-based Research National Centre for Register-based Research, Aarhus University, Business and Social Sciences, Aarhus V, Denmark.

Aim: To examine the risk of psychiatric disease in individuals recorded in the Danish CentralCytogeneticRegister **(**DCCR) as carriers of chromosomal abnormalities**Background:** Chromosomal abnormalities conferring moderate to high risk of psychiatric disorders have in the later years been identified (1). However, there is still little knowledge on the clinical and epidemiological consequences at the population level of these genomic variants, including the clinical manifestation, disease trajectories, treatment response and social outcome. The Danish Cytogenetic Central Register (DCCR) was established in 1960 and prospectively collects all pre- and postnatal results from individuals clinically referred to genetic testing throughout Denmark. **Methods:** As an example, we identified and extracted all individuals in DCCR carrying the 22q11. 2 microdeletion in Denmark (N=270). Each individual was linked by their unique personal identification number to the Danish nationwide registers and survival analysis using Poisson regression was conducted and adjusted for the following covariates: sex, age, calendar time, place of birth, maternal and paternal age, parental origin and family history of psychiatric disorders. **Results:** The basic model showed an incidence rate ratio (IRR) in carriers of the 22q11. 2 microdeletion for schizophrenia of 8. 13 (95% CI: 3. 65-18. 09). The adjusted IRR of schizophrenia was 6. 55 (95% CI: 2. 94-14. 59). Thus, 22q11. 2 microdeletion carriers have a significantly increased risk of developing schizophrenia compared to the general Danish population qualifying previous association findings (1,2). **Perspectives:** We will report data from similar analysis applied to other chromosomal abnormalities identified in the DCCR including the 22q11. 2 microduplication, Turners and Kleinfelter syndrome. Survival analysis of clinically identified individuals carrying chromosomal abnormalities provide risk estimates for disease useful in genetic counseling and guidance of symptomatic monitoring and early clinical intervention. **References:**1. Concurrent loss of heterozygosity and mosaic deletion 12p. *J. F. Mazzeu[1,2,4], R. S. Faria[2], C. P Oliveira[2,3], M. T. A. S. Rosa[2,3], M. S. Cordoba[4], A. P. Taylor[5], S. F. Oliveira[5], I. Ferrari[1,4].* 1) Faculdade de Medicina, Universidade de Brasilia, Brasilia, Brazil; 2) Programa de Pós-graduação em Ciências Médicas, Universidade de Brasília, Brasília, Brazil; 3) Hospital de Apoio de Brasília, Brasília, Brazil; 4) Hospital Universitério, Universidade de Brasília, Brasília, Brazil; 5) Departamento de Genética e Morfologia, Universidade de Brasília, Brasília, Brazil.

Deletions of the short arm of chromosome 12p are the rarest subtelomeric imbalances. Less than 20 patients have been reported to date, of which microdeletions were identified either by FISH or array-CGH without SNP data. Here we describe a patient with a mosaic 12p microdeletion and loss of heterozygosity (LOH) extending to the distal adjacent segment. Clinical examination at age nine revealed intellectual disability, short stature, facial dysmorphims including a small face, small downslanted palpebral fissures, protruded ears with overfolded helices, high nasal root, overbite, high narrow palate, retrognathia, irregular dental implantation and clinodactyly. Chromosome microarray analysis using Cytoscan HD platform (Affymetrix) disclosed a deletion in mosaic on the terminal portion of the short arm of chromosome 12 affecting bands p. 13. 33-p. 13. 32 within genomic positions chr12:1-4, 576,632 (hg19). SNP data revealed loss of heterozygosity at the deleted segment extending 4 Mb in the distal adjacent segment. To the best of our knowledge this is the first report of LOH in constitutional 12p rearrangements. Our patient presents a rearrangement appearing in mosaic, which could the result of a post-zygotic mitotic event, consistent with an error in DNA replication during mitosis, as proposed by the MMBIR model. Since previously reported cases were not investigated by SNP arrays we cannot speculate as to whether this mechanism is recurrent in the formation of 12p microdeletions. This study was approved by the institutional ethics committee and the family provided written informed consent.

2499F

Two sisters with similar phenotype, a shared unbalanced translocation, and discordance for a microdeletion. *A. Nastro[1], A. Shrimpton[2], N. Dosa[1], R. R. Lebel[1].* 1) Center for Development, Behavior, and Genetics, SUNY Upstate Medical University, Syracuse, NY; 2) Department of Pathology, SUNY Upstate Medical University, Syracuse, NY.

Two sisters presented with dysmorphism and global developmental delays, the elder more severely impaired (aggressive and destructive behavior) than the younger. They were examined at 27 and 23 years of age. They had emigrated from Poland as children; chromosome analysis there had documented 8p dup and a balanced 8p;11p translocation in their father. Microarray analyses at our clinic revealed an identical unbalanced translocation involving a loss of 11p15. 5 and a 26. 6 MB duplication of 8p21. 2-p23. 3 (the segment known to be translocated onto 11p). The 8p duplication involves 107 genes, while the 11p15. 5 deletion involves none. The younger sister also has a 1. 33 MB deletion at 10p11. 22 (variant of unknown clinical significance), that is not found in the elder sister not seen in the younger. Both sisters had underdeveloped breasts, abnormal EEG, a wide mouth, multiple nevi on the torso, a vocabulary consisting of only a few words that only the parents understand. The younger sister has a prominent forehead, square face, and decrescendo systolic murmur (all absent in the elder). The 10p11. 2 VUS includes only four genes, and hemizygosity for these is not known to be pathogenic. Thus 8p duplication probably is the sole cause of their adverse phenotypes. The small literature on 8p duplication generally involves inverted duplication. We found no report of 8p dup translocated to 11. Literature about 8p23. 1 duplication syndrome (which is implicated in marked developmental and speech delays), suggests that only four genes appear to clearly be dosage sensitive: *GATA4*, *TNKS1*, *SOX7*, and *XKR6*. Our patients have the first three of these genes duplicated. *TNKS1* is implicated in behavioral problems, *SOX7* in developmental delay, *GATA4* and *SOX7* both may cause heart defects, and the role of *XKR6* is not currently known. The family history is significant for multiple spontaneous miscarriages in the paternal grandparents, and in the father's brother's union, raising the possibility of a translocation segregating in the family. There was also a paternal half-brother who died at one hour of age due to "a spinal abnormality".

2500F

Mosaic supernumerary marker with Y chromosome material detected by NIPT in a newborn female. *V. Potluri[1], R. Burnside[2], G. S. Sekhon[3], H. Xie[3], L. Kline[2], P. Papenhausen[2].* 1) Div Lab Corp America, Dynagene, 3701 Kirby Dr, Suite 528, Houston, TX 77098; 2) Laboratory Corporation of America (R) Holdings, Research Triangle Park, NC 27709; 3) Integrated Genetics, 2000 Vivigen Way, Santa Fe, NM 87505.

Gender discrepant results from NIPT testing have been reported in the literature, the etiology of which is not always clear. Additionally, NIPT results may indicate a structural abnormality for which further invasive prenatal or postnatal testing is required to clarify. A newborn phenotypic female was referred for chromosome analysis and SNP microarray analysis due to NIPT results in which Y chromosome material was detected. Specifically, the NIPT report described the presence of Yp material and the absence of detectable Yq material. Invasive prenatal testing was declined, but placental villi, and peripheral blood from the neonate were sent for further cytogenetic study. Chromosome analysis revealed a mosaic supernumerary marker chromosome in 15 out of a total of 20 cells. Further FISH studies showed that the marker was negative for SRY, explaining the female phenotype. Using DYZ1 and DYZ3, the marker was positive for only DYZ3. Concurrent microarray analysis from the peripheral blood specimen detected a 979 Kb duplication at 1q43 [hg19] (241,108,507-242,087,176), 596 Kb triplication of 5q14. 3 [hg19] (83,523,414-84,119,787), two gains at Yp11. 2 (260 kb and 2. 51 Mb) and two gains within Yq11. 222->q11. 223 (557 kb and 437 kb). *TSPY1*, thought to increase gonadoblastoma risk in females with Y material, was present in the Yp duplication. The autosomal copy number gains do not include genes known to result in abnormal phenotypes, and may be a part of the marker chromosome. Interestingly, maternal chromosome analysis also demonstrated a non-mosaic marker chromosome similar in appearance to that of the proband. Additional FISH studies are in progress to investigate the nature of the maternal marker and whether the autosomal copy number gains are also part of the marker.

2501F

Molecular mechanisms of formation of insertional translocations. *P. Stankiewicz[1,2], M. A. Magrina[3], C. A. Bacino[1,2,4], S. R. Lalani[1,2,4], A. M. Breman[1,2], J. L. Smith[1,2], A. Patel[1,2], S. W. Cheung[1,2], W. Bi[1,2].* 1) Dept of Molecular & Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Miraca Genetics Laboratories, Houston, TX; 3) Medical Specialties Unit From City Hall São José dos Campos, SP, Brazil; 4) Texas Children's Hospital, Houston, TX.

Insertional translocations (ITs) are genomic rearrangements with a chromosome segment inserted into a non-homologous chromosome or a different region on the same chromosome. ITs constitute ~ 2% of non-recurrent copy-number gains and are usually revealed through FISH or chromosome analyses. Very little is known about the molecular mechanism(s) of IT formation. Recently, microhomologies at the insertion sites were found in a few IT cases, suggesting a replicative mechanism of formation. We present a family with a mother with mild intellectual disability, carrier of an apparently balanced insertion ins(19)(p13q13. 3q13. 3), and her two affected children who inherited the reciprocal IT products: the 19q13. 3 deletion or duplication. Surprisingly, we found that the duplication in one child (~3. 461 Mb) is slightly larger than the apparently reciprocal deletion in the other sib (~3. 334 Mb). Supporting this finding, chromosomal microarray analysis in the mother revealed two small copy-number gains, 108 kb and 41 kb in size in 19q13. 3, at both ends of the duplication transmitted to one child, but absent in the deletion in the other offspring, indicating DNA replication error. To determine the prevalence of this phenomenon, we are analyzing 51 other ITs from our CMA database. We have identified 11 families with an apparently balanced IT in one parent detected by FISH analysis, 31 families with a gain associated with a simple IT event in the affected patients, and 9 families with an unbalanced IT accompanied by additional copy-number changes in the vicinity of the insertion sites. To search for CNVs in the parents with the apparently balanced ITs and characterize their structure, we have designed customized high resolution array CGH. In conclusion, we propose that a significant fraction of apparently balanced ITs may harbor small flanking copy-number gains and is caused by DNA replication errors.

2502F

Molecular and clinical delineation of the 2p15-16. 1 microdeletion syndrome. *J. Levy[1], A. Coussement[2], C. Dupont[1], F. Guimiot[1], Y. Capri[1], G. Viot[2], C. Baumann[1], S. Passemard[1], A. Verloes[1], C. Leroy[1], B. Benzacken[1], JM. Dupont[2], AC. Tabet[1].* 1) Genetic Department, Robert Debre Hospital, APHP, Paris, France; 2) Cytogenetic unit, Cochin hospital, APHP, Paris, France.

Interstitial 2p15-p16. 1 microdeletion is a rare microdeletion syndrome previously reported in 14 patients. It is characterized by moderate to severe intellectual disability, autism spectrum disorder, microcephaly, short stature, dysmorphic features, structural brain anomalies and multiple congenital organs defects. It is considered a contiguous gene syndrome involving deletion of several genes. Deletions previously reported are variable in size (from 203 kb to 6. 9 Mb) and have non recurrent breakpoints. We report here three additional patients carried a 2p15-p16. 1 microdeletion shown by SNP-array analysis (Cyto12-SNP, Illumina) : a prenatal case and two postnatal cases. The prenatal and one of the postnatal cases share an overlapping 2p15p16. 1 deletion of 105 kb including only *XPO1* and the distal end of *USP34*. Both patients presented features overlapping the clinical spectrum of the 2p15p16 microdeletion syndrome including dysmorphic facial features and brain structural abnormalities. We confirm that one or both genes are probably involved in facial dysmorphic features, cognitive impairment and brain structural abnormalities observed in 2p15p16. 1-deletion syndrome. The third patient we reported on is a 4 years-old male with an heterozygous de novo a 427 kb deletion at 2p16. 1 (chr2:60624940-61051867) containing *BCL11A* and *PAPOLG* and a phenotype characterized by speech delay, autistic traits and stereotyped behavior but without microcephaly. Considering previous deletions in the 2p15p16. 1 region and our three new cases, we precise the genotype-phenotype correlation of the microdeletion syndrome. Moreover we suggest that the *REL* gene could be considered as a candidate gene for microcephaly.

2503F

Is there significant evidence to associate intronic deletions in the *AUTS2* gene with the typical features seen in *AUTS2* microdeletion syndrome? *R. E. Pyatt[1,2], A. McKinney[1], L. Erdman[1], C. Weber[1], M. Haughn[1], E. de Los Reyes[3], S. Thomas[4], S. E. Hickey[5,6], J. Indyk[5], L. Lehwald[7], S. Santoro[6], D. Lamb Thrush[1,5], S. Hashimoto[1], C. Astbury[1,2].* 1) Pathology and Laboratory Medicine, Nationwide Children's Hospital, Columbus, OH; 2) Department of Pathology, The Ohio State University, Columbus, OH; 3) Department of Neurology, Nationwide Children's Hospital, Columbus, OH; 4) The Center for Child Development, Wood County Hospital, Bowling Green, OH; 5) Department of Pediatrics, The Ohio State University, Columbus, OH; 6) Molecular and Human Genetics, Nationwide Children's Hospital, Columbus, OH; 7) Pediatric Neurology, Nationwide Children's Hospital, Columbus, OH.

Exonic deletions in *AUTS2* have been associated with syndromic features including low birth weight, intellectual disability, autism, short stature, microcephaly, cerebral palsy, and mild facial dysmorphisms. Exonic deletions have also been linked with ADHD, heroin dependence, schizophrenia, and speech/language disorder. As part of routine clinical microarray testing, we have occasionally seen deletions in *AUTS2* which are limited to a single intron and interpretation of these findings can be challenging. Oksenberg et al (2013) demonstrated functional enhancers in zebrafish and mice in introns 1 through 4 and 6. A review of the Database of Genomic Variants showed no reports of copy number variation limited to intron 1 and rare reports of individuals with intron 4 losses. Copy number variation was more frequently observed within introns 5 and 6. The Clinical Genome Research database contains a single clinical case of an intron 1 deletion which was *de novo* and interpreted as pathogenic in an individual with autism. We have assembled a series of clinical cases to investigate whether intronic *AUTS2* deletions are associated with a common phenotype. This series included two cases with deletions limited to intron 1, two deletions within intron 4, one deletion within intron 5, and one deletion within intron 6, which were all interpreted as variants of unknown significance. Inheritance information was not available for any of these cases. The intron 5 deletion was co-identified with a pathogenic duplication at 2q13 in a 2 month old with cleft lip/ palate and subtle dysmorphic features. One of the intron 1 losses was co-identified with a pathogenic 14q32. 3q32. 31 loss in an individual with learning difficulties, precocious puberty, low birth weight, growth retardation, short stature, and hypotonia. The second intron 1 loss was reported in an individual with ADHD, but autism was excluded using the Autism Diagnostic Observation Schedule. One of the intron 4 deletions was identified in an individual with autism, but the second was reported in an individual with dysmorphic features and gross motor delay, with no concern for autism. The individual with the single intron 6 deletion presented with ataxia, cyclic vomiting, and tonic paroxysmal upgaze but no significant neuropsychological issues. While neurodevelopmental features are present in some cases, this could be the result of ascertainment bias as no common phenotype is evident across this case series.

2504F

Two Cases with De Novo 3q26. 31 Microdeletion Reveal the Role of *FNDC3B* in Human Craniofacial Development. *Y. Cao, E. Mitchell, N. Hoppman.* Cytogenetics Laboratory, Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.

Here we report the first two cases with de novo 3q26. 31 microdeletions. An 18-month-old girl with dysmorphic facial features was referred to the Mayo Clinic Cytogenetics laboratory for testing. Chromosomal microarray analysis (CMA) on a peripheral blood specimen identified a novel 513 kilobase deletion at 3q26. 31 (171,677,940-172,191,359, genome build hg19), containing two known genes (*FNDC3B*, OMIM #611909; *GHSR*, OMIM #601898). Subsequently, a second patient with a similar 3q26. 31 deletion was ascertained. In this case, CMA on a peripheral blood specimen identified a 345 kilobase deletion at 3q26. 31 (171,622,716-171,968,102, genome build hg19), containing only the *FNDC3B* gene in a 9-day-old boy with dysmorphic facial features. Subsequent metaphase FISH studies for each case confirmed 3q26. 31 deletion, and parental FISH studies demonstrated that both deletions were de novo; therefore, these two 3q26. 31 microdeletions likely contribute to each patient's dysmorphic features. The 9-day-old male patient has a large anterior fontanelle, broad forehead, mild plagiocephaly, hypertelorism, proptosis, short anteverted nose, clinodactyly, and 5th finger hypoplasia. No additional information is available on the 18-month old patient as she was lost to follow-up. Interestingly, both de novo 3q26. 31 microdeletions share the *FNDC3B* gene in common. FNDC3B (fibronectin domain III-containing protein 3B), also known as FAD104 (factor for adipocyte differentiation-104), was first identified as a positive regulator of adipogenesis in a mouse model. Excitingly, further studies in a mouse model have recently demonstrated that *FNDC3B* is required for normal calvarial bone formation and negatively regulated calvarial cell differentiation through inhibition of BMP/Smad signaling. *fndc3b*-deficient mice have multiple cranial and skeletal malformations, such as craniosynostosis-like premature calvarial ossification, and skeletal deformities in the anterior fontanel and femurs. In summary, we report the first two patients with de novo 3q26. 31microdeletions. Both have dysmorphic features, consistent with the phenotypes seen in *fndc3b*-deficient mice in animal studies, which implies a critical role of *FNDC3B* in human craniofacial development.

2505F

A recurrent 47. 5 kb deletion downstream of the *SHOX* gene: is it pathogenic? *L. Matyakhina, D. Pineda, Z. Xu, G. Li, T. Brandt, G. Richard, J. Meck.* GeneDx Inc, Gaithersburg, MD.

SHOX, located in the pseudoautosomal region 1 (PAR1) of the sex chromosomes, is implicated in human growth. *SHOX*-related haploinsufficiency causes Leri-Weill dyschondrosteosis (LWD), a skeletal dysplasia characterized by short stature and/or the Madelung deformity, and isolated idiopathic short stature (ISS). Deletions of the downstream regulatory domain (DR) that encompasses three active enhancer sequences (AESs) have been reported to result in a phenotype similar to that of patients with mutations in the *SHOX* coding region. Reported deletions varied in size but generally included a common 200 kb region starting 48 kb downstream of *SHOX*. Smaller deletions containing one or two AESs have been also observed. A recurrent 47. 5 kb deletion, possibly involving another potential AES and located 160 kb downstream of the *SHOX* gene, has been recently suggested to cause LWD and ISS. We retrospectively reviewed 6672 cases referred to our diagnostic laboratory for chromosome microarray (CMA) to determine if any had a deletion limited to the DR and if the reported phenotype was consistent with LWD or ISS. Using a custom designed Agilent 180K array, we detected the heterozygous 47. 5 kb deletion in 30 patients with various phenotypes, primarily including developmental disorders. Of these, none were referred due to ISS and only 3 patients had some features overlapping with LWS: one patient had short stature, the other had radio-ulnar dysostosis, and the third had Madelung deformity. However, each of these cases had additional clinical features, such as cardiac defects, ADHD and café-au lait spots, and intellectual disability, respectively. Fourteen of the 30 cases (46%) showed additional array findings: 9 cases had pathogenic aberrations, 4 cases had copy number variants of unknown significance, and one patient had multiple blocks of homozygosity. The age of our patients varied from newborn to 34 years old, with 10 patients older than 9 years. Though deletion of AES is thought to have reduced penetrance as compared to individuals carrying mutations within the *SHOX* gene or larger downstream PAR1 deletions, our data do not support pathogenicity of this 47. 5 kb deletion for LWD or ISS and indicate that more unbiased data are needed to clarify its clinical significance.

Cerebral palsy (CP) represents a group of non-progressive, clinically heterogeneous disorders that are characterized by motor impairment and early age of onset, frequently accompanied by co-morbidities. The cause of CP has historically been attributed to environmental stressors resulting in injury to the developing brain although interplay with genetic vulnerability is suspected. Guidelines for diagnostic assessment of children with CP recommend against routine genetic testing. However, with emerging evidence for a genetic contribution to CP etiology, and the increasing number of reports of etiologic copy number variants (CNVs) in other neurodevelopmental disorders, we hypothesized that CNVs might be contributory. Using microarrays, we genotyped a population-based prospective cohort of children with CP from the Canadian CP Registry and their parents. *De novo* CNVs were detected in 8/115 (6. 9%) of CP patients (~1% rate in controls). In four children, large chromosomal abnormalities deemed pathogenic were found, and they were significantly more likely to have severe motor impairments than those CP subjects without such alterations (p=0. 04). Rare-inherited CNVs affecting loci of established clinical relevance (e. g. 1q21. 1, 16p13. 11, *DMD*) were also found in other unrelated families. In this cohort, the CNV data would have impacted our diagnosis or classification of CP in 11/115 (9. 6%) of families.

2507F

Novel genotype-phenotype correlations for exonic and intronic *NRXN1* deletions. *C. Lowther[1], M. Speevak[2], M. Gazzellone[3], A. C. Lionel[3], C. R. Marshall[3], S. W. Scherer[3], E. McCready[4], D. J. Stravopoulos[5], A. S. Bassett[1].* 1) Institute of Medical Science, University of Toronto, Toronto, Ontario, Canada; 2) Trillium Health Partners Credit Valley Site, Toronto, Ontario, Canada; 3) The Centre for Applied Genomics, The Hospital for Sick Children, Toronto, Ontario, Canada; 4) Department of Pathology and Molecular Medicine, McMaster University, Hamilton, Ontario, Canada; 5) Cytogenetics Laboratory, Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, Ontario, Canada.

Background: Rare pathogenic copy number variations (CNVs) overlapping *NRXN1* exons have been identified in individuals with neurodevelopmental and/or neuropsychiatric conditions. However, consistent genotype-phenotype correlations have not been established. Also, few intronic *NRXN1* deletions have been reported and their pathogenicity remains unclear. Objectives: To 1) further characterize the extended phenotype of exonic *NRXN1* deletions and 2) systematically evaluate the pathogenicity of intronic *NRXN1* deletions in order to help inform clinical diagnostic practice. Methods: We examined clinically ascertained cases from three Canadian cytogenetic laboratories for novel exonic *NRXN1* deletions. Referring physicians were contacted and invited to complete a clinical checklist including a comprehensive medical, psychiatric, and physical assessment to identify major lifetime features and illnesses. One lab's clinically referred cases were available to investigate the prevalence of intronic *NRXN1* deletions in comparison to 15,254 controls. For all *NRXN1* deletion cases, genome-wide CNV data from high resolution microarrays were investigated for the presence of additional rare variants. Results: We identified 41 (0. 21%) novel exonic *NRXN1* deletions among 19,263 clinically referred cases, an over eight-fold increase compared to controls (p<0. 0001). Novel phenotypes identified in two or more exonic *NRXN1* deletion cases included movement disorders, automutilation, sleep disorders and obsessions and preoccupations. All nine of the adults with exonic *NRXN1* deletions had a dual diagnosis of intellectual disability and a psychiatric illness. In contrast, the prevalence of congenital anomalies in exonic *NRXN1* deletion cases was low. There was no difference in the prevalence of intronic *NRXN1* deletions between clinical cases (19/6,022; 0. 32%) and controls (55/15,524; 0. 35%). Additional pathogenic variants located elsewhere in the genome were four times more common in intronic (n=6/19; 31. 6%) compared to exonic (n=3/41; 7. 3%) *NRXN1* deletion cases. Conclusions: These data suggest that the expression of exonic *NRXN1* deletions is primarily neuropsychiatric and may associated with comorbid intellectual disability and a psychiatric condition in adulthood. To our knowledge this is the first study to demonstrate that the majority of intronic *NRXN1* deletions by themselves are unlikely to cause clinical phenotypes, however further study on their potential functional impact is needed.

The complexity of non-recurrent duplications detected by microarray: a review of 167 cases. *J. Nicholl[1], S. Brown[1], C. Barnett[2], E. Haan[2], E. Thompson[2], J. Liebelt[2], L. McGregor[2], L. Hinton[1], S. Smith[1], A. Attwood[1], Y. Hull[1], S. Yu[1].* 1) Cytogenetics, SA Pathology, North Adelaide, SA, Australia; 2) South Australian Clinical Genetic Service, North Adelaide, SA, Australia.

Between May 2010 And December 2014 our laboratory has carried out microarray on ~7,700 patients with ID/DD/dysmorphism/malformation. Our laboratory uses reporting criteria whereby duplications < 400kb are not reported unless they contain one or more OMIM disease related genes. We have identified ~550 duplications involving autosomes using these criteria. Excluding unbalanced translocations, marker chromosome and recurrent microduplications, ~167 duplications were classified as non-recurrent duplications. We have reviewed the oligo/SNP array profiles, FISH results and family follow-up information for these non-recurrent duplication cases and summarised the outcomes and complexity. TRIPLICATIONS: Five changes had Log2 ratios which suggested 3 or more copies; including a 3Mb triplication at 15q21. 1 which segregates with developmental delay in a 3 generational family and a *de novo* 1. 3Mb region at chromosome 6p24. 1-p25. 1 involving 6 OMIM genes. Inspection of the array profile revealed that these triplications were derived from normal two copies, not from a duplicated region. INSERTIONAL TRANSLOCATIONS: Five duplications were the result of insertional translocations; including a duplication at chromosome 14q32 inserted into Xq27. 3, adjacent the FMR1 gene, and a paternally inherited 7q11. 22 intra-chromosome insertion. FISH is the only way to detect these cases. MORE THAN ONE CNV: Five patients were found to have a 2nd change (all deletions). In all five patients, the2nd change was considered likely to be the cause of the patient's medical condition. PATHOGENICITY: 29 (17%) were considered likely pathogenic based on gene content, size or inheritance. Sixty eight duplications (41%) were classified as "unknown clinical significance", with forty four involving a single inherited duplication as the only copy number variant (cnv). The remaining twenty four cases had a more complex picture with either more than one inherited cnv, or involving a disease gene not related to the patient's phenotype. Twenty patients (12%) had inherited duplications classified as non-pathogenic based on available evidence (DECIPHER, ISCA, DGV literature, segregation in the family). We concluded that the non-current duplications can be very complex and routine FISH and parental /family testing are necessary to reveal the complexity and to determine the pathogenicity of the duplication.

Comparison of CNVs results in the group of the patients with autistic spectrum disorders by MLPA and aCGH – one center experience. *J. Srovnal[1,2], P. Capkova[2], H. Slavik[1], V. Curtisova[2], K. Adamova[2], K. Staffova[1], R. Vrtel[2], M. Prochazka[2], M. Hajduch[1].* 1) Institute of Molecular and Translational Medicine, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic; 2) Department of Medical Genetics, Faculty of Medicine and Dentistry, Palacky University and University Hospital Olomouc, Czech Republic.

Abstract: Autistic spectrum disorders (ASD) are characterized by simultaneous deficits in three domains of behavior: reciprocal social interaction, communication and stereotyped and restricted behaviors. Submicroscopic CNVs can have causal or susceptibility-related role in heritability ASD. The aim of our one-center study was to compare MLPA and aCGH results in ASD patients. **Method:** In total, 42 patients with ASD characteristics were referred for genetic testing using MLPA and aCGH. Genomic DNA purified from peripheral blood was obtained after informed consent. MLPA kits (SALSA MLPA P343 Autism 1, P297 and P245 Microdeletions, P070 and P036 Subtelomers, MRX P106, MRC-Holland, Amsterdam, Netherlands) and Cytoscan HD (Affymetrix, Santa Clara, CA, USA) were used for CNV detection. **Results:** In the group of the children with ASD three likely pathogenic CNVs were identified. Microduplication 16p11. 2 (576kb) inherited from father, microduplication 1q. 21. 1q21. 2 (1. 3Mb) de novo, unbalanced translocation with microdeletion 20q13. 33 (1. 58Mb) and microduplication 22q13. 33 (app. 170-190kb) covering SHANK3 de novo. MLPA results were confirmed in all cases using aCGH. In another four cases, the inherited variants of unknown significance involving genes NRXN1, SNRPN, MAPK3 and CD160 were identified using aCGH not MLPA. The microdeletion 16p11. 2 (611kb) was incidentally found in the female patients with Mayer-Rokitansky-KØster-Hauser Syndrome (MRKHS) without autistic features. The loss of 1. 3Mb in 15q13. 2q13. 3 was also discovered by MLPA P343 Autism 1 in the patient suffered from intellectual disability but without ASD. **Conclusion:** SALSA MLPA probemix P343 Autism 1 has proved to be efficient for detection CNVs in the group of children with ASD. However, the simultaneous tests with another probemixes (P297, Human Telomere 3 and 5 etc.) or with aCGH are recommended especially when intellectual insufficiency in the patient is present. The high variability in the CNVs expression suggests polygenic etiology in ASD. Massive parallel sequencing is a promising platform for further research in this area. **Disclosure:** Nothing to disclose. **Acknowledgment:** This work was financially supported by IGA UP LF 2015_010, NPU LO1304, CZ. 1. 05/2. 1. 00/01. 0030 and CZ. 1. 07/2. 3. 00/30. 0004.

2510F

Deciphering isolated 4q deletion syndrome cases with a focus on an inherited case of 4q35. 1q35. 2 deletion. *N. Inamdar[1], R. W. MARION[2], R. NAEEM[3].* 1) MOLECULAR PATHOLOGY, MONTEFIORE MEDICAL CENTER, 1635 POPLAR ST. , BRONX, NEW YORK, NY 10461; 2) THE CHILDREN'S HOSPITAL AT MONTEFIORE, 3415 BAINBRIDGE AVE, BRONX, NY 10467; 3) MOLECULAR PATHOLOGY, MONTEFIORE MEDICAL CENTER, 111 EAST 210TH ST. , BRONX, NEW YORK, NY 10467.

4q deletion syndrome is characterized by a proximal, interstitial, or distal regional loss of the long arm of chromosome 4. Phenotypic presentation varies even among individuals with overlapping deleted intervals and the syndrome is rare with an incidence of about 1 in 100,000. Making phenotype-genotype correlations is therefore a challenge and there is hence, a need to document all cases of 4q deletion syndrome. To contribute to the knowledge base of this syndrome we reviewed our aCGH cases for the last seven years and identified 13 individuals with isolated 4q deletion. Six of them, including three members of one family, harbor a distal deletion. Deletion intervals were identified to be 4q32. 2q35. 2, 4q32. 3, 4q32. 3q35. 2, and 4q35. 1q35. 2. We used 44K Agilent microarray. We present phenotype-genotype correlations for all available cases and further studies of one family of two siblings and their father with heterozygous ~4Mb deletion in 4q35. 1q35. 2 region. The deletion was inherited by the siblings from their apparently phenotypically normal father. The proband is a four year old (at the time of diagnosis) male with developmental delay, mildly affected sleep pattern, and autism spectrum-like disorder. Of the several known genes localized to the deleted region, two are of particular relevance: MTNR1A and FAT1. MTNR1A, one of the melatonin receptors, is expressed in the hypothalamic suprachiasmatic nucleus that is associated with circadian rhythm. It is interesting to note that variants of the protocadherin gene FAT1 have not only been associated with autism spectrum and bipolar affective disorders but more recently have been linked to facioscapulohumeral muscular dystrophy (FSHD)-like phenotype. Neuromuscular deficits are a common finding in 4q deletion syndrome. While the exact gene/s responsible for FSHD is/are not known, chromatin remodeling arising from D4Z4 repeat truncation and/or hypomethylation of 4q35. 1q35. 2 region is thought to deregulate expression of genes located in the vicinity leading to FSHD. It would be interesting to decipher if similar change in methylation status/chromatin remodeling occurs in 4q cases leading to deregulation of genes flanking the deleted regions. Such a mechanism could potentially be responsible for the phenotypic variations/incomplete penetrance seen in individuals harboring the same deletions as in our inherited case where the father is apparently unaffected.

Array-CGH analysis in fetuses with multiple malformations reveals 50% of cases with pathogenic deletions/duplications or variants of unknown significance. *E. Di Gregorio[1,2], G. Gai[1], G. Botta[3], A. Calcia[2], P. Pappi[1], F. Talarico[1], E. Savin[1], M. Ribotta[3], S. Cavalieri[1], E. Giorgio[2], C. Mancini[2], M. Ferrero[2], E. Pozzi[2], E. Riberi[2], G. Restagno[4], G. B. Ferrero[5], E. Grosso[1], A. Brusco[1,2], A. Brussino[2].* 1) Città della Salute e della Scienza University Hospital, Torino, Italy; 2) University of Torino, Department of Medical Sciences, Turin, 10126, Italy; 3) Città della Salute e della Scienza University Hospital, Department of Pathology, Turin, Italy; 4) Città della Salute e della Scienza University Hospital, Laboratory of Molecular Genetics, Turin, Italy; 5) University of Torino, Department of Public Health and Pediatrics, Turin, Italy.

Major congenital malformations (MCMs) are anatomic anomalies affecting life expectancy or organ normal function occurring in about 2-3% of live born infants. Fetuses with abnormal ultrasound findings show chromosomal aberrations detected by standard karyotype in 9–35% of the cases, depending on the presence of single or multiple anomalies. The etiology of MCMs remains uncovered in the majority of cases. In the last few years, several studies evaluated the diagnostic role of array-CGH analysis (a-CGH) on fetuses with malformations detected in prenatal diagnostic setting or after interrupted pregnancy. While a-CGH diagnostic yield in the postnatal population has been established at 10-12%, studies investigating fetuses reported pathogenic variants in 0-12. 5% of cases. The aim of our study was to evaluate the diagnostic yield of array-CGH analysis in a selected group of fetuses with MCMs. We used whole-genome a-CGH (60K Agilent) to investigate 28 fetuses presenting at least two MCMs detected on autopsy with or without ultrasound. Standard karyotype was performed in 18 out the 28 cases and failed to provide a diagnosis. Array-CGH disclosed Copy Number Variants (CNVs) in 50% of the analyzed fetuses (14/28). We identified a clinical significance in 32% of the cases (9/28) and variants of unknown pathogenic significance (VOUS) in 18% (5/28). Three of the nine positive cases carried a known microdeletion: a 22q11. 21 deletion, a central chromosome 22q11. 21 deletion and a TAR syndrome). In six the rearrangement was always >11 Mb and the gene content or the region involved were correlated with the phenotype. VOUS were 130-900 kb in size (four duplications and one deletion) and contained 1-7 genes. In conclusion, our study showed a-CGH is a powerful technique to unravel the genetic etiology of fetal major congenital malformations. Differences in the proportion of significant results among various cohorts may be related to the design of the array used and the different inclusion criteria based on the severity and number of fetal malformations.

Unusual translocations t(2;11)(q23;q13) y t(9;14)(q12;q11. 2) in acute promyelocytic leukemia. *A. Corona-Rivera[1,2], C. Almodóvar-Cuevas[2], E. Torres-Anguiano[1], C. Ortega de la-Torre[2], H. Pimentel-Gutiérrez[2], C. Barba-Barba[2], G. Serafín-Saucedo[2], G. Macías-Salcedo[2], M. Velázquez-Rivera[2], A. Márquez-Mora[2], S. Gallegos-Castorena[3], F. Sánchez-Zubieta[3], I. Bobadilla-Morales[1,2].* 1) Universidad de Guadalajara,Centro Universitario de Ciencias de la Salud, Instituto de Genética Humana "Dr. Enrique Corona Rivera", Laboratorio de CitoGenética Genotoxicidad y Biomonitoreo, Guadalajara, Jalisco, México; 2) Unidad de CitoGenética, Nuevo Hospital Civil "Dr. Juan I. Menchaca", División de Pediatría, Servicio de Hematología Oncología Pediátrica , Guadalajara, Jalisco, México; 3) Servicio de Hematología Oncología Pediátrica , Nuevo Hospital Civil "Dr. Juan I. Menchaca", Guadalajara, Jalisco, México.

Acute promyelocytic leukemia (AML-M3) is a biologically and clinically distinct variant of AML, approximately 92 percent of patients with AML-M3 carry the balanced translocation t(15;17). It involves the retinoic acid receptor alpha (*RARA*) gene on chromosome 17 and the*PML*gene on chromosome 15. Although several variant translocations involving *RARA* have been identified, including t(11;17) and t(5;17), a small number of AML-M3 cases lacking t(15;17) have been described**.** We present the cytogenetic alterations of a four-year-old patient with a diagnosis of AML-M3, without the usual translocation t(15;17). A four-year-old female diagnosed with AML-M3, with two years of disease evolution. Laboratory findings showedleukocytosis (20,000/µl), lymphocytes of 35. 4%, neutrophils of 58. 9%, Hb 7. 92 g/dl, hematocrit of 24. 7%, MCV 86. 3 fl, MCH 27. 7 pg, platelet count of183,000/dl. The treatment began with the national protocol and two subsequent cycles continued PETHEMA 99 protocol. The patient achieved complete remission until the second cycle, after seven months in the maintenance phase she presented a bone marrow relapse. Mitoxantrone was administered as a rescue protocol and reaches the second complete remission up to the second cycle. Six months after relapse, she died by therapeutic failure. At diagnosis, cytogenetic studies demonstrated the absence of translocation. By RT-PCR analysis, the*PML/RARA*transcript was not detected. On the other hand, *PML/RARA*fusion signal was not detected by FISH analysis. Cytogenetic study was carried out on cells from bone marrow aspiration in relapse stage. The karyotype was interpreted as 45~46,XX,t(2;11)(q23;q13),t(9;14)(q12;q11. 2),18[11]/46XX[8]. This case report reveals different alterations to the t (15; 17) that produce the same phenotype AML-M3. There are no reports of translocations with cleavage sites observed in this type of disease. In the present case, treatment with ATRA and chemotherapy showed a poor response. These findings may indicate that these translocations are indicators of poor prognosis.

2513F

A t(17;19)(q21;p13. 3) involving *TCF3* , a t(1;9)(p13;p13) and a 5'*IGH@* abnormality in a case of adult B-cell Acute Lymphoblastic Leukemia. *R. Chow[1], D. Shabsovich[1], G. Schiller[2], M. Kallen[1], S. T. Pullarkat[1], N. Rao[1], C. A. Tirado[1].* 1) Pathology & Laboratory Medicine, UCLA, Los Angeles, CA; 2) Medicine, Hematology & Oncology, UCLA, Los Angeles, CA.

TCF3(19p13. 3) abnormalities are relatively common in B-cell acute lymphoblastic leukemia (B-ALL). Although the t(1;19)(q23;p13) involving*PBX1*is the most common of these rearrangements, rare variants involving different partner genes have been observed. Among these, the t(17;19)(q21;p13. 3), which results in a chimeric gene involving*TCF3*and*HLF*(17q21), is associated with an extremely poor prognosis in B-ALL. Herein, we present the case of a 25-year-old male diagnosed with B-ALL who underwent a hematopoietic stem cell transplant (HSCT) and experienced multiple relapses. Conventional cytogenetic analysis prior to the patient's first relapse revealed a t(17;19)(q21;p13. 3). Fluorescence in situ hybridization (FISH) analysis confirmed that the t(17;19) involved*TCF3*and also revealed a loss of the 5'*IGH@*(14q32) region, suggesting a deletion or an unbalanced rearrangement involving 14q32. Conventional and molecular cytogenetic analysis after the first relapse prior to HSCT revealed a t(3;10)(q27;q24) as an additional abnormality. After undergoing a HSCT, the patient experienced another relapse, at which point a bone marrow biopsy revealed a hypocellular marrow with lymphoblasts consisting of 85% of total marrow elements. Conventional cytogenetic studies revealed an abnormal karyotype bearing the (17;19) translocation, a t(1;9)(p13;p13), and complex structural anomalies involving chromosomes 5, 7, and 14. FISH studies confirmed the involvement of*TCF3*and structural abnormalities involving chromosomes 5 and 7, but did not show any*IGH@*abnormalities. As of now, the patient is undergoing re-induction therapy with Blinatumomab. The t(1;9)(p13;p13) has been reported in a single case of B-ALL involving*PAX5*(9p13) and*HIPK1*(1p13) but to the best of our knowledge, this is the second reported case of t(17;19) bearing a concomitant 9p13 rearrangement as a secondary abnormality in the context of a complex karyotype and the first reported case of t(17;19)-ALL with a concomitant*IGH@*(14q32) abnormality. This case provides insight into the clonal evolution of t(17;19)-ALL and the possible involvement of*PAX5*and*IGH@*in this subset of malignancies.

2514F

Unusual phagocytosis in a woman with a non-specific B-cell chronic lymphoproliferative disorder. *M. Dominguez[1], C. Borjas[1], M. Magaña[2], J. González[2].* 1) Universidad de Guadalajara, Guadalajara, Jalisco, México; 2) División de Genética, CIBO, Instituto Mexicano del Seguro Social, México.

Introduction. Phagocytosis is the mechanism by which a dead or dying cell is internalized and degraded by another living cell. The normal process of phagocytosis comprises several steps: invagination, engulfment, internalization, formation of the phagocytic vacuole, fusing of lysosomes to the phagocytic vacuole, and release of digested products. We describe an unusual phagocytic activity in a woman with a non-specific B-cell chronic lymphoproliferative disorder. **Case.** A 78 year-old woman had abdominal pain, fever, hepatomegaly, left axillary and mediastinum lymph node. Values of laboratory test were: Hb 11. 4 g/dL; 34,500 leucocytes/mm3 (with 76% of lymphocytes); 293,000/mm3 platelets; HIV, hepatitis B and Hepatitis C were negative. Immunophenotype of peripheral white blood cells was concordant with a non-specific B-cell chronic lymphoproliferative disorder. Nearly after the cytogenetic study, the patient passed away. **Materials and methods.** Chromosomes were obtained from a peripheral blood culture stimulated with a mixture of phorbol myristate acetate and Pokeweed mitogen. The karyotype analysis was done by GTG-banding. Posteriorly, we performed a fluorescent in situ hybridization with the AML1/ETO probe (Cytocell). **Results and discussion.** We observed the karyotype 46,XX,inv(14)(q11q32)[2]/46,XX[20]. Additionally, at the GTG-banding analysis, we observed several strange dyad-cell-like structures (or an hourglass-cell conformation) that looked like cell-in-cell structures in ~3% of the total cells. In several of these dyad-cell-like structures seemed as if they were suffering a nuclear fusion process. FISH analysis with the dual color AML1/ETO probes disclosed two green and two red expected signals on only one of the two cells of each dyad; whereas, the another cell was negative for the expected FISH signals. In addition, we found that 57 of 348 (16%) individual cells in our patient showed any AML1/ETO signals, which was statistically significant ($p<0.001$) when compared with values observed in a control sample where 12 of 349 (3. 5%) individual cells had no FISH signals. We discarded the occurrence in vitro of such dyad-cell structures, because they were present in the patient's peripheral blood and bone marrow smears taken the same day we did the cell culture. Conclusion. A strange form of phagocytosis was present in this patient. The main difference between the patient's phagocytosis with the normal process is the absence of an internalized phagocytic vacuole.

2515F

An adult male presenting with concurrent plasma cell myeloma involving an *IGH@/CCND1* translocation and chronic myelogenous leukemia with a variant (9;22) translocation. *C. Tirado, D. Shabsovich, Y. Naeini, N. Rao.* Pathology & Laboratory Medicine, UCLA, Los Angeles, CA 90024.

The t(11;14)(q13;q32) involving *IGH@* and *CCND1* as well as the t(9;22)(q34;q11. 2) involving *BCR* and *ABL1* are common abnormalities in plasma cell myeloma (PCM) and chronic myelogenous leukemia (CML), respectively. However, the concurrence of the two malignancies is extremely rare and reported infrequently in the literature. Herein, we present the case of an 87 year-old male who presented with anemia and monocytosis, hemoglobin of 10. 2 g/dL with mean corpuscular volume of 95. 7 fL and white blood cells count of 11. 9 K/uL, with a differential of 50. 9% granulocytes, 41. 8% lymphocytes, and 7. 3% monocytes. A bone marrow biopsy showed a mildly hypercellular marrow (50% cellularity) with mild myeloid hyperplasia. Plasma cells were increased in number and they occurred scattered in the marrow. Identified were 8-10% monoclonal kappa-restricted plasma cells, consistent with a plasma cell dyscrasia. Flow cytometry performed on the bone marrow aspirate demonstrated B-cells with normal antigen expression and kappa:lambda ratio, with no evidence of a monotypic B-cell population. Granulocytes were left shifted but they showed normal antigen expression. Monocytes also showed normal antigen expression. CD34-positive blasts were within the normal range and comprised 1% of the total cells. An abnormal plasma cell population was identified, comprising approximately 2. 8% of the total cells. This population showed kappa light chain restriction, and was positive for CD38, CD138, partial CD45, CD20, dim CD27, and CD200, and negative for CD19, CD56, CD117, CD28, and CD81, consistent with a plasma cell dyscrasia. FISH studies on a sample enriched for plasma cells detected a t(11;14) involving *IGH@* and *CCND1* in 92% of nuclei, consistent with a plasma cell neoplasm. However, conventional cytogenetic analysis on a sample not enriched for plasma cells revealed an apparent t(9;22)(q34;q11. 2) in 40% of metaphases. Interphase and metaphase FISH studies on the same sample confirmed the presence of the *BCR-ABL1* fusion in 88% of nuclei, but did not show any signals corresponding to the derivative 9, suggesting a variant t(9;22) with a deletion or additional material of unknown origin at the 9q34 band of the derivative 9 and a derivative 22 bearing the *BCR-ABL1* fusion gene. This case provides insight into the coexistence of PCM and CML. .

2516F

Myelodysplasia transforming to mast cell leukemia with t(9;22): A rare occurrence. *G. Velagaleti[1], C. Mendiola[1], M. Shupe[2], V. Ortega[1].* 1) Dept Pathology, Univ Texas Hlth Sci Ctr, San Antonio, TX; 2) Dept Hematology/Oncology, San Antonio Military Medical Center, San Antonio, TX.

Mast cell leukemia (MCL) is a rare form of systemic mastocytosis in which an abnormal increase in mast cells (MCs) proliferates in tissues. MCs are distinct hematopoietic, multifunctional cells originating from uncommitted myeloid progenitor cells expressing a unique profile of antigens, involved in vascular cell regulation and allergic disease states. MCs involvement in myelodysplastic or leukemic disease states have rarely been described and mast cell lineage involvement in leukemic disease states is an uncommon event. There are limited reports of AML/MDS with transformation to MCL. Although there are clonal abnormalities reported in both MCL and mastocytosis, there are no characteristic or consistent chromosome abnormalities identified. We report a unique case of high risk MDS with progression to MCL with t(9;22). An 80-year-old female presented with new onset pancytopenia in 2012. Chromosome analysis on the bone marrow showed 46,XX,del(20)(q11. 2q13. 1)[16]/46,XX[4] and FISH analysis with AML/MDS panel showed 20q deletion and monosomy 7/del 7q. Following palliative chemotherapy with azacitidine, she did not show remission with follow-up studies in 2013, showing similar cytogeneticsas before but without the monosomy 7/7q deletion. In 2014, she presented to the ER with complaints of weakness, nausea, vomiting, as well as abdominal pain. Bone marrow biopsy showed features consistent with MCL transforming from her MDS. Bone marrow chromosome analysis showed clonal evolutionwith the karyotype 46,XX,del(20)(q11. 2q13. 1)[10]/46,idem,t(9;22)(q34;q11. 2)[7]/46,XX[3]. Additional FISH studies with BCR/ABL probes confirmed BCR/ABL rearrangement. FISH analysis withBCR/ABLon her two previous stored bone marrow samples showedno BCR/ABL rearrangement. Although MDS transforming to AML or ALL with t(9;22) has been reported, presence of BCR/ABL fusion in MCL transformed from MDShas never been reported before. Overall MCL carries a poor prognosis given the aggressiveness of the disease and ineffective treatments. Due to inability to tolerate aggressive chemotherapy and the poor prognosis associated with this rare case of MCL with t(9;22), our patient was counseled and provided palliative care after which she passed away. Further investigation may provide insight to the molecular basis of this rare disease and the clinical significance of the t(9;22), if any, in our patient, and allow guidencefor proper management and targeted therapies for these patients.

2517F

Double trisomy (48, XXY,+ 21) in a foetus associated with Atrioventricular septal defects (*AVSD*) and agenesis of the corpus callosum. *S. K. Bhattacharya[1], U. Radhakrishna[2], V. Lal[1].* 1) Department of Cytogenetics, Dr. Lal Path Labs. Pvt. Ltd. , New Delhi, India; 2) Department of Obstetrics and Gynaecology, Oakland University William Beaumont School of Medicine, Royal Oak, MI, USA.

The incidence of double aneuploidy in the same individual is relatively uncommon. In addition dual aneuploidies involving both autosomal and sex chromosomes have rarely been reported to be associated with developmental defects such as congenital heart defects (CHD). Most reported cases of double aneuploidy are presented in the form of recurrent miscarriages and abortions. A 20-weeks old male fetus with double aneuploidy associated with atrioventricular septal (*AVSD*)and other developmental defects has been analysed. This is the first child of healthy and non-consanguineous parents, which was aborted after 20 weeks of gestation. The estimated foetal weight was 232 gm (35th percentile). Using 4-D ultrasonography, the cavum septum pellucidum in the brain was not observed. Electroencephalogram showed mildly diffuse cortical dysfunction without abnormal epileptiform discharges. Lateral ventricles were also dilated. Only a thin rim of cerebral cortex was present. Choroid plexus and medial wall of ventricle separation was 7. 2 mm (normal < 3 mm). All the conditions were suggestive of agenesis of corpus callosum. Fetal echocardiographic findings indicated congenital heart disease with atrioventricular septal defects (AVSD). Chromosomal and Fluorescence in situ hybridization (FISH) techniques with LSI21 and DYZ3 alpha satellite and CEP X alpha satellite probes analysis showed a karyotype of 48,XXY,+21: a double aneuploidy of DS and Klinefelter syndrome (KS), very few such cases have been reported in the literature. A detailed genetic and clinical report of the present case and current knowledge on causes and consequences of double aneuploidy in humans will be presented.

2518F

Severity of oro-dental phenotype in Down Syndrome based on chromosome analysis. *E. Severin[1], A. PŭN[1], R. Baltag[1], A. Stan[2], C. Funieru[1].* 1) Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2) Genetic Lab - Bucharest, Romania.

The extra chromosome 21 or part of its long arm (including 21q22 band) can come indistinct genetic ways, such as, full trisomy 21, mosaic trisomy 21 or translocation trisomy 21 causing Down's syndrome (DS). The severity of clinical features, including oral-facial abnormalities, varies from an individual with DS to another and it is hard to predict how much a fetus/newborn will be affected as a child or an adult. DS has the highest incidence at birth of any chromosomal abnormality and every paediatric dentist can expect to deal with oro-dental problems relating to DS. The aims of the study were to analyze the oro-dental phenotype of 52 subjects with DS, to determine the pattern of dental anomalies in these cases and to find if the severity of oro-dental features can be predicted based on chromosome analysis. Methods: Children and adults with DS were chromosomally investigated in order to confirm the clinical diagnosis of DS. To characterize the oro-dental phenotypic spectrum of DS persons were performed extra / intra-oral examinations, and radiological evaluations. Results: Based on cytogenetically analysis results, persons with full trisomy 21, mosaicism for trisomy 21 and translocation trisomy 21 were identified. Most oro-dental features including teeth, gingiva, tongue, palate and oclussion anomalies were variable in both frequency and expression. The most common dental anomaly was hypodontia followed by microdontia. All persons with DS presented oclussal problems. Eruption of both dentitions was delayed in mostcases. Conclusion: Variation of oro-dental phenotype is not associated with specifically chromosomal mechanisms of trisomy 21. Clinical relevance: cytogenetic testing is not a good predictor for oro-dental features severity for DS butthe study provides data that could help the dentists to improve their knowledge and clinical practice.

2519F

Trisomy 9p. Rethore syndrome, case report. *R. Silva-Cruz[1], L. Bobadilla-Morales[1,2], HJ. Pimentel-Gutiérrez[2], C. Barba-Barba[2], C. Ortega de la-Torre[2], G. Macías-Salcedo[2], A. Márquez-Mora[2], ME. Velázquez-Rivera[2], JR. Corona-Rivera[1,2], F. Sánchez-Zubieta[2], A. Corona-Rivera[1,2].* 1) Laboratorio de CitoGenética, Instituto de Genética Humana "Dr. Enrique Corona Rivera", CUCS, Universidad de Guadalajara; 2) Unidad de CitoGenética, Servicio Onco-hemato Pediatría, Hospital Civil de Guadalajara "Dr. Juan I. Menchaca.

Introduction. Trisomy 9p, known as Rethore syndrome is a chromosomal abnormality characterized by total or partial duplication of chromosome 9p. It is characterized by delayed closure of sutures, ocular hypertelorism and hypoplastic distal phalanges. The phenotypic variability is large due to the variable size of the trisomic fragment involved. **Objective**: to describe a case of trisomy 9p with conventional and molecular cytogenetic approach, in clinical monitoring. **Clinical report.** Male, 7 months old, mother of 40-year-old with right renal hypoplasia, G1, father of 45-year-old healthy. Nonconsanguineous. He was born at 35 weeks, 1,470 g birth weight, APGAR unknown, spontaneous crying and breathing. Cephalic support at 6 months. FE: head circumference 41 cm, height 61 cm, broad forehead, short neck, trichomegaly of lashes, epicanto, strabismus, bulbous nose, micrognathia, thin lower lip, forked tongue, dysplastic ears, single transverse palmar crease, unique flexion crease in 5th right finger, agenesis of the nipple, umbilical hernia, micropenis, clubfoot. In laboratory tests, T3 3. 4 pq/ml, T4 0. 93 nq/dl, TSH 1. 43 uIU/ml. Hemoglobin 11. 33 g/dl, ALT 28. 20 U/L, AST 37. 20 iU/L. IgG 433 mg/dl, IgA 35 mg/dl, IgM 48 mg/dl, IgE 126. 01 UI/ml. USG abdomen shows left kidney in hemiadomen, normal morphology. Skull tomography without alterations. Karyotype 46,XY,add(9)(p13-p24). nuc ish dup(9)(p13p24)(wcp9+). He goes to early stimulation. Shows improvement in the acquisition of developmental milestones, he attained sitting and emit some sounds and some disyllabic. **Conclusions.** Although it is known that this entity genetic presents variability according to the region of arm p (partial or complete), we can see that our case has phenotypes which are common in Rethore syndrome and some others with low frequencies that often appear in cases considered sporadic.

2520F

Dyskeratosis congenital. A X-linked dominant. Case report. *L. Bobadilla-Morales[1, 2], S. A. Brukman-Jiménez[1, 2], L. Zúñiga-Guzmán[1], S. Borrayo-Dorado[1], J. Franco-Pérez[1], F. Zánchez-Zubieta[2], A. Orozco-Alvarado[1], R. Navarro-Martín del Campo[2], G. Macías-Salcedo[2], A. Corona-Rivera[1, 2].* 1) Instituto de Genética Humana "Dr. Enrique Corona Rivera" CUCS, Universidad de Guadalajara; 2) Unidad de CitoGenética, servicio Onco-hemato Pediatría, Hospital Civil de Guadalajara "Dr. Juan I. Menchaca".

Dyskeratosis congenital is an inherited disorder characterized by muco-cutaneous abnormalities (leukoplakia, reticulate hyperpigmentation and nail dystrophy), bone marrow failure, premature ageing phenotype and an increased risk of malignancy. This phenotype is triggered by known mutations in components of telomerase and telomere shelterin which is clinically and genetically heterogeneous, with X-linked recessive (MIM #305000), autosomal dominant (MIM #127550) and autosomal recessive (AR) (MIM #224230) inheritance patterns. Objective: historically X-linked recessive is the most common inheritance pattern of this disease, our case report suggests a X-linked dominant inheritance pattern. Clinical report: 16 years old female, whose parents do not share clinical phenotype. Hyperpigmentation in the sun exposed areas of the skin appeared when she was 6 years old. At 15 years old, she showed nail dystrophy, reticulate hyperpigmentation and leukoplakia, being candidate to bone marrow transplantation. Weight 39kg (Z= -2. 49), size 1. 50mts (Z= -1. 39), head circumference 53cm (Z= -1. 69), hemoglobin 10. 48g/dl. Bone marrow biopsy: aplastic with fatty infiltration. Karyotype mos46,XX[46]/47,XX,+mar[4]. Chromosomal instability positive. Conclusions: Altogether the clinical manifestations and family tree described in this case are not consistent with the previously reported inheritance patterns of this disease. Being a female patient with severe clinical phenotype, we suggest a X-linked dominant inheritance pattern, which has not been previously reported.

Our experience at Children's National Health Systems using CytoScan® Dx Assay. *k. Cusmano-Ozog, m. seprish, s. hofherr.* childrens national, washington, DC.

The Molecular Diagnostics Laboratory in the Division of Laboratory Medicine at Children's National Health Systems established chromosomal microarray (CMA) in the summer of 2013 to better support the Division of Genetics and Metabolism with over 7,000 patient encounters a year. In August 2014, we went live with CytoScan® Dx, the first FDA-cleared chromosomal microarray assay. During the first 10 months of offering this assay, 517 samples were received, tested and resulted. Of the 517, 147 (28%) had a positive finding and 370 (72%) were negative. Of the positive results, 111 (21% of all tested) had a copy number variant (CNV) detected and 36 (7% of all tested) had significant area(s) of homozygosity (AOH). For those with a CNV, there were 45 duplications, 51 deletions and 9 complex rearrangements. Additionally, there were six times where aneuploidy was detected: Trisomy 21, Trisomy 18, Trisomy 13, 47,XXY, 47,XYY and 48,XXYY. In addition, there was one case each of mosaic Trisomy 14, mosaic ring X and tetrasomy 18p. The most common deletion syndromes identified were: 22q11. 21 (VCF, n=6), 15q11. 2 (PWAS, n=3), 7q11. 23 (Williams, n=4) and 16p11. 2 (autism, n=3). The remaining deletions and duplications identified were evenly dispersed among the chromosomes. In regards to the inheritance of CNVs detected, thus far 15 are de novo, 29 are maternal and 11 are paternal in origin. Of those with AOH, 18 (3% of all tested) were found to have AOH >2. 5% of the autozygome suggestive of identity by descent and 9 (2% of all tested) were suggestive of uniparental disomy (UPD) or isodisomy. This study demonstrates the high detection rate of CMA, especially in the pediatric population that led initially for it to be recommended as a first-tier test by ACMG and more recently approval by the FDA for the detection of CNVs associated with developmental delay and/or intellectual disability (DD/ID), congenital anomalies, and/or dysmorphic features.

2522F

Discordant Circulating Fetal DNA and Subsequent Cytogenetics Reveal False Negative, Placental Mosaic, and Fetal Mosaic Genotypes. *R. V. Lebo[1], R. W. Novak[1], K. Wolfe[2], M. Michelson[2], H. Robinson[3], M. Mancuso[2].* 1) Dept Pathology, Akron Children's Hosp, Akron, OH; 2) Maternal Fetal Medicine, Akron Children's Hospital, Akron, OH; 3) Genetics, Akron Children's Hospital, Akron, OH.

Noninvasive Prenatal Testing (NIPT) of the circulating fetal DNA in maternal blood (cfDNA, trophoblast DNA, placental DNA) can be rechecked by ultrasound and ordering a fetal sample karyotype by Maternal Fetal Medicine clinics. This abstract reviews two significant additional cases. In the first case, we found twice our previously reported number of abnormal NIPT results now adding a balanced reciprocal translocation that was undetected by NIPT analysis which nonetheless correctly identified trisomy 21. In the second case, further analysis revealed one phenotypically *normal* newborn with a complex mosaic karyotype substantially decreasing the newborn's eventual reproductive fitness. Together these two cases emphasize the prudence of pretest counseling. In addition, the second case establishes the importance of karyotyping the placenta and cord or peripheral blood when inconsistent or mosaic results are identified following a NIPT result with a normal newborn phenotype. Since the first discordant NIPT result, the 112 amniocenteses karyotyped by Akron Children's Hospital Cytogenetics Laboratory include 29 positive testing NIPT cases. These 29 cases (~26%) are attributable to a substantial proportion of positive NIPT screened cases referred to Maternal Fetal Medicine specialists. Cytogenetic analysis confirmed ~60% of these cases tested by NIPT. Our original results plus these new cases confirm (1) a normal NIPT test result followed by a 20 week anatomical ultrasound detected a false negative trisomy 18 NIPT result, (2) a substantial proportion of abnormal NIPT tests identified chromosomal mosaicism that may or may not be confined to the placenta, (3) follow up karyotyping should be ordered on the newborn placenta when the amniocyte karyotype does not confirm the NIPT reported abnormality in order to identify ongoing risk for mosaic symptoms, (4) considering our ~4,000 reported amniocenteses, karyotyping all high risk fetuses will define ~24% of chromosome abnormalities not currently screened by NIPT, and (5) ongoing counseling will facilitate these improved screening results. These Maternal Fetal Medicine referrals demonstrate that positive NIPT results identify abnormal karyotypic frequency as well as a substantial proportion of discordant circulating fetal DNA results.

2523F

Disruption of the MBD5 gene by a small deletion of the 2q23. 1 in a family with mental retardation and language impairment. *Y. G. Oh, J. O. Lee, B. H. Lee, E. J. Seo.* Medical Genetics Center, Asan Medical Center, Univ. of. Ulsan College of Medicine.

The 2q23. 1 deletion syndrome is a recently identified neurodevelopmental disorder characterized by developmental delay, seizures, intellectual disability, and autistic-like behavior. The deletions at the 2q23. 1 range in size from 38 kb to greater than 19 Mb. Methyl-CpG-binding domain 5 (MBD5) is regarded as a causative gene of this syndrome with haploinsufficiency. In this study, we describe a family with MBD5 disruption resulting from a 163 kb deletion. The proband was a 15-year old girl who presented with developmental delay, motor delay, severe mental retardation, language impairment, autistic-like symptom, short stature, normocephaly, and skeletal abnormalities including pes planus and clinodactyly. Conventional chromosomal analysis showed a normal karyotype. Chromosomal microarray using Agilent SurePrint G3 Human 180K revealed a 163 kb deletion at the 2q23. 1, which encompassed exons 1 to 6 of ORC4 and exons 1 to 2 of MBD5. The proband's father and younger sister were found to have the same deletion of the 2q23. 1 using chromosomal microarray. They presented with short stature, mild to moderate mental retardation, and language impairment, but less pronounced features than proband. Interestingly, seizures or craniofacial abnormalities in this family were unremarkable. This result suggested that the haploinsufficiency of MBD5 caused by complete deletion or gene disruption might be closely associated with mental retardation and language impairment among variable clinical manifestations of the 2q23. 1 deletion syndrome.

Clinical Characteristics of Chromosome Microarray Studies. *E. Purifoy[1], V. Goitia[1], M. Cua[1], C. Wang[2].* 1) Pediatrics, Driscoll Children's Hospital, Corpus Christi, TX; 2) Neurology, Driscoll Children's Hospital, Corpus Christi, TX.

Chromosome microarray study (CMS) is widely utilized in clinical settings. However, interpretation of results can be difficult due to the lack of clear clinical correlates. In order to better understand the clinical utility of CMS we conducted a comprehensive retrospective study and analyzed all CMS performed at Driscoll Children's Hospital (DCH). Patients aged 0-21 years who had a CMS performed between the years 2008-2014 were included. We constructed a searchable electronic database including detailed genotypes and clinical information. Phase I data analysis investigated positive rates in demographic subgroups, different clinical subspecialties, and different clinical diagnostic categories. All subjects were classified into the following diagnostic categories: autism, congenital anomalies, and others (including several other clinical diagnoses). Phase II data analysis focused on the positive results and the clinical characteristics of different genotypes. A total of 807 CMS were identified. The overall positive rate was 29%. There were 529 males (66%) and 278 females (34%). The largest age group was 1-5years (364 subjects). Neurologists ordered the largest number of tests. We found a 15% positive rate for autism, 27% for congenital anomalies and 27% for other diagnoses. Interestingly, there was a significant increase in the rate of positive test results when the subject had two of these diagnoses. The rate of positivity was 56% for subjects with both autism and congenital anomaly, 37% for autism and other, 43% for congenital anomaly and other. In our phase II data analysis we found that chromosomes 15, 16 and X were the most commonly affected chromosomes overall. The chromosomes with the most mutation sites in autism were 10, 15, and 16. For congenital anomalies the most commonly affected chromosomes were 7 and X. Chromosomes 1,2,16, and X had the most mutation sites for subjects with the other diagnoses. A gender comparison of the chromosome mutations sites in autism was performed and revealed that there was a significant difference in the distribution of mutation sites between males and females. Our finding that a patient with two clinical diagnoses significantly increases the likelihood of a positive test has not been reported previously.

2525F

High detection rate of clinically relevant genomic abnormalities in plasma cells enriched using magnetic-activated cell sorting from consecutive patients with multiple myeloma. *S. Chan[1], Z. Singh[2], M. R. Baer[3], A. Z. Badros[3], Y. Huang[4], Y. S. Zou[2].* 1) Department of Human Genetics and Genomic Medicine; 2) Department of Pathology; 3) Department of Medicine and Greenebaum Cancer Center, University of Maryland School of Medicine, Baltimore, MD; 4) Department of Mathematics and Statistics, University of Maryland, Baltimore County, MD.

Multiple myeloma (MM) is a plasma cell malignancy. Each year approximately 24,050 cases of MM are diagnosed, with a mortality of 11,090 individuals. Chromosome and FISH studies are used to provide prognostic information useful for refining risk stratification and predicting therapeutic response. Chromosome studies are frequently limited by lack of proliferation of plasma cells in vitro, and FISH analysis is hampered by small plasma cell percentages in marrow samples. To alleviate this problem, we implemented a protocol of magnetic-activated cell sorting (MACs) to isolate CD138+ plasma cells followed by FISH study to detect MM-related genomic abnormalities (the MACs FISH method) in July 2013. Before that, FISH was performed on BM samples without plasma cell isolation (the conventional FISH method). 286 consecutive patients diagnosed with MM at the University of Maryland Greenebaum Cancer Center were analyzed by the conventional FISH method (from January 2012 to June 2013) and 180 patients were analyzed by the MACs FISH method (from July 2013 to January 2015). Although demographics and laboratory data of patients from January 2012 to June 2013 and from July 2013 to January 2015 were similar, the MACs FISHmethod identified significantly more abnormal cases (69. 5% vs. 28. 9% cases, P < 0. 01) than did the conventionalFISH method. The MACs FISH method yielded significantly higher detection rates of del(13q14/*RB1*), del(17p/*TP53*), 1q21/*CKS1B* gain, *CCND1*/*IGH*, *FGFR3*/*IGH*, and other *IGH* gene rearrangements (P<0. 01) than the conventional FISH method. The MACs FISH method was able to detect a significantly greater number of abnormal cytogenetic subtypes associated with MM (average 1. 5 vs. 0. 4 per case, P<0. 01) than the conventional FISH method. We conclude that plasma cell enrichment of BM specimens by the MACs FISH method significantly increasesFISHsensitivity for detecting clinically relevant genomic abnormalities in MM. These results, in combination with clinical data, can be of value in improving risk stratification and patient management.

2526F

Molecular cytogenetic analysis of recurrent chromosomal abnormalities in pancreatic cancer. *D. Shabsovich[1,2], L. Fonseka[2], K. Park[2], L. Yang[2], N. Rao[2], C. A. Tirado[2].* 1) MICROBIOLOGY, IMMUNOLOGY, AND MOLECULAR GENETICS, UCLA, SANTA MONICA, CA; 2) Pathology & Laboratory Medicine , UCLA, Los Angeles, CA 90024.

Pancreatic cancer is the fourth leading cause of cancer-related death worldwide, with an average 5-year survival rate of approximately 7 percent. However, due to extensive intratumor and intertumor cytogenetic heterogeneity, there are no cytogenetic assays utilized in the clinical management of the malignancy. Herein, we perform Giemsa banding and fluorescence in situ hybridization (FISH) analysis of 15 pancreatic cancer cell lines using probes specific to the following genomic loci : *ARID1A* (1p36), *TGFBR2* (3p22), *MLH1* (3p22), 7q31, centromere 8, *MYC* (8q24), *CDKN2A* (9p21), *TP53* (17p13), and *SMAD4* (18q21). By conventional cytogenetic analysis, the most common numerical aberrations involve chromosomes 20, 22, 7, 12, 13, 14, 18, X and Y. Additionally, structural aberrations most commonly involved chromsomes 1p, 3p, and 8p. FISH analysis revealed a range of abnormal signal patterns and clonal subpopulations bearing various numerical and structural abnormalities both observed and not observed by conventional cytogenetic analysis. In particular, the average copy numbers of the studied genes were found to be different from that of the ploidy of the overall specimen, suggesting a wide range of locus-specific cytogenetic aberrations present in the malignancy involving genes previously associated with pancreatic and other gastrointestinal cancers. To the best of our knowledge, this is the first study that used FISH to investigate *ARID1A*, *TGFBR2*, and *MLH1* abnormalities in pancreatic cancer. These findings provide insight into the chromosomal and molecular nature of the disease and suggest targets for future investigation. Ultimately, phenotypic correlation of chromosomal abnormalities in pancreatic cancer can provide a framework for the development of diagnostic and prognostic cytogenetic assays that can be utilized in the clinical management of the malignancy.

2527F

Application of fluorescence in situ hybridization (FISH) and immunohistochemistry (IHC) for detecting PTEN loss in diagnostic prostate cancer needle biopsies. *J. A. Squire[1,2,3], C. G. Picanco-Albuquerque[3], C. L. Morais[4], F. L. F. Carvalho[4], S. B. Peskoe[6], J. L. Hicks[4], O. Ludkovski[1], H. Fedor[4], E. Humphreys[7], M. Han[7], E. A. Platz[4,5,6], A. M. De Marzo[4,5,7], D. M. Berman[1,4,7], T. L. Lotan[4,5].* 1) Department of Pathology and Molecular Medicine, Queen's University, Kingston, ON, Canada; 2) Department of Pathology, Ribeirao Preto Medical School, University of Sao Paulo, Ribeirao Preto, Brazil; 3) Department of Genetics, Ribeirão Preto Medical School, University of Sao Paulo, Ribeirão Preto, Brazil; 4) Department of Pathology, Johns Hopkins University School of Medicine; 5) Department of Oncology, Johns Hopkins University School of Medicine; 6) Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health; 7) Department of Urology and the James Buchanan Brady Urological Institute, Johns Hopkins University School of Medicine.

Loss of the phosphatase and tensin homolog (*PTEN*) tumor suppressor gene by genomic deletion occurs in approximately 20-30% of prostate cancers. *PTEN* loss at radical prostatectomy has been shown to correlate with early biochemical recurrence, extracapsular and seminal vesicle invasion, castrate resistant disease, metastasis and prostate cancer-specific death. Differentiation of aggressive from indolent tumors remains a high priority for the appropriate management of prostate cancer and the avoidance of unnecessary treatments and side effects in patients with indolent disease. The prognostic value of PTEN loss has primarily been evaluated by either fluorescence in situ hybridization (FISH) or immunohistochemistry (IHC) using radical prostatectomy specimens. This case control cohort was designed to determine the effectiveness of PTEN loss by IHC in predicting the need to upgrade the Gleason score based on the pre-operative needle core biopsies. In this study a subset of 111 needle core samples were analyzed by *PTEN* FISH to determine the predictive value of FISH to upgrade the Gleason score. *PTEN* deletion were found by FISH in 26. 7% (12/45) of upgraded cases compared with 10. 6% (7/66) of controls (p =0. 04). Tumors with *PTEN* deletions were more likely to be upgraded at radical prostatectomy than those without a deletion, when adjusting for age (odds ratio = 3. 40 (1. 14–10. 11; P=0. 028)). Overall the IHC and FISH assays were highly concordant: of 93 evaluated biopsies scored with protein intact, *PTEN* FISH indicated 89 (95. 7%) had no deletion. Of 18 biopsies with PTEN protein loss 15 showed homozygous or hemizygous *PTEN* gene deletion by FISH. Only 4 biopsies of the 93 (4. 3%) with PTEN protein intact had a deletion by FISH. In these four biopsies regions of uncertainty were systematically studied at the cellular level by FISH to demonstrate that intratumoral variation of *PTEN* deletion could account for variation in immunoreactivity. Collectively, this study demonstrates the complementary advantages of both the IHC and FISH assays for analyzing PTEN loss in histologic sections from newly diagnosed prostate cancer patients.

2528F

Clinical features of *TWIST2* heterozygous carriers in a Mexican patient with a 2q37 deletion syndrome (Albright´s hereditary osteodystrophy-like syndrome). *D. E. Cervantes-Barragan[1], L. J. EDELMANN[4], M. J. GAYTAN-GARCIA[1], L. D. LOPEZ-VELAZQUEZ[2], S. RUIZ-PEREZ[3], I. NAZARENKO[4], B. H. LEE[4,5], J. I. NAVARRETE-MARTINEZ[1], R. J. DESNICK[4].* 1) DEPARTMENT OF GENETICS, HOSPITAL CENTRAL SUR DE ALTA ESPECIALIDAD PEMEX, MEXICO CITY, Mexico City, Mexico; 2) Department of Ophthalmology, Hospital Central Sur de Alta Especialidad PEMEX, Mexico city; 3) Department of Pediatrics, Hospital Regional Ciudad Madero, Tamaulipas, Mexico; 4) Department of Genetics and Genomic Sciences, Mount Sinai School of Medicine, New York, New York, USA; 5) Department of Pediatrics, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea.

The 2q37 deletion syndrome or Albright´s hereditary osteodystrophy-like syndrome (OMIM # 600430) is a rare chromosomal disorder reported in more than 115 cases. The cardinal features of the phenotype include developmental delay, obesity, type E brachydactyly, autism and facial dysmorphism. At least 197 genes were mapped in the 2q37 locus, 11 were potentially candidate genes involved in the phenotype, for example *HDAC4, FARP2* and *TWIST2* genes. Homozygous *TWIST2* mutations have been identified in patients with Focal Facial Dermal Dysplasia type 3 or Setleis syndrome (OMIM #227260). The Setleis phenotype includes bitemporal "forceps like" marks, distichiasis, superior triple eye row eyelashes, absence or lower eyelashes and facial dysmorphism. Some carries (*TWIST2* heterozygotes) present with subtle facial dysmporhism and aberrant eyebrows and eyelashes conformation. The exact role of the*TWIST2* phenotype in the 2q37 deletion is poorly understood. We present a 2q37 deletion patient with the clinical features of *TWIST2*heterozygotes. A 7 year 5 month old male patient was referred for moderate developmental delay, scoliosis secondary to a lumbar hemivertebrae, type E brachydactyly, low height and facial dysmorphism (cupped ears and full lips with bow arrow of superior lip). He was the first child of the parents, conceived by *in vitro* fertilization with an unrelated sperm donor. Initial 550-band peripheral blood karyotype revealed a 46,XY,del(2)(q37), confirming an Albright´s osteodystrophy-like syndrome phenotype. High resolution oligonucleotide array-CGH are in progress. Intentional heterozygous onphysical exam, the patient had a right upper eyelashes triple row and distichasis with a V-shaped nasal tip. TWIST2 is a basic-helix-loop-helix transcription factor that is involved in regulation of dermal and bone development during mammalian embryogenesis. *TWIST2* has been proposed as a strong candidate gene for various skeletal malformations involved in 2q37 deletion, including, brachydactyly type E, short limbs, and abnormal vertebrae, but not craniofacial features. Ophthalmologic (eyelashes and eyebrows) and facial (nasal and jaw) features are present in few *TWIST2* heterozygotes. Additional to skeletal involvement, *TWIST2* would explain facial dysmorphysm in patients with 2q37 deletion. Ophthalmologic features of heterozygotesshould be considered in patients with 2q37 deletion.

2529F

Two recurring deletions of 18p with variable expressivity of the 18p minus syndrome. *K. Phillips, R. Burnside, I. Gadi, J. Tepperberg, V. Jaswaney, J. Schleede, A. Penton, H. Risheg, V. Potluri, B. Rush, R. Pasion, H. Taylor, H. Cabral, J. Shafer, L. Kline, M. Johansen, K. Riley, S. Molinari, S. Schwartz, P. Papenhausen.* Cytogenetics, LabCorp, CMBP, RTP, NC.

18p deletion syndrome occurs in 1 in 40,000 births but is common in infants with malformations. Previous studies have mapped clinical features including learning difficulties, ptosis, and short neck to proximal 18p deletions and clinical features such as growth delay, seizures, holoproscencephaly, dystonia, hypotonia, and round face to distal 18p deletions. Holoprosencephaly (HPE4) is associated with loss of function mutations in the *TGIF1* gene. Using SNP microarray, we have analyzed 19 cases of isolated 18p terminal deletions. These cases all reported with terminal deletions and did not include deletions mediated by ring formation, translocations, adjacent inversion duplications, or familial interstitial copy loss variants. Most of the patients were referred only for microarray without accompanying karyotype analysis, and only 2 of 19 patients had parental follow-up analyses done by our lab. Patient results were sorted into 2 groups: those with deletions of the entire p-arm (~15 Mb withnumerous OMIM genes: *USP14->SPIRE1* or *MC2R*) and those with a karyotypically cryptic distal deletion of ~5 Mb (proximal OMIM gene: *DLGAP1*). Patient-age at time of referral ranged from newborn to 62 years, and adult patients were present in both groups. Reasons for referral varied and included cleft lip/palate, holoprosencephaly, encephalopathy, delayed milestones and developmental delay, intellectual disability, FTT, hypotonia, multiple congenital anomalies, heart septal defects, minor anomalies, muscle disorder, and short stature. Break points of distal deletions occurred in the gap between *DLGAP1* telomerically and *EPB41L3* centromerically, and whole p arm deletion breakpoints consistently occurred near the centromere. Although clinical features in patients with 18p deletion syndrome are reported to be dependent upon the size of the deletion and the genes involved, in this study severity of the patient phenotype did not appear to correlate with size of the deletion or breakpoint, as the patients in both groups were phenotypically similar. These data suggest that a limited number of genes predict the phenotype and other genomic and environmental factors likely play an important role in 18p deletion syndrome.

2530F

Cryptic deletion adjacent to the breakpoints of the t(9;22)(q34;q11) translocation in patients with chronic myeloid leukemia. *C. Borjas[1,2], M. Dominguez[1,2], J. González[1,2].* 1) Universidad de Guadalajara, Guadalajara, Guadalajara, Mexico; 2) División de Genética CIBO Instituto Mexicano del Seguro Social.

Introduction Chronic Myeloid Leukemia (CML) is a malignant disorder that results from a reciprocal translocation t(9;22)(q34;q11. 2). Conventional cytogenetic analysis identifies the t(9;22) translocation in 90% of patients. There are factors that determine a poor response to treatment. One such factor could be the sub-microscopic deletion in the derivative 9, which mostly implies the 5'*ABL1*/3'*BCR* sequence. Its incidence is unknown in the Mexican population and its clinical impact. We investigated the frequency of cryptic deletion adjacent to the breakpoints of the t(9:22) translocation by fluorescence in situ hybridization (FISH) in CML patients and evaluate its impact on some clinical and laboratorial parameters. . **Material and methods**We conducted a cross-sectional, descriptive, observational study. We analyzed bone marrow samples as well as the clinical and laboratorial characteristics of the patients with CML at diagnosis. The analysis included GTG-banding and FISH with dual color, dual fusion probes (DC-DF). Statistical analysis was performed using the Student t test for independent samples and Fisher exact test. **Results**Twenty-four CML patients were analyzed, 12 men and 12 women. Mean age was 35. 3 years. The Sokal low risk was present in 38%. The study by GTG banding disclosed the standard t(9;22) in 16 patients (66. 6%), a complex translocation in 6 (25%), a patient with concealed t(9;22) translocation had the karyotype 47,XY,+8 (4. 2%) and a case where metaphases could not been obtained (4. 2%). All patients showed the *BCR/ABL1* fusion by FISH. The *ABL1* cryptic deletion was found in 4 patients (16. 6%). The patient 47,XY,+8 was diagnosed as positive for the BCR/ABL1 fusion and for the deletion of the der(9) sequences by DC-DF FISH. However, a complex arrangement that included a re-translocation *5'ABL1/3'BCR* on the derivative 22 was identified by tricolor-DF FISH. **Discussion** We found that the splenomegaly was significantly higher in men (mean = 13. 8) than females (mean = 7. 0). Also, leukocytosis values showed significant differences when grouping the patients by severity of anemia. No statistical significance between other clinical and laboratorial variables with the cryptic deletion of the *ABL1* sequence was found. **Conclusion** The frequency of cryptic deletion 5'*ABL/3'BCR* in our population is similar to that reported for other populations, and no association was found between the cryptic deletion of *ABL1* with the clinical phenotype of the disease at diagnosis.

2531F

Clinical and molecular characterization of an infant with a 4p16. 3p15. 33 deletion and Xp22. 33p22. 31 duplication. *M. E. S. Colovati[1], S. Bragagnolo[1], R. S. Guilherme[1], A. G. Dantas[1], M. Z. Souza[1], M. F. Soares[2], A. B. A. Perez[1], M. I. Melaragno[1].* 1) Genetics Division, Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, Brazil; 2) Department of Imaging Diagnosis, Universidade Federal de São Paulo, São Paulo, Brazil.

Wolf-Hirschhorn syndrome (WHS, OMIM #194190) is a contiguous gene syndrome with frequency estimated at 1 in 20,000 to 1/50,000 births. Approximately 50-60% individuals have a*de novo*4p16 pure deletion and 40-45% have an unbalanced translocation, *de novo*or inherited from a parent with a balancedrearrangement. We describe a 2 year-old female patient who presented Wolf-Hirschhorn syndrome features with apparent facial assimetry, high forehead, ears tags, left microtia, cleft palate, pectus carinatum, pré-sacral pit, pulmonary stenosis, atrial septal defect, and gastroesophageal reflux. She showed growth retardation and developmental delay, as well as, epibulbar dermoids in the right eye, a typical characteristic of the oculoauriculovertebral spectrum (OAVS). Karyotype was considered normal but high-resolution genomic array analysis showed a ~13 Mb 4p16. 3p15. 33 deletion associated with a ~9 Mb Xp22. 33p22. 31 duplication due to a maternal balanced translocation identified by FISH. The deletion in chromosome 4 includes the WHS critical region, as well as, *BAPX1* and *HMX1* genes that have been associated with OAVS. The patient's and mother's rearrangement breakpoints were mapped by custom genomic array, and sequence analysis of the junction fragments indicated no gene disruption. The mother's der(X) showed 10 additional nucleotides and the patient's and mother's der(4) showed 4 pb deletion. The mother's rearrangement could have been produced by Non Homologous End Joining mechanism (NHEJ), leavinga 'molecular scar' at the DNA junction. In the breakpoints of both chromosomes, repetitive sequences were found (segmental duplications and LTR66 in Xp and Charlie17a in 4p) that could be involved in the rearrangement formation. Thus, the atypical proband clinical phenotype could not be explained by gene disruption but could be due to the presence of sensitive dosage genes in the chromosome regions with 4p monosomy and funcional Xp disomy. This case supports the hypothesis that the 4p region is a candidate for OAVS. Our data revealed the first case of WHS and OAVS features in a patient with functional Xp disomy due to a maternal balanced translocation, a rare cytogenetic finding in females. Financial support: FAPESP.

2532F

A female teenager with sporadic Williams-Beuren syndrome and a familial inv(X)(p22q22). *A. Ramírez[1], H. Rivera[1,2], AI. Vásquez[2], P. Barros[2], L. Figuera[2], MG. Domínguez[2].* 1) Universidad de Guadalajara, Guadalajara, Jalisco, México; 2) División de Genética, CIBO, Instituto Mexicano del Seguro Social, Guadalajara, México.

Introduction: Williams-Beuren syndrome (WBS; OMIM 194050) is typically due to a hemizygous deletion of either 1. 55 or 1. 84 Mb (90% and 8% respectively) on chromosome 7q11. 23with an incidence of 1/7500 [1]. These deletions contain 25 or 28 genes and include the *ELN* gene [2]. The WBS phenotype consists of characteristic facial features, cardiac defects, structural brain abnormalities, and a specific cognitive profile [3]. Pericentric inversions of the X chromosome occur at a frequency of 1/28,000-1/30,000 individuals [4]. We report on a female patient with a 46,X,inv(X)(p22q22) karyotype and a clinical diagnosis of Williams-Beuren syndrome confirmed by FISH. **Clinical report:** This female patient was diagnosed with WBS at 14 years of age. She was born at term to non-consanguineous parents; her birth-weight was 2,700 g. The patient had a typical WBS facies with bitemporal narrowing, epicanthal folds, prominent cheekbones, small and spaced teeth, large mouth, thick lips, prominent eyebrows, bulbous nose, and micrognathia. She also presented short stature, delayed development, supravalvular aortic stenosis (SVAS), visuospatial impairment, and friendly personality. **Methodology:** Chromosomes were analyzed by GTG banding with resolution of 450 bands in 50 metaphases from lymphocyte cultures. FISH assays were carried out with the dual WBS (LSI ELN Spectrum Orange/LSI D7S486, D7S522 Spectrum Green) and Kallmann (LSI KAL Spectrum Orange/CEP X (DXZ1) Spectrum Green), Downers Grove, IL) probes. **Results:** G- banding in the patient and her mother revealed an inv(X)(p22q22), the father karyotype was normal. These breakpoints were confirmed with the Kallmann probe whose signal remained in place; the *ELN* probe revealed a concomitant 7q11. 23 deletion. **Discussion:** About 40 X-chromosome pericentric inversions have been reported including a single case with similar breakpoints ascertained in another Mexican family [5]; since both families came from the same region, they may be related. The co-occurrence of WBS with other alteration is rare; there is a report of a patient with *de novo* typical 7q11. 23 and 22q11. 2 deletions and a combined phenotype of WBS and DiGeorge syndromes [6]. Genetic counseling for carriers of an X-chromosome pericentric inversion should consider the risks of spontaneous abortions, infertility, and recombinant offspring [7]. The concurrence here reported appears to be a fortuitous one.

Bilateral aniridia due to de novo deletion in 11p. 1-p13 region may have resulted from HPV infction. *S. G. Cevik[1], M. O. Cevik[2].* 1) Ophtalmology, Bursa Sevket Yilmaz Training and Research Hospital, Bursa, Turkey; 2) Adiyaman University School of Medicine Department of Medical Genetics, Adiyaman, Turkey.

WAGR syndrome is an acronym forWilms tumor, aniridia, genitourinary anomalies, and mental retardation that are prevalent in most of the patients of this syndrome. We present a one year old babygirl with bilateralaniridia, an absence of the iris. She had loss ofvisual acuityand increased sensitivity to photophobia. She did not have cataracts, noglaucoma, but hadnystagmus-involuntary eye movements. Current status, she has no Wilms tumor. Her karyotype analysis revealed 46,XX karyotype. However her array CGH analysis revealed a heterozygous 6. 7 Mb deletion in chromosome 11p. 1-p13 region that arr [hg19] 11p14. 1-p13(29,209,743-35,961,997)x1. These region includes genes PAX6, WT1,DCDC1 genes. PAX6 gene is known to be responsible from aniridia. WT1 is helşd responsible from Wilms tumor. On the intact side of the WT1 gene region, we found that there is a homozygous G>C replacement at 267. nucleotide (3'UTR+267G>C). Her familal history included HPV infection in gestational period her mother. .

Unique Patterns of Allelic Imbalances Found by SNP-based Microarray: A Tale of Two Chimeras. *C. A. Marcou, U. Aypar, E. C. Thorland, N. L. Hoppman, H. M. Kearney.* Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.

Genome-wide single nucleotide polymorphism (SNP)-based microarrays are powerful tools used to identify copy number imbalances in addition to providing genotype information for multiple polymorphic loci throughout the genome. The inclusion of SNP alleles allows for the recognition of copy neutral absence of heterozygosity (AOH) associated with recessive disease and uniparental disomy (UPD) as well as unique allelic patterns associated with mosaicism and, more rarely, chimerism. We report two cases of constitutional chimerism detected by recognition of unique patterns of SNP allele imbalance. The first case involves 2-year-old dizygotic male/female twin siblings with previously unrecognized twin-twin transfusion. The second case demonstrates diploid/triploid mosaicism (mixoploidy) in a 2-week-old male referred for dwarfism, physical abnormalities, cardiac defects, misshapen ears, and polydactyly. In both cases, characteristic SNP allele patterns allowed for the identification of two genetically unique cell lines, consistent with chimerism, and additional cytogenetic testing characterized the nature of the chimerism. When encountering mixed gender chimerism, it is important to distinguish chimerism limited to the hematopoietic lineage from that with more extensive somatic involvement. The latter may be associated with disorders of sexual development and other abnormal features, where the former may be clinically benign. The clinical consequences, if any, of chimerism/mixoploidy will rely on the percent and tissue distribution of the two independent cell lines. It is likely that chimerism is more common than previously recognized, and will be diagnosed more commonly through routine use of SNP-based microarrays. Therefore, recognition of unique SNP allelic patterns can lead to increased diagnostic utility of SNP-based microarrays in the constitutional setting.

The importance of intragenic duplications within VPS13B in the causation of Cohen syndrome. *JL. Smith, SW. Cheung.* Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Mutations in the VPS13B gene are associated with Cohen syndrome, an autosomal recessive disorder characterized by psychomotor disability, microcephaly, facial dysmorphism, childhood hypotonia, joint laxity and neutropenia. Types of mutations described in various ethnic backgrounds include nonsense, frameshift, splice site and missense mutations as well as small deletions. MLPA has been used to detect intragenic duplications in a few patients. We report a pair of siblings with homozygous duplications in VPS13B each detected by a different chromosomal microarray platform. A custom 400k Agilent array revealed an 81 kb intragenic gain spanning from intron 3 to 13 in one sibling; the log2 ratios indicated the presence of 4 copies of the region. The sibling's array was performed on the Affymetrix Cytoscan HD platform which showed a similar sized intragenic gain of 89 kb involving the same exons of VPS13B and a copy number state of 4. These intragenic duplications are predicted to disrupt the gene. The Cytoscan array also showed that the gain was in a 6. 7 Mb contiguous region of AOH; review of the Agilent array SNP data indicated the sibling's gain was in a small region of AOH. Agilent arrays were performed on both parents and both were found to carry a heterozygous duplication within VPS13B. Consanguinity was denied; however, both parents are from a small town in Mexico, hence a common ancestor is possible. Clinical assessment and hematological testing of both children are consistent with Cohen syndrome. Review of our data base of over 40,000 Agilent arrays did not detect any other cases of homozygous intragenic gains in VPS13B; however, it did detect four gains judged to be heterozygous. The literature indicates that some patients who fit the clinical description of Cohen syndrome have not been confirmed by laboratory analysis of VPS13B to have a homozygous mutation. These data demonstrate that microarray analysis may be another alternative to consider for full assessment of the mutational status of the VPS13B gene in patients who fit the clinical description of Cohen syndrome.

Microdeletion 15q13. 2-q13. 3 syndrome: case report of a patient with facial dysmorphisms, developmental delay, autism spectrum disorder and epilepsy. *E. D. F. Carvalho[1, 2,3], K. M. Carvalho[2, 3], M. D. F. Carvalho[1, 2, 3].* 1) Medical Genetics, Unichristus, Fortaleza, Brazil; 2) Medical Genetics, Genpharma, Fortaleza, Brazil; 3) Renorbio, Universidade Estadual do Ceará, Fortaleza, Brazil.

Microdeletions and chromosomal microduplications are increasingly being diagnosed in patients with developmental delay and intellectual disability, and the majority of cases were revealed by Comparative Genomic Hybridization (CGH array). The microdeletion 15q13. 2-q13. 3is not a syndrome with well defined clinical features and with an easy recognition. Their carriers appear to be more prone to a range of clinical manifestations that vary widely and may include learning disabilities, seizures, autism, neuropsychiatric disorders and congenital heart disease. In 75% of cases, the microdeletion is inherited from one parent. The microdeletion can also be present in unaffected individuals, featuring an incomplete penetrance, therefore, the microdeletion should be research in the parents for an appropriate genetic counseling. We report a case of a female child with facial dysmorphisms, developmental delay, autism spectrum disorder and epilepsy who was diagnosed with microdeletion 15q13. 2-q13. 3 syndrome. She is the second child of non consanguineous parents. The prenatal period was marked by mother hypertension that progressed to pre-eclampsia from the fifth month. The antenatal ultrasound performed was normal. She was born at 31 weeks of gestation by Caesarean section and had a birth weight of 1,429 g, a birth length of 39 cm and an occipital frontal circumference of 30cm . Her Apgar score was 7 and 9 at 1 and 5 min, respectively. At 2 years old, and her physical examination disclosed: developmental delay, short stature, facial discrete dysmorphisms (long palpebral fissures, open mouth, anteverted nostrils). The clinical follow-up was marked by epilepsy, autism spectrum disorder and behavioral changes at 3 years age. Echocardiogram, abdominal USG and transfontanellar and G-banded karyotype were normal. Skull MRI revealed discrete ectasia not hypertensive of the lateral ventricles and Esophageal pH monitoring showed pathologic distal gastroesophageal reflux. The CGH array revealed a microdeletion of 1. 5 MB size at 15q13. 2-q13. 3 involving seven genes: TRPM1, KLF13, OTUD7A, CHRNA7, TRPM1. The CHG array of the parents was performed, but the result is not available yet. Our patient shows clinical signs already reported in this microdeletion syndrome, but with additional clinical features not previously reported as facial dysmorphisms and important gastroesophageal reflux which can lead us to think that the phenotype has not yet been fully clarified.

qPCR confirmation and follow-up testing of copy number variants identified by microarray analysis. *J. Schleede[1], T. Tepperberg[1], S. Schwartz[1], S. Schepis[1], B. Williford[1], B. Burnside[1], V. Jaswaney[1], I. Gadi[1], K. Phillips[1], H. Risheg[2], A. Penton[1], P. Papenhausen[1].* 1) Laboratory Corporation of America® Holdings, Department of Cytogenetics, Research Triangle Park, NC,; 2) Laboratory Corporation of America® Holdings, Houston, TX, 3Dynacare Laboratories, LabCorp, Seattle, WA.

Microarray technology has revolutionized the identification and classification of small copy number variants (CNVs). Fluorescence in situ hybridization (FISH) using BAC probes is widely accepted as the method of choice for confirmation and familial follow-up of CNVs identified by microarray analysis. However, FISH is time consuming, costly, and is not always applicable for the detection of very small CNVs. Real-time quantitative PCR (qPCR) analysis allows for the rapid detection of CNVs at a fraction of the cost of traditional FISH analysis. We have recently added qPCR analysis to our comprehensive microarray follow-up protocol using the Affymetrx® VeriQuest SYBR Green qPCR Master Mix. CNV specific primer pairs are designed using the online resource Primer3Plus while specificity is assayed using the UCSC In-Silico PCR tool. Three normal controls are run in triplicate in conjunction with all samples to ensure both precision and accuracy. qPCR analysis gives reliable and reproducible CNV detection from all sample types including blood, buccal, amnio, CVS, and other tissues. All abnormal prenatal microarrays and CNVs smaller than 50 kilobases can now be quickly and definitively confirmed using this technology. Furthermore, qPCR analysis has become our first round test for all parental follow-up analyses of variants of unknown significance. In the case of *de novo* CNVs we continue to offer parental follow-up FISH analysis to rule out the possibility of a balanced rearrangement with significant recurrence risk. Although one caveat of qPCR testing has been the need to very carefully select primer pairs for complex CNVs that involve small clusters of repeat elements, a clear benefit is the elucidation of chromosome structure associated with genomic gains. We have found that single copy gain by array shows as multi-copy gain by qPCR. This may be the result of various repeat elements in the genome (e. g. small segmental duplications, LINES, SINES, Alu repeats, etc).

Atypical Angelman Syndrome Caused by a Familial Imprinting Center Deletion. *S. S. Costa, A. C. Krepischi, C. Rosenbeg.* Genetics and Evolutionary Biology Dpt. , University of Sao Paulo, Sao Paulo, SP, Brazil.

Angelman syndrome (AS) is caused by different genetic abnormalities involving the chromosome 15q11-13 region, which is subject to genomic imprinting. Imprinted gene expression in the region is regulated by a bipartite imprinting centre (IC). The AS-IC lies around 35 kb upstream of *SNRPN* exon 1 and has been mapped to a region of just 0. 88 kb. Its prevalence is 1-2 per 10,000 individuals. Most patients are affected by AS due to one of four mechanisms: (1) large interstitial deletion of 15q11-q13; (2) paternal uniparental disomy (UPD) of chromosome 15; (3) imprinting defect (ID); or (4) mutation in the E3 ubiquitin protein ligase gene (*UBE3A*). In the few remaining patients, the mechanism is unidentified. Major characteristics of AS include developmental delay, severe mental retardation with lack of speech, movement ataxia, hyperactivity, seizures, aggressive behavior, and excessive inappropriate laughter. At clinical examination, AS was not considered as a diagnostic hypothesis for two siblings who presented only absent speech and intellectual disability. Ataxia and epilepsy were absent, and EEGs reveal no abnormality and, therefore, the phenotype was not characteristic of Angelman syndrome. Array-CGH (180K - Oxford Gene Technology) disclosed in both patients a deletion of 53 Kb encompassing exons U1 to U6. 5 of the *SNRPN* gene. Further, array-CGH showed that the phenotypically normal mother is a carrier, while the normal daughter did not carry the *SNRPN* deletion. DNA methylation of the *SNURF-SNRPN* exon 1/promoter was tested and the patients showed AS methylation pattern. Our results point to the importance of considering mild and atypical Angelman syndrome phenotypes within the spectrum of intellectual handicap, particularly for clarifying the genetic risk to other family members. Financial support: FAPESP/CAPES.

2539W

Mutations in *KIAA0586* cause lethal ciliopathies ranging from hydrolethalus phenotype to short-rib polydactyly syndrome. *C. Alby[1,2], K. Piquand[1], C. Huber[3], A. Megarbané[4], A. KIAA0586, the human ortholog of chicken *Talpid3*, encodes a centrosomal protein that is essential for primary ciliogenesis and its disruption in animal models causes defects attributed to abnormal hedgehog signaling including polydactyly and abnormal dorsoventral patterning of the neural tube. Here we report homozygous mutations of *KIAA0586* in 4 families with lethal ciliopathies ranging from a hydrolethalus phenotype to short-rib polydactyly (SRP). Consistent with a role of Talpid3 in primary cilia biogenesis, we show defective ciliogenesis in cells derived from affected individuals as well as abnormal response to SHH signaling activation. Whereas centriolar maturation seems unaffected in mutant cells, we observed an abnormal extended pattern of CEP290, a centriolar satellite protein previously identified as a ciliopathy protein. Our data show the crucial role of KIAA0586 in human primary ciliogenesis and subsequent abnormal Hedgehog signaling through abnormal GLI3 processing. Our results thus establish that *KIAA0586* mutations cause lethal ciliopathies.

Regulation of exocrine and endocrine pancreas by ciliopathy genes. *T. L. Hostelley, S. Lodh, N. A. Zaghloul.* Division of Endocrinology, Diabetes and Nutrition, Department of Medicine, University of Maryland School of Medicine, Baltimore, MD.

Ciliopathies are rare autosomal recessive disorders characterized by dysfunction in genes associated with the primary cilium. Two ciliopathies, Alström Syndrome (Alms) and Bardet-Biedl Syndrome (BBS), are distinct in the highly prevalent rates of obesity. Interestingly, however, they have strikingly different rates of diabetes. The rate is much higher among Alms patients relative to BBS patients. To gain insight into potential genetic mechanisms for this discrepancy we carried out whole transcriptome sequencing on zebrafish depleted of either Alms1 or Bbs1 expression. We identified gene expression changes between these disorders and found 8 genes that were differentially expressed in opposite directions between the two models. Among these, several exocrine pancreas digestive enzymes were found to be downregulated in Alms and/or upregulated in BBS. These changes in gene expression were validated by qRT-PCR. Based on these observations and our previous identification of discrepant β-cell mass between the two models, we hypothesized that the expression of exocrine pancreas enzymes may have an effect on endocrine pancreas function. This might suggest that the development of diabetes in Alms may be due to impaired endocrine function in the pancreas due to the reduced expression of exocrine pancreas enzymes, which is not seen in BBS as a result of increased expression of these enzymes. To test this, we overexpressed each enzyme in transgenic zebrafish embryos, in which β-cell mass can be visualized by fluorescent marker. We also overexpressed these enzymes in Alms1-depleted embryos to determine if overexpression of the exocrine pancreas enzymes could rescue the loss of β-cells observed in those animals. Overexpression of the exocrine pancreas enzymes significantly increased the area of the β-cell mass as well as the number of β-cells, suggesting that these enzymes play a role in regulating β-cell proliferation and endocrine pancreas function. Taken together, these findings suggest that global gene expression analysis can inform mechanisms of disease in rare genetic disorders as well as more common phenotypes associated with them.

Uncovering the variation in phenotypes arising from mutations causing ciliopathic disorders. *J. P. Whalley, I. Gut, Ciliopathies Exome Sequencing Initiative.* CNAG, Barcelona, Spain.

Ciliopathies encompass rare Mendelian diseases that affect cellular cilia. Interesting, several of the genes found containing causative mutations that result in ciliopathies, have been linked to syndromes affecting different tissues. Notably the gene *CEP290* and; Meckel syndrome type 4 (MKS4 [MIM #611134]), which primarily affects the kidneys, Leber's congenital amaurosis 10 (LCA10 [MIM #611755]), a severe retinal dystrophy and Joubert syndrome 5 (JBTS5 [MIM #610188]), which in the majority of cases, affects the brain. Why a mutation in this gene can lead to differing phenotypes is an interesting area of research. To work on this problem we have been granted access to the 1058 whole exome sequenced samples of the Ciliopathies Exome Sequencing Initiative. We also make full use of databases covering protein interactions and gene expression. We have uncovered two possible explanations on the discrepancy in the phenotypes expressed for mutations in *CEP290*. Firstly this may be linked to the position of the mutation. Joubert syndrome 5 mutations tend to cluster in the second half of the gene, while Meckel syndrome type 4 and Leber's congenital amaurosis 10 mutations are found uniformly across the gene. Enticingly this may be linked to a suspected isoform of the CEP290 protein, which does not include the first 940 amino acids. Another explanation may come from working with genomic sequencing and expression data. *CEP290* interacts with other genes, which may have an effect on the phenotypes observed. A good candidate gene is *PCNT*, which has expression in kidney tissue, but no detectable expression in brain tissue (in contrast to *CEP290* which has high expression in the tissue of the brain and the kidney). Great progress in rare disease research has been made in identifying causative mutations. This research is part of the next step in going further and trying to find out why seemingly very similar causative mutations have such a difference in the type and the intensity of phenotypes of rare diseases observed.

2542W

Functional genome-wide siRNA screen identifies *KIAA0586* as mutated in Joubert syndrome. *S. Roosing[1], M. Hofree[2], S. Kim[1,3], E. Scott[1], B. Copeland[1], M. Romani[4], J. L. Sylhavy[1], R. O. Rosti[1], J. Schroth[1], P. Aza-Blac[5], S. Heynen-Genel[5], T. Ideker[2], B. D. Dynlacht[3], J. E. Lee[6], E. M. Valente[4,7], J. Kim[8], J. G. Gleeson[1], Joubert Syndrome consortium.* 1) Laborator for Pediatric Brain Disease, The Rockefeller University, New York, NY; 2) Department of Computer Science and Engineering and Department of Medicine, University of California, San Diego, USA; 3) Department of Pathology and Cancer Institute, Smilow Research Center, New York University School of Medicine, New York, USA; 4) Mendel Institute, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy; 5) High Content Screening Systems, Burnham Institute, La Jolla, USA; 6) Samsung Genome Institute (SGI), Department of Health Sciences and Technology, SAIHST, Sungkyunkwan University, Seoul, South Korea; 7) Section of Neurosciences, Department of Medicine and Surgery, University of Salerno, Salerno, Italy; 8) Korea Advanced Institute of Science and Technology (KAIST), School of Medical Science and Engineering, Daejeon, South Korea.

Defective primary ciliogenesis or cilium stability forms the basis of human ciliopathies, including Joubert syndrome (JS), with defective cerebellar vermis development. We performed a high-content genome-wide siRNA screen to identify genes regulating ciliogenesis as candidates for JS. We analyzed results with a supervised learning approach, using SYSCILIA gold standard, Cildb3. 0, a centriole siRNA screen and the GTex project, identifying 591 likely candidates. Intersection of this data with whole exome results from 145 individuals with unexplained JS identified six families with predominantly compound heterozygous mutations in *KIAA0586*. A c. 428del base deletion in 0. 1% of the general population was found in *trans* with a second mutation in an additional set of 9 of 163 unexplained JS patients. *KIAA0586* is an orthologue of chick *Talpid3*, required for ciliogenesis and sonic hedgehog signaling. Our results uncover a relatively high frequency cause for JS and contribute a list of candidates for future gene discoveries in ciliopathies.

2543W

A role for BBS4 in regulation of BDNF/TrkB signaling and hypothalamic neuronal specification. *C. Leitch, S. Lodh, N. Zaghloul.* Division of Endocrinology, Diabetes and Nutrition, Department of Medicine, University of Maryland, Baltimore, Baltimore, MD.

Bardet-Biedl Syndrome (BBS) is an autosomal recessive ciliopathy characterized by highly penetrant obesity that is likely a result of defects in centrally mediated regulation of food intake: hypothalamic regulation of satiety. The extent to which regulation of hypothalamic neuronal signaling pathways are dependent on proper BBS protein function or ciliary regulation are unknown. To examine this possibility, we investigated a potential relationship between the BBS protein, BBS4, and a major neuronal signaling pathway involved in regulation of food intake, brain derived neurotrophic factor (BDNF) signaling. We investigated the role of BBS4 in modulation of BDNF signaling through its receptor, TRKB. We found that BBS4 is necessary for proper activation of the TRKB receptor by BDNF and that localization of TRKB to the axoneme of the cilium may play a role. Examination of the relevance of these findings to embryonic production of neuronal populations in zebrafish revealed an important role for BBS4 in modulating the balance between neuronal populations necessary for hunger and satiety, including hunger-inducing NPY/AgRP neurons. These effects could be ameliorated by addition of exogenous BDNF, potentially implicating the pathway in the production of these neurons. Additionally, reduction of BBS4 resulted in increased NPY expression levels, which was also ameliorated by addition of exogenous BDNF. Our findings suggest an important role for BBS4 and ciliary localization in transduction of BDNF signaling through TRKB. These data also suggest a potential role for BBS4 in mediation of the BDNF signaling pathway and in hypothalamic neurogenesis during development.

The role of the BBSome in visual function during eye development and adulthood. *Y. Hsu, J. E. Garrison, D. Y. Nishimura, K. E. Bugge, C. C. Searby, V. C. Sheffield.* University of Iowa , Iowa city , IA.

The outer segments of photoreceptor cells are specialized sensory **cilia**, and share features with other primary and sensory cilia. The BBSome, a protein complex consisting of BBS1, 2, 4, 5, 7, 8, 9 and 18, is required for the proper localization of proteins important for visual function such as rhodopsin. Human patients with Bardet-Biedl syndrome (BBS) and knockout mouse models of core BBSome components have retinal degeneration. However, it is not clear whether the BBSome plays a developmental role in the formation of photoreceptors in addition to maintaining normal functions of photoreceptors throughout life. Using a mouse model that enables the tamoxifen inducible deletion of BBS8, a core BBSome protein, we test whether the loss of the BBSome in adulthood, after the completion of eye development, disrupts visual function. We found that the inducible deletion of *Bbs8* in adult mice causes significant deterioration of visual functions measured by electroretinogram. Furthermore, we found that the deletion of *Bbs8* in juvenile mice at specific time points of retinal maturation causes rapid vision deterioration comparable to congenital *Bbs8* knockout mice. The data suggest that the BBSome plays a role in photoreceptor development as well as the continual function of photoreceptors after eye development is complete. Finally, using a hypomorphic mouse model where a gene trap is inserted between exon 3 and 4 of *Bbs8*, we investigated the functional relationship between vision and the expression levels of *Bbs8*. We show that visual function is sensitive to the gene expression levels of Bbs8, and that homozygous gene trap mice are able to retain partial visual function due to a low level of *Bbs8* expression. We show that the BBSome is required throughout life for the function and survival of photoreceptors. The deletion of BBSome components during the late stage of eye development causes accelerated vision deterioration compared to the deletion of BBSome components during adulthood, which causes a slower but significant rate of vision deterioration.

Transcriptional and translational dynamics of cell fate specification in pluripotent stem cells define the unique biology of individual human genomes. *A. Jaishankar, G. Stein-O'Brien, SK. Kim, S. Seo, E. Fertig, J. Shin, J. Chenoweth, D. Hoeppner, C. Colantuoni, R. McKay.* Lieber Institute for brain development, Baltimore, MD.

Human pluripotent stem cells have been proposed as a powerful tool for drug development as well as to define cellular deficits associated with genetic risk for disease. However, these applications require an understanding of factors that control cell fate specificationas well as the ability to consistently distinguish the cellular behavior of individual genomes. Novel bioinformatic analysis ofRNA-seq data obtained from multiple human pluripotent stem cell lines in conditions that support self-renewal or differentiation to mesendodermal and neuroectodermal fates, reveals lineage bias and distinct transcriptional dynamics in individual lines that accurately predicts their differentiation potential. We use high content imaging to map these spatial and temporal changes during lineage specification as human pluripotent stem cells rapidly organize into zones biased to form either the brain or the body. The key signaling pathways regulating stem cells continue to have a major role in brain development and dysregulation of these pathways contribute to risk for neurodevelopmental disorders. The AKT/mTOR signaling pathway regulates pluripotency. We have shown that this occurs in specific domains biased towards different regional states that form the organs and tissues of the new individual. A pharmacological approach will be presented to define how differences in AKT/mTOR signaling regulate the spatial organization of this early epithelium and the subsequent epigenetic trajectories these cells traverse. Applying these concepts, tools and novel data analysis opens the door to interrogate genetic and pharmacology diversity of human brain development from a powerful novel perspective.

Atypical cadherin FAT1 is essential for optic fissure closure in mouse and zebrafish. *A. George[1], S. BHARTI[1], R. SHARMA[2], F. ONOJAFE[1], S. DUTTA[1], H. McNEILL[3], K. BHARTI[2], B. P. BROOKS[1].* 1) Ophthalmic Genetics and Visual Function Branch, National Eye Institute/NIH, BETHESDA, MD; 2) Section on Epithelial and Retinal Physiology and Disease, National Eye Institute/NIH, Bethesda, MD; 3) Mt. Sinai Hospital, Department of Molecular Genetics, University of Toronto, Canada.

Expression profiling using microarray during mouse optic fissure closure (OFC) revealed that *Fat4* is dynamically expressed at the closing edges of the optic fissure in the developing mouse eye, suggesting that it might have a potential role in the pathogenesis of a potentially-blinding ocular malformation, coloboma. Upon histological analysis of *Fat4*-/- mice, no abnormality was observed in the OFC. On the contrary, a closely related family member *Fat1*-/- consistently exhibited OFC defects. Expression of other members of the FAT family i. e. *FAT2* and *FAT3* was not observed in the developing mouse eye. Expression patterns for *Pax2*, *Pax6*, *Mitf* and *Chx10* were similar between WT and *Fat1*-/- mice, suggesting the lack of early patterning defect. The phospho Histone-3 positive cells were significantly increased in the *Fat1*-/- mice compared to WT but the total number of cells in the optic cup remained equal. Activated Caspase-3 levels were relatively unchanged. As compared to WT, increase in cytoplasmic β-catenin staining was observed in the *Fat1*-/- mice retinal pigmented epithelium flat-mounts. To further delineate the possible mechanism we shifted our focus to zebrafish. Consistent with the findings in mice, morpholino mediated knock-down of *fat1* resulted in coloboma whereas it was not observed with *fat4* knock-down zebrafish embryos. The abnormal phenotypes, including cystic pronephros and brain defects were consistent with previous reports and suggests a possible role for Hippo signaling. Defects in Hippo signaling results in nuclear translocation of *yap1* resulting in growth defects. Concomitant knock-down of *yap1* together with *fat1* resulted in partial rescue of the OFC defects. Interestingly, over-expression by mRNA injection and morpholino mediated knock-down of *yap1* resulted on OFC defects. Mutations in *YAP1* and deletion of *SCRIBBL* gene, both of which play an important role in Hippo signaling, have already been reported to cause coloboma in humans, though the underlying mechanism remains obscure. .

The *Gfi-Cre* knock-in mouse as a tool for inner ear gene expression analysis. *M. Matern[1], B. Milon[1], R. Elkon[2], Y. Song[1], R. Hertzano[1].* 1) University of Maryland, Baltimore, Baltimore, MD; 2) Tel Aviv University, Tel Aviv, Israel.

Hearing depends on the proper functioning of hair cells, which are specialized neuroepithelial cells present in the inner ear. In adult mammals, cochlear hair cells are post-mitotic, meaning that once they are damaged they cannot be regenerated. Therefore, most forms of traumatic hearing loss from noise or ototoxic drug exposure result in a permanent loss of hair cells. Additionally, congenital non-syndromic sensorineural hearing loss can result from mutations in over 150 genes, many of which are expressed in hair cells. For years, the mouse model organism has proved to be an invaluable tool for understanding the genetics of hearing loss. However, molecular analyses of hair cell specific changes that occur in response to noise, drugs or genetic manipulations have been limited by the heterogeneous nature of the auditory sensory epithelium in which the hair cells comprise less than 2% of cells. More recently, RiboTag mice and transgenic mice expressing fluorescent markers have made tissue and cell type-specific analyses of gene expression possible. Specifically, the *Gfi1-Cre* knock-in mouse is commonly used for hair cell-specific recombination to analyze conditional knockout mice in the auditory field. Here we performed a comprehensive analysis of these mice to determine the specificity and utility of the *Gfi1-Cre* driver in analyzing hair cell-specific gene expression in the newborn inner ear. Specifically, we crossed *Gfi1-Cre* mice with both Ai14 and RiboTag mice to perform hair cell transcriptome and translatome analyses. Our results show that *Gfi1-Cre* mice produce a broader pattern of gene recombination than previously described. This is likely due to a more extensive expression pattern of the *Gfi1* transcription factor in the developing mouse otocyst. We further compare the inner ear transcriptomes of both wild type and heterozygous *Gfi1-cre* mice to determine whether the omission of one copy of *Gfi1* affects overall gene expression. Finally, we compare the hair cell translatome as obtained using the *Gfi1-Cre*/RiboTag mice with transcriptomes of sorted hair cells and critically discuss our results. This study is the first to evaluate the utility of the *Gfi1-Cre* mice as a tool for hair cell-specific genomic analysis in the inner ear. While our results show that the expression of *Gfi1-Cre* is not specific to hair cells as previously described, these mice are still a valuable tool for inner ear research.

2548W

Molecular genetic characterization of TGF-β mechanism in embryonic rescue for the secondary palate with overexpression of Smad2 using genetic models. *H. A. Al Omer[1, 3], G. E-H. Gawish[2, 3].* 1) Prince Abdulrahman Advanced Dental Institute (PAADI), Riyadh, Saudi Arabia; 2) Medical Genetics, College of Medicine, Al Imama Muhammad Ibn Saud Unversity; 3) Oral Biological Medical Science, University of British Columbia, Canada.

Cleft palate is a common birth defect in the human population. In analyses of non-syndromic cleft palate, a linkage to TGF-β3 has been shown. Signalling of TGF-β is mediated in the cell through Smad2. The aim of this study was to understand the mechanism of palatal fusion in the rescue mice compared to wild-type. The heads of embryos at age (E14. 5) of rescued, Smad2 overexpression and wild-type models were embedded in paraffin after genotyping and fixation. Serial 7 micron sections were studied for detection of apoptosis and epithelial mesenchymal transition using immunohistochemistry. Images were captured with confocal laser microscope. Activation of Smad2 was studied with phospho-Smad2 antibody, and the level of Smad2 in each embryo normalized with immunoblotting. We observed that TGF-β3 null mice developed a secondary palatal cleft while the TBF-β3 null mice that had also inherited the K14-Smad2 gene had fusion of the secondary palate. The effect of the K14-Smad2 expression was analyzed in the medial edge epithelium of the rescue mice; the MEE had a much higher ratio of cells with cleaved caspase, a marker of apoptosis, than in the control fused palates. The increase in apoptosis was correlated with increased p-Smad2 in the same cells while p-Smad2 in the control mice with normal palatal fusion was not associated with high levels of apoptotic MEE. We concluded that Smad2 overexpression might rescue the cleft in the secondary palate of mice by increasing apoptosis of epithelial cells in the middle seam. Thus the mechanism of rescue is not identical to the events that normally occur during palatal fusion.

Modeling distal hereditary motor neuropathies in zebrafish. *A. Kondo, B. Mitchell, L. L. Smith, A. H. Beggs, V. A. Gupta.* Genetics/Genomics, Boston Children's Hospital, Boston, MA.

The distal hereditary motor neuropathies (dHMN) are a heterogeneous group of diseases that are characterized by degeneration, loss of lower motor neurons, and skeletal muscle atrophy. Some forms of dHMN may have sensory abnormalities and overlap with axonal forms of Charcot-Marie-Tooth disease (CMT2). dHMNs are classified in to several forms based on mode of inheritance and phenotype (dHMN I-dHMNVII and X-linked dHMN). DHMN-VI or spinal muscular atrophy with respiratory distress type 1 (SMARD1) is a severe, autosomal-recessive infantile neuropathy. The most prominent symptoms are diaphragmatic paralysis and predominant involvement of the upper limbs and distal muscles. SMARD1 is caused by mutations in the gene immunoglobulin μ binding protein 2 (*IGHMBP2*). IGHMBP2 is an ATP dependent helicase that unwinds RNA and DNA duplexes and finally regulates the protein translation. Recent studies have identified *IGHMBP2* mutations underlying CMT2 and axonal sensorimotor neuropathies, expanding the clinical spectra of this gene mutations. To advance the understanding of SMARD1 and associated disorders, we have created a vertebrate zebrafish animal model of IGHMBP2 deficiency. Transient knock-down of zebrafish *ighmbp2* resulted in impaired motor function and muscle defects as observed in human patients. To study the long-term effects of IGHMBP2 deficiency and develop therapies, we have utilized a CRISPR/Cas9 system to create a knockout zebrafish model. Targeting three different exons yielded high rates of mutagenesis, resulting in insertions or deletions in *ighmbp2*. Mutant embryos exhibit motor neuron abnormalities and weak skeletal muscles in IGHMBP2 deficiency. These abnormalities are observed during early development of zebrafish embryos (2 dpf) suggesting that IGHMBP2 is required for development and function of primary motor neurons and skeletal muscles as mutations in human patients are also associated with early congenital abnormalities. The study of IGHMBP2 in zebrafish offers a promising model for the study of dHMN and will lead to a clearer understanding of the cellular and molecular abnormalities underlying this disease.

2550W

A novel mouse model of Uveal Coloboma due to genetic rearrangement on Chr13. *R. P. Alur[1], F. I. Onojafe[1], A. Dutra[2], E. Pak[2], J. Thomas[3], M. Fruttiger[4], W. D. Richardson[5], S. Pieke-Dahl[6], P. F. Hitchcock[6], B. P. Brooks[1].* 1) National Eye Institute, National Institutes of Health, Bethesda, MD, 20892; 2) NHGRI, NIH, Bethesda, MD, 20892; 3) NISC, NHGRI, NIH, Bethesda, MD, 20892; 4) UCL Institute of Ophthalmology, London, U. K; 5) Wolfson Institute for Biomedical Research, University College London, London, U. K; 6) University of Michigan, Ann Arbor, MI.

Statement of purpose: Uveal coloboma is a potentially blinding congenital ocular malformation caused by failure of the optic fissure to close during the 5th week of human gestation and at around 11. 5 days in the mouse. Many genetic studies in human and mouse have suggested genetic heterogeneity and incomplete penetrance. Known genes explain a minority of cases, implying the role of other developmentally regulated genes. In this study, we characterize the RICO (**R**etinal & **I**ris **CO**loboma) mouse and propose a model for genetic rearrangement. **Methods used: The** RICO mouse model was created by the transgenic insertion of a human VEGF (hVEGF) expression vector. The insertion site was localized with FISH using commercially-available BAC clones for mouse chromosome 13 and the original transgenic plasmid. Embryos and mice were genotyped using a combination of FISH and PCR/TaqMan assay and were phenotyped grossly and histopathologically. The insertion site was evaluated using a combination of Comparative Genomic Hybridization (CGH), BAC library construction, shot gun sequencing of two BAC clones and whole genome sequencing of RICO genomic DNA. Further, Array Star mouse lncRNA (long non-coding RNA) array was performed to study the regulatory elements in this genomic region. **Summary of results:** Uveal coloboma in C57BL/6J-RICO mice was generally bilateral (≥60%; N=310), affecting the iris, retina/choroid, and optic nerve. Transmission was semi-dominant with nearly 100% penetrance and homozygous embryonic lethality. The *NSE-hVEGF* transgene inserted on mouse chromosome 13C was transcriptionally silent. CGH array of heterozygote RICO DNA showed no large duplications or deletions on Chr 13. From the BAC library, shotgun sequencing and whole genome sequencing, we propose a model for the duplication, genetic insertion/re-arrangement responsible for the phenotype. Further, analysis of the lncRNA array results with focus on re-arranged genomic region showed down regulation of a lncRNA element in the close proximity of Nr2f1 (3. 64 fold change and intergenic in nature) in the homozygous RICO mouse. Further confirmation of the lncRNA elements by qRT-PCR and investigations into the functions of these regulatory elements are underway.

Normal palate development requires *Prdm16* expression in the mandible, not the palate. *B. C. Bjork, I. B. Emerson, K. Lundry, L. Pitstick.* Department of Biochemistry, Midwestern University, Downers Grove, IL.

The *Prdm16* transcription factor gene functions in many different tissues and biological processes, including hematopoietic and neuronal stem cell maintenance and brown adipose tissue cell fate determination. *Prdm16*is expressed in both the palate, mandible and tongue,and *Prdm16* loss-of-function mutations cause cleft secondary palate (CP). CP in these mutants occurs secondary to micrognathia due to failed palate shelf elevation similar to human Pierre Robin Sequence-type CP. To determine the role of *Prdm16* during palate formation, we carried out tissue-specific ablation experiments using a novel conditional gene trap allele of *Prdm16, Prdm16cGT*, and palate mesenchyme-specific (*Osr2::cre*) and mandible-specific (*Hand2::cre*) *cre*-expressing strains. Palate-specific ablation of *Prdm16* did not adversely affect palate shelf elevation or fusion; however, we observed micrognathia and CP inmandible-specific knockout embryos. We also observed that *Prdm16* null mutant heads with mandibles and tongues removed undergo normal palate shelf elevation and fusion in an *in vitro* suspension culture system. These results confirm that *Prdm16* expression in the mandible and not the palate, is necessary for normal palate formation. Furthermore, we tested if *Prdm16* expression in the mandible is sufficient for normal palatogenesis via mandible-specific rescue of *Prdm16* expression to the mandible only in an otherwise null *Prdm16cGT* embryo. These crosses yielded both *Prdm16* null mutant embryos with cleft palate and micrognathia and *Prdm16* null mutant embryos with *Prdm16* expression returned to the mandible only that exhibit rescue of the CP phenotype. This result further demonstrates a palate-extrinsic role for *Prdm16* during palate formation. Beyond understanding the developmental mechanism of clefting in *Prdm16* mutants, we are interested in identifying genes and pathways within which *Prdm16* acts during normal mandible and palate formation. Screening of mandible markers via whole-mount *in situ* hybridization identified *Goosecoid* (*Gsc*) as being down-regulated in the mandibular arch in *Prdm16* null mutant embryos. We are examining the possibility that *Gsc* is a direct transcriptional target of PRDM16 using *in vitro* luciferase reporter assays and Chromatin Immunoprecipitation (ChIP). In addition, we are using a Next-Generation sequencing approach to determine global expression differences that occur as a consequence of *Prdm16* loss in the developing mandible.

2552W

Mitochondrial deficiency by Gtpbp3 depletion affects further development in zebrafish. *D. Chen, F. Li, Q. Yang, M. Tian, Y. Chen, M. Guan.* Institute of genetics, Zhejiang University, Hangzhou, Zhejiang, China.

Mitochondria are eukaryotic organelles that generate most of the energy in the cell by oxidative phosphorylation. Mitochondrial respiratory chain deficiencies exhibit a wide variety of clinical phenotypes, which could be caused by either mutations in the mtDNA or mutations in nuclear genes coding for mitochondrial proteins. We have previously reported the identification and characterization of human *MSS1* homolog, *GTPBP3*, the first identified vertebrate gene related to mitochondrial tRNA modification, and found the mutations in human *GTPBP3* manipulate the penetrance of deafness associated with mitochondrial 12S rRNA mutation. The Gtpbp3 is the mitochondrial GTPase evolutionarily conserved from bacteria to mammals. Here, we reported a novel Gtpbp3 depletion animal model using antisense morpholinos in zebrafish. A marked decrease of mitochondrial ATP generation accompanied by increased levels of apoptosis and reactive oxygen species were observed in *gtpbp3* knockdown zebrafish embryos. The Gtpbp3 morphants exhibited melanin, oedema, curved tails, bleeding and most of them died within 5 days post fertilization. Taken together, our results suggest that zebrafish Gtpbp3 is a structural and functional homolog of human and yeast Gtpbp3, and the impairment of mitochondrial ATP generation caused by Gtpbp3-deficiency may lead to zebrafish embryonic development arrest in an apoptosis dependent way.

2553W

A Forward Genetics Approach to Discover Modifiers of Holoprosencephaly and Cleft Lip/Palate. *K. A. Geister[1], A. E. Timms[1], S. Ha[1], R. J. Lipinski[2], D. R. Beier[1].* 1) Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA; 2) Department of Comparative Biosciences, University of Wisconsin-Madison School of Veterinary Medicine, Madison, WI.

The discovery of modifier genes in human and mouse has seen slow progress. In mice, this is largely due to the reliance on inherent variability among inbred strains, which makes identifying the causal variant, even in highly resolved mapped loci, quite challenging. We have developed a fast and cost-effective method for genetic mapping of causal ENU-induced mutations using Next Generation Sequencing that combines single nucleotide polymorphism (SNP) discovery, mutation localization, and identification of causal sequence variants. This approach precludes the need for an outcross to facilitate mapping, as we use the ENU-induced variants as SNP markers. This strategy allows us to perform both primary screens and modifier screens on fully inbred lines. We have successfully mapped causal mutations using this approach, and we are currently testing the efficacy of this strategy with regard to modifier discovery using two C57BL/6 congenic strains as our sensitized lines. One is a loss-of-function allele of the SHH transcriptional effector *Gli2*, which can be modified by prenatal ethanol exposure to generate holoprosencephaly-like phenotypes. The other is a spontaneous loss-of-function allele of *Pibf1* that causes cleft lip/palate and ciliopathy-like phenotypes. Both alleles could reveal modifiers of genes involved in craniofacial, brain, and skeletal development as well as those involved in the formation and function of the primary cilium. In the simplest cases, whole-genome sequencing will reveal areas of homozygosity shared between mutants with a consistent "modified" phenotype, and allow us to narrow our focus to the induced variants included in these homozygous regions. We anticipate that we may ascertain more complex genetic interactions as well as new ENU-induced mutant phenotypes that model human birth defects.

2554W

Distinct requirement for the basal plate in the regionalization of the posterior diencephalon. *B. Lee, Y. Jeong.* Genetic engineering, Kyunghee University, Yongin-si, Kyunggi-Do, South Korea.

The developing diencephalon is the posterior region of the embryonic forebrain, and undergoes dynamic regionalization including its subdivision along the dorsoventral and anteroposterior axes. The alar plate of the posterior diencephalon is partitioned into three different prosomeres (designated p1-p3), which develop into the pretectum, thalamus, and prethalamus, respectively. In the present study, we show the developmental outcomes of genetic ablation of cell populations from the diencephalic basal plate. The strategy for conditionally regulated cell ablation is based on the targeted expression of the diphtheria toxin gene (DTA) to the diencephalic basal plate via tamoxifen- induced, Cre-mediated recombination of the ROSADTAallele. Our results show that activation of DTA leads to specific cell loss in the basal plate of the posterior diencephalon, and disrupted early regionalization of distinct alar territories. In the basal plate-deficient embryos, the p1 alar plate displayed reduced expression of subtype-specific markers in the pretectum, whereas p2 alar plate failed to further subdivide into two discrete thalamic subpopulations. We also report that these defects lead to abnormal nuclear organization at later developmental stages. Our data have strong implications for increased understanding of the interactive roles between discrete diencephalic compartments.

2555W

Reeling in the Effect of Decreased Sulfate on Embryonic Development and Risk of Autism Spectrum Disorder through Disruption of *slc13a1* in Zebrafish. *C. G. Perry, L. M. Yerges-Armstrong, A. R. Shuldiner, N. A. Zaghloul.* Division of Endocrinology, Diabetes, and Nutrition, and Program for Personalized and Genomic Medicine, University of Maryland School of Medicine, Baltimore, MD.

Autism spectrum disorder (ASD) affects approximately 1 in 68 children in the United States. The heritability of ASD is estimated to be 50%, suggesting that both genetic and environmental risk factors contribute significantly to the development of ASD. Many of these risk factors have yet to be identified; however, previous studies suggest that sulfate deficiency may be an important risk factor. In fact, such investigations have shown that blood sulfate concentration is reduced in 92% of children with ASD compared to age-matched controls (0. 55 vs. 4. 90 nmol/mg protein, respectively). Though not routinely measured, sulfate is an essential micronutrient integral in the biotransformation of multiple compounds, such as hormones, neurotransmitters, proteoglycans, and xenobiotics, via sulfation. Interestingly, the solute carrier family 13, member 1 *(SLC13A1)* gene, which encodes an apical membrane, sodium-sulfate cotransporter (NaS1) that mediates sulfate (re)absorption across renal and intestinal epithelia, resides in the Autism Susceptibility Locus 1 (*AUTS1*) on chromosome 7q. We previously reported on two rare, non-linked, nonsense variants in *SLC13A1* (c. 34C>T, p. R12X and c. 144G>A, p. W48X) that are enriched in the Amish and associated with hyposulfatemia (P=9x10-20). Mammals with homozygous loss-of-function variants in *Slc13a1* display developmental and growth abnormalities, consistent with the critical role of sulfation in the regulation of growth and development. With this in mind, we injected zebrafish embryos with morpholino targeting *slc13a1*, which resulted in a significant decrease in *slc13a1* mRNA expression, and assessed embryonic growth and neurological development at 48 hours post fertilization. Strikingly, *slc13a1* morphants display 3- to 7-fold higher frequencies of gross, tail, and gastrointestinal abnormalities, along with a 14% reduction in body length, compared to injected controls (P<0. 0001). These results are consistent with abnormal development in tissues known to require sulfate for proper development. Furthermore, *slc13a1* morphants exhibit a 22% decrease in eye area, a 7% decrease in midbrain width, and a 5% increase in forebrain:midbrain width, compared to injected controls (P<0. 0005). Together, these results suggest a role for *slc13a1* and/or sulfate in embryonic growth and neurological development, offer insight into sulfate's role in human physiology and disease, and provide support for additional phenotyping of human R12X and W48X carriers.

Brain region specific roles for CHD7, the gene mutated in human CHARGE syndrome. *J. M. Skidmore[1], M. A. Durham[2], H. Yao[1], D. M. Martin[1,3].* 1) Dept Pediatrics, Univ Michigan, Ann Arbor, MI; 2) Baylor College of Medicine, Houston, TX; 3) Dept Human Genetics, Univ Michigan, Ann Arbor, MI.

Impairments in central nervous system (CNS) processing of peripheral sensory functions (vision, hearing, balance and olfaction) are common in autism spectrum disorders (ASDs). CHARGE syndrome, a congenital anomaly disorder and leading cause of multisensory impairment and deafblindness, is one of many genetic forms of ASD. The underlying mechanisms leading to ASD behaviors in CHARGE are not known; however, CNS developmental abnormalities including arrhinencephaly, holoprosencephaly, corpus callosum agenesis/dysgenesis and cerebellar defects are common. CHARGE is caused by heterozygous mutations in CHD7, an ATP dependent chromodomain remodeling protein that regulates gene expression. *Chd7* heterozygous mutant mice exhibit defects in development of inner ear and craniofacial structures similar to those in humans with CHARGE. In mice, *Chd7* is expressed in the developing and mature brain regions (olfactory bulb, hypothalamus, midbrain, hindbrain, and cerebellum), and in areas of adult neurogenesis (dentate gyrus of the hippocampus and subventricular zone). Prior studies identified roles for *Chd7* in neurogenesis in the developing mouse inner ear and olfactory placode, where CHD7 is expressed in neural stem cells and regulates proneural gene expression, and in the CNS forebrain subventricular zone, where CHD7 regulates neural stem cell proliferation and fate. Here we present data from conditional mice with loss of one or both copies of *Chd7* in the brain. We also report on the generation and characterization of a novel Chd7-iCre transgenic line for lineage tracing and CHD7-specific deletions. *Nestin-Cre*-mediated *Chd7* deletion in neural progenitors leads to mild anxiety phenotypes, whereas *Wnt-1Cre*-mediated conditional deletion of *Chd7* in the midbrain/hindbrain is postnatal-lethal and results in cerebellar hypoplasia and reduced foliation. Loss of *Chd7* by *Wnt1-Cre* also leads to attenuation of *Wnt1* and *Fgf8* expression domains at the embryonic day 11. 5 midbrain/hindbrain boundary, consistent with roles for *Chd7* in early midbrain-hindbrain patterning. Expression analysis suggests dual origins of CHD7 cells in the cerebellar ventricular zone and rhombic lip. Temporal deletion of *Chd7* in developing granule cellswith Atoh1-CreERT2 mice is underway. Our results provide novel insights into roles for *Chd7* in brain and cerebellar development, and may shed light on mechanisms by which CHD7 haploinsufficiency leads to ASD and other cerebellar mediated behaviors.

2557W

B-cell CLL/Lymphoma 9-like (Bcl9l) and eye development. *D. Wu, A. Anderson, A. Slavotinek.* University of California San Francisco, San Francisco, CA.

B-cell CLL/Lymphoma 9 (*Bcl9*) and B-cell CLL/Lymphoma 9-like (*Bcl9l*) mediate the interaction between β-catenin and two Pygopus proteins, Pygo1 and Pygo2, in Wnt signaling in vertebrates. The interaction between Bcl9 and Bcl9l and Pygo occurs through two highly conserved protein domains called HD1 and HD2. Studies in mice using two 'knock in' models to remove the function of either HD1 or HD2 showed that deletion of HD1 blocked the recruitment of Pygo proteins to the β-catenin transcriptional complex, but enabled β-catenin binding and thus signaling through β-catenin (Cantù et al. , 2014). Deletion of HD2 blocked β-catenin binding, but was predicted to enable Pygo2 binding. Transgenic mutant mice without capacity for HD1 signaling for both Bcl9 and Bcl9l had absence of the lens placode and lens (Cantù et al. , 2014), implying that the Pygo proteins were relevant to lens development. We are interested in the role of Wnt signaling in eye development and chose to further examine the effects of loss of function for Bcl9l to determine if reduced function for this gene alone is relevant to lens formation. We first used a splice site antisense morpholino targeting *bcl9l*, the *Danio rerio* orthologous gene, to screen for eye defects associated with loss of function. Morphant larvae showed a consistent phenotype with a smaller eye, with eye size being dose dependent and not rescued by co-injection of p53 antisense morpholino. Sectioning of morphant larvae showed a smaller lens, although the remainder of the eye appeared normally formed. We then used Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) to make fish with stable loss of bcl9l function, and have generated one mutant that is a homozygous for a frameshift mutation prior to the HD1 domain. This fish appears normal externally, but the second *Danio rerio* orthologue of Bcl9l has not been targeted and reduced function for this gene or *bcl9* may be required for a phenotype. We also investigated the effects of *BCL9L* on Wnt signaling *in vitro*, and found that targeting *BCL9L* using siRNA decreased β-catenin signaling at the RNA level without effects on *PYGO2* or *BCL9* expression in ARPE19 cells from human retinal pigment epithelium. These preliminary results support a role for *Bcl9l* on lens development acting through β-catenin, and our studies are ongoing. Cantù et al. Genes Dev. 2014;28:1879.

KLF14 involves in controlling inflammation in the white adipose tissue. *C. Tayama[1], E. Takanashi[2], J. Tomikawa[1], H. Okita[3], K. Hata[1], T. Okamura[2], K. Nakabayashi[1].* 1) Dpt. of Maternal-Fetal Biol. , Nat. Res. Inst. for Child Health and Development, Tokyo, Japan; 2) Dept. of Infectious Dis. , Res. Inst. , Natl. Ctr. for Global Health and Med. , Tokyo, Japan; 3) Dept. of Pathology, Keio University School of Medicine, Tokyo, Japan.

KLF14 is imprinted in both mice and humans. eQTL and GWA studies have suggested that KLF14 acts as a master regulator of key metabolic genes in adipose tissue, and demonstrated that cis-regulatory SNPs in the *KLF14* locus are associated with susceptibility to multiple metabolic diseases including T2D. We revealed by qRT-PCR analyses that *Klf14* was highly expressed in the embryos at 9. 5pdc or later and only in the white adipose tissue (WAT) among 15 adult tissues examined. Maternal allele-specific expression of *Klf14* in WAT was consistently maintained in all adult stages examined. We obtained a *Klf14* knock-out mouse line from KOMP. *Klf14*-/- mice showed no morphological and growth abnormalities. We fed *Klf14*-/- mice (n=11) and wild-type littermates (n=7) with a high-fat diet for 8 weeks (from 9 to 16 weeks of ages) and examined their metabolic phenotypes. No significant difference was observed in the items inspected such as body weight, GTT, and ITT. We subsequently subjected the WAT samples from *Klf14*-/- and WT mice with high-fat diet treatment to a gene expression array analysis (n=5 each). Both of GO and GSEA analyses for differentially expressed genes, 1033 up- and 1441 down-regulated genes with t-test *P*-value < 0. 05, revealed that only the latter was enriched with genes related to inflammation and immune cell activation, indicating that obesity-induced inflammation characterized by macrophage infiltration was alleviated in *Klf14*-/- WAT. The expression levels of key pro- and anti-inflammatory adipokines were also altered in *Klf14*-/- WAT. Our results suggest that KLF14 involves in controlling inflammation in WAT possibly through transcriptional regulation of adipokine genes.

Genetic dissection of globozoospermia reveals a role for centrosomal proteins and regulation of the ubiquitin-proteasome system. *E. C. Oh, S. C. Brodar, N. Katsanis.* Center for Human Disease Modeling, Duke University, Durham, NC.

The ciliopathies are clinically complex multisystemic disorders that have informed our understanding of the cilium and the centrosome. Given that ciliopathy males are infertile, not always because of a structural failure of the sperm flagellum, and that loss of intraflagellar transport proteins in mice results in flagella and spermatid head defects, we asked whether other sperm maturation syndromes such as globozoospermia might be associated with centrosomal dysfunction. Computational analysis of the ten known globozoospermia loci showed a direct link of 7/10 with the centrosome, while cellular localization of five disease proteins were visualized at this organelle in spermatogonial cells. Expression studies during spermatogenesis identified a common profile between the known globozoospermia genes and five ciliary/centrosomal proteins, including PCM1, an interactor of ciliopathy proteins. Ablation of *Pcm1* in the mouse caused male infertility characterized by acrosomeless spermatazoa, defects in nuclear shaping, and impaired maintenance of the mitochondrial sheath. The overlap in mouse and human phenotypes prompted us to sequence *PCM1* in 36 infertile male patients and we discovered mutations that segregated with the phenotype and performed as pathogenic alleles in a zebrafish model. Since protein and organellar degradation is necessary for the maturation of germ cells and that the centrosome is a known hub for proteasomal degradation, we show that globozoospermia proteins are ubiquitinated, they interact with components of the 26S proteasome, and are required for protein clearance. Finally, we show that developmental phenotypes in zebrafish mutants for globozoospermia proteins and sperm defects in *Pcm1*-/- mice can be ameliorated by treatment with a chemical proteasomal agonist. Taken together, our data support a centrosomal hypothesis for globozoospermia and suggest that targeting proteasomal function might be of clinical utility in this disorder, and possibly other ciliopathies.

Corpus callosum (CC) is the major brain commissure connecting the homologous areas of both hemispheres at the midline. CC malformations (CCM) are the most frequent brain malformations with an incidence of 1/4000 newborn, often associated with chromosomal anomalies or mendelian syndromes. Recurrence is observed in 5 % of cases. Children with CCM have an uncertain neuro-developmental outcome. Therefore, counseling remains challenging, especially prenatally. We systematically reviewed the data of 138 fetuses with CCM as isolated or associated autopsy findings in our center. We first completed the cytogenetic analysis by a CGH array then applied whole exome or targeted exome sequencing of a panel of genes involved in CCM in human or animal models. Combined fetal imaging, fetal autopsy, cytogenetic and molecular analysis allowed the identification of the cause in 44 fetuses, 30 % of fetuses with 15% of chromosomal anomaly and 15 % of mendelian disorder. In undiagnosed cases, we used exome sequencing in 10 trios and a targeted high throughput sequencing strategy including 423 genes in 64 fetuses. NGS allowed a diagnosis in 12% of cases, such as PDH deficiency (*PDHA1*), PCH with ACC (*AMPD2*), genitopatelar (*KAT6B*), Primrose (*ZBTB20*), Coffin-Siris (*ARID1A* and *ARID1B*), Chudley Mac Cullough syndrome (*GPSM2*). Interestingly some diagnosis were not possible antenatally due to the absence of specific signs, but reevaluation of fetalpathological data (reverse phenotyping) allowed to support NGS findings. Several novel candidate genes are currently being studied. Since the completion of the Human Genome Project in 2003, the rapid development of CGH and NGS sequencing have allowed the identification of many new genes involved in human disorders involving the CC development. The application of NGS in clinical diagnosis holds much promise and will hopefully enable the identification of pathogenic variants and hence influence diagnosis, genetic counseling and the identification of new genes involved in CCM. All together, combined fetal imaging, fetal necropsy, cytogenetic and molecular analysis allowed the identification of the cause in 40 % of our fetal cohort. The additional anomalies after autopsy found in 17% of fetuses prenatally described as having an isolated CCM and the necessary reverse phenotyping following NGS sequencing underlines the importance of fetal autopsy following pregnancy terminations.

Network analysis of genome-wide selective constraint reveals a gene network active in early fetal brain intolerant of mutation. *J. Choi[1], P. Shooshtari[1], K. E. Samocha[2,3,4,5], M. J. Daly[2,3,4], C. Cotsapas[1,2,3,4,6].* 1) Department of Neurology, Yale School of Medicine, New Haven CT, USA; 2) Analytic and Translational Genetics Unit, Department of Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA; 3) Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, Massachusetts, USA; 4) Stanley Center for Psychiatric Research, Broad Institute of Harvard and MIT, Cambridge, Massachusetts, USA; 5) Program in Genetics and Genomics, Biological and Biomedical Sciences, Harvard Medical School, Boston, Massachusetts, USA; 6) Department of Genetics, Yale School of Medicine, New Haven CT, USA.

Using robust, integrated analysis of multiple genomic datasets, we show that genes depleted for non-synonymous *de novo* mutations form a subnetwork of 72 members under strong selective constraint. We further show this subnetwork is preferentially expressed in the early development of the human hippocampus and is enriched for genes mutated in neurological, but not other, Mendelian disorders. We thus conclude that carefully orchestrated developmental processes are under strong constraint in early brain development, and perturbations caused by mutation have adverse outcomes subject to strong purifying selection. Our findings demonstrate that selective forces can act on groups of genes involved in the same process, supporting the notion that adaptation can act coordinately on multiple genes. Our approach provides a statistically robust, interpretable way to identify the tissues and developmental times where groups of disease genes are active. Our findings highlight the importance of considering the interactions between genes when analyzing genome-wide sequence data. .

BREATH: A web-accessible database of normal human and mouse lung development developed by the Molecular Atlas of Lung Development Program (LungMAP). *N. C. Gaddis[1], J. L. Levy[1], Y. Xu[2], M. Duparc[1], G. P. Page[3], J. A. Whitsett[2], S. M. Palmer[4], R. F. Clark[1], LungMAP Data Coordinating Center (DCC).* 1) RTI International, Research Triangle Park, NC; 2) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 3) RTI International, Atlanta, GA; 4) Duke Clinical Research Institute, Duke University School of Medicine, Durham, NC.

The lung is a complex organ with high cellular heterogeneity, and research is needed to define the interactive gene networks and dynamic crosstalk among multiple cell types that coordinate normal lung development. Significant knowledge gaps exist in the understanding of lung development from late fetal to perinatal stages and through early childhood, a critical period when the diverse lung cells go through terminal differentiation and maturation and when alveoli form. Coordination and integration of information from disparate assays and experimental approaches is critically needed to help the pulmonary research community uncover the molecular determinants of lung development. The goal of LungMAP is to build an open-access resource providing a comprehensive molecular atlas of late-stage lung development in humans and mice, making otherwise dispersed data, reagents, and protocols freely available to the research community. We have created the Bioinformatics REsource ATlas for the Healthy lung (BREATH) database, applying novel data management and bioinformatics approaches to manage high-throughput multidimensional experimental data. BREATH is built on a triple store database backbone, integrated with anatomical ontologies for lung development, and provides access to novel web-based tools for the analysis and visualization of data generated by the four Research Centers and Human Tissue Core of the LungMAP Consortium. The current version of BREATH contains confocal immunofluorescence images, *in situ* hybridization images, and 3D confocal and uCT images of developing mouse lung at several time points, as well as single-cell RNAseq data from mouse lung cells. The LungMAP website (www. lungmap. net) provides an entry portal to the BREATH database and tools for exploring and interacting with the lung images and RNAseq data. Future versions of BREATH will incorporate additional data types, including proteomic, lipidomic, metabolomic, and epigenetic data, and novel tools for cross-datatype analysis. A better understanding of the basic molecular pathways that regulate normal lung development will enable development of innovative treatments that successfully manipulate, enhance and improve lung injury repair and regeneration.

Functional validation in a zebrafish model of *ZFHX4* mutations that cause a novel recessive disorder with progressive ophthalmologic, neurodevelopmental, and endocrine dysfunction. *Y. Jing[1], E. McCormick[2], E. Place[1,2], M. Peng[2], M. Consugar[1], C. Seiler[3], Q. Zhang[1], E. Pierce[1], M. Falk[2], X. Gai[1].* 1) Ocular Genomic Institute, Massachusetts Eye and Ear Infirmary, Harvard Medical School, Boston, MA, USA; 2) Division of Human Genetics, Department of Pediatrics, The Children's Hospital of Philadelphia and University of Pennsylvania Perelman School of Medicine, Philadelphia, Pennsylvania, USA; 3) Zebrafish Core Facility, The Children's Hospital of Philadelphia Research Institute, Philadelphia, Pennsylvania, USA.

Background. *ZFHX4* (zinc finger homeobox4), a recently identified 397 kDa transcription factor, that plays an important role in human neural development. A prior report identified CNVs involving this gene in patients with intellectual disability and congenital bilateral ptosis. Here, we report compound heterozygous *ZFHX4* mutations in a patient with multi-system disease identified by whole-exome sequencing (WES). Phenotypes from *ZHFX4* loss of function was studied by morpholino (MO) knockdown in zebrafish. **Case Description**. The proband was a 28-year-old Caucasian man who presented global developmental delay, mild intellectual disability, lifelong ataxia, spasticity, hyperreflexia, progressive resting tremor, nystagmus since 6 months old, complete blindness since age 18 attributable to both optic atrophy and progressive pigmentary retinopathy, inferior cerebellar vermis mild hypoplasia, type I diabetes mellitus , hypothyroidism, severe liver dysfunction in infancy and early childhood, hypocholesterolemia, and short stature. Following enrollment in CHOP IRB study #08-6177, WES was performed on the proband and his unaffected patents. Bioinformatics analysis identified two novel, biparentally-inherited, compound heterozygous mutations in highly conserved regions of *ZFHX4* (c. 7025C>T;p. T2342I) and c. 9233A>G;p. Q3078R). **Results of functional analyses.** The large gene size prevented cDNA rescue. Zebrafish *ZFHX4* morphants exhibited body axis curvature, edema and smaller eye size on 3 day post fertilization (dpf). Histologic examination showed normal eye lamination with well-defined inner and outer segments in control larvae eyes at dpf 6 but. morphants revealed defective photoreceptor morphogenesis, with shortened, and disorganized outer segments, which was further confirmed by transmission electron microscopy Morphants also exhibited defect in sarcomere assembly orientation, showing smaller somites in muscle development. Furthermore, optokinetic response analysis demonstrated an impaired visual behavior in morphant larvae. **Conclusions.** *ZFHX4* gene mutations could cause an autosomal recessive multi-system disorder with global developmental delay, intellectual disability, cerebellar ataxia, spasticity and tremor, blindness due to progressive retinitis pigmentosa and optic atrophy, hearing loss, and multiple endocrine problems (diabetes mellitus, hypothyroid, hypocholesterolemia, and short stature).

MicroRNA in Cell Fate Determination. *L. Li[1], Y. K. Suen[1], S. Gu[2], H. H. Cheung[1], W. N. Law[1], D. D. Cao[1], W. Y. Chan[1].* 1) The Chinese University of Hong Kong - Chinese Academy of Sciences Guangzhou Institute of Biomedicine and Health Joint Laboratory on Stem Cell and Regenerative Medicine, School of Biomedical Sciences, Faculty of Medicine, The Chinese University of Hong Kong; 2) Department of Human and Molecular Genetics, Baylor College of Medicine, Houston, Texas, USA.

Human induced pluripotent stem cells (hiPSC) have the potential to differentiate into all somatic cell types. Because the introduction of these cells does not evoke immune rejection and the use of these cells does not encounter any ethical issues, iPSCs have become the most promising source of cells for therapy as well as for developmental studies. microRNAs (miRNA) are known to regulate gene expression post-transcriptionally. Previous studies have shown that miRNA can induce de-differentiation and trans-differentiation of cells. These observations suggest that the possibility of manipulating hiPSC differentiation with miRNAs is high. In order to understand the role of miRNAs in lineage-specific differentiation, we have established a platform to differentiate the same iPSCs to three germ layers, namely, hepatocyte for endoderm, nephron progenitors for mesoderm, and neural progenitors for ectoderm. Profiling of miRNA expression in samples collected from different time points (day0, 3, 6 and 10) during differentiation with microarrays allowed us to perform vertical and horizontal comparisons among the three representative lineages of the three germ layers. A combination of target gene prediction (TargetScan and miRDB) and functional annotation (DAVID Functional Annotation Tool) related to development were used to select candidate miRNAs, the expression of which was confirmed by qPCR. By following this strategy, we identify 6 candidate miRNAs potentially regulating neural progenitor differentiation, which are miR-125-5p, -23c, -362-5p, 3714, -4465, -532-5p. In further analysis, PUFY3, ANPEP and PAFAH1B1 were predicted to be regulated by miR-125-5p in neural development, which need further confirmation by luciferase reporter assay. As miR-125-5p increased continuously from day0 to day 10, both indicated by array and qPCR, it is expected to induce neural progenitors formation. The roles of candidate miRNAs in lineage specification including three lineages will be further studied via functional analysis including gain- and loss-of-function assays, and generation of miRNA-specific expressing transgenic mice. We hope to reveal the miRNA(s) that is located in the center of the network of cell fate decision and lineage specification.

Characterizing neuronal differentiation of human iPSCs by single cell RNA-seq reveals distinct developmental trajectories. *J. D. Robertson[1], E. Oni[2], A. Halikere[4], A. Tiethof[2], M. Swerdel[2], A. Toro-Ramos[2], J. C. Moore[3], Z. Pang[4], R. Hart[2], L. A. Goff[1,5].* 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Cell Biology and Neuroscience, Rutgers University, Piscataway, NJ; 3) Department of Genetics, Rutgers University, Piscataway, NJ; 4) Child Health Institute of New Jersey, Robert Wood Johnson Medical School, New Brunswick, NJ; 5) Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD.

Precise characterization of the transcriptional kinetics of gene expression in a heterogeneous mixture of cells is crucial for identifying key pathways affected in neurodevelopmental diseases. However, in vitro time course experiments on differentiating cells designed to reveal relevant genes, pathways, and expression dynamics are confounded by variation in cell identity, and progress through differentiation. Average gene expression values do not reflect the diversity of intermediate cell types, or alternative cell fates that may be present in culture. We used single cell RNA-seq on mNgn2-induced neurons (iN) from human iPSCs in order to detect differentially regulated genes at 0, 2, 5, and 14 days of differentiation. Next, to order individual cells according to their differentiation state, we hand selected a set of 625 curated genes known to be differentially expressed between neural progenitors and mature neural cell types. We performed independent component analysis on the expression profiles of these genes to establish a 'pseudotemporal' ordering of these cells reflecting their individual progress through differentiation. We identified two discrete developmental paths or trajectories that occur during iN differentiation. One trajectory was significantly enriched for classical markers of sensory neurons such as ILS1, NEUROD1, NTRK1, and NTRK3 while the other was enriched for motor neuron development markers such as BCL6, CDH13, CD44, CRIM1, DIAPH3, and PDLIM1. This suggests that the single factor mNgn2 is capable of inducing multiple neuronal cellular identities in vitro. In addition to this cell fate heterogeneity, we also detected significant differences in the developmental trajectories between iN neurons and neurons differentiated by culture in neural induction media (PSC) alone. Interestingly, on day 0, ~1% had already spontaneously begun differentiation and by day 5 post-mitotic, intermediate, and undifferentiated cell types were detected. This approach can be used to understand the precise effects of disease-associated mutations that lead to defects in neuronal differentiation, and identify the affected phase of differentiation. We are able to detect transient intermediate cell types, key genes and pathways that are differentially affecting during neuronal differentiation, and key transition points that affect cell fate and variability in phenotypic outcomes which would not be revealed by sequencing of bulk RNA.

2566W

Incorporated Cesium-137 in Pregnant Women and Congenital Anomaly Rates in a Chornobyl Impacted Polissia Region of Ukraine. *W. Wertelecki[1], L. Yevtushok[2,3], A. Koerblein[2], N. Zymak-Zakutnia[2,4], O. Komov[5], I. Kuznietsov[6], S. Lapchenko[2], Z. Sosyniuk[2,3].* 1) OMNI-Net for Children, Mobile, AL, USA; 2) OMNI-Net for Children, Rivne, Ukraine; 3) Rivne Province Regional Medical Diagnostic Center, Rivne, Ukraine; 4) Khmelnytsky City Perinatal Center, Khmelnytsky, Ukraine; 5) Rivne Province State Sanitary-and-Epidemiology Service, Rivne, Ukraine; 6) Human and Animal Physiology Department, Eastern-European University, Lutsk, Volyn, Ukraine.

Neural tube defects (NTD), microcephaly and microphthalmia (M/M) population-based rates are persistently higher in the Chornobyl radiation impacted Polissia region of the Rivne Province of Ukraine and are among the highest in Europe. The aim of our investigation was to compare regional differences in Rivne Province of specific congenital anomaly (CA) rates and patterns of incorporated cesium-137 by ambulatory patients and pregnant women. **Methods:** Analysis of yearly population rates (2000-2012) of specific CA and whole body counts (WBCs) of incorporated cesium-137 above 100 Bq of 34786 adult ambulatory patients (2001-2010), including repeated WBCs, and 3492 pregnant women (2011-2013), restricted to first WBC determinations. **Results:** NTD and M/M population rates were persistently and statistically significantly higher in Polissia than in non-Polissia in contrast to cleft lip with or without cleft palate and Down syndrome which were similar across regions. The average WBCs of male and female ambulatory patients in Polissia were 2640 and 2223 becquerel (Bq) respectively, and in non-Polissia ambulatory patients were 507 and 435 Bq respectively. Among pregnant women from Polissia and non-Polissia, the mean WBCs were 2767 and 738 Bq, respectively, and the specific activity was 43. 5 and 11. 7 Bq per kilogram body weight (Bq/kg), respectively. **Conclusions:** The results confirm the co-occurrence of persistent significantly elevated NTD and M/M CA rates and higher incorporation of cesium-137 by pregnant women in Polissia compared to non-Polissia. A direct association of cesium burden (Bq/kg) and of other nuclides with NTD and M/M risk still needs to be determined.

2567W

Full-length cDNA Sequencing of Alternatively Spliced Isoforms Provides Insight into Human Cancer. *T. Clark, T. Hon, E. Tseng.* Pacific Biosciences, Menlo Park, CA.

The majority of human genes are alternatively spliced, making it possible for most genes to generate multiple proteins. The process of alternative splicing is highly regulated in a developmental-stage and tissue-specific manner. Perturbations in the regulation of these events can lead to disease in humans (1). Alternative splicing has been shown to play a role in human cancer, muscular dystrophy, Alzheimer's, and many other diseases. Understanding these diseases requires knowing the full complement of mRNA isoforms. Microarrays and high-throughput cDNA sequencing have become highly successful tools for studying transcriptomes, however these technologies only provide small fragments of transcripts and building complete transcript isoforms has been very challenging (2). We have developed a technique, called Iso-Seq™ sequencing, that is capable of sequencing full-length, single-molecule cDNA sequences. The method employs SMRT® Sequencing from PacBio, which can sequence individual molecules with read lengths that average more than 10 kb and can reach as long as 40 kb. As most transcripts are from 1 – 10 kb, we can sequence through entire RNA molecules, requiring no fragmentation or post-sequencing assembly. Jointly with the sequencing method, we developed a computational pipeline that polishes these full-length transcript sequences into high-quality, non-redundant transcript consensus sequences. Iso-Seq sequencing enables unambiguous identification of alternative splicing events, alternative transcriptional start and polyA sites, and transcripts from gene fusion events. Knowledge of the complete set of isoforms from a sample of interest is key for accurate quantification of isoform abundance when using any technology for transcriptome studies (3). Here we characterize the full-length transcriptome of paired tumor/normal samples from breast cancer using deep Iso-Seq sequencing. We highlight numerous discoveries of novel alternatively spliced isoforms, gene-fusion events, and previously unannotated genes that will improve our understanding of human cancer. 2568T

Conventional and Pagetic Giant Cell Tumor of Bone: are they distinct entities? *G. Divisato[1], T. Esposito[1], L. Pazzaglia[2], D. Merlotti[3], M. S. Benassi[2], D. Rendina[4], L. Gennari[3], F. Gianfrancesco[1].* 1) Institute of Genetics and Biophysics, National Research Council of Italy, Naples, Italy; 2) Laboratory of Experimental Oncology, Rizzoli Orthopaedic Institute, Bologna, Italy; 3) Department of Clinical, Surgical and Neurological Sciences, University of Siena, Siena, Italy; 4) Department of Clinical and Experimental Medicine, Federico II University, Naples, Italy.

The alteration of bone turnover could result in the uncontrolled proliferation of mesenchymal spindle-like stromal cells, as in the case of Giant cell tumor of bone (GCT), an aggressive bone tumor also characterized by pathological multinucleated osteoclast-like giant cells that rarely could arise on tissues affected by Paget's Disease of Bone (GCT-PDB). A recent study showed that conventional GCT is due to recurrent somatic mutations in *H3F3A* gene, that encodes a histone variant H3. 3, in the mesenchymal stromal cells. Otherwise, the genetic and molecular basis of GCT-PDB remain to be defined. We analysed the genetic profile of mesenchymal stromal cells selected "ad hoc" by Laser Capture MIcrodissection (LCM), isolated from heterogenous tissue of conventional GCT to reduce the contamination of the surrounding cells identifying somatic mutations in *H3F3A* gene in 38 out of 44 cases (86%). In contrast, the analysis of patients with Paget's disease of bone (PDB) associated with giant cell tumor did not show any mutation in *H3F3A* gene, at both somatic and germline level, suggesting a different genetic background. We recently reported an extended Italian family in which 4 out of 14 PDB affected members developed multiple GCTs at pagetic skeletal sites. Whole exome sequencing, in this family identifies a missense mutation in a novel uncharacterized zinc finger protein, that interacts with an histone reader to form a transcription coregulator complex. These evidences suggested that GCT, associated or not with PDB, is due to mutations in different genes, both acting in nuclear context and also showed a different histological background, suggesting that common or different molecular signatures are responsible for these two phenotypes.

2569W

A method for characterization of breast cancer samples from archived formalin-fixed, paraffin-embedded (FFPE) tissues. *P. Apopa[1], M. Orloff[1,2].* 1) Dept. of Epidemiology, University of Arkansas for Medical Sciences, Little Rock, AR; 2) Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR.

Development of molecular tools in diagnosis and prognosis of cancer is critical to the understanding and management of the disease. The gold standard for genetic comparative studies and genotyping is DNA sequencing. Using archival collection of formalin-fixed, paraffin-embedded (FFPE) breast cancer samples with known clinical outcomes is a good resource for retrospective studies. Unfortunately the preparation, preservation and age of FFPE samples have led to DNA fragmentation making it very challenging to obtain a good quality and decent sized DNA fragments for downstream analyses. This study sought to investigate the suitability of using archival tissues to assess previously identified and novel mutations through direct DNA sequencing. Further, we sought to validate the FFPE findings in matched frozen fresh tissues from the same individuals. Using FFPE samples, we isolated genomic DNA and miRNA. DNA purity and quality was determined by spectroscopy. Similarly extraction of DNA and miRNA was done in matched fresh frozen tissues. DNA was amplified using specific primers targeting exonic regions, exon/intron junctions and 3'UTR of the *OLFML3* and *EGFR.* The amplicons were gel purified and sequenced by Sanger method. 20 (FFPE and fresh frozen tissue) samples were sequenced. We determined that by using amplicons not exceeding 300bps, we can get clear sequences from FFPE samples. We identified non-synonymous coding mutations in both *EGFR* and *OLFML3*. A high concordance was also observed in FFPE and matched frozen samples. Like previous studies based on the small fragment size of miRNA, it was not challenging to replicate miRNA expression profiles in FFPE breast cancer tissues compared to previously reported expression profiles. Specifically, miR135A, miR144 and miR451 were relatively overexpressed in FFPE breast cancer tissues validating previously reported findings in fresh frozen tissues. FFPE samples can therefore be effectively used to identify mutations and regulatory elements on breast cancer patient samples. Further, this can also aid in identifying suitable biomarkers for late stage breast cancer. The age of the FFPE sample will influence the quality of nucleic acid product.

2570T

Systematic identification of significantly mutated regions reveals a rich landscape of functional molecular alterations across cancer genomes. *C. L. Araya[1], C. Cenik[1], J. A. Reuter[1], G. Kiss[2], V. S. Pande[2], M. P. Snyder[1], W. J. Greenleaf[1].* 1) Genetics, Stanford University, Stanford, CA; 2) Chemistry, Stanford University, Stanford, CA.

Cancer genome sequencing studies have primarily focused on identifying cancer-driver genes from the increased accumulation of protein-altering mutations. However, the positional distributions of coding mutations, and the 79% of somatic variants in exome data that do not alter protein sequence or RNA splicing, remain largely unstudied. We employed density-based clustering methods on ~4,700 exomes from 21 tumor types to detect variably-sized significantly mutated regions (SMRs). SMRs reveal recurrent alterations across a diverse spectrum of coding and non-coding elements, including microRNAs, transcription factor binding sites, and untranslated regions that are individually mutated in up to ~15% of samples in specific cancer types. The discovery of non-coding SMRs constituting the second, third, and fourth most frequent non-coding alterations described in any cancer-type to date, and validated in independent cohorts and reporter assays, firmly establish the utility of our approach for evaluating pathogenic, exon-proximal non-coding variation. Mapping SMRs to protein structures revealed spatial clustering of somatic mutations at known and novel cancer-driver domains and molecular interfaces. These include recurrent alterations at a histone H3. 1 interface, with an associated potential impact on patient survival. We demonstrate cancer-specific SMR mutation frequencies within PIK3CA domains, as exemplified by a previously uncharacterized α-helix that is recurrently and directionally mutated in endometrial cancers. Molecular dynamics indicate mutations in this region alter regulatory subunit (PIK3R1) binding through modulation of a salt-bridge network thereby describing a novel mechanism of pathogenic alteration in a key oncogene. SMRs often associated with changes in gene expression and signalling. For example, NFE2L2 alterations affecting KEAP1-binding interfaces are associated with consistent transcriptional signatures across bladder, endometrial, lung squamous cell carcinomas, and head and neck cancers. Yet, mutation frequencies in SMRs demonstrate that distinct protein regions can be differentially mutated among tumor types, and display differential signaling as evidenced in TP53 and PIK3CA. The functional diversity of SMRs underscores both the varied mechanisms of oncogenic misregulation and valuable opportunities in complementing extant, gene- and pathway-level with unbiased, multi-scale analysis of genomic variation to identify disease drivers. .

Evaluation of candidate risk loci in familial lung cancer families linked to 6q. *J. E. Bailey-Wilson[1], C. L. Simpson[1], A. Musolf[1], S. M. Pinney[2], M. de Andrade[3], C. Gaba[4], P. Yang[3], M. You[5], A. G. Schwartz[6], D. Mandal[7], Y. Liu[8], M. R. Spitz[8], E. Y. Kupert[5], C. I. Amos[9], M. W. Anderson[5].* 1) Computational and Statistical Genomics Branch, NIH/NHGRI, Baltimore, MD; 2) University of Cincinnati College of Medicine, Cincinnati, OH; 3) Mayo Clinic, Rochester, MN; 4) University of Toledo Dana Cancer Center, Toledo, OH; 5) Medical College of Wisconsin, Milwaukee, WI; 6) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 7) Louisiana State University Health Sciences Center, New Orleans, LA; 8) Baylor College of Medicine, Houston, TX; 9) Geisel School of Medicine, Dartmouth College, Lebanon, NH.

We have published evidence of linkage of familial lung cancer (FLC) risk to a region on 6q (PMID: 15272417, 20215501). Wilson et al. (doi:10. 1038/onc. 2013. 396) found that *EYA4* (in our linkage region) was frequently inactivated biallelically in sporadic lung cancer (LC), displays tumor suppressor gene-like properties and affects DNA repair, and that 5 of 17 common SNPs in this 0. 3Mb region showed nominal association to FLC ($p<0.05$) although these associations are not significant after correction for multiple testing. Here, we sequenced 75 individuals from our 9 most strongly 6q-linked families, using Illumina technology and a custom Agilent kit to capture 37Mb of chromosome 6 from 130Mb to 167Mb. To detect sharing of variants among affecteds in each family while allowing for phenocopies, singlepoint affected-only linkage analysis was performed on lung cancer affection status for all sequence variants using the Elston-Stewart algorithm implemented in the R package paramlink assuming penetrance of 0. 01, 0. 1 and 0. 1 for dd/Dd/DD and a disease allele (D) frequency of 0. 01, at theta=0. The highest total LOD score (summed across families) in the 37Mb targeted region was not near *EYA4*. No family had a variant in or near EYA4 that was on the linked haplotype or had a LOD score close to the maximum family-specific LOD score in the region. The highest total LOD score in the region was found at a missense coding variant, rs41267809 at 6:160953642-SNV (LOD=1. 099), in the lipoprotein-A, *LPA*, gene. This signal was driven almost entirely by a single family. This variant has a frequency ranging from 1-3% in European-derived populations in 1000 Genomes and 3 heterozygotes for this variant were observed in a replication sample of 55 independent FLC cases (5. 4%). We have previously published evidence that a rare variant in PARK2 may be a risk allele in one of these families although there are also other candidate regions in this family. Other families have their strongest linkage signals in other non-coding regions including intronic variants in ARID1B. Additional annotation of non-coding variants is ongoing in these families. Thus, EYA4 is unlikely to be harboring functional variants that explain the linkage to 6q in these families. LPA is a candidate in one family. Non-coding elements or coding variants in different genes across families may explain the multipoint linkage signal in this cancer candidate gene-rich region.

2572T

DKK1 is upregulated in mesenchymal stem cells of patients with Multiple Myeloma. *O. Bashti[1, 2], M. Mashadikhan[2], A. Saremi[2], M. Ahmadvand[2], M. Noruzinia[1, 2].* 1) Dept. Medical Genetics, Tarbia Modares University, Tehran, tehran, Iran; 2) Sarem Cell Research Center, Tehran, Iran.

Multiple Myeloma Mesenchymal stem cells contribute primarily in osteolytic lesion due to their impaired osteogenic potential. Bone lesions in patients with multiple myeloma are in addition a sign of enhanced osteoclast formation of MM MSCs. Recent studies have reported a significant role of wnt signaling in aberrant osteogenic activity of MM MSCs. In this research the role of DKK1 as one of the wnt signaling pathway was investigated in MM MSCs compared to normal MSCs. Material and methods:BM nucleated cells (BMNC) from 6 normal donors and 6 MM patients were plated, cultured ina-MEM medium aftercentrifugation. MSCs of passage 3 were put through flowcytometry RT PCR and in vitro differentiation to confirm presenceof MSCs. RT PCR for transcripts of genes involved in wnt signaling RUN2 and DKK1, and VEGF were performed to compare the two patients and normal groups. Results:Immunophenotyping confirmed absence of myeloma cells. RT PCR, invitro differentiation and flowcytometry confirmed the presence of MSCs. RUNX2 was expressed in mesenchymal stem cells of MM patients. However the expression was significantly lower in patient than normal group ($p<0.05$). On the other hand DKK1 showed an increase in expression MM MSCs compared to normal MSCs($P<0.05$). VEGF shows an increase in expression in MM MSCs. Discussion:Bone marrow Mesenchymal stem cells are among factors in MM microenvironment which play crucial roles directly and indirectly. We show in this research that MM MSCs are different from normal MSCs at least in wnt signaling pathway. Genome wide analysis has shown that MM MSCs are different in expression of many genes involved in osteoblastogenesis. It has been shown by our team and others that these two cells are epigenetically different. In total, our results confirm the role of MM MSCs and wnt signaling in the pathogenesis of the bone lesions in MM patients. Epidrug therapy in mesenchymal stem cells targeting wnt to normalize their expression could enhance the efficacy of the current treatments of osteolytic lesions in these patients.

Advances in Breast Cancer Biomarker Discovery Methods. *K. Bramlett[1], J. Schageman[1], V. Bagai[1], K. Lea[1], J. Gu[1], J. Wittliff[2].* 1) Life Sciences Solutions Group, Thermo Fisher Scientific, Austin, TX 78744; 2) Dept of Biochemistry and Molecular Biology, Institute for Molecular Diversity and Drug Design, University of Louisville, Louisville, Kentucky 40292.

Forecasting clinical behavior and therapeutic response of human cancer currently utilizes a limited number of tumor markers in combination with characteristics of the patient and their disease. Although few tumor markers and molecular targets exist for evaluation, the wealth of information derived from recent sequencing advancements provides greater opportunities to develop more precise tests for diagnostics, prognostics, therapy selection and monitoring in the future. The objectives of this study are to decipher miRNA and mRNA expression profiles of laser capture microdissection (LCM)-procured carcinoma cells and intact serial sections of breast cancer tissue samples using next generation sequencing (NGS) methods. Our hypothesis is that miRNA signatures discerned from specific carcinoma cell populations more precisely correlate with behavior than that provided by conventional biomarkers from intact tissue samples. Additionally, we hypothesize the data generated in this study will present mRNA signatures informative for breast cancer research and support our miRNA findings through suggesting relevant miRNA:mRNA target associations. De-identified frozen breast cancer research samples of primary invasive ductal tumors of known grade and biomarker status containing 35-70% tumor were selected from an IRB-approved Biorepository. Comparison of expressed miRNAs from intact tissue sections with those of cognate tumor cells procured by LCM revealed, in general, that smaller defined miRNA gene sets were expressed in LCM isolated populations of carcinoma cells. In addition to miRNA sequencing, targeted RNA sequencing with the Ion AmpliSeq™ Transcriptome Human Gene Expression Kit was used to capture mRNA expression information. Data presented here demonstrates high mapping rates for targeted mRNA (>91% of reads) and miRNA (> 88% of reads) libraries. We also demonstrate high technical reproducibility between multiple libraries from the same tumor sample for both mRNA ($R>0.99$) and miRNA ($R>0.97$) libraries. Results suggest potential miRNA:mRNA target associations identified in our set of breast cancer research samples. These data provide insights into breast cancer biology that may lead to new molecular diagnostics and targets for drug design in the future as well as an improved understanding of the molecular basis of clinical behavior and potential therapeutic response.

2574T

Recrutiment mechanisms for the establishment of an African American breast cancer cohort for genetic studies in Alabama. *M. R. Chandler, N. D. Merner.* Department of Drug Discovery and Development, Harrison School of Pharmacy, Auburn University, 2316 Walker Bldg. , Auburn, AL.

African American (AA) women have a higher incidence rate of breast cancer (BC) under the age of 40 when compared to Caucasians. Considering that an early age of onset is a hallmark of hereditary BC, our laboratory has developed protocols to recruit AA BC individuals/families in order to identify the genetic risk factors that are contributing to this BC disparity. The Auburn University Institutional Review Board (IRB) approved two recruitment protocols (#14-232 and #15-111); #14-232 involves hospital recruitment through collaboration with East Alabama Medical Center (EAMC), and #15-111 is a community-based recruitment (CBR) mechanism. The enrollment criteria include individuals (1) diagnosed with BC (at any age) who have a family history or (2) diagnosed with BC under the age of 45 without a family history. Participation requires a blood draw. At the EAMC Cancer Center, a research nurse consents patients once identified by EAMC oncologists (recruitment began on February 11, 2015). CBR targets medically under-served individuals who are not usually offered the chance to participate in research projects; it is a strategic mechanism that aims to reach out to the community in order to educate and build trust (recruitment began on March 23, 2015). DNA is extracted from each blood sample and stored in a DNA bank (IRB #14-335). To date, 69 DNA samples are stored in the DNA Bank from 36 BC families; 18 probands (average age of onset: 38; age range: 23-52) have been recruited through EAMC, and 18 probands (average age of onset: 48; age range: 34-60) have been recruited through CBR. CBR has been the most effective mechanism of AA recruitment (11/18) compared to EAMC (4/18). Three key AA families have been recruited through CBR with a total of 8 (3 affected), 6 (5 affected) and 4 (3 affected) individuals recruited per family. All probands are being screened for 87 known or candidate BC susceptibility genes using an Agilent Technologies custom-designed HaloPlex probe capture kit followed by massively parallel sequencing on an Illumina platform. Mutation-negative families will be exome sequenced in order to identify novel susceptibility genes; no AA exome sequencing studies have been published to date. This effort marks the start of a unique AA cohort from the under-studied Alabama population, and demonstrates how we plan to contribute to the understanding of AA BC genetics and disparities.

2575W

Replication of cervical cancer GWAS-identified variants in Taiwanese population. *T. Chang[1], Y. Yang[2,3], Y. Lee[1,4,5], T. Chen[2], W. Lin[1], S. Chang[1].* 1) Med Res Dept, Mackay Memorial Hosp, New Taipei, Taiwan; 2) Dept of Gynecology and Obstetrics, Mackay Memorial Hosp, Taipei, Taiwan; 3) Dept of Gynecology and Obstetrics, Taipei Medical University, Taipei, Taiwan; 4) Pediatrics, Mackay Memorial Hosp, Taipei, Taiwan; 5) Pediatrics, Taipei Medical University, Taipei, Taiwan.

Genetic epidemiological studies show that genetic factors contribute significantly to cervical cancer carcinogenesis. Recently, a few genome-wide association studies (GWAS) have revealed new genetic polymorphisms associated with cervical cancer susceptibility. The aim of this study is to replicate four GWAS-identified single nucleotide polymorphisms (SNPs) which were associated with cervical cancer in Chinese women. The rs13117307 *C/T*, rs8067378 *A/G*, rs4282438 *T/G*, and rs9277952 *G/A* SNPs were genotyped in 507 cervical squamous cell carcinoma (CSCC) patients and 507 age/sex matched healthy controls by using the Pre-Developed TaqMan Allelic Discrimination Assay. The presence and genotypes of HPV in CSCC patients were determined by PCR. In our case-control study, only rs4282438 *G/G* genotype and *G* allele were found to significantlyassociate with CSCC risk (OR = 1. 96, 95% CI = 1. 42-2. 72, *P* = 4. 18 x 10-5; OR = 1. 41, 95% CI 1. 14-1. 75, *P* = 1. 32 x 10-3, respectively). In addition, significant increases of *G/G* genotype and *G* allele frequencies were observed between HPV-16 positive CSCC patients and controls (OR = 2. 25, 95% CI 1. 55-3. 28, *P* = 1. 75 x 10-5; OR = 1. 61, 95% CI 1. 24-2. 06, *P* = 2. 73 x 10-4, respectively). Although we validated the GWAS-associated rs4282438 SNP in our Taiwanese population, the result was inconsistent with the Chinese one which showed rs4282438 *G* allele is protective against cervical cancer (OR = 0. 75, 95% CI 0. 71-0. 79, *P* = 4. 52 x 10-27). In conclusion, our findings provided convincing evidence that rs4282438 *T/G* significantly associated with CSCC susceptibility.

2576T

Germline cytotoxic lymphocytes defective mutations in Chinese lymphoma patients. *X. Chen, Y. Zhang, F. Wang, W. Teng, Y. Lin, X. Han, F. Jin, Q. Yin, C. Tong, H. Liu.* Hebei Yanda Ludaopei Hospital, Langfang, Hebei, China.

PurposeIt has been reported that some lymphoma patients may harbor mutations in PRF1, UNC13D, STX11, STXBP2 or SH2D1A, which caused function defects of cytotoxic lymphocytes. Data of the association between genetic defects and the development of lymphoma in Chinese patients is limited to date. The aim of the present study is to detect germline cytotoxic lymphocytes defective mutations in Chinese lymphoma patients. **Methods** Patients with either Hodgkin or non-Hodgkin lymphomas were collected. All coding exons and flanking sequences of UNC13D, PRF1, STXBP2, STX11, SH2D1A, and XIAP were amplified and sequenced. **Results**A total of 90 patients were collected (age, 3-60 years), including 48 males and 42 females. Mutations were observed in 24 of them (26. 67%). Sixteen patients carried mutations in UNC13D, including twelve with monoallelic mutations, one with homozygous mutation and three with compound heterozygous mutations. Seven patients had PRF1 mutations, including four with monoallelic mutations, one with homozygous mutation and two with compound heterozygous mutations. One patient carried STX11 monoallelic mutation. All mutations were confirmed to be germline derived. UNC13D c. 2588G>A/p. G863D mutation was detected in nine patients (10. 00%) and in only five of 210 controls (2. 38%). It was predicted to be pathogenic and the 1000 genomes database showed it reserved only in Chinese and Japanese populations. **Conclusion**The present study provides evidence that impaired cytotoxic machinery may represent a predisposing factor for the development of lymphoma. Moreover, it describes a distinct mutation spectrum in Chinese lymphoma patients, with mutations in UNC13D the most frequent. In addition, we find UNC13D c. 2588G>A mutation to be a founder mutation in Chinese patients.

2577W

Germline and somatic HIF2A mutations associated with Phaeochromocytoma and Paragangliomas. *G. R. Clark[1], D. M. Walsh[2], G. Kirby[2,3], M. A. Simpson[4], R. C. Trembath[4], E. R. Woodward[2,3], E. R. Maher[1].* 1) Medical Genetics, University of Cambridge, Cambridge, Cambridgeshire, United Kingdom; 2) Centre for Rare Diseases & Personalised Medicine, University of Birmingham, Birmingham, United Kingdom; 3) West Midlands Regional Genetics Service, Birmingham Women's Hospital, Birmingham, United Kingdom; 4) Division of Genetics and Molecular Medicine, King's College London, London, United Kingdom.

Phaeochromocytomas (PCCs) and paragangliomas (PGLs) are rare autonomic nervous system tumours, which typically hypersecrete catecholamines. A notable feature of PCCs/PGLs is the high incidence of inherited cases, such that germline mutations in at least 12 susceptibility genes can be detected in 30-40% of all cases. Recent gene expression profiling studies have shown that a large proportion of inherited cases show activation of the hypoxic gene response pathways. It has also been shown that loss of function mutations in *VHL* and *SDH* subunit genes lead to the stabilisation of the hypoxia-inducible factor (HIF) proteins. These HIF proteins are a family of transcription factors (HIF-1, HIF-2 & HIF-3) that bind to and activate multiple genes associated with angiogenesis, glycolysis and cell growth. The stability of the HIF proteins is dependent on two specific proline residues located in the oxygen dependent degradation domain, that are hydroxylated by the oxygen dependent prolyl hydroxylases (PHDs). Once hydroxylated, the HIF proteins can be targeted for proteasomal degradation by the VHL complex. Recently, several groups have reported gain of function mutations in *HIF2A/EPAS1* in PCC/PGL cases, which result in the stabilisation of the HIF-2 protein. To date, the majority of the *HIF2A* mutations have been detected as somatic mutations, with little evidence of germline mutations. Here we report the finding of six novel variants, four of which were found present in the germline, and cluster around the secondary hydroxylation site. We also present functional data, which provides further evidence that these variants are pathogenic.

2578T

Identification of candidate target regions physically interact with prostate cancer risk loci. *MJ. Du[1], L. Tillmans[3], JZ. Gao[4], N. Sahr[2], TZ. Yuan[1], RL. Dittmar[1], T. Wang[2], SN. Thibodeau[3], L. Wang[1].* 1) Department of Pathology and Cancer Center, Medical College of Wisconsin, Milwaukee, WI 53226; 2) Division of Biostatistics, Institute for Health & Society, Medical College of Wisconsin, Milwaukee, WI 53226; 3) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN 55905; 4) Beijing 3H Medical Technology Co. Ltd. , Beijing, China, 100176.

Genome wide association studies have identified more than 80 common variants that are associated with prostate cancer risk. However, the vast majority of these SNPs lie in noncoding regions of the genome. To testwhether these risk SNPs regulate their target genes through long-range chromatin interactions, we applied a capture-based 3C-seq to investigate possible *cis*-interactions at ten prostate risk loci in six cell lines. We identified statistically significant interactions between risk region-contained regulatory elements and their putative target genes, such as: CAPG at 2p11. 2, RFX at 6q22. 1, NFASC at 1q32. 1, PCAT1, MYC and PVT1 at 8q24. 1. The most significant interaction was between capture fragment (chr2:85769616-85778503-85781283) at 2p11. 2 and the promoter region of the gene CAPG. This interaction was not tissue-specific because we observed it in all cell lines tested. However, the interactions at 6q22. 1 loci with RFX and interactions at 1q32. 1 with NFASC were prostate tissue specific because they were only found in prostate cell lines. To further determine whether the tag SNPs rs2028898 (2p11. 2), rs10089608 (8q24. 21), rs339331 (6q22. 1), rs4245739 (1q32. 1) were associated with expression levels of target genes *CAPG, RFX, NFASC, PCAT1* and *MYC*, we carried out expression quantitative trait locus (eQTL) analysis using RNA-seq data on 476 normal prostate tissues. We observed suggestive eQTL signal at rs699664 (a proxy for rs2028898, r2 = 0. 99) for *CAPG*, rs339331 for *RFX*, rs4245739 for *NFASC*, and rs10086908 for PCAT1 (p value<0. 05). To validate these interactions, we applied 3C-qPCR and 4C-seq and confirmed their interactions at risk regions of 2p11. 2 and 8q24. We found that these significant interactions were characterized by DNase I hypersensitive and active histone modifications that correlate with active enhancers (H3K27ac, H3K4me1), active promoters (H3K4me3) and/or binding sites for specific transcription factors. Our results demonstrate that the capture-based 3C-seq along with eQTL analysis may facilitate identification of functional SNPs and their candidate genes at prostate cancer risk regions. Further understanding genetic effect and biological mechanism of these chromatin interactions will shed light on the newly discovered regulatory role of the risk locus in PC etiology and progression.

Discovery of Rare Variants in Prostate Cancer Susceptibility via Custom Microarray Genotyping. *N. Emami[1], T. Hoffmann[1], J. Mefford[1], K. Lindquist[1], C. Cario[1], C. G. Tai[1], E. Wan[1], S. Wong[1], J. Gollub[2], A. Finn[2], D. Aaronson[4], J. Presti[4], L. Habel[3], E. Jorgenson[3], L. Sakoda[3], M. Kvale[1], P. Kwok[1], C. Schaefer[3], N. Risch[1,3], S. Van Den Eeden[3], J. Witte[1].* 1) University of California, San Francisco, San Francisco, CA; 2) Affymetrix, Inc. , Santa Clara, CA; 3) Division of Research, Kaiser Permanente, Northern California, Oakland, CA; 4) Department of Urology, Kaiser Oakland Medical Center, Northern California, Oakland, CA.

The influence of rare genetic variants on common disease susceptibility is currently an area of wide interest. In light of the missing heritability of complex human traits and the ongoing search for causal germline biomarkers of disease, it has been hypothesized that rare variants with high effect sizes may contribute considerably to complex trait heritability and underlie the signals of common single nucleotide polymorphisms (SNPs) discovered in genome wide association studies (GWAS) via linkage disequilibrium (LD). Accordingly, it has been shown that moderate penetrance rare variants can drive synthetic associations of tagging common polymorphisms and a number of rare variants have been implicated in common disease susceptibility. However, the minor allele frequencies of putatively causal rare variants presents certain challenges to their discovery. While fine mapping all significant, common GWAS lead SNPs through next generation sequencing may detect all variants at a given locus, the current cost of sequencing precludes the usage of cohort sizes large enough to assess the significance of rare variants. Moreover, although certain efforts have demonstrated the feasibility of imputing rare variants using GWAS data, incomplete LD presents uncertainty and obstacles to their imputation. Previously we described the design of a custom Affymetrix Axiom microarray for directly assaying putative rare variants and fine mapping loci previously associated with prostate cancer (PrCa), a highly heritable, common disease in men and ideal complex trait for studying rare variant association due to appreciable missing heritability. Using our custom array, 416,047 markers were genotyped in a population of 8,480 prostate cancer cases and 8,128 controls nested within the Kaiser Permanente Research Program on Genes, Environment, and Health (RPGEH), ProHealth and California Men's Health Study. Preliminary results replicate previously discovered PrCa susceptibility loci at 7p15. 2, 8q24. 21, 10q11. 23, 11q13. 3, 17q12, and 19q13. 33, including significant and suggestive p-values for SNPs in the intermediate (1% < MAF < 5%) and rare (MAF < 1%) allele frequency ranges in single marker association tests. Future conditional analyses may distinguish whether these associations are independent signals, and to what extent rare variants drive heritability and synthetic associations at PrCa susceptibility loci.

2580T

Hormone-related pathway genes and risk of breast cancer subtypes in African American women. *S. A. Haddad[1], K. L. Lunetta[2], E. A. Ruiz-Narváez[1], J. T. Bensen[3], C. C. Hong[4], L. E. Sucheston-Campbell[4], S. Yao[4], E. V. Bandera[5], L. Rosenberg[1], C. A. Haiman[6], M. A. Troester[3], C. B. Ambrosone[4], J. R. Palmer[1].* 1) Slone Epidemiology Center at Boston University, Boston, MA; 2) Department of Biostatistics, Boston University School of Public Health, Boston, MA; 3) Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC; 4) Department of Cancer Prevention and Control, Roswell Park Cancer Institute, Buffalo, NY; 5) Cancer Prevention and Control, Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; 6) Department of Preventive Medicine, Keck School of Medicine, University of Southern California/Norris Comprehensive Cancer Center, Los Angeles, CA.

Background: Breast cancer (MIM 114480) in women of African ancestry (AA) has been relatively understudied. Given extensive evidence that steroid hormones affect breast cancer risk, it is possible that variants in steroid hormone pathway genes may contribute to susceptibility in this and other populations. *Methods:* We investigated variation in steroid hormone genes in relation to risk of breast cancer, overall and by subtype, in the African American Breast Cancer Epidemiology and Risk (AMBER) Consortium, which includes data from four large studies of AA women – the Carolina Breast Cancer Study, the Women's Circle of Health Study, the Black Women's Health Study, and the Multiethnic Cohort Study. Genotyping and imputation yielded data on 143,934 SNPs in 308 candidate genes for 3663 breast cancer cases (1098 estrogen-receptor negative (ER-), 1983 ER+, 582 ER unknown) and 4687 controls. Gene-level associations were evaluated using the adaptive rank truncated product (ARTP) statistic. *Results:* The most significantly associated genes were *GHRH* (MIM 139190), *CALM2* (MIM 114182), *CETP* (MIM 118470), and *AKR1C1* (MIM 600449) for overall breast cancer (nominal p ≤0. 01); *NR0B1* (MIM 300473), *IGF2R* (MIM 147280), *CALM2*, *CYP1B1* (MIM 601771), and *GRB2* (MIM 108355) for ER+ breast cancer (p ≤0. 02); and *PGR* (MIM 607311), *MAPK3* (MIM 601795), *MAP3K1* (MIM 600982), and *LHCGR* (MIM 152790) for ER- disease (p ≤0. 02). Evaluation of all SNPs with pairwise r2 <0. 8 in the top genes identified 10 common SNPs (in *CALM2*, *CETP*, *NR0B1, IGF2R, CYP1B1*, and *PGR)* that were significantly associated with overall, ER+, or ER- breast cancer after gene-level correction for multiple testing. Rs11571215 in *PGR* (progesterone receptor) was the SNP most strongly associated with ER- breast cancer; this SNP is monomorphic in 1000 Genomes European ancestry samples. *Conclusion:* We identified six genes in steroid hormone pathways that contain common variants associated with breast cancer in AA women, including the PGR gene for ER- breast cancer. Although there were several associated SNPs, these may not be the causal variants. Future work should consider the entire gene.

A comparative analysis of network mutationburdens across 21 tumor types predicts newcandidate cancer genes. *H. Horn[1,2], M. S. Lawrence[2], J. Xin Hu[1,2,3,4], N. Ilic[2,5], Y. Shresta[2], E. Kim[2,5], A. Kamburov[2], A. Kashani[1,2], W. C. Hahn[2,5], J. S. Boehm[2], G. Getz[2], K. Lage[1,2].* 1) Department of Surgery, Massachusetts General Hospital, Harvard Medical School, Boston, MA; 2) Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA; 3) Center for Biological Sequence Analysis, Technical University of Denmark, DK2800 Copenhagen, Denmark; 4) NNF Center for Protein Research, University of Copenhagen, DK2200 Copenhagen, Denmark; 5) Department of Medical Oncology, DanaFarber Cancer Institute, Boston, MA 02215, USA.

Heterogeneity across cancer makes it difficult to find driver genes with intermediate (2-20%) and low frequency (<2%) mutations, and we are likely missing entire classes of networks (or pathways) of biological and therapeutic value. Here, we quantify the extent to which cancer genes across 21 tumor types have an increased burden of mutations in their immediate gene network derived from functional genomics data. We formalize a classifier that accurately calculates the significance level of a gene's network mutation burden (NMB) and show it distinguishes both classic cancer genes and new driver genes in the majority of tested tumors. Our approach predicts 62 genome-wide significant candidate cancer genes - 44% of which point to new cancer biology. NMB identifies proportionally more (4x) low-frequency cancer genes than gene-based tests, and provides molecular clues in patients without established driver mutations. Our quantitative and comparative analysis of pan-cancer networks across 21 tumor types gives new insights into the biological and genetic architecture of cancers and illustrate an approach to augment discovery from existing cancer genomes that will become more powerful as datasets improve in the future.

2582T

Identifying pancreatic cancer susceptibility genes in the Czech Republic. *M. Janatova[1], M. Borecka[1], J. Soukupova[1], M. Vocka[2], P. Soucek[3], Z. Kleibl[1].* 1) Institute of Biochemistry and Experimetal Oncology, First Faculty of Medicine, Charles University in Prague, Prague 2, Czech Republic; 2) Department of Oncology, First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague 2, Czech Republic; 3) The National Institute of Public Health, Prague 10, Czech Republic.

Pancreatic cancer (PC) is the sixth most frequent cancer and the fifth most frequent cause of death in the Czech Republic. It has one of the worst prognoses of any type of cancer. Early detection and subsequent surgical treatment combined with chemotherapy can improve 5-year survival up to 20%. Inherited genetic factors play an important role in PC risk but the genetic background of pancreatic cancer is highly heterogeneous. Recently, *PALB2* was identified as a breast and pancreatic susceptibility gene. It plays a role in DNA repair. The MRN (*MRE11*, *RAD50*, *NBN*) complex is also important for DNA damage response pathway. Heterozygous mutations in *NBN* predispose to various cancers, especially breast cancer. The Slavic common founder mutation c. 657del5 represents the majority of *NBN* mutations in the Central or Eastern Europe. We examined peripheral blood DNA samples of 196 unselected PC patients. All *PALB2* exons and flanking intron-exon boundaries were analyzed by direct sequencing. Exon 6 of the *NBN* gene was studied by HRM analysis. Identified mutations were analyzed in a group of 915 non-cancer control samples by HRM analysis. We identified three truncating mutations in the *PALB2* gene (3/196; 1. 5%). Only one mutation was found in control samples (1/915; 0. 1%; P=0. 02). We revealed six carriers of the *NBN* c. 657del5 mutation (6/196; 3. 1%), whereas two mutations were found in controls (2/915; 0. 2%; P=0. 0005225). Our results provide new evidence that the *PALB2* and *NBN* genes contribute to PC susceptibility in a significant proportion of unselected PC patients in the Czech Republic. Thus, both genes should be implemented in multi-gene panel testing. Genetic testing of PC patients is one of the approaches for identification of high-risk individuals. The mutation carriers with PC can undergo a specific therapy and their relatives can be offered appropriate screening methods for associated tumors. Nevertheless, further studies are needed to precisely estimate the risk of PC for the *PALB2* and *NBN* mutation carriers. Subsequent segregation analysis and penetrance determination will help to improve a clinical management for the unaffected carriers. Supported by grants: IGA MZCR NT 14006-3/2013, and NT13343-4/2012, PRVOUK-P27/LF1/1, and SVV-UK 260148/2015.

2583W

Germline genetic variants in men with prostate and other primary cancers. *A. Johnson[1], P. Pilie[1], E. Koeppe[2], M. Dayno[3], K. Zuhlke[1], L. Okoth[1], E. Stoffel[2], K. Cooney[1].* 1) Internal Med Hem/Onc, Univ Michigan, Ann Arbor, MI; 2) Internal Med GI, Univ Michigan, Ann Arbor, MI; 3) Medical School, Univ Michigan, Ann Arbor, MI.

Prostate cancer (PCa) has a significant heritable component and men with early age of diagnosis and/or positive family history of the disease have been studied to identify PCa susceptibility genes. Men with PCa and one or more additional primary cancers may also be more likely to harbor a germline susceptibility allele but these individuals have not been routinely studied in this context. Here we screen germline DNA from men with PCa as well as >1 additional primary cancer(s) for germline variants in a set of cancer-related genes. One hundred three men with PCa and >1 additional primary cancer were selected from the University of Michigan Prostate Cancer Genetics Project or Cancer Genetics Clinic. Each individual met at least one additional inclusion criteria: 1) early age of onset of first malignancy (age<55), 2) rare tumor type or atypical presentation of a common tumor including male breast cancer, sarcoma, pancreatic cancer, and/or 3) three or more primary malignancies. Average age of first cancer diagnosis was 50. 2 yrs and the average age of PCa diagnosis was 55. 2 yrs. The most common non-PCas were melanoma (34 cases), bladder (17 cases), kidney (13 cases), head and neck (10 cases), lung (10 cases), and colorectal (9 cases). Germline DNA from the 103 multiple primary subjects was sequenced using the GeneRead DNASeq Human Comprehensive Cancer Panel (Qiagen, Valencia, CA) and Illumina HiSeq 2000 (Illumina, San Diego, CA) platform. Within the coding regions of 160 cancer genes ~3500 variants were detected, including 5 inframe coding indels, and 524 missense SNPs. Protein truncating variants (2 nonsense SNPs, 7 frameshift indels) were identified in 9 of the 103 (8. 7%) subjects, including 1 individual with variants in both *BRCA2* and *MLH1*, 3 with *BRCA2*, 2 with *ATM,* and 1 each with *BRIP1*, *PALB2*, and *FGFR3*. All truncating variants were verified through Sanger sequencing and genotyped in family members with DNA available. Amongst truncating variant carriers, the most common non-PCas were thyroid (3 cases), bladder (2 cases) and kidney (2 cases). Taken together, the prevalence of protein truncating germline mutations in this cohort of men with multiple-primary cancers including PCa is 9%. Given the fact that most of these men do not fulfill clinical criteria for genetic testing based on their personal or family cancer history, larger studies should be performed to fully characterize the spectrum of germline mutations in these high risk men.

2584T

Variation in genes used for multigene expression profiling is associated with pretreatment cognitive function in postmenopausal women with breast cancer. *T. A. Koleck[1], C. M. Bender[1], S. M. Sereika[1,2], Y. P. Conley[1,3].* 1) School of Nursing, University of Pittsburgh, Pittsburgh, PA; 2) Graduate School of Public Health, Department of Biostatistics, Epidemiology, and Clinical Translational Science, University of Pittsburgh, Pittsburgh, PA; 3) Graduate School of Public Health, Department of Human Genetics, University of Pittsburgh, Pittsburgh, PA.

Research suggests that variability in changes in cognitive function (CF) experienced by breast cancer (BC) survivors before they begin systemic adjuvant therapy may be related to cellular level BC characteristics. In order to test this hypothesis using a genetic association approach, we first identified biologically-plausible candidate genes from across five commercially available multigene expression profiles for BC, which are used clinically to characterize the biology of BC cells; genes utilized in three or more profiles were prioritized for investigation. Thus, the purpose of this study was to examine relationships between variation in genes used for multigene expression profiling and pretreatment CF in women with BC. Eight CF factors were assessed at pretreatment (i. e. , after primary surgery but prior to initiation of adjuvant therapy) in two cohorts of postmenopausal women diagnosed with early-stage BC prescribed chemotherapy plus anastrozole (n=56) or anastrozole alone (n=85) and a cohort of healthy, age- and education-matched controls (n=84) using a comprehensive neuropsychological test battery. Subjects were genotyped for 14 functional/tagging single nucleotide polymorphisms (SNPs) of the *CCNB1*, *CENPA*, *MELK*, *MYBL2*, and *ORC6* genes using DNA extracted from blood or saliva. Multiple linear regression was used to determine if the presence or absence of one or more variant alleles accounted for variability in CF factors. Analyses controlled for age, estimated intelligence and levels of depressive symptoms, anxiety, fatigue and pain. The strongest findings from these analyses relate to three functional SNPs in the 5' regulatory region of the *CCNB1* gene. The presence or absence of variant alleles (rs164390: TT+GT vs. GG; rs350099: CC+CT vs. TT; rs350104: TT vs. CC+CT) was found to be significantly (p<. 001 to p=. 088) associated with poorer pretreatment CF in BC survivors prescribed chemotherapy plus anastrozole or anastrozole alone compared to healthy controls. Furthermore, all *CCNB1* SNP by prescribed treatment interactions were associated with the same four CF factors - visual memory, visual working memory, verbal memory and executive function. Our results suggest that host variation in genes known to affect BC tumor aggressiveness may influence CF in women diagnosed with BC. In particular, differences in *CCNB1* expression may impact pretreatment cognitive performance in women diagnosed with BC, especially as it relates to memory and executive function.

2585W

Identification of rare genetic variation predisposing to lobular breast cancer. *C. Petridis[1,2], R. Roylance[3], E. J. Sawyer[1], M. A. Simpson[2].* 1) Research Oncology, Guy's Hospital, King's College London, London, United Kingdom; 2) Medical and Molecular Genetics, Guy's Hospital, King's College London, London, United Kingdom; 3) Centre for Molecular Oncology, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom.

Lobular breast cancer is the second most common type of breast cancer and accounts for about 15% of all cases. We have recently shown evidence of a distinct genetic aetiology compared to the common ductal breast cancer with both the identification of a lobular specific common variant susceptibility locus, and the identification of germline *CDH1* truncating mutations in ~8% of females with bilateral lobular disease. Here we aim to further evaluate the role of rare and low frequency variation in the genetic susceptibility to lobular breast cancer. To identify potential predisposition genes we have undertaken exome sequencing using an extreme phenotype study design. Affected females with early onset (<45), bilateral disease or family history of breast cancer have been selected from the GLACIER (Genetics of LobulAr Carcinoma In situ in EuRope) cohort (N=2535). The GLACIER study (MREC 06/Q1702/64) has ascertained patients from throughout the UK with the aim of understanding genetic predisposition to lobular breast cancer. 47 females met the inclusion criteria. Germline DNA was extracted from peripheral blood and exome sequencing performed using Agilent SureSelect exome capture and 2x100bp paired end reads on Illumina HiSeq2000. Two individuals had rare truncating alleles in *BRCA2* that have previously been reported as pathogenic (c. C5645A:p. S1882X, and c. C5655A:p. C1885X) and three harbour rare truncating alleles in *CDH1* (c. 2398delC:p. R800fs, c. G1942T:p. E648X, and c. 48+1G>A). We have undertaken a gene based case-control analysis using the data from the remaining 42 cases and 536 European female controls. Variants included in these analyses were selected on the basis of population frequency (MAF<1%), and predicted functionality (truncating and CADD>30). The analysis revealed 10 genes that are the site of rare putative functional variation in 2 or more affected individuals, and in which no equivalent variation is observed in the control group. To evaluate the relevance of these genes in lobular breast cancer disease population we are resequencing the coding regions (and intronic portions flanking splicing sites) in the entire GLACIER cohort (2535 cases and 2121 controls).

2586T

Association Between DNA Repair Gene Variants and Prostate Cancer Susceptibility using the iCOGS genotyping array. *E. Saunders[1], T. Dadaev[1], D. Leongamornlert[1], A. Amin Al Olama[2], S. Benlloch[2], K. Govindasami[1], K. Muir[3], D. Easton[2], R. Eeles[1], Z. Kote-Jarai[1], The PRACTICAL Consortium.* 1) Oncogenetics, Institute of Cancer Research, Sutton, Surrey, United Kingdom; 2) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Strangeways Research Laboratory, Cambridge, United Kingdom; 3) Institute of Population Health, University of Manchester, Manchester, United Kingdom.

Prostate cancer (PrCa) is the most frequently diagnosed male cancer in developed countries and amongst the leading causes of cancer related death. More than 100 common, low penetrance susceptibility variants have been identified by genome-wide association studies (GWAS), in addition to a small number of rare variants giving rise to greater risk; the majority of which are in DNA repair genes. We have previously genotyped 211,155 SNPs on a custom chip (iCOGS) in blood DNA from 21,780 PrCa cases and 21,727 controls of European ancestry from the PRACTICAL Consortium. This dataset has been recently imputed to the 1000 genomes phase 3 reference panel using SHAPEIT and IMPUTE2. In a literature review, we identified 179 genes with a primary function in DNA repair. SNPs within a 20kb flanking region of our gene set according to GENCODE release 19 were selected from the imputed iCOGS dataset. After removal of imputed variants with an IMPUTE2 INFO<0. 3, 98,255 DNA repair gene SNPs were available for single variant and gene-level association analyses. Analyses were adjusted for the first eight principal components and study groups, significance levels were set using the Bonferroni correction (single = P<5×10-7, gene = P<2. 7×10-4). Single variant analysis for association of DNA repair gene variants with PrCa identified only the previously reported association with *RAD51B* (Chr14q24; P = 1. 29x10-10). Several other genes showed non-significant association peaks, however no other variants were within one order of magnitude of the Bonferroni correction threshold. Gene-level analysis identified a novel significant association with the *MSH5* gene (Chr6p21; P = 1. 68x10-4) using the SKAT-C test. *MSH5* is involved in DNA mismatch repair and is a reported lung cancer susceptibility locus. This potential PrCa susceptibility locus warrants additional follow-up in independent datasets. We also investigated association between DNA repair gene variants and phenotypic characteristics of PrCa; to examine whether any of these variants could confer risk towards developing aggressive disease rather than increasing the risk of developing PrCa *per se*. No significant associations were observed at either the variant or gene levels; however these analyses were constrained by small numbers between the comparison groups.

2587W

Biochemical Pathways Involved in Betel Nuts Induced Oral Squamous Cell Carcinoma. *Y. S Shih[1], A. V Vu[3], T. L Liang[3], A. Z Zhang[4], C. C Chen[2], S. S Saharti[2], Y. E Elshimali[3].* 1) La Sierra University, Riverside, CA; 2) UCI Irvine, CA 92697; 3) UCLA Los Angeles, CA 90095; 4) Diamond Bar High School 21400 Pathfinder Rd, Diamond Bar, CA 91765.

Areca nut and betel quid chewing are traditional habits practiced throughout East and Southeast Asia with serious health consequences. Long term use has been associated with oral submucosal fibrosis, pre-cancerous oral lesion, and squamous cell carcinoma of the oral cavity and esophagus. Betel nuts contain several known carcinogenic compounds in high concentration,including hydroxychavicol, safrole and arecoline. Arecoline, a nicotinic acid-based alkaloid is the primary active ingredient in betel nuts responsible for CNS effectsand is a powerful carcinogen. Areca nut extract (ANE), when added to cultured human oral mucosal epithelium, can result in micronuclei formation, DNA damage, and apoptosis of the cells. One study concluded that over 17% of leukoplakia eventually developed into oral squamous cell carcinoma,suggesting the premalignant component of leukoplakia. Different studies have suggested that genetic components of oral squamous cell carcinoma with certain SNP genotypes, predispose one to increased-susceptibility and/or resistance towards progression to malignancy. Due to the complex interactions between environmental and genetic factors which result in the pathogenesis of betel nut induced oral squamous cell carcinoma, we use multiple approaches to analyze potentially relevant biochemical pathways in the pathogenesis. First, we conducted a comprehensive literature review of relevant genes implicated in pathogenesis of betel nut induced squamous cell carcinoma, regardless of the types of studies involved. Using the KEGG Pathway Database, we then identified relevant biochemical pathways where individual genes are involved, especially pathways that appeared more than 3 times in at least 2 independent studies. Overall, 5 biochemical pathways were identified including the MAPK signaling pathway, ErB signaling pathway, PI3K-Alk signaling pathway, AMPK signaling pathway, and VEGF signaling pathways. Currently, we are designing a targeted capture system for genes on these 5 pathways. Using 5 oral squamous cell carcinoma tissues and their associated normal controls from paraffin embedded tissue blocks, we will use the custom capture system to perform RNA sequencing on the Illumina MiSeq sequencer to identify potential mutations and fusion transcripts. Identifying these mutations may provide insight for identification of possible driver mutations.

2588T

How big of a role does *TP53* play in *BRCA1/2* negative familial breast cancer? Data from the SIMPLEXO consortium. *T. P. Slavin[1], K. N. Maxwell[2], S. Hart[3], V. Joseph[4], K. Schrader[5], L. Guidugli[3], T. Thomas[4], R. Moore[3], C. Hu[3], B. Wubbenhorst[6], S. M. Domchek[2], M. E. Robson[7], P. Radice[8], P. Peterlongo[8], J. Ford[9], J. Garber[10], C. Szabo[11], S. Neuhausen[12], K. Offit[7], K. L. Nathanson[6], F. J. Couch[3], J. N. Weitzel[1,12], SIMPLEXO Consortium.* 1) Department of Medical Oncology, Div of Clinical Cancer Genetics, City of Hope, Duarte, CA; 2) Department of Medicine, Division of Hematology-Oncology, University of Pennsylvania, Philadelphia, PA; 3) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 4) Clinical Genetics Research Lab, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY; 5) Hereditary Cancer Program, British Columbia Cancer Agency, Vancouver, BC; 6) Department of Medicine Division of Translational Medicine and Genetics, University of Pennsylvania, PA; 7) Clinical Genetics Service, Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, NY; 8) IFOM, the FIRC Institute of Molecular Oncology, and Department of Preventive and Predictive Medicine, Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; 9) Division of Oncology, Stanford University School of Medicine, Stanford, CA; 10) Center for Cancer Genetics and Prevention, Dana Farber Cancer Institute, Boston, MA; 11) National Institutes of Health, Bethesda, MD; 12) Beckman Research Institute of City of Hope, Duarte, CA.

Current known common, low risk polymorphisms and rare, moderate, and high risk alleles in cancer predisposing genes account for approximately half of the hereditary relative risk of breast cancer. Identification of individuals at high hereditary risk of breast cancer may lead to precision screening, prevention, and therapeutic strategies for patients and their families. To identify novel genes that confer an inherited risk of breast cancer, whole exome sequencing was undertaken in 333 *BRCA1/2* negative independent families with at least one primary breast and ovarian cancer or with a proband and at least two first to third degree relatives with breast cancer under age 70. This approach led to a validation set of 564 candidate genes that were evaluated using next-generation sequencing in 2331 *BRCA1/2* negative individuals with familial breast cancer. Analysis of the validation data revealed multiple individuals with rare variants in the Li-Fraumeni (LFS) associated gene *TP53*. A custom bioinformatics pipeline and the ACMG variant classification guidelines were used to identify and classify the variants. Twenty-nine variants found at less than 0. 1% minor allele frequency in the ExAC and EVS databases were identified in 33 individuals (1. 4%). Of these, 18 individuals were found to have 18 likely pathogenic/pathogenic mutations (0. 77% of the overall population), of which four were truncating and 14 were missense mutations in the DNA binding domain or tetramerization domain of p53. Ten of the 14 missense mutations were identified as pathogenic or likely pathogenic in Clinvar. Three missense mutations were classified as likely pathogenic due to *in silico* models, presence in the DNA binding domain and transactivation functional data from the TP53 IARC database. Finally one missense mutation was classified as likely pathogenic based on literature review. Of the 11 remaining rare variants, nine were classified as variants of uncertain significance (VUS) and two were classified as likely benign polymorphisms. Overall, these results show that *TP53* is a rare (0. 77% herein) but important contributor to familial breast cancer in *BRCA1/2* negative individuals.

2589W

Fine-mapping of the differentiated thyroid cancer risk susceptibility loci at 9q22 and 14q13 in populations from Metropolitan France and from New Caledonia. *c. Tcheandjieu[1,2], F. Lesueur[2,3], M. Sanchez[1], T. Truong[1,2], P. Guenel[1,2].* 1) INSERM, Villejuif, France; 2) University of Paris SUD, Le Kremlin Bicetre, France; 3) Institut Curie, Paris, France.

Context: Recently, GWAS have identified several susceptibility loci in differentiated thyroid carcinoma (DTC); the most robust associations were reported at loci 9q22 (rs965513 and rs1867277) and 14q13 (rs942289 and rs116909734). It remains however unclear whether these SNPs represent independent signals of association or if there are other independent signals within each locus. We aimed to replicate the 4 previously identified SNPs at 9q22 and 14q13 in a population of European descent in Metropolitan France and in a very high risk population of Melanesians in New Caledonia (NC). We also sought to identify novel DTC susceptibility SNPs and to find out whether SNPs at 9q22 and 14q13 can explain the differences in incidence rate reported between the 2 populations **Methods**: We included subjects from 2 case-control studies, conducted in Metropolitan France and in NC. We genotyped and imputed 81 and 561 SNPs respectively at loci 9q22 and 14q13 in 625 cases and 776 controls of European descent and 244 cases and 189 controls of Melanesian ethnicity. Odds ratio (OR) were performed using logistic regression assuming a log-additive model. We conducted conditional and haplotype analysis to identify independent signals and used bioinformatics tools to predict function of SNPs. **Results**: In Europeans, we replicated the association between previously reported GWAS SNPs and DTC at 9q22 (rs965513 [OR=1. 52, p=6. 10-6] and rs1867277 [OR=1. 38, p=3. 10-4] and at 14q13 (rs944289 [OR=0. 41, p=5. 10-4] and rs116909374 [OR=1. 97, p=3. 10-3]). In Melanesian, only rs944289 (OR=0. 74, p=1. 10-3) was replicated but magnitude of ORs for rs965513 and rs1867277 were similar to those observed in Europeans. At locus 9q22, no other SNP was significantly associated with DTC after conditioning the analysis on rs965513 and functional analysis suggestedrs10759944 in strong LD with rs965513 as a potential functional SNP. At locus 14q13 we reported a significantly high risk haplotype rs944289-rs116909374-rs999460 (OR=0. 51, p=3. 10-6) in Europeans. In Melanesians, the most significant signal was observed for an independent SNP rs1755774 (OR=0. 57, p=2. 10-5) which is in LD with rs2787423, a potential functional SNP. **Conclusion**: We confirmed the previously reported associations of DTC with SNPs at loci 9q22 and 14q13 and identified new interesting susceptibility SNPs in both ethnic groups. SNPs at both loci cannot account for the difference in incidence rates observed between Europeans and Melanesians.

2590T

Whole-exome sequencing in Taiwanese nasopharyngeal carcinoma (NPC) families to detect NPC susceptibility genes and pathways. *G. Yu[1], W. Hsu[2], M. Yeager[1], CGR. Cancer Genomics Research Lab[1], C. Wang[2], P. Lou[2], S. Diehl[3], C. Chen[4], A. Hildesheim[1], A. Goldstein[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; 2) National Taiwan University, Taiwan; 3) Rutgers School of Dental Medicine, Newark, NJ; 4) Academia Sinica, Taiwan.

NPC is a cancer that is known to be caused by infection with Epstein-Barr virus (EBV), a ubiquitous DNA virus that establishes lifelong latency in infected individuals. While >90% of the world population is infected with EBV during childhood or early adult life, only a very small fraction of infected individuals develop NPC. It is believed that, in addition to EBV infection and other environmental factors, genetic predisposition plays an important role in the pathogenesis of NPC. However, little is known about the genetic basisi of NPC. In this study, we sequenced 259 exomes from 99 NPC families with 2-4 cases by Nimblegen v2. 0 and v3. 0 exome capture array and the Illumina HiSeq2000 sequencer. Reads were aligned using Novoalign and variants were called using GATK software. We prioritized 9 genes with EBV/NPC related function (literature-based) and rare deleterious variants co-segregating in >=2 families (frequency <0. 5% in dbSNP, 1000 genomes or NHLBI Exome Sequencing Project exome variant server; no segmentally duplicated genes/variants; not in a repeat region; predicted as deleterious by Combined Annotation Dependent Depletion (CADD) score greater than 15; at least 10 reads and fitting a dominant segregation model in families with multiple NPC patients sequenced). In addition, we performed pathway enrichment analyses for 611 prioritized rare deleterious variants by Ingenuity Pathway Analysis and identified significant enrichment of Notch signaling pathway genes in NPC cases (P=0. 001). Notch signaling pathway is critical for cell survival, growth and metastasis. In total, 13 genes (including NOTCH1 et. al) were identified as candidate NPC susceptibility genes and will be evaluated further in a large NPC case-control study (~3000 samples) from the same Taiwanese population that generated the families.

Germline and Somatic *SDHx* Alterations in Apparently Sporadic Differentiated Thyroid Cancer. *Y. Ni[1,9,10], S. Seballos[1], S. Ganapathi[1], D. Gurin[1], B. Fletcher[1], J. Ngeow[1,4], R. Nagy[5,7], R. Kloos[6,7], M. Ringel[6,7], T. LaFramboise[1,8,10], C. Eng[1,2,3,8,10].* 1) Genomic Medicine Institute, Lerner Research Institute, Cleveland Clinic, Clevland, Ohio; 2) Taussig Cancer Institute, Cleveland Clinic, Cleveland, Ohio; 3) Stanley Shalom Zielony Nursing Institute, Cleveland Clinic, Cleveland, Ohio; 4) Division of Medical Oncology, National Cancer Center, Singapore; 5) Divisions of Human Genetics, Department of Medicine, The Ohio State University, Columbus, Ohio; 6) Divisions of Endocrinology and Metabolism, Department of Medicine, The Ohio State University, Columbus, Ohio; 7) Comprehensive Cancer Center, Arthur G. James Cancer Hospital and Richard G. Solove Research Institute, The Ohio State University, Columbus, Ohio; 8) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, Ohio; 9) Department of Epidemiology and Biostatistics, Case Western Reserve University School of Medicine, Cleveland, Ohio; 10) CASE Comprehensive Cancer Center, Case Western Reserve University, Cleveland, Ohio.

Along with breast and endometrial cancers, thyroid cancer is a major component cancer in Cowden syndrome (CS). Germline variants in *SDHB/C/D* (*SDHx*) genes account for subsets of CS/CS-like cases, conferring a higher risk of breast and thyroid cancers over those with only germline *PTEN* mutations. To investigate whether *SDHx* alterations at both germline and somatic levels occur in apparently sporadic breast cancer and differentiated thyroid cancer (DTC), we analyzed *SDHx* genes in the following four groups: i) 48 individuals with sporadic invasive breast adenocarcinoma for germline mutation; ii) 48 (expanded to 241) DTC for germline mutation; iii) 37 pairs DTC tumor-normal tissues for germline and somatic mutation and mRNA expression levels; and iv) 476 the Cancer Genome Atlas thyroid carcinoma dataset for validation. No germline *SDHx* variant was found in a pilot series of 48 breast cancer cases. As germline *SDHx* variants were found in our pilot of 48 thyroid cancer cases, we expanded to three series of DTC comprising a total 754 cases, and found 48 (6%) with germline *SDHx* variants (P<0. 001 compared with 0/350 controls). In 513 tumors, we found 27 (5%) with large somatic duplications within chromosome 1 encompassing *SDHC*. Both papillary and follicular thyroid tumors showed consistent loss of *SDHC/D* gene expression (P<0. 001), which is associated with earlier disease-onset and higher pathological-TNM stage. Therefore, we conclude that both germline and somatic *SDHx* mutations/variants occur in sporadic DTC but are very rare in sporadic breast cancer, and overall loss of *SDHx* gene expression is a signature of DTC.

2592T

Identification of Retrotransposon Insertion Mutations in Hereditary Cancer. *Y. Qian, D. Mancini-DiNardo, T. Judkins, H. C. Cox, C. Daniels, J. Holladay, M. Ryder, B. Coffee, K. R. Bowles, B. B. Roa.* Myriad Genetics, Inc. , Salt Lake City, UT.

Background: Traditional assays or techniques may underestimate the presence of certain types of large rearrangement mutations. Retroelements (RE) such as Alu and L1 elements are located ubiquitously throughout the human genome, and may cause disease if they result in genetic instability or direct disruption of gene function by inserting into a critical domain. **Methods:** We designed a targeted testing strategy that allows us to clearly characterize these large insertions in patients for whom hereditary cancer genetic testing was performed. **Results:** In this study, we identified 17 retroelement insertions in the exonic regions of 7 genes, which are *APC, ATM, BRCA1, BRCA2, MLH1, MSH2* and *PALB2*. As expected, the personal and family history of cancer was similar to those patients carrying other pathogenic truncating mutations. Strikingly, 9 of the 15 Alu insertions were identified in *BRCA2* exonic regions, four of which are located in exon 11, the largest exon in *BRCA2*, suggesting that this locus may be a hotspot of retroposon insertions of the genome. Interestingly, a few Alu insertions in *BRCA2* are enriched in certain ethnic populations. The individuals with c. 5007_5008insAlu (5235insAlu) share the same haplotype and were only identified in patients with recorded Latino/Caribbean ancestry. Similarly, 19 out of 29 patients carrying the c. 3407_3408insAlu (3635insAlu) mutation were recorded as having African ancestry. For the remaining 10 patients, 7 were of unknown ethnicity and three patients reported Latino or Native American ancestry; however, all the patients shared a common haplotype for *BRCA2*. This suggests that the two Alu insertions might be founder mutations in Latino/Caribbean and African populations, respectively. **Conclusions**: Current technologies are limited in their ability to identify RE insertions. However, when the presence of a large insertion is suspected, targeted follow-up studies are imperative to precisely characterize and classify such large rearrangements.

2593W

Integrated analysis of case-control and tumor-normal pair whole-exome data in breast cancer. *F. Hu, Y. Yu, S. Sivakumar, H. Hu, P. Scheet, X. Wu, C. Huff.* Epidemiology, MD Anderson Cancer Center, Houston, TX.

Genetic susceptibility has a well-established role in the etiology of breast cancer, but the contribution of rare genetic variants to breast cancer risk is underexplored. To address this gap, we conducted an analysis of whole-exome sequencing data to identify and characterize rare coding variants contributing to breast cancer susceptibility. We used VAAST 2. 1 to perform gene-based association tests from whole-exome sequencing data in 783 European ancestry breast cancer cases from TCGA and 1,451 European ancestry population controls from various sources. We constrained the analysis to variants with population minor allele frequencies of less than 1%. Our results replicated four well-established breast cancer-gene associations at p < 0. 05, *BRCA1* (p = 0. 003), *BRCA2* (p = 0. 01), *PALB2* (p = 0. 04), and *CHEK2* (p = 0. 04). In addition, we observed nominally significant associations for two genes previously identified in breast cancer GWAS, *RECQL5* (p = 0. 04), and *LGR6* (p = 0. 03). We also observed evidence of an association with *FANCC* (p = 0. 02), which has been previously implicated in breast cancer susceptibility. Our single marker analyses also identified two nominally significant variants in the above genes, G998E in *PALB2* (OR = 1. 86, p < 0. 005) and S26F in *FANCC* (OR = 3. 47, p = 0. 001). To further characterize putative germline susceptibility variants, we analyzed tumor-normal pair data from the 783 cases to test for evidence of somatic-germline interaction. We detected loss of heterozygosity events using hapLOH and tested for evidence of one-hit and two-hit models of carcinogenesis using SGI, reporting the results for each candidate gene as well as the top signals in a genome-wide analysis. Our results provide further support for the role of rare exonic variation in breast cancer susceptibility.

Mutations in the estrogen receptor (*ESR1*) occur at very low rates in primary breast tumors, but are frequently observed in endocrine resistant metastatic breast cancer. Preliminary studies indicate that mutant *ESR1* is partially resistant to current endocrine therapies. To understand the role of *ESR1* mutations in tumor progression, we employed digital droplet PCR to search for six previously reported *ESR1* mutations in primary tumors (n=43), bone metastases (n=12), brain metastases (n=38), and circulating free (cf) DNA (n=29) from 121 patients. *ESR1* D538G, Y537S, and Y537C were detected in 3/43 primary specimens, 3/38 brain specimens, 1/12 bone specimens, and 7/29 cfDNA, however, *ESR1* S463P, K303R, or Y537N were not observed. Multiple mutations were found in two patients. *ESR1* mutations identified in multiple blood draws were also detected in matched metastatic specimens and the frequencies correlated with disease progression, suggesting the potential value of *ESR1* mutations as a biomarker to monitor response to systemic endocrine therapy. The most frequently detected mutation (*ESR1* D538G) was also introduced into cell line genomic DNA using CRISPR/CAS technology to characterize phenotypic features of the ER mutant. Co-culturing D538G mutant and parental wild-type cells confirms the evolution of ESR1 mutants under anti-ER treatments. Our study shows that *ESR1* mutations are a measurable biomarker and a potential mechanism for endocrine resistance in breast cancer.

Targeted germline DNA sequence in men with family history of Prostate Cancer (PROFILE STUDY). *C. Cieza-Borrella[1], C. Mikropoulos[1], D. A. Leongamornlert[1], S. Saya[1], E. Bancroft[1], E. J. Saunders[1], T. Dadaev[1], E. Castro[1,2], Z. Kote-Jarai[1], R. A. Eeles[1,2], The PROFILE Study Steering Committee.* 1) The Institute of Cancer Research, 123 Old Brompton Road, London, UK; 2) The Royal Marsden NHS Foundation Trust, Fulham Road, London, UK.

Prostate Cancer (PrCa) is one of the most heritable solid tumours and mutations in DNA repair genes have been shown to predispose to its development. Genetic testing for *BRCA1* and *BRCA2* mutations is widely available for breast cancer, but with the introduction of next generation sequencing (NGS) it is feasible to screen for mutations in a panel of candidate genes and correlate these with PrCa risk. In this study, we included 86 men enrolled on the PROFILE PILOT study, a prospective PrCa screening study using prostate biopsy in asymptomatic men aged 40-69 with significant PrCa family history (FH). Blood samples were taken for PSA measurement and DNA extraction. gDNA samples were enriched for 22 tumour suppressor genes (the BROCA panel) using a custom Agilent SureSelect bait library. Sequencing was performed on the Illumina Miseq platform and reads aligned to the '1000 Genomes project' Phase 1. Sanger sequencing was used to confirm identified sequence variants in patients and their relatives where DNA was available. In total we identified 105 missense mutations, 54 synonymous variants, two nonsense mutations, one splice site mutation and one in-frame deletion with a population MAF of <5%. Within these, two likely pathogenic (Class 4) mutations were found: a splice-site variant in *BRCA1* (rs80358033) and a non-synonymous missense *BRCA2* mutation (rs80359104). The *BRCA1* mutation carrier refused prostate biopsy however the *BRCA2* mutation carrier was diagnosed with PrCa (GS 3+4). A novel *BARD1* stop-codon mutation was identified in a man with a benign biopsy outcome. This cohort will undergo 10-years follow-up to determine future PrCa incidence and in total will recruit 350 men with PrCa FH. This study shows the potential clinical utility of NGS in men with PrCa FH for: (i) assessing risk in patients and their family members and, (ii) potential future PrCa treatment options.

LncRNA expression influence DNA damage response in acute lymphoblastic leukemia. *R. Gioia[1, 3], M. Ouimet[1, 3], M. Lajoie[1], S. Drouin[1], C. Richer[1], R. Vidal[1], D. Sinnett[1, 2].* 1) Division of Hematology-Oncology, Research Center, Sainte-Justine Hospital, 3175 Chemin de la Cote-Sainte-Catherine, Montreal, QC, H3T 1C5, Canada; 2) Department of Pediatrics, Faculty of Medicine, University of Montreal, Montreal, QC, H3T 1C5, Canada; 3) These author collaborated equally to this work.

Acute lymphoblastic leukemia (ALL) represents 75% of cases of childhood leukemia, with approximately 3,000 children in the US and 5,000 in Europe diagnosed annually. Most cases involve chromosomal and genetic abnormalities, occurring spontaneously in genes that are important regulator of proliferation and cell death. According to current estimates, long non-coding RNAs (lncRNAs) account for up to 75% of the transcribed genome. However, our knowledge about their functions is scarce. We have initiated a study to identify and characterize lncRNAs involved in childhood ALL. We identified more than 800 lncRNAs whose expression is significantly up- or downregulated in patient samples as compared to CD19+ primary B-cells. We have characterized the role of three downregulated lncRNAs in the development of the disease by overexpressing them in pre-B leukemic cell lines. Two of these, located very close to each other in the genome, increased apoptosis levels after treatment with camptothecin, a DNA-damaging agent, without a concomitant increase in cell death, suggesting a role in DNA damage response. Supporting this, phospho-H2A. X levels in these cell lines are significantly increased compared to controls when exposed to camptothecin. Finally, cells lines in which the third lncRNA was overexpressed show significantly lower proliferation rate. We are currently further investigating the mechanistic underpinning of these effects to identify pathways in which these lncRNAs are implicated. .

Functional characterization of melanoma risk-associated locus on chromosome band 1q21. 3. *MA. Kovacs[1], J. Choi[1], T. Zhang[1], M. Xu[1], L. Aoude[2], M. Gartside[2], D. Gorkin[3], S. Loftus[4], W. Pavin[4], NK. Hayward[2], KM. Brown[1].* 1) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD 20892, USA; 2) QIMR Berghofer Medical Research Institute, Herston, Brisbane, QLD, Australia; 3) Ludwig Institute for Cancer Research, 9500 Gilman Drive, La Jolla, CA 92093, USA; 4) Genetic Disease Research Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland 20892, USA.

Cutaneous melanoma (CM) is the most aggressive form of skin cancer, accounting for nearly 50,000 deaths worldwide each year. Understanding CM genetic predisposition may shed light on pathways involved in CM pathophysiology and could reveal novel drug targets or biomarkers that may facilitate early detection. A recent genome-wide association study by MacGregor et al. identified a locus on chromosome band 1q21. 3 that significantly correlates with melanoma risk (OR = 0. 89). Fine mapping and conditional analyses have revealed that the association signal is most likely explained by a single genetic variant. The purpose of our study has been to pinpoint the functional variants in the 1q21. 3 locus, which are expected to be in tight LD with the region's lead SNP rs3768013, and to determine the CM-predisposing gene(s) regulated by these variants. To identify functional variants, we developed a bioinformatics tool using R that could annotate variants according to their potential to function as *cis*-regulatory variants. We took into account signature enhancer histone marks and open chromatin regions using histone ChIP-seq and DNaseI hypersensitivity sequencing data available from ENCODE and the Roadmap Epigenomics Project. Our annotation revealed 24 variants tightly linked to rs3768013 that have a high probability of functioning as *cis*-regulatory variants. We are using allele-specific protein binding assays to determine which of these variants could play a functional role in CM susceptibility. To elucidate the biological mechanism by which these variants mediate disease risk, we performed eQTL analysis in melanoma cell lines, as well as in tumor samples from The Cancer Genome Atlas (TCGA) skin melanoma project. Our analysis revealed that increased expression of *GOLPH3L* significantly correlates with the CM risk allele. Because *GOLPH3L* is a paralog of *GOLPH3*, a potent oncogene targeted for amplification in a number of cancers (Scott et al.), we evaluated whether ectopic *GOLPH3L* overexpression could transform human primary melanocytes in conjunction with oncogenic *BRAFV600E*. In sum, we have employed a generalizable system of variant ranking to parse through the vast set of risk-associated variants in the 1q21. 3 GWAS locus to identify a more limited set of variants that may be functional. We have demonstrated the possibility that these variants might regulate *GOLPH3L* expression in an allele-specific manner, indicating a potential novel oncogene involved in CM etiology.

2598T

Exome sequencing for detection of pathogenic rare variants in familial papillary thyroid cancer. *A. L. Camilleri[1], S. G Wilson[1,2,3], J. P. Walsh[1,3], L. C. Ward[3], J. Goldblatt[4].* 1) School of Medicine and Pharmacology, University of Western Australia, Crawley, Australia; 2) Department of Twin Research and Genetic Epidemiology, King's College London, London, UK; 3) Department of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Nedlands, Australia; 4) School of Paediatrics and Child Health, University of Western Australia, Crawley, Australia.

Thyroid cancer is the most common endocrine malignancy, and the reported incidence is increasing. Papillary thyroid cancer (PTC), accounts for 80% of thyroid malignancies. Most PTCs occur in younger adults and therefore occur during peak employment and reproductive years. Despite low mortality rates, local recurrence occurs in up to 20% of patients. For this group of patients, re-operative surgery can cause significant morbidity and apart from radioactive iodine ablation, there is no adjuvant therapy available. Familial PTC (FPTC) occurs in several multi-organ cancer syndromes, but also occurs in isolation with features of a Mendelian autosomal dominant disorder with incomplete penetrance; the gene or genes involved are largely unknown. Approximately 3-7% of all PTC cases are thought to be familial. We performed an exome sequencing study on individuals from 13 families with FPTC. Individuals were recruited from an endocrinology practice and study subjects provided a family cancer history which was confirmed directly by pathology or otherwise from patient records. Whole exome sequencing (WES) was performed on DNA extracted from blood collected for 27 individuals using the Illumina TruSeq Exome Enrichment Kit for exome capture and the Illumina HiSeq2000 platform for sequencing. Results were annotated using ANNOVAR and were analysed using VarSifter which allows easy visualisation and manipulation of the data, and VAAST which ranks the genes from most damaging to least damaging based on the composite likelihood ratio test (CLRT). Exome sequencing yielded an average 76. 6 Mb of DNA target sequence per sample with mean coverage achieved across all targets (20,794 genes across the genome) of 76. 8x. Analysis of the data from one family revealed mutations in the following genes: *ACIN1, LRRC49, CSPG4* and *CHEK2*. One gene variant was identified that was of particular interest in *CHEK2*, located on chromosome 22. The *CHEK2* gene in one FPTC family contained a 1 bp deletion of a G nucleotide at position 29091857 on chromosome 22, causing a frameshift mutation. In summary, our strategy for rare variant detection led to the identification of a potentially damaging mutation which may contribute to FPTC risk in this family. Whilst it has been suggested that this mutation contributes to a risk of PTC, this is the first report of a *CHEK2* truncating mutation in an FPTC family and studies are ongoing to understand the biologic implications.

Interleukin 7 gene region is associated with mesothelioma survival in Australian males. *G. Cadby[1], F. Brims[2], A. Reid[3], I. Dick[4], C. Robinson[4], P. Melton[1], E. Moses[1], B. Robinson[2,4,5], B. Musk[2,4], J. Creaney[4,5]*. 1) Centre for Genetic Origins of Health and Disease, University of Western Australia, Crawley, WA; 2) Department of Respiratory Medicine, Sir Charles Gairdner Hospital, Nedlands, WA; 3) Epidemiology and Biostatistics, School of Public Health, Curtin University, Bentley, WA; 4) National Centre for Asbestos Related Diseases, School of Medicine and Pharmacology, University of Western Australia, Crawley, WA; 5) The Australian Mesothelioma Tissue Bank, Sir Charles Gairdner Hospital, Nedlands, WA.

Malignant mesothelioma (MM) is an incurable malignant tumour of the pleura or peritoneum with increasing incidence worldwide. There is currently no known effective treatment for MM which is uniformly fatal with a median survival time of ~12 months. A role for genetic variation in MM survival has been observed in various murine genetic backgrounds; however no published studies have examined the germline genetic contribution to human MM survival. The aim of this study was to perform a genome-wide association study of MM survival. Clinical data and DNA were obtained from 371 men with a confirmed diagnosis of MM who attended Sir Charles Gairdner Hospital in Perth, Western Australia. Genome-wide genotyping was performed on the Illumina 660W Quad Array and approximately 500,000 single nucleotide polymorphisms (SNPs) were available for testing after quality control checks. Survival analysis was performed using Cox regression assuming proportional hazards. Age at diagnosis and the first three principal components were included as covariates in the analysis. Median survival was 13 months for those who had died (n=361) and 52 months for those with censored observations (n=10). Average age at diagnosis was 67. 3 years. No single SNP achieved formal genome-wide significance using a Bonferroni correction for multiple testing ($p < 9. 6x10-8$). A region including the Interleukin 7 (*IL7*) gene showed some evidence for association with MM survival (*IL7* rs6993386: hazard ratio=1. 56; p=1. 46x10-7). The IL7 protein (encoded by the *IL7* gene) functions primarily as a growth and anti-apoptotic factor for B and T cells, and has previously been implicated in the progression of haematopoietic and solid malignancies. Further analyses are planned, including replication analysis in independent cohorts of Italian and American MM cases.

Identifying inherited genetic variation associated with molecular phenotypes in colon cancer. *D. Chang[1], T. Bhangale[1], R. Graham[1], S. Bezieau[2], H. Brenner[3], A. T. Chan[4], J. Chang-Claude[5], S. J. Chanock[6], T. A. Harrison[7], M. Hoffmeister[3], L. Hsu[7], T. J. Hudson[8], P. A. Newcomb[7], J. D. Potter[7], M. L. Slattery[9], E. White[7], U. Peters[7], R. Gentleman[10].* 1) Genentech, South San Francisco, CA USA; 2) Service de Génétique Médicale, CHU Nantes, Nantes, France; 3) Division of Clinical Epidemiology and Aging Research, German Cancer Research Center, Heidelberg, Germany; 4) Division of Gastroenterology, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA; 5) Division of Cancer Epidemiology, German Cancer Research Center, Heidelberg, Germany; 6) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD, USA; 7) Public Health Sciences Division, Fred Hutchinson Cancer Research Center, Seattle, WA, USA; 8) Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 9) Department of Internal Medicine, The University of Utah School of Medicine, Salt Lake City, UT, USA; 10) 23andMe, Mountain View, CA, USA.

Molecular characterization of colon cancer tumors includes assaying microsatellite instability (MSI), methylation (e. g. CpG island methylator phenotype, CIMP), as well as somatic mutations in the tumor. In a parallel effort, GWAS have identified inherited genetic variants involved in colorectal cancer (CRC) risk. The goal of this study is to assay whether variants associated with CRC risk are also associated with tumor-related phenotypes. To carry out a GWAS on tumor phenotypes, we used an array of tumor and adjacent non-tumor colon data available from The Cancer Genome Atlas (TCGA) project. We carried out a GWAS for each of the four binary tumor phenotypes relevant to CRC: CIMP status, MSI status, and presence of somatic mutations in *APC*, and *TP53*. After removing samples of non-European ancestry, 375 individuals remained. Each of the tumor phenotypes was regressed on genetic variants to test for association between inherited genetic variation and tumor-related phenotypes. As phenotype data across the four phenotypes were not available for all individuals, there were 301-375 samples in each GWAS depending on the phenotype. None of the 66 SNPs associated with CRC in the NHGRI GWAS catalog and for which we had data on, were significantly associated with a tumor phenotype. We next applied two complementary gene-association methods, MixMAP and VEGAS that can increase power by reducing the number of tests and leveraging information across multiple SNPs within a region to detect gene-level association. We tested for association across 20,873 genes with tumor phenotypes in the TCGA dataset and for association with CRC risk in the GECCO dataset (a GWAS of over 20,000 samples). Seventeen genes were associated with CRC risk in the GECCO dataset at a significance threshold adjusted for 20,873 tests ($P<2. 4x10-6$ across the 17 genes). Testing these 17 genes for association in the TCGA data, we found that *CLDN4* and *WBSCR27* are associated with *TP53* mutation status (PMixMAP $< 2. 9x10-5$ for both genes); and *FOLH1B* is associated with MSI status (PMixMAP=3. 07x10-4). All are significant at a threshold adjusted for 17 tests. In conclusion, incorporation of tumor molecular data with inherited genetic variation can provide relevant CRC subtypes in which variants associated with CRC risk may play a role. Larger sample sizes are needed to confirm these findings.

2601W

Using genetic variants and classical epidemiology risk factors in a risk prediction model for lung cancer among female non-smokers. *L. Chien[1], I. Chang[1,2], P. Yang[3], C. Chen[4], C. Hsiung[1].* 1) Division of Biostatistics and Bioinformatics,Institute of Population Health Sciences, National Health Research Institutes, Zhunan, Taiwan; 2) National Institute of Cancer Research, National Health Research Institutes, Zhunan, Taiwan; 3) Division of Pulmonary Medicine, Department of Internal Medicine, National Taiwan University Hospital and College of Medicine, Taipei, Taiwan; 4) Genomics Research Center, Academia Sinica; and Graduate Institute of Epidemiology, College of Public Health, National Taiwan University, Taipei, Taiwan.

It is estimated that 25% of lung cancer cases arise in never-smoking individuals. Death caused by lung cancer in never-smokers ranks as the seventh most common cause of cancer death worldwide. Epidemiology studies have shown that the incidence of lung cancer in never-smoking women is particularly high in Asia and lung adenocarcinoma is the most common histology subtype among never-smoking lung cancer cases. Several SNPs (single nucleotide polymorphisms) have been identified to be associated with lung cancer susceptibility among never-smokers by genome-wide association studies (GWAS). It is of interest to assess the value of these loci in the context of genetic counselling and population screening for lung cancer. We constructed a multivariate logistic regression model for the computation of absolute risk of a female developing lung cancer within a 5-year period, based on age, classical epidemiological risk factors and these known susceptibility SNPs and illustrate some of its possible uses. Data used in this model development included those from cohort GELAC (genetic epidemiology study of lung adenocarcinoma in Taiwan), on which GWAS were based, and female lung ADC incidence rate based on Taiwan Cancer Registry and census data. GELAC is a case-control study; 1996 lung cancer cases and 1405 healthy controls were used in the model development. Since smoking rate in women is low, between 3-5% for the past decades, we assume females are never-smokers in building the model. This model is potentially useful in designing lung cancer screening programs. For example, applying this model to females with age between 55 and 74 and considering an absolute risk of 0. 83 (1. 28) % as cutoff, 10 (3) % of the population could be identified in which 32 (15) % of the cases would arise. If confirmed in validation studies, it could provide an estimate of lung cancer risk among never-smoking female in Taiwan to guide discussions and decisions regarding prevention and surveillance. Using risk distributions, we also compared our model with the model built on covariates without SNPs, providing an assessment of the value of these susceptibility genetic variants. For example, only 11. 4% of the lung cancer cases would arise from the most risky 3% population if they are identified by the model without any SNP. This study provides a framework to evaluate from the risk assessment viewpoint the value of conducting more GWAS that look for new lung cancer susceptibility loci.

2602T

The genetic contribution to risk of Acute Lymphoblastic Leukemia (ALL) differs across the lifespan in patients treated with unrelated donor allogeneic hematopoietic cell transplant (URD-HCT). *A. Clay[1], T. Hahn[2], L. Preus[1], Q. Zhu[3], L. Yan[3], Q. Liu[4], Q. Hu[3], S. Liu[3], CB. Ambrosone[1], X. Zhu[5], CA. Haiman[6], DO. Stram[6], LC. Pooler[6], X. Sheng[6], D. Tritchler[4], S. Battaglia[7], D. Weisdorf[8], S. Spellman[9], M. Pasquini[10], PL. McCarthy[2], K. Onel[11], LE. Sucheston-Campbell[1].* 1) Department of Cancer Prevention and Control, Roswell Park Cancer Institute, Buffalo, NY; 2) Department of Medicine, Roswell Park Cancer Institute, Buffalo, NY; 3) Department of Biostatistics and Bioinformatics, Roswell Park Cancer Institute, Buffalo, NY; 4) Department of Biostatistics, SUNY-Buffalo, Buffalo, NY; 5) Center for International Blood and Marrow Transplant Research, Medical College of Wisconsin, Milwaukee, WI; 6) Department of Preventive Medicine, University of Southern California, Los Angeles, CA; 7) Department of Pharmacology and Therapeutics, Roswell Park Cancer Institute, Buffalo, NY; 8) Department of Medicine, University of Minnesota, Minneapolis, MN; 9) Center for International Blood and Marrow Transplant Research, Minneapolis Campus, Minneapolis, MN; 10) Department of Medicine, Medical College of Wisconsin, Milwaukee, WI; 11) Department of Pediatrics, The University of Chicago, Chicago, IL.

Introduction: Genome-wide (GW) significant SNPs associated with pediatric ALL are in *GATA3* (rs3824662), *IKZF1* (rs6964969), *CDKN2A/B* (rs3731217/rs3218005), *ARID5B* (rs10821936), *CEBPE* (rs7157021) and *BMI1-PIP4K2A* (rs7088318), while adolescent young adult (AYA) ALL associates with only the *GATA3* SNP. We tested these SNPs for association with ALL in pediatric (<20 yrs), AYA (20-40 yrs) and adults (>40 yrs) treated with URD-HCT, and with survival. **Methods:** Cohort 1 (C1) and Cohort 2 (C2) controls included 2,229 and 889, respectively, unrelated healthy donors genotyped on Illumina OmniExpress chip along with 504 (C1) and 101 (C2) ALL cases of European Ancestry. C1 and C2 are from the Center for International Blood and Marrow Transplant Research registry. SNPs were tested for association with ALL overall and by age. SNP association with death due to ALL or TRM 1 year post URD-HCT was measured with competing risk models. **Results:** Overall (C1/C2) and age-stratified models (C1 only) are presented (Table) due to the significance of age in all SNP models (p<10e-38). The A allele in rs3824662 was the only SNP associated with hazard of death (Transplant Related Mortality HR=. 66 ±. 16, p=. 008).

SNP	Gene	Overall (C1/C2)		Pediatric		AYA		Adult	
		OR (95%CI)	P	OR (95%CI)	P	OR (95%CI)	P	OR (95%CI)	P
rs3824662	GATA3	1. 6 (1. 4,1. 9)/ 1. 7 (1. 2,2. 4)	6. 4-09/ 0. 002	1. 6 (1. 2,2. 0)	0. 001	1. 4 (1. 1,1. 8)	0. 004	1. 9 (1. 5,2. 5)	2. 6e-07
rs11980379 (LD=1. 0 rs6964969)	IKZF1	1. 5 (1. 3,1. 7)/ 1. 4 (1. 0,1. 9)	4e-07/ 0. 05	1. 8 (1. 4,2. 3)	6. 5e-07	1. 4 (1. 1,1. 7)	0. 006	1. 2 (1. 0,1. 6)	0. 1

rs7090445 (LD=1. 0 with rs10821936)	ARID5B	1. 1 (1. 0,1. 3)/ 1. 2 (0. 9,1. 6)	0. 1/ 0. 3	1. 4 (1. 1,1. 7)	0. 009	1. 0 (0. 8,1. 2)	0. 9	1. 1 (0. 8,1. 4)	0. 6
rs7157021	CEBPE	0. 8 (0. 7,0. 9)/ 1. 3 (1. 0,1. 7)	0. 02/ 0. 09	0. 8 (0. 6,1. 0)	0. 07	0. 9 (0. 8,1. 2)	0. 6	0. 8 (0. 6,0. 9)	0. 03
rs7088318	BMI1-PIP4K2A	0. 9 (0. 8,1. 0)/ 0. 9 (0. 7,1. 3)	0. 09/ 0. 7	0. 8 (0. 7,1. 1)	0. 1	0. 9 (0. 7, 1. 1)	0. 5	0. 9 (0. 7,1. 1)	0. 4

Conclusions: SNP associations varied across the lifespan, indicating that susceptibility to ALL may differ by age of onset. It is possible that associations are specific to ALL subtypes that differ by age, thus we are currently testing these relationships. The *GATA3* A allele association with hazard of transplant related mortality requires validation. The null associations with known GW significant pediatric SNPs (ie *ARID5B*) in our study may indicate those treated by URD-HCT for ALL have different genetic susceptibilities.

2603W

ENCAPP: elastic-net-based prognosis and biomarker discovery across human cancers. *J. Das[1,2], K. M. Gayvert[3], H. Yu[1,2].* 1) Department of Biological Statistics & Computational Biology, Cornell University, Ithaca, NY; 2) Weill Institute for Cell and Molecular Biology, Cornell University, Ithaca, NY; 3) Tri-Institutional Training Program in Computational Biology and Medicine, New York 10065, NY, USA.

With the explosion of genomic data, there has been significant effort to understand the molecular basis of cancer using informatics approaches. One particularly challenging problem is to determine prognosis for different patients. Conventional clinical approaches rely on overall physiological and histological parameters and have been shown to be inaccurate. Alternatively, traditional genomic approaches use alterations in transcriptomic profiles to predict outcome but assume independence between genes, a major limitation since the proteins encoded by these genes are part of a protein-protein interaction network within the cell. Here, we present ENCAPP, an elastic-net-based approach that uses interaction dynamics, a combination of gene expression data with the topological structure of the reference human protein interaction network, to predict outcome for different human cancers. Our method identifies functional modules that are differentially expressed between patients with good and bad outcomes and uses these to fit an elastic-net-based regression model for cancer prognosis. ENCAPP is successful at outcome prediction across cancer types and subtypes (median AUCs = 0. 79 and 0. 69 for two clinically distinct breast cancer subtypes, 0. 67 and 0. 77 for colon, and ovarian cancers, respectively) and performs significantly better than existing methods (increase in AUC of 0. 07 over the best existing method). It can also predict outcome across breast cancer subtypes: trained on one subtype, it is works reasonably well at outcome determination for a different subtype (median AUC = 0. 65). Finally, ENCAPP can be used for prognosis across related cancer types: trained on colon cancer data, it is successful at predicting rectal cancer outcome (median AUC = 0. 80). Our method is highly robust to incompleteness of the reference protein network. It also works well for alternate definitions of prognosis i. e. , different outcomes such as death or metastasis and different cutoffs for right censoring of the outcome variable. Furthermore, we find that top differentially expressed functional modules used as decision boundaries in outcome prediction are enriched for known cancer genes. Thus, these modules can be leveraged to identify novel prognostic biomarkers that can be probed to generate mechanistic and therapeutic insights.

2604T

Genetic propensity to allergic rhinitis is associated with sex-specific leukemia risk reduction in children. *E. Elhauge[1], J. Wiemels[2], M. Wrensch[2], A. Molinaro[2], M. van der Laan[1], L. F. Barcellos[1], K. Walsh[2].* 1) School of Public Health, Division of Epidemiology, UC Berkeley, CA; 2) Dept. of Neuroepidemiology, UCSF, San Francisco, CA.

Previous epidemiologic studies have observed inconsistent associations between acute lymphoblastic leukemia (ALL [MIM 613065]) risk and measures of atopic disease. To address this, we quantified the effect of genetic propensity to allergic rhinitis (AR [MIM 607154]) on the risk of ALL. An instrumental variable (IV) was constructed utilizing genome-wide SNP data and adaptive statistical methods to predict medically diagnosed AR in an adult population; this AR IV predicts the genetic propensity to AR. The AR IV was then applied to an independent ALL case-control dataset to test whether the AR IV was associated with ALL risk. This study is the first to leverage the size and SNP data available from the Kaiser Genetic Epidemiology Research on Aging (GERA) medical cohort (N=78,000, European-ancestry) to create a predictive and generalizable IV for propensity to AR of higher power than is typically available in a case-control studies. A causal model was built that depended exclusively on the AR IV of each subject and their genetic ancestry; this model meets the assumptions of Mendelian Randomization, preserved analytical power and eliminated multiple-testing correction. To produce the most predictive AR IV, machine-learning, cross-validation methods (ML) were used. ML selected sparse, partial least squares as the most predictive model. ML was used to guide a dimensionality-reduction process from the Axiom genome-wide array to just 983, highly-predictive SNPs. The use of ML blocked model overfitting, while the use of an independent test dataset eliminated any confounding due to residual overfitting. The ALL case-control subjects included cases from The Children's Oncology Group (n=980, European-ancestry) and controls from The Wellcome Trust Case-Control Consortium (n=2,624, European-ancestry), genotyped on the Affymetrix 6. 0 array. Among males, the AR IV was associated with a reduced risk of ALL: RR 0. 43, 95% CI [0. 20, 0. 94], P-value 0. 04; suggesting that inherited propensity to atopic disease is associated with reduced leukemia risk. Among females, the AR IV had a weak protective effect that was not significant: RR 0. 86, 95% CI [0. 38, 1. 96], P-value 0. 73. Ongoing work will attempt to: a) validate this association in additional ALL case-control datasets, b) characterize functional pathways for AR propensity SNPs, c) understand the sexual dimorphism of this effect, and d) reduce the variance and increase the predictive power of the AR propensity estimation.

Common Genetic Variants in 11q13. 3 and 9q22. 33 Are Associated With Molecular Subgroups of Multiple Myeloma. *S. W. Erickson[1,2], C. Stein[3], O. W. Stephens[3], S. S. Chavan[3], N. Sanathkumar[3], E. Tian[3], J. Epstein[3], G. Morgan[3], B. Barlogie[3], C. J. Heuck[3], A. J Vangsted[4].* 1) Department of Biostatistics, University of Arkansas for Medical Sciences, Little Rock, AR; 2) Currently: Genetic Epidemiology and Omics Research, RTI International, Research Triangle Park, NC; 3) Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, AR; 4) Department of Hematology, Rigshospitalet, Copenhagen University, Denmark.

Weinhold et al (2013) reported the association of a potentially functional SNP in *CCND1* with increased incidence of the t(11;14) translocation in multiple myeloma (MM). MM can be classified by gene expression profiling (GEP) into seven well-defined molecular subgroups (Zhan et al, 2006), of which four are strongly influenced by specific translocations involving the immunoglobulin heavy chain (IgH) locus. The generation of fusion proteins with functional consequences is one of the biological impacts of IgH-related translocations, and this forms the basis of the translocations and cyclin D expression (TC) classification system of MM. We investigated whether SNPs previously associated with overall risk of MM or t(11;14) are associated with GEP- and TC-based disease subsets. Genotypes at 777,681 SNPs in a discovery set of 713 newly diagnosed MM patients of European ancestry (EA) and 1064 cancer-free controls, plus a replication set of 252 more recent EA MM patients genotyped at selected SNPs, were used for this study. GEP data from CD138-selected plasma cells taken within 3 months prior to treatment were available for all MM patients. The SNP rs603965, located in *CCND1* at 11q13. 3, was significantly associated with the TC-based CCND1 subgroup in the discovery set (OR=1. 82, p=1. 7 x 10-4) and in our replication set (OR=2. 19, p=1. 3 x 10-4), which confirms the finding of Weinhold et al (2013). We found that overall survival of CCND1 patients trended worse among non-carriers of the G allele than either heterozygous or homozygous carriers, although with marginal statistical significance (p=0. 08). The SNP rs73486634 at 9q22. 33, located between and upstream of *FOXE1* and *XPA*, was associated with the proliferative (PR) GEP-based subgroup in the discovery set (OR=5. 06, p=6. 0 x 10-9) and was confirmed in the replication set (OR=3. 16, p=0. 006). The PR subgroup exhibits increased expression of proliferation-associated genes and is characterized by high rates of relapse, but almost always in the absence of IgH translocations. Variants in *FOXE1* and *XPA* have been associated with carcinogenesis, and lung and colorectal cancer. Our findings confirm previous results and identify novel association loci, showing that genetic variation influences the risk for specific subgroups of MM.

2606T

Large scale meta-analysis identifies several new risk loci for development of esophageal adenocarcinoma and Barrett's esophagus in individuals of European descendents. *P. Gharahkhani[1], R. Fitzgerald[2], T. Vaughan[3], I. Tomlinson[4], I. Gockel[5], C. Palles[4], M. Knapp[6], MM. Noethen[7, 8], J. Becker[7, 8], S. MacGregor[1], P. Pharoah[9], DC. Whiteman[10], J. Jankowski[11,12], J. Schumacher[7, 8], Barrett's and Esophageal Adenocarcinoma Consortium (BEACON), wellcome Trust Case Control Consertium.* 1) Statistical Genetics, QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia; 2) Medical Research Council (MRC) Cancer Cell Unit, Hutchison-MRC Research Centre and University of Cambridge, Cambridge, United Kingdom; 3) Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, USA; 4) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK; 5) Department of Visceral, Transplant, Thoracic and Vascular Surgery, University Hospital of Leipzig, Leipzig, Germany; 6) Institute for Medical Biometry, Informatics, and Epidemiology, University of Bonn, Bonn, Germany; 7) Institute of Human Genetics, University of Bonn, Bonn, Germany; 8) Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany; 9) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, United Kingdom; 10) Cancer Control, QIMR Berghofer Medical Research Institute, Brisbane, QLD 4029, Australia; 11) University Hospitals Coventry & Warwickshire NHS Trust, Warwickshire, England; 12) Warwick Medical School, University of Warwick, Warwickshire, England.

Esophageal adenocarcinoma (EA) is a fatal cancer with rising incidence in the developed world. Barrett's esophagus (BE), a metaplastic change of esophageal epithelium, is associated with greatly increased risk of EA. Genetic predisposition to BE and EA is incompletely understood. Although genome-wide association studies (GWAS) have identified eight loci associated with development of BE and/or EA, these loci together explain small proportion of phenotypic variance. To investigate additional loci increasing the risk of BE and EA, we performed the largest meta-analysis of GWAS results conducted for BE and EA to date, including 6,177 cases of BE, 4,120 cases of EA, and 17,067 unscreened controls. All participants were of European descent. Since we recently showed a significant genetic overlap between BE and EA, we also performed a combined analysis of BE and EA (10,297 cases of BE+EA combined) to maximize power. Imputation was carried out using the June 2014 release of the 1000 Genomes Phase I haplotypes as the reference panel. Meta-analysis was performed using fixed-effects inverse variance weighting approach. Our analysis of BE+EA identified eight new loci increasing risk of BE and EA in single variant tests and three additional loci in gene-based tests. These include an association in the gene *CFTR* (rs17451754 [G], P=5. 21×10-10, OR=1. 19) as well as two other associations to regions known to affect obesity related traits (*TPPP/CEP72* and *MFHAS1* loci). The *TPPP/CEP72* locus has been also associated with ulcerative colitis in a previous study. Additionally, at the gene *HTR3C* (rs9823696 [A], P=2. 01×10-8, OR=1. 17), we identify for the first time an association signal where the effect is only on EA and not mediated via BE (rs9823696 [A], P= 0. 494, OR= 1. 02 for BE). Functional annotation shows several of the novel loci are either expressed in gastrointestinal tract, change sequence motifs for binding of several proteins and/or are eQTL in adipose or other tissues. These new loci, in addition to the previously identified risk loci, will improve risk profiling and management of high-risk individuals. Further investigation of these new risk loci and downstream biological pathways will help in better understanding the etiology of BE and EA, and paves the way for subsequent development of treatments.

2607W

Non-Small Cell Lung Carcinoma patient survival with ALK polysomy vs. ALK-EML4 rearrangement identified by Fluorescence In Situ Hybridization analysis. *R. Gupta[1], L. Cannizzaro[2], L. Vasovic[3], K. H. Ramesh[2].* 1) Montefiore Medical Center, Bronx, NY; 2) Albert Einstein School of Medicine, Bronx, NY; 3) Cornell University, New York, NY.

Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related mortality world-wide with a 5-year survival rate of 15%. Polysomy, defined as three or more gene copies, is commonly seen in a wide variety of cancers and plays an oncogenic role. A fusion oncogene consisting of an inversion in chromosome 2, anaplastic lymphoma kinase (ALK)-echinoderm microtubule-associated protein-like 4 (EML4), is described in 2-5% of NSCLC and is associated with the progression of disease. ALK polysomy and ALK-EML4 gene rearrangement cases were first identified by Fluorescence In situ Hybridization (FISH) analysis. FISH was performed on formalin-fixed paraffin embedded tumor tissue cases with NSCLC, using the ALK gene break-apart probe (Abbott Molecular, USA, FDA approved). Areas representative of tumor were selected by reviewing pathologists, serial unstained sections were prepared for FISH with deparaffinization and pretreatment using the Vysis ThermoBrite FDA approved protocol. Image analysis was performed using the Metasystem Ikaros Software (Metasystem, Germany). A sample was considered positive if >50% cells were positive; negative if <10% cells were positive; and equivocal if 10-50% of the cells were positive. The aim of our study was to assess the survival difference in NSCLC patients without a history of tobacco use with ALK polysomy or the fusion oncogene. Using the Clinical Looking Glass database at Montefiore Medical Center, we retrospectively identified four cases of ALK-EML4 gene rearrangement and 108 cases of ALK polysomy by FISH analysis from 2011-2014. Amongst the two groups, there were no significant differences in age (p=0. 47) and there was a higher percentage of female patients in the rearrangement group than in the polysomy group (3/4Vs. 54/54). Using log-rank statistical analysis, there were no significant differences in survival from the date of NSCLC diagnosis between the polysomy and rearrangement groups (p=0. 37). In conclusion, the lack of statistical significance in survival between the two groups may suggest that the oncogenicity of polysomy of ALK and the ALK-EML4 gene rearrangement in NSCLC patients works by similar mechanisms. However, the small sample size and single center study preclude any definitive conclusions in the survival differences. With clear knowledge of mortality in the two groups with a larger cohort of patients, molecular targets can be identified for the formulation of drugs that can prolong survival.

2608T

Association of *-31 C/T* polymorphism of the *IL-1*β gene was associated with colorectal cancer patients from Mexican population. *I. A. Gutierrez[1, 2], A. Y. NARANJO[3], V. TRUJILLO[3], M. G. VILLA[3], L. E. FIGUERA[4], A. M. PUEBLA[5], M. P. GALLEGOS[1].* 1) MEDICINA MOLECULAR, INSTITUTO MEXICANO DEL SEGURO SOCIAL, GUADALAJARA, JALISCO, Mexico; 2) DOCTORADO EN GENETICA HUMANA, CENTRO UNIVERSITARIO DE CIENCIAS DE LA SALUD, UNIVERSIDAD DE GUADALAJARA, GUADALAJARA, JALISCO, MEXICO; 3) SERVICIO DE ONCOLOGIA, UMAE, HOSPITAL DE ESPECIALIDADES, CENTRO MEDICO NACIONAL DE OCCIDENTE, INSTITUTO MEXICANO DEL SEGURO SOCIAL; 4) DIVISION DE GENETICA, CIBO, IMSS; 5) LABORATORIO DE INMUNOFARMACOLOGIA, CUCEI, UNIVERSIDAD DE GUADALAJARA.

Background: A quarter of malignant lesions of colorectal cancer (CRC) are rooted in chronic inflammatory processes, however, the exact mechanism is still unknown, but several studies have shown that inflammatory cells modulate colon carcinogenesis through cell stimulation and synthesis stromal mitogenic molecules. Some Studies evidences that role of inflammation in CRC showing that proinflammatory cytokine gene polymorphisms increase the risk of cancer and its precursors. The *IL-1b-31C/T* has been shown to be functionally significant with the *T* allele that being associated with increased production of IL-1 cytokine. Our goal is to evaluate the association of polymorphism *-31C/T* in colorectal cancer patients from Mexican populations. **Methods:** 206 samples (UMAE Hospital Especialidades, CMNO, IMSS) and 124 controls group (health Mexican population) were included in this study. The *-31C/T* polymorphism genotyping was determinate by PCR method. **Results**: The genotype *-31 TT* was associated with colorectal cancer [OR = 2. 3 (95% CI 1. 2 – 4. 4), p = 0. 007]. **Conclusion:** These results suggest that the *-31 TT* genotype of the *IL-1b* polymorphism was associated with colorectal cancer patients from Mexican population.

A common variant on 2q31. 3 reduces lung cancer risk among light smokers: Transdisciplinary Research in Lung Cancer Consortium. *S. Han[1], I. Cheng[2,3], Y. Han[4], D. Christiani[5], R. Hung[6], H. Bickeböller[7], X. Wu[8], P. Brennan[9], C. Amos[4].* 1) Department of Radiology, Stanford University, Stanford, CA; 2) Epidemiology, Cancer Prevention Institute of California, Fremont, CA; 3) Stanford Cancer Institute, Stanford, CA; 4) Biomedical Data Science, Dartmouth, Hanover, NH; 5) Harvard School of Public Health; Boston, MA; 6) Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada; 7) Department of Genetic Epidemiology, University Medical Centre Göttingen, Göttingen, Germany; 8) Department of Epidemiology, the University of Texas MD Anderson Cancer Center, Houston, TX; 9) International Agency for Research on Cancer, Lyon, France.

Background: Heavy smoking increases the risk of lung cancer (LC) by 50-fold. However, the lifetime risk of LC is between 15-20% even among heavy smokers, raising the question whether there may be protective factors that mitigate the carcinogenic risk of smoking. Previously, we have shown significant gene-smoking interactions on chromosome 15q25. 1, with genetic variants in this region associated with minimal increased risks of LC among never smokers, but substantially increased risks among smokers. Studies contrasting LC risk between heavy and light smokers have not been conducted, and little is known about protective factors that may reduce LC risk for certain smokers. **Methods:** To identify genetic factors that may reduce LC risk by levels of smoking, we conducted a genome-wide case-only analysis to detect gene-smoking interactions for LC, comparing heavy smokers (≥ 30 cigarette pack-years) versus light smokers (< 30 cigarette pack-years). The case-only design provides improved power for detecting gene-environment interactions provided there is no correlation between the genetic factor and the environmental exposure in the underlying population. Genotype data for 4,639 heavy smoker cases and 1,824 light smoker cases were meta-analyzed from 7 studies within the Transdisciplinary Research in Cancer of the Lung (TRICL) consortium. Imputation was conducted based on the 1000 Genomes Project to analyze data on roughly 9 million genetic variants. **Results:** The most significant gene-smoking interaction was found on 2q31. 3 with rs62180069 (*P*=5x10-8; OR=0. 76). This SNP lies between the *SCHLAP1* gene encoding the SWI/SNF complex antagonist associated with prostate cancer 1 and the *UBE2E3* gene. While this variant showed no association with risk of LC among heavy smokers (OR=1. 03; 95% confidence interval (CI): 0. 94-1. 13), it significantly lowered the risk of LC among light smokers (OR=0. 85; CI: 0. 78-0. 93). There was no evidence of gene-smoking correlation among controls (*P*=0. 41) and no evidence of heterogeneity in the associations across studies (*P*=0. 94). **Conclusions:** Our large-scale meta-analysis identified a protective genetic variant for LC that reduces the risk of disease among light smokers. Further studies are needed to characterize the biological mechanism underlying the interaction between rs62180069 and smoking behavior and the functional impact of this variant on LC risk.

2610T

Interactions of Family History with Baseline Risk Factors at 5-year Follow-up in a Colorectal Cancer (CRC) Screening Study in US Veterans. *E. R. Hauser[1,2], L. W. Musselwhite[2], R. B. McNeil[1], D. H. Abbott[1], C. M. Thomas[1], M. C. O'Leary[1], S. F. Morris[1], L. Wagner[1], Z. F. Gellad[1,2], D. G. Weiss[3], D. A. Lieberman[4], D. T. Provenzale[1,2].* 1) Cooperative Studies Program Epidemiology Center, Durham VAMC, Durham, NC; 2) Duke University Medical Center, Durham, NC; 3) Department of Veterans Affairs, Perry Point, MD; 4) Oregon Health & Science University, Portland, OR.

The Veterans Health Administration Cooperative Studies Program Study #380 (CSP380) "Prospective Evaluation of Risk Factors for Large (>1 cm) Colonic Adenomas in Asymptomatic Subjects" is a longitudinal study of 3121 participants enrolled for screening colonoscopy (CP)in 1994-1997. CSP380 also includes a biorepository of blood, serum, DNA, and normal rectal tissue in 815 subjects along with sections of large polyps removed during the baseline CP. Longitudinal pathology specimens are available in individuals with repeat CPs. The VA EMR allows follow-up of medical conditions over the ~20 years since the baseline visit. Risk factors were assessed by detailed survey data collected at the time of study enrollment. Per the CSP380 protocol, follow-up CPs wereperformed at either 5 years or 2 and 5 years. Advanced neoplasia (AN)was defined as tubular adenoma >10mm, adenoma with villous histology, adenoma with high-grade dysplasia, or invasive cancer. Of the 1193 participants with follow-up CPs, 92 hadAN, 392 had small adenomas, and 709 had no neoplasia(NN)detectedup to5-years post baseline. In CSP380 models comparing AN to NN, after adjustment for sex, race, smoking, BMI, alcohol consumption, coronary heart disease, and family history (FH, defined as positive for any 1st degree relative with CRC), baseline risk factors for ANat 5 years included older age, baseline neoplasia, and diabetes (self-report at baseline), which were significantlyassociated with AN at 5 years. Family history (FH)has been implicated in increasing CRC risk in younger individuals and individuals with AN at baseline. Diabetes has a strong genetic component and the most well-replicated type-2 diabetes gene *TCF7L2* displays multiple somatic mutations in analysis of CRC tumors. We hypothesized that FH would interact with baseline age, baseline neoplasia, or diabetes to multiplicatively increase risk of AN at 5 years. In multivariable models, after adjusting for all other baseline risk factors, we observed no evidence of a multiplicative interaction between FH and age (p-value for interaction=0. 65) or baseline neoplasia (p-value for interaction=0. 39). We observed evidence for amultiplicative interaction between FH and diabetes (p-value for interaction=0. 04). Future genomic analysis will include sequencing of *TCF7L2* in neoplastic and normal tissues. The CSP380 dataset provides a unique opportunity to evaluate the lifestyle and genetic aspects of lifetime risk of AN and CRC.

Identification of Subtype Specific Somatic Mutations in Korean Patients with Acute Myeloid Leukemia. *S. Heo[1,2], Y. Koh[3], J. Kim[4], J. Jung[5], H. Kim[1], S. Yoon[3], J. Park[2].* 1) Ewha Womans University, Seoul, South Korea; 2) Hallym University, Chuncheon, South Korea; 3) Seoul National University Hospital, Seoul, South Korea; 4) National Cancer Center, Seoul, South Korea; 5) Syntekabio Inc. , Seoul, South Korea.

Acute myeloid leukemia (AML) is a biologically and clinically heterogeneous cancer of the bone marrow characterized by rapid growth of abnormal myeloid cells. Recent next-generation sequencing approach is capable of extending AML research to genome-wide scope at a single-base resolution. We performed analysis of somatic mutations for AML followed by subtype-specific analyses (M2 and M3) and survival analyses using the whole-exome sequencing data of 36 Korean patients with *de novo* AML. We identified 61 significantly mutated genes in AML which include six M2 subtype-specific genes, *CEBPA*, *EP400*, *MAGI1*, *MAML2*, *ZFHX3*, and *TRIM49* and seven M3 subtype-specific genes, *ATXN3*, *TDG*, *HCLS1*, *IGSF3*, *CDC27*, *PDE4DIP*, and *CFHR1*. We also demonstrated that the patients with mutations in a tumor suppressor gene,*RUNX1* (HR=2. 25, *p*=0. 007) anda notch pathway gene, *MAML3* (HR=2. 39, *p*=0. 037) showed worse prognosis compared to the patients with no mutationin the total AML patients and the group with M2 subtype respectively. We explored the functional impact of the genes identified in the mutation analysesand highlighted the functions of these genes incell aging (GO:0045766, *p*=2. 78×10-3), myeloid cell differentiation (GO:0030099, *p*=0. 03), and AML signaling pathway (hsa05221, *p*=0. 001), which plays an important role in AML tumourigenesis. Future studies would be worthwhile to evaluate the usefulness of these genes in genetic testing for early diagnosis and prognosis prediction of AML patients.

2612T

Focused analysis of a panel of DNA repair-related genetic polymorphisms reveals *MGMT* as a novel susceptibility gene for papillary thyroid carcinoma in Belarusian children exposed to radiation. *F. Lesueur[1], C. Lonjou[1], F. Damiola[2], M. Moissonnier[3], G. Durand[4], V. Tenet[5], I. Malakhova[6], V. Masyakin[7], F. Le Calvez-Kelm[4], E. Cardis[8], G. Byrnes[9], A. Kesminiene[3].* 1) Inserm U900, Institut Curie, Mines ParisTech, Paris, France; 2) CRCL, CNRS UMR5286, INSERM U1052, Centre Léon Bérard, Lyon, France; 3) Environment and Radiation, IARC, Lyon, France; 4) Genetic Cancer Susceptibility, IARC, Lyon, France; 5) Infections and Cancer Epidemiology, IARC, Lyon, France; 6) Republican Scientific and Practical Center for Medical Technologies, Informatisation, Administration and Management of Health (RSPC MT), Minsk, Belarus; 7) Republican Research Center of Radiation Medicine & Human Ecology, Gomel, Belarus; 8) Centre for Research in Environmental Epidemiology (CREAL), IMIM (Hospital del Mar Research Institute), CIBER Epidemiología y Salud Pública (CIBERESP), Barcelona, Spain; 9) Biostatistics, IARC, Lyon, France.

BACKGROUND. The genetic contribution to papillary thyroid carcinoma (PTC) risk is greater than that of any other cancer but most of the heritable risk of PTC remains unexplained. Moreover inter-individual variability in response to radiation exposure suggests that carriers of susceptibility alleles may modify the risk of PTC in populations exposed to ionising radiation. In a previous study we showed that common variation within the DNA damage recognition gene *ATM* contributes to the risk of PTC in Belarusian children exposed to fallout from the Chernobyl power plant accident. Here we further explored the role of single nucleotide polymorphisms (SNPs) in DNA repair genes acting downstream of *ATM* in the same population. METHODS. Using a pathway-based approach we examined the association of 146 SNPs included in the Illumina Cancer SNP panel array andlocated in 43 DNA repair genes in 82 PTC cases and 325 population controls matched to cases for age at the time of accident, sex, and type of settlement. The studied population corresponds to a sub-group of subjects from the population-based case-control study carried out in the most contaminated areas of Belarus to evaluate the risk of thyroid cancer after exposure to radioactive iodine in childhood. All genotyped subjects are from the Gomel region in Belarus, and were younger than 15 years at the time of the Chernobyl accident. SNP and gene-based associations were evaluated using conditional logistic regressions with PLINK. A combined p-value for the joining effects of all markers within a gene was calculated using the rank truncated product method. Statistical significance was evaluated empirically by permutation. RESULTS. The intronic SNP rs2296675 in *O6-methylguanine-DNA methyltransferase*, *MGMT*, was significantly associated with an increased PTC risk [per minor allele odds ratio (OR) 2. 44 95%CI 1. 47-4. 04, P= 0. 00039]. This association remained significant after adjusting for multiple testing (Pperm=0. 001). Suggestive association was also found for SNPs rs1047768 in *ERCC5*, (Pperm=0. 03), rs17349 in *PCNA* (Pperm=0. 04), and rs1051685 in *XRCC5* (Pperm=0. 07). CONCLUSIONS. Our results support the involvement of several DNA repair genes acting in distinct functional modules in the risk of developing PTC. In particular, the role of *MGMT* involved in the direct repair module is highlighted and investigation of the functional properties of the methyltransferase may further enhance our understanding about the etiology of PTC.

Longer telomere length estimated by a genetic risk score is associated with increased risk of non-Hodgkin lymphoma. *M. Machiela[1], Q. Lan[1], L. Teras[2], J. Vijai[3], J. Spinelli[4], R. Vermeulen[5], N. Camp[6], S. Slager[7], M. Yeager[8], Z. Wang[8], A. Nieters[9], K. Smedby[10], J. Cerhan[7], S. Wang[11], S. de Sanjose[12], C. Skibola[13], S. Berndt[1], B. Birmann[14], S. Chanock[1], N. Rothman[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD; 2) Epidemiology Research Program, American Cancer Society, Atlanta, GA; 3) Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; 4) Cancer Control Research, BC Cancer Agency, Vancouver, British Columbia, Canada; 5) Institute for Risk Assessment Sciences, Utrecht University, Utrecht, The Netherlands; 6) Department of Internal Medicine, University of Utah School of Medicine, Salt Lake City, UT; 7) Department of Health Sciences Research, Mayo Clinic, Rochester, MN; 8) Cancer Genomics Research Laboratory, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Gaithersburg, MD; 9) Center for Chronic Immunodeficiency, University Medical Center Freiburg, Freiburg, Baden-Württemberg, Germany; 10) Department of Medicine, Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden; 11) Division of Cancer Etiology, City of Hope Beckman Research Institute, Duarte, CA; 12) Cancer Epidemiology Research Programme, Catalan Institute of Oncology-IDIBELL, L'Hospitalet de Llobregat, Spain; CIBER en Epidemiología y Salud Pública (CIBERESP), Barcelona, Spain; 13) Department of Epidemiology, School of Public Health and Comprehensive Cancer Center, Birmingham, AL; 14) Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Non-Hodgkin lymphoma (NHL) is a cancer of lymphocytes with variation in incidence, aggressiveness, and treatment based on subtype. Common NHL subtypes include chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL), diffuse large B-cell lymphoma (DLBCL), follicular lymphoma (FL), and marginal zone lymphoma (MZL). Evidence from previous nested case-control studies in prospective cohorts measuring peripheral white blood cell telomere length by qPCR suggests peripheral leukocyte telomere length is positively associated with NHL risk. However, nested case-control studies might be confounded by very early disease and could miss biologically relevant time periods if cohort follow-up is not long enough. Therefore, we performed an analysis on inferred telomere length and NHL risk in 10,102 NHL cases (CLL/SLL, DLBCL, FL, and MZL subtypes) and 9,562 controls using genetic proxies of telomere length identified by previous telomere length genome-wide association studies. We investigated individual associations with 9 telomere length-associated single nucleotide polymorphisms (SNPs), as well as with a combined genetic risk score that summed up risk alleles across the 9 telomere length-associated SNPs and weighted risk alleles by their previously reported telomere length regression values. Our analysis detected an excess of significant associations (P-value <0. 05) between telomere length-associated SNPs and NHL risk overall and for CLL/SLL and FL subtypes determined by an exact binomial test. The telomere length genetic risk score, which is an unconfounded proxy for telomere length, was positively associated with overall NHL risk (P-value=8. 8×10−5). Subtype-specific analyses indicated CLL/SLL was the main NHL subtype contributing to this association (OR=3. 02, 95% CI=2. 13-4. 30, P=7. 1×10−10), although a marginal association was observed for DLBCL (P-value=0. 06). In addition, the CLL/SLL association was stronger in men (OR=4. 22, 95% CI=2. 69-6. 62, P-value=3. 96×10−10) than women (OR=1. 85, 95% CI=1. 05-3. 27, P-value=0. 03, P-value interaction= 0. 02). Our results suggest that individuals with a genetic background favoring longer telomere length may have an increased risk for CLL/SLL and possibly other NHL subtypes and that the effects are especially pronounced among men.

2614T

Germline variation in inflammation-related pathways and risk of Barrett's esophagus and esophageal adenocarcinoma. *M. M. Madeleine[1,2], M. F. Buas[1], Q. He[1], L. G. Johnson[1], L. Onstad[1], D. M. Levine[3], A. P. Thrift[4], D. C. Whiteman[5], T. L. Vaughan[1,2], BEACON Consortium Investigators.* 1) Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Department of Epidemiology, University of Washington, School of Public Health, Seattle, WA; 3) Department of Biostatistics, University of Washington, School of Public Health, Seattle, WA; 4) Department of Medicine, Baylor College of Medicine, Houston, TX; 5) Cancer Control, QIMR Berghofer Medical Research Institute, Brisbane, Australia.

Incidence of esophageal adenocarcinoma (EA) has risen sharply in Western countries over recent decades. Local and systemic chronic inflammation, operating downstream of disease-associated exposures, appear to be important drivers of the development of BE and its progression to EA. Strong risk factors have been identified for EA and its precursor, Barrett's esophagus (BE), including reflux, obesity, and smoking. An understanding of the role of inherited genetic susceptibility has recently been emerging. To explore whether germline genetic variation related to inflammatory processes may influence susceptibility to BE/EA, we used data from a genome-wide association (GWA) study of 2,515 EA cases, 3,295 BE cases, and 3,207 controls. Our analysis included 10,774 single nucleotide polymorphisms (SNPs) in 455 genes assigned to five pathways: cyclooxygenase (COX), cytokine signaling, oxidative stress, MHC, and NFkB. A principal-components-based framework was employed to evaluate pathway-level and gene-level associations with disease risk. We identified a significant signal for variation in the COX pathway in relation to risk of BE (P=0. 0059, FDR q=0. 03), and in subsequent gene-level analyses found an association with the *MGST1* locus (microsomal glutathione-S-transferase 1; P=0. 0005, q=0. 005). Assessment of 36 *MGST1* SNPs identified 14 variants associated with elevated risk of BE (q<0. 05), including a cluster of 3' intronic variants and several 5' SNPs near the transcriptional start site. Eight of these variants were similarly associated with increased risk of EA. This study provides the most comprehensive evaluation to date of inflammation-related germline variation in relation to risk of BE/EA, and suggests that variants in *MGST1* may influence disease susceptibility.

Association of MDM309 polymorphism of the MDM2 gene was associated with breast cancer patients from Mexican population. *M. G. Marquez[1,2], H. MONTOYA[1], J. SANCHEZ[1], M. P. GALLEGOS[1].* 1) Medicina Molecular, Instituto Mexicano del Seguro Social, Guadalajara, Jalisco, Guadalajara, Jalisco, Mexico; 2) Doctorado en Genetica Humana, Centro Universitario de Ciencias de la Salud, Universidad de Guadalajara.

BACKGROUND: The MDM2 gene encodes a phosphoprotein that negatively regulates the activity of TP53. T309G polymorphism in the promoter of MDM2 gene has been reported to be associated with enhanced MDM2 expression and tumor development in breast cancer risk. However, the results have been inconsistent. Our goal is to evaluate the association of T309G polymorphism of MDM2 gene in breast cancer patients from Mexican populations. **Methods:** 510 samples (UMAE Hospital de Gineco-Obstetricia, CMNO, IMSS) and 237 controls group (health Mexican population) were included in this study. The MDM309 polymorphism genotyping was determinate by PCR method. **Results**: The genotype MDM309GG was associated with breast cancer [OR = 1. 49 (95% CI 1. 04 – 2. 1) , p = 0. 028]. **Conclusion:** These results suggest that the MDM309 GG genotype was associated with breast cancer patients from Mexican population.

Study of DNA sequence and expression variation in miRNAs and target genes to explore risk of two types of oral precancerous lesions and cancer. *R. Roy, B. Roy.* Human Genetics Unit, Indian Statistical Institute, 203,B. T. Road, Kolkata, India.

Background: In the last few years, study of expression deregulation of microRNAs and their target genes has emerged as a promising field in the area of cancer research as these variations may have functional consequences. **Objectives**: To study effect of polymorphisms and expression deregulation of microRNAs and their target genes in two types of oral precancerous lesions and cancer. **Methods**- Variations in 8 microRNAs and 4 miRNA processing genes were studied in 452 oral cancer patients, 299 leukoplakia patients and 451 healthy controls. Cumulative risk of these SNPs along with gene-environment interaction was calculated. Relative expression of 4 microRNAs (*miR-26a, miR-29a, miR-34b and miR-423*) and miRNA target genes were studied in oral normal, lichen planus, leukoplakia and cancer tissues, with sample size of 20 in each group and data was analyzed to explore their role in carcinogenesis. **Result-** Variant genotypes at *miR-34b* reduced risk of both leukoplakia and cancer. Variant genotypes in *miR-196a2, miR-26a-1* and *RAN* increased cancer risk while that in *XPO5* and *GEMIN3* reduced leukoplakia risk. Cumulative risk of leukoplakia and cancer increased by 2-3 times when individual harbored risk alleles at multiple loci. Gene environment interaction analysis showed *tobacco habits* in combination with *Xpo5, miR-423, miR-34b* and *miR 29a* significantly modulated risk of leukoplakia. Normalized expression of *miR-423, miR-29a, miR-34b and miR-26a* were distinctly different in two precancer and cancer tissues. Expressions of some of the target genes of these microRNAs were significantly down regulated. Based on expression profile of deregulated miRNAs and their target genes, individuals could be accurately clustered. Pathway analysis of the deregulated targets gives hits in EGFR signaling, hemostasis and growth factor related pathways. Also interestingly, the negative correlation between microRNAs and their target genes was observed in normal tissues but got disrupted in the disease tissues including cancer leading to a hypothesis that repression potential of microRNAs on several targets get lost in diseased state. **Conclusion**: We found that SNPs in microRNAs and their biogenesis genes indeed conferred risk of leukoplakia and oral cancer. We not only observed differential miRNA expression in cancer and precancer but also that the miRNAs showed different ability in targeting oncogenes and/or tumor suppressor genes.

2617W

Genome-wide analysis for prostate cancer biochemical recurrence identifies novel loci for disease progression at 9p23. *C. G. Tai[1], T. Hoffmann[1,2], N. Emami[3], E. Jorgenson[4], C. P. Quesenberry[4], J. Shan[4], D. Aaronson[4], J. Presti[4], L. A. Habel[4], C. R. Chao[4], N. R. Ghai[4], D. K. Ranatunga[4], C. Schaefer[4], N. J. Risch[2,4], S. K. Van Den Eeden[4,5], J. S. Witte[1,2,5,6].* 1) Department of Epidemiology & Biostatistics, UCSF, San Francisco, CA; 2) Institute for Human Genetics, UCSF, San Francisco, CA; 3) Biological and Medical Informatics Program, UCSF, San Francisco, CA; 4) Kaiser Permanente Division of Research, Oakland, CA; 5) Department of Urology, UCSF, San Francisco, CA; 6) Diller Family Cancer Center , UCSF, San Francisco, CA.

Prostate cancer continues to account for a large proportion of the cancer burden in the United States as the most common non-skin cancer diagnosed among men. Although the latest estimate for 5-year survival for prostate cancer is about 98. 9%, one of the long-standing challenges has been to distinguish indolent disease from aggressive disease. Previous efforts have defined aggressive disease as high Gleason score at diagnosis or prostate cancer mortality within 10 years, but disease progression may be more clinically relevant. Using a clinically comprehensive dataset that allowed for estimation of time to disease progression based on biochemical recurrence, we were able to conduct a genome-wide association analysis for prostate cancer progression. The analysis was conducted in two datasets defined by first course of treatment: in 3,495 men with prostate cancer who received radiation therapy and in 2,248 men with prostate cancer who underwent radical prostatectomy from the Kaiser Permanente Research Program on Genes, Environment, and Health, the ProHealth study, and the California Men's Health study. They were genotyped at over 650,000 SNPs across the genome on four race/ethnicity-specific Affymetrix Axiom arrays, for Europeans, African-Americans, East Asians, and Latinos. Biochemical recurrence after radiation therapy was defined using the Phoenix definition, a rise in prostate specific antigen (PSA) level of at least 2. 0 ng/mL above PSA nadir following external beam radiation therapy with or without androgen deprivation. Biochemical recurrence after surgery was defined as two consecutive measures of PSA at or above 0. 2 ng/mL following surgery. Among those who received radiation therapy, we identified 783 men (52 African-Americans) who experienced biochemical recurrence (BCR) and compared them to 2,712 men (210 African-Americans) who did not. We identified a significant tag SNP (rs35098745) at 9p23 (p=4. 2x10-8) within the African ancestry subpopulation in strong linkage disequilibrium (LD r2 = 1. 0) with rs62540661, which is located in a DNase hypersensitive region specific to a prostate cancer cell line, LNCaP. This finding may suggest mechanisms for prostate cancer progression due to changes in DNAse hypersensitivity, which can affect transcription of nearby genes and regulatory factors.

2618T

Analysis of Rare Variants in Finnish Colorectal Cancer Patients. *T. Tanskanen[1], R. Katainen[1], J. Kondelin[1], U. Hänninen[1], T. Cajuso[1], JP. Mecklin[2], H. Järvinen[3], L. Renkonen-Sinisalo[3], E. Pitkänen[1], K. Palin[1], LA. Aaltonen[1].* 1) Department of Medical Genetics, University of Helsinki, Helsinki, Finland; 2) Department of Surgery, Jyväskylä Central Hospital, University of Eastern Finland, Jyväskylä, Finland; 3) Department of Surgery, Helsinki University Central Hospital, Helsinki, Finland.

Colorectal cancer (CRC) accounts for 10% of the incidence of cancer worldwide. Inherited factors influence CRC risk substantially, but much of the heritability remains explained. In particular, the significance of rare, intermediately penetrant variants is unclear, and such variants may be population-specific. In this study, we analyze protein-coding loss-of-function variants in 345 Finnish unselected CRC cases and 2 437 Finnish controls using exome and whole-genome sequencing. Analysis methods will include single-variant testing and rare variant association methods (SKAT and CMC). To improve statistical power, we sequenced CRC cases with phenotypic characteristics suggesting high genetic risk (familial cancer, age of onset less than 40 years, more than one primary CRC). Also, because Finland is an isolated founder population, allele frequencies ofcertain disease-causing variants may be highdue to genetic bottleneck and drift effects, which may substantially facilitate their discovery. In addition, we will use whole-genome sequencing and SNP genotyping data to impute low-frequency variants in 1 474 independent Finnish CRC cases and 8 645 Finnish controls. SNP genotyping data will also be used to assess allelic imbalance in the respective tumor samples (n = 1 642). In preliminary analyses, joint variant calling was performed for currently availablewhole genomes (218 cases) and exomes (1 453 controls) using separate bioinformatic workflows. Within the coding target regions (32 Mb), the per-sample mean number of SNVs was 20 800 for exomes and 21 500 for whole genomes with ti/tv ratios of 2. 76 and 2. 89, respectively. An average of 1 300 indelsper sample were called in both exomes and whole genomes. Althougha potential source of genomic inflation, the joint analysis of whole-genome and exome sequencing data seems feasible in this setting, and whole genomes offer the advantage of genotype imputation from population-matchedSNP panels.

2619W

Genome-wide Association Study on Secondary Cancer Risk among Patients with Basal Cell Carcinoma (BCC) of the Skin. *W. Wu[1], P. Kraft[2,4], L. Liang[2,4], J. Han[1,3].* 1) Department of Epidemiology, Richard M. Fairbanks School of Public Health, Melvin and Bren Simon Cancer Center, Indiana University, Indianapolis, Indiana; 2) Department of Epidemiology, Harvard School of Public Health; 3) Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital; 4) Department of Biostatistics, Harvard University School of Public Health, Boston, Massachusetts.

Previous studies suggest a positive association between personal history of non-melanoma skin cancer (NMSC) and risk of subsequent cancer at other sites. To identify underlying genetic mechanisms of second primary cancer after basal cell carcinoma, we conducted a genome-wide association study (GWAS) in two large US cohorts, the Nurses' Health Study (NHS) and the Health Professionals' Follow-up Study (HPFS). We conducted the GWAS among 1,428 BCC patients without subsequent second cancer development and 305 BCC patients with other internal cancers in Caucasians. We used 1000 Genomes version 1 phase 3 reference imputation panel. The most promising variant (association P =1. 32* 10–6) was an intronic SNP located at Staphylococcal nuclease and tudor domain containing 1 (SND1) gene. 76,364 SNPs (P value <= 0. 01) were further grouped into gene transcripts within 20 kb in distance and then into Kyoto Encyclopedia of Genes and Genomes pathways, BioCarta pathways for further pathway analysis. Seven pathways were significantly associated with risk of second cancer: Arrhythmogenic right ventricular cardiomyopathy (ARVC) (p = 3. 85 * 10 -5, Bonferroni p = 0. 0069), Pathways in cancer (p = 4. 99 * 10 -5, Bonferroni p = 0. 0089), Calcium signaling pathway (p = 1. 18 * 10 -4, Bonferroni p = 0. 021), Gap junction pathway (p = 1. 58 * 10 -4, Bonferroni p = 0. 028). Functional annotation using data from Genotype-Tissue Expression (GTEx) project eQTL analysis in whole blood identified seven top associated genes LRRC37A, ALDH16A1, CRHR1-IT1, SETD9, SNX16, TNFAIP6 and ZNF429. This is the first GWAS to our knowledge on second cancer risk among BCC patients, and the findings might advance understanding of the etiology of subsequent malignancies among individuals with BCC.

2620T

Whole-exome case-control association and somatic-germline interaction analyses in melanoma. *Y. Yu, H. Hu, A. Deshpande, R. Fowler, X. Wu, P. Scheet, H. Zhao, C. Huff.* Epidemiology, The University of Texas M. D. Anderson Cancer Center, Houston, TX.

While skin cutaneousmelanoma (SKCM) has a strong hereditary component, the majority of familial clustering of SKCM is still unexplained. To evaluate the contribution of rare, protein-coding variation to SCKM risk, we conducted a whole-exome case-control study of individuals with European ancestryinvolving 314 cases from the Cancer Genome Atlas (TCGA) and a population control set of 2,424 individuals from three sources: 1000 Genomes, controls from a Swedish schizophrenia study, and cancer-free controls recruited at MD Anderson. We performed a gene-based association analysis across the exome using VAAST 2. 1, incorporating a new quality control pipeline for next-generation sequencing data to greatly mitigate systematic biases from sequencing-platform artifacts (with final genomic inflation factor, λ equal to 1. 3). Although no gene reached genome-wide significance, our results replicated several genes previously implicated in melanoma risk, including *MC1R* (p<1x10-5), *MITF* (p = 4. 9x10-4), *BRCA2* (p = 2. 8x10-3), *ATM* (p = 6. 8x10-3), *CHEK2* (p =0. 02) and *TP53* (p = 0. 02). Our results also provide suggestive support for *FANCA* (p = 2x10-3), a gene associated with melanoma survival. In addition, we performed an exome-wide somatic-germline interaction analysis of rare, putatively damaging germline variants and somatic loss of heterozygosity (LOH) events in tumors using the tools hapLOH and SGI. We observed significantly fewer LOH events in the tumors of individuals with putatively damaging *MC1R* variants relative to non-carriers (p = 0. 04), supporting a one-hit model and suggesting that *MC1R* susceptibility variants are incompletely dominant at the cellular level in SKCM tumorigenesis. Additionally, we report the top genome-wide signals in our case-control and somatic-germline analyses. In conclusion, our results confirm previously established SKCM-susceptibility loci and provide a foundation for future rare-variant association studies in SKCM.

2621W

The genetics of gene expression in human pancreatic tissues. *M. Zhang[1], W. Xiao[2], J. Hoskins[1], I. Collins[1], J. Jia[1], H. Parikh[1], J. Powell[3], R. Kurtz[4], J. Smith[5], S. Olson[4], J. Shi[1], G. Petersen[6], N. Chatterjee[1], L. Amundadottir[1].* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, Maryland 20892, USA; 2) Division of Bioinformatics and Biostatistics, National Center for Toxicological Research, FDA, Jefferson, AR 72079; 3) Division of Computational Bioscience, Center for Information Technology, National Institutes of Health, Bioinformatics and Molecular Analysis Section, Bethesda, MD 20892, USA; 4) Department of Epidemiology and Biostatistics, Memorial Sloan-Kettering Cancer Center, New York, NY, 10065, USA; 5) Division of Gastroenterology & Hepatology, Georgetown University Hospital, Washington, DC 20007, United States; 6) Division of Epidemiology, Department of Health Sciences Research, Mayo Clinic, Rochester, Minnesota.

Analyses of RNA-seq data have demonstrated its power in investigating the role non-coding germline variation plays in the regulation of gene expression in multiple tissues. Due to the limited availability of such data for pancreatic tissue samples, pancreas specific expression quantitative trait loci (eQTLs) are still largely unknown, while the identification of these regulatory loci are of particular interest for understanding the development of pancreatic diseases. In this study, we analyzed RNA-seq data and 1000 Genome imputed genotype data for 98 normal and 115 tumor derived (PAAD, TCGA) human tissue samples to explore pancreas specific eQTLs as well as to compare tumor-specific and shared eQTLs in pancreas. We tested the association between ~6M SNPs and expression of ~17,000 genes across the whole genome. After adjusting for multiple testing based on a permutation procedure, we identified 359 cis-eQTL genes and 4 trans-eQTL genes in normal pancreatic tissues as well as 198 cis-eQTL genes and 5 trans-eQTL genes in pancreatic tumor tissues at an FDR<0. 05. 73 out of the 359 cis-eQTL genes in normal tissues have cis-eQTLs in the tumors and 79 out of the 198 cis-eQTL genes in tumor have cis-eQTLs in the normal tissues. Cis-eQTLs were significantly enriched in DNase I hypersensitivity sites (2. 3-6. 8 fold) and histone modification marks/transcription factor binding sites (2. 9-14. 7 fold) based on ENCODE DNase-seq and ChIP-seq data for pancreatic cells. Of interest, such enrichments were more prominent in datasets specific for pancreatic cells as compared to all cell types combined. In addition, enrichment of cis-eQTLs in H3K4me3 binding sites (9. 4 fold) was replicated in an independent ChIP-seq dataset for PANC-1 (9. 5 fold) and h-TERT pancreatic cell lines (8. 8 fold). Cis-eQTLs were more likely to be located closer to the transcription start sites (TSSs) compared to the non-significant SNPs (8-fold enrichment for eQTLs located within 1kb from TSSs). Besides the understanding of gene regulatory mechanisms in pancreas, the identification of pancreas eQTLs aids in the interpretation of genome-wide association studies (GWAS) of pancreatic cancer.

Mendelian randomization to assess the causal role of dietary calcium on colorectal cancer risk. *N. Zubair[1], M. Du[1], J. Gong[1], P. A. Newcomb[1], L. Hsu[1], A. P. Thrift[2], J. A. Baron[3], H. Brenner[4], G. Casey[5], A. T. Chan[6], S. J. Chanock[7], M. Cotterchio[8], M. Hofmeister[4], L. Le Marchand[9], J. D. Potter[1], M. L. Slattery[10], E. White[1], P. T. Campbell[11], J. Chang-Claude[4], U. Peters[1].* 1) Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Baylor College of Medicine, Houston, TX; 3) University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, NC; 4) German Cancer Research Center (DKFZ), Heidelberg, Germany; 5) University of Southern California, Keck School of Medicine, Los Angeles, CA; 6) Massachusetts General Hospital and Harvard Medical School, Boston, MA; 7) National Cancer Institute, National Institutes of Health, Bethesda, MD; 8) Cancer Care Ontario, Toronto, ON; 9) University of Hawaii Cancer Center, Honolulu, HI; 10) University of Utah Health Sciences Center, Salt Lake City, UT; 11) American Cancer Society, Atlanta, GA.

Background: While some observational studies have reported an inverse relationship between dietary calcium intake and colorectal cancer risk, other studies have reported no association. Inherent limitations of bias and confounding in observational studies may explain these inconsistent results. We therefore used Mendelian randomization (MR) and instrumental variable methods to reassess the role of dietary calcium intake on colorectal cancer risk. **Methods:**Participants included 10 912 individuals with confirmed colorectal adenocarcinomas and 10 908 population-based controls from the Genetics and Epidemiology of Colorectal Cancer Consortium (GECCO) and the Colon Cancer Family Registry (CCFR). We used the rs4988235 variant in *MCM6* as an instrumental variable for dietary calcium; this genetic marker is used in genetic tests of lactose intolerance. We used a two-stage approach to estimate the causal association of dietary calcium intake with colorectal cancer risk. First, we fit a multivariable linear regression model to predict dietary calcium. In the second-stage, using a multivariable logistic regression model, we examined the association between genetically predicted dietary calcium and colorectal cancer risk. In each stage we adjusted for age, sex, study, and the first 3 principal components of genetic ancestry. **Results:**In the first-stage (F statistic = 141. 5), each copy of the T allele of rs4988235 was associated with a 60. 66 mg/day (95% CI= 50. 19-71. 13) increase in dietary calcium. In the second stage, we found no association, between genetically predicted dietary calcium and colorectal cancer risk. **Conclusions:**In 21,820 individuals, we did not detect a causal role for genetically predicted dietary calcium intake in colorectal cancer risk. Despite our sizable study population, this null association is difficult to interpret given that the observed association between dietary calcium intake and CRC risk is not strong. Our data suggest that even larger scale MR analyses will be required to corroborate these findings.

2623W

Variants in *ELL2* influencing immunoglobulin levels associate with multiple myeloma. *B. Swaminathan[1], G. Thorleifsson[2], M. Jöud[1,3], M. Ali[1], E. Johnsson[1], R. Ajore[1], P. Sulem[2], B-M. We report a novel risk locus for multiple myeloma (MM) at ELL2 (rs56219066T; odds ratio (OR)=1. 25; P=9. 6×10-10). This gene encodes a stoichiometrically limiting component of the super-elongation complex that drives secretory-specific immunoglobulin mRNA production and transcriptional regulation in plasma cells. We found that the MM risk allele harbors a Thr298Ala missense variant in an ELL2 domain required for transcription elongation. Consistent with a hypomorphic effect, we found that the MM risk allele also associates with reduced levels of immunoglobulin A and G in healthy subjects (P=8. 6×10-9 and P=6. 4×10-3, respectively) and, potentially, with an increased risk of bacterial meningitis (OR=1. 30; P=0. 0024). .

Genome Wide Association Study of Estrogen Receptor Positive Breast Cancer In Ashkenazi Jews Using A Pooled Genotyping Approach. *J. Vijai[1], C. Manschreck[2], J. Przybylo[3], D. Villano[1], T. Thomas[1], A. Maria[1], N. Hansen[4], R. Sakr[1], T. Kirchhoff[5], S. Domchek[6], K. Nathanson[6], M. Robson[1], T. King[1], K. Offit[1].* 1) Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; 2) School of Medicine and Biomedical Sciences, University of Buffalo, New York; 3) Stanford University, Palo Alto, California; 4) Kaiser Permanente , San Diego, CA; 5) NYU Cancer Institute, New York University School of Medicine, New York, NY; 6) Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA.

Genome wide association studies (GWAS) have identified numerous genomic loci associated with increased breast cancer [MIM 114480] risk. While a small set of high-penetrance genes account for 25-30% of inherited risk, other identified genetic loci are low-penetrance, common single nucleotide polymorphisms (SNPs). GWAS studies typically require large number of cases and controls to have sufficient power to detect further low-risk SNPs. Individual genotyping of cases and control DNA is necessary in the presence of population stratification and heterogeneity to find meaningful association. Here, we studied the Ashkenazi Jewish (AJ) founder population as a test case to discover novel DNA variations that could explain association with estrogen receptor positive (ER+) breast cancer using a pooled design. In Stage 1, we created precisely quantitated equimolar pools of individual DNA and genotyped these pools on Illumina Human OmniExpress array. In total, 2 case pools and 3 control pools were sourced from 758 and 1,114 unique samples, respectively. To reduce inaccuracies in estimating population allele frequencies, pooling errors and array batch variance were minimized by separately constructing each pool in triplicate and hybridizing each pooled replicate thrice. After accounting for replicate variance, we ranked our SNPs based on the pooled test-statistic for association. The 32 SNPs with the highest association in our Stage 1 dataset were added to a Sequenom panel, which was used in Stage 2 to individually genotype the same validation cohort of 1,204 cases and 1071 controls. Several of these 32 SNPs were not previously associated with cancer incidence, and most were validated in our Stage 2 analysis at a nominal significance of p=0. 05, while the top variant (rs1115245) approached genome-wide significance (p=5. 47x10-6; OR=0. 735). Case and control allele frequencies estimated in the Stage 1 pooled data were replicated in Stage 2 (Rcase = 0. 957, Rcontrol = 0. 962), a considerable improvement in the ability to estimate population allele frequencies over previous pooled GWAS. Our study represents a technical advancement in the accuracy and scale of pooled GWAS, and suggests novel SNPs potentially associated with ER positive breast cancer in Jews. This confirms the method's efficacy and encourages further use of pooled genotyping or sequencing in the discovery stage of GWAS. The total cost of this GWAS was 7. 5X cheaper than an individually genotyped GWA study.

2625W

Haplotype analysis of common variants in the *BRCA1* and *BRCA2* genes in Turkey. *B. Saglam Ada[1], K. Bilecen[1,2], K. Yararbas[3], T. Hatipoglu[4], M. Say[1], C. Tuncer[3], E. Kavak[5], A. Tukun[1,6].* 1) Genetic Diagnosis Center, Duzen Laboratories Group, Ankara, Turkey; 2) Konya Food and Agriculture University, Department Of Moleculer Biology and Genetic Engineering,Konya,Turkey; 3) Genetic Diagnosis Center, Duzen Laboratories Group, Istanbul, Turkey; 4) Ankara University Biotechnology Institute,Ankara, Turkey; 5) Genomize Inc; 6) Department of Medical Genetics, Faculty of Medicine, Ankara University , Ankara, Turkey.

IntroductionBreast cancer is one of the most common cancers seen in women. About one in eight women will develop breast cancer in her lifetime. Around 10% of overall breast cancer cases have family history. Carriers of *BRCA1* or *BRCA2* germline mutations have been estimated to have a 65-85% lifetime risk of developing breast/ovarian cancer. To take advantage of personalized cancer prevention strategies and for early diagnosis patients and family members at higher risk of breast/ovarian cancer are routinely tested to see whether they are BRCA1/2 carriers. In addition to pathogenicalterationsof BRCA1/2 genes, several polymorphisms have alsobeen reported. Many of them are shown to have protective or possible causal effect on breast cancer. Interestingly, several studies showed that some of these polymorphisms tend to occur together despite of their controversial effects. In this study, *BRCA1/2* single nucleotide polymorphisms (SNPs) were examined for the identification of haplotypes and to evaluate the prevalence of these haplotypes among sporadic early-onset breast cancer patients, familial breast cancer patients, and healthy high risk females in multiple-ethnic regions of Turkey. **Method**Peripheral blood DNA from 271 subjects were investigated by next-generation sequencing using *Illumina MiSeq* between 2014 January and 2015 May. Genomize-Seq and SeqPilot softwares were used for analysis of NGS data. Mutations in the coding gene sequence were screened and all observed mutations have been checked for their pathogenicity at Human Gene Mutation Database. Statistical evaluation of all SNPs and mutations in study group were carried out using by using in-house developed Python scripts. **Results**c. 4837A>G, c. 3113A>G, c. 2311T>C, c. 4308T>C, c. 4485-63C>G, c. -19-115T>C, c. 2082C>T, c. 3548A>G in BRCA1 were determined as a haplotype in the population. All SNP's allele frequency is 33,76%. Either the heterozygosity or homozygosity was identical among all samples. Homozygote haplotype ratio was 6,64%, heterozygote ratio was 27,12% in all cases. c. 426-89T>C, c. 1365A>G, c. 2971A>G, c. 7435+53C>T, c. 865A>C, c. 425+67A>C in BRCA2 were determined as a haplotype in population of Turkey. All SNP's allele frequency is 7,01%. All of them are homozygote or heterozygote in each case. Homozygote haplotype ratio was 0,73%, heterozygote ratio was 6,27% in all cases. Our study indicates a high incidence of one haplotype in BRCA1 gene and one haplotype in BRCA2 gene in our study population.

Predicting breast and ovarian cancer risks for *BRCA1* and *BRCA2* mutation carriers using common genetic variants. *K. Kuchenbaecker[1], J. Simard[2], K. Offit[3], F. Couch[4,5], D. Easton[1], G. Chenevix-Trench[6], A. Antoniou[1] On behalf of the Consortium of Investigators of Modifiers of BRCA1 and BRCA2 (CIMBA).* 1) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK; 2) Centre Hospitalier Universitaire de Québec (CHUQ) Research Center, Laval University, Quebec City, Quebec, Canada; 3) Department of Medicine, Memorial Sloan-Kettering Cancer Center, New York, New York, USA; 4) Department of Health Sciences Research, Mayo Clinic, Rochester, Minnesota, USA; 5) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, Minnesota, USA; 6) Cancer Division, QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia.

Women who carry a pathogenic mutation in the *BRCA1* or *BRCA2* gene are at increased breast (BC) and ovarian cancer (OC) risk. Genome-wide association studies have identified >100 common genetic variants that are associated with BC or OC risks. Several of these variants are also individually associated with risk of BC or OC for *BRCA1* and *BRCA2* mutation carriers. However, no study has evaluated the combined effects of all the known common genetic variants on BC or OC risk for *BRCA1/2* mutation carriers. We constructed Polygenic Risk Scores (PRS) derived from population-based studies to systematically assess the combined effects of all known common BC and OC susceptibility variants on the risks for *BRCA1/2* mutation carriers. We used data for 15,252female-*BRCA1* and 8,211 female*BRCA2*carriers who were genotyped on the iCOGS custom array. Each PRS was formed by the sum of the number of risk alleles across the variants weighted by their log-Odds Ratio estimate from population-based studies. We investigated 3 PRS for BC: overall, estrogen receptor (ER) positive, and ER-negative; and one PRS for OC. The association of each PRS with BC or OC risk was evaluated within a retrospective cohort framework with time to diagnosis as the outcome and estimated the Hazard Ratios (HR) per standard deviation increase in the PRS. All PRS were significantly associated with cancer risks for *BRCA1/2* carriers. The PRS for ER-negative BC displayed the strongest association with BC risk in *BRCA1* carriers (HR=1. 29 [1. 25-1. 33], p=8x10-64). In *BRCA2* carriers, the strongest association was seen for the overall BC PRS (HR=1. 26 [1. 21-1. 31], p=3x10-27). The OC PRS was strongly associated with OC risk for both *BRCA1* (HR=1. 26 [1. 20-1. 31], p=1x10-23) and *BRCA2* carriers (HR=1. 51 [1. 39-1. 64], p=9x10-22). These relative risks translate to large differences in absolute risks for carriers: e. g. , the 10% of *BRCA2* carriers with the lowest OC PRS had a ≤8% lifetime risk compared to ≥19% for the 10% of *BRCA2* carriers with the highest PRS. Our findings imply that there is a large overlap in susceptibility loci in the general population and in mutation carriers once stratified by tumor subtype. Tumor subtype-specific PRS derived from population-based studies could be used to predict individualized cancer risks for *BRCA1/2* mutation carriers and should be incorporated into risk prediction models to inform decisions on the cancer risk management for *BRCA1/2* mutation carriers.

Quantitative analysis of aberrant *BRCA1* and *BRCA2* RNA splicing using targeted RNA-Seq. *M. Blok[1], R. Brandão[2], K. Mensaert[3], D. Tserpelis[1], T. De Meyer[3], R. Szklarczyk[1].* 1) Department of Clinical Genetics, Maastricht University Medical Center, Maastricht, Netherlands; 2) Maastricht Science Programme, Maastricht University, Kapoenstraat 2, 6211 KW Maastricht, the Netherlands; 3) Department of Mathematical Modeling, Statistics and Bioinformatics, Ghent University, Coupure Links 653, B9000, Ghent, Belgium.

Targeted RNA-Seq appears to be a promising method to sequence transcripts in depth and to study alternative splicing in detail for specific genes of interest. We investigated if this technology can be used to detect putative pathogenic changes in RNA splicing caused by genetic variants in the hereditary breast and ovarian cancer genes *BRCA1* and *BRCA2*. We used RNA isolated from IL2/PHA stimulated peripheral blood leukocytes collected from patients with a genetic variant in either *BRCA1* (n=4: c. 213-12A>G; c. 693G>A; c. 4987-3C>G; c. 5277+1G>A) or *BRCA2* (n=4: c. 516+1G>T; c. 6935A>T; c. 7806-1G>T; c. 9117G>A). Except for c. 7806-1G>T, these variants are well characterized for their effect on splicing based on previously published data from RT-PCR studies. These effects include *de novo* exon skipping and intron retentions, and relative changes in the abundance of normal isoforms compared to healthy controls. We performed targeted RNA-Seq according to a protocol from Agilent Technologies (CA, USA) on poly A+ enriched mRNA, using custom designed SureSelect baits (double tiling over the complete locus including UTRs), to enrich for *BRCA1/BRCA2* transcripts. Sequencing was performed on the Illumina HiSeq platform. We developed an in-house data analysis pipeline to detect and prioritise the most significant alternative splicing events in comparison to the other samples. All known relevant alternative splicing events were detected as top prioritised events in an extensive list of other non-significantly different events, except increased exon 12 skipping levels for *BRCA2* c. 6935A>T. The potential sources for the discrepancy between RT-PCR and RNA-Seq will be discussed in more detail. For *BRCA2* c. 7806-1G>T, we report the use of a cryptic splice acceptor site in exon 17 in stead of the theoretically expected complete exon 17 skipping, which causes a pathogenic translation frame shift. Our results confirm that targeted RNA-Seq can serve as a generic, high throughput method to test *BRCA1* and *BRCA2* genetic variants for their putative effect on RNA-splicing. It enables detection of changes in (cryptic) RNA splicing caused by deep intronic variants or missense variants in splice-enhancer/silencer sites which are currently not routinely included in genetic DNA screening or their effect is poorly predicted, respectively. Our RNA-Seq pipeline can also easily be adapted to other genes of interest by the use of other enrichment baits.

Targeted RNA sequencing with cBROCA to identify and characterize variants altering transcription in breast cancer genes. *S. Casadei[1], S. Gulsuner[1], M. Lee[1], A. Thornton[1], J. Mandell[1], M. -C. King[1, 2], T. Walsh[1].* 1) Dept. Medical Genetics, University of Washington, Seattle, WA; 2) Genome Sciences, University of Washington, Seattle, WA.

A major challenge of clinical genetic testing is to identify DNA variants that alter gene splicing. In addition to appearing at canonical splice sites, such variants may lie deep within exons or introns, where they may alter splice enhancers or introduce new splice acceptors or donors. To identify such variants anywhere in breast cancer genes, we developed a targeted RNA sequencing approach, which we named cBROCA, followed by validation by RT-PCR and cloning. cBROCA entails isolating RNA from patient blood or lymphoblasts, generating cDNA, then hybridizing to our BROCA gene panel. BROCA targets the entire loci, not only exons, of known and candidate breast cancer genes. After capture and barcoding, cBROCA samples are multiplexed and sequenced on our HiSeq2500. Genomic DNA from the same patients is hybridized to the same BROCA panels and run in parallel. The goals are simultaneously to identify all genomic variants of each subject and to determine if any are associated with altered transcription. Two challenges encountered in characterizing transcript effects are the low abundance of mutant transcripts due to nonsense-mediated decay (NMD) and normal expression of multiple transcripts of the same gene even from wildtype sequences. To address NMD, we treated EBV-transformed lymphocytes with 500ug/ml puromycin for 6 hours prior to harvesting, so as to retain mutant transcripts. To address the problem of noise introduced by expression of multiple transcripts from wildtype sequences, we normalized to gene expression levels of multiple controls. Independently, we also evaluate variants for allelic imbalance at transcribed SNPs. As a pilot study, we tested cDNA from 49 individuals with variants previously confirmed experimentally to alter transcription by whole or partial exon skipping, inclusion of new exons, intron retention, or a combination thereof (complex events). RNA was extracted from patients' blood, lymphoblasts, or both. Altered transcript expression was accurately identified by cBROCA for all 49 events. Compared to genome-wide RNA-Seq, targeted RNA sequencing allows very high coverage and multiplexed sequencing. Our data suggests that identification and characterization of transcript effects can be performed in this high-throughput fashion using cBROCA and that gene targeting can robustly detect low abundance transcripts using RNA from patients' blood or lymphoblast cell lines.
