

# American Society of Human Genetics 67<sup>th</sup> Annual Meeting October 17–21, 2017 in Orlando, Florida

## POSTER ABSTRACTS

Session Topic/Title	Abstract/Poster Board Numbers	
	Start #	End #
Genome Structure and Function	373	438
Prenatal, Perinatal, and Reproductive Genetics	439	498
Genetic Counseling, ELSI, Education, and Health Services Research	499	593
Cancer Genetics	594	845
Mendelian Phenotypes	846	1180
Bioinformatics and Computational Approaches	1181	1457
Omics Technologies	1458	1541
Epigenetics and Gene Regulation	1542	1691
Developmental Genetics and Gene Function	1692	1795
Complex Traits and Polygenic Disorders	1796	2280
Evolution and Population Genetics	2281	2369
Molecular and Cytogenetic Diagnostics	2370	2601
Cardiovascular Phenotypes	2602	2760
Statistical Genetics and Genetic Epidemiology	2761	3020

**Posters should remain on the board for all three days (Wednesday through Friday)**

The program and abstract/poster board number next to each listing is followed by an **W** (Wednesday), **T** (Thursday), or **F** (Friday) to indicate the day on which authors must be present at their poster boards.

**373W**

**The effect on the infection of Plasmodium falciparum by the increased Young's Modulus of G6PD deficient erythrocyte membrane.** *W. Jiang<sup>1</sup>, Z. Zhang<sup>1,2</sup>, C. Jiang<sup>1</sup>, X. Chen<sup>3</sup>, Z. Fang<sup>1</sup>, Y. Feng<sup>1</sup>.* 1) Department of Medical Genetics, Zhongshan School of Medicine, Sun Yat-sen Univer, Guang Zhou, Guangdong, China; 2) Reproductive Medicine Research Center, Sixth Affiliated Hospital, Sun Yat-Sen University, Guangzhou, 510275, China; 3) Department of Endocrinology, Guangzhou Women and Children's Medical Center, Guangzhou, 510623, China.

We screened more than 40,000 patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency and found that the G6PD Kaiping allele was under the most positive selection for fighting against malaria in the Chinese population. However, the mechanism is unknown. The current study was designed to investigate the anti-malarial effect and mechanism of G6PD deficiency. Dehydroepiandrosterone (DHEA) was utilised for inhibiting the G6PD activity of erythrocytes. Giemsa staining of blood smears were used for the detection of *Plasmodium falciparum* infection. An atomic force microscopy (AFM) was used for the analyses of morphology, roughness and Young's Modulus of the infective erythrocyte membrane. When G6PD activity was inhibited by DHEA, the infection rate of *P. falciparum* decreased and the Young's Modulus of the erythrocyte membrane increased with increasing DHEA concentrations. On the other hand, we found the number of knobs on the infective red blood cell surface decreased with increasing of DHEA concentrations by AFM. In the erythrocytic stage, the merozoites attached to the receptors on the surface of erythrocyte membrane through site specific identification. This will cause erythrocyte to generate extensive deformation. A parasitophorous vacuole will be formed around the merozoite recessed, merozoite can invade to erythrocyte through this parasitophorous vacuole, and it will be sealed after the invasion. We used spherical tip to detect the Young's Modulus of the erythrocyte membrane, and found it increased with increasing of DHEA concentrations. Tip: with the decrease of G6PD activity, under the same stress, the erythrocyte membrane deformability and elasticity decreased, stiffness increased, that is not conducive to the performance of the merozoite invasion of erythrocytes. So, the infection rate of *P. falciparum* declined. Understanding these points will have a major effect on searching for new anti-malarial drug targets.

**374T**

**High-throughput functional genomic assessment of known and novel HNF1A missense variants to support clinical diagnostic interpretation.** *S. Althari<sup>1</sup>, L.A. Najm<sup>2,3</sup>, A.J. Bennett<sup>1</sup>, M. van de Bunt<sup>1,4</sup>, P.R. Njølstad<sup>5,6</sup>, A.R. Majithia<sup>6,7,8,9</sup>, M.I. McCarthy<sup>1,4,10</sup>, A.L. Gloyn<sup>1,4,10</sup>.* 1) Oxford Centre for Diabetes, Endocrinology and Metabolism, University, of Oxford, Oxford, United Kingdom; 2) Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway; 3) Jebesen Center for Diabetes Research, Department of Clinical Science, University of Bergen, Bergen, Norway; 4) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; 5) Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 6) Programs in Metabolism and Medical & Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 7) Diabetes Research Center, Diabetes Unit, Department of Medicine, Massachusetts General Hospital, Boston, MA, USA; 8) Center for Human Genetic Research, Massachusetts General Hospital, Boston, MA, USA; 9) Department of Medicine, Harvard Medical School, Boston, MA, USA; 10) Oxford NIHR Biomedical Research Centre, Churchill Hospital, Oxford, United Kingdom.

Depending on frequency, penetrance and functional impact, heterozygous alleles in the transcription factor-encoding gene, *HNF1A*, cause Maturity Onset Diabetes of the Young (MODY), and/or increase Type 2 Diabetes (T2D) risk. A reliable molecular diagnosis for *HNF1A* variant carriers is a) crucial for effective disease management and treatment, and, b) contingent on an accurate understanding of the functional consequences of known and novel sequence variants. To mitigate this challenge in diagnostic interpretation, we have adopted an experimental strategy to interrogate all possible missense variants in *HNF1A* (11,989 alleles) *en masse*, using transcriptional targets as discriminators of molecular dysfunction. Markers of HNF-1a transactivation have not been identified for the purpose of massively parallel allelic screening; therefore, we conducted a systematic search for HNF-1a regulated transcripts in a high-throughput-compatible, physiologically relevant cell system. Based on cytogenetic, transcript and proteomic characterisation, the human liver cell line, HepG2, was selected. HepG2 cells were transduced with doxycycline (dox)-inducible *HNF1A* sequences. RNA from samples that showed dose-dependent induction of *HNF1A* was sequenced to identify differentially regulated targets. A total of 226 transcripts were differentially expressed (FDR  $\leq$  1%,  $\log_2FC \geq 0.5$  or  $\leq -0.5$ ) across dox doses (0-5  $\mu$ g/ml), with highest exogenous *HNF1A* induction at 5  $\mu$ g/ml ( $P=1.98 \times 10^{-5}$ ). We tested cell surface expressed targets, *CUBN* ( $P=1.48 \times 10^{-6}$ ), *CLDN2* ( $P=2.60 \times 10^{-6}$ ), *TMEM27* ( $P=3.07 \times 10^{-6}$ ), and *TM4SF4* ( $P=2.59 \times 10^{-6}$ ), for their ability to sensitively discriminate a series of *HNF1A* alleles (with strong genetic, clinical, and functional evidence) on the basis of molecular function. We achieved robust allelic segregation using *TM4SF4* as a readout in flow cytometric analyses. The allelic series displayed a range of functional effects reflected by activity-dependant distributions of *TM4SF4*-positive cell populations: 2-8% from MODY-causal loss-of-function alleles, 30% from a low frequency allele associated with T2D risk, 60-70% from neutral alleles, and >80% from wild-type. In conclusion, we have built a robust and scalable assay that will allow pooled functional interrogation of an *HNF1A* saturation mutagenesis library, using endogenous transcriptional targets as markers of *HNF1A*-deficiency. The emerging data will aid in the interpretation of variants in the clinical diagnostic setting.

**375F**

**A novel IDS gene mutation in two Japanese patients with severe mucopolysaccharidosis type II and correlation between developmental outcomes.** S. Kasuga<sup>1</sup>, C. Kadoh<sup>2</sup>, S. Kudou<sup>3</sup>, K. Fujita<sup>3,4</sup>, N. Hikita<sup>1</sup>, S. Nishigaki<sup>5</sup>, T. Seto<sup>1</sup>, T. Hamazaki<sup>6</sup>, H. Shintaku<sup>3</sup>. 1) Department of Pediatrics, Osaka City University Graduate School of Medicine, Osaka, Japan; 2) Department of Pediatrics, Osaka City University Graduate School of Medicine, Osaka, Japan; 3) Department of Pediatrics, Osaka City University Graduate School of Medicine, Osaka, Japan; 4) ATOX Co., Ltd.

**Background:** Mucopolysaccharidosis type II (MPSII, Hunter syndrome) is an X-linked recessive disorder caused by a deficiency of the lysosomal enzyme iduronate-2-sulphatase (IDS). Since not all the reported nonsense mutations of IDS gene caused severe phenotype, it is important to describe natural histories of patients with a specific mutation. Here we report a novel nonsense IDS gene mutation caused severe phenotypes in two unrelated patients. We further performed comparative structural analysis on this novel mutation with previously reported mutations and tentatively identified a critical region to manifest severe phenotype. **Patients and Methods:** We investigated two unrelated Japanese patients with the same unreported MPS II gene mutation, Q272X. They were diagnosed with high urinary glycosaminoglycans, low IDS enzyme activity in lymphocytes, and IDS gene mutation. We used Developmental Quotient (DQ) score by the Kyoto Scale of Psychological Development. Genomic DNA were isolated from their peripheral blood and PCR amplified each exon of *IDS* gene was analyzed by direct sequencing. The tertiary structure imaging of IDS was constructed using arylsulfatase as a template by homology modeling. **Results:** The first patient is 18 years old boy. He was diagnosed as MPSII at 1 year old by hepatomegaly and language delay. Head control was showed by 4 months after birth, walked alone by 14 months, and talked words by 18 months. Severe developmental retardation had manifested with constant declining in Developmental Quotient(DQ) score after 2 years old. He lost the ability of walking alone at 6 years old. Enzyme replacement therapy (ERT) was introduced since he was 9 years old, but now he is bedridden with enteral nutrition. The second patient is 4 years old boy. Limbs joint contraction was pointed out at the 3 years and ERT was initiated soon after the diagnosis. Although he had good development and growth history until by 3 years old, DQ score started declining thereafter. Based on our IDS structural analysis in silico, we found that severe phenotype was associated with surroundings of catalytic domain of IDS enzyme. **Conclusions:** In cases of nonsense or frame shift mutation of IDS, we may be able to predict the phenotypes of MPSII patients at early stage of the disease. It will be beneficial for the patients to intervene early when novel brain targeted treatments become available.

**376W**

**Novel frame-shift mutation in the extracellular domain of WNT coreceptor, low-density lipoprotein receptor-related protein 6 in a Japanese family with autosomal dominant oligodontia and early onset metabolic syndrome.** H. Goto<sup>1,9</sup>, M. Kimura<sup>1,3,4</sup>, M. Nakashima<sup>1</sup>, N. Tsuchida<sup>4,5</sup>, J. Machida<sup>1,2</sup>, T. Tatematsu<sup>1,9</sup>, H. Miyachi<sup>6</sup>, K. Takahashi<sup>6</sup>, H. Izumi<sup>7</sup>, A. Nakayama<sup>8</sup>, Y. Higashi<sup>8</sup>, K. Shimoza<sup>1</sup>, N. Matsumoto<sup>4</sup>, Y. Tokita<sup>1,9</sup>. 1) Maxillofacial Surgery, Aichi-Gakuin University, aichi ken nagoya shi, aichi, Japan; 2) Department of Oral and Maxillofacial Surgery, Toyota Memorial Hospital, Toyota, Japan; 3) Department of Oral and Maxillofacial Surgery, Ogaki Municipal Hospital, Ogaki, Gifu, Japan; 4) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan; 5) Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Kanagawa, Japan; 6) Department of Oral and Maxillofacial Surgery, School of Medicine, Kyoto University, Kyoto, Japan; 7) Department of Occupational Pneumology, Institute of Industrial Ecological Science, University of Occupational and Environmental Health, Kitakyushu, Japan; 8) Department of Embryology, and 9) Department of Perinatology, Institute for Developmental Research, Aichi-Human Service Center, Kasugai, Japan; 9) Department of Perinatology, Institute for Developmental Research, Aichi-Human Service Center, Kasugai, Japan.

**Purpose:** Congenital tooth agenesis is one of the most common anomalies in human development. The etiology of tooth agenesis, however, still remains unknown in many patients. We thus investigated the genetic cause of tooth agenesis in Japanese patients. **Methods:** We performed whole exome sequence analysis of a number of Japanese families with congenital tooth agenesis and their relatives. **Results:** A novel single nucleotide insertion in the *LRP6* gene (NM\_002336.2:c.1924dup) was identified. This gene is responsible for WNT/ $\beta$ -catenin signaling as a coreceptor for WNT ligands. The single nucleotide insertion causes a frame-shift and introduces a premature stop codon in the extracellular region (p.(Ile642Asnfs\*11)). Interestingly, tooth agenesis patients with this mutation had been diagnosed as hyperlipidemia. **Conclusions:** It has been demonstrated that null mutations in the *LRP6* gene cause selective tooth agenesis (STHAG7: MIM 616724), while other mutations in the *LRP6* gene leading single amino acid substitution at the extracellular domain are reported as causes for autosomal dominant early coronary artery disease and metabolic syndrome (ADCAD2: MIM 610947) to date. Our current study, however, shows that the gene mutation of *LRP6* truncated form can cause a syndromic disease of familial hypercholesterolemia with tooth agenesis.

**377T****Primary bilateral macronodular adrenocortical hyperplasia due to mutations in *ARMC5*: New mutations in humans and modeling in zebrafish.**

A.G. Maria<sup>1</sup>, F.R. Faucz<sup>1</sup>, A. Berthon<sup>1</sup>, F. Hannah-Shmouni<sup>1</sup>, B. Feldman<sup>2</sup>, J. Bertherat<sup>3</sup>, C.A. Stratakis<sup>1</sup>. 1) Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH), Bethesda, Maryland, USA; 2) Division of Developmental Biology, Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH), Bethesda, Maryland, USA; 3) Institut National de la Santé et de la Recherche Médicale (INSERM) U1016, Centre National de la Recherche Scientifique (CNRS) UMR 8104, Institut Cochin, Paris, France; Department of Endocrinology, Referral Center for Rare Adrenal Diseases, Assistance Publique Hôpitaux de Paris, Hôpital Cochin, Paris.

Primary bilateral macronodular adrenocortical hyperplasia (PBMAH), a rare cause of ACTH-independent Cushing's syndrome (CS), is characterized by massive enlargement of the adrenal glands with multiple nodules (>1cm) with or without internodular atrophy and increased cortisol and/or aldosterone production. Armadillo Repeat Containing 5 (*ARMC5*) is a putative tumor suppressor gene whose mutations have recently been identified in about half of the patients with PBMAH. We sequenced blood DNA from 80 subjects with PBMAH for *ARMC5* variants. The functional role of *ARMC5* was determined using a zebrafish model. Knockdown of the zebrafish ortholog *ARMC5* was performed using an antisense morpholino oligonucleotide (MO). The RNA from 100 3dpf (days post fertilization) embryos (50 from each group) was extracted and RNAseq was performed in those two groups and in the RNA extracted from an uninjected control group. Eighteen subjects (22.5%) had a damaging variant in *ARMC5* as predicted by an *in silico* analysis, including three not previously described: two missense (p.W476X and p.R362W) and one frameshift (p.C5795fs\*112) variant. Two of eleven subjects with primary aldosteronism had damaging variants in *ARMC5*. All predicted damaging variants were located in regions that are shared by the three most frequent human *ARMC5* isoforms. Zebrafish RNAseq data suggest a role for *Armc5* in apoptotic processes and steroid biosynthesis. Taken together, these data confirm our previous findings that damaging variants in *ARMC5* are frequent in PBMAH. Furthermore, the zebrafish model agrees with previously published human *in vitro* experiments and demonstrates a conservation of *ARMC5* function in vertebrates. Pathway analysis highlights new candidates involved in post-translational modifications that may be involved in tumor formation initiated by *ARMC5* mutations.

**378F****Cargo of miRNAs from synovial fluid exosomes contributes to pathogenesis of primary osteoarthritis.**

M. Czarny-Ratajczak<sup>1</sup>, V. Dasa<sup>2</sup>, J. Li<sup>3</sup>, J. Eastwood<sup>1</sup>, C. Monjure<sup>1</sup>, S.M. Jazwinski<sup>1</sup>. 1) Department of Medicine, Center for Aging, Tulane University, School of Medicine, New Orleans, LA; 2) Department of Orthopedic Surgery, Louisiana State University Health Sciences Center, New Orleans, LA; 3) Department of Global Biostatistics and Data Science, Tulane School of Public Health, New Orleans, LA.

Osteoarthritis (OA) is a chronic degenerative joint disorder and despite the high frequency of OA, the cause of the primary form of this disorder is still not elucidated. We have investigated the content of exosomes from synovial fluid and whether these vesicles released by synoviocytes into synovial fluid, transport the unique set of miRNAs that are involved in initiation and progression of osteoarthritis. The current knowledge about the exosomal miRNAs from synovial fluid is limited and a full profile of these molecules is not known. Exosomes were isolated from synovial fluid collected during joint replacement surgery in patients with osteoarthritis. We confirmed via electron microscopy and immuno-gold labeling the presence of exosomes in an isolated fraction. Expression of exosomal markers was confirmed via Western blot. RNA-Seq of miRNAs from nine patients was completed on the Ion Proton system and results were validated via qPCR in additional ten patients. NGS data were analyzed with small RNA analysis plugin (Ion Torrent Suite software) and edgeR. The analysis of potential targets of identified miRNAs and networks was conducted with the following databases: TargetScan, DIANA LAB, PICTAR, MIRANDA miRDB and IPA. We observed that the top ranked miRNAs are part of the networks, which include *TP53*, *IL-6*, NFKB complex and *ERK1/2*, according to IPA. Five miRNAs from this list are already linked to osteoarthritis. Target genes of top ranked miRNAs that overlap in four databases include: *TP53*, *MDM4*, *AFF4*, *NFIB* etc. We also detected TERRA transcripts in synovial fluid exosomes. Based on the current literature, this is the first study that shows the full profile of miRNAs from synovial fluid exosomes of patients with osteoarthritis and indicates that they are actively involved in the initiation and progression of this disorder. Targets regulated by these miRNAs are in control of cell death, cell cycle and inflammatory responses, which play significant role in OA pathogenesis. In addition, TERRA transcripts, which were identified by us in synovial fluid exosomes are known to stimulate inflammatory cytokines. This research was funded by the NIGMS (NIH) grant 4P20GM103629 (to S.M.J.), 4P20GM103629 and 1-U54-GM104940 (NIGMS) as pilot projects (to M.C-R) and by the 2016 Irvin Cahen award to V.D. and M.C-R. RNA-Seq was completed in the Tulane Genomics and Biostatistics Core funded by the grant 4P20GM103629.

**379W**

**Capture Hi-C identifies chromatin interactions between psoriasis-associated genetic loci and disease candidate genes.** *H.F. Ray-Jones<sup>1,2</sup>, A. McGovern<sup>1</sup>, P. Martin<sup>1</sup>, K. Duffus<sup>1</sup>, S. Eyre<sup>1</sup>, R.B. Warren<sup>1,2</sup>.* 1) Arthritis Research UK Centre for Genetics and Genomics, Division of Musculoskeletal and Dermatological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom; 2) The Dermatology Centre, Salford Royal NHS Foundation Trust, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom.

**Purpose:** Psoriasis is a common, complex autoimmune condition of the skin. Genome-wide association studies (GWAS) in psoriasis have identified many risk loci, but most lead variants are non-coding with an unknown function. It is hypothesised that these variants regulate gene function through enhancer-promoter chromatin interactions. Capture Hi-C (CHI-C) is a method combining chromosome conformation capture technology with a targeted capture step to discover interactions in specific regions of the genome. This work aimed to apply CHI-C in psoriasis risk loci using relevant cell types and conditions. **Methods:** CHI-C libraries were generated in duplicate using relevant cell lines: MyLa (CD8+ T cells) and HaCaT (keratinocytes). Two libraries were also generated from HaCaT cells stimulated with interferon gamma (IFN- $\gamma$ ). RNA capture baits were designed to target all known psoriasis-associated GWAS loci; each locus was defined by a set of variants in linkage disequilibrium with the lead SNP ( $r^2 > 0.8$ ). The libraries underwent next-generation sequencing generating 75 bp paired ends. The sequences were analysed using the bioinformatics pipelines HiCUP and CHICAGO. **Results:** Interaction data was obtained for psoriasis risk loci across the genome represented by 107 lead variants (59 in Europeans, 42 in Chinese and 6 in both populations). CHICAGO identified 13393, 6737 and 6956 significant interactions in MyLa, unstimulated HaCaT and stimulated HaCaT cells, respectively (CHICAGO score  $> 5$ ). In approximately 25% of cases, interactions overlapped with gene promoter regions defined by fragments within 500bp of a transcription start site, corresponding to 1075 genes and non-coding RNAs in total. The data suggested gene targets in several loci; for example *KLF4* in 9q31.2 and *NFKB1Z* in 3q12.3. The intergenic locus at 1p36.23 harbours several potential gene targets including *TNFRSF9* and *SLC45A1*; however in HaCaT cells the psoriasis-associated variation interacted with the promoter of nearby *ERRF1*. This gene encodes a protein that inhibits epidermal growth factor receptor signalling and is thought to be required for normal keratinocyte proliferation. **Conclusions:** This is the first use of CHI-C across all psoriasis risk loci and demonstrates how intergenic variation may contribute towards the pathogenicity of psoriasis. Continued analysis, such as integration of gene expression data, will help to further identify gene candidates for downstream functional investigation.

**380T**

**Exome-wide copy number association study for arsenic-induced skin lesions: A prospective study.** *M.G. Kibriya<sup>1</sup>, F. Jasmine<sup>1</sup>, F. Parwez<sup>2</sup>, T. Islam<sup>3</sup>, A. Ahmed<sup>3</sup>, M. Rakibuz-Zaman<sup>3</sup>, R. Rahaman<sup>1</sup>, J.H. Graziano<sup>2</sup>, H. Ahsan<sup>1</sup>.* 1) Public Health Sciences, University of Chicago Medicine, Chicago, IL, USA; 2) Environmental Health Sciences, Mailman School of Public Health, Columbia University, NY, USA; 3) University of Chicago Research Bangladesh, Dhaka, Bangladesh.

**Background:** Exposure to arsenic in drinking water is a global public health problem and arsenic-induced skin lesions (ASL) are hallmark of chronic arsenic toxicity. Previously we and others have reported some SNPs as risk factors for ASL. The role of copy number variation (CNV) in the germline DNA in this regard is unknown. Conventional GWAS SNP-chips typically covers mainly intronic or inter-genic regions. Recently, using conventional GWAS chip, for the first time, we have identified some CNVs mainly in intronic regions and lincRNA regions to be associated with higher risk of development of ASL. In this study, we used microarray based Exome chip to detect CNVs in the exome regions and explore if any exonic CNVs are associated with higher risk of arsenic toxicity in subjects exposed to different level of arsenic through drinking water. **Material & Methods:** From a large and long-term (96 months) prospectively followed-up cohort in Bangladesh, exposed to arsenic, we randomly selected 1874 subjects (m=821, f=1053) without any ASL at enrollment and genotyped their whole blood DNA samples at baseline on Illumina HumanExome-12v1-1 SNP chips to generate DNA copy number. Participants were followed up every 2 years for a total of 8 years, especially for the development of ASL. In Cox regression models, each CNV segment was used as a predictor, accounting for other potential covariates, for incidence of skin lesions. **Results:** A total of 373 subjects (m=270, f=103) developed ASL. Male gender, older age, and high urinary arsenic creatinine ratio (UACR) were independently associated with higher risk of developing ASL. We identified multiple CNV regions with amplification/gain to have significant associations (FDR 5%) with the development of ASL, independent of gender, age and arsenic exposure level. The significant top most high-risk CNVs include amplification of oncogene *MAFK* [adjusted HR 1.72 (95% CI 1.27 – 2.33),  $p=4.1 \times 10^{-4}$ ] with a frequency of 7.4% and among the top most protective CNVs is amplification of tumor suppressor gene *PRDM2* [adjusted HR 0.26 (95% CI 0.14 – 0.49),  $p=3.1 \times 10^{-3}$ ] with a frequency of 8.9%. **Conclusion:** This first Exome-wide Copy Number Variant (CNV) analysis in arsenic exposed cohort, prospectively followed up for incidence of ASL, reveals that amplification of an oncogene *MAFK* in germline DNA may predispose an individual to a higher risk of development of ASL; and amplification of a tumor suppressor gene *PRDM2* provides protection against ASL.

**381F**

**Gene correction of epidermolysis bullosa simplex mutations using CRISPR/Cas9 technology.** M. Bchetnia<sup>1</sup>, L. Girard<sup>1</sup>, J. Powell<sup>2</sup>, C. McCuaig<sup>2</sup>, A. Dupéree<sup>3</sup>, C. Morin<sup>3</sup>, L. Germain<sup>4</sup>, J.P. Tremblay<sup>5</sup>, C. Laprise<sup>1</sup>. 1) Université du Québec à Chicoutimi, Saguenay, Canada; 2) Hôpital Sainte-Justine, Montréal, Canada; 3) Centre de santé et de services sociaux de Chicoutimi, Saguenay, Canada; 4) Centre LOEX de l'Université Laval, Génie Tissulaire et Régénération, Québec, Québec, Canada; 5) Centre de Recherche du CHU de Québec, Université Laval, Québec, Canada.

Epidermolysis Bullosa Simplex (EBS) is a rare autosomal dominant skin disease characterized by non-scarring blisters and erosions caused by minor mechanical trauma. EBS is caused by different mutations within the *KRT5* or the *KRT14* gene and resulted in mis-folded proteins thus impaired normal assembly of the keratin intermediate filaments. *In vitro*, this is reflected by the formation of keratin aggregates in the mutant patient cells. To date, there is no efficient therapy for this hereditary disease and current therapies are palliative, aimed at treating infections and maintaining an acceptable quality of life. Recently, the clustered regularly interspaced short palindromic repeat (CRISPR)-Cas9 technology emerged as a potent tool to edit DNA in a fast, cost-effective and precise method. As our goal is to develop an effective and permanent therapy for EBS, we propose to use the CRISPR/Cas9 technology to correct the genomic mutations that cause the EBS phenotype and engineer autologous gene corrected skin tissue grafts. This would be a viable option to alleviate blistering apparent and improve survival of EBS patients. Here, we assess the potential of CRISPR-Cas9 genome editing tool to repair two single point mutations in *KRT5* and *KRT14* genes respectively and responsible of the severe EBS form (EBS-gen sev) by enhancing the levels of homologous recombination in the presence of a wild type DNA donor template. We selected three single guide RNAs sequences (sgRNA) specific for each mutation and we show the high efficiencies of these sgRNAs to guide the Cas9 nuclease to create DNA double-strand breaks (DSBs) at the precise location close to the site of the mutation both in HEK293T cells and in primary fibroblasts derived from the two EBS patients carrying the two studied mutations. Successful induced homologous recombination was observed in HEK293T cells either when using single-stranded oligonucleotides (ssDNA) as donor template or a plasmid donor template. Experiments are ongoing in EBS fibroblasts in order to validate phenotypic correction. Gene repaired cells will serve to engineer skin tissue that will be transplanted to patients as autografts, which will potentially avoid the patient's immune system graft rejection. Our work supports our hypothesis that the CRISPR/Cas9 system may be used to treat EBS and other genetic dermatological pathologies.

**382W**

**ATP7B gene variants for Alzheimer's disease affects ATP7B structure and markers of copper status.** M. Rongioletti<sup>1</sup>, R. Squitti<sup>1,2</sup>, C. McCan<sup>3</sup>, M. Siotto<sup>3</sup>, S. Lutsenko<sup>3</sup>. 1) Clinical Pathology Department, San Giovanni Calibita Hospital, Rome, Italy; 2) IRCCS Istituto Centro San Giovanni di Dio- Fatebenefratelli, Italy Molecular Markers Laboratory; 3) Department of Physiology, Johns Hopkins University, Baltimore, MD, USA; 4) Don Carlo Gnocchi ONLUS Foundation, Milan, Italy.

**Background:** ATP7B is a copper chaperone that loads the metal into the serum copper-protein ceruloplasmin during its synthesis, escorts superfluous copper into bile, and represents a key protein in copper failure. Impaired function of this ATPase is associated with a well-known inborn error of copper metabolism, Wilson's disease (WD). Four specific gene variants of the ATP7B gene and a WD rare mutation have a statistical association with AD. These gene variants are informative on the ATP7B gene structure. **Methods:** We have examined the effect of these AD-related gene variants (allele rs1061472 and 732774) on the expression and localization of ATP7B. Four ATP7B protein variants R9R8 for R952/R832; R9K8 for R952/K832; K9K8 for K952/K832; and K9R8 for K952/R832 were generated and expressed in HEK293 cells. Effects of the corresponding gene variants in 81 healthy controls were analyzed also in blood stream markers of copper status, namely, serum copper, ceruloplasmin, copper not bound to ceruloplasmin (non-Cp Cu) and the Cu to Cp ratio (Cu:Cp), which is a surrogate of the stoichiometry between copper and ceruloplasmin. In particular we stratified the sample in carriers of at least one ATP7B R832 variant (corresponding to GG+AG rs1061472 genotype) and carriers of at least at one ATP7B K952 (corresponding to TT +CT rs732774). **Results:** Following transient expression by Western blot analysis we found that protein abundance in cells differed despite similar mRNA levels. The ATP7B variant with both risk gene variants, K9R8, had the lowest protein level and the variant with neither risk allele, R9K8, has the highest protein level (p-value=0.0075). We have also examined the localization and trafficking of the variants and observed differences in their response to Cu-elevation. Furthermore, healthy subjects carriers of R832, carriers of K952 and carriers of both R832/K952 ATP7B variants had values of non-Cp Cu and Cu:Cp higher than non-carriers subjects. Moreover carriers of K952 and carriers of both R832/K952 ATP7B variants showed also ceruloplasmin values lower than non-carriers group. **Conclusions:** The two alleles investigated affect ATP7B stability, with a consequent decrease of ceruloplasmin concentrations, and increase of non-Cp Cu concentrations and of Cu:Cp ratio in blood stream. These results demonstrate a causative link of ATP7B variants and copper imbalance in AD etiology.

**383T**

**Age-related structural changes of the olfactory receptor subgenome in human blood cells and autologous brain regions.** *K. Szigeti, B. Birkaya, A. Ouf, L. Yan.* Dept Neurology, University at Buffalo, Buffalo, NY.

Olfactory identification deficit is associated with aging and neurodegenerative diseases including Alzheimer's disease (AD). To study whether *de novo* somatic structural variants in the olfactory receptor (OR) subgenome contribute to the mechanism of OID we developed an OR specific microarray (Agilent, coverage 90%). Using a cohort of 841 subjects (234 normal controls (NC), 192 amnesic mild cognitive impairment (aMCI) and 415 AD), age range 55-94, we found that structural variants in the OR subgenome are distributed differentially in younger (age 1<sup>st</sup> quartile) and older subjects (age 4<sup>th</sup> quartile), older subjects harboring more losses than expected. There was no difference between control and disease groups ( $p=0.8$ ). Genome wide age correlation identified several regions contributing to the signal, chr 15 q11.2 and chr 11 q11.1 with the largest effect. Megabase - and Kilobase - range variants were identified, ranging from 3-187 CNVs per sample, none of the samples were outliers. The frequency of events at CNV loci ranged 10.6%-59% (mean 17.4%). The majority of high frequency associated regions were within 2Mb of the telomeres or centromeres yielding 77% of CNV for centromeric region and 13% and 10 % for p and q telomeric regions respectively. The associated CNVs were validated with TaqMan assay. aCGH of autologous olfactory bulb and temporal lobe DNA from eight autopsy specimens detected structural variants with 90% Variant correlation detected in the blood cohort suggesting existence of recombination hotspots. The same individual's brain region specific CNV is a result of postmitotic tissue specific *de novo* events with various levels of mosaicism. CNV content gene annotation revealed an enrichment for genes involved in innate and acquired immunity. Age related structural changes, specifically haploinsufficiency, may contribute to the immunosenescence observed during the aging process. Replication studies in the ADNI, NIA-LOAD, TGEN, TARCC, MIRAGE and ADC GWAS datasets is ongoing. .

**Molecular mechanisms in C9orf72 ALS/FTD using the BAC transgenic mouse model with behavioral, neuropathological and molecular features of disease.** *A. Pattamatta, H.R Olafson, Y. Liu, M.M Scotti, L. Nguyen, T. Reid, T. Zu, J. Richardson, A. Berglund, E.T. Wang, L.P.W. Ranum.* University of Florida, Gainesville, FL.

Hexanucleotide repeat expansions in the first intron of *C9orf72* gene are the most common genetic cause of familial ALS and FTD. To understand the disease mechanisms, we generated a BAC transgenic mouse model of the disease (C9-500), which contains the entire *C9orf72* gene, 500 GGGGCC repeats and substantial flanking sequence. These mice show behavioral, molecular and neuropathological features of ALS and FTD including paralysis, anxiety-like behavior, decreased survival and widespread neurodegeneration of the entire motor unit, hippocampus and layers II/III of the cortex. Repeat associated non-ATG (RAN) protein aggregates increase with age and disease severity in these mice. Similar to human patients, some C9-500 mice show rapidly progressing phenotypes, others have a more slowly progressing disease and 17% show no overt phenotypes at 1 year of age. To better understand this phenotypic variability, we performed RNA-Seq on ten pre-symptomatic C9-500 females to identify transcriptome changes that occur early in disease and may explain the variability of disease presentation and penetrance. Interestingly, 30% of the C9-500 mice clustered together on a principal component analysis plot compared to non-transgenic or the other 70% of C9-500 animals. We are currently characterizing the gene expression and splicing differences in these mice to identify triggers of disease. Additionally, due to repeat instability, we have established a transgenic sub-line from the C9-500 line, in which the expansion grew to ~800 repeats. These C9-800 mice show decreased survival and increased disease penetrance at an earlier age of onset compared to the C9-500 mice. These data demonstrate that disease penetrance and severity are increased with increases in the GGGGCC repeat tract. We are currently using this mouse model to understand the molecular underpinnings of disease and to test therapeutic strategies that can increase survival and mitigate disease.

Pelizaeus–Merzbacher disease (PMD) is a rare X-linked dysmyelinating leukodystrophy of the central nervous system. PMD manifests with a wide spectrum of clinical severity caused by different classes of mutations affecting the dosage-sensitive gene, *PLP1*. *PLP1* copy-number gain is the predominant cause of PMD; however, cataloging each of the observed patterns of complex structural variations (SVs) at this locus remains to be performed. We have molecularly studied 148 PMD samples with non-recurrent SVs involving *PLP1*; 138 were of copy-number gains and ten were of copy-number losses. Herein we characterize the novel *PLP1* SVs (61/138) and compare these data to our previous findings. Consistently, many of the novel copy-number gains have one or more breakpoints overlapping critical low-copy repeats (LCRs) in the region, termed PMD-LCRs. Additionally, we find that 56% of all described copy-number gain events appear as simple duplications, whereas 44% present as complex genomic rearrangements (CGRs). Duplication followed by triplication and subsequent duplication, DUP-TRP-DUP, is the predominantly observed pattern (43%) of all examined copy-number gain CGR cases. Another commonly observed CGR pattern is interspersed duplication separated by a copy-neutral segment, DUP-NML-DUP (33%). Importantly, we report additional samples of known but less frequently observed patterns. Our analyses further support the contention that PMD patients predominantly harbor copy number gains, many with complexities and LCR involvement. These data indicate that replicative DNA repair processes are often involved in PMD rearrangements. Furthermore, our study has shown that deletions of *PLP1* range from 6.7 kb to 5.6 Mb in size and in contrast to gain events, deletions of *PLP1* were rarely associated with complexities; wherein 90% appear as simple events. Sequence-mapped breakpoints of deletions overlap with distinctive genomic architecture in each of the studied cases including *Alu* elements, LINEs, as well as LCRs. Finally, we investigated potential molecular mechanisms for the penetrance and variable phenotypic expressivity in deletion carrier females by exploring X-inactivation patterns as well as possible bi-allelic variation in the *PLP1* region. This study expands our knowledge of CGR patterns at a discrete locus, their mechanisms of formation, and the molecular pathogenicity of PMD.

**Immunotherapy development for *C9ORF72* ALS/FTD using a BAC transgenic mouse model and human antibodies targeting RAN proteins.** L. Nguyen<sup>1</sup>, F. Montrasio<sup>2</sup>, A. Pattamatta<sup>1</sup>, N. Cavegn<sup>2</sup>, K. Nakamura<sup>1</sup>, O. Bhardi<sup>1</sup>, M. Laughrey<sup>1</sup>, T. Zu<sup>1</sup>, J. Grimm<sup>2</sup>, L.P.W Ranum<sup>1</sup>. 1) Center for NeuroGenetics, Molecular Genetics and Microbiology, University of Florida, College of Medicine, Gainesville, FL; 2) Neurimmune, Zurich, Switzerland.

There is considerable interest in the development of immunotherapy for neurodegenerative diseases including Alzheimer's disease, Parkinson's disease and SOD1 ALS. The overall approach is to use human or humanized antibodies to target disease-specific misfolded proteins for neutralization and clearance by the immune system. While antibody therapies for neurodegenerative diseases to date have had mixed results in clinical studies, striking interim results have been reported for Aducanumab, a recombinant human antibody drug that targets A $\beta$  aggregates and is currently in phase III trials. We recently developed a BAC transgenic mouse model of *C9orf72* ALS/FTD that recapitulates key phenotypic and molecular features of the disease including motor neuron loss and the accumulation of dipeptide RAN proteins. Due to mounting evidence that RAN proteins contribute to *C9orf72* ALS/FTD and other expansion disorders, tools that target these proteins are increasingly important for the development of therapeutic strategies. We have generated a panel of human-derived recombinant monoclonal antibodies and selected lead candidates based on their binding profiles to RAN proteins expressed *in vitro* and *in vivo*. To explore blood-brain-barrier penetration and target engagement of these antibodies we performed peripheral administration of antibodies by *i.p.* dosing. Interestingly, IHC and IF analyses using a human secondary antibody showed that injected antibodies crossed the blood brain barrier and localized within the brain as punctate intracellular aggregates in a pattern similar to the RAN protein aggregates previously detected by IHC. These aggregates were found using both frozen and fixed paraffin embedded tissues. To determine if the peripherally injected human antibodies find the C9 RAN protein targets *in vivo*, we performed double labeling IF studies and show that the human antibodies co-localize with the intracellular RAN protein signal from a mouse monoclonal GA antibody. No similar signal was present in isotype control or uninjected animals or when the secondary human antibody was omitted. Taken together, these data show that peripherally injected human antibodies that recognize C9 RAN proteins enter the brain and colocalize with intracellular RAN protein aggregates. Murinized versions of these human antibodies are currently being tested in these C9 BAC mice for therapeutic efficacy.

**Prolonged pentylenetetrazole exposure modulates the Rho Family GTPases pathway in the zebrafish brain.** *M.C.S. Nunes<sup>1</sup>, J.F.de Vasconcellos<sup>2</sup>, V.S. Zago<sup>3</sup>, A.S. Vieira<sup>3</sup>, C.S. Rocha<sup>3</sup>, B.S. Carvalho<sup>4</sup>, I. Lopes-Cendes<sup>3</sup>, C.V. Maurer-Morelli<sup>1</sup>.* 1) Zebrafish Laboratory, Department of Medical Genetics, School of Medical Sciences – UNICAMP, Campinas, SP- Brazil; 2) Genetics of Development and Disease Branch, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health; 3) Molecular Genetics Laboratory, Department of Medical Genetics, School of Medical Sciences – UNICAMP, Campinas, SP- Brazil; 4) Department of Statistics, Institute of Mathematics, Statistics and Scientific Computing, UNICAMP, Campinas, SP-Brazil.

**Purpose:** To investigate the molecular mechanisms underlying seizures, we analyzed the response of different seizure-induced protocols in the zebrafish brain by transcriptome analysis. For a comprehensive understanding of the biological mechanisms affected by the transcripts that were counter-regulated by the treatments, interactive networks and pathways analyses were performed using a systems biology approach. **Methods:** Wild-type zebrafish larvae at 7dpf were separated into three groups: control (CG, n=3), acute seizure (AS, n=2) and *status epilepticus*-like (SE, n=3). Larvae from groups AS and SE were exposed to PTZ 15mM for 20 minutes and 3 hours, respectively. Messenger RNA libraries were achieved after using Illumina's Sample Prep Kit and validated libraries were sequenced in the Illumina HiSeq 2500 System. Gene interactions and correlation networks were identified with the Ingenuity Pathway Analysis (IPA) software content version March/2017 (Ingenuity Systems, Mountain View, CA). The fold change threshold was >3 or ≤-3 and the signaling pathways were considered statistically significant with a p<0.05. All IPA available databases at the time of the analysis were used in this study. **Results:** The most activated signaling pathway for AS vs. CG and SE vs. CG was the *AMPK Signaling*, but in opposite directions, since in the SE it was activated (positive z-score), and in the AS inhibited (negative z-score). However, comparisons between AS vs. SE showed that *RhoGDI Signaling* (p=1.06E-07) and *Signaling by Rho Family of GTPases* (p=1.20E-07) are the top-pathways inhibited (negative z-score) and activated (positive z-score), respectively, in the SE group. **Discussion:** Transcriptome studies followed by signaling pathway analysis showed that AS and SE have distinct molecular responses. We also found that RhoGDI pathway is down-regulated and the Rho Family of GTPases is up-regulated in the SE compared to AS group. The RhoGDI family of genes regulate signaling through RhoGTPases by inhibiting the disassociation of Rho members from GDP, thus keeping these factors in an inactivated state. Also, it is known that the Rho family of GTPases have an important role in the morphogenesis of neurons' dendritic spines and contribute to the synaptic plasticity that is observed in epilepsy. This study supports the relevance of the zebrafish as a model for investigating seizures. **Support:** FAPESP 14/15640-8, CEPID-BRAIN FAPESP 13/07559-3 and Intramural Research Program of NIDDK/NIH. .

**Chromosome 16q22-q24 uniparental disomy unmasks a rare recessive cause of early infantile onset epileptic encephalopathy 28.** *M. Davids<sup>1,2</sup>, S. Thomas<sup>1,2</sup>, C. Adams<sup>1,2</sup>, L.A. Wolfe<sup>1,2</sup>, T. Markello<sup>1,2</sup>, C.J. Tiffit<sup>1,2</sup>, W.A. Gahl<sup>1,2,3</sup>, M.C.V. Malicdan<sup>1,2,3</sup>.* 1) Undiagnosed Diseases Program, Common Fund, NHGRI, National Institutes of Health, Bethesda, MD; 2) Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 3) Section of Human Biochemical Genetics, Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

**Introduction.** The genetic etiologies of many rare disorders, including infantile onset epileptic encephalopathies, are largely undiagnosed. The recent decade has seen a surge in the availability of next generation sequencing; several cases remain unsolved, likely due to unusual inheritance patterns that are not routinely evaluated. We report the discovery of the gene causing early onset epileptic encephalopathy by careful analysis of next generation sequencing data. **Methods.** The patient was evaluated at the NIH Undiagnosed Diseases Program (UDP) under the protocol 76-HG-0238. Whole exome sequencing (WES) and single nucleotide polymorphism (SNP) genotyping arrays were performed on DNA from all members of the immediate family. **Results.** A 5-year-old girl presented to the UDP with a history of neurodegenerative disorder, profound intellectual disability, infantile onset seizures, chronic respiratory failure, dysmorphisms, and an atrial septum defect. She also had neutropenia, thrombocytopenia and hypoglycemia. WES did not reveal gene candidates that could explain the phenotype in full, but on SNP-array analysis a large region of homozygosity was discovered on chromosome 16, spanning q22-q24. Upon closer inspection, it was discovered that the homozygosity was caused by maternal uniparental disomy (UPD) that included an exon 6 deletion in *WWOX* (NM\_016373). *WWOX* is thought to play a role in apoptosis as a mediator of p53 and is potentially involved in steroid metabolism, skeletal morphogenesis and central nervous system development. Digital droplet PCR confirmed that the homozygous region was caused by uniparental disomy and was not a result of mosaicism. mRNA expression analysis revealed nonsense mediated decay of this transcript. Exon 6 of an alternative transcript (NM\_130791) is utilized; that transcript lacks the short chain dehydrogenase domain. **Conclusion.** The deletion of exon 6 in *WWOX*, which is associated with early infantile onset epileptic encephalopathy 28, explains most of the phenotype in our patient. Whether the atrial septum defect, skeletal and hematological abnormalities represent an expansion of the *WWOX* phenotype or are attributable to other variants in the disomic region, or 3 identified variants elsewhere in the genome that may contribute to the phenotype, is under current investigation. Our report underscores the importance of UPD as an underlying mechanism of rare autosomal recessive disorders.

**389T****Gene discoveries in autism are biased towards intellectual disability.**

M. Jensen<sup>1</sup>, L. Pizzo<sup>1</sup>, V. Kumar<sup>1</sup>, M.D. Singh<sup>1</sup>, F. Hormozdiari<sup>2</sup>, S. Girirajan<sup>1</sup>.

While dozens of genes have been linked to autism spectrum disorders (ASD), definitively connecting these genes to autism phenotypes has been difficult due to extensive comorbidities between ASD and other psychiatric disorders. Here, we show that the ASD gene discoveries to date have been biased towards genes that contribute to ASD comorbid with intellectual disability (ID). We analyzed 2,297 probands with autism from the Simons Simplex Collection (SSC), and found that probands with rare pathogenic copy-number variants ( $p=0.0310$ ) and *de novo* loss-of-function (LOF) variants ( $p=0.00197$ ) have significantly lower IQ than SSC probands without pathogenic variants. Further, we found no change in autism severity, as measured by SRS T-scores, between the two groups ( $p>0.05$ ), indicating that pathogenic mutations used to identify autism genes in fact capture genes that contribute mainly to ID phenotypes. In addition, SSC probands with *de novo* mutations in 76 previously well-described ASD genes not only manifested more severe ASD ( $p=0.0232$ ), but also a significantly lower IQ ( $p=2.65\times 10^{-6}$ ), showing that the current set of autism genes are not specific to autism only. We next isolated 397 probands with high-functioning autism (SRS>75 and IQ>100), and found they were less likely to carry rare pathogenic CNVs ( $p=0.0497$ ) or *de novo* LOF mutations ( $p=0.0437$ ) than the rest of the SSC cohort. These probands were also less likely to carry *de novo* LOF mutations in the 76 known ASD genes ( $p=0.0068$ ). Additionally, we found that 42 genes with *de novo* LOF variants in individuals with high-functioning autism are less resistant to variation, with higher RVIS scores than genes with *de novo* LOF variants in probands with IQ<70 ( $p=0.0121$ ). Mouse knockout models of these genes also have less severe developmental phenotypes, including neurological, growth and behavioral features, than those of known ASD genes ( $p<0.05$ ). We also used computational methods to cluster variants into modules based on proband phenotypes, and found clustering of modules within neurodevelopmental pathways for *de novo* LOF mutations in probands with ASD and ID. However, significant clustering within these pathways were only observed for missense mutations in probands with ASD-only phenotypes. Overall, our results suggest that pathogenic rare CNVs and *de novo* LOF mutations associated with autism actually contribute to both ASD and ID, and subtler genetic changes contribute to pathogenicity in high-functioning autism.

**390F****Marker chromosome architecture and temporal origin revealed in a family with pleiotropic psychiatric phenotypes.**

Small supernumerary marker chromosomes (sSMC) are chromosomal fragments that are inherently difficult to genetically characterize due to their small size and abnormal genetic structure. Here we detail a mother and proband who present with neuropsychiatric disorders and a marker chromosome that segregates with disease. We explored the genomic architecture of this marker and investigated its temporal origin in the family. A customized array comparative genomic hybridization (aCGH) revealed 4 duplications and 2 triplications that spanned the short arm of chromosome 9, suggesting a chromoanaysynthesis event. Subsequent FISH analysis showed the DUP/TRP segments were present on the marker and droplet digital PCR (ddPCR) revealed the presence of mosaicism. The discovery that the mother had two different subsets of cells, one carrying the marker (blood DNA) and one not carrying the marker (lymphoblastoid cell line (LCL)) provided a unique opportunity to distinguish between these two genotypes. A SNP array was performed in the distinct cell types; and using SNPs that were homozygous in the mother's LCLs, but heterozygous in her blood, we were able to delineate the genotype of the marker. Examining those same positions across the family, we were able to infer that the chromosomal fragments of the marker likely were inherited from the grandmother, who does not carry the marker itself, suggesting it was formed during a germline level event. Additional ddPCR assays were used to interrogate the junctions present and showed a duplication of breakpoints. To understand the exact architecture of the fragments on the marker, we performed whole genome sequencing (WGS) of the blood DNA from the mother, proband and grandmother. Using genomic locations derived from the aCGH, we located those regions in the WGS data and found reads with mate-pairs matched to regions on the other side of a breakpoint. This nucleotide resolution allowed for Sanger-sequencing of 5 out of 6 breakpoints and facilitated the creation of a proposed genomic architecture for the marker. The combination of multiple copy number gains as well as the complex rearrangement is indicative of chromoanaysynthesis via a DNA replicative repair mechanism such as FoSTeS/MMBIR. While CNVs have been previously associated with neuropsychiatric disorders, here we detail their precise architecture on a marker. A better understanding of how these changes can contribute to disease may provide avenues for targeted therapies.

**Local and global chromatin interactions are altered by large genomic deletions associated with human brain development.** *A. Urban<sup>1</sup>, Y. Zhang<sup>2</sup>, X. Zhang<sup>3</sup>, X. Zhu<sup>4</sup>, C. Purmann<sup>1</sup>, M. Haney<sup>1</sup>, T. Ward<sup>1</sup>, J. Yao<sup>3</sup>, S. Weissman<sup>4</sup>.* 1) Psychiatry and Genetics, Stanford University, Palo Alto, CA; 2) Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Cell Biology, Yale University, New Haven, CT; 4) Genetics, Yale University, New Haven, CT.

Large copy number variants (CNVs) in the human genome are strongly associated with common neurodevelopmental, neuropsychiatric disorders such as schizophrenia and autism. Using Hi-C for the genome-wide analysis of long-range chromosome interactions and ChIP-Seq for the analysis of regulatory histone marks we studied the epigenomic effects of the prominent large deletion CNV on chromosome 22q11.2, in a cohort of lymphoblastoid cell lines (LCLs), and also replicated a subset of the findings in LCLs with the common large deletion CNV on chromosome 1q21.1. We found that, in addition to local and global gene expression changes, there are pronounced and multilayered effects on chromatin states, chromosome folding and topological domains of the chromatin that emanate from the large CNV locus. Regulatory histone marks are altered in the deletion proximal regions, and in opposing directions for activating and repressing marks. There are also significant changes of histone marks elsewhere along chromosome 22q and genome wide. Chromosome interaction patterns are weakened within the deletion boundaries and strengthened between the deletion proximal regions. We detected a change in the manner in which chromosome 22q folds onto itself, namely by increasing the long-range contacts between the telomeric end and the deletion proximal region. Further, the large CNV affects the topological domain signal that is spanning its genomic region. Finally, there is a widespread and complex effect on chromosome interactions genome-wide, i.e. involving all other autosomes, with some of the effect directly tied to the deletion region on 22q11.2. These findings indicate novel principles of how such large genomic deletions can alter nuclear organization and affect genomic molecular activity. [manuscript under review] [no conflicts of interest to report].

Chromosome aberrations are considered as alterations in the chromosome number or structure. They are mainly due to gametogenesis inborn error (meiosis) or occur during the zygote first cellular divisions where DNA repair processes are deficient. Two Wolf Syndrome patients and two cri-du-chat patients or patients with deletion of the short arm of chromosome 4 and 5, respectively, and deletion of chromosome 9 in one patient, were observed among 4617 karyotype studies performed from 1992 to 2016, at the Hospital Para El Niño Poblano (Pediatric Hospital) in Mexico. These chromosome structural alterations or deletions at chromosomes 4, 5 and 9, observed among five patients from three different families were chosen to analyze their clinical characteristics, medical or surgical treatments and their medical evolution according to the genetic disease. Key words: Chromosome, deletion, chromosome aberration, structural changes, karyotype.

**Loss of Kctd13 in mice causes short-term memory deficiency.** *T. Arbo-gast<sup>1</sup>, R. Rodriguez<sup>2</sup>, W. Wetzel<sup>3</sup>, P. Razaz<sup>3</sup>, T. Aneichyk<sup>3</sup>, J. Ellegood<sup>4</sup>, M. Henkelman<sup>4</sup>, M. Talkowski<sup>5</sup>, N. Katsanis<sup>5</sup>, C. Golzio<sup>5</sup>.* 1) Duke University, Cell Biology, Center for Human Disease Modeling, Durham, NC, USA; 2) Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC, USA; 3) Molecular Neurogenetics Unit and Psychiatric and Neurodevelopmental Genetics Unit, Center for Human Genetic Research, Massachusetts General Hospital, Boston, MA, USA; 4) Mouse Imaging Center, The Hospital for Sick Children Toronto, Ontario, Canada; 5) Institut de Génétique et de Biologie Moléculaire et Cellulaire, Illkirch, France.

Molecular cytogenetic approaches have identified a substantial number of copy number variants (CNVs) underlying human diseases, including a CNV at the 16p11.2 locus. Deletion and duplication of this genomic region have been associated with both intellectual disability and autism spectrum disorders. Additionally, a reciprocal effect of 16p11.2 gene dosage on body mass index and head size has been noted. The most common CNV at this locus corresponds to a 600 kb fragment of 31 genes including *KCTD13* (Potassium Channel Tetramerization Domain containing 13). We showed previously that overexpression of *KCTD13* human transcript in zebrafish embryos induces the microcephaly phenotype associated with 16p11.2 duplication, whereas suppression of the *kctd13* zebrafish ortholog yields the macrocephalic phenotype associated with 16p11.2 deletion, capturing the mirror phenotypes observed in humans. Recently, *KCTD13* has been shown to regulate RhoA ubiquitination and degradation which may, in turn, lead to disrupted cell migration and influence brain size during prenatal development. To evaluate further the candidacy of *KCTD13* in neurodevelopmental phenotypes, we generated a ubiquitous knockout (KO) of *Kctd13* in the mouse and asked whether loss of *Kctd13* leads to behavioral and anatomical phenotypes. Mutant mice were tested in various behavioral assays to evaluate activity, anxiety, memory, and sociability. By performing novel object recognition, novel location recognition, and social transmission of food preference tests, we observed short-term memory deficits in both heterozygous (Het) and homozygous (Hom) KO mice. While MRI analysis indicated no anomalies in the brain architecture of mutant mice, spine density and morphology analysis on hippocampal pyramidal neurons revealed a reduction in density of mature spines in both Het and Hom KO animals. RNAseq analysis of wild-type, Het and Hom mice show a stepwise decrease in *Kctd13* expression for both cortex and hippocampal tissues, which is consistent with the expression changes of *Kctd13* in the cortex of mice carrying a deletion for the full 16p11.2 segment. Furthermore, a significant number of genes differentially expressed in *Kctd13* KO cortex has been found to be enriched in the 16p11.2 mouse coexpression module. Taken together, these results tentatively implicate *KCTD13* in the intellectual disability phenotype observed in patients carrying the 16p11.2 deletion.

**The use of NGS 10X Genomics linked-reads to solve complex break-points mapping in individuals with balanced translocation.** *F. Mafra<sup>1</sup>, M. Moisés<sup>2</sup>, M. Gonzalez<sup>2</sup>, R. Pellegrino<sup>2</sup>, C. Kao<sup>2</sup>, G. Monteiro<sup>3</sup>, L. Kulikowski<sup>3</sup>, J. Garifallou<sup>1</sup>, K. Kaminski<sup>1</sup>, M. Melaragno<sup>2</sup>, H. Hakonarson<sup>1,4</sup>.* 1) Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Disciplina de Genética, Departamento de Morfologia e Genética, UNIFESP, São Paulo, SP, Brazil; 3) Faculdade de Medicina de São Paulo, São Paulo, Brazil; 4) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Introduction: Chromosomal rearrangements can cause genetic diseases by disrupting or inactivating specific genes rendering the characterization of breakpoints of critical importance in the molecular elucidation of a wide variety of complex phenotypes. Despite the technological advance, current whole exome and targeted NGS sequencing still represent a challenge due the short reads. To overcome these limitations, we utilized a NGS-based method to resolve breakpoints using linked reads generated by the 10x Genomics Chromium technology in combination with WES using custom Agilent SureSelect baits. Methods: We performed experiments on six well represented samples that were previously investigated by karyotyping and microarray. High molecular weight DNA was extracted and the size verified by Genomic Tape Station (60kb required). We used the Chromium platform developed by 10x Genomics to generate barcoded reads. The Gel Bead-In-Emulsions were submitted to an isothermal reaction, followed by library preparation and target enrichment using a premium bait design (Agilent SureSelect) containing "bridging baits" were spaced within intronic and intergenic regions to preserve long-range information following capture. We subsequently sequenced individual samples using the Illumina HiSeq2500 at ~85X coverage. Results: We were able to confirm five of the six cases translocation events, including 46,X,t(X;22)(p22.31;q11.2), 46,X,t(X;2)(q24;p16.2), 46,XY,t(10;18)(p11.2;q11.32)dn, 46,XX,t(2;7)(p13;q22)dn and 46,XX,t(4;7)(q27;p22). The one sample that we were not able to solve (karyotype 46,XY,t(16;17)(p13.3;p11.2)dn) has both breakpoints in repetitive regions, 16p subtelomeric and 17p pericentromeric respectively, suggesting that this strategy is not capable of calling structural variations in highly repetitive regions since there are no baits in these genomic regions due the high repetitive nature. However, we successfully narrowed down the breakpoints for the other five different chromosomal rearrangements all of which were complex events. Conclusions: Using the Chromium platform to generate barcoded reads we have successfully mapped breakpoints for five complex chromosomal rearrangements, demonstrating that the improvement in bait design along with the linked-reads technology can facilitate the "one-test" approach for unresolved balanced translocation events not detected by microarrays, a notable advancement for the cytogenomics field and clinical diagnostics in general.

**Identification of a novel frameshift mutation in the *MCPH1* gene causes primary microcephaly in a Saudi family.** M.I. Naseer<sup>1</sup>, O.Y. Muthaffar<sup>2</sup>, M. Rasool<sup>1</sup>, A.J. Sabbagh<sup>3,4</sup>, A.G. Chaudhary<sup>1</sup>, M.H. Al-Qahtani<sup>1</sup>. 1) Center of Excellence in Genomic Medicine Research, King Abdulaziz University, Jeddah, Makkah, Saudi Arabia; 2) Consultant of Pediatric Neurology Department of Pediatric, King Abdulaziz University Jeddah, 21589 Saudi Arabia; 3) Research and Development, Clinical Skill Simulation Center, King Abdulaziz University Jeddah, 21589 Saudi Arabia; 4) Pediatric Neurosurgeon, College of Medicine, King Abdulaziz University Jeddah, 21589 Saudi Arabia.

Primary microcephaly (MCPH) is a rare developmental defect characterized by impaired cognitive functions, retarded neurodevelopment and reduced brain size. It is genetically heterogeneous and so far more than seventeen genes associated with this disease have been identified. Primary microcephaly type 1 (*MCPH1*) gene encodes a protein called microcephalin, which is implicated in chromosome condensation and DNA damage induced cellular responses. It is suggested to play a role in neurogenesis and regulation of the size of the cerebral cortex. In our study whole exome sequencing revealed a novel, homozygous frameshift mutation (c. 373\_374delAA) in *MCPH1* gene in exon 5 resulting in frameshift change from p.Lys125Glnfs\*7). Whole exome sequencing data was further validated by using Sanger sequencing by designing the primers of the identified mutation. Moreover this frameshift mutation was not found in 100 healthy unrelated controls, while parents and one sister were heterozygous and one sister were normal as healthy controls. Our report presents the results of the simultaneous analysis of the trio exome data of both unaffected parents and their affected son with the phenotype of primary microcephaly. A homozygous frameshift variant in the *MCPH1* gene was identified as a plausible candidate causal variant for the clinical phenotype in this Saudi family.

**Single cell allele specific expression (ASE) in T21 and common trisomies: A novel approach to understand Down syndrome and gene dosage effects in aneuploidies.** G. Stamoulis<sup>1</sup>, F. Santoni<sup>2</sup>, P. Makrythanassis<sup>2</sup>, A. Letourneau<sup>1</sup>, M. Guipponi<sup>2</sup>, M. Garier<sup>1</sup>, N. Panouis<sup>1</sup>, D. Popovic<sup>1</sup>, L. Pelkmans<sup>4</sup>, E. Falconnet<sup>1</sup>, P. Ribaux<sup>1</sup>, C. Borel<sup>1</sup>, S.E. Antonarakis<sup>1,2,3</sup>. 1) University of Geneva, Geneva, Switzerland; 2) Geneva University Hospitals-HUG; 3) iGE3 Institute of Genetics and Genomics of Geneva; 4) University of Zurich, Zurich, Switzerland.

Trisomy 21 (T21), is a model disorder of altered gene expression. We have previously used monozygotic-twins discordant for T21 to study the dysregulation of gene expression, (*Nature*:508;345-350;2014). The majority of previous studies on aneuploidies were conducted on cell-populations or tissues. Studies on gene and allelic-expression of single-cells (SC) may reveal important biological insights regarding the cellular impact of aneuploidy elucidating the fundamental mechanisms of gene dosage. We have studied the allele-specific-expression (ASE) from RNAseq of ~1000 single-cell fibroblasts in different aneuploidies: 352 SC (172 Normal-179 T21 cells) from the pair of monozygotic-twins discordant for T21, 166 from a mosaicT21, 176 mosaicT18, 151 mosaicT8, and 146 from mosaicT13. In the monozygotic-twins, a considerable number of observations for heterozygous sites genome-wide were expressed monoallelically (Normal:73.5%-564,668 observations, and T21:78.7%-549,799 observations). There was considerable monoallelic-expression for chromosome 21 sites in Normal and, surprisingly, in T21 cells as well (Normal:63.3%-5,009 observations, T21:72.8%-6,456 observations). We classified chr21 genes in three classes according to the level of the aggregate monoallelic-expression of their corresponding sites (9-monoallelic, 29-intermediate, 2-biallelic). We hypothesize that each class of genes contributes in a specific way to the phenotypic variability of Down-Syndrome (DS). Similar results, (i.e. extensive monoallelic-expression of genes on the supernumerary chromosomes), were also observed in the other aneuploidies. Our analysis demonstrated that, for genes with monoallelic-expression, the altered gene dosage induced by the aneuploid chromosome is due to a higher fraction of cells expressing the gene on the supernumerary chromosome. This difference in the fraction of expressing cells could contribute to the development and variability of phenotypes in aneuploidies. Indicatively, the fold difference between Trisomic and Normal and cells T/N regarding the fraction of cells which express the monoallelic genes ranging from 1.2-1.6 fold in trisomies studied. This finding was also supported by sm-RNA-FISH showing higher fraction of expressed cells for specific monoallelic genes in the trisomic group compared to the normal. This study provides a new fundamental understanding of gene dosage effects in aneuploidies and propose a new gene dosage imbalance mechanism in trisomies.

**A sequential screening strategy for efficient rare gene discovery in small families.** X.Z. Liu<sup>1,2</sup>, S. Blanton<sup>1,2</sup>, M. Tekin<sup>1,2</sup>, D. Yan<sup>1</sup>. 1) Otolaryngology, University of Miami Miller School of Medicine, Miami, FL; 2) Dr. John T. Macdonald Department of Human Genetics and John T. Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL 33136, USA.

The extreme heterogeneity of nonsyndromic sensorineural hearing loss (NSHL) makes serial sequencing approaches unfavorable in terms of efficiency and cost. However, the discovery that genes at only a few loci account for a major component of human deafness in most populations suggested that sequential screening of probands in multiplex sibships for mutations would be a cost effective strategy. Although next-generation sequencing (NGS) has expedited the discovery of genetic variants, the large number of variants naturally present in each individual makes it challenging to pinpoint the causative mutations. We aim to identify the genetic cause of NSHL through an integrated paradigm combining microarray, copy number variations (CNVs) analysis, whole exome sequencing (WES) and whole genome sequencing (WGS), and a hearing-centric database. We are using a DNA microarray panel (Miami-CapitalBio) as the initial screening to simultaneously detect the most common deafness-causative mutations in four genes in MiamiOtoGenetic repository (*GJB2*, *GJB6*, *SLC26A4* and 12S rRNA). Samples are also subjected to a custom capture/ NGS gene panel (MiamiOtoGenes) composed of 180 known deafness genes. Patients who screen negative with both panels undergo WES for detection of single-nucleotide variants (SNVs), insertion/deletions (Indels) and CNVs. Genesis 2.0 (<https://www.genesis-app.com/>) is used for data analysis. Computational functional prediction algorithms and conservation scores are also applied. Causative mutations are stored in our HL Genotype Database, GeneHeal. In this study we performed WES on five families that screened negative on both panels. Approximately, 92,000 SNVs and 9,206 INDELS per sample were obtained before variant filtering. Coverage of targeted exons for >10 reads ranged from 90.3% to 93.5% and >20 reads from 80% to 83.5%. With our filtering strategy, we have rapidly identified homozygous and heterozygous variants in the five families presenting with autosomal recessive and dominant NSHL, respectively. Sanger sequencing confirmed co-segregation of the variants with the disease phenotype in each family. We have identified several novel NSHL genes. Our study shows that the integrated screening strategy is an efficient approach to rare HL gene discovery in small families not suitable for linkage analysis. If variants are not found in the genes included on Miami-CapitalBio and MiamiOtoGenes, WES should be considered in small multiplex families.

**398T**

**Using a combined approach of comparative genomic analysis, luciferase assay and CRISPR/Cas9 to identify and characterize cis-regulatory elements in the critical region of the 9p deletion syndrome.** X. Hauge<sup>1</sup>, D. Fortech-ngochi<sup>1</sup>, J. Sloan<sup>2</sup>, K. Traver<sup>3</sup>. 1) Dept. of Molecular and Cellular Biology, Kennesaw State University, Kennesaw, GA; 2) EGL Genetics Eurofins Clinical Diagnostics, Tucker, GA; 3) Oncology Cytogenetics, Emory University School of Medicine, Atlanta, GA.

Deletions of the terminal region of the short arm of chromosome 9 are associated with trigonocephaly, dysmorphic facial features and mental retardation. The deletion of Cerberus 1 (*CER1*) gene located at 14.7 Mb from the 9p terminus has been postulated as the cause of trigonocephaly. However, several independent studies showed that patients with typical 9p deletion phenotype possess smaller than 12.4 Mb deletions. Therefore, these patients have two, intact copies of the *CER1* gene. It raises the possibility that cis-regulatory elements for the *CER1* gene could be located in the first 12.4 Mb region of 9p. Our group has previously identified 8 conserved non coding sequences in the deletion breakpoint region between 10 Mb and 12.4 Mb of 9p. We tested the regulatory activity of these sequences in dual luciferase assays. Of these, we found a strong enhancer element 5008 and a strong repressor 3362. Enhancer element 5008 showed a cell-type specific activity. It increased the luciferase activity 14 fold in a human mesenchymal progenitor cell line derived from H9 hESCs as compared to a 3.5-fold increase of the luciferase activity in the HEK293T cells. We also detected an increase in the *CER1* gene expression in the mesenchymal progenitor cell line after the treatment with osteogenic differentiating medium. We utilized *S. aureus* Cas9 and 4 guide RNAs to excise the enhancer element 5008. We obtained 4 different constructs with deletions ranging from 500 bp to 2000 bp, which correspond to the core DNA sequence of the enhancer element 5008 and the surrounding genomic region, respectively. Screening of the transfected human cell lines is in progress, including the human mesenchymal progenitor cells. In addition, we are planning to investigate the effect of allelic deletion of the enhancer element 5008 on the *CER1* gene expression. In summary, we integrated comparative genomic analysis, the dual luciferase assay, and CRISPR/Cas 9 technology to investigate the genetic mechanism of the key phenotype of the 9p deletion syndrome.

**Trisomy 21 and chromatin.** S.E. Antonarakis<sup>1</sup>, F. Bezrukov<sup>1</sup>, C. Borel<sup>1</sup>, O. Delaneau<sup>1</sup>, B. Ren<sup>2</sup>, SysGenetiX project consortium. 1) Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) Ludwig Institute for Cancer Research, UCSD School of Medicine, CA, USA.

We hypothesize that the presence of a supernumerary ~45 Mb chromosome 21 may substantially disturb the chromatin structure, so that some of the phenotypes of Down Syndrome may result from this disturbance. Our previous study using monozygotic twins discordant for Trisomy 21 (T21) has shown genome-wide dysregulation of gene expression that is organized in large genomic domains (GEDDs Gene Expression Dysregulation Domains, Letourneau et al Nature 2014). Here we use *insitu* Hi-C experiments to study the chromatin interactions in T21 versus normal, using fibroblasts from the pair of discordant monozygotic twins and 4 additional samples (3 T21 and 1 N). These experiments indicated: i/ there is no difference in the TAD structure in T21 suggesting that the short range regulation is unchanged; ii/ there is considerable quantitative difference of long range chromatin interactions within a chromosome (interchromosomal interactions) seen in the samples from the twins; iii/ There are more transchromosomal interactions with chromosome 21 sequences as expected; moreover the intensity of interactions of chromosome 21 (particularly the distal half of the long arm) with the other chromosomes follows a pattern that is compatible with the GEDDs. Remarkably there is an inverse correlation between the strength of transchromosomal contacts of chromosome 21 with the fold difference of gene expression T21/N (rho 0.4). We conclude that the chromatin interaction differences due to the extra chromosome 21 may mediate the genomewide expression differences in T21. Using data from 320 LCL and 80 fibroblasts from normal individuals (genome variants, gene expression, ChIP-seq for H3K27ac, H3K4me1 & H3K4me3) as part of the SysGenetiX project we were able to identify Chromatin Regulatory Domains (CRD) on chromosome 21. These CRDs largely correspond to TADs and could be interpreted as the functional chromatin domains as opposed to the structural domains represented by TADs. The transchromosomal interactions of CRDs are currently under investigation in order to further understand the functional disturbances of the chromatin due to the presence of an additional unbalanced genomic material as the whole chromosome 21.

**A comprehensive portrait of human somatic mosaicism.** S. Vattathil<sup>1,2</sup>, J.M. Akey<sup>1,2</sup>. 1) Dept. of Ecology and Evolutionary Biology, Princeton University, Princeton, NJ; 2) Lewis Sigler Institute for Integrative Genomics, Princeton University, Princeton, NJ.

An adult human body contains on the order of  $10^{15}$  cells, all of which can be traced back to a single zygote. The large number of cell divisions that occur during an individual's lifetime provides many opportunities for somatic mutations to arise and accumulate. Somatic mutations have been found to drive many forms of cancer, play an important role in ageing phenotypes, and contribute to an increasingly large catalog of human diseases. Theoretical and empirical studies suggest that the burden of somatic mutation in humans is high, but few systematic and comprehensive studies have been conducted to date to characterize human somatic variability in apparently healthy individuals. To address this question, as part of the enhanced Genes, Tissues, and Expression (eGTEx) Project, we generated high-coverage (>150x) exome sequence data from 14 individuals sampled for a median of 18 tissues (ranging from 11 to 32 tissues per subject). We developed a novel mixed model framework to take advantage of the unique data structure to jointly call variants across tissues from the same subject. The multi-tissue sampling design also allows us to infer the developmental timing of mutations and compare somatic mutation profiles across tissue types. We also leveraged our data to characterize large somatic chromosomal imbalances (deletions, duplications, and copy-neutral loss of heterozygosity), and assess the relationship between the burden of somatic mutations and covariates such as age and sex. Collectively, our data provides substantial new insights into the landscape and determinants of human somatic variability, and we anticipate that our comprehensive catalog of somatic mutations will enable new insights into development, mutational processes and mechanisms, and provide guidance for interpreting mutations observed in cancer samples.

**The commitment complex *in vivo* over long intron genes.** *Y. Leader, G. Lev Maor, G. Ast.* Department of Human Molecular Genetics & Biochemis, Tel Aviv University, Tel Aviv, Israel.

The first and critical step in mRNA splicing is identification of the two splice sites delimiting an intron and bring them into proximity – termed the commitment complex. Within the commitment complex U1 small nuclear ribonucleo-protein particle (snRNP) binds the 5' splice site and form a protein bridge with U2AF65 (also called U2AF2) that binds the 3' end of that intron. Although the commitment complex was study extensively *in vitro*, how the same pairing occurs *in vivo* for splice sites separated by long introns (>400 bases) is still obscure. Our laboratory proposed a new model, suggesting a dynamic pairing between the two splice sites involving interplay of RNA polymerase II (RNAPII), splicing factors and chromatin organization. We propose that U1 snRNP and U2AF65, associate with the CTD of RNAP II when that travels from one end of an intron downstream. We propose that U1 binds to 5' splice site while being associates to the CTD of RNAPII. When the 3' end of the intron is synthesize, U2AF65 binds the 3' splice site and the commitment complex is formed. In my research I will examine the validity of this model. I already demonstrated that *in vivo* U1 and U2AF65 are associated with RNAPII when the polymerase is in the elongating and pausing phases. I will further explore how the interaction of U1 and U2AF65 with RNAPII facilitate the formation of the commitment complex using CRISPR method.

**Exon-intron architecture in high and low GC-content genes affects alternative splicing.** *L. Tamer, A. Savchinko, D. Dollander, G. Ast.* Human Molecular Genetics & Biochemistry, Tel Aviv University, Haim Lebanon 30, Tel Aviv 6997801, Israel.

The splicing machinery recognizes exons and introns by using multiple signals. Two splicing signals that delineate proper exon-intron boundaries are the 5' and 3' splice sites. Alternative splicing is a major mechanism that enhances transcriptomic diversity. Our previous studies revealed that gene architecture had evolved from an ancestral state of low GC-content, in exons flanked by short introns of lower GC-content. One group of genes maintained the low GC-content and their introns became longer. In another group mutations accumulated, leading to elevation of the GC-content, which revoked the differential GC-content between exons and introns. In this group introns are under selection to remain short. Our research hypothesis is that the splicing machinery selects exons and introns differently between the two groups of exon-intron architecture. This hypothesis is based on my lab's previous findings that exon skipping predominantly associates with the low GC-content genes and intron retention with the higher GC-content genes. To examine this hypothesis we reduced the affinity of the splicing machinery to the 5' splice-site using site-specific mutations. According to the results we concluded that the splicing machinery recognizes the exons and introns of the two GC-content gene groups differently. Also, our bioinformatics analysis revealed that the high GC-content genes harbor an even higher GC content region downstream of the 5' splice-site. we examined the functionality of that sequence by replacing it with even higher or lower GC-content segments. Our results show that this region is important for the inclusion of the upstream exon. Furthermore, we checked how the splicing machinery can switch between intron definition and exon definition through the formation of exon-intron differential GC-content. And how intron lengthening impacts intron definition in high GC-content genes. Overall, our research shed light on genomic elements that contribute to the diversity in splicing recognition units in the high and low GC-content families.

**Chitinases mRNA levels quantified by qPCR in crab-eating monkey tissues.** M. Uehara, E. Tabata, M. Ohno, M. Sakaguchi, F. Oyama. Department of Chemistry and Life Science, Kogakuin University, Hchoji, Japan.

Crab-eating monkey (*Macaca fascicularis*) is one of the most important nonhuman primate animal models in basic and applied biomedical researches. Chitin is a polymer of *N*-acetyl-D-glucosamine. Although mammals do not contain endogenous chitin, mammals express two active chitinases, acidic mammalian chitinase (AMCase) and chitotriosidase (CHIT1). Because the level of expression of these chitinases is increased in many inflammatory conditions including Gaucher disease and mouse models of asthma, both chitinases may play important roles in the pathophysiological conditions. Here, we performed gene expression analysis of crab-eating monkey chitinases by quantitative real-time PCR (qPCR) using a single standard DNA molecule to quantify the expression levels of chitinases and reference genes. Our analysis showed that AMCase mRNA was expressed at exceptionally high level in the stomach than other tissues, whereas CHIT1 mRNA was predominantly expressed in the lung.

**404T**

**Comparison of chitinolytic activities among mammalian chitinases and bacterial chitinase.** M. Kimura, T. Umeyama, S. Wakita, K. Okawa, M. Sakaguchi, F. Oyama. Department of Chemistry and Life Science, Kogakuin University, Hachioji, Tokyo 192-0015, Japan.

Humans and mice express two active chitinases, chitotriosidase (Chit1) and acidic mammalian chitinase (AMCase). Chit1 and AMCase have attracted considerable attentions due to their increased expression in individuals with different pathological conditions. Chit1 is increased in individuals with Gaucher disease, chronic obstructive pulmonary disease (COPD) and Alzheimer's disease. AMCase expression and activity are also upregulated during allergic airway responses in mouse models of asthma. In addition, polymeric chitin induces the AMCase expression and the recruitment of immune cells associated with allergy and asthma. These results strongly suggest that chitinolytic enzymes play important roles in many pathophysiological conditions. In this study, we clarify the functional differences between the mammalian chitinase. Furthermore, their functions were compared with *Serratia marcescens* chitinase B (Sm\_ChiB) which is a well-studied bacterial chitinase and structurally similar to the mammalian chitinases. AMCase possesses maximal activity at pH 2.0, whereas Chit1 and Sm\_ChiB exhibit at around pH 5.0. AMCase had the highest activity at around pH 2.0 among tested enzymes. At pH 5.0-7.0 Sm\_ChiB showed higher activity, followed by Chit1 and AMCase. Our results indicate that mammalian chitinase can function under various pH conditions and possess similar chitinolytic activity comparable to bacterial chitinase.

**Revisiting the mouse reference genome: Single molecule sequencing of C57BL/6J “Eve”.** A. Srivastava<sup>1</sup>, V.K. Sarsani<sup>1</sup>, I. Fiddes<sup>2</sup>, V.A. Schneider<sup>3</sup>, L.G. Reinholdt<sup>1</sup>. 1) The Jackson Laboratory, Bar Harbor, ME; 2) University of California, Santa Cruz, Santa Cruz, CA; 3) DHHS/NIH/NLM/NCBI, 45 Center Drive-Natcher Bldg, Bethesda, MD.

The mouse reference genome, GRCm38, represents the most widely used inbred laboratory mouse strain, C57BL/6J; a strain that is maintained and distributed by The Jackson Laboratory. The currently available C57BL/6J mice sourced from the The Jackson Laboratory source are up to 26 inbreeding generations removed from the samples used to generate the mouse reference genome. Moreover, the strain is now maintained through periodic reintroduction of mice from cryopreserved embryo stock, a husbandry practice that is designed to maximize genetic homogeneity by effectively limiting the number of inbreeding generations over time. The embryo stock is derived from a single breeder pair, named C57BL/6J Adam and Eve. This genetic divergence explains a sub-set of true positive variants that are found when comparing currently available C57BL/6J genomes to the mouse reference genome. Additionally, while GRCm38 is one of the highest quality and well-characterized published mammalian genome assemblies, it has some features that may contribute to increased false positive rates in variant discovery. There are 187 gaps and 211 problematic regions reported by Genome Research Consortium in Mouse Genome Build 38, patch 5 and the genome does not represent a single individual. To better represent C57BL/6J mice that are currently in use by the research community and to understand/resolve the problematic regions in the existing reference genome, we have generated a whole genome de novo assembly of C57BL/6J Eve using ~60X PacBio single molecule sequencing and optical map data generated from Bionano Genomics platform. This hybrid assembly approach yielded 12,690 scaffolds with N50 scaffold size of 1.5MB and went under comprehensive annotation using comparative annotation toolkit from UCSC. Using this data, we resolved 1,788 repeats in reference genome and corrected 134 recurring C57BL/6J exome variants. Further, we were able to find the B6Eve scaffolds that span four of the reported gaps completely and span seven gaps partially, implying the utility, albeit limited, of gap closures with our assembly. Finally, with the help of PacBio brain transcriptome (Iso-Seq data) of mouse and assembled B6Eve genome, we were able to identify novel isoforms of two important mouse genes. This B6Eve assembly will provide an extremely useful resource to scientific community working with C57BL6/J mouse in genomics research as well as genetic engineering/mouse model development.

**Heat regulation of germ cell transcriptome: A bid to identify novel targets for contraception.** A. Pandey, S.K. Yadav, L. Kumar, R. Vishvkarma, J.P. Maikhuri, R. Singh, G. Gupta. Endocrinology, CSIR-Central Drug Research Institute, Lucknow, India.

Mammalian spermatogenesis is extremely sensitive to body temperature and fails rapidly; but occurs normally at 3-6°C lower temperature. The scrotum is nature's uniquely designed organ to maintain testes at a lower temperature than the body. Cryptorchidism (abdominal testes) is a common congenital abnormality affecting 1-5% of full-term male births and is a risk factor for sub-fertility. Limited clinical studies have reported that transient testicular heating of adult human males results in reversible spermatogenic arrest, hence could be used as a method of contraception. The spermatogenesis is regulated at transcriptional, post-transcriptional, and epigenetic levels by the integrated expressions of an array of testicular genes in a precise temporal sequence. The meiotic (pachytene/diplotene spermatocytes) and post-meiotic (round spermatids) germ cell types are most vulnerable to testicular heating. The heat sensitive changes in germ cell transcriptome reflecting early changes in these cells, if known, could identify novel targets that could be exploited to achieve 'molecular heating' in testis leading to contraception. We have employed centrifugal elutriation to isolate >90% pure germ cells from normal and surgically-cryptorchid rat testis, and NGS technology to analyse their transcriptome and miRNA profile. Some significant changes have been noted in genes of different biological processes like metabolism (*MCT2*, *MCT4*, *Glut3*, *LDHc*), lipid biogenesis (*Acly*), ROS and Ca<sup>2+</sup> signaling (*Daxx*, *Camk2d*), and apoptosis (*Daxx*), that were further validated by RT-PCR. Functional validation studies would reveal their application in transient arrest of spermatogenesis for contraception.

**Breakpoint analysis of chromosomes having inverted duplication with terminal deletion by NGS.** H. Inagaki<sup>1,2</sup>, K. Kanyama<sup>1</sup>, T. Kato<sup>1</sup>, Y. Uchi<sup>1,2</sup>, T. Yamamoto<sup>3</sup>, H. Kurahashi<sup>1,2</sup>. 1) Division of Molecular Genetics, ICMS, Fujita Health University, Toyoake, Aichi, Japan; 2) Genome and Transcriptome Analysis Center, Fujita Health University, Toyoake, Aichi, Japan; 3) Institute of Medical Genetics, Tokyo Women's Medical University, Shinjuku, Tokyo, Japan.

Inverted duplication with terminal deletion (inv dup del) is one of the complex constitutional structural variations of chromosomes. The most frequent inv dup del known to date is located at 8p. In 8p inv dup del, a non-allelic homologous recombination (NAHR) between segmental duplications in inverted orientation produces a dicentric chromosome, and it induces breakage between the two centromeres during mitotic division. In this study, we investigated other types of inv dup dels as well as inverted triplication with terminal deletions (inv trip dels) of 4p, 9p, 10q, 11q, 18p and 21q to find a common mechanism by using cytogenetic microarray and whole genome sequencing techniques. By means of mate pair libraries of approximately 9 kb in average, we identified the fusion structures of breakpoint regions by NGS. Although complete palindromic structures at the center of the inverted duplications had been predicted, the whole genome sequencing data showed asymmetric spacer region with several thousand bps in size in all cases. Sequencing of these regions by PCR amplification reveals the size of the spacer was from 1744 to 3547 bp. The junctions appeared to utilize microhomology. This structure could be generated in two possible mechanisms: formation of complete palindromic sequence at the breakpoint of dicentric chromosome, followed by the deletion of the central region due to instability of the palindromic sequences in living cells, or formation of dicentric chromosome with asymmetrical inverted breakpoint regions with several thousand bp gaps. Possibility of replication-based mechanism generating the similar deletion sizes around 2 kb is discussed.

**408F**

**MethylHiC reveals long-range genetic-epigenetic and epigenetic-epigenetic interactions within the same single molecule.** Y. Liu<sup>1,2</sup>, G. Li<sup>3</sup>, B. Ren<sup>2,4</sup>, M. Kellis<sup>1,2</sup>. 1) CSAIL, MIT, Cambridge, MA; 2) The Broad Institute of MIT and Harvard, Cambridge, MA; 3) Ludwig Institute for Cancer Research, La Jolla, CA; 4) Department of Cellular and Molecular Medicine, School of Medicine, University of California San Diego, La Jolla, CA.

DNA methylation is the most extensively studied epigenetic marker that plays direct role in mammalian gene regulation, such as gene silencing and imprinting. Recent studies on allelic specific methylation (ASM) have revealed the direct effect of genetic variants on DNA methylation at local region. Association studies of methylation quantitative trait loci (meQTLs) further suggest the genetic variants may influence DNA methylation level across large genomic intervals. Epigenetic gene silencing and activation has also long been envisaged as a local event. Very recent investigations indicate that large regions of chromosomes can be co-coordinately suppressed or activated. The direct genome wide experimental approach to explore the long-range genetic-epigenetic and epigenetic-epigenetic interactions, however, is limited especially for the current whole genome bisulfite sequencing (WGBS) based on short reads platform. Long read sequencing technology (SMRT or MinION) may potentially reveal DNA methylation coordination in longer region, but the distance is still limited at kilobases level. Chromosome Conformation Capture followed by massively parallel sequencing (Hi-C) provides long-range interaction between regulatory elements and linear organization of genome sequences along the entire chromosomes that had been used to assemble haplotype. Here, we developed MethylHiC, which applies *in situ* Hi-C followed by bisulfite treatment to understand the long-range genetic-epigenetic and epigenetic-epigenetic interactions within the same single DNA molecule. First, we validated that MethylHiC is globally consistent with both of *in situ* Hi-C and WGBS data generated from the same cell line. Second, we found that DNA methylation is highly concordant at distal interacted regulatory regions within the same DNA molecule. The concordance level varies and shows different patterns between regions at different chromatin states. We also detected long-range allelic specific methylation for the first time. Further, we showed that these long-range genetic-epigenetic and epigenetic-epigenetic interactions can be disrupted by Ten-eleven Translocation (TET) knockout. Moreover, by incorporating additional DNA methylation concordance information into the analysis, we can largely improve the Hi-C resolution. Our method here paves the road to evaluate the direct long-range effect of genetic and epigenetic alterations at different pathological conditions within the same DNA molecule.

**Complementary long and short-read sequencing techniques identify rearrangement structures and concurrent single nucleotide variant formation on chromosome 17p11.2.** C.R. Beck<sup>1</sup>, C.M.B. Carvalho<sup>1</sup>, Z.C. Akdemir<sup>1</sup>, Z. Chong<sup>2</sup>, E.S. Chen<sup>1</sup>, P.C. Thornton<sup>1</sup>, P. Liu<sup>1</sup>, B. Yuan<sup>1</sup>, M. Withers<sup>1</sup>, S.N. Jhangiani<sup>3</sup>, A.C. English<sup>3</sup>, D.M. Muzny<sup>4</sup>, R.A. Gibbs<sup>5</sup>, C.A. Shaw<sup>1</sup>, P.J. Hastings<sup>1,6</sup>, J.R. Lupski<sup>1,3,4,5,6</sup>. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Genetics and the Informatics Institute, the University of Alabama at Birmingham, Birmingham, AL; 3) Human Genome Sequencing Center, BCM, Houston, TX; 4) Department of Pediatrics, BCM, Houston, TX; 5) Texas Children's Hospital, Houston, TX; 6) Dan L Duncan Comprehensive Cancer Center, BCM, Houston, TX.

A majority of Smith-Magenis Syndrome (SMS MIM #182290) and Potocki-Lupski Syndrome (PTLS MIM #610883) patients have *de novo* deletion or duplication of chromosome 17p11.2, respectively. These copy number variants (CNVs) affect the dosage-sensitive gene *RAI1*. Approximately 80% of rearrangements at this locus are due to recurrent non-allelic homologous recombination events between low copy repeats (LCRs) leading to 3.7Mb CNV, and ~15% of the deletions and duplications are non-recurrent. Repeats comprise almost a quarter of 17p, and ~60% of non-recurrent 17p11.2 rearrangements contain one breakpoint in an LCR, making characterization of breakpoint junctions a challenge. Further complexities at non-recurrent CNV junctions such as inversions and/or evidence for additional template switches (TS) and single nucleotide variants (SNVs) that can accompany complex genomic rearrangements formed by replicative repair (e.g. FoSTeS/MMBIR) necessitate comprehensive molecular and genomic analyses of individual rearrangements. To gain mechanistic insights into the formation of rearrangements at 17p11.2, we combined array comparative genomic hybridization (aCGH) with a targeted 7Mb Illumina and Pacific Biosciences SMRT sequencing approach. Preliminary data from 19 subjects with non-recurrent rearrangements identified junctions in 16 cases and found complexities not seen by high-density aCGH. Additionally, 32 *de novo* SNVs were revealed within the 7Mb capture region; only one would have been identified by breakpoint PCR. This yields a mutation rate of  $2.4 \times 10^{-7}$  or 10-fold higher when compared to the intergenerational germline spontaneous *de novo* rate ( $\sim 2 \times 10^{-8}$ /bp/generation). Whole exome sequencing of the 19 trios underscored the association of the CNV with the *de novo* point mutations, as SNV mutation rates were not globally higher. The majority (~70%) of observed SNVs were transversion substitutions and ranged from 202bp to ~1.1Mb away from the nearest junction. Our findings are consistent with the use of an error prone polymerase with reduced fidelity and processivity (reflected by iterative TS at the breakpoint junction) that switches to a more processive polymerase with greater fidelity as the replisome proceeds. These data show that complementary approaches can resolve rearrangements in complex genomic regions, identify point mutations far from breakpoint junctions, and indicate a higher local mutation rate accompanying CNV as predicted for replication-based mechanisms.

**Method for deciding detection limit of droplet digital PCR for rare mutations.** T. Takahashi, M. Umekage, M. Nomura, T. Hanatani, H. Dohi, Y. Sato, N. Takasu, N. Amano. Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan.

In order to ensure safety of induced pluripotent stem cells (iPSCs) and differentiated cells, we are investigating droplet digital PCR (ddPCR) to assess the quantity for rare mutations. Especially, we are checking cancer related mutations in the following two gene lists, cosmic census gene list and Japan pharmaceuticals and medical devices agency (PMDA) gene list for medical application of iPSCs. In this study, we discussed how to decide a detection limit of rare mutant allele frequencies when false positive droplets were detected using ddPCR. The iPSCs were differentiated, cultured and evaluated a certain mutation in the differentiated cells. As the result, the mutant allele frequencies of the differentiated cells and negative control were 0.41% and 0.27%, respectively. We faced an issue to determine whether the 0.41% was noise or not. To solve this problem, we decided the detection limit of this mutation by considering dilution series of positive samples and three independent negative samples. The droplet counts of the three negative samples were merged and adjusted using Poisson statistics. We conducted the experiments 3 times, and decided the detection limit using the averages and standard deviations. The detection limit was 0.5% for the specific probe. We concluded the allele frequency 0.41% of the differentiated cells was lower than the detection limit of this mutation. In addition, we repeatedly measured 10 times, and confirmed that all measurements of the differentiated cells were below the detection limit. In the near future, we will successfully apply ddPCR to measure rare structure variant and mosaic for medical application of iPSC and differentiated cells.

**Targeted next-generation sequencing for identifying genes related to horse temperament.** S. Song<sup>1</sup>, D. Oh<sup>2</sup>, G. Cho<sup>3</sup>, D. Kim<sup>4</sup>, Y. Park<sup>5</sup>, K. Han<sup>1</sup>.

1) Nanobiomedical science, Dankook University, Cheonan, South Korea; 2) Livestock Research institute, Gyeongsangbuk-Do, Yeongju, South Korea; 3) College of Veterinary Medicine, Kyungpook National University, Daegu, South Korea; 4) Department of Anesthesiology and Pain Management, College of Medicine, Dankook University, Cheonan, South Korea; 5) Department of Equine Industry, Korea National College of Agriculture and Fisheries, South Korea.

It is a fundamental challenge to discover the association of genetic traits with phenotypic traits. In this study, we aimed to identify possible genetic traits related to horse temperament. Based on previous findings, we selected 71 candidate genes related to temperamental trait and examined them in the human and horse reference genomes (hg38 and equCab2, respectively). We found 16 orthologous genes and, by comparing with the human reference genome, 17 homologous genes in the horse reference genome. We designed probes specific for the 33 horse genes. Using the probes, we built sequencing libraries of the genomic DNA samples from 8 aggressive and 8 docile horses, and sequenced the constructed libraries using the Illumina HiSeq2500 platform. Through the analysis of the targeted exome sequences, we identified single nucleotide polymorphisms (SNPs) in the genes. SNPs could be served as genetic markers to evaluate aggressive or docile levels of horses. To examine whether any genetic variants are associated with horse temperament, we performed genome-wide association study (GWAS) using the SNP data. GWAS analysis identified 10 variants ( $p$ -value  $< 0.05$ ) which could be related to horse temperament. We validated the variants using Sanger sequencing. The most significant variants were found in *MAOA* (c.1164+41T>C) and *AR* (c.1047+27G>T) genes with  $8.09 \times 10^{-4}$   $p$ -value. We suggest that the variants might be used to assess horse temperament and to determine superior horses for riding or racing.

**Cross-tissue protein expression and genetic regulation of transcription factors and cell signaling genes in enhancing Genotype-Tissue Expression (eGTEX) samples.** M. Oliva<sup>1,2</sup>, M. Fernando<sup>1,2</sup>, F. Wu<sup>1,2</sup>, C. Linke<sup>1,2</sup>, A.D. Skol<sup>1,2,3</sup>, B.E. Stranger<sup>1,2,3</sup>, Genotype-Tissue Expression (GTEX) Consortium. 1) Section of Genetic Medicine, Department of Medicine, University of Chicago, IL; 2) The Institute for Genomics and Systems Biology, University of Chicago, IL; 3) Center for Data Intensive Science, University of Chicago, IL.

The human transcriptome has been studied extensively but investigations of the proteome have been limited by the lack of robust technologies for large-scale protein quantification. However, the proteome comprises a vital element in the causal network linking genetic variation to higher order organismal phenotypes. As part of the enhancing Genotype-Tissue Expression program (eGTEX), in which additional -omics assays are performed on human tissue samples that have been deeply characterized at the transcriptomic and genetic level, we aim to quantify the cross-tissue protein expression levels within and between GTEX tissues and to characterize the effect of genetic variation on protein expression in humans. We have adapted microwestern arrays to quantify the expression of 353 transcription factors (TFs) and cell signaling proteins in 203 GTEX samples of 33 tissues from 14 individuals. Tissue clustering profile derived from the protein expression data recapitulates tissue similarity relationships derived from transcriptome data. Relative protein abundance levels reveal strong tissue specificity: proteins are expressed in a tissue-enriched (39%) or -enhanced (36%) manner. Brain, muscle and skin are enriched for tissue-specific TFs relative to other tissues. For the majority of the proteins assayed, cross-tissue protein and mRNA abundances do not correlate, possibly indicating buffering or a "translation on demand" mechanism. We observe a subset of proteins (e.g. ZNF35, HMGXB4, SHPRH) that are strongly anti-correlated with mRNA levels, suggesting negative feedback regulation. We are quantifying the same 353 proteins in N=165-192 samples from ten GTEX tissues to better characterize the protein expression landscape, assess the genetic basis of protein expression variation and build protein-mRNA regulatory networks. We have quantified this set of proteins in 174 skeletal muscle GTEX samples and have characterized local and distal protein expression quantitative trait loci (cis- and trans- pQTLs). Preliminary results indicate that mRNA-protein correlations within tissues are weak and cis-pQTLs are both less prevalent and have significantly smaller effect sizes compared to cis-eQTLs, suggesting cellular mechanisms that buffer the effects that genetic variation exerts at a transcript level. In addition, a fraction of significant cis-pQTLs are not eQTLs, suggesting genetic effects on post-transcriptional regulation.

**Hanwoo-specific structural variations generate genomic diversity in the cattle genome.** *J. Park, W. Shin, S. Mun, K. Han.* Nanobiomedical science, Dankook university, Cheonan, South Korea.

The total length of the bovine genome is approximately three billion base pairs, which has been containing 29 autosomes and sex chromosomes. Among them, as much as about a half of the bovine genome (~46%) is composed of transposable elements (TEs). TE insertions directly affect host genome diversity caused by the structural variations. In addition, they can change the gene expression and function related to nearby their regions. Therefore, it is generally believed to be difference of the interspecies properties in details. We anticipate that TE-mediated insertion and deletion (INDEL) has a strong influence on the bovine genome to geographic speciation since the divergence of Korean native cattle (Hanwoo) and other cattle species. We investigated TE-mediated INDELS by comparing *Bos taurus* (UMD3.1.1, Reference), Jersey, Holstein, Angus, and Hanwoo whole genome data, respectively. Among them, we collected the Hanwoo-specific TE-mediated INDEL candidates through a bioinformatics approach. To make certain the structural variations in the Hanwoo genome, we conducted the amplification of targeted-sites for Sanger sequencing and comparatively analyzed the sequencing data. In this study, we found the Hanwoo-specific TE-mediated INDEL regions and inspected how to make structural changes related to TE in the Hanwoo genome. In addition, we suggest that Hanwoo-specific TE-mediated INDELS could be helpful to understand the genomic variations and the species differentiation in the bovine genome as well as in Hanwoo genome.

**Study of G2 phase cell cycle arrest and its application in mediating SOX9 mutagenesis in pluripotent stem cells (PSCs).** *T.Y. Ha, H.H. Cheung, W.Y. Chan.* School of Biomedical Sciences, Faculty of Medicine, the Chinese University of Hong Kong, Shatin, N.T., Hong Kong SAR.

Pluripotent Stem Cells (PSCs) have been widely used to study early developmental events, together with genome engineering techniques such as CRISPR/Cas9. However, mutagenesis is a challenging task since both DNA repair pathways, Homology Directed Repair (HDR) and Non-homologous End Joining (NHEJ) have their own limitations. HDR, although regarded as a precise repair mechanism, has extremely low efficiency in PSCs. On the other hand, NHEJ is an error-prone mechanism which generates insertion-and-deletions (indels) and in-frame mutations, which may lead to formation of inactive proteins. Between these two pathways, HDR, although being inefficient, is the preferred DNA repair pathway for PSCs. In the search for methods to increase HDR efficiency, several groups suggested that HDR efficiency could be increased by synchronization of G2/M phase in cell cycle. Nonetheless, optimizations and benchmarking of this method is required. In an attempt to increase HDR efficiency, we used siRNA against a cell cycle related gene to induce cell cycle arrest in 293T and HepG2 cells. Results showed that G2 phase arrest could be achieved in both cell lines and there is a potential to achieve similar results in pluripotent stem cells. To demonstrate in principle that the efficiency of HDR could be increased using cell cycle arrest, a GFP rescue assay in 293T cells was performed. In addition, different methods reported in literature such as using NHEJ inhibitor in PSCs will be compared with the cell cycle arrest approach proposed above. Two parameters, apoptosis and aneuploidy after manipulations of cell cycle arrest and the addition of NHEJ inhibitor will be assessed by cell cycle analysis. Moreover, to demonstrate that the method is applicable to PSCs, mutagenesis of SOX9 with CRISPR/Cas9 in PSCs will be created and HDR efficiency will be assessed. In conclusion, we propose that cell cycle arrest could be an efficient method to increase HDR efficiency. The method is applicable to PSCs in order to achieve precise genome editing and this method could be a potential application for the study of early developmental events.

**Detection of novel L1 insertions in the chimpanzee (*Pan troglodytes*) genome.** S. Lee<sup>1</sup>, W. Lee<sup>1</sup>, S. Mun<sup>1</sup>, K. Han<sup>1</sup>, W. Tang<sup>2</sup>, P. Liang<sup>2</sup>. 1) Dankook University, Cheonan, Chungnam, South Korea; 2) Brock University, St. Catharines, Ontario, Canada.

Long Interspersed Element-1 (LINE-1 or L1) is known as a most successful retrotransposon in the primate genomes and has contributed to their genome diversity and variations during the primate evolution. With complete chimpanzee genome sequencing, it was demonstrated that L1s are powerful genetic elements as well as responsible for more than 5.0 MB of genomic differences between human and chimpanzee. Thus, we here aimed to identify novel L1 insertions, which can generate genome difference between chimpanzee individuals, by using an advanced target-enrichment sequencing method and bioinformatics analysis. Targeted enrichment is an appropriate system to detect regions of interest, generally where genetic variants such as gene fusions and copy number variations occurred. First, to design the chimpanzee L1-specific probe, we collected ~2,000 chimpanzee-specific L1s from the chimpanzee reference genome (UCSC panTro5) and sorted out full-length of chimpanzee-specific L1s (> 6kb) that have conserved 5' UTR sequences. Then, the probe for sequence enrichment containing a part of chimpanzee-specific L1s was designed in the conserved region of the L1 consensus sequence. We produced family-based sequencing data with DNA samples from father, mother, and offspring chimpanzees by using target-enrichment sequencing. The results of this study suggest that L1 target-enrichment sequencing is useful to identify novel L1 insertions.

**Detection of non-reference L1 insertions in the human genome by using a target enrichment method.** W. Shin, S. Mun, K. Han. Nanobiomedical Science, Dankook University, Cheonan, South Korea.

Long interspersed element-1s (L1s) have been successfully expanding in the mammalian genomes during the evolutionary time of their genome structure. L1s are a common large family of retrotransposons which constitute ~17% of the human genome and have resided in the mammalian genomes for >150 million years. Previous studies suggested that a retrotransposition activity in the human genome and the majority of these elements have driven human genomic variations. Some of the new L1 elements have recently inserted into the human genome that are polymorphic in human individuals. A few human-specific L1s (L1Hs) have been widely known to be capable of extremely high levels of mobilizing activity and result in several human genetic diseases. Here, we describe a developed method for detecting non-reference L1 insertions using target enrichment method. We suggest the development of a NGS system that advanced an approach for detection non-reference L1 insertion in the human genome through targeted-probe method. In conclusion, we identified the candidate regions of 566 non-reference novel L1 insertions in the human genome through bioinformatics approach and targeted-sequencing. Based on a variety of analysis, we suggest that a target enrichment method is efficient for detecting specific elements such as transposable elements. Thus, our method could be useful for developing a new polymorphic genetic marker across human individuals.

**Gene expression analysis and enzyme function of pig mammalian chitinase.** *E. Tabata, A. Kashimura, S. Wakita, M. Ohno, M. Sakaguchi, Y. Sugahara, F. Oyama.* Department of Chemistry and Life Science, Kogakuin University, Hachioji, Tokyo, Japan.

Pigs are an ideal biomedical model for human diseases and conditions bridging the gaps between mouse models and humans. Chitin, a linear polymer of  $\beta$ -1, 4-linked *N*-acetyl-D-glucosamine (GlcNAc), is the second most abundant natural polysaccharide in nature and functions as a major structural component in fungi, crustaceans and insects. Although mammals do not produce chitin, humans and mice express two active chitinases. Firstly, chitotri-oxidase (Chit1) was identified in macrophages of Gaucher disease patients. Acidic mammalian chitinase (AMCase) was discovered later and has attracted substantial attention due to its expression fluctuations under certain pathological conditions such as asthma, allergic inflammation, ocular allergy, dry eye syndrome and gastric cancer. Recently we showed that mouse AMCase can function as a protease-resistant major glycosidase under the conditions of stomach and intestine. However, the physiological roles of the AMCase in other mammals remain unknown. Here, we show that AMCase mRNA was predominantly expressed in pig stomach using quantitative real-time RT-PCR system and it was much higher than that of Chit1, housekeeping genes and gastric mucosa genes. Porcine AMCase has highest chitinolytic activity at pH of around 2-4. Also, it was resistant to endogenous pepsin digestion and degraded polymeric chitin substrates under mimicking stomach condition. Our study suggests that AMCase functions as a part of the host defense against chitin-containing pathogens or as a digestive enzyme that breaks down chitin in pig stomach tissues.

**Gene expression signature as a potential treatment monitoring biomarker for active tuberculosis in Thailand.** *R. Miyahara<sup>1</sup>, N. Satproedpra<sup>2</sup>, N. Wichukchinda<sup>2</sup>, H. Yana<sup>3</sup>, L. Toyo-oka<sup>3</sup>, K. Tokunaga<sup>3</sup>, S. Mahasirimongkol<sup>3</sup>.* 1) Department of Human Genetics, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan; 2) Medical Genetics Center, Medical Life Science Institute, Department of Medical Sciences, Ministry of Public Health, Thailand; 3) Fukujiji Hospital, Japan Anti-Tuberculosis Association (JATA), Kiyose, Japan.

[Introduction] Recent research suggested that blood transcription signatures by a set of 7 genes could discriminate between the active TB patients and healthy controls. This 7 genes set is potentially useful as potential biomarkers for monitoring TB patients after their treatment. Further, we described the influence of blood cell counts on each genes expression to identify the blood cell populations influencing these genes expression in active TB patients. [Methods] 12 active TB patients confirmed by TB culture positive were invited to Chaingrai Prachanukroh Hospital in Northern Thailand and collected blood samples at enrollment, 2weeks, 2months and 6months after the TB treatment initiation. Using the whole blood samples, the gene expression levels of the 7 genes (*FCGR1A*, *FCGR1B* variant1, *FCGR1B* variant2, *APOL1*, *GBP5*, *STAT1* and *KCNJ15*) and 2 novel candidates (*MAFB* and *KAZN*) were measured by real-time PCR. The number of each types of white blood cell was counted by standard flowcytometry. The gene expression levels were compared at two time points (first visit vs 6months) by paired t-test. In order to predict each gene expression level by white blood cell counts and the type of blood cell counts, we fit a multivariate regression model by backwards stepwise selection. [Results] All 9 gene expression levels were decreased at 6 months after TB treatment initiation compared to the enrollment. Especially, *FCGR1A*, *FCGR1B* variant1 and *FCGR1B* variant2 showed statistically significant decreased by 1.74, 1.49 and 1.33 (log scale), respectively ( $p < 0.001$  by paired t-test). Absolute lymphocyte, monocyte and neutrophil counts were correlated with *FCGR1A*, *FCGR1B* variant1, *FCGR1B* variant2 gene expression especially at enrollment and 2 weeks after the treatment start. The regression model only including neutrophil counts could fit to *FCGR1A* gene and *FCGR1B* variant2 gene expression at enrollment ( $R$ -squared=43% and 54%). [Conclusion] *FCGR1A* and *FCGR1B* gene expression levels decreased after TB treatment. Among lymphocyte, monocyte and neutrophils counts, neutrophil counts were the main influencing factor contributed to their expression levels. Previous studies implied that *FCGR1A* (*CD64*) and *FCGR1B* is associated with bacteria infection and TB infection. *FCGR1A* (*CD64*) and *FCGR1B* might be an effective and inexpensive biomarker not only identify active TB cases but also monitoring the TB treatment. .

**419T****Heterogeneity of human ribosomes inferred from rDNA and rRNA**

**sequencing.** R. Nagaraja<sup>1</sup>, J.H Kim<sup>2</sup>, A.T. Dilthey<sup>3</sup>, H.S. Lee<sup>3</sup>, S. Koren<sup>4</sup>, D. Dudekula<sup>1</sup>, W.H. Wood III<sup>1</sup>, Y. Piao<sup>1</sup>, A.Y. Ogurtsov<sup>1</sup>, K. Utani<sup>1</sup>, V.N. Noskov<sup>2</sup>, S.A. Shabalina<sup>4</sup>, D. Schlessinger<sup>1</sup>, A.M. Phillippy<sup>3</sup>, V. Larionov<sup>2</sup>. 1) Laboratory of Genetics and Genomics, NIA/NIH, Baltimore, MD; 2) National Cancer Institute, Developmental Therapeutics Branch, Bethesda, MD; 3) National Human Genome Research Institute, Computational and Statistical Genomics Branch, Bethesda, MD; 4) National Center for Biotechnology Information, National Library of Medicine, Bethesda, MD.

Human cells contain several hundred ribosomal DNA (rDNA) genes clustered in nucleolar organizer regions (NORs) on the short arms of five acrocentric chromosomes. Each NOR is a tandemly repeated unit of 43 kb transcribed into 13.3 kb 45S, encoding 18S, 5.8S and 28S rRNAs, and a 29.7 kb intergenic spacer (IGS). However, little is known about their precise structure and variation. Prior attempts to characterize NOR sequences have failed due to their highly repetitive structure, and these regions are missing from the human reference genome. We targeted chromosome 21 NOR sequences using transformation-associated recombination in yeast, starting from a rodent/human hybrid cell line. After conversion to BACs they were sequenced on PacBio and Illumina platforms, enabling assembly. Structures were validated using an Oxford Nanopore protocol capable of ~90 kb of single-read sequence. Thirteen clones, (0.4-fold coverage, ~0.8 Mb) of the chr. 21 NOR, revealed variants of standard rDNA reference. We identified 216 variant alleles in the 45S region, 90 in mature rRNAs sequences, as well as 7 inversion breakpoints in the IGS resulting in palindromic structures. The 90 sequence variations, compared to predicted 18S and 28S rRNA 2D structures, showed most located in species-specific expansion segments and rather than universal functional cores of 18S and 28S rRNA. Therefore, these variants are less likely to influence the catalytic core function of ribosome. However, variations in RNA 2D structure of the 5' ETS would likely affect structural stability, consistent with a possible role in fine-tuning rRNA transcription. In addition, a predicted candidate gene was found in the IGS for a subset of clones. The candidate gene, IGS breakpoints, and 61% of variant alleles were also seen in independent whole-genome PacBio and Illumina data. Thus, we have constructed a new ~45 kb rDNA reference sequence that has improved support from whole-genome data. This also provides an approach to full analysis of NORs and reagents for the study of human NOR function.

**Discovery of rare, diagnostic *AluYb8/9* elements in diverse human populations.** J. Feusier, D.J. Witherspoon, W.S. Watkins, C. Goubert, T.A. Sasani, L.B. Jorde. Human Genetics, University of Utah, Salt Lake City, UT.

Polymorphic human *Alu* elements are excellent tools for assessing population structure, and new retrotransposition events can contribute to disease. Next-generation sequencing has greatly increased the potential to discover *Alu* elements in human populations, and various sequencing and bioinformatics methods have been designed to tackle the problem of detecting these highly repetitive elements. However, current techniques for *Alu* discovery may miss rare, polymorphic *Alu* elements. Combining multiple discovery approaches may provide a better profile of the polymorphic *Alu* mobilome. *AluYb8/9* elements have been a focus of our recent studies as they are young subfamilies (~2.3 million years old) that contribute ~30% of recent polymorphic *Alu* retrotransposition events. We have modified and improved our ME-Scan methods for detecting *Alu* elements and have applied these methods to discover new insertions in a large set of individuals with diverse ancestral backgrounds. We identified 5,288 putative *Alu* insertion events, including 313 putative novel *AluYb8/9* elements from 213 individuals from 18 diverse human populations. Hundreds of these loci were specific to continental populations, and 23 non-reference population-specific loci were validated by PCR. We PCR validated 68 rare *AluYb8/9* elements, of which 11 have hallmarks of an active source element. The subfamily distribution of these rare *AluYb8/9* elements is consistent with previous datasets, and may be representative of rare loci. We also find that while ME-Scan and low-coverage, whole-genome sequencing detect different *Alu* elements in 41 1000 Genomes individuals, the two methods yield similar population structure results. Current *in-silico* methods for *Alu* discovery may miss rare, polymorphic *Alu* elements. Therefore, using multiple techniques can provide a more accurate profile of *Alu* elements in individuals and populations. We improved our false-negative rate as an indicator of sample quality for future ME-Scan experiments. In conclusion, we demonstrate that ME-Scan is a good supplement for next-generation sequencing methods and is well-suited for population-level analyses.

**421W****Identification of active LINE-1 retrotransposons in the baboon genome.**

W. Lee<sup>1,2</sup>, W. Tang<sup>3</sup>, P. Liang<sup>3</sup>, K. Han<sup>1,2</sup>. 1) Dankook University, Cheonan, South Korea; 2) DDKU-Theragen institute for NGS analysis (DTiNa), South Korea; 3) Brock University, St. Catharines, Ontario, Canada.

Long INterspersed Element-1 (LINE-1 or L1) retrotransposons and *Alu* elements belonging to Short INterspersed Element (SINE) are most successful retrotransposons which have generated genetic diversity in primate genome evolution and they are accounted for around 27.7% of the primate genome. In the mechanism of transposition, L1 and *Alu* copies have spread into a new location in the genome by RNA intermediate transposition, known as "copy-and-paste" mechanism. In the previous baboon genome study, the nine times higher expansion of race-specific *AluY* subfamilies were observed in the baboon genome compared with the human genome. Thus, we speculate that the huge expansion of *AluY* subfamilies during baboon genome evolution might be correlated with L1 activity at the same moment, because the expansion of *Alu* copies is dependent on L1-encoded protein activities such as endonuclease and reverse transcriptase. Here, we identified 493 baboon-specific full-length L1 candidates from the baboon reference genome and observed functionality and phylogenetic relationship of active L1 copies through comprehensive analysis to understand correlation between the active L1 copies and the expansion of *AluY* subfamilies in baboon.

**422T****Extending and improving GENCODE gene annotation.**

J.E. Loveland<sup>1</sup>, The GENCODE Consortium<sup>2,3,4,5,6,7,8</sup>, A. Frankish<sup>1,2</sup>, P. Flicek<sup>1,2</sup>. 1) European Molecular Biology Laboratory, European Bioinformatics Institute, Wellcome Genome Campus, Hinxton, Cambridge, CB10 1SD, United Kingdom; 2) Wellcome Trust Sanger Institute, Wellcome Trust Campus, Hinxton, Cambridge CB10 1SA, United Kingdom; 3) University of California, Santa Cruz, California 95064, USA; 4) Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA; 5) Center for Integrative Genomics, University of Lausanne, 1015 Lausanne, Switzerland; 6) Centre for Genomic Regulation (CRG) and UPF, 08003 Barcelona, Catalonia, Spain; 7) Yale University, New Haven, Connecticut 06520-8047, USA; 8) Spanish National Cancer Research Centre (CNIO), E-28029 Madrid, Spain.

High quality gene models are essential for annotation of sequence variation in clinical samples. Incomplete and inaccurate annotation of gene structure and function has the potential to introduce errors in identification of causal variants identified from genome and exome sequence. As part of the GENCODE project, we are responsible for producing detailed reference annotation of all human and mouse protein-coding genes, pseudogenes, long non-coding RNAs and small RNAs. GENCODE gene annotation is available from [gencode.org](http://gencode.org) and via the Ensembl and UCSC genome browsers. Updates to annotation are made continuously. To allow access to inter-release gene annotation changes we have created a track hub that is updated every 24 hours and available at [ftp://ngs.sanger.ac.uk/production/gencode/update\\_trackhub/hub.txt](http://ngs.sanger.ac.uk/production/gencode/update_trackhub/hub.txt). We will describe how GENCODE is improving the annotation of the human reference genome at the level of gene loci and alternatively spliced transcripts. More than 90 completely novel protein-coding genes have been identified in our analysis of un-annotated regions which have evolutionarily conserved coding potential by phyloCSF. Integrating multiple orthogonal datasets, especially RNAseq and CAGE libraries, has made it possible to annotate genes that were previously missed because of their restricted expression. In order to produce the most complete gene set possible we are integrating novel transcriptomic data into our analysis pipeline. These data suggest that we have missing genes from GENCODE as well as many missing exons and alternatively spliced transcripts. A study using public transcriptional evidence on next-generation sequence data from human brain was undertaken to re-annotate 140 genes from a reference diagnostic panel for Early Infantile Epileptic Encephalopathies (EIEE). CAGE was used to confirm transcriptional start sites followed by, RNAseq, SLRseq and PacBio reads to find new alternative splicing events including novel exons and splice site shifting. Despite previous annotation by GENCODE these new data enabled us to annotate many hundreds of alternatively spliced transcripts, novel exons, shifted splice sites and over 150kb of additional genomic coverage. These efforts suggest that despite the current GENCODE human gene set (v26) being the most comprehensive to date, it is still far from complete. The challenge now is to utilise new data effectively and efficiently to provide the most complete gene set for the clinical community.

**Updates to the human reference genome assembly (GRCh38).** *T. Rezaie<sup>1</sup>, V.A. Schneider<sup>1</sup>, T. Graves-Lindsay<sup>2</sup>, K. Howe<sup>3</sup>, P. Flicek<sup>4</sup> for the Genome Reference Consortium.* 1) National Center for Biotechnology Information, National Institutes of Health, Bethesda, MD; 2) The McDonnell Genome Institute at Washington University, St. Louis, MO; 3) The Wellcome Trust Sanger Institute, Hinxton, Cambridge, UK; 4) European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, Cambridge, UK.

The Genome Reference Consortium (GRC) provides users with updates to the human reference genome assembly. In the era of high quality genome assemblies and the accessibility of clinical genome sequencing, the reference genome provides the coordinate system for genomic-based analyses and gene annotations, facilitates identification of disease-associated variants and represents the diversity of the human population to both basic and clinical research communities. Despite providing the highest quality model of the human genome, reference assembly representations of some highly complex and medically important genomic regions, as well as population variation, remain problematic or incomplete and thus still need improvement. Since the 2013 release of GRCh38, the latest coordinate-changing update to the human reference, the GRC has continued to provide public assembly updates in the form of non-coordinate changing patch releases. As of GRCh38.p10 (GCA\_000001405.25), the reference assembly includes 53 fix and 49 novel patch scaffolds, which represent chromosome path changes and alternate representations of chromosome sequences, respectively. These patches, which are stand-alone accessioned scaffolds, are given chromosome context via alignments that are available for download with the rest of the assembly. The current suite of patches covers 32 Mb (~1% of the total chr. length), of which 1.42 Mb is novel sequence, and includes coding regions. We will show examples of recent patches that close assembly gaps, improve reference representations of genes, including clinically important loci, as well as those that add genomic diversity, and discuss their usage in basic and clinical analyses. We will describe how GRC curation efforts have been impacted by the public availability of new, highly contiguous, genome assemblies from different populations, optical maps, as well as genomic studies that provide allele frequency data, and how these data are contributing to discussions regarding the future of the reference assembly. The GRC is committed to making its curation efforts publicly accessible. These can be viewed at the GRC website (<https://www.genomereference.org>) and in browser tracks that are accessible via track hub. We will review the tracks and how to access them in browsers at NCBI, EMBL-EBI and elsewhere. We will also discuss the resources available at the GRC website, including mechanisms for contacting the GRC with general questions and assembly curation requests.

**Deep characterization of the contribution of short tandem repeats to gene expression across tissues.** *S. Feudjio Feupe<sup>1,2</sup>, M. Gymrek<sup>1,3</sup>.* 1) Department of Medicine, University of California San Diego, La Jolla, CA; 2) Department of Biomedical Informatics, UC San Diego, La Jolla, CA; 3) Department of Computer Science and Engineering, University of California San Diego, La Jolla, CA.

Recent studies have identified thousands of genetic variants contributing to variation in gene expression across dozens of tissues and cell types. However, these efforts have mainly focused on the contribution of single nucleotide polymorphisms (SNPs), and have largely ignored more complex variants such as repetitive regions and structural variants. This is due both to bioinformatic limitations in genotyping complex variants from short reads and low coverage sequencing data, and to the challenge of performing traditional association tests at highly multiallelic loci. STRs have been implicated in dozens of Mendelian diseases such as Huntington's disease and Fragile X Syndrome and have been shown to affect human phenotypes through a variety of mechanisms. Recent evidence suggests an important role of STRs in gene regulation. For instance, a genome-wide survey of the effects of STRs on gene expression identified more than 2,000 STRs whose lengths were linearly associated with expression of nearby genes (eSTRs). These STRs explained 10-15% of gene expression heritability due to cis variants, suggesting an important role for STRs in complex traits. Previous studies of the contribution of STRs to gene expression variability faced several important limitations. First, short read lengths and low coverage sequencing resulted in low quality genotypes, reducing power to detect true associations. Second, analyses were restricted to a single cell type, limiting the biological insight and generalizability of the results in different contexts. Here we look at impact of STRs on gene expression across multiple tissue types. First, we used HipSTR, a new and accurate STR profiling algorithm, to genotype STRs in 147 high coverage (30x) whole genome sequencing datasets from the Genotype-Tissue Expression (GTEx) project. We performed association tests relating STR lengths and expression levels of nearby genes, and identified 2,448 genes with eSTRs across seven tissues at 5% FDR; including 694 genes with eSTRs in two or more tissues. Finally, using the extensive GTEx resource we fine-map the contribution of different variant classes to gene expression, identify putative causal regulatory variants overlapping GWAS loci, and characterize tissue-specific features of predicted causal eSTRs. Overall, our analysis provides a valuable resource for future efforts to integrate STRs into complex trait analyses.

**The effect and mechanism of inhibiting G6PD activity on the proliferation of *Plasmodium falciparum*.** Z. Zhang<sup>1,2</sup>, W. Jiang<sup>2</sup>, X. Chen<sup>3</sup>, C. Jiang<sup>2</sup>, Z. Fang<sup>2</sup>, Y. Feng<sup>2</sup>. 1) Reproductive Medicine Research Center, Sixth Affiliated Hospital, Sun Yat-Sen University, Guangzhou, China; 2) Department of Medical Genetics, Zhongshan Medicine School, Sun Yat-sen University, Guangzhou, China; 3) Department of Endocrinology, Guangzhou Women and Children's Medical Center, Guangzhou, China.

Glucose-6-phosphate dehydrogenase deficiency (G6PD deficiency, OMIM 305900), an X-linked inherited disease, is the most common human enzyme deficiency which affects over 400 million people worldwide. This disease often occurs in malaria endemic areas. The global distribution of G6PD deficiency was highly consistent with the geographic distribution of malaria, and the correlation between them have been confirmed by epidemiology, but the effect and mechanism were not clear. Therefore, we investigated the effect and mechanism of G6PD deficiency against malaria, hope to reveal the anti-malaria selection mechanism. Dehydroepiandrosterone (DHEA) as a potent uncompetitive inhibitor of mammalian gluG6PD was utilized for inhibiting the G6PD activity of erythrocytes. Quantitative real-time PCR were used for the detection and quantification of *Plasmodium falciparum* infection. A transmission electron microscope was used to observe the structural changes of *P. falciparum*. We found that with the increase of DHEA concentrations, the proliferation of *P. falciparum* decreased by qPCR. We further observed the cell nucleus of *P. falciparum* shrank, the cell organelles and metabolites were reduced gradually by transmission electron microscope. Because the *P. falciparum* in erythrocytic stage need to synthesize large amounts of nucleic acid to complete proliferation. Therefore, *P. falciparum* multiplication would be inhibited in G6PD deficient erythrocytes because the *P. falciparum* organelles could not obtain enough electron source (NADPH) and the raw material(ribose-5-phosphate). So, the cell nucleus of *P. falciparum* shrank, the cell organelles and metabolites were reduced gradually and eventually died. These results will play an important role in understanding the mechanism of antimalarial resistance selection of G6PD deficiency.

**Integration of Hi-C chromatin loop calls across multiple resolutions identifies loops that are consistent across cell types and functionally associated.** H. Li<sup>1</sup>, WW. Greenwald<sup>2</sup>, P. Benaglio<sup>3</sup>, A. Schmitt<sup>4</sup>, Y. Qiu<sup>2</sup>, B. Ren<sup>1,5,6,7</sup>, M. D'Antonio<sup>1</sup>, EN. Smith<sup>3</sup>, KA. Frazer<sup>1,3</sup>. 1) Institute for Genomic Medicine, University of California San Diego, La Jolla, CA; 2) Bioinformatics and Systems Biology Graduate Program, University of California San Diego, La Jolla, CA; 3) Department of Pediatrics and Rady Children's hospital, University of California San Diego, La Jolla, CA; 4) Arima Genomics, San Diego, CA; 5) Ludwig Institute for Cancer Research, La Jolla, CA; 6) Moores Cancer Center, University of California San Diego, La Jolla, CA; 7) Department of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA.

Hi-C allows for the characterization of 3D chromatin architecture by identifying regions of the genome that spatially colocalize through chromatin looping. However, identification of high confidence chromatin loops is challenging as the sparseness of data requires binning the genome to identify statistically significant regions, and loop calling algorithms are sensitive to their bin size parameter. Here, we investigated if integrating loop calls across multiple resolutions from two algorithms results in larger and better-quality loop sets that show consistency between cell types and are enriched for functional ROADMAP chromatin states. We performed in-situ Hi-C on paired iPSC and iPSC-derived cardiomyocyte (iPSC-CM) lines, generated ~6 billion reads, and constructed 2kb resolution contact maps for each cell type. We called loops at 21 resolutions using Fit-Hi-C (10-30 restriction enzyme fragments) and HICCUPS (5kb-25kb), and identified a total of 50,612 distinct Fit-Hi-C and 17,782 distinct HICCUPS loops in iPSC, and 61,315 distinct Fit-Hi-C and 20,609 distinct HICCUPS loops in iPSC-CMs, many of which were only called at one resolution. Visual inspection of Hi-C contact frequency heatmaps indicated loops unique to a single resolution were often not supported by the underlying data, whereas loops present in at least 7 Fit-Hi-C or 3 HICCUPS resolutions tended to be supported, suggesting that aggregate loop sets are more accurate than single resolution loop sets. We therefore merged and filtered the loops based on the above aggregation criteria, resulting in 13,314 Fit-Hi-C loops and 12,362 HICCUPS loops in iPSC, and 13,118 Fit-Hi-C loops and 15,138 HICCUPS loops in iPSC-CM. As chromatin loops are often conserved across multiple cell types, we calculated the proportion of loops shared between iPSC and iPSC-CM for each single-resolution loop set and for the aggregate loop sets. We found that the aggregate loop sets contained considerably more loops than the single resolution loop sets (up to 2.3 times more) and that they were more consistent between the two cell types than any single resolution set (up to 12% more). Additionally, we observed that the aggregate loops contained more functional chromatin state bases than the average across the single resolution sets. These results suggest that the integration of chromatin loops at multiple resolutions is an effective method to identify the greatest number of functionally relevant chromatin interaction intervals.

**427W****Moving into the darkness: Improving variant analysis with linked-reads.**

*A.W. Xu, S. Garcia, S. Williams, C. Catalanotti, M. Schnall-Levin, D.M. Church, P. Marks.* 10x Genomics, Pleasanton, CA., United States.

Structural variants (SVs) are important contributors to disease, but are notoriously difficult to detect using short read (SR) data. Balanced and complex events are particularly challenging because they do not result in variation of read coverage and can span long genomic distances, making them intractable with SR data alone. Targeted approaches pose additional challenges as stochastic and systematic coverage variation between samples and probes can resemble single exon deletion or duplication events and yield false diagnostic results. To address these shortcomings, we partition limiting amounts of high molecular weight DNA such that unique barcodes can be added as part of library generation. This approach allows us to couple long-range information with high-throughput, accurate SR sequencing, generating a data type known as Linked-Reads. Our reference-based pipeline, Long Ranger™, leverages the unique properties of Linked-Reads to call a broader range of variant types. Linking heterozygous variants to distinct barcodes enables haplotype reconstruction, providing increased power for variant calling across all variant types, but particularly for balanced events and single exon deletions and duplications. Algorithms assessing barcode overlap between distant regions enable large balanced and unbalanced SV detection. Assessing barcode coverage, rather than read coverage, provides increased sensitivity for exome/targeted applications, obviating the need for a pool of samples to detect coverage variations- the unaffected haplotype serves as the internal sample control. Using NA12878 as a truth sample, we demonstrate the ability to call and haplotype challenging variants including long insertions, heterozygous deletions, and SNPs on distinct paralogous loci. For full depth (median 30x coverage) whole genome sequencing (WGS), the PPVs/sensitivities are 1/0.94 for large deletions ( $\geq 30\text{kb}$ ) and 0.8/0.86 for short deletions (50bp - 30kb). For exome sequencing (median 75X coverage), these values are 0.73/0.72 for short heterozygous deletions and 0.83/1 for short homozygous deletions. For lower coverage (1-10x coverage) WGS, all large structural events, including balanced and unbalanced events ( $\geq 200\text{kb}$ ), were detected across multiple samples. Linked-Reads are critical for enabling the analysis and discovery of SVs in the human genome, particularly for cost-effective targeted exome sequencing approaches that canonically are unable to detect structural variation.

**428T****Detection of rare copy number variants (CNV) in Kaiser cohort using DNA microarray data from Affymetrix axion array.** *T. Haldar, K.N. Mark, T.J. Hoffmann, N. Risch.* Institute for Human Genetics, University of California, San Francisco (UCSF).

Affymetrix axion platform is not optimized for copy number variant (CNV) detection: the amplification step is believed to reduce difference in total intensity due to copy number changes. Moreover, a majority of the SNPs within a common CNV region deviate from Hardy Weinberg equilibrium (HWE) and are removed from the array. We explored the SNP content of the Affymetrix axion array customized for European population and observed that the number of SNPs typed in the chromosomal regions containing common deletions are significantly smaller compared to other regions. As expected, most of the SNPs typed within the chromosomal regions containing common deletions significantly deviate from HWE and in general, an additional cluster consisting of off-target variants (OTV) is clearly visible in the log-intensity plot of these SNPs. We analyzed the data of 69,508 European individuals in the Kaiser GERA cohort who were genotyped on the Affymetrix axion array customized for European population. Using the exome sequence data of 194 individuals, we found that these OTV clusters correspond to the individuals with null copy number at a locus. So it is evident that some CNV signals are present in the Affymetrix axion data. Even though it may be difficult to identify single deletions in a common CNV region due to small number of typed SNPs, we hypothesize that the axion data can be used to detect long rare CNVs. We observed in our data that the presence of a single long deletion at a locus generally results in a long run of homozygosity (ROH) by the design of the Affymetrix genotype calling algorithm. So we propose a new approach combining the ROH and intensity data to identify long rare deletions. However several confounding factors should be adjusted while using the intensity data, e.g., variation across chips, waving pattern of intensity with GC content, length of deletions, etc. Using this method, we have identified a large number of CNVs which include a significant number of deletions at 10q21.3 (a known hotspot for long rare deletions). We did not observe any significant difference in the number of rare deletions detected among males and females. There is also no significant change in rare CNV loads with age.

**429F**

**Genomic and structural integrity of human induced pluripotent stem cells.** K. Kanchan<sup>1</sup>, C. Malley<sup>1</sup>, L.R. Yanek<sup>1</sup>, L. Cheng<sup>1</sup>, Z. Wang<sup>1</sup>, D. Becker<sup>1</sup>, L. Becker<sup>1</sup>, I. Ruczinski<sup>2</sup>, R.A. Mathias<sup>1</sup>. 1) Department of Medicine, School of Medicine, Johns Hopkins University, Baltimore, MD; 2) Department of Biostatistics, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD.

Human induced pluripotent stem cells (hiPSCs) constitute model systems with enormous capability to shed light on the pathogenesis and mechanisms for a wide range of human diseases. Their application as disease models depends on the genomic integrity and stability through their generation. Recent studies confirm various genomic instabilities, such as, chromosomal aberrations, copy number variations (CNVs) and differences in single nucleotide polymorphisms (SNPs) in hiPSCs. We analysed genome-wide genotype array data (Illumina Infinium MEGA Chip) on 1,321,228 genetic variants to evaluate genomic instability of 132 hiPSC lines generated from their matched peripheral blood mononuclear cells using non-integrating episomal vectors. We observed very low levels of genotype mismatch between genetic variants available on the genotype array between the 132 donor and hiPSC pairs (mean mismatch error rate = 0.004%). Processed SNP array data were subjected to automated CNV calling followed by manual inspection of all CNVs. For automated analysis, we applied Hidden Markov Models on the genotype data to identify CNVs in the samples using R package 'VanillaICE'. Given prior documentation of high rates of false positive CNV calls through automated pipelines, sub-chromosomal plots were generated from the log R ratios and B-allele frequencies for manual inspection and confirmation of the automated calls. Our automated pipeline detected no differences in average numbers of CNVs between the hiPSC and donor DNA. There was an average of 7 deletions and 3 amplifications per hiPSC line, and 6 deletions and 3 amplifications per donor sample. All called CNVs were then compared within the hiPSC and donor pair to identify non-overlapping CNVs (i.e. those called in the hiPSC but not the donor, or those that overlap but were of differing lengths between the hiPSC and donor). Manual inspection of the non-overlapping CNVs revealed that most pairs (N=124) had no detectable difference in CNVs called in the hiPSC from those in the donor DNA. Eight hiPSC lines had 1 or more differences compared to the donor: 6 lines had 1 deletion, one line had 2, and one had 3 deletions. The deletions ranged in size from 3.8-181.2kb, with an average size of 35.5kb. Our results suggest that much of the called CNVs in the hiPSC are pre-existing in the donor DNA. Further, there are only low levels of genomic instability in our lines as quantified by CNV differences between the hiPSC and its paired donor DNA.

**FusorSV: An algorithm for optimally combining data from multiple structural variation detection methods.** A. Malhotra<sup>1</sup>, T. Becker<sup>2</sup>, W.P. Lee<sup>1</sup>, J. Leone<sup>1</sup>, Q. Zhu<sup>1</sup>, C. Zhang<sup>1</sup>, J. Sargent<sup>1</sup>, K. Shanker<sup>1</sup>, A. Mil-Homens<sup>1</sup>, E. Cerqueira<sup>1</sup>, M. Ryan<sup>1</sup>, J. Cha<sup>1</sup>, F.C.P. Navarro<sup>3</sup>, T. Galeev<sup>3</sup>, M. Gerstein<sup>3</sup>, R. Mills<sup>4,5</sup>, D.G. Shin<sup>2</sup>, C. Lee<sup>1</sup>. 1) Jackson Laboratory for Genome Medicine, Farmington, CT; 2) Department of Computer Science and Engineering, University of Connecticut, Storrs, CT; 3) Yale University Medical School, Computational Biology and Bioinformatics Program, New Haven, CT; 4) Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 5) Department of Human Genetics, University of Michigan, Ann Arbor, MI.

Comprehensive and accurate discovery of Structural Variations (SVs) from next generation sequencing data remains a major challenge. Existing popular approaches to overcome performance limitations of any one SV identification method are to use multiple complementary methods to determine the SV loci and naively merge them based on coordinates with no consideration of their individual biases. These approaches do not take into account the strengths and weaknesses of individual method and hence either under or over merge the variant loci resulting in missing and/or false SV calls. Here, we present FusorSV, an open source algorithmic framework that uses a truth set to train a fusion model by comparing calls from different SV calling algorithms to the truth set. FusorSV uses discriminating features (such as SV Type and Size) to promote subsets of algorithms that are complementary to each other. For example, DELLY and LUMPY appear similar in methodology and produce very similar deletion calls but diverge significantly for inversion calls. Hence, we empirically determine the similarity/dissimilarity of each combination of SV calling algorithms for each SV type. Integration of individual algorithm performance, along with the pairwise similarity/dissimilarity of algorithms across SV types, allows FusorSV to select subsets of algorithms for each SV type that are more comprehensive and balanced (maximum discovery with minimal false positives) in nature. We built a SV fusion model using an ensemble of nine SV calling algorithms to analyze 27 deep coverage (50X) human genomes that were investigated as part of the 1000 Genomes Project (1000GP). Our model identified an additional 562 (~10%) novel SV calls that were not reported in these 27 samples by the 1000GP. Experimental validation of a subset of these novel SV calls yielded a validation rate of 86.15%. These results highlight the power of the FusorSV approach and we believe that it has the potential to become a new gold standard for SV calling from short read whole genome sequencing datasets.

## 431T

**Pervasive transcriptional dosage compensation buffers impact of autosomal structural variation.** *R.C. McCoy, J.M. Akey.* Department of Genome Sciences, University of Washington, Seattle, WA.

Structural variation (SV) is known to contribute to human disease through its impact on gene dosage. Yet population-scale maps of SV have revealed that many genomic regions can be duplicated or deleted with no apparent phenotypic consequences. We sought to reconcile these observations by characterizing the genome-wide prevalence and molecular mechanisms of autosomal dosage compensation. To this end, we developed a generalized linear mixed model approach to combine expression data from multiple individuals and tissues to systematically test hypotheses about dosage compensation at 1,906 autosomal genes fully encompassed by an SV. We applied this approach to data from the GTEx Consortium, comprising SV detected in whole-genome sequences from 147 individuals and corresponding RNA-seq data from a total of 53 tissues (median 15 tissues per individual). We found that both duplicated and deleted genes show strong evidence of dosage compensation, with expression distributions significantly deviating from dosage-proportionate expectations in the direction of diploid expression levels. Substantially more deleted (34.9%) than duplicated (9.5%) genes exhibited dosage compensation (10% FDR), consistent with the known predominance of haploinsufficiency over triplosensitivity. Interestingly, dosage compensation was extremely common among highly expressed deleted genes (69.3%), but extremely rare among highly expressed duplicated genes (4.5%). These findings suggest that directionally-biased buffering mechanisms have evolved under stabilizing selection to maintain high or low gene expression. Furthermore, dosage compensation of duplications, but not deletions, varied substantially according to gene class, with duplicated short noncoding RNAs showing stronger dosage compensation than protein-coding, long noncoding, and pseudogenes ( $\beta = -0.332$ ;  $P = 9.15 \times 10^{-6}$ ). This result suggests that low-expressed regulatory RNAs may be under strong expression constraint. Intriguingly, duplicated protein-coding genes with greater density of miRNA binding sites exhibited stronger dosage compensation ( $\beta = -0.0957$ ;  $P = 9.56 \times 10^{-6}$ ), indicating that miRNA may mediate dosage compensation via mRNA degradation of duplicated genes. Together, our results reveal functional and evolutionary characteristics of mechanisms buffering the transcriptional effects of autosomal dosage alteration, with implications for dissecting the causal basis of pathogenic SV.

## 432F

**Germline de novo mutation clusters arise during oocyte aging in genomic regions with increased double-strand break incidence.** *C. Gilissen<sup>1</sup>, J.M. Goldmann<sup>2</sup>, V.B. Seplyarskiy<sup>3,4</sup>, W.S.W. Wong<sup>5</sup>, T. Vilboux<sup>6</sup>, D.L. Bodian<sup>5</sup>, B.D. Solomon<sup>5,6,7</sup>, J.A. Veltman<sup>1,8</sup>, J.F. Deeken<sup>5</sup>, J.E. Niederhuber<sup>5,9</sup>.* 1) Human Genetics, Radboud University Medical Center, Nijmegen, Netherlands; 2) Department of Human Genetics, Radboud Institute for Molecular Life Sciences, Radboud University Medical Center, Geert Grooteplein 10, 6525 GA Nijmegen, the Netherlands; 3) Division of Genetics, Brigham & Women's Hospital, Harvard Medical School, Boston, Massachusetts, USA; 4) Institute for Information Transmission Problems of the Russian Academy of Sciences (Kharkevich Institute), Bolshoi Karetny pereulok 19, Moscow 127994, Russia; 5) Inova Translational Medicine Institute (ITMI), Inova Health Systems, Falls Church, VA, USA; 6) Department of Pediatrics, Inova Children's Hospital, Inova Health System, Falls Church, VA, USA; 7) Department of Pediatrics, Virginia Commonwealth University School of Medicine, 1201 E Marshall St, Richmond, VA, USA; 8) Institute of Genetic Medicine, International Centre for Life, Newcastle University, Newcastle upon Tyne, United Kingdom; 9) Johns Hopkins University School of Medicine, 733 North Broadway Street, Baltimore, MD, USA.

Clustering of mutations has been found both in somatic mutations from cancer genomes and in germline de novo mutations (DNMs). To investigate the underlying mutational mechanisms of clustered DNMs (cDNMs) we used whole-genome sequencing data from 1,291 parent-offspring trios and identified 1,755 cDNMs across 799 clusters. By performing read-phasing, we successfully identified the parent-of-origin for 700 cDNMs across 400 clusters. In addition, we created a replication dataset of published studies, resulting in a total of 1,643 cDNMs across 745 clusters. We found that although the number of paternal cDNMs did not show a significant correlation with the paternal age ( $p=0.087$ ), we found a highly significant correlation of maternal cDNMs with maternal age ( $p<10^{-10}$ ), accounting for 23% (c.i. 7-38%) of the maternal age effect. This maternal age effect of clusters stems mostly from clusters with intra-mutational distances greater than 1kb. Moreover, the maximum number of DNMs in the clusters of an individual, correlates positively with maternal age ( $p<10^{-10}$ ), but only marginally significant with paternal age ( $p=0.050$ ). Interestingly, 58.4% of maternal cDNMs localize to chromosomes 8, 9 and 16 ( $p<10^{-16}$ , Chi-square test) whereas the number of paternal correlates with chromosome length ( $R^2=0.72$ ,  $p=6*10^{-7}$ ). The maternal cDNMs on these three chromosomes occur specifically in regions that are also enriched for maternal unclustered DNMs and their mutation spectrum is strongly enriched for C>G substitutions compared to other maternal cDNMs (bootstrapping  $p=0.022$ ). Finally, we investigated whether maternal clusters associate with processes involving double-stranded-breaks (DSBs). We found that sites with meiotic gene conversions (MGC) co-localize with maternal cDNMs significantly more often than expected ( $p<0.004$ , bootstrapping). In addition, we identified 45 *de novo* CNVs, of which 5 have a total of 17 DNMs within 100kb flanking the breakpoints. Exactly 15 of these 17 DNMs are cDNMs ( $p<2.2*10^{-16}$ , Fisher's exact test). All 5 CNVs and all phased cDNMs arose on the maternal allele ( $p=0.03$ , Fisher's exact test). Lastly, we found that maternal recombination scores at maternal clusters are significantly higher than paternal recombination scores at paternal cluster locations ( $p=0.004$ , bootstrapping). Overall these findings suggest accumulation of DSB-induced mutations throughout oocyte aging as an underlying mechanism leading to maternal mutation clusters.

**Linked-reads for high resolution individual genome analysis via haplotype reconstruction.** S. Williams, S. Garcia, C. Catalanotti, A.W. Xu, P. Marks, M. Schnall-Levin, D.M. Church. 10x Genomics, Pleasanton, CA.

Next-generation sequencing is a standard tool for identifying the molecular underpinnings of disease. This has been driven by cost-efficient and accurate short reads which lack long-range information, limiting long-range haplotype reconstruction. Some regions of the genome are inaccessible to short reads and many variant types, particularly structural variants, are missed with standard approaches. Efficient and effective interpretation of these genomes has not been realized and the diagnostic yield for both genome and exome approaches is lower than anticipated. To advance the utility of NGS sequencing assays, we developed a technology that retains long-range information while maintaining the power, accuracy, and scalability of short read sequencing. At its core, haplotype-level dilution of long input molecules into >1 million bar-coded partitions creates a novel data type called 'Linked-Reads' that enables high-resolution genome analysis with minimal DNA input (~1 ng). Using Linked-Reads, we show improved performance in regions of the genome typically inaccessible with traditional short read technology due to the presence of paralogous sequence/highly repetitive regions. Highly homologous sequences which traditionally lead to ambiguous mapping can now be analyzed when associated with distinct barcodes. We rescued ~50 Mb of previously inaccessible sequence, enabling the identification of tens of thousands of novel single nucleotide variants (SNV) per genome. Clinically-relevant variants were identified in genes within these previously inaccessible regions including CYP2D6, SMN1, and STRC. Including phase information in consequence prediction not only disambiguates local variation such as compound and exon spanning variation, but because of the long distance phase information captured by Linked-Reads we are able to decipher the true impact of genetic variation at megabase range. Next, we tested variant effect prediction tools tuned for phased genotypes which have shown promise in local variation but currently struggle to fully take advantage of data which phases variation at great distance. Improvements in this area will be critical for improved genome interpretation. Linked-Reads, coupled with improved variant classification tools has the potential to be a first line assay for identification, classification, and clinical interpretation of how genetics impact the pathology of disease.

**Characterisation and genotyping structural variation at the malaria-associated human glycoporphin A-B-E cluster.** W. Algady<sup>1</sup>, P. Brajer<sup>1</sup>, D. Mateja<sup>1</sup>, S. Gomes<sup>2</sup>, E. Weyell<sup>1</sup>, F. Yang<sup>2</sup>, E. Hollox<sup>1</sup>. 1) Department of Genetics and Genome Biology, University of Leicester, Leicester, UK; 2) Wellcome Trust Sanger Institute, Hinxton, Cambridge, UK.

Human glycoporphins A and B are proteins expressed on the surface of erythrocytes, and are receptors for invasion of the malaria-causing *Plasmodium falciparum* parasite. The proteins are encoded by the genes *GYPA* and *GYPB* which, together with *GYPE*, reside on a tandemly-duplicated repeat region on chromosome 4q31.21. Recent genomewide analysis has suggested that a structural variant within this region (DUP4) is common in East Africans and is strongly protective against severe malaria. DUP4 and other structural variants can be genotyped by detailed analysis of whole genome Illumina sequencing, but a suite of rapid, cost-effective assays to reliably genotype structural variants on small degraded DNA samples is lacking. Here, we use the paralogue ratio test (PRT), a comparative PCR method which has been shown to be more robust than real-time quantitative PCR for typing genomic CNV, and has been previously used on a wide variety of CNV loci. It requires <20ng genomic DNA and has a low cost per sample, making it ideal for genotyping large DNA cohorts to test for association with malaria severity, for example. We also present detailed characterisation of structural variation across this region using fiber-FISH, long PCR and sequencing. This allows exact mapping of structural variant breakpoints and development of junction-fragment PCRs for particular structural variants, using paralog-specific PCR based on linked nucleic acids. These junction-fragment PCRs enable validation of PRT results, or rapid genotyping across a very large cohort for a particular structural variant, in, for example, basic molecular biology labs. These assays can be used in budget-limited settings for population-based screening of malaria susceptibility variants at the glycoporphin locus.

**435F**

**Low coverage sequencing of inbred animal backcrosses to check and correct genome assemblies.** *G.W. Nelson<sup>1</sup>, C. McIntosh<sup>2</sup>, J. Lautenberger<sup>3</sup>, S. Burkett<sup>4</sup>, V. David<sup>4</sup>, A.O. Perantonis<sup>5</sup>.* 1) Leidos Biomedical Research, Frederick National Laboratory, Frederick, MD; 2) Genomics Analysis Unit, CCR, NCI, Frederick, MD 21702; 3) Molecular Cytogenetics Core Facility (MCGP), CCR, NCI, Frederick, MD 21702; 4) Basic Research Laboratory, CCR, NCI, Frederick, MD 21702; 5) 5Cancer and Developmental Biology Laboratory, CCR, NCI, Frederick, MD 21702.

Different inbred animal strains of the same species are distinguishable by essentially fixed SNP differences. To map a locus for the Noble rat's susceptibility to a nephroblastoma analogous to the human Wilms tumor we sequenced 71 rats, Noble-Fischer hybrid backcrossed to Fischer, at an average of 2x coverage. This provided calls for ~70% of the ~3 million SNP differences between these strains, yielding a recombination map at ~2 Kbp resolution. This resolution revealed genomic regions with sharply defined boundaries within which the genomic ancestry of multiple rats was uncorrelated with the genomic ancestry of the surrounding regions, suggesting errors in the RN6 reference sequence. Of these we have clearly delineated 20, with sizes ranging from 120 Kbp to 4.4 Mbp. Comparison of the ancestry within the region to ancestry across the genome indicated, with high statistical confidence, correct genomic locations for 7 of these. We performed fluorescence in situ hybridization (FISH) to verify the proposed remapping of two of these regions. We designed probes to hybridize to reference sequence inside the anomalous regions, and with a different color label to hybridize to reference sequence in regions flanking these regions. If the RN6 assembly were correct, the probes would colocalize. The FISH results were inconsistent with the mapping to RN6, but consistent with the proposed corrections. For a region mapped to the reference sequence near the center of chr. 2, but predicted close to the chromosome end, the flanking probes appeared at the center of the chromosome, but the probes for the anomalous region localized to an end of the chromosome. For a region mapped to the reference sequence near the start of chr. 8, but predicted to occur on chr. 1, the flanking probes appeared at an end of a small chromosome, but the probes for the anomalous region hybridized to the largest chromosome. We have used the recombination map to assign locations to unmapped RN6 fragments. Subtracting chr. Y fragments, there are 240 fragments carrying informative SNPs, of which we can assign definite locations to 81. Demonstrating the power of this approach, all fragments with identified chromosome mapped to the named chromosome, and we have assigned locations to 32 fragments with unknown chromosome. Low coverage whole genome sequencing of backcrosses to one parental strain, of hybrids of two strains, are a cost-effective way to obtain accurate recombination maps. .

**The mechanism and function of targeting lincRNAs by NMD in mammals.**

*L. Hu<sup>1</sup>, X. Kong<sup>1</sup>, Z. Zhang<sup>2</sup>, M. Jin<sup>1</sup>.* 1) Inst Hlth Sci, Shanghai, Shanghai, China; 2) Department of Biology, University of Rochester, Rochester, New York 14627, United States of America.

Thousands of long noncoding RNAs (lncRNAs) have been identified in a mammalian genome, but their functions remain elusive. Recent studies showed that lncRNAs' expression is affected by nonsense-mediated mRNA decay (NMD), providing an avenue to infer lncRNAs' functions because RNA stability was reportedly correlated with functions. In this study, we evaluate the properties of human intergenic lncRNAs, i.e. lincRNAs, in order to answer two questions: how can NMD affect lincRNAs' expression given that NMD relies on translation while lincRNAs are generally untranslated, and what is the function of NMD-targeted lincRNAs? First, we find that 11.27% of lincRNAs are affected by NMD. Second, we provide evidence for that NMD can directly target lincRNAs, including bound by the NMD factor UPF1 and exon-exon junction complex (EJC), cleaved by the NMD factor SMG6, and scanned by ribosomes. Third, we find that NMD-affected lincRNAs are more lowly expressed and less conserved than the other lincRNAs, suggesting that NMD-affected lincRNAs are more likely expression noise than functional products. Notably, all these properties resemble those of NMD-targeted mRNAs. Taken together, lincRNAs can be directly targeted by NMD, and such targeted lincRNAs are probably noise stemming from erroneous or leaky transcription.

**Human germline mutation hotspots are characterized by a transversion-rich mutation signature.** J. Carlson<sup>1</sup>, J.Z. Li<sup>1,2</sup>, S. Zöllner<sup>3,4</sup>, *The BRIDGES Consortium*. 1) Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 2) Human Genetics, University of Michigan, Ann Arbor, MI; 3) Biostatistics, University of Michigan, Ann Arbor, MI; 4) Psychiatry, University of Michigan, Ann Arbor, MI.

The germline mutation rate in humans is highly variable across the genome, and is influenced by many factors including meiotic recombination rate, replication timing, and the nucleotide sequence flanking each mutation site. Despite these well-documented effects, the factors that contribute to the spatial heterogeneity of mutation rates are still largely unknown. Previous studies have applied parametric models to identify potential drivers of spatial mutation rate heterogeneity, but these models are subject to specification bias and measurement error among the considered features. Moreover, such models are generally trained on small datasets of *de novo* mutations, rendering them underpowered and limited in scope. To overcome these constraints, we present a nonparametric approach which leverages a high-resolution dataset of ~36 million extremely rare variants observed in a sample of 3,716 whole-genome sequences. With these data, we apply non-negative matrix factorization to summarize spatial mutation rate heterogeneity as a composite of three distinct mutation signatures. We show that this model captures cryptic patterns of spatial heterogeneity among *de novo* mutations with greater accuracy than previously proposed parametric models. The clear majority of the genome (94.5% of 1-megabase windows) is dominated by a balanced contribution of the three mutation signatures, suggesting that broad regional perturbations to the germline mutation rate are generally uncommon. The remaining 5.5% of the genome, however, is characterized by an exceptionally high concentration of transversion mutations, with transversion rates per 1Mb window up to 6 times higher than the genome-wide average. This transversion-rich mutation signature occurs predominantly in subtelomeric regions of chromosomes 7, 8, 9, and 16. Importantly, these loci overlap known mutation hotspots (e.g., 8p21-23), suggesting that regimes of germline hypermutability are not simply an artifact of uniform variability in mutation rates but rather correspond to asymmetric shifts in the frequencies of point mutation types. Accounting for a set of known mutagenic genomic features explains only a fraction of the observed excess of transversion mutations in these regions, implying that additional causative mechanisms have yet to be identified. Our findings thus warrant further investigation into the relationship between the germline mutation rate and corresponding features of the genomic landscape.

**Predicting hotspots of *Alu/Alu*-mediated rearrangements in the human genome.** X. Song<sup>1</sup>, C.R. Beck<sup>1</sup>, R. Du<sup>1</sup>, I.M. Campbell<sup>1</sup>, Z.C. Akdemir<sup>1</sup>, S. Gu<sup>1</sup>, A.M. Breman<sup>1,2</sup>, C.A. Shaw<sup>1,2</sup>, J.R. Lupski<sup>1,3,4,5</sup>. 1) Molecular and Human Genetics, BCM, Houston, TX; 2) Baylor Genetics, Houston, TX; 3) Department of Pediatrics, BCM, Houston, TX; 4) Human Genome Sequencing Center, BCM, Houston, TX; 5) Texas Children's Hospital, Houston, TX.

The short interspersed element *Alu* comprises ~11% of the human genome and numbers >1 million copies per haploid genome. *Alus* are enriched at the breakpoint junctions of genomic rearrangements, and can mediate the formation of copy number variants (CNVs) between pairs. These *Alu/Alu*-mediated rearrangements (AAMR) can cause Mendelian diseases including spastic paraplegia 4 and Fanconi anemia. Further understanding of the genome-wide impact of AAMR on variation and human health is limited by current experimental technologies. We have developed a bioinformatic approach to investigate characteristics of *Alus* involved in mediating CNVs (CNV-*Alus*) and have predicted genome-wide AAMR hotspot loci. First, we collected and analyzed 219 CNV-*Alu* pairs with experimental evidence supporting their role in deletion formation. Second, we characterized *Alu* sequence features and genomic architectural features enriched in CNV-*Alus* relative to locus-specific control *Alus*. CNV-*Alus* tend to be longer, have better pairwise alignment, contain internal pol III promoters that are more likely to be active, and have higher GC percentages and a longer poly-A tail. Next, we developed a classification model to predict CNV-*Alu* pairs based on these distinct properties. The test dataset was built by choosing *Alu* pairs that are in the same orientation, span at least one exon, and are located <250 Kb from each other. As a result, ~18% of the 78 million *Alu* pairs in the test dataset were predicted as high risk for AAMR. We further determined the relative risk of AAMR in 12,075 human genes using the density of predicted CNV-*Alu* pairs. Finally, we experimentally validated this prediction with 89 samples selected by correlating hotspot genes with a database of ~54,000 chromosomal microarrays (CMA). We fine-mapped 47 duplications, 40 deletions and 2 complex rearrangements with a custom designed array comparative genomic hybridization (aCGH). We then mapped 50 of these breakpoint junctions at nucleotide-level resolution with PCR and Sanger sequencing. 74% of the junctions are mediated by *Alu* pairs, 20% have one end in an *Alu* and only 6% are mediated by non-*Alu* sequences. Remarkably, ~80% of the *Alu* pairs were predicted by our classifier as being at high risk for AAMR. These results demonstrate the utility of our predictive model, give insights into the genomic features and mechanisms underlying AAMR, and provide a general framework for improved assessment of AAMR and its role in human disease.

## 439W

**Chromosomal microarray analysis in fetuses with congenital heart disease: 5 years of clinical experience.** P. Hu, Y. Wang, ZF Xu. Obstetrics and Gynecology Hospital Affiliated to Nanjing Medical University, Nanjing, Jiangsu, China.

**Purpose:** Currently, chromosomal microarray analysis (CMA) is considered as the first-tier test in pediatric care and prenatal diagnosis. However, the diagnostic yield of CMA for prenatal diagnosis of congenital heart disease (CHD) has not been evaluated based on a large cohort. Our aim was to evaluate the clinical utility of CMA as the first-tier test for chromosomal abnormalities in fetuses with CHD. **Methods:** In this prospective study, 602 prenatal cases of CHD were investigated using SNP array over a 5-year period. **Results:** Overall, pathogenic chromosomal abnormalities were identified in 130 (21.6%) cases, with 50% of them being numerical chromosomal abnormalities. The detection rates of likely pathogenic copy number variations (CNVs) and variants of uncertain significance were 2.8% and 5.1%, respectively. The detection rate in CHD plus extra cardiac anomalies group was significantly higher than that in isolated CHD group (48.9% vs. 15.4%,  $P < 0.05$ ). There was no significant difference between the detection rates in CHD plus nonstructural anomalies and isolated CHD groups (21.8% vs. 15.4%). The detection rate in fetuses with CHD plus mild ventriculomegaly was significantly higher than those with other types of soft markers (50.0% vs. 15.6%,  $P < 0.05$ ). Notably, three recurrent likely pathogenic CNVs were identified, including microduplications at 18p11.23, 15q11.2 and 22q11.22, of which, 18p11.23 duplication involving *PTRPM* was likely to be the candidate locus for CHD. Our study suggests CMA is a reliable and high-resolution technology and should be used as the first-tier test for prenatal diagnosis of CHD in clinical practice.

## 440T

**Do fetal endothelial nitric oxide synthase (eNOS) gene haplotypes influence prolonged preterm rupture of fetal membranes (PPROM)?** K. Yanamandra, D. Napper, J.A. Bocchini Jr., R. Dhanireddy. 1) Pediatrics, LSU Health Science Center, Shreveport, LA; 2) Neonatology section, UT Health Science Center, Memphis, TN.

PPROM is a multifactorial etiology leading to growth restriction of the fetus in utero. It could risk severe prematurity, small for gestation, and fetal distress leading to respiratory failure after birth. Animal studies suggest that NO in placental vasculature is required to facilitate fetal growth. Earlier studies showed that preterm infants with severe respiratory failure respond favorably to inhaled nitric oxide. These infants may have a deficiency in the inflammatory response, including a defect in nitric oxide generation in airspaces. We have previously reported that the mutant eNOS genotypes, leading to decreased Nitric oxide, increased the risk of respiratory distress, chorio-amnionitis, and IUGR, in premature infants. To study the potential association of infant eNOS genotypes and PPRM, we analyzed eNOS gene haplotypes (T786C, G894T, intron 4 VNTR b/a genotypes), in 161 preterm infants (62 PPRM and 99 Non-PPROM controls), using microplate PCR genotyping methods. Our data on eNOS double marker (T786C and G894T) analysis revealed that PPRM infants showed 31% mutant C/T haplotypes compared to 16% without PPRM history among the Caucasians. Our eNOS triple marker (T786C, G894T, and intron 4 VNTR b/a) analysis in Caucasians infants with PPRM showed 27% vs. those without PPRM history of 15%. Among the African American (AA) infants our analysis revealed 11% vs. 6%; 19% vs. 13% in PPRM infants compared to infants without PPRM history in double and triple marker analyses respectively. Table: eNOS gene haplotypes in Caucasian and AA PPRM & Non-PPROM premature infants.

eNOS Diplo & Haplotype	PPROM Caucasians	Non-PPROM Caucasians	OR pValue	PPROM AA	Non-PPROM AA	OR (95% CI) pValue (AA)
CC-TT	1 0.06	2 0.02		0	0	0
TC-GT	8 0.5	23 0.27		24	0.22	14 0.12
TT-GG	7 0.44	61 0.71		86	0.78	102 0.88
C-T	10 0.31	27 0.16	2.5(1-6.2)0.036	24	0.11	14 0.064)0.06
T-G	22 0.69	145 0.84		196	0.89	218 0.94
CC-aa-TT	1 0.04	3 0.02		6	0.04	3 0.02
TC-ba-GT	11 0.46	31 0.24		51	0.31	42 0.24
TT-bb-GG	12 0.5	94 0.73		106	0.65	128 0.74
C-a-T	13 0.27	37 0.15	2.2(1-4.8)0.003	63	0.19	44 0.132.5)0.027
T-b-G	35 0.73	219 0.85		263	0.81	294 0.87

Our data suggest a significant association with the eNOS mutant haplotype only with triple marker (C-a-T) in both Caucasians and AA infants, but not with double marker in AA. Infants with PPRM have higher frequencies of mutant haplotypes, reducing the endogenous NO; this is the first report to suggest the influence of eNOS gene haplotypes in the etiology of PPRM in premature newborn infants.

**Alteration of the expression and methylation modification of RAS in cardiomuscular tissue of the mice conceived by in-vitro fertilization.** Q. Wang<sup>1,2</sup>, F. Zhang<sup>1,2</sup>, Y. Zhang<sup>1,2</sup>, Y. Lou<sup>1,2</sup>, L. Wang<sup>1,2</sup>, M. Yuan<sup>1,2</sup>, M. Hu<sup>1,2</sup>, F. Jin<sup>1,2</sup>. 1) Department of Reproductive Endocrinology, Women's Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, Ch, Hangzhou, Zhejiang, China; 2) Key Laboratory of Reproductive Genetics, National Ministry of Education (Zhejiang University), Women's Reproductive Health Laboratory of Zhejiang Province, Hangzhou, Zhejiang, China.

Epidemiological studies have found that newborns conceived by in vitro fertilization (IVF) had an increased risk of cardiovascular malformations and cardiovascular dysfunction, suggesting that IVF may disturb the process of embryonic and fetal development. However, the exact mechanisms have not been investigated and its long-term effects on the health of IVF offspring remain unclear. In the present study, the expressions of renin-angiotensin system (RAS) in the cardiomuscular tissue of IVF mice from childhood to old age have been measured. Meanwhile the methylation levels of CpG island of *Ctgf* and *Col1a1* and the regulatory functions of microRNAs and DNA methyltransferases (*Dnmts*) were investigated. The altered expression levels of COLI/COLIII and RAS-COLI/COLIII related epigenetic regulators were also observed, which indicates that IVF process may cause abnormal expression of RAS-COLI/COLIII in the offspring through microRNA-mediated pathway. The results showed that IVF could cause long-lasting alterations in RAS expression of cardiomuscular tissue of IVF mice.

**Ancestral disparities in genetic architecture of life course correlations between early growth and adulthood cardiometabolic disorders.** F. Tekola Ayele<sup>1</sup>, T. Workalemahu<sup>1</sup>, A. Amare<sup>2</sup>. 1) NICHD, National Institutes of Health (NIH), Bethesda, MD; 2) School of Medicine, University of Adelaide, Adelaide, SA, Australia.

Aberrant fetal growth has been consistently associated with cardiovascular diseases and diabetes in adulthood. Recent genome-wide association studies found genetic loci that influence both growth in early life and cardiometabolic diseases in later life. However, whether and to what extent genetic variations contribute to the enigma of disparities in fetal growth and cardiometabolic diseases among diverse ancestral populations is poorly understood. In the present study, we (1) tested whether the burden of genetic variants that increase the risk of reduced birthweight and cardiometabolic diseases varies by ancestry, (2) evaluated the distributions of the genetic risk alleles with reference to the "common-disease common-variant hypothesis" in diverse ancestral populations, and (3) determined whether genetic selection contributed to enrichment of rare variants associated with increased burden of reduced growth and cardiometabolic disorders. Genotype data were extracted from phase 3 of the 1000 genomes project for 2,504 participants from 26 global populations grouped into five super-populations, namely Europeans, Africans, Admixed Americans, East Asians, and South Asians. Genetic risk burden (GRB) was calculated as the weighted sum of the number of genetic variants associated with increased risk for low birthweight, type 2 diabetes, obesity, and dyslipidemia (n=416 SNPs). We found differences between Europeans and non-Europeans in the allelic architecture and cumulative burden of genetic risk of early growth and cardiometabolic abnormalities. Specifically, GRB was significantly higher in Africans, Admixed Americans, East Asians, and South Asians compared to Europeans for type 2 diabetes, dyslipidemia, and low birthweight, but not for obesity. In all traits, risk genetic variants in Africans and East Asians were enriched for rare alleles ( $P < 0.001$ ), displaying the greatest deviation from the expectation of the "common disease-common variant" hypothesis. GRB of ancestral alleles was significantly higher and that of derived alleles was significantly lower in non-Europeans compared with Europeans ( $P < 0.001$ ). We also found that negative selection did not explain the relatively higher proportion of rare genetic risk loci. Our findings suggest that genetic variations, interacting with environmental factors, contribute to observed population disparities in the life course correlations between early growth and adulthood cardiometabolic disorders.

**443T****PheWAS analysis of 13,000 individuals detects a common genetic variant that tags the Rh D blood group system in the European population.**

*J. Fadista<sup>1</sup>, L. Skotte<sup>1</sup>, J. Bybjerg-Grauholm<sup>2</sup>, F. Geller<sup>1</sup>, H. Boyd<sup>1</sup>, H. Hjalgrim<sup>1,3</sup>, D.M. Hougaard<sup>2</sup>, M. Melbye<sup>1,4,5</sup>, B. Feenstra<sup>1</sup>.* 1) Department of Epidemiology Research, Statens Serum Institut, Copenhagen, Denmark; 2) Danish Centre for Neonatal Screening, Department of Clinical Biochemistry, Immunology and Genetics, Statens Serum Institut, Copenhagen, Denmark; 3) Department of Haematology, Rigshospitalet, Denmark; 4) Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; 5) Department of Medicine, Stanford University School of Medicine, Stanford, California, USA.

The Rh D blood group system is the second most important blood group system after ABO, and besides its role in transfusion medicine, the D antigen is of primary importance in obstetrics due to its causal role in hemolytic disease of the newborn. By using existing genotype data on 3500 mothers of European ancestry (GWAS and HRC imputed) and performing association testing against all their ICD-8 and ICD-10 codes from the Danish National Patient Registry we were able to detect a PheWAS significant ( $P < 5 \times 10^{-9}/626$  ICD codes) association in the *RHD* gene for the ICD-10 code "Prophylactic Immunotherapy – Z29.1" (OR=33,  $P=1.5 \times 10^{-72}$ , 272 cases). The top SNP rs72660908 perfectly tags the *RHD* gene deletion as detected by copy number variation analysis. Moreover, for a subset of mothers for which we had blood group information, we confirmed that homozygous GG individuals for rs72660908 were all Rhesus D negative. The fact that the ICD-10 code "Prophylactic Immunotherapy – Z29.1" was always registered within 6 months before the second pregnancy delivery date, further confirms that this ICD-code tags the known anti-D prophylaxis in pregnancy for preventing Rhesus alloimmunisation for Rh-negative women who developed Rh-negative antibodies during their first pregnancies with Rh-positive fetuses. This result was replicated in an independent cohort of 9500 individuals, also GWAS and HRC imputed, from the Michigan Genomes Initiative ( $P=3.2 \times 10^{-19}$ , <50 cases). In conclusion, by using a common variant that perfectly tags the Rh D blood group system, it is possible to impute this blood group in populations of European ancestry. Rh D status can then be tested against clinically relevant health outcomes.

**444F****Compromised DNA repair and genomic imbalances in human male infertility.**

*V. Singh<sup>1</sup>, K. Singh<sup>1</sup>, S. Rajender<sup>2</sup>.* 1) Molecular and Human Genetics, Banaras Hindu University, Varanasi, India; 2) CSIR-Central Drug Research Institute, Lucknow, India.

**Introduction** DNA repair mechanisms are important to maintain the fidelity and genomic stability of developing germ cells. Defects in DNA repair during spermatogenesis underlie a major cause of testicular failure. **Objective** To investigate the expression of strong candidate genes of DNA repair pathway and whole genome imbalances in infertile male individuals. **Materials and Methods Study Population** The study was approved by the Institutional Human Ethics Committee, Faculty of Science, Banaras Hindu University, Varanasi, India (Dean/2011-12/119 & Dean/2012-13/546). Informed written consent was obtained from every participant of each group. **Histological and Cytogenetic analysis** Histological analysis of testicular biopsies was performed by routine histopathology stain. Cytogenetic analysis was carried out using standard PHA stimulated whole blood culture followed by karyotyping using standard human chromosome nomenclature. Y-Chromosome deletion mapping using genomic DNA was performed by standard methods. **Expression analysis of DNA repair pathway genes** Relative expression of genes in testicular biopsies of infertile patients (n=4) vs control (n=1) was done using Human DNA Repair RT<sup>2</sup> Profiler™ PCR Array (SABiosciences, Frederick, MD, USA). Data analysis was performed using web-based automated analysis methods provided by SA Biosciences. Results of PCR array were validated in more number of samples (n=52) using Quantitative real-time PCR analysis of selected genes followed by data analysis using comparative CT Method ( $\Delta\Delta CT$  Method). **Genomic imbalances in infertile patients** To identify the genomic imbalances in infertile patients (n=23) vs fertile controls (n=10), we employed CytoScan™ 750K Array (Affymetrix, USA). The data were analyzed using Chromosome Analysis Suite (ChAS) software package (Affymetrix, USA). **Results** Expression analysis of DNA repair pathway genes showed a significant down-regulation of majority of the genes. The cytogenetic array analysis detected a common gain on chromosome 19p13.3 region in 4 (17.3%) cases. The analysis also identified &gt;5Mb Loss of Heterozygosity on chromosome 3p21.31 region in 6 (26%) cases. **Conclusion** The results clearly indicate compromised DNA repair machinery and genomic imbalances in infertile patients and opens new horizons for further investigation of the role of these genes in spermatogenesis. **Support** This study was funded by Board of Research in Nuclear Sciences (BRNS), Mumbai, India.

**445W**

**Validation of a novel copy number variant detection algorithm for CFTR from targeted next-generation sequencing data.** *K. Kosheleva, K. Robinson, N. Faulkner, M. Umbarger.* Good Start Genetics, Cambridge, MA.

Cystic fibrosis (CF) is a severe, recessive disorder resulting from the inheritance of two null copies of the cystic fibrosis transmembrane conductance regulator (CFTR) gene. While most causative mutations for CF are single nucleotide variants, insertions, and deletions, it is estimated that CFTR copy number variants (CNVs) represent about 1-2% of pathogenic mutations underlying CF. Here, we outline the validation of a new strategy for utilizing targeted NGS data to call copy number variants in the CFTR gene. Specifically, we have developed a read-count based CNV calling algorithm to detect deletions and duplications in the CFTR gene at single-exon resolution. The algorithm employs a log odds ratio statistic derived from the number of reads mapping to each exon, which are first corrected for batch-, sample- and exon-specific sources of variability, to assess the relative probability of different copy number states. To evaluate the performance of the method, we estimated specificity and sensitivity by applying our algorithm to a panel of 25,203 patient DNA samples. This panel included 16 samples identified as containing CFTR CNVs via genotyping or multiplex ligation dependent probe amplification, as well as 140 cell-line-derived controls carrying a deletion of CFTR exons 2 and 3. Next, to evaluate sensitivity across a broader array of CNV sizes and positions, we simulated single- and multi-exon duplications and deletions of varying lengths and assessed the rate at which these simulated CNVs were called via our analysis methodology. Our method correctly identified all 156 samples known to contain CNVs. Among the remaining 25,187 samples, we estimated a sample-level specificity of 99.85% +/- 0.05% and, using simulation data, an average sensitivity of 99.998% +/- 0.001% for deletions (100% whole-gene; 99.988% single-exon) and 99.978% +/- 0.001% for duplications (99.98% whole-gene; 99.97% single-exon). Of note, these statistics include the historically challenging paralogous region of exon 10 (99.97% single-exon sensitivity). In summary, we have developed and validated a CNV calling algorithm that is able to detect single exon to whole gene deletions and duplications at high sensitivity and specificity, thereby further enhancing the clinical sensitivity of our NGS-based CF carrier screening test.

**Genetic diagnosis of disorders of sex development (DSD): A national registry for disease-specific precision health.** *E.C. Delot<sup>1,2</sup>, J.C. Papp<sup>1</sup>, H. Barseghyan<sup>1,2</sup>, D.E. Sandberg<sup>3</sup>, E. Vilain<sup>1,2</sup>, The DSD-TRN Genetics Workgroup.* 1) Dept Human Genetics, Gonda Center, UCLA, David Geffen School of Medicine, Los Angeles, CA, USA; 2) Center for Genetic Medicine Research, Children's National Medical Center, 111 Michigan avenue, Washington DC, NW, USA; 3) Dept. Pediatrics & Communicable Diseases & the Child Health Evaluation and Research Center, University of Michigan Medical School, 1500 East Medical Center Drive, Ann Arbor, MI 48109, USA.

The 2005 DSD Consensus Conference called for the establishment of an infrastructure for collaborative interdisciplinary clinical practice and research, to integrate scientific understanding of DSD with real-time standardization and improvement in clinical practice. In response, the DSD-Translational Research Network (DSD-TRN) was created, the first such North American infrastructure, with the collaboration of patient advocates convened by Accord Alliance, a network of 4 (now expanded to 12) US research and clinical sites and a central registry. To address variability within and across medical, surgical, and behavioral health aspects of care, the DSD-TRN is dedicated to scientific discovery and the standardization of diagnostic and treatment protocols, including an early and comprehensive diagnostic process, associated with extensive standardized phenotyping and psychosocial screening of patients and families. An accurate diagnosis is critical to predicting occurrence of life-threatening crises, response to hormone-replacement therapy, stability of gender identity, fertility, recurrence risk, cancer risk, and patient quality-of-life outcomes. Genomic technologies, chromosomal microarrays, and next-generation sequencing are revolutionizing the approach to DSD diagnosis. With exome sequencing and DSD-specific panels now routinely available in the clinical realm, DSD-TRN best practice guidelines recommend early, comprehensive genetic testing as a means to improve the path to an accurate diagnosis and optimized clinical management. Longitudinal data collection and monthly clinical activity reports allow tracking of the effort, success, completion, and timeline of the diagnostic process for each clinical team. Relative diagnostic efficacies of genetic testing methods, frequencies of the different DSD conditions, and rates of definitive genetic diagnosis were analyzed. Analysis of data for 144 probands at 9 clinical sites showed that genetic diagnostic efforts by DSD-TRN teams were rewarded by a substantial increase in patients with a firm diagnosis: from 24% to 46%. The rate of successful diagnosis can however be vastly improved by increased adherence to DSD-TRN diagnostic guidelines: for almost all (97%) of the patients who remain without a diagnosis, currently available diagnostic methods (such as trio exome sequencing and chromosomal microarray) have not been exhausted.

**447F**

**Transethnic meta-analyses from genome-wide association studies of fibroid characteristics in African and European American women.** *M.J. Bray<sup>1</sup>, M.F. Wellons<sup>2</sup>, T.L. Edwards<sup>1,2,3,4</sup>, D.R. Velez Edwards<sup>1,4,5,6</sup>.* 1) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, TN; 2) Department of Medicine, Vanderbilt University, Nashville, TN; 3) Division of Epidemiology, Vanderbilt University, Nashville, TN; 4) Institute of Medicine and Public Health, Vanderbilt University, Nashville, TN; 5) Vanderbilt Epidemiology Center, Vanderbilt University, Nashville, TN; 6) Department of Obstetrics and Gynecology, Vanderbilt University, Nashville, TN.

The majority of women in the US will develop at least one uterine fibroid by menopause. Fibroids are heterogeneous varying in size and number, leading to a range of symptoms from chronic pelvic pain to heavy, painful periods. While the heritability of fibroid characteristics such as size and number is unknown, the estimated heritability for fibroid risk ranges between 26-69%. It is possible that specific fibroid characteristics are heritable and that this heritability is driven by genetic loci. To address this, we performed transethnic meta-analyses from genome wide association studies (GWAS) on fibroid characteristics on African and European American women. Using BioVU, a clinical cohort from the Vanderbilt University Medical Center, and the Coronary Artery Risk Development in Young Adults (CARDIA) cohort, a prospective cohort, we identified 1,520 women with documented fibroid characteristics. We imputed ungenotyped SNPs using the 1000 Genomes Cosmopolitan reference panel phase 1 version 3. We performed single SNP association analyses on  $\log_{10}$  transformed volume of largest fibroid,  $\log_{10}$  transformed largest fibroid dimension, and fibroid number (1 vs >1) for common SNPs (minor allele frequency >5%) and adjusted for age, BMI, and five principal components. Finally, we performed fixed effects inverse-variance weighted meta-analyses. We then evaluated associations between genetically predicted gene expression and fibroid characteristics using MetaXcan using results from GWAS meta-analyses. We identified nominal genetic signals ( $p < 1 \times 10^{-5}$ ) on chromosomes 1q31.1 and 4q35.1 for fibroid volume, on chromosomes 6q27, 4p16.1, and 10p11.22 for largest fibroid dimension, and on chromosomes 15q15.3, 7p14.3, and 1q24.1 for fibroid number. The strongest signal from the meta-analyses was in 1q31.1 with flanking genes phospholipase A2 group IVA (*PLA2G4A*) and BMP/retinoic acid inducible neural specific 3 (*BRINP3*) (rs6605005,  $\beta = 0.24$ ; 95% confidence interval: 0.15, 0.33;  $p = 7.68 \times 10^{-8}$ ). MetaXcan results showed an association between the predicated gene expression of ER degradation enhancing alpha-mannosidase like protein 2 (*EDEM2*) in thyroid tissue for fibroid number ( $p = 6.34 \times 10^{-6}$ ). In summary, this study found many associations between genetic loci as well as gene expression and fibroid size and number. This work will help lay the foundation for understanding the link between genetic variation and fibroid characteristics.

**448W**

**Non-immune hydrops fetalis with long bones fragility: A new subtype of osteogenesis imperfecta type II or a new form of skeletal dysplasia?** *G.A. Molfetta<sup>1,2,3,5</sup>, A. Piram<sup>4,5</sup>, A.J. Machry<sup>2</sup>, T.O. Anjos<sup>3</sup>, A.A. Marques<sup>3</sup>, W.A. Silva Jr<sup>1,2,3</sup>.* 1) Department of Genetics, Ribeirao Preto Medical School, University of São Paulo, Ribeirao Preto, SP, Brazil; 2) Center for Medical Genomics at General Hospital of the Ribeirao Preto Medical School, University of São Paulo, Ribeirao Preto, SP, Brazil; 3) Regional Blood Center at General Hospital of the Ribeirao Preto Medical School, University of São Paulo, Ribeirao Preto, SP, Brazil; 4) Gemina Women's Diagnostic Clinic, Londrina, PR; Brazil; 5) Authors Equally Contributed to the Work.

A 29-year-old primigravida was referred at the 22<sup>nd</sup> week of gestation for second trimester morphology ultrasound because of hydrops fetalis. She and her husband were no consanguineous. During the assessment at the fetal medicine clinic, the finding of massive hydrops markedly in face and skull on a phenotypically female fetus was confirmed and additional anomalies were detected such as small nose, slight rhizomelic shortening of upper extremities, radial hands deviation, slight ankle varus deformity, important shortening of femurs and unilateral angulated ulna suggesting ulnar fracture, small ventricular septal defects. Amniocentesis procedure was scheduled for the 23<sup>rd</sup> week of gestation when it was found the fetus was already dead. Postmortem examination of the spontaneous expelled fetus weighing 540 grams confirmed the ultrasound findings. X-rays images showed osteopenia throughout the skeleton with multiple bone fractures and deformities of the long bones more accentuated on lower limbs and left upper limb resembling Osteogenesis Imperfecta (OI). Both fetal blood and amniotic fluid samples for cytogenetic and molecular studies were collected. Based on the radiological images indicating a major clinical suspicion of OI, a NGS panel was employed to screen for mutations the fourteen genes coding for OI. No pathogenic mutations were detected. Regarding the in utero differential diagnosis, we ruled out the presence of Campomelic Dysplasia and Thanatophoric Dysplasia due to no pathogenic mutations in *SOX9* and *FGFR3*, respectively. In addition, we ruled out Achondrogenesis type 1B and Hypophosphatasia by the clinical criteria. Severe forms of OI are frequently diagnosed prenatally as consequence of in utero ultrasound scanning. The main classical sonographic features of OI type II include diffuse hypomineralization of the skeleton, shortening and bowing of long bones, multiple fractures. The three subtypes of OI type II (A, B and C) are characterized by different radiological features. Hydrops fetalis can be seen in association with the subtype IIA. In the present case, it was not observed undermineralization of the skull and ribs abnormalities. Whole Exome Sequencing is being executed and might help to elucidate this case. Depending on the findings of a mutated gene other than *COL1A1/CO1A2*, whose protein product is involved with the collagen pathway or the findings of a non-related to collagen gene, we will be able to better describe this clinical phenotype.

## 449T

**Prenatal diagnosis of diastrophic dysplasia: Importance of prenatal approach with NGS panel.** M. Tamayo, M. Garcia-Acero, L. Mora. Instituto de Genética Humana, Facultad de Medicina, Bogota DC, Colombia.

**Introduction:** Diastrophic Dysplasia (DD) is a congenital osteochondrodysplasia with an autosomal recessive inheritance pattern. The most common clinical findings are short stature, cleft palate, cysts pinna with calcified cartilage and micromelia, associated to scoliosis, cervical kyphosis, hypoplasia of the cervical vertebrae, lumbar lordosis, clubfoot, joint contractures with progressive degenerative changes, brachydactyly, abductees and hypermobile thumbs and symphalangism. During the neonatal period mortality can reach up to 25% mainly due to airway obstruction and aspiration pneumonia. For those who survive this period the prognosis for life is good. **Case presentation:** We present a male patient of 1 year old, son of non-consanguineous parents but of the same location, with prenatal diagnosis at 13 weeks of short long bones, bilateral clubfoot and abducted hitchhiker thumb, with history of sister with unknown skeletal dysplasia who dies due to pulmonary hypoplasia. Was requested molecular diagnostic through NGS panel of skeletal dysplasia in sample of amniocentesis, which identified two heterozygous pathogenic variants in *SCL26A2* gene (c.532C>T and c.835C>T), changes were demonstrated in each parent. At birth with evidence of rhizomelic shortening, clubfoot, passive and active reduced mobility, abduction and earlier implementation of the thumb. Radiologic studies showed shortening of long bones with metaphyseal widening, short tubular bones, short and wide first metacarpal and bilateral clubfoot. Currently with clubfoot corrected, he has a sitting position and starts crawling and is in multidisciplinary monitoring. **Discussion.** It was made molecular prenatal diagnostics of DD suspected by the ultrasonographic findings, ruling out the presence of a lethal skeletal dysplasia given the history of the affected sister. DD is marked by short stature with short extremities and joint malformations can lead to either limitation of joint movement or hyperlaxity. The severity of the clinical manifestations is variable, ranging from very severe to moderate forms that may be diagnosed very late as clinical heterogeneity of skeletal dysplasia. **Conclusion.** The availability of NGS panel for Skeletal dysplasia lead establish an early diagnosis to determine the prognosis and to prepare the delivery team. Modifying the course of an initial suspicion of lethal skeletal dysplasia.

## 450F

**Neurodevelopment in Japanese singletons, aged 4–6 years, conceived by assisted reproductive technologies.** T. Shimada<sup>1</sup>, T. Kawamoto<sup>2,3</sup>, A. Yoshida<sup>4</sup>, Y. Takehara<sup>5</sup>, T. Kuroda<sup>6</sup>, N. Kawasaki<sup>6</sup>, K. Kato<sup>5</sup>, K. Shimodaira<sup>5</sup>, Y. Osuga<sup>7</sup>, Y. Kamei<sup>8</sup>, T. Okai<sup>8</sup>, N. Kato<sup>9</sup>, T. Sasaki<sup>9</sup>. 1) Office for Mental Health Support and Communication Support Room, Division for Counseling and Support, the University of Tokyo, Tokyo, Japan; 2) Faculty of Letters, Keio University, Tokyo, Japan; 3) Research fellow of Japan Society for the Promotion of Science; 4) Reproduction Center, Kiba Park Clinic, Tokyo, Japan; 5) Kato Ladies Clinic, Tokyo, Japan; 6) Department of Obstetrics and Gynecology, Showa University School of Medicine, Tokyo, Japan; 7) Department of Obstetrics and Gynecology, Faculty of Medicine, the University of Tokyo, Tokyo, Japan; 8) Department of Neuropsychiatry, Showa University School of Medicine, Tokyo, Japan; 9) Division of Physical and Health Education, Graduate School of Education, the University of Tokyo, Tokyo, Japan.

**Background:** Assisted reproductive technologies (ART) are infertility treatments which handle gametes. The number of children born using ART sharply increases from 1990s. Similarly, the prevalence of neurodevelopmental disorders (NDD) increases rapidly over the last several decades. On the other hand, recent studies suggest that *de novo* mutations and epimutations in the genome play a role in NDD. ART may have effects on NDD and neurodevelopment of children through these processes. A number of studies have examined effects of ART on child neurodevelopment. Although most of the studies found no significant effect, the conclusion remains to be reached, due to several confounders including parental age and traits of neurodevelopment which were not fully or at all adjusted for. Differences in the effects according to ART methods (i.e. *in vitro* fertilization (IVF), vs. intracytoplasmic sperm injection (ICSI), and fresh vs. frozen embryo transfer) also remain to be studied. **Methods:** We conducted clinic-based multicenter retrospective cohort study, to investigate effects of ART on neurodevelopment, with careful adjustment for confounders. Neurodevelopment was compared between Japanese singletons, with maternal age at birth < 36 years, born after ART (n = 300) and natural conception (NC) (n = 181), at age of 4–6 years using parent-reported Child Behavioural Checklist (CBCL) and Social Responsivity Scale (SRS). Effects according to ART subtype (IVF (without ICSI, n = 168) vs ICSI (n = 130), and fresh (n = 136) vs frozen embryo transfer (n = 158)) were examined. Propensity score with doubly robust estimation was employed to control for potential confounders, including parental neurodevelopmental traits assessed using Autism Spectrum Quotient score and Adult ADHD Self-Report Scale. **Results:** Total problems, externalizing and internalizing scores of CBCL were significantly better in the ART than the NC group (standardized difference (95% CI): -0.29 (-0.48 — -0.10), -0.20 (-0.39 — -0.10) and -0.20 (-0.39 — -0.02), respectively). No significant difference was observed between IVF and ICSI. The scores, however, were significantly better in the fresh than the frozen embryo subgroup. The SRS total score was not different between NC and ART or ART subgroups, while some SRS subscores were significantly better in the ART group/subgroups than NC group. **Conclusions:** A negative effect of ART on child neurodevelopment was not suggested in a Japanese population.

## 451W

## Perinatal outcomes have little influence on FSIQ in children with

**22q11.2DS.** T. Crowley<sup>1</sup>, R. Sharkus<sup>1,2</sup>, M. Unolt<sup>1,3</sup>, A. Silverman<sup>1</sup>, B. Emanuel<sup>1</sup>, E. Zackai<sup>1</sup>, D. McDonald-McGinn<sup>1</sup>. 1) Children's Hospital of Philadelphia, Philadelphia, PA; 2) Rowan University School of Osteopathic Medicine, Stratford, NJ; 3) Sapienza University, Rome, Italy.

**BACKGROUND:** Perinatal outcomes, such as prematurity and low birth weight have been reported in association with lower FSIQ scores and higher risk of psychosis in adults with 22q11.2DS, however, to our knowledge, no similar study has been conducted in a pediatric cohort. **METHODS:** We reviewed birth weight (BW), gestational age (GA), Apgar Scores and early (<72 hours) neonatal complications in 368 patients with 22q11.2DS and FSIQ measures. **RESULTS:** Overall mean age at assessment was 9.8 years. FSIQ was 76.22. Prematurity (~34 to <37 weeks) was noted in 53/350 (15%). 11% had VLBW; 4% had ELBW. No correlation ( $R^2=.01$ ) was found between FSIQ and GA or BW ( $R^2=.01$ ). Of 297 full term (FT) infants 10% were SGA and 6% were LGA with no correlation ( $R^2<.01$ ) between FSIQ and GA or BW ( $R^2<.01$ ). Thus, regardless of BW, when FSIQ of the FT group (76.7) was compared with the premature group (73.5) no significant difference was found ( $p=.16$ ). In contrast, 7/138 patients (5%) had low Apgar Scores (< 7 at 5 minutes) associated with significantly lower FSIQ, though the small sample size was small. Early neonatal complications of any type (RDS, cyanosis, seizures, jaundice) were described in 45% while the remainder had an uncomplicated perinatal course (discharged to home on DOL 2 or 3). Surprisingly, the presence of 1 or more perinatal complication did not effect FSIQ. **CONCLUSIONS:** We found no significant correlation between perinatal outcomes and FSIQ in our pediatric cohort apart from low Apgar Scores at 5 minutes in a small subset, which may reflect an ascertainment bias related to the lack of decline in FSIQ observed in older patients or rather that the effect of the 22q11.2 deletion supercedes all other factors except a very severe secondary insult. Lastly, we found a lower prevalence of SGA full term births than previously reported (10% vs 20.3%) disputing the suggestion that SGA is a common feature of 22q11.2DS.

## 452T

## Independent head-to-head comparative diagnostic accuracy of NIPT methods in a prospective Canadian cohort of high-risk and low-risk pregnant women: The PEGASUS study.

Genomics-based Non-invasive prenatal screening (NIPS) is recognized as a second-tier prenatal screening test for common major aneuploidies (T13, T18 and T21). However, NIPS assays are laboratory developed tests and there is little data on the comparative performance of different NIPS assays. Further, most of the NIPS test offer is currently available through commercial laboratories. We aimed at independently comparing head-to-head, in a prospective cohort, the screening performance of two NIPS platforms implemented in Canadian public laboratories for detecting T21, T18, T13 and 45,X. **Methods** We recruited prospectively 2012 high-risk and 1807 low-risk pregnant women (NCT01925742). Clinical outcomes collected were: prenatal screening results, cytogenetic analysis, newborn exam and follow-up outcome at age 6 weeks. 69 cases were lost to follow up. 3616 samples were randomly selected for analysis. Two untargeted (MPSS) NIPS assays were implemented in three Canadian public labs (Illumina's HiSeq-2500 and LifeTech's Proton). Samples were randomized between labs and tested by both assays sequencing 4-8 million random maternal ccfDNA fragments to compute chromosomal ratio's z-scores. Chromosomal-ratios mean CVs were XX0.47 for T21, 0.33 for T18 and 0.31 for T13. Fetal fraction was estimated with SeqFF. **Results** The cohort included 155 cases of T21, 50 T18, 8 T13, 22 45,X. Detection rates(DR) and false positive rates(FPR) for T21, T18, T13 and Turner were not statistically different between platforms: mean DR 99% (T21), 100% (T18, T13); 70% (Turner); FPR 0.3% (all). The no-result rate was not significant (between assays, nor between high-risk and low-risk : mean 3.7% (Chi2 1df<0.9, p>0.7). For both methods in high-risk pregnancies, PPV were 97%(T21), 89% (T18), 75% (T13) and 70% (Turner). NPV>99.9 for aneuploidies except Turner (99.5% vs 99.8%). **Conclusions** Our results suggest that both MPSS methods compared (semiconductor-based NGS and optical-based NGS) showed equivalent and excellent test performance. Although slight differences between labs and methods were observed, overall the two assays and the three public laboratories performed well in this independent study. NIPS could be implemented and covered by the public health care system as a second tier screening test for high-risk women identified by traditional prenatal screening at higher risk of aneuploidy. Implementation of this approach as a first-tier screening test remains to be investigated.

**453F****Single-cell RNA sequencing in sperm from fathers of autistic children.**

*J.A. Rosenfeld<sup>1</sup>, D. Tomoiaga<sup>2</sup>, S. Shrestha<sup>2</sup>, S. Levy<sup>3</sup>, C.E. Mason<sup>2</sup>.* 1) Pathology, Rutgers, NJ; 2) Weill Cornell Medical College, New York, NY; 3) Hudson Alpha Institute for Biotechnology, Huntsville, AL.

The incidence of autism has been shown by numerous studies to be correlated an increase in the age of the father at the time of conception. This connection is thought to be related to the increase in de novo mutations or copy number variations in sperm. In addition to autism, there are many other disorders associated with advanced paternal age that are collectively known as paternal age effect (PAE) disorders. There is currently no effective method to test sperm for the presence of mutations related to PAE disorders. The current guidance from clinical geneticists is for patients to avoid having children when the male is older, but there is no clear way to screen out those younger men who could have mutations or dys-regulated genes in their sperm. Until recently, the only way to look for rare mutations in sperm would be to take a bulk sample of cells, sequence them to a very high depth and then to look for variants identified by a very small number of reads. This type of assay is expensive, and it is difficult to differentiate the very low frequency variants from those that are a result of a sequencing errors or allelic drop-out (ADO). This problem has been alleviated with the introduction of systems such as the 10X Genomics Chromium instrument. Using an innovative molecular bar-coding scheme and the separation of individual cells, the Chromium allows for the direct sequencing of single cells. For each cell, the amount of RNA for each gene is identified and the cells can be grouped by expression patterns. We have used this technology, for the first time, to examine the individual sperm of donors who have children with autism as compared to control sperm from donors who do not have autistic children. We have sequenced >10,000 sperm cells in the donors and patients and determined that germline-specific gene expression patterns are specifically enriched in these samples. Moreover, we observe significant differences in the developmental pathways between the cases and controls, indicating this may be a method to reveal baseline functional genomics differences in sperm donors. Using innovative computational methods, we have been able to call SNP variants from the RNA-seq data. It is hoped that this work will lead to a screen for sperm to determine which patients are at a higher risk of having a child affected with autism or another PAE disorder.

**The Dutch TRIDENT studies: Implementing NIPT as part of the national prenatal screening program.** E.A. Sijm<sup>1</sup>, L. Henneman<sup>1</sup>, H. Scheffer<sup>2</sup>, M.J. Pieters<sup>3</sup>, M. Macville<sup>3</sup>, M.N. Bekker<sup>4</sup>, C.J. Bax<sup>5</sup>, A.R.M. van Opstal<sup>6</sup>, F.T.J. Sleutels<sup>7</sup>, M.M. Weiss<sup>1</sup>, A.J.E.M. van der Ven<sup>1</sup>, R.-J.H. Galjaard<sup>1</sup>, the Dutch NIPT Consortium. 1) Clinical Genetics, VU University Medical Center, Amsterdam, The Netherlands; 2) Department of Clinical Genetics, Maastricht UMC+, Maastricht, The Netherlands; 3) Department of Obstetrics and Gynecology, Grow, School for Oncology and Developmental Biology, Maastricht University Medical Center (MUMC), Maastricht, The Netherlands; 4) Department of Obstetrics, University Medical Center Utrecht, The Netherlands; 5) Department of Obstetrics, Academic Medical Center, Amsterdam, The Netherlands; 6) Verlofskandinavienpraktijk Velp e.o., Velp, The Netherlands; 7) Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, The Netherlands.

Non-Invasive Prenatal Testing (NIPT) has been rapidly introduced worldwide. In many countries this has been done by companies and/or (academic) medical centers, without any governmental guidance. In the Netherlands, a license from the Minister of Health must be obtained before offering prenatal screening for Down syndrome, because of the Population Screening Act. In 2014 the Dutch NIPT Consortium, which includes all stakeholders that are involved in prenatal care, obtained a license for the TRIDENT-1 study, allowing NIPT for women with high-risk pregnancies based on first trimester combined test (FCT) results or medical history. TRIDENT-2, which aims at implementing NIPT for all pregnant women within the framework of the national prenatal screening program, started April 1<sup>st</sup> 2017. In TRIDENT-2, NIPT will become available for all pregnant women in the Netherlands (on average 180,000 women/year). The Minister decided to invest €26 million/year to ensure that NIPT analysis would be affordable to all women. Women who want to have prenatal screening can now choose which test they prefer (NIPT or FCT). As in TRIDENT-1, a whole genome sequencing approach is used for NIPT. Women have the choice between receiving results for chromosomes 21, 13 and 18 only, or for all autosomes. Sex chromosomal abnormalities will not be analyzed and reported. As the numbers of participants in TRIDENT-2 are much higher than for TRIDENT-1, the entire chain from counselor to laboratory and back needed to be revised. The set-up of the project was closely supervised by the Ministry of Health during monthly meetings and included: training of ~3000 counselors; development of informational booklets and websites for pregnant women and professionals; increase of the laboratory capacity; contracting organizations for blood withdrawal; adapting the national prenatal screening database for ordering the NIPT test and reporting results; writing a grant for questionnaire and interview studies to study the women's perspective. During the first 7 weeks approximately 10,000 NIPT analyses were requested. The turnaround time is 6-7 working days for most of the samples. No major problems were encountered during the first weeks. Detailed information on the results will be presented at the meeting. We expect that this 3-year study will provide us with all the results needed for the final decision on the responsible introduction of NIPT in the Dutch National prenatal screening program.

**456F**

**Large-scale cytogenomic analysis of samples from conception to childhood: A comprehensive assessment of the landscape of unbalanced genomic abnormalities.** T. Sahoo, M.N. Strecker, S.B. Commander, M.K. Travis, N. Dzidic, C.E. Doherty, L. Dragan, K. Hovanec. CombiMatrix Diagnostics, Irvine, CA.

**Background:** No large studies have cataloged chromosomal imbalances and their phenotypic consequences over the course of human development, from conception through early childhood. **Methods:** We undertook a multi-year analysis of ~32,000 samples submitted for cytogenomic evaluation at different stages of human development, including embryo biopsies (N=6883), miscarriage (N=12324), prenatal (N=4176), neonatal (N=1564), and pediatric (N=7047) samples. Embryo biopsy samples were analyzed by arrayCGH or NGS and all other samples were analyzed by chromosomal microarray analysis (CMA). **Results:** Clinically significant chromosome abnormalities (CSCAs) were identified in 46% (3105/6683) of embryo biopsies. The majority (70%) were autosomal whole chromosome aneuploidies (WCAs): 32% monosomies, 29% trisomies and 8% with monosomy and trisomy. Another 17% samples had complex abnormalities. In miscarriage samples, 54% (6665/12324) demonstrated CSCAs, the most common being autosomal trisomies (63%), triploidy (12%) and monosomy X (11%). Autosomal monosomies were rare (<1%). CSCAs were present in 13% (542/4176) of prenatal samples, with trisomies (41%) and segmental deletions/duplications (44%) being the most common. In neonatal samples 18% (273/1564) had CSCAs; WCAs (34%) and segmental abnormalities (65%) were the most frequent. For pediatric samples, CSCAs were present in 12% cases (854/7047); most frequent were deletions (60%) or duplications (23%). **Conclusions:** This study provides a comprehensive view of the evolution of unbalanced genomic abnormalities with adverse effects on development from conception up to early childhood. Across all groups studied, the most severe chromosome abnormalities were detected in embryos and early pregnancy loss, resulting in failed implantation and/or non-viable pregnancy. The high frequency of autosomal monosomies in embryonic samples, rarely seen at later developmental stages, reflects the extreme vulnerability of cellular mechanisms that help maintain normal and stable genomic content. In contrast, the genomic alterations detected prenatally and neonatally are not necessarily incompatible with life, and the pediatric samples demonstrated a preponderance of less drastic deletions/duplications with significant diversity in terms of type and chromosomal involvement. These data reveal an interesting pattern of genomic alterations of decreasing severity as human growth progresses from conception through childhood.

**457W**

**Perinatal features and genotype-phenotype correlations in a large cohort of 355 patients with Prader-Willi syndrome.** V. Kimonis. UC Irvine, Irvine, CA.

Background: Prader Willi Syndrome (PWS) is caused by lack of expression of genes on the paternal chromosome 15q11.2 - 13 . There is an evolving phenotype for those patients with either a Deletion, Uniparental Disomy (UPD) or an Imprinting Center Defect (ICD). Objectives: We evaluated the early manifestations of PWS in pregnancy and early neonatal period to identify clinical features that would lead to early detection of PWS. We also looked for genotype-phenotype correlations for the genetic subtypes. Methods: Data from 355 patients from the Rare Diseases Clinical Research Network (RDCRN) PWS registry were used to analyze multiple clinical maternal and neonatal factors. Results: Out of 355 patients 61% had deletion, 36% had UPD and 3% had an IC defect. 54% were born by C-section (population 32%). Fetal movements were decreased in 72%. Mean birth weight was 2.71 kg. All babies were hypotonic, 72% needed gavage feeding and 23% needed G-tube placement, these values being significantly higher than the general population. Maternal age was significantly higher in the UPD group as was pre-pregnancy weight. Conclusions: There is a higher incidence of babies born with UPD to older mothers with higher pre-pregnancy weights. Although few significant differences were found in the variables between the different genetics subgroups, the incidence of C-section, low fetal movements, lower birth weight and other variables was significantly higher than the general population. The goal of this study is to increase awareness of the perinatal and neonatal features of PWS thus enable earlier diagnosis, treatment and prevention of morbid obesity and co-morbidities. .

**Next generation sequencing based carrier screening study in Chinese population.** G. Chen, Y. Xu, Q. Zhang, Q. Zhao, Y. Bai, D. Wang, Y. Meng, S. Chang, X. Ma, Y. Xie, L. Wei, P. Fang, L. Liu. WuXi NextCODE Genomics.

Obtaining carrier status information for severe recessive diseases can help individuals to make reproductive decisions. The current next generation sequencing (NGS) technique allows development of carrier screening test containing large number of genes with affordable price. Simultaneously analyze large number of genes can identify variants of significant clinical impact and facilitate establishing detection rate and reproductive risk of associated recessive Mendelian diseases for diverse populations. We have developed a NGS based expanded carrier screening test containing about 200 genes associated with 135 recessive diseases specifically for Chinese population. The selected genes are associated with early onset, severe inherited disease with known relatively high incidence in Chinese or East Asia population. After NGS sequencing and bioinformatics analysis, all variants are manually curated based on published The American College of Medical Genetics and Genomics (ACMG) guidelines. Pathogenic and likely pathogenic variants are reported as positive carrier status while variants of uncertain significance (VUS) are reassessed annually and reported out if they are upgraded to pathogenic or likely pathogenic. In total, 614 healthy Chinese adults were tested. 245 individuals were identified to carry at least one pathogenic or likely pathogenic variant, accounts for nearly 40% of the total tested individuals. Top five genes with highest carrier frequencies are *SLC25A13* (4.72%) , *GJB2* (2.92%) , *ATP7B* (2.76%) , *USH2A* (2.60%) and *GALC* (2.12%), and the corresponding top five diseases are Citrin deficiency, autosomal recessive hearing loss type 1A, Wilson disease, Usher syndrome type 2A and Krabbe disease, respectively. Our results demonstrate unique gene/disease spectrum in Chinese population. This information would help us to develop a more focused basic panel suitable for a nationwide carrier screening customized to Chinese population. In addition, data obtained from this study would facilitate improved genetic counseling in China.

**459F**

**Carrier screening for 316 monogenic recessive diseases revealed high carrier frequency of rare known pathogenic mutations.** *D. Bercovich*<sup>1,2</sup>, *S. Horn-Saban*<sup>2</sup>, *E. Kellerman*<sup>2</sup>, *J. Ronen*<sup>3</sup>, *R. Gershoni*<sup>2</sup>. 1) Biotechnology, Tel Hai College, Tel Hai, Gellil Elyon, Israel; 2) Galil Genetic Analysis Center, Galilee, Israel; 3) KaryoBank, Ramat Hasharon, Israel.

Genetic mutations can deter genes from functioning properly and disrupt the proteins which they encode. Being a carrier for an autosomal recessive genetic disease does not usually affect one's health. However, if both biological parents happen to carry mutations in the same gene, their offsprings are at increased risk of incurring the related genetic disease. In most countries carrier screening addresses only common mutations based purely on domestic ethnicity. Consequently, babies are still born with genetic diseases that could have been avoided. Using NGS technology we screened several hundred healthy sperm and egg donors for mutations along entire coding regions and exon-intron boundaries of 316 genes related to common monogenic diseases. To avoid reporting VUS (variants of unknown significance), we reported only Indels, stop codons, splicing and missense mutations with known pathogenic effect according to HGMD® Professional, ClinVar, NCBI (PubMed & OMIM), Alamut (v.2.7.1) or in our database. The presence of these mutations was confirmed by Sanger sequencing. The carrier rates amounted to 2 to 7 mutations per DNA sample with an average of 2.8 mutations. 80% of mutations were known rare mutations which are not screened by genetics labs on regular basis. Missense mutations which do not appear in these databases and had a population frequency of less than 1% were defined as VUS and were not reported. 0.001% of couples were both carriers of mutations in the same gene which can lead to approximately  $8.3 \times 10^{-5}$  unhealthy offsprings out of all births per year in Israel. These results indicate the importance of full gene sequencing for common monogenic diseases for the detection of rare recessive mutations in the general population and prevention of sick babies being born. We advise that such full gene sequencing be applied as routine pre-conceptual screening, followed by genetic counseling.

Gibbs*<sup>1,3</sup>, *I. Van den Veyver*<sup>1,4</sup>, *M. Walkiewicz*<sup>1,2</sup>, *Y. Yang*<sup>1,2</sup>, *C. Eng*<sup>1,2</sup>. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030; 2) Baylor Genetics Laboratories, Houston, TX 77021; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX 77030; 4) Department of Obstetrics and Gynecology, Baylor College of Medicine, Houston, TX 77030.

Fetal anomalies occur in approximately 3% of pregnancies, many of which have a genetic etiology. While karyotyping and chromosomal microarray (CMA) are invaluable first-tier tests for prenatal genetic diagnosis, single gene defects cannot be detected by these methods. With the continuous improvement of exome sequencing, including updated instrumentation, shorter turnaround time (TAT), and improved analysis, clinical exome now provides a valuable diagnostic option in such cases. Here, we report on 116 consecutive prenatal samples referred to our diagnostic laboratory for exome sequencing from March 2012 to April 2017. We define a prenatal sample as one obtained through a diagnostic procedure or a product of conception from a fetus with at least one structural anomaly detected by fetal imaging. Next-generation sequencing was performed on an Illumina HiSeq platform and 97% of targeted exome regions were sequenced at 20X depth. Sequencing data were analyzed for small nucleotide changes and large CNVs using the Illumina HumanExome-12v1 array. Among 116 prenatal samples, exome yielded a molecular diagnosis in 35% of cases. This diagnostic rate did not vary appreciably based on whether brain and/or cardiac anomalies were present. The diagnostic rate also did not differ based on whether there was a significant family history, but the distribution of *de novo* versus inherited variants did differ significantly between these cohorts. Seven families used their prenatal exome results for targeted mutation analysis in subsequent pregnancies. Three genes were causative for multiple unrelated samples: *KMT2D* (3 samples), *COL1A1* (3 samples), and *COL1A2* (2 samples). Three test options were available to ordering physicians: proband exome (12 week TAT, parental samples for Sanger-based inheritance studies, proband report only); standard trio exome (8 week TAT, trio-based variant interpretation, proband and parental reports issued); and prenatal trio exome (introduced in April 2015, 2-3 week TAT excluding cell culture time, trio-based variant interpretation, fetal and parental reports). Prenatal trio exome was ordered for 44 of 116 cases. The mean TAT was 2.0 weeks and 43% received a molecular diagnosis. Overall, our results demonstrate that exome sequencing is a valuable diagnostic tool and may be considered in prenatal cases where structural anomalies suggest a genetic etiology, but for which other genetic tests such as karyotyping and CMA are unlikely to provide a diagnosis.

Perinatal death (PD) refers to the stillbirth of a foetus from 20 weeks gestation or the neonatal death of a liveborn baby within 28 days of birth. Current autopsy procedures have identified congenital abnormalities as the leading cause of death, accounting for more than 33% of cases, yet the underlying cause of the malformation is rarely determined. A further ~15% of PD is due to or is complicated by infectious causes. In this study, we examine the utility of a 'genomic autopsy' in not only elucidating the genetic causes underlying congenital abnormalities but also in identifying causative infectious agents. Whole exome sequencing (WES) and whole genome sequencing (WGS) are being performed using either an Illumina HiSeq 2500 (WES) or X Ten System (WGS). For cases of congenital abnormality, major phenotypes investigated include neurologic abnormalities, ciliopathy-like disorders, urinary tract malformations, non-immune hydrops, and musculoskeletal abnormalities. An analysis pipeline incorporating bioinformatic and experimental laboratory techniques has been developed to identify and causally link novel variants and genes to disease. Of 14 families investigated to date, 6 have resulted in the identification of causative genetic variants; 2 in known disease genes, 2 expanding the phenotypic spectrum of known disease genes (*TPI1*, *B3GAT3*), and 2 in novel disease genes (*FGFR2*, *TMEM212*). 4/6 families are using this information for preimplantation genetic diagnosis, already leading to one successful reproductive outcome. A further 3 cases likely representing novel discoveries are currently under investigation. For cases of perinatal infection, samples with both known and suspected infectious causes are being investigated. Standard nucleic acid preparation protocols are being compared to microbial enrichment approaches to assess the feasibility of a single WGS test to detect multiple causes of PD. Preliminary results from non-microbial enriched WGS data show ~5% of reads do not map to the human genome, but many can be mapped at high quality to viral or bacterial genomes. This ongoing work demonstrates the power of a genomic autopsy in identifying genetic variation causal of congenital abnormalities and in characterising novel genes critical in embryonic developmental pathways. It also suggests that a genomic autopsy approach has the potential to identify infectious agents, together, allowing a precise cause of PD to be established in up to 50% of cases.

Schreiber<sup>6,7</sup>, K. Kassahn<sup>2,3</sup>, H.S. Scott<sup>2,3,6,7</sup>. 1) Pediatric & Reproductive Genetics Unit, Women's and Children's Hospital, North Adelaide, South Australia, Australia; 2) Department of Genetics and Molecular Pathology, SA Pathology; 3) Centre for Cancer Biology, an alliance between SA Pathology and University of South Australia; 4) Department of Anatomical Pathology, SA Pathology at the Women's and Children's Hospital; 5) Kinghorn Centre for Clinical Genomics, the Garvan Institute; 6) School of Biological Sciences, University of Adelaide; 7) ACRF Cancer Genomics Facility, Centre for Cancer Biology, SA Pathology; 8) University of Adelaide, Faculty of Health and Medical Sciences.

Background: In 2016, the Genomic Autopsy Study was introduced at ASHG and in this paper we present our updated data. Congenital abnormalities are the most frequent reason for mid-term stillbirth and termination of pregnancy. Unexplained late fetal deaths in utero, or in the newborn period, affect ~3.5/1000 births. Despite a high rate of formal post-mortem examination in South Australia, a definitive cause of the congenital abnormalities or death is only identified in 25-50% of cases. Aim: To use whole exome sequencing (WES) and whole genome sequencing (WGS) to identify genetic causes of fetal and newborn abnormalities that result in termination of pregnancy, death due to congenital abnormalities, death in utero or death in the newborn period, in view to providing families with answers regarding cause and likelihood of recurrence of these congenital problems. Methods: WES and/or WGS are being performed on cases of perinatal death, using the Illumina HiSeq X 10 system. Samples are available for ~1200 cases. Ethical approval has been granted for prospective cases referred to the Pediatric and Reproductive Genetics unit (parent-fetus trios) and retrospective cases from stored autopsy samples (singletons). High priority cases are fetuses with congenital abnormalities with consanguineous parents, fetuses with multiple malformations; and unexplained fetal/newborn death. Statistical, bioinformatics and experimental laboratory techniques are being used to confirm causality of variants. Results: Data from the first 50 WES/WGS's will be presented. We will present data on new gene discovery, new syndrome identification, novel severe fetal presentations of existing rare pediatric disease, diagnosis of ultra-rare disorders that would not have been identified without a WES/WGS approach, missed diagnoses by commercial testing and successful IVF pregnancies following preimplantation genetic diagnosis based on the results of the Genomic Autopsy Study. Discussion: Our results indicate that genomic autopsy using WES/WGS should be a routine component of the investigation of multiple unexplained congenital malformations leading to termination of pregnancy or death. Further work will ascertain its utility as an adjunct to traditional autopsy for families who have experienced unexplained pregnancy loss, death in utero or in the newborn period.

## 463W

**Novel pathogenic point mutation of KDM6A identified in a Chinese woman with Kabuki Syndrome type 2.** *W. Shi<sup>1</sup>, J. Zhang<sup>1,2</sup>, C. Xu<sup>1,2</sup>.* 1) The International Peace Maternity & Child Health Hospital Affiliated to Shanghai Jiao Tong University School of Medicine; 2) Department of Reproductive Genetics, The International Peace Maternity & Child Health Hospital Affiliated to Shanghai Jiao Tong University School of Medicine.

**ABSTRACT Introduction:** Kabuki syndrome (KS) is a rare congenital mental retardation condition with typical facial dysmorphism, visceral and skeletal malformations and developmental delay. KDM6A (NM\_021140.2) is one of the causative gene of Kabuki syndrome type 2 (KS2), accounting for 3%-8% of KS cases. **Materials and methods:** We report a 24-year-old Chinese woman who came for pre-pregnancy consultation, presenting moderate learning difficulties, typical facial features, short stature, skeletal malformations including brachydactyly and hip dysplasia. To clarify the diagnosis and provide pre-pregnancy genetic counseling, the multigene panel approach on the basis of next-generation sequencing was used. **Results:** Peculiar facial features and clinical examinations of the patient, a Chinese 24-year-old married woman, was in line with the typical manifestations of Kabuki Syndrome. Furthermore, it was identified that the patient harbored a de novo point mutation of KDM6A (c.3521G>A), inducing a premature termination codon (p.Trp1174\*) of KDM6A, as the same locus in the patients' healthy parents who were confirmed by identity testing is normal. In view of pre-pregnancy consultation, due to KS2 is a X-linked dominant inherited disease, the risk for the patient to give birth to an affected son or daughter is 50%, a prenatal genetic diagnosis or preimplantation genetic diagnosis (PGD) will be definitely necessary for the baby when she gets pregnant. **Discussion:** We discuss the sex-biased phenotypic severity in KS2 patients and analysis the published KDM6A variants, as well as the identified mutation in our study, finding that variants in exon 6 are most frequent so that may be a mutational hot spot. X-linked dominant inherited KS2 has been reported only once in China, thus our study enrich the KDM6A mutation database for further investigations.

Laurent<sup>7</sup>, L. Faivre<sup>1,2,3</sup>, C. Thauvin-Robinet<sup>1,2,3</sup>.* 1) UMR1231, Equipe Génétique des Anomalies du Développement, Dijon, Burgundy, France; 2) Fédération Hospitalo-Universitaire Médecine Translationnelle et Anomalies du Développement, CHU Dijon, Dijon, Burgundy, France; 3) Centre de Génétique Médicale, CHU Dijon, Dijon, Burgundy, France; 4) UF Diagnostic-Innovation génomique des maladies rares, Laboratoire de Cytogénétique et Génétique moléculaire, CHU Dijon, Dijon, Burgundy, France; 5) Génétique Biologique Histologie, CHRU de Besançon, Besançon, Franche-Comté, France; 6) Service de Gynécologie-Obstétrique, CHU Dijon, Dijon, Burgundy, France; 7) Service d'Anatomopathologie, CHU Dijon, Dijon, Burgundy, France.

Some rare monogenic disorders could be considered differential diagnoses of congenital infections. Congenital Infection-Like Phenotypes (CILP) include Aicardi-Goutières syndrome (AGS), pseudo-TORCH syndrome (PTS), *PCDH12*-linked phenotypes and *JAM3*-linked phenotypes. Even though whole-exome sequencing (WES) is a powerful tool for the genetic investigation of heterogeneous causal hypotheses, clinical indications, especially for the prenatal period, should be defined. We aimed to describe prenatal AGS cases to identify specific differentiating characteristics and to define clinical criteria to justify WES. We initially identified a fetal case of AGS presenting with microcephaly, hyperechoic bowel, hepatosplenomegaly, ascites and pericardial effusion. We have now collected data for five prenatal forms of AGS. Four homozygous causal variants were identified in the five AGS cases from four consanguineous families: 2 *TREX1* frameshift (p.Leu133Serfs\*17 and p.Leu123Cysfs\*27), 1 *RNASEH2A* missense (p.Leu106Pro) and 1 *RNASEH2B* missense (p.Lys162Tyr), all inherited from healthy heterozygous parents. Fetuses presented intracranial calcifications (3/5), mild ventriculomegaly (3/5), congenital microcephaly (2/5) and neuronal migration disorders (2/5), ascites (2/5), hepatosplenomegaly (2/5) and hyperechogenic bowel (2/5). AGS was suspected in three fetuses during the prenatal period, leading to termination of the pregnancy. We compared these features with the classical phenotype reported in PTS and *PCDH12*-linked phenotypes. These syndromes present high clinical heterogeneity and significant phenotypic overlap. Citerna Magma anomalies appear to be more frequent in PTS, whereas digestive anomalies and ventriculomegaly predominate in AGS. There is no difference for congenital microcephaly and intrauterine growth restriction. Even though AGS is considered the main syndrome that mimics fetal infections, other entities, such as *JAM3*-linked phenotypes, must also be considered even if no prenatal form has been reported to date. In conclusion, in the prenatal diagnosis of CILP, the phenotypic overlap between CILP and fetal infections does make it possible to define criteria to justify molecular analysis. WES should be discussed in CILP, because of the importance for genetic counseling. Indeed, the identification of molecular bases is essential to organize an early prenatal diagnosis for future pregnancies given the risk of recurrence of these autosomal recessive diseases. .

**465F**

**Prenatal diagnosis of Roberts syndrome suspected on sonogram in a consanguineous couple: A case report and a review of the literature.** *J.R. King, T. Goldwaser, J. Powers, S. Klugman, P. Dar.* Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY.

**Introduction:** Roberts syndrome is a rare autosomal recessive disorder with approximately 150 cases reported. Roberts syndrome is characterized by prenatal growth restriction, limb malformations, and craniofacial abnormalities. Mortality is high among severely affected pregnancies and newborns. Although there have been previous reports of prenatally suspected Roberts syndrome in the literature, few of these cases have been confirmed with molecular diagnostic testing. **Case presentation:** 27 yo G4P3 of Argentinian Jewish descent presented for genetics consultation at 21 weeks gestation after fetal anomalies were noted on sonogram. She had no prior prenatal aneuploidy screening. Family history was significant for consanguinity, mother and partner are first cousins. The patient declined expanded carrier screening. Sonogram demonstrated severe growth restriction, with head circumference, abdominal circumference, and femur length <3%. Other findings included absence or severe shortening of the distal long bones bilaterally (radius, ulna, fibula and tibia), the hands and feet were in an abnormal position, and bilateral abnormal thumbs were noted. The fetal profile was also abnormal with a sloping forehead, mild exophthalmus and suspicion of cleft palate. Based on these findings, there was concern for Roberts syndrome. The patient received genetic counseling and elected to proceed with amniocentesis and karyotype, microarray, and NGS single gene full sequencing of the ESCO2 gene. The karyotype resulted normal female, 46 XX. The microarray showed normal female dosage but with long contiguous regions of homozygosity in multiple chromosomes. The NGS single gene full sequencing detected a homozygous pathogenic splice site variant (c.1674-2A>G) in the ESCO2 gene. This variant is considered pathogenic and causative for Roberts syndrome. The patient received these results and additional genetic counseling. She elected to continue her pregnancy. **Conclusion:** ESCO2 is the only gene in which pathogenic variants are known to cause Roberts syndrome. The splice variant c.1674-2A>G mutation was first described in contributing to the pathogenesis of Roberts syndrome in 2008 by Gordillo et. al via familial DNA testing. To our knowledge, this is the first report of this mutation detected prenatally. Although not commonly obtained, molecular confirmation of ultrasound findings can aid in the management and counseling of patients with suspected skeletal dysplasias.

**Identifying the genetic causes underlying prenatally diagnosed structural congenital anomalies (SCAs) by whole exome sequencing (WES).**

*G.K.C. Leung<sup>1</sup>, C.C.Y. Mak<sup>1</sup>, S.L.C. Pei<sup>1</sup>, M.H.Y. Tsang<sup>1</sup>, M.H.C. Yu<sup>1</sup>, K.S. Yeung<sup>1</sup>, G.T.K. Mok<sup>1</sup>, A.P.W. Hui<sup>2</sup>, M.H.Y. Tang<sup>2,3</sup>, K.Y.K. Chan<sup>2,3</sup>, A.S.Y. Kan<sup>2,3</sup>, B.H.Y. Chung<sup>1,2,3</sup>.* 1) Department of Paediatrics and Adolescent Medicine, LKS Faculty of Medicine, The University of Hong Kong, HKSAR; 2) Department of Obstetrics and Gynaecology, Queen Mary Hospital, The University of Hong Kong, HKSAR; 3) Prenatal Diagnostic Laboratory, Department of Obstetrics and Gynaecology, Tsan Yuk Hospital, HKSAR.

**Background:** Despite WES being extensively used in the clinical diagnosis of pediatric genetic disorders, routine application of the technology in pregnancies with SCAs is yet to be widely accepted. We aim to identify the genetic causes underlying SCAs in fetuses without a definitive diagnosis after conventional genetic testing. **Methods:** Couples with SCAs of the fetus detected during pregnancy were recruited from the prenatal diagnostic service, Tsan Yuk Hospital. Their antenatal histories were reviewed and those with a known cause of SCA, including aneuploidy or clinically significant chromosomal abnormalities on karyotyping and microarray, were excluded. WES was performed as trios if possible. **Results:** Thus far from 25 fetuses (23 trios, 2 singleton) analyzed, we identified 3 plausible disease-causing mutations. One fetus with small cerebellum and flexed elbows carried a *de novo* mutation in *EEF1A2*. Pathogenic alteration in *EEF1A2* leads to an autosomal dominant neurodevelopmental disorder with infantile epileptic encephalopathy. Two inherited compound heterozygous mutations, in *DIS3L2* and *NPHP4* are known to cause Perlman syndrome and Senior-Loken syndrome respectively. They were plausible explanations for the phenotypes of agenesis of corpus callosum and dandy-walker malformation identified from prenatal ultrasound of these fetuses. Our analysis also identified mutations in a novel gene that may cause a fetal cerebellar malformation syndrome that will require further functional work to characterize. **Conclusion:** WES aids the identification of genetic causes of prenatal SCA in ~10% families with negative clinical testing. Hence we suggest that the use of WES for prenatal diagnosis is practically feasible in Hong Kong. The findings could make a major impact in genetic counselling and lead to novel genes discovery, or phenotypic expansion of known genetic syndromes. **Acknowledgement:** We would like to thanks the Health and Medical Research Fund (ref# 02131816) offered by the Government of HKSAR.

**467T****Increased nuchal translucency and Noonan Spectrum Disorders – A**

**Mount Sinai hospital experience.** *P. Sinajon<sup>1</sup>, H. Sroka<sup>2</sup>, S. Carmona<sup>3</sup>, M. Roifman<sup>4</sup>, E. Kolomietz<sup>5</sup>, A. Noor<sup>6</sup>, K. Murphy<sup>6</sup>, D. Chitayat<sup>6</sup>, K. Chong<sup>6</sup>.* 1) Clinical and Metabolic Genetics, The Hospital for Sick Children, Toronto, Ontario, Canada; 2) GeneDX, Whole Exome Sequencing Program; 3) Medical Informatics – Information Sciences, Mount Sinai Hospital, Joseph and Wolf Lebovic Health Complex; 4) Prenatal Diagnosis and Medical Genetics, Department of Obstetrics and Gynecology, Mount Sinai Hospital – Joseph and Wolf Lebovic Health Complex; 5) Division of Diagnostic Medical Genetics, Department of Pathology and Laboratory Medicine, Mount Sinai Hospital – Joseph and Wolf Lebovic Health Complex; 6) Maternal and Fetal Medicine, Department of Obstetrics and Gynecology, Mount Sinai Hospital – Joseph and Wolf Lebovic Complex.

**Objective:** To examine a cohort of patients seen at the Prenatal Diagnosis and Medical Genetics Program - Mount Sinai Hospital between 2013 – 2015, with fetal ultrasound findings of an increased nuchal translucency (NT  $\geq$  3.5mm), and to: 1. Correlate between the NT measurements and a diagnosis of Noonan Spectrum Disorders (NSD) 2. Conduct a systematic literature review to determine the correlation between NT measurement and a diagnosis of NSD 3. To create a clinical protocol to guide physicians in the investigation of an increased fetal NT **Methods:** A cohort of patients presenting between 2013 – 2015 with fetal ultrasound findings of increased NT. All patients were offered amniocentesis/CVS for QF-PCR as a first line test. If negative, patients proceeded to karyotype/microarray analysis and NSD panel testing. Patients were also offered fetal ultrasounds at 16 weeks and 18 – 22 weeks gestation (GA) along with fetal echocardiogram. A systematic review was conducted in accordance to PRISMA criteria. Pubmed, Embase, Ovid MEDLINE and Web of Science were searched from January 2005 – August 2016 for articles involving NSD and increased NT. Seventeen papers were included for analysis. **Results:** 226 patients with increased fetal NT were seen. In 116/226 patients, chromosomal aneuploidy was detected through QF-PCR. The remaining 110/226 patients had further testing. 8 had karyotype abnormalities, 13 had abnormal microarray findings and 5 had NSD findings through DNA analysis. **Discussion:** Based on the cohort findings and literature review the following guidelines were created regarding the best approach to a fetus with an increased NT: 1. QF-PCR and microarray should be performed for NT  $\geq$  3.5 mm 2. If QF-PCR/microarray analysis is normal, DNA analysis for NSD should be performed for NT  $\geq$  4.0 mm 3. Early anatomic ultrasounds at 16 weeks GA 4. Fetal echocardiogram at 18 – 22 weeks GA 5. Detailed fetal ultrasound at 18 – 22 weeks GA.

**WES identifies likely pathogenic *FANCG* variants in a fetus with multiple congenital anomalies.** *B.D. Webb<sup>1,2</sup>, L. Tambini-King<sup>3</sup>, B. Rosenn<sup>3</sup>, J. Liao<sup>1,2</sup>, L. Edelmann<sup>1,2</sup>, L. Mehta<sup>1</sup>.* 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 2) Sema4, a Mount Sinai venture, Stamford, CT, USA; 3) Department of Obstetrics and Gynecology, Icahn School of Medicine at Mount Sinai, New York, NY, USA.

Fetal whole exome sequencing (WES) may be used to identify a genetic etiology for fetal ultrasound anomalies after karyotype, microarray, and standard of care testing are unrevealing. Here we report the use of WES to identify the genetic etiology of a condition presenting with multiple congenital anomalies. A consanguineous, healthy Egyptian couple was seen for genetic counseling due to fetal ultrasound findings of enlarged fetal bladder and umbilical cord cyst at 11 weeks. The couple's three prior pregnancies resulted in perinatal losses. The first pregnancy was terminated at 20 weeks gestation due to bilateral renal agenesis resulting in severe oligohydramnios and Potter sequence. Autopsy of the female fetus revealed absent bladder, radial aplasia, and absent thumb. The second pregnancy was a male, 27 weeks gestation fetus that died shortly after birth; the pregnancy was complicated by severe oligohydramnios. The third pregnancy resulted in a first trimester loss of unknown cause. Chorionic villus sampling of the current pregnancy showed normal karyotype; chromosomal microarray showed a maternally inherited deletion of 552 kb on chromosome 2q12.3 of uncertain clinical significance. The pregnancy was terminated at 14 weeks, and autopsy revealed: renal cystic dysplasia; massively dilated, thin-walled bladder; pulmonary hypoplasia; cloacal dysgenesis with urethral atresia; high anorectal malformation; absence of external genitalia; and absent thumb of the right hand. The couple enrolled in a fetal WES study available through the genetic testing laboratory at Mount Sinai. WES was completed using DNAs isolated from the CVS sample and peripheral blood samples from the couple. A homozygous likely pathogenic variant in *FANCG* was identified in the fetal sample: c.1133C>A; p.S378\* (NM\_004629.1). Both members of the couple were heterozygous for this variant. Pathogenic variants in *FANCG* cause Fanconi anemia (FA), complementation group G (MIM 614082). Common malformations in this type of FA include renal, radial and gastrointestinal defects (Feben, *et al*, 2013); however, the diagnosis of FA is rarely suspected in the prenatal setting. *FANCL* mutations have been reported in perinatal lethal cases by NGS based testing (Vetro, *et al*, 2015). This case further highlights the utility of WES in the setting of prenatal fetal anomalies. A severe VACTERL-like presentation, particularly with radial and renal anomalies, should alert the clinician to the possibility of FA.

**469W**

**Large genome-wide meta-analysis of age at menopause including X chromosome, gene–environment interactions and Mendelian randomization analysis.** *F. Day<sup>1,2</sup>*. 1) on behalf of The ReproGen Consortium; 2) MRC Epidemiology Unit, University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom.

Previous GWAS meta-analysis by the ReproGen consortium in 70,000 women identified 44 genetic loci containing 56 signals that together explain ~6% of population variance in age at natural menopause (ANM). We aimed to identify further low-frequency and common genetic variants associated with ANM, by using imputation to the denser 1000 Genomes reference panel and also for the first-time including chr X. We went on to use these genetic variants to explore gene–environment interactions and the impact of menopause timing on various health outcomes by Mendelian randomization (MR) analysis. We carried out a meta-analysis of 108,000 women from European populations in 35 studies. We identified 123 independent signals at 101 loci (MAF 1–49%; per allele effect -0.1 to -1.4yrs; smallest  $P < 5 \times 10^{-8}$ ) including 60 new signals, multiple signals at 14 loci and 4 signals on chr X. Non-synonymous variants were found in LD with 25 signals ( $r^2 > 0.8$ ). As in previous analyses, DNA repair genes were enriched, including new signals in *FANCA* (per allele effect -0.1yrs;  $P = 2 \times 10^{-9}$ ) and *FANCM* (per allele effect -0.2yrs;  $P = 1 \times 10^{-10}$ ). Other new signals included a non-synonymous variant in *CALCR* (per allele effect -0.1yrs;  $P = 8 \times 10^{-9}$ ) and an intronic variant in *FTO* (per allele effect -0.3 yrs;  $P = 3 \times 10^{-9}$ ) which was an eQTL for *FTO* ( $P = 2 \times 10^{-7}$ ) and was independent of the known BMI signal at this locus. The effect of a ANM genetic risk score (GRS) was higher in women whose mother smoked during pregnancy ( $P$ -interaction =  $9 \times 10^{-4}$ ). From MR analyses, later ANM in women ( $P < 1 \times 10^{-6}$ ) was causally related to: higher bone mineral density (BMD); lower risk of osteoporosis (women only); higher uterine fibroids and female specific cancers (all  $P < 5 \times 10^{-5}$ ). In conclusion, by increasing the sample size and using a denser imputation we have more than doubled the number of known genetic signals for ANM. The resulting GRS explains 8.5% of the population variance in ANM, and provides a powerful instrument for causal modelling analyses. Our results suggest a novel role for *FTO* in reproductive lifespan. Finally, gene–environment interactions highlight the importance of the uterine environment during oocyte formation, and suggest that *in utero* exposures can modify genetic susceptibility to reproductive lifespan. We anticipate that these analyses will be further reinforced by the imminent inclusion of the final phase of UK Biobank.

Maternity Log Study is a Japanese prospective cohort study that aims to predict or prevent of pregnancy-related diseases by multi layered omics analysis. Approximately 300 pregnant women have been recruited in the first or second trimester of pregnancy. We collected peripheral blood samples of the participants as well as urine samples and many kinds of daily lifelog information. Hypertensive Disorders of Pregnancy (HDP) is a serious pregnancy-related disease that is major cause of maternal and fetal death. It is caused by a complex interaction of genetic factors and environmental factors such as lifestyle. In our study, the proportion of HDP cases was approximately 10%. In this study, we initially focused on the understanding to the genetic factors of HDP towards the future analysis of the complex interaction of both genetic factors and environmental factors. For this purpose, we have obtained hundreds whole-genome sequencing data from the DNA from the participants of Maternity Log Study by using a short-read sequencing technology. Usually, genetic functionalities were affected by variants on the gene. Thus it is conceivable that cases have more deleterious variants than controls on their HDP associated genes. Based on this hypothesis, we have gathered candidates of HDP associated genes from literatures and public databases, and applied Burden-Test to select significant genes among them. In detail, we gathered HDP associated single nucleotide variants (SNVs) from online databases and several researches on HDP meta-analysis. Next, we investigated the genes that contain those SNVs with reference to The Human Gene Mutation Database and approximately a hundred genes were chosen as HDP associated genes. For each gene, we counted all SNVs with high functional impacts, i.e. missense, nonsense, splicing, and frameshift mutation. We then performed Mann–Whitney U test between the total SNVs of cases and controls, and the p-value was adjusted by Benjamini–Hochberg procedure to correct multiple comparisons. Interestingly, almost all HDP associated genes in cases showed more mutations than controls. Additionally, cases have more missense mutations than controls. In conclusion, our study has suggested the significantly enriched genes and their causal relationship to the onset of HDP in Japanese. Towards a health care of pregnant women in Japanese, we are planning to combine these genetic factors and other omics data to construct more accurate prediction model of HDP.

**Prenatal evaluation of a fetal cystic hygroma: An unexpected finding of a de novo fetal BRCA1 deletion.** *N.S. Seligman<sup>1</sup>, S. Laniewski<sup>2</sup>, M.A. Iqbal<sup>1</sup>.* 1) Obstetrics and Gynecology, University of Rochester Medical Center, Rochester, NY; 2) Pathology & Laboratory Medicine, University of Rochester Medical Center, Rochester, NY.

**Objective:** Fetal cystic hygromas are associated with an increased risk of aneuploidy, non-chromosomal genetic syndromes, and congenital anomalies. The American College of Obstetricians and Gynecologists recommends chromosomal microarray in patients undergoing prenatal diagnosis for structural fetal anomalies. We report a de novo fetal BRCA1 deletion. **Methods:** Karyotype was produced using standard G banding techniques. Reflex aCGH was performed on the ISCA 4 × 180K plus SNP v2.0 platform (Agilent Technology Inc. Santa Clara, CA). FISH was performed using SureFISH (Agilent Technology Inc. Santa Clara, CA) and TelVysion (Abbott Molecular Inc. Des Plaines, IL). **Results:** 33 year old G3P0020 at 13w0d was referred for a 6mm septated cystic hygroma. Following genetic counseling, the patient opted for chorionic villus sampling. G-banding revealed a normal 46, XX karyotype. Chromosomal microarray showed an 80kb loss at 17q21.31 from 41186542 to 41266359 basepairs encompassing the BRCA1 gene, confirmed by BRCA1 (41162433-41265378) SureFISH probe. FISH analysis of parental blood samples with BRCA1 probe showed no evidence of deletion 17q21.31 confirming the deletion is de novo in this fetus. Subsequent anatomic ultrasound and fetal echocardiogram revealed no gross anomalies. The pregnancy was complicated by the development of gestational diabetes which was controlled with Glyburide. The patient had an uncomplicated vaginal delivery at 38w4d. Neonatal evaluation was unremarkable. **Conclusion:** This is the first report of a de novo 80kb fetal BRCA1 deletion. The fetus is a heterozygous carrier of a pathogenic BRCA1 gene deletion and is anticipated to be at increased risk of developing breast, ovarian, and/or pancreatic cancer though the penetrance is still being actively studied. Increased understanding of the BRCA1 gene has shown that it is involved in multiple biological processes. BRCA1 gene deletions have also been implicated as a genetic factor in brain development and neural tube defects (NTD) based possibly though regulation of neurulation. While this fetus did not have spina bifida, NTDs are known to be multifactorial in origin. Close follow-up of neurodevelopment is needed.

**Detection of fetal subchromosomal aberration with cell-free DNA screening led to diagnosis of parental translocation: Review of 11344 consecutive cases in a university hospital.** *Y.Q. Qian, X.Q. Wang, M. Chen, Y.Q. Luo, K. Yan, Y.M. Yang, B. Liu, L.Y. Wang, Y.Z. Huang, H.G. Li, H.Y. Pan, F. Jin, M.Y. Dong.* Women's Hospital, School of Medicine, Zhejiang University, Hangzhou, Zhejiang, China.

**Purpose:** Fetal chromosome aberrations and sub-chromosomal copy number variations (CNVs) are not rare. There are several ways to detect duplications and deletions; cell-free DNA screening (cfDNA screening) is nowadays an accurate and safe detection method. The purpose of this study is to report the feasibility of cfDNA screening as an indicator of parental balanced chromosome translocation. **Results:** From February 2015 to March 2016, cfDNA screening was offered to 11344 pregnant women. 137 out of 11344 individuals tested positive for aneuploidies using cfDNA screening were confirmed by karyotyping. 6 additional cases also tested positive for other deletion/duplication were confirmed by chromosomal microarray analysis (CMA). 11201 patients tested negative and 10342 of them were confirmed through interviews after delivery. Among the 137 cases that were screened positive in cfDNA screening, 91 were common trisomies (63 cases of trisomy 21, 25 cases of trisomy 18 and 3 cases of trisomy 13) and 46 cases were positive for sex-chromosomal abnormalities. In addition, 6 cases were positive for other deletion/duplication in which 2 were identified as terminal duplication and deletion on different chromosomes. The cfDNA screening findings were confirmed by CMA or karyotyping, and the origins of CNVs were validated afterward by karyotyping or fluorescence in situ hybridization (FISH) using parental blood samples. **Conclusion:** CfDNA screening may help identify deletions and duplications in fetus, which in some cases may indicate risk of a parent being a balanced rearrangement carrier, and that the diagnostic follow-up testing is necessary.

## 473T

**Fetal cell-free DNA fraction in maternal plasma is affected by fetal trisomy.** N. Suzumori<sup>1</sup>, T. Ebara<sup>2</sup>, T. Yamada<sup>3</sup>, O. Samura<sup>4</sup>, J. Yotsumoto<sup>5</sup>, M. Nishiyama<sup>6</sup>, K. Miura<sup>7</sup>, H. Masuzaki<sup>8</sup>, Y. Kamejima<sup>9</sup>, H. Sago<sup>6</sup>, J. Murotsuki<sup>6</sup>, H. Sawai<sup>10</sup>, J.-S. Saldívar<sup>11</sup>, N. Dharajiya<sup>11</sup>, A. Sekizawa<sup>12</sup>. 1) Department of Obstetrics and Gynecology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2) Department of Occupational and Environmental Health, Nagoya City University Graduate School of Medical Sciences, Nagoya; 3) Department of Obstetrics and Gynecology, Kyoto University Graduate School of Medicine, Kyoto; 4) Department of Obstetrics and Gynecology, The Jikei University School of Medicine, Tokyo; 5) Department of Genetic Counseling, Ochanomizu University, Tokyo; 6) Center of Maternal-Fetal, Neonatal and Reproductive Medicine, National Center for Child Health and Development, Tokyo; 7) Department of Obstetrics and Gynecology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; 8) Department of Obstetrics and Gynecology, Saitama Medical University, Saitama; 9) Department of Obstetrics and Gynecology, Tohoku University Graduate School of Medicine, Sendai; 10) Department of Obstetrics and Gynecology, Hyogo College of Medicine, Nishinomiya; 11) Sequenom Laboratories, San Diego, CA, USA; 12) Department of Obstetrics and Gynecology, Showa University School of Medicine, Tokyo.

The purpose of this noninvasive prenatal testing (NIPT) study was to compare the fetal fraction of singleton gestations by gestational age, maternal characteristics, and chromosome specific aneuploidies as indicated by z-scores. This study was a multicenter prospective cohort study. Test data were collected from women who underwent NIPT. Relationships between fetal fractions and gestational age, maternal weight and height, and z-scores for chromosomes 21, 18, and 13 were assessed. A total of 7,740 pregnant women enrolled in the study of which, 6,993 met the study criteria. Approximately 95.5% of this study cohort included women of 35 years age or older. As expected, fetal fraction was inversely correlated with maternal weight ( $p < 0.001$ ). The median fetal fraction of samples with euploid result ( $n=6,850$ ) and trisomy 21 ( $n=70$ ) were 13.7% and 13.6% respectively. In contrast, median fetal fraction values for samples trisomy 18 ( $n=35$ ) and 13 ( $n=9$ ) were 11.0% and 8.0% respectively. The fetal fraction of samples with trisomy 21 NIPT result is comparable to that of samples with euploid result. However, the fetal fractions of samples with trisomy 13 and 18 is significantly lower compared to that of euploid result, which may make detecting these two trisomies more challenging.

Unexplained infertility affects 2-3% of reproductive aged couples. One approach to identifying genes involved in infertility is to study subjects with a clinical phenotype accompanied by a *de novo* balanced chromosomal aberration (BCA) through the Developmental Genome Anatomy Project (DGAP). DGAP230 has oligospermia and 46,XY,t(20;22)(q13.3;q11.2). While BCAs may reduce fertility by production of unbalanced gametes, a chromosomal rearrangement may also disrupt or dysregulate genes important in fertility. By large-insert whole genome sequencing, we refined the location of chromosomal breakpoints in DGAP230. A qPCR walk across all genes in the topologically associated domains (TADs) at the sites of rearrangement revealed exclusive dysregulation of *SYCP2* (overexpressed 20-fold by RNA [N=3;  $p < 0.02$ ] and five-fold by protein [N=3;  $p < 0.0032$ ]), which resides 1.5 Mb away from the der(20) breakpoint. By comparing sequence traces of DGAP230 DNA and RNA from a polymorphic region in *SYCP2*, we found that this misexpression derives from a single allele. We developed a novel chromatin conformation capture and nested PCR technique and found that the expressed allele resides in *cis* with the der(20) breakpoint. 4C-Seq is being used to identify putative enhancers from chr22 that may be responsible for the misexpression. *SYCP2* encodes synaptonemal complex protein 2 (MIM 604105), a member of the synaptonemal complex (SC) involved in homologous chromosome synapsis in meiosis I. We hypothesize that *SYCP2* misexpression may impair proper spermatogenesis by meiotic nondisjunction. To model the impact on meiosis, we misexpressed *RED1*, the functional axial element homolog of *SYCP2* in *S. cerevisiae*, using a  $\beta$ -estradiol-induced promoter system. By performing Red1 immunolocalization on surface-spread meiotic nuclei, we discovered that excess Red1 leads to formation of polycomplexes. This disrupts the structural integrity of the SC, leading to failed incorporation of the transverse filament Zip1 (N=50;  $p < 0.0001$ ). In support of the hypothesis that genetic variants causing infertility would be eliminated from the general population, we found a depletion of *SYCP2* loss of function variants (by 90%; pLI = 1.00) and coiled-coil domain missense mutations (by 85%;  $p < 0.04$ ), prompting ongoing genetic case-control human studies. In addition to pinpointing a putative genetic etiology for DGAP230's oligospermia, our study more generally illustrates an additional mechanism for BCA-mediated infertility.

**Differential miR-346 and miR-582-3p expression in association with selected maternal and fetal complications.** *M. Su, P. Tsai, H. Tsai.* National Cheng-Kung University Hospital, Tainan City, Taiwan Department of Obstetrics and Gynecology, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Taiwan.

**Introduction:** Several miRNAs are expressed in human gestational tissue, and some have been shown to be associated with placental dysfunction and complicated pregnancy outcomes. **Objectives:** To investigate the roles of miR-346 and miR-582-3p in adverse obstetric events. **Patients & Methods:** We analyzed these 2 miRNAs in three samples (maternal blood, umbilical cord blood and placenta) obtained from pregnant women in five groups, including healthy control (n=60), preeclampsia (n=29), preterm delivery (n=38), preterm premature rupture of the membranes (n=12) and small for gestational age (n=19) patients. **Results:** The expression levels of miR-346 and miR-582-3p in all included adverse obstetric outcome groups were significantly higher in the maternal plasma samples but lower in the placenta samples (all p value <0.05). In addition, the miR-346 expression levels in fetal cord blood were also significantly lower in all of the included adverse obstetric outcome groups (all p<0.05). Subgroup analysis of the three specimens from healthy and compromised term pregnancies (>37 weeks) gave the same results. **Conclusion:** Aberrant miR-346 and miR-582-3p expression level in pregnancy was associated with multiple maternal and fetal complications. Their differential expression in maternal blood, umbilical cord blood and placenta could be potential biomarkers or therapeutic targets for adverse obstetric outcomes.

**Challenges associated with increasing the predictive power of AMH in controlled ovarian stimulation.** *S.E. Parets, R. Shraga, M. Berliss, S. Munne, A. Bisignano, O. Puig.* Phosphorus, New York, NY.

Reproductive endocrinologists rely on clinical factors such as age and anti-mullerian hormone (AMH) to assess ovarian reserve and counsel patients regarding expectations for controlled ovarian stimulation (COS). Although AMH has emerged as an accurate predictor of ovarian response, previous studies have identified genetic variants that influence COS outcomes. Our objective was to determine whether the addition of genotypes increases the power of AMH to predict ovarian response. We retrospectively enrolled from women between the ages of 18 and 42 undergoing COS (N=369) at five fertility centers. Patients with a history of polycystic ovarian syndrome, cancer, chemotherapy, or bone marrow transplant were excluded. We used an Illumina microarray panel comprised of genes previously associated with infertility. Response categories were defined as low response (<5 oocytes retrieved) and high response (>20 oocytes retrieved). A single genotype association analysis (N=217) was performed by transforming the number of oocytes retrieved into a binary variable and fitting to a series of logistic regression models, with AMH and individual genotypes as the dependent variables. To create a polygenic predictive model, samples were divided into discovery (70%) and validation (30%) sets. We used the discovery set to rank genotypes by predictive capacity in three ways: associated p-value from the single genotype analysis; calculated p-value from subsets of data using a bootstrapping procedure; and a random order as a negative control. Logistic regression models were trained on the discovery set using these ranked lists and model performance was measured on the validation set using the area under the ROC curve. The average clinical characteristics of participants reflected the general population seeking fertility treatment. Single genotype analysis yielded no significant results after multiple test correction ( $p > 5.7 \times 10^{-3}$ ). For the polygenic predictive model, genotypes failed to add predictive value to AMH alone. Therefore, the genotypes tested did not increase the predictive power of AMH in COS. Although we were unable to detect significance in this pilot study, previous research has identified genetic factors that influence ovarian response. Our results reflect decreased power related to heterogeneous phenotypes and a small sample size. Further investigation may clarify the role of genetics in infertility and improve COS outcomes.

## 477F

**Association of multiple TLR6-TLR1-TLR10 gene cluster SNPs with preterm birth in a Wisconsin cohort suggests a potential evolutionary selection bias.** C. Hoffman<sup>1</sup>, T. Ranade<sup>1</sup>, W. Luo<sup>2</sup>, J. Eickhoff<sup>3</sup>, B.R. Pattnaik<sup>2,4</sup>, M. Baker<sup>2,5</sup>, D.-A.M. Pillers<sup>2,6,7</sup>. 1) University of Wisconsin, Madison, WI; 2) Department of Pediatrics, University of Wisconsin, Madison, WI; 3) Department of Biostatistics & Medical Informatics, University of Wisconsin, Madison, WI; 4) Department of Ophthalmology & Vision Sciences, University of Wisconsin, Madison, WI; 5) Wisconsin State Laboratory of Hygiene, Madison, WI; 6) Department of Medical Genetics, Laboratory of Genetics, Crow Institute for Evolution, University of Wisconsin, Madison, WI; 7) Department of Pediatrics, University of Illinois, Chicago, IL.

**Background:** Preterm birth (PTB) is the leading cause of neonatal and childhood mortality and affects 11% of live births. Infection is a major causative factor for PTB. The first line of defense against infection is the innate immune system, and the portal of entry is the Toll-like receptor (TLR). TLRs are pattern-recognition receptors that recognize pathogen-associated molecular patterns (PAMPs). Genetic variation including SNPs in TLRs is associated with susceptibility to infectious diseases. We speculated that SNPs in fetal TLR genes may be associated with PTB. We have previously reported results for SNPs in three TLR receptors (TLR1, 2, and 4). We found that *TLR1* SNPs (N248S, H305L, and S602I) in fetal DNA are associated with PTB in Wisconsin infants. Interestingly, TLR1 is part of the TLR6-TLR1-TLR10 gene cluster reported to be associated with inflammation and infection. **Purpose:** We sought to determine whether SNPs in other TLR genes in the TLR6-TLR1-TLR10 cluster are associated with preterm birth. We hypothesized that *TLR6* SNP rs5743810 (P249S) and *TLR10* SNP rs11096957 (N241H) also associate with an increased risk for preterm birth. **Methods:** We used DNA samples from residual newborn screening specimens from Wisconsin infants of gestational ages (GA), 23-42 wks. IRB approval was secured. We collected 3000 DNA samples. To date, 194 of these samples have been subjected to *TLR6* SNP (P249S) analysis, and 581 of them for *TLR10* SNP (N241H) analysis. The SNP genotype was determined using standard TaqMan SNP Genotyping Assays (Lifetechnologies, CA). An Odds ratio (OR) analysis was used to determine whether a SNP predicted preterm birth. **Results:** *TLR6* SNP (P249S) minor allele T was associated with PTB at GA < 34 wks with OR 2.33 (P < 0.00006), and at GA < 37 wks with OR 2.22 (P < 0.00016). In contrast, there was no association of *TLR10* SNP (N241H) with PTB. The OR for *TLR10* SNP (N241H) minor allele C at GA < 28 wks was 0.95 (P = 0.84), at GA < 34 wks was 0.97 (P = 0.83), and at GA < 37 wks was 0.83 (P = 0.13). **Discussion:** We found a significant association between *TLR6* SNP (P249S) and preterm birth in a Wisconsin newborn cohort. We have shown that multiple SNPs in the TLR6-TLR1-TLR10 gene cluster are associated with PTB, suggesting potential involvement of genetic variation within this cluster in the pathogenesis of preterm birth. The association with this linkage group also suggests that a potential evolutionary selection bias is contributing to preterm birth.

## 478W

**Off the street phasing (OTSP): Free no hassle haplotype phasing for molecular PGD applications.** G. Altarescu<sup>1</sup>, F. Zahdeh<sup>1</sup>, Y. Kling<sup>2</sup>, P. Renbaum<sup>1</sup>, E. Levy-Lahad<sup>1</sup>, S. Carmi<sup>2</sup>, D.A. Zeevi<sup>1</sup>. 1) Preimplantation Genetic Unit, Medical Genetics, Shaare Zedek Medical Center, Jerusalem, Israel; 2) 2 Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel.

**Introduction:** Parental phasing of mutation-flanking haplotypes is an essential, yet time-consuming, laborious, and costly pre-requisite for preimplantation genetic diagnosis (PGD) of monogenic disorders. **Aim:** To validate rapid, low cost, population-assisted haplotype derivation in a pre-clinical setting. **Materials and Methods:** Targeted sequencing of *CFTR* variants and gene-flanking polymorphic SNPs in 38 Jewish individuals from 9 different PGD families was performed at the SZMC PGD lab. Heterozygous genotype calls were both trio-phased to obtain ground-truth haplotypes, and also population-phased using Shapit software. Reference panels for population phasing were derived from either '1000 Genomes' or from 128 or 574 sample Ashkenazi Jewish whole genome sequences. Accuracy of resulting haplotypes was benchmarked against trio-phased haplotypes. The study population consisted of 4 subgroups of Jewish individuals: a) Non-Ashkenazi (NA; 10 negative controls); b) Full Ashkenazi (FA; 10 individuals); c) Partial Ashkenazi (13 individuals featuring at least 1 Ashkenazi and 1 non-Ashkenazi ancestor) without Ashkenazi *CFTR* founder mutation (PANM); and d) Partial Ashkenazi (5 individuals) with W1282X *CFTR* Ashkenazi founder mutation (PAWM). **Results:** The 574 sample Ashkenazi genome reference was the most accurate and appropriate for population-based phasing. Virtually all phase errors in the FA group (and the PAWM group, along a subregion of 3Mb) were traceable to low-coverage sequencing errors in the ground-truth. **Discussion:** These results indicate that it is possible to replace experimental haplotype phasing with clinical "OTSP," population-based phasing, provided that one has access to an appropriate population-matched reference dataset of sufficient size.

**479T****Novel genes for male infertility: Genetic and functional perspectives.**

*D.V.S. Sudhakar<sup>1</sup>, S. Nizamuddin<sup>1</sup>, R. Phanindranath<sup>1</sup>, R. Singh<sup>2</sup>, N.J. Gupta<sup>3</sup>, R. Dada<sup>4</sup>, K. Singh<sup>5</sup>, M. Deenadayal<sup>6</sup>, K. Thangaraj<sup>1</sup>.* 1) Centre for Cellular and Molecular Biology, Hyderabad, India; 2) Central Drug Research Institute, Lucknow, India; 3) Institute of Reproductive Medicine, Kolkata, India; 4) All India Institute of Medical Sciences, New Delhi, India; 5) Banaras Hindu University, Varanasi, India; 6) Infertility Institute and Research Center, Hyderabad.

**Introduction:** Approximately one out of every seven couples are infertile worldwide and the male factor infertility accounts for 30-50% of the infertility cases. Previous studies from our lab have shown that about 8.5% Indian men are infertile due to Y chromosome microdeletions. Further, analysis of a few autosomal genes and mitochondrial genome accounted for additional 21% of the genetic factors responsible for infertility among Indian men. However, etiology of large proportion (71%) of infertile men still remained unknown. Therefore, we have performed exome sequencing to identify novel autosomal genetic causes of male infertility. **Materials and methods:** We have performed exome sequencing of 44 idiopathic infertile men (azoospermia and severe oligozoospermia) using Illumina HiSeq-2000 platform with 100X coverage. Various bioinformatics tools and custom pipelines were used for data analysis and prioritizing the variants. We have identified 61 novel and rare variants (from 58 genes) and genotyped them in 740 cases and 700 ethnically matched controls. We have identified 14 variants (12 genes), which are strongly associated with infertility. Further, we have genotyped 14 additional damaging variants from the above 8 genes in 960 individuals. Expression pattern of all the 8 genes in various human tissues was studied using Western blotting. Of the novel genes identified, *CETN1* has been found to be a potential candidate; hence variants of this gene (one 5'UTR variant and one missense variant) were further genotyped using Taqman® probes in 552 samples, characterized using biophysical (CD, ITC and NMR etc.), cell biology approaches, luciferase reporter assays and tubulin polymerization assays. **Results:** We have identified a total of 21 novel, rare, nonsense and missense variants from 10 genes. Of which, rs189882379 (*ANKRD7*) and rs61734344 (*CETN1*) showed highly significant association with male infertility ( $p=3.455e-34$  and  $p=1.658e-35$  respectively). Multiple mutations in combination were found in azoospermic men. Some mutations were exclusively found in infertile men. Functional studies have shown that rs61734344 (p. Met72Thr) alters calcium binding affinity, thermodynamic properties, surface hydrophobicity and disrupts spindle formation during cell division; suggesting its role in infertility. 5'UTR variant rs367716858 (*CETN1*) has abolished a methylation site and showed increased luciferase activity compared to wild type. .

**Modeled fetal disease risk of a 175 condition expanded carrier screening panel.** *K.A. Beauchamp, K.E. Kaseniit, P. Grauman, G.J. Hogan, K.R. Haas, G.M. Gould, K.K. Wong, G. Lazarin, E.A. Evans, D. Muzzey.* Counsyl, Inc., South San Francisco, CA.

**Introduction:** Expanded carrier screening (ECS) identifies couples whose future children are at increased risk of Mendelian conditions. Recent ACOG guidelines identified ECS as an acceptable screening strategy and proposed general principles for selecting panel diseases. Inspired by these guidelines, here we use modeled fetal disease risk (MFDR) to predict the clinical sensitivity of a new 175-condition NGS-based ECS panel that also incorporates panel-wide copy number variant (CNV) deletion calling. **Methods:** Pathogenic allele frequencies were estimated using a cohort of 9,150 consecutive anonymized patients. Allele frequencies also included CNV deletion calling on most genes; CNV duplications are also called in DMD and CFTR. Copy number calling was performed using a Hidden Markov Model on NGS depth data. The MFDR, defined as the probability that a random fetus is affected by a panel disease, was estimated for a US-census weighted population. **Results:** A previous 94 condition panel was found to assess 183 affected fetuses per 100,000 births, with 10% attributed to the 78 least-prevalent conditions and 29% attributed to technically challenging conditions (e.g., fragile X syndrome). The present panel assesses approximately 350±50 affected fetuses per 100,000 births. The 146 least prevalent conditions contribute approximately 11% of the total risk, while technically challenging conditions contribute 13% of the total risk. Furthermore, CNV deletion and duplication calling contributes 16% of the total risk, most of which is attributed to DMD. **Conclusions:** Using a 9,150 patient cohort, we evaluated the impact of augmenting an existing ECS panel to include panel-wide deletion CNV calling and 81 additional conditions. The expanded panel suggests that the long-tail of rarer diseases, technically challenging conditions, and copy number variants each contribute substantially to the clinical sensitivity of ECS.

**Analysis of blood plasma metabolomic profile analysis of pregnancy and the association analysis with pregnancy-related diseases in Maternity Log Study.** Y. Harada<sup>1</sup>, D. Saigusa<sup>1</sup>, R. Yamashita<sup>1</sup>, D. Ochi<sup>2,1</sup>, T. Yamauchi<sup>2,1</sup>, Y. Tsunemoto<sup>2</sup>, S. Koshiba<sup>1</sup>, O. Tanabe<sup>1</sup>, S. Hiyama<sup>2</sup>, M. Nagasaki<sup>1</sup>, J. Sugawara<sup>2,3</sup>, G. Maternity Log Study Group<sup>1</sup>. 1) Tohoku University, Sendai, Japan; 2) NTT DOCOMO, INC., Yokosuka, Japan; 3) Tohoku University Graduate school of Medicine, Sendai, Japan.

In Japan, about 200,000 people are affected by pregnancy-related diseases including hypertensive disorders of pregnancy, gestational diabetes and premature deliveries each year. Pregnancy-related diseases are multifactorial diseases caused by a complex interaction of genetic factors and environmental factors such as lifestyle and living environments. Identification of substances in biospecimens such as blood and urine that reflect pathophysiological conditions during pregnancy is important to develop methods for early prediction of these diseases. For these objectives, we are conducting a prospective cohort study "Maternity Log Study" in which biospecimens and health information are collected from pregnant women. Three hundred participants have been recruited at Tohoku University Hospital, and have donated their blood, urine, saliva, and dental plaque samples for multi-omics analyses, i.e. genomic, transcriptomic, proteomic, metabolomic, and microbiomic analyses, but also reported daily health information through smartphones such as grades of morning sickness, abdominal pain, and uterine contractions, as well as physiological data such as body weight, blood pressure, heart rate, and body temperature. Metabolite analysis is a powerful methodology for biomarker discovery and elucidation of disease pathophysiology. It is well known that maternal physiological conditions change drastically during pregnancy, but their relationship with genetic factors and changes in metabolomic conditions are still unclear. In this study, we focused on pregnant women's metabolic profile analysis. Blood plasma samples were collected twice during pregnancy and once after birth. 279 metabolomic profiles of 95 pregnant women's blood plasma were acquired using gas chromatography-mass spectrometry (GC-MS) employing chemical derivatization pretreatment. We detected 143 metabolites, of which 83 were detected from all subjected samples. Now we have been analyzing the relationship between these metabolites and the pregnancy-related diseases, and we have a plan to report it in our presentation.

**Newborn metabolomics: Accurate prediction of gestational age from cord blood.** E. Jasper<sup>1</sup>, S. Oltman<sup>2,3</sup>, B. Bedell<sup>4</sup>, J. Dagle<sup>5</sup>, P. Jagannathan<sup>6</sup>, T. Clark<sup>6</sup>, G. Dorsey<sup>6</sup>, E. Rogers<sup>7</sup>, L. Jelliffe-Pawlowski<sup>2,3</sup>, K. Ryckman<sup>1,4</sup>. 1) Department of Epidemiology, College of Public Health, University of Iowa, Iowa City, IA; 2) Department of Epidemiology and Biostatistics, School of Medicine, University of California San Francisco, San Francisco, CA; 3) University of California San Francisco (UCSF) Preterm Birth Initiative, San Francisco, CA; 4) Department of Pediatrics, Carver College of Medicine, University of Iowa, Iowa City, IA; 5) Department of Medicine (Infectious Diseases), Stanford University Medical Center, Stanford, CA; 6) Department of Medicine, School of Medicine, University of California San Francisco, San Francisco, CA; 7) Department of Pediatrics, School of Medicine, University of California San Francisco, San Francisco, CA.

**Background:** Accurate estimation of gestational age is critical for clinical care decision of newborns. While prenatal ultrasound dating is the most accurate method for estimating gestational age, it is not feasible in certain settings. Previous research has demonstrated that metabolic and endocrine markers, captured in routine newborn screening, may be an accurate alternative method for estimating gestational age after birth. This research aimed to replicate this finding using metabolites from banked cord blood. **Methods:** Between 2001 and 2016, 938 newborns were enrolled at the University of Iowa Hospitals and Clinics. Cord blood was obtained from the infants and banked before being spotted on 903 Whatman filter paper. These samples were then analyzed by the State Hygienic Laboratory in Iowa. Forty-seven metabolites, including biomarkers of amino acid and fatty acid metabolism, thyroid-stimulating hormone, and 17-hydroxyprogesterone, were examined. Multiple linear regression modeling was performed, with gestational age, in weeks, as the outcome measure. Coefficients of determination and root-mean-square error were utilized to evaluate models. The best model was subsequently used to predict gestational age of newborns in a small, independent, East African population. **Results:** An algorithm containing metabolites and birthweight was better at discriminating between preterm and term infants compared to a model that relied solely on birthweight (AUC: 0.9877 vs. 0.9679). The top prediction algorithm contained 37 variables, including 17 metabolites, 12 squared metabolite terms, 6 cubed metabolites, and birthweight. When the algorithm was applied to the East African population, it was able to predict gestational age within 2 weeks for 83% of infants. When differentiating between infants born prematurely versus those born at term, only one premature infant was misclassified; whereas no control (term) infant was incorrectly classified (sensitivity: 83.33%, specificity: 100%). **Conclusions:** The newborn metabolic profile, derived from cord blood, is an accurate method for estimating gestational age. The model utilizing metabolites and birthweight predicts gestational age to a better degree than newborn birthweight alone. Newborn metabolic screening via cord blood may be an effective method for determining the gestational age of infants at birth, particularly in settings where prenatal ultrasound measurements are infeasible.

## 483F

**Bacterial taxonomic analysis of oral microbiome in spontaneous preterm birth for Maternity Log Study.** D. Ochi<sup>1,2</sup>, T. Yamauchi<sup>1,2</sup>, R. Yamashita<sup>2</sup>, Y. Tsunemoto<sup>2</sup>, M. Wagata<sup>2</sup>, Y. Harada<sup>2</sup>, S. Ogishima<sup>2</sup>, O. Tanabe<sup>2</sup>, S. Hiyama<sup>1</sup>, M. Nagasaki<sup>2</sup>, J. Sugawara<sup>2,3</sup>, Maternity Log Study Group. 1) Research Laboratories, NTT DOCOMO, INC., 3-6 Hikarino-oka, Yokosuka, Kanagawa, Japan 239-8536; 2) Tohoku Medical Megabank Organization, Tohoku University, 2-1, Seiryomachi, Aoba-ku, Sendai, Miyagi, Japan 980-8573; 3) Department of Gynecology and Obstetrics, Tohoku University Graduate school of Medicine, 1-1, Seiryomachi, Aoba-ku, Sendai, Miyagi, Japan 980-8574.

**Objective:** Pregnancy related diseases, including preterm birth (PTB) are caused by complex interactions of genetic and environmental factors such as lifestyle and living environments. We are conducting a prospective cohort study named Maternity Log Study to investigate unrevealed mechanisms of those diseases. Three hundred pregnant women were recruited at Tohoku University Hospital. We collected 900 dental plaque samples and saliva samples from the participants at several time points during and after pregnancy, as well as blood and urine samples, and daily lifelogs of physiological data and symptoms to analyze the complex interaction of genetic and environmental factors. Several previous studies showed relationship between periodontitis and preterm birth. Despite the critical role of microbiota as a part of environmental factors, the dynamic composition during pregnancy is still unclear. We have focused on bacterial taxonomic analysis of maternal dental plaque and investigated the possible relationship with spontaneous PTB (SPTB). **Methods:** Maternal dental plaque specimens were collected twice during pregnancy (first between 12 and 23 weeks of gestation, and second between 24 and 34 weeks) and once after birth from 15 women who spontaneously delivered preterm and 130 women with term birth. Species in plaque were determined by sequencing the 16S rRNA genes. We compared the relative bacterial abundances between the SPTB case group and the term-birth control group. **Results:** In the analysis of dental plaque collected between 12 and 23 weeks of gestation, a set of species in the SPTB group showed significantly lower relative abundances compared to the control group. However, in the samples collected later between 24 and 34 weeks, the difference in the abundances of these species between the two groups was not significant, because of the higher relative abundances of the set of species in the SPTB group at this period compared to the earlier period. **Discussions:** The relative abundances of the set of species in the SPTB group changed dynamically, although those in the control group were rather stable. It may reflect dynamic changes in the maternal physiological condition during pregnancy. We will further investigate the physiological changes by multi-layered omics analyses of blood and urine samples as well as lifelog analysis in addition to the changes in oral microbiome including the set of species, and thereby establish a prediction model for SPTB.

## 484W

**Maternal oral microbiota profile associated with hypertensive disorders of pregnancy.** T. Yamauchi<sup>1,2</sup>, D. Ochi<sup>1,2</sup>, R. Yamashita<sup>2</sup>, M. Wagata<sup>2</sup>, J. Kawashima<sup>2</sup>, Y. Tsunemoto<sup>2</sup>, Y. Harada<sup>2</sup>, T. Takai<sup>2</sup>, O. Tanabe<sup>2</sup>, S. Hiyama<sup>1</sup>, M. Nagasaki<sup>2</sup>, J. Sugawara<sup>2,3</sup>, Maternity Log Study Group. 1) Research Laboratories, NTT DOCOMO, INC., 3-6 Hikarino-oka, Yokosuka, Kanagawa, Japan 239-8536; 2) Tohoku Medical Megabank Organization, Tohoku University, 2-1, Seiryomachi, Aoba-ku, Sendai, Miyagi, Japan 980-8573; 3) Department of Gynecology and Obstetrics, Tohoku University Graduate school of Medicine, 1-1, Seiryomachi, Aoba-ku, Sendai, Miyagi, Japan 980-8574.

**Objective:** Despite the seriousness of pregnancy complications including hypertensive disorders of pregnancy (HDP), which often causes maternal and fetal death, the pathogenesis and progression have not been well elucidated. Pregnancy complications are multifactorial diseases caused by a complex interaction of genetic and environmental factors. In addition, it has been reported that human microbiota is involved in the onset. Several studies have revealed causal relationship between vaginal microbiota during pregnancy and preterm birth. However, there have been few studies on other body sites and other pregnancy complications. Oral microbiota affects not only caries and periodontal diseases, but also systemic diseases such as cardiovascular diseases. Therefore, it is conceivable that oral bacteria may also affect pregnancy complications. In this research, we analyzed maternal oral microbiota profile to clear the association between the microbiota and HDP. **Methods:** We used the dental plaque collected in Maternity Log Study, which is a Japanese prospective cohort study for pregnant women. In this study, pregnant women were recruited in the first or second stage of pregnancy at Tohoku University Hospital. Study participants uploaded daily physiological data such as blood pressure and body weight. Furthermore, this study collected maternal dental plaque, blood, and urine. Plaque specimens were gathered twice during pregnancy, and once in about one month after birth. Using approximately 900 plaque specimens from over 300 women, we estimated microbiota in plaque specimens by 16S rRNA gene sequencing. Based on relative abundances of genus or species per specimen, we performed principal component analysis (PCA). **Results:** PCA showed that cases and controls formed different genus clusters, especially, there was a significant difference between severe HDP cases and controls. *Rothia* was one of the genus greatly contributing to PC1. **Discussions:** We demonstrated new findings maternal oral microbiota profile associated HDP. *Rothia dentocariosa* is a common species of the human oral cavity. In the previous reports, *Rothia dentocariosa* was found in the blood culture of deceased fetuses and the amniotic fluid of pregnant women with preterm pre-labor rupture of membranes. Our results indicate a possible relationship between the oral microbiome and these pregnancy complications. Further research may lead to elucidate the detailed mechanism and prevent the onset of HDP.

**Prenatal screening for 22q11.2 deletions using a targeted microarray-based cell-free DNA (cfDNA) test.** J. Shabbeer<sup>1</sup>, M. Schmid<sup>1</sup>, E. Wang<sup>1</sup>, P. Bogard<sup>1</sup>, J. Zahn<sup>1</sup>, C. Hacker<sup>1</sup>, S. Wang<sup>1</sup>, J. Doshi<sup>1</sup>, K. White<sup>1</sup>, J. Kaplan<sup>1</sup>, A. Sparks<sup>1</sup>, J. Jani<sup>2</sup>, R. Stokowski<sup>1</sup>. 1) Ariosa Diagnostics Inc., Roche Sequencing Solutions Inc; 2) Department of Obstetrics and Gynecology, University Hospital Brugmann, Université Libre de Bruxelles, Brussels, Belgium.

**Objective:** Cell-free DNA (cfDNA) testing provides high sensitivity for common trisomies and a lower false positive rate than traditional prenatal screening methods. Recently, the scope of testing has expanded to include subchromosomal deletions. Here we aim to determine the performance of a targeted microarray-based cfDNA test (Harmony Prenatal Test®) to screen for pregnancies at increased risk for a 22q11.2 deletion. **Methods:** Test performance was determined in two steps including a total of 1,953 plasma samples. Analytical validation was performed in 1736 plasma samples. Clinical verification of performance was performed in an additional 217 prospectively ascertained samples from pregnancies with fetal deletion status determined by diagnostic testing. **Results:** Analytical sensitivity was 75.4% (95% CI: 67.1-82.2%) based on 122 samples with deletions ranging from 1.96 to 3.25 Mb. In 1614 presumed unaffected samples, specificity was determined to be at least 99.5% (95% CI: 99.0-99.7%). In the clinical cohort, 5 of 7 samples from pregnancies affected with 22q11.2 deletion were determined to have a high probability of deletion. There were no false positive results in the 210 unaffected samples in this cohort. This clinical data is consistent with the performance demonstrated in the analytical validation. **Conclusions:** Cell-free DNA testing using targeted microarray quantitation is able to identify pregnancies at increased risk for 22q11.2 deletions of 3.0 Mb and smaller while maintaining a low false positive rate.

**486F**

**Correlation between nutrigenetic variants, adherence to the Mediterranean diet and obesity in male infertility.** M. La Rovere<sup>1</sup>, M. Franzago<sup>1</sup>, M. De Santo<sup>2</sup>, GM. Tiboni<sup>3</sup>, P. Piomboni<sup>4</sup>, L. Stuppia<sup>1</sup>. 1) Laboratory of Molecular Genetics, Department of Science, Psychology of Health and Territory, "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy; 2) Private nursing home Synergo Pierangeli, Spatocco, Chieti, Italy; 3) Department of Medicine and Aging Sciences, "G. d'Annunzio" University of Chieti-Pescara, Chieti, Italy; 4) Department of Molecular Medicine and Development, University of Siena, Policlinico Le Scotte, Siena, Italy.

It is estimated that 15-20% of couples in industrialized countries have fertility problems. This percentage is expected to grow under the influence of genetic and environmental factors. Many studies have stressed the correlation between male nutrition and infertility, and obesity is also closely related to infertility, as several studies reported that males with high BMI have a reduced reproductive potential and a progressive decline in seminal parameters. The purpose of this study was to evaluate the relationship between seminal parameters and 9 nutrigenetic variants involved in food metabolism (namely: *PPARG2* rs1801282; *PPARGC1A* rs8192678; *TCF7L2* rs7903146; *LDLR* rs2228671; *MTHFR* rs1801133; *APOA5* rs662799; *GCKR* rs1260326; *FTO* rs9939609 and *MC4R* rs17782313) in 120 male subjects of infertile couple undergoing ART. In particular, 49 subjects had normal weight (BMI 18.5-24.99), 56 were overweight (BMI 25-29.99) and 15 were obese (BMI > 30). According to the sperm count and morphology, each group was further subdivided in i) subjects with altered spermatogenesis (mild oligo/astheno/teratozoospermia) and ii) subjects with a normal spermiogram. Adherence to the Mediterranean Diet has been evaluated through the MedDiet software. A significant association between obesity and variants in *FTO* gene has been identified. Indeed, the frequency of the AA genotype in *FTO* was higher in obese (46.7%) than in normal (30.6%) and overweight (17.9%) subjects ( $p < 0.05$ ). In addition, also the frequency of CC genotype in *MC4R* was higher in obese (13.3%) than in normal (6.1%) and overweight (5.4%) subjects, but this difference was not statistically significant. Moreover, a possible correlation between the aforementioned polymorphisms and a worsening of the phenotypic picture of the spermiogram can be hypothesized, since in the group of overweight and obese subjects a greater frequency of *FTO* AA and *MC4R* CC genotypes was observed in subjects with an altered spermiogram compared to those with normal spermiogram (AA: 25% vs. 20%, CC: 11.1% vs 2.9%). However, also in this case the difference was not statistically significant, likely due to the limited number of cases analyzed. In conclusion, our data supports an association between *FTO* and BMI. On the other hand, a direct relationship between *FTO* and *MC4R* variants with seminal parameters in obese subjects can not be confirmed, suggesting that the link between obesity and infertility is not related to common genes of susceptibility.

**487W**

**Knowledge and attitudes on non-invasive prenatal pharmacogenetic testing among pregnant and preconception women.** *M.J. Ross<sup>1</sup>, H. Naik<sup>1</sup>, S.A. Suckiel<sup>1</sup>, E. Boniferrero<sup>2</sup>, E. Bazinet<sup>2</sup>, Z. Nelson<sup>2</sup>, D. Reed<sup>3</sup>, S.A. Scott<sup>1,4</sup>.* 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY 10029; 2) Department of Obstetrics and Gynecology, Mount Sinai West, New York, NY 10019; 3) Department of Obstetrics and Gynecology, Tufts Medical Center, Boston, MA 02111; 4) Sema4, a Mount Sinai venture, Stamford, CT 06902.

Drug metabolism and transport during pregnancy is an understudied area, as the potential teratogenic effects of most commonly prescribed medications are currently unknown. The safety profiles of these medications are likely influenced, in part, by maternal, placental and fetal pharmacogenetic variability, suggesting that pharmacogenetic-guided drug selection and/or dosing during pregnancy may be possible in the future. Moreover, fetal and maternal pharmacogenetic genotyping may be feasible with non-invasive prenatal screening (NIPS) using cell-free fetal DNA (cffDNA) derived from maternal peripheral blood. Although non-invasive prenatal pharmacogenetic testing (NIPPT) is not currently available, we sought to determine the interest and attitudes of pregnant and preconception women regarding NIPPT. Women presenting for prenatal and preconception counseling were recruited from two Mount Sinai reproductive genetic counseling clinics (n=114) and administered an anonymous survey. The majority of subjects (n=86; 75.4%) were previously unaware of the availability of pharmacogenetic testing; however, 91 participants (80%) reported an interest in NIPPT, which was comparable to their interest in NIPS for chromosomal abnormalities (86%). Greater interest in NIPPT was associated with previous awareness of NIPS (p=0.031), a history of adverse drug reactions (p=0.021), and general interest in pharmacogenetic testing (p<0.001). The motivation for wanting to pursue NIPPT was driven by potential benefits related to medication efficacy and reduced adverse drug effects for both mother and fetus. However, the main concerns with NIPPT were that results would impact health insurance eligibility and that physicians would be unable to identify medications suitable for both mother and fetus. Taken together, these results indicate that pregnant women are interested in pursuing NIPS for prenatal applications beyond aneuploidy screening, including pharmacogenetic testing, as NIPPT results could directly inform maternal medication use and fetal teratogenicity risk. However, as technical advances enable the future availability of NIPPT and related cffDNA-based testing, careful assessment of clinical utility and continued patient reassurance of genetic nondiscrimination is warranted.

**488T**

**Association between *MTHFR*, *MTHFD1* and *RFC1* gene polymorphisms and unexplained spontaneous pregnancy loss in Korean women.** *S. Shim<sup>1</sup>, S. Sung<sup>1</sup>, J. Kim<sup>2</sup>, J. Park<sup>1</sup>, K. Kang<sup>1</sup>, Y. Shin<sup>1</sup>, M. Chin<sup>1</sup>, Y. Jung<sup>2</sup>, S. Lyu<sup>2</sup>, D. Cha<sup>1,2</sup>.* 1) Genetic Lab, CHA Gangnam Medical Center, Seoul, South Korea; 2) Department of Obstetrics and Gynecology, CHA Gangnam Medical Center, CHA University Seoul, Korea.

The previous studies have been reported that relationship between polymorphisms in folate metabolism is closely associated with the homocysteine-folate balance, and recurrent pregnancy loss. This study aimed to investigate the association between unexplained spontaneous pregnancy loss and genetic polymorphism in mother-newborn and mother-POC matched sample. A total of 91 Korean women with spontaneous abortion and 92 women with normal delivery were recruited. Genomic DNAs were extracted from mothers, POC samples and newborn samples. This Study was approved by the Internal Review Board of CHA Gangnam Medical Center and written informed consent was obtained from all participants. The *RFC1* 80A>G, *MTHFD1* 1958 G>A, *MTHFR* 677C>T and *MTHFR* 1298A>C variation were examined. Genotyping for each variation was accomplished by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP). Statistical significances of allele distribution in mother-POC group and mother-newborn group were evaluated by Fisher's exact test and logistic regression test. The frequency of the C allele of *MTHFR* 1298 was significantly higher in mother group with spontaneous abortion (SA) than in mother with newborn (P<0.05). The frequency of the AG genotype of *RFC1* was significantly higher in POC samples than in newborn (P<0.05). We subdivided POC samples based on karyotype results. The frequency of the GA genotype of *MTHFD1* was significantly higher in POC samples with normal karyotype than in newborn (P<0.05). On the other hand, the frequencies of the AG genotype of *RFC1* 80A>G and the CC genotype of *MTHFR*1298A>C were statistically significant in POC samples with abnormal karyotype compare with newborn. The allele combinations of *MTHFR* 677/*MTHFD1* 1958 and *RFC1* 80/*MTHFR*677/*MTHFD1* 1958 (T-A and G-T-A) was significantly higher in mother with POC samples than in mother with newborn compared with the reference combination. Our study is the first to elucidate the association between *MTHFR*, *MTHFD1* and *RFC1* polymorphisms and unexplained pregnancy loss in mother-newborn and mother-POC matched sample. However, since it was carried out on a small sample limited only Koreans, further studies are necessary to confirm our results more large and heterogeneous populations. .

**Lessons from prenatal CMAs in low- and high-risk pregnancies: Is the incidental truly incidental?** A.E. Eilat, V. Meiner, S. Shkedi-Rafid, H. Daum, A. Szmulewicz, N. Zvi, A. Frumkin, S. Yagel. Hadassah Medical Center, Jerusalem, Israel.

**Background:** Chromosomal-microarray-analysis (CMA) is gradually replacing karyotyping in prenatal diagnosis. Reporting copy-number-variants (CNVs) conferring risk for adult onset and autosomal-recessive conditions is controversial. We report three cases that illustrate the complexities of disclosing such findings. **Cases:** (1) A 38-year-old woman of Ashkenazi-Jewish descent underwent amniocentesis because of advanced maternal age. A paternally inherited 1250Kb deletion was identified on chromosome 13, which includes the *BRCA2* gene, in a female fetus. Negative result for Ashkenazi *BRCA2* founder mutation ruled out Fanconi anemia in the fetus and the pregnancy resulted in the birth of a healthy baby. (2) A 37 year-old woman, of Ashkenazi origin, underwent amniocentesis because of IUGR. A maternally inherited 76Kb deletion, which includes part of the *BLM* gene associated with Bloom syndrome on chromosome 15, was identified. Positive testing of the Ashkenazi father for the common *BLM* founder mutation led us to direct testing of the fetus and diagnosis of Bloom syndrome. (3) A 32-year-old woman, underwent amniocentesis following an ultrasonic finding of macrocephaly. *de novo* deletion of the *PTEN* gene was identified. The future risk of later onset malignancies and developmental delay was discussed with the parents who opted to continue the pregnancy. **Discussion:** The use non-targeted advanced genomic tests in pregnancy may reveal risks for adult-onset and autosomal-recessive conditions in the ongoing pregnancy. Although reporting of such findings is not unanimously recommended, we stress that at least in some cases, benefit of disclosure outweighs potential harms.

**490W**

**Revealing transcriptome and methylome landscapes in a human oocyte by parallel sequencing.** T. Lee<sup>1</sup>, Y. Qian<sup>1</sup>, J. Liao<sup>1</sup>, L. Ch<sup>2</sup>, G. Kong<sup>3</sup>, C. Chung<sup>2</sup>, T. Leung<sup>2</sup>, K. Yip<sup>3</sup>, K. Chow<sup>4</sup>, W. Chan<sup>1</sup>, T. Li<sup>1</sup>. 1) School of Biomedical Sciences, The Chinese University of Hong Kong, Shatin, Hong Kong; 2) Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong; 3) Department of Computer Science and Engineering, The Chinese University of Hong Kong; 4) Division of Life Science, Hong Kong University of Science and Technology.

Oocyte quality plays a critical role in fertility, embryonic development and fetal health. Previous studies have reported that morphological assessment is limited and was not associated with fertilization rate, embryo quality or implantation rate after intracytoplasmic sperm injection. Molecular assessment based on genetics and epigenetics signatures would be an alternative strategy. With the recent development of single cell sequencing technologies, several studies have established single oocyte transcriptome and methylome profiles separately. In this study, we aimed to profile the simultaneous transcriptome and methylome landscapes in a single human oocytes by adopting a modified single cell parallel methylome and transcriptome sequencing (scM&T-seq). We performed scM&T-seq on two oocytes donated from a 32-year-old in vitro fertilization patient through follicle induction approach. A total of 10317 genes were commonly expressed in the two oocytes, and the correlation of two transcriptomes was 0.984 using Pearson's correlation test. For RRBS libraries, the mapping efficiency was 25.1% and 26.9% respectively, whereas the bisulfite conversion ratios were 98.5% and 96.7% respectively. We detected 222,335-464,057 CpG sites covered by at least one reads and 146,040-322,323 CpG sites covered by at least five reads. Two samples shared 3450 CpG islands. Nearly half of detected CpG sites (43% and 45%) were located in gene promoters and the majority of CpG sites were annotated in CpG islands or shores. A high correlation ( $R=0.870$ ) of methylation level between two single oocytes was observed in 1000-bp bin size window. Maternal imprinted gene, *IGF2R*, were fully methylated in both two oocytes. Furthermore, we also observed a positive correlation between gene expression and methylation level in gene body, but not in promoter regions. In summary, we are the first to perform single-cell parallel M&T sequencing on a single human oocyte. The technique allows delineating the dynamics between epigenetic modification and transcriptional activity in parallel fashion. We demonstrated that the quality of transcriptome and methylome profiles are comparable to conventional single-cell transcriptome or methylome approach. We also showed the two single oocytes from the same donor exhibited a positive correlation between gene expression and methylation level on gene body region. The study therefore provides a foundation for the development of molecular diagnosis on oocyte quality.

**491T**

**Targeted next generation sequencing-based preimplantation genetic screening can enable detection of uniparental isodisomy, familial relationships, and polyploidy.** *M. Umbarger, E. Boyden, N. Faulkner, M. Zhu, K. Robinson, D. Neitzel, G. Porreca.* Good Start Genetics, Cambridge, MA.

We previously validated the FAST-SeqS technology for targeted next generation DNA sequencing-based detection of full chromosome and segmental aneuploidy in human embryos (Gole et al 2016, Umbarger et al 2016). While not leveraged in those validations, we observed that the loci captured by FAST-SeqS include thousands of polymorphic sites. The representation of alleles at such sites can be used to derive information beyond segmental and full chromosome aneuploidy. Here, we assessed the feasibility of using single nucleotide polymorphism (SNP) information captured by FAST-SeqS to detect uniparental isodisomy (UPD), familial relationships among samples, and polyploidy. First, to evaluate whether FAST-SeqS can detect UPD we ran cell line-derived samples containing isodisomic chromosomes through FAST-SeqS and assessed whether the captured SNP genotypes were consistent with the expected UPD. We observed an abnormally low frequency of heterozygous SNP calls within isodisomic chromosomes (1.2% vs 62% for control samples), providing a clear metric that could be utilized to call UPD. Next, to determine if FAST-SeqS can recapitulate expected familial relationships, samples from a 17-member multi-generation family were tested in replicate and per-sample SNP genotypes were called and subsequently used to cluster the samples. We observed that the resulting dendrogram perfectly matched the expected family tree. Finally, to assess the ability of FAST-SeqS to identify polyploidy, we examined FAST-SeqS data for 200 embryo biopsies for which sex chromosome and autosome copy number calls were potentially consistent with polyploidy (69,XXY; 69,XYY; 92,XXXYY) and evaluated the degree to which the observed allele fraction distributions at polymorphic loci supported such karyotypes. For the majority (74.2%) of these biopsies the observed allele fraction distributions displayed characteristic multi-modal patterns that could readily be identified using an automated kernel fitting and peak finding strategy. Collectively, our studies illustrate the feasibility of leveraging embryo-derived SNP information captured by FAST-SeqS to detect UPD, familial relationships among samples, and polyploidy, likely extending to karyotypes that are not currently detectable with most NGS-based preimplantation genetic screening technologies, including whole genome-amplified low-pass sequencing.

**492F**

**The revelation of complex chromosomal rearrangements through genome-wide cfDNA testing.** *T. Boomer, S. Caldwell, E. Almasri, J. Wardrop, S. Boshes, M. Hackbardt, P. Cacheris, R. McCullough.* Sequenom Laboratory, San Diego, CA.

**Background:** Recent adoption of genome-wide cfDNA prenatal screening provides unique insight into placental findings not previously recognized. Here we present data from our first 28K clinical samples for expanded cfDNA screening, including genome-wide aneuploidy detection and subchromosomal copy number variants (CNVs)  $\geq 7$ Mb, with specific attention to complex chromosomal rearrangements. **Methods:** Maternal blood samples submitted for genome-wide cfDNA testing were subjected to DNA extraction, library preparation, and whole-genome massively parallel sequencing as described by Jensen et al. Sequencing data were analyzed using a novel algorithm as described by Lefkowitz et al. **Results:** A total of 28,760 samples were submitted to the clinical laboratory, resulting in 1392 positives (4.8%) reported: • 53% Common trisomies (Trisomy 13, 18, 21) • 18% Sex chromosomal aneuploidies • 3% Microdeletions • 14% Esoteric chromosomal aneuploidies (e.g. Trisomy 7) • 7% Isolated CNVs • 4% Complex CNVs ( $\geq 2$  segments, e.g. translocations) Complex CNV samples showed an enrichment of ultrasound findings (61%), high risk personal and/or family histories (34%) and multiple high risk indications (20%) when compared to our testing population as a whole (20%, 6%, and 12% respectively). CNV sizes range  $<10$ Mb to  $\sim 100$ Mb, with the majority 10-20Mb. Of the 64 complex CNVs reported, 49 were interpreted as possible translocation events between two chromosomes and 15 as possible recombinant events, isolated to one chromosome. Subsequent fetal confirmation was reported in the majority (56%), with 27% pending, 11% lost to follow-up, and 5% discordant. Prior knowledge of a parental rearrangement (e.g. translocation, insertion, inversion) was true for 22% of complex results, while 19% were identified post testing. A minority of cases (6%) were de novo, with the remaining subset pending full parental assessment (56%). Totals will be updated prior to final publication. **Conclusions:** Identification of complex chromosomal rearrangements via cfDNA prenatal screening marks a new era in prenatal testing. These findings tend to segregate with significant high risk prenatal indications. Many known familial rearrangements not previously amenable to cfDNA screening may now benefit from early identification or added reassurance. New discovery of families at risk of carrying a recombinant event often helps to explain past pregnancy complications, as well as clarify future reproductive risk.

**Comparing maternal malignancies and multiple aneuploidies on prenatal cell-free DNA (cfDNA).** *E. Soster, B. Dyr, T. Boomer, S. Caldwell.* Integrated Genetics, 3400 Computer Drive, Westborough, MA 01581.

Maternal malignancies are a rare cause of prenatal cfDNA testing results that are non-reportable or discordant for fetal status. Although prenatal cfDNA testing is not currently designed or validated to detect neoplasm, cases associated with maternal malignancies do rarely occur (~1 in 10000 samples in our laboratory), creating challenges for both the clinician and laboratory. With the advent of prenatal genome-wide cfDNA testing, a handful of cases have identified an increased risk for multiple aneuploidies in a pregnancy, which may raise concomitant concern for a neoplasm. However, data from these samples is often distinct from cases of known maternal malignancy. Maternal blood samples submitted for genome-wide cfDNA screening were subjected to DNA extraction, library preparation, and whole genome massively parallel sequencing. Sequencing data were analyzed using an algorithm to detect trisomies and sub chromosomal, genome-wide events 7Mb and larger.<sup>2</sup> In data suggestive of multiple aneuploidy, events are generally confined to specific chromosomes, appear as full trisomies, and are consistent with the sample's expected fetal representation. These have been reported out by the laboratory as positive for multiple aneuploidy. Conversely, the case examples below with malignancy known or later confirmed were reported out as non-reportable (NR) due to their chaotic appearance and genome-wide aberrant sequencing data. Results suggestive of multiple aneuploidies in cfDNA testing are rare but challenging. Such results in an ongoing pregnancy are most likely associated with placental mosaicism<sup>2</sup> which is reflected in the laboratory reports. While malignancy cannot be ruled out with any result, cases in which maternal neoplasm is present often look distinctly different. Currently, cfDNA testing during pregnancy is not validated to detect or rule out cancer; however, this insight into some differences in laboratory data may help clinicians navigate these complex results.

Lab Call	Positive: Trisomy 13, 15, 20	Positive: Trisomy 8 & 22	Positive: Trisomy 8 & 14	NR	NR	NR
Referral	Maternal age (MA)	MA	Serum screen	Personal/family history	MA	MA
Status	Ongoing pregnancy; Amniocentesis: normal karyotype; normal maternal karyotype; Normal first trimester analytes, nuchal translucency, anatomy scan	Ongoing pregnancy; Amniocentesis: normal karyotype	Ongoing pregnancy; Amniocentesis: normal Karyotype	Breast Cancer confirmed, diagnosed recent to cfDNA draw	Known advanced breast cancer	Known colon cancer

**Broad spectrum of prenatal cultural artifacts detected by microarray.** *V. Potluri<sup>1</sup>, A. Penton<sup>2</sup>, K. Rudd<sup>2</sup>, N. Leach<sup>3</sup>, H. Risheg<sup>4</sup>, J. Knops<sup>5</sup>, G. Sekhon<sup>5</sup>, R. Pasion<sup>2</sup>, R. Burnside<sup>2</sup>, P. Papenhausen<sup>2</sup>.* 1) Cytogenetics, Lab Corp, Houston, TX 77040; 2) Laboratory Corporation of America, 1904 Alexander Drive, RTP, NC 27709; 3) Integrated Genetics, 3400 Computer Drive, Westborough, MA 01581; 4) Laboratory Corporation of America Holdings/Dynacare, Seattle, Washington; 5) Integrated Genetics, 2000 Vivigen Way Santa Fe, NM 87505.

The importance of direct microarray analysis (CMA) of prenatal cells can be emphasized by a retrospective study of mosaic results detected in parallel flasks grown for f/u of cytogenetic analysis. The delayed CMA studies were usually part of reflex testing if the chromosome analysis was normal or if more detail was desired concerning an abnormal result. The cohort being cited includes 9 amniocyte cultures and 4 CVS cultures which were in culture from 16 to 43 days before CMA. Eight of the cultures were between 16 and 21 days in culture. The percentage of mosaicism primarily ranged from 8-25%, although a 40% loss of Y (35 days in culture) and a 30% copy neutral segmental UPD of 9q (21 days in culture) were also seen. The artifacts were primarily whole chromosome gain (isolated chromosome gain of 5, 7, 9,) with the one case of Y loss. More complicated artifacts included one triple aneusomy (+2,-4,+14) and another with four trisomies (+3,+4,+5,+10) and a dup(17q). Segmental changes with single alterations included deletions of 3q, 4q and 12q, along with isolated duplications of 1q, 14q and Xq. All these mosaic cases were visually confirmed as artifacts by separate original culture analyses in extended analysis of all available metaphases. Two cases required BAC FISH follow-up due to the small size of the CNV, but are not included in this report. Whenever cultured cells are necessary for CMA it is important to have a parallel culture of separate origin to properly interpret the many artifacts that arise from even a moderate time in vitro.

**Prenatal NGS testing confounded by low levels of maternal cell contamination.** Z. Wolf<sup>1,2</sup>, S. Bandyadka<sup>1</sup>, E. Murphy<sup>1</sup>, M. Lebo<sup>1,2</sup>, H. Mason-Suares<sup>1,2</sup>. 1) Laboratory for Molecular Medicine, Partners Personalized Medicine, Cambridge, MA; 2) Department of Pathology, Harvard Medical School and Brigham and Women's Hospital, Boston, MA.

Next generation sequencing (NGS) is rapidly becoming the standard of care in prenatal diagnostics for high risk pregnancies, but working with prenatal samples requires particular care and considerations. Unlike other sample types used in molecular diagnostics, prenatal samples can be contaminated with maternal cells, which can introduce errors leading to misdiagnosis and pregnancy mismanagement. While the level of maternal admixture that affects the sensitivity and specificity for NGS is unknown, studies involving other assays suggest as little as 10% maternal cell contamination (MCC) can result in misdiagnoses. To define these levels for NGS, this study examines the consequence of maternal admixture on the interpretation of NGS results from prenatal samples with varying levels of MCC. MCC was simulated at levels of 2.5%, 5%, 7.5%, 10%, 20%, 30%, 40%, and 50% by spiking maternal DNA into fetal DNA samples previously confirmed to be negative for MCC. NGS was then performed using a targeted capture kit of 78 genes, and variants were called according to GATK best practices. Samples had an average coverage of 350X. Discordant variant calls between maternal and prenatal samples were examined in the spiked-in samples and analyzed based on clinically relevant scenarios. Simulation of disorders with an autosomal recessive inheritance, where the maternal sample was heterozygous and the fetal sample was homozygous for a given allele, demonstrated that as little as 5% MCC compromised test interpretation with 19% of variants being miscalled and passing quality control (QC) metrics. Simulation of disorders with a de novo autosomal dominant inheritance, where the maternal sample was homozygous for the reference allele and the fetal sample was heterozygous, showed that variants were miscalled starting at 20% MCC. In summary, here we report that very low-levels of MCC can confound NGS test results, leading to erroneous interpretation of clinical results and ultimately affecting pregnancy management. This study highlights that MCC must always be considered when interpreting results from prenatal samples, since levels as low as 5% may result in incorrect findings.

**496W**

**FXPOI: Modifying factors may play a larger role among the most vulnerable mid-range premutation group of women.** E.G. Allen<sup>1</sup>, K. Charen<sup>1</sup>, H. Hipp<sup>1</sup>, L. Shubeck<sup>1</sup>, C. Trevino<sup>1</sup>, W. He<sup>1</sup>, A. Amin<sup>1</sup>, A. Glicksman<sup>2</sup>, N. Tortora<sup>2</sup>, S.L. Nolin<sup>2</sup>, H.R. Johnston<sup>1</sup>, D.J. Cutler<sup>1</sup>, M. Zwick<sup>1</sup>, M.P. Epstein<sup>1</sup>, P. Jin<sup>1</sup>, S.T. Warren<sup>1</sup>, S.L. Sherman<sup>1</sup>. 1) Department of Human Genetics, Emory University, Atlanta, GA; 2) New York State Institute for Basic Research in Developmental Disabilities, Albany, NY.

Fragile X-associated primary ovarian insufficiency (FXPOI) is seen in about 20% of women who carry a *FMR1* premutation allele (55-200 CGG repeats). These women develop hypergonadotropic hypogonadism with menstrual dysfunction before the age of 40. A non-linear association with repeat size and risk for FXPOI has been confirmed in multiple studies: those with a mid-range of CGG repeats are at highest risk (~70-100 CGG repeats). Importantly, not all female carriers with 70-100 CGG repeats experience FXPOI. We hypothesize that other factors modify the risk for FXPOI, including those associated with the characteristics of the repeat as well as other genetic and environmental factors. We have determined age at menopause on 415 women with a premutation based on self-report reproductive questionnaires and interviews with a reproductive endocrinologist. To identify genetic modifying factors, we have conducted whole genome sequencing (WGS) on 70 early-onset cases of FXPOI and 55 late-onset controls. From these results, we will identify candidate genes to investigate in a *Drosophila* model screen. In parallel, we are investigating *FMR1* molecular modifying factors, including repeat size, AGG interruption pattern, transcript levels, and X-inactivation ratio among subsets of this population and potential environmental modifying factors including smoking, body mass index, and autoimmune disorders. To start, we characterized the amount of variation in age at menopause explained by repeat size using a model that included the repeat size and the quadratic form of repeat size to test the non-linear relationship. This model was highly significant ( $p < 0.0001$ ); however, only 6% of the variation in age at menopause was explained ( $r^2 = 0.06$ ). Neither the AGG interspersed pattern nor X-inactivation ratio was significantly associated with age at menopause. Interestingly, although the sample size was limited (N=66), adding transcript level and the product of repeat size and transcript level to this model was significant (full model  $p = 0.0060$ ) and explained 21% of the variation in age at menopause ( $r^2 = 0.21$ ). In addition to these molecular findings, we will present potential modifying genes identified from our WGS and investigate environmental factors and their effect on the risk for FXPOI.

**Novel application of fragile X CGG repeat analysis in a clinical setting: Outcomes and data derived from 716 embryos undergoing preimplantation genetic diagnosis (PGD).** R. Cabey, D. Goldberg-Strassler, B. Chu, N. Goodall, A. Jordan, R. Prates, M. Konstantinidis. CooperGenomics, a Cooper-Surgical Company, Livingston, NJ.

Analyses of fragile X mental retardation gene (*FMR1*) CGG repeat testing have always been done on samples derived from living individuals or prenatal testing. This is the first study with a significant amount of data derived from human preimplantation embryos undergoing preimplantation genetic diagnosis (PGD). Between 01/2014 and 04/2017, 98 patients, with average maternal age of 34.1±0.3 (standard error of the mean), underwent PGD for fragile X syndrome via a linkage-based technology (Karyomapping; Illumina, USA), and direct CGG repeat analysis. Samples from 716 embryos were received from 163 IVF cycles. 28 patients banked embryos from multiple IVF cycles. A total of 132 PGD tests were performed; 123 of these included aneuploidy screening via aCGH or NGS (Illumina, USA). Following exclusion of embryos with no diagnosis, sex aneuploidy, or that were untested, CGG repeat results were obtained in 641/653 samples (98.2%). Patients who banked embryos had more embryos tested per PGD cycle (6.8±0.7) compared to patients who did not (4.9±0.3). Analysis of expansion patterns revealed that the premutation allele expanded to a full mutation at the following rates per category group: 0% (0/59) in the maternal premutation group of 55-59 CGG repeats, 8.2% (6/73) in the 60-69 group, 9.5% (4/42) in the 70-79 group, 30.8% (8/26) in the 80-89 group, 91.7% (22/24) in the 90-99 group, and 100% (47/47) in the 100-199 group. Overall, 47.2% of embryos inherited the maternal normal allele. Of the embryos that inherited the mutant allele, only 32.1% expanded to a full mutation. Interestingly, 1.1% (7/641) of embryos contracted from the maternal allele size (ranging from 64 to >200). The average number of embryos available for transfer per PGD cycle, increased significantly from 1.4±0.1 (normal *FMR1* alleles only) to 2.1±0.2 when including premutation embryos ( $P<0.001$ ). Follow up from patients revealed that 53 normal allele embryos, 5 premutation, and 2 normal or premutation embryos were transferred; altogether resulting in 26 live births and 6 ongoing pregnancies. Subsequent confirmatory testing was pursued by 3 patients revealing concordant results with PGD. This unique data set provides a novel insight into the *FMR1* CGG repeat patterns at the preimplantation embryo stage and clinical implications of such testing. The ability to distinguish premutation and full mutation preimplantation embryos provides more options and information for embryo transfer decisions.

**CarrierTest: The first experience with expanded preconception carrier screening.** M. Koudová, F. Lhota, F. Zembol, M. Bittóová, L. Dohnalová, Z. Vilimová, B. Honysová, D. Stejskal. GENNET - Clinic of Genetics and Reproductive Medicine, Prague, Czech Republic.

**Introduction** Over 1300 recessive disorders have been described with estimated cumulative birth prevalence of recessive homozygotes/hemizygotes 3/1000. Preconception carrier screening testing asymptomatic individuals for single copy mutations and estimating risk of recessive disorders of their offspring has a potential to decrease this burden. **Methods:** We have designed a NGS (next-generation sequencing) amplicon-based panel testing 860 key mutations of 79 genes which can influence reproductive health of prospective parents or can cause recessive disorders in offspring. We have developed a bioinformatic pipeline using local installation of Ensembl genomic database for annotation and SQL server variant database for data handling and clinical reporting. To replace MLPA and fragmentation analysis methods we developed coverage analysis-based CNV detection of frequent large deletions of *SMN1* and *CFTR* genes. A software tool developed for this application generates report semi-automatically. **Results:** Results are grouped according to clinical impact: (1) mutations in genes associated with severe recessive disorders in offspring (e.g. *SMN1*, *CFTR*, *GJB2* genes), (2) low penetrant mutations in genes associated with disorders influenced by environment (*SERPINA1*, *HFE*, *BCHE*), (3) mutations in set of genes predisposing to blood hypercoagulation- thrombophilic profile (*F2*, *F5*, *MTHFR*, *ANXA5*- M2 haplotype), (4) ovarian response to FSH (*FSHR* polymorphism). The report contains in addition to general information on found variants and associated disorders residual risk estimation and couple's preconception compatibility. **Conclusion:** CarrierTest can contribute to individualization and therefore more effective treatment of infertility and prevention of rare genetic disorders. There is a clinical option of preimplantation or prenatal diagnostics or using compatible donor gametes for couples with significant risk of having affected offspring.

**Potential impact of predictive genetic testing among at-risk female relatives of *ATM* heterozygotes on breast cancer surveillance recommendations.** *D. Almanza<sup>1</sup>, C. Lewis, MS, CGC<sup>2</sup>, K. Ray, MS, CGC<sup>1</sup>, A. Cantor, MS, CGC<sup>3</sup>, R. Hayes Morgan<sup>4</sup>, K. McReynolds<sup>4</sup>, G. L. Wiesner, MD<sup>4</sup>, T. Pal, MD<sup>4</sup>.* 1) Moffitt Cancer Center, Tampa, FL; 2) St. Jude Children's Research Hospital, Memphis, TN; 3) NYU Langone Medical Center, New York, NY; 4) Vanderbilt University Medical Center/Vanderbilt-Ingram Cancer Center, Nashville, TN.

**Purpose:** Widespread multi-gene panel testing for inherited cancer risk, inclusive of moderate penetrance genes, has led to the identification of many *ATM* heterozygotes. Heterozygous *ATM* pathogenic variants impart >20% lifetime female breast cancer (BC) risk, the threshold for high-risk breast surveillance. Among a registry-based sample of probands with a pathogenic (P) or likely pathogenic (LP) variant in *ATM*, we sought to assess the impact of *ATM* positivity on BC surveillance recommendations for at-risk female relatives. **Methods:** Using a registry-based sample of 47 *ATM* heterozygotes, lifetime BC risks were calculated for unaffected female first-degree relatives (FDRs) and second-degree relatives (SDRs) under age 80 using BOADICEA and summary statistics were generated for level of BC risk. **Results:** Among 90 eligible FDRs and 137 eligible SDRs, most (74.4% and 81.8%, respectively) had lifetime BC risk estimates <20% using risk modeling. **Conclusion:** Our results suggest that *ATM* positivity would alter BC surveillance recommendations for the majority of at-risk female relatives, as most had lifetime BC risks <20% thus would not qualify for high risk surveillance based on family history alone. Our data highlight the potential utility of risk modeling to inform clinical utility of predictive testing for moderate penetrance BC genes, such as *ATM*, among at-risk relatives.

**500T**

**Genetic testing in adult cancer patients in palliative care: What they understand, want, and may need.** *J. Bodurtha<sup>1</sup>, M. Abusamann<sup>2</sup>, L. Bailey<sup>2</sup>, O. Emidio<sup>2</sup>, J. Kang<sup>3</sup>, B. Ma<sup>3</sup>, O. Owudunn<sup>2</sup>, J. Quillin<sup>2</sup>, R. Razzak<sup>4</sup>, B. Yu<sup>5</sup>, T. Smith<sup>4</sup>.* 1) Institute of Genetic Medicine, Johns Hopkins, Baltimore, MD; 2) Bloomberg School of Public Health, Baltimore, MD; 3) Johns Hopkins University, Baltimore, MD; 4) Johns Hopkins Hospital, Baltimore, MD; 5) Massey Cancer Center, VCU, Richmond, VA.

**Background:** Hereditary cancer (CA) assessment and communication about family history (FH) risks in palliative care (PC) are underexplored and could be critical for surviving at-risk relatives. Yet, FH assessment and offer of appropriate GT may be suboptimal in PC. This study explored the need for genetics services among PC CA patients, and their related knowledge and attitudes. **Methods:** A cross-sectional study was conducted including interviews that assessed knowledge and attitudes toward GT, DNA banking, and FH knowledge and reviews of participants' medical records. **Results:** Seventy-five adult English-speaking CA patients enrolled (66% response rate). Forty-one (55%) self-identified as male; 20 (27%) as black, 49 (65%) white, and 6 (8%) as other race. Thirty-two (43%) thought it likely that their CA had a genetic or inherited component. Twenty-five (33%) answered that they had heard or read "a fair amount" or a "lot" about GT for CA risk. Eleven (15%) reported having had genetic testing for inherited cancer risk, although this could only be confirmed for two (3%) patients by systematic chart review. Participants may not have understood the difference between somatic vs. germline GT. Twenty-eight (37%) met ACMG-NSGC criteria for genetics referral, with minimal chart evidence by standardized review of consideration, referral, or discussion about GT by oncology services. Forty-eight (64%) thought that the PC setting was the right place to consider the implications of a CA FH. Fifty-seven (76%) wanted CA prevention measures, like smoking cessation, to be offered to relatives as part of PC services. Seventy-three (97%) participants were interested in receiving GT information. Seventy-four (99%) participants reported wanting to share results with relatives. Six (8%) patients had either banked DNA themselves or knew a relative who had banked DNA. 54(72%) thought Angelina Jolie had done the right thing by sharing her story. The mean comfort level in addressing the survey questions was 8.7 on a 10-point scale with 10 indicating extremely comfortable. **Conclusions:** Enhanced openness to these topics among PC providers, oncology specialists, and families, review of FH and access to GT might enhance CA prevention, especially among high-risk families. Patients are willing to discuss FH and risk in the palliative care setting. There appears to be room for improvement in how FH and GT are integrated in CA care and palliative care. .

**501F**

**Educational and support needs of Lynch Syndrome probands and their relatives.** *W. Kohlmann<sup>1</sup>, J. Petersen<sup>2</sup>, C. Koptiuch<sup>1</sup>, K. Szczotka<sup>2</sup>, M. Keener<sup>1</sup>, S. Johnson<sup>1</sup>, P. Kanth<sup>1</sup>, A. Soisson<sup>1,2</sup>, K. Kaphingst<sup>1</sup>.* 1) Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; 2) Department of Obstetrics and Gynecology, University of Utah, Salt Lake City, UT; 3) Department of Human Genetics, University of Utah, Salt Lake City, UT; 4) Division of Gastroenterology, University of Utah, Salt Lake City, UT.

The benefit of identifying colorectal and endometrial cancer patients with Lynch syndrome (LS) is maximized when relatives are tested for the pathogenic variant (PV) and take screening and prevention actions. However, uptake of testing and adherence to screening remains suboptimal and educational interventions are needed. To assess the educational preferences of LS families, semi-structured telephone interviews were conducted with probands and their relatives. Participants were identified from registries, family referral and clinic records. 25 probands (mean age 59 yrs, 88% with prior cancer) and 49 relatives (mean age 46 yrs, 27% with prior cancer) enrolled. The majority of probands received the diagnosis of LS from a genetic counselor (GC) (52%) and received informational resources (76%). The diagnosis of LS was most commonly shared with siblings (84%) and children (76%) and less so with aunts/uncles (50%) and cousins (46%). No probands reported withholding the diagnosis from anyone, and the majority (75%) felt confident discussing LS. Relatives were notified of the diagnosis of LS in person (47%) and by phone (33%). Only 10% were informed via email/social media. Disclosure of the LS diagnosis in the family to relatives was less commonly accompanied by informational resources (49%). Of the 88% of relatives who had genetic testing, 55% met with a GC and 88% were positive for the familial PV. Withholding information from others was rare among relatives, with only 7% not disclosing results due to young age or lack of close relationship. When asked preferences for ongoing education, probands rated the following as very/extremely helpful: LS specialty clinic (84%), other family (77%), website (74%), primary care provider (PCP) (68%) and printed materials (64%). While relatives preferred: LS specialty clinic (84%), website (80%), talking with PCP (68%), and other family (64%). A minority indicated social media (probands 40%, relatives 30%) or in person support groups (probands 44%, relatives 33%) as preferred methods for ongoing education. These findings show that family members actively share the diagnosis of LS and are often significant sources of support and information for each other. New methods of communicating, such as social media, may be useful for some. However, traditional resources such as access to specialists and PCPs who are knowledgeable about LS and websites continue to be important, needed resources for LS families.

**502W**

***MSH6* and *PMS2* germline pathogenic variants implicated in Lynch syndrome are associated with breast cancer.** *M.E. Roberts<sup>1</sup>, S.A. Jackson<sup>1</sup>, L.R. Susswein<sup>1</sup>, N. Zeinomar<sup>2</sup>, X. Ma<sup>2</sup>, M.L. Marshall<sup>1</sup>, A.R. Stettner<sup>1</sup>, B. Milewski<sup>1</sup>, Z. Xu<sup>1</sup>, B.D. Solomon<sup>1</sup>, M.B. Terry<sup>2</sup>, K.S. Hruska<sup>1</sup>, R.T Klein<sup>1</sup>, W.K. Chung<sup>2</sup>.* 1) GeneDx, Gaithersburg, MD; 2) Department of Epidemiology, Columbia University, New York, NY; 3) Departments of Pediatrics and Medicine, Columbia University, New York, NY.

**Statement of Purpose:** An association of Lynch syndrome (LS) with breast cancer has been long suspected in the cancer genetics community but available data are conflicting. The aim of our study was to characterize the respective breast cancer risk for each LS-associated gene (*MLH1*, *MSH2*, *MSH6* and *PMS2*) in women with a single germline pathogenic or likely pathogenic variant (collectively, PV) identified via a multi-gene hereditary cancer panel.

**Methods:** In a retrospective query of over 50,000 women who had panel testing, 423 were identified as harboring a single PV in *MLH1*, *MSH2*, *MSH6*, or *PMS2*. Women with a second PV in these or another gene were excluded. An in-depth review of personal medical and family histories was completed. The standard incidence ratio (SIR) of breast cancer was calculated by comparing the cancer frequencies in our study cohort with those in the general population (SEER: Surveillance, Epidemiology, and End Results Program) and a Chi-square test was used to obtain p-values. **Results:** Of the 423 women, the distribution of PVs was 33% (n=140) in *MSH6*, 29% (n=124) in *PMS2*, 22% (n=94) in *MSH2* and 15% (n=65) in *MLH1*. A personal history of breast cancer was reported in 25.3% (107/423) of women with PVs, with 1.4% (6/423) reporting a history of more than one primary breast cancer. Age-standardized breast cancer risk was approximately 2-fold higher in our cohort of women with a LS-associated PV compared to the general population (SIR = 1.96; 95% CI, 1.62-2.37). When evaluating risk by gene, *MSH6* (SIR = 2.11; 95% CI, 1.56-2.86) and *PMS2* (SIR = 2.92; 95% CI, 2.17-3.92) were associated with a statistically significant risk for breast cancer, while no association was observed for *MLH1* (SIR = 0.87; 95% CI, 0.42-1.83) or *MSH2* (SIR = 1.22; 95% CI, 0.72-2.06). Of the 423 women, those with PVs in *MSH6* or *PMS2* were more likely to have a personal or family history of breast cancer and no history of colon, endometrial, or ovarian cancers (*MSH6*: 8.0%, 11/137; *PMS2*: 24.6%, 30/122) compared to women with PVs in *MLH1* and *MSH2* (*MLH1*: 0%, 0/65; *MSH2*: 2.2%, 2/92) (p = <0.001). **Conclusions:** Our data demonstrate that *MSH6* and *PMS2* are associated with a modest but statistically significant increased risk for breast cancer, and should be considered when ordering genetic testing for individuals who have a personal and/or family history of breast cancer. Women with PVs in *MSH6* and *PMS2* may benefit from increased breast cancer screening.

**503T**

**Could population-level genomic screening be cost effective? An economic analysis informed by a large sequencing study.** *D.L. Veenstra<sup>1</sup>, G.F. Guzauskas<sup>1</sup>, M.F. Murray<sup>2</sup>, M.S. Williams<sup>2</sup>.* 1) Pharmaceutical Outcomes Research and Policy Program, University of Washington, Seattle, WA; 2) Genomic Medicine Institute, Geisinger Health System, Danville, PA.

**Background:** The identification of clinically actionable, highly penetrant, and relatively common genomic variants in the general population, combined with low cost genomic assays, has brought consideration of population-level genomic screening into the realm of possibility. However, significant challenges and uncertainties remain. Our objective was to model the potential clinical and economic impacts of population-level genomic screening. **Methods:** We developed a decision-analytic policy model to project the quality-adjusted life years (QALYs) and lifetime costs associated with genomic screening for risk of breast and colon cancer, familial hypercholesterolemia, cardiomyopathy, and inherited cardiac arrhythmias. The model was informed by previously developed cost-effectiveness models, variant prevalence estimates from a large exome sequencing study (>92,000 sequenced participants) conducted in an integrated healthcare delivery system, and the published literature. We modeled the long-term clinical benefits and risks of interventions indicated by genomic findings, as well as costs associated with screening and downstream interventions. We assumed a range of testing costs. Value of information analyses were conducted to assess the value of conducting further research to reduce uncertainty in genomic and behavioral parameters. **Results:** An average of 81 (95% credible range [CR]: 53-125) QALYs were generated per 10,000 patients screened. At a testing cost of \$250, the increase in total cost of approximately \$6.9M (95% CR: \$4.6M-\$9.1M). The incremental cost-effectiveness ratio was \$93,100/QALY, and screening was cost effective in 71% of simulations at a \$100,000 willingness-to-pay per QALY threshold. Value of information simulations indicate improving estimates of penetrance and healthcare behavior could provide a maximal societal value of \$5B. **Conclusion:** Population-level genomic screening may be effective and cost effective, but significant uncertainty remains. Large prospective and well controlled studies that improve our understanding of population-level gene penetrance and healthcare behaviors in response to both positive and negative genomic findings are needed to inform adult genomic screening policies.

**504F**

**Clinical predictors of gene panel choice when selected by the patient.** *E.K. Courtney<sup>1</sup>, J.C. Allen<sup>2</sup>, J. Ngeow<sup>1,3,4</sup>.* 1) Cancer Genetics Service, National Cancer Centre Singapore, Singapore, Singapore; 2) Centre for Quantitative Medicine, Duke-NUS Medical School, Singapore, Singapore; 3) Oncology Academic Clinical Program, Duke-NUS Medical School, Singapore, Singapore; 4) Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, Singapore.

**PURPOSE** The Cancer Genetics Service (CGS) at the National Cancer Centre Singapore has offered multi-gene panel testing for hereditary cancer syndromes to patients since it was established in 2014. Unlike other testing models where panel selection is entirely dependent on clinical indication, the CGS has adopted a 'menu' approach where patients are given the choice whether to opt for the clinically indicated panel or a broader panel covering a wider range of hereditary cancer syndromes. The present study sought to investigate clinical factors associated with panel choice by the patient.

**METHODS** Female breast and ovarian cancer patients who were referred to the CGS for consideration of genetic testing for hereditary breast and ovarian cancer syndrome and who subsequently underwent panel testing were included. Demographic, clinical, panel (breast cancer panel, BCP or multi-cancer panel, MCP) and genetic result information were collected. Univariate, multiple and stepwise multiple logistic regression analyses were used to identify clinical factors predictive of panel choice. **RESULTS** A total of 265 breast and ovarian cancer patients were included in this study. Subjects who chose the broader MCP compared with the targeted BCP were significantly more likely to be aged  $\geq 50$  years (49 vs. 31%,  $P < 0.05$ ), Chinese (76 vs. 47%,  $P < 0.001$ ) and have a personal history of ovarian cancer (41 vs. 8%,  $P < 0.001$ ). Various permutations of family history data were not significantly associated with panel choice, including (i) family history of any cancer, (ii) family history of breast cancer only and (iii) family history of colorectal and/or endometrial cancer. Multiple stepwise logistic regression identified race and personal history of ovarian cancer as the best predictors of panel choice. **CONCLUSION** Interestingly, our results indicate that personal factors, rather than family history, are more likely to predict whether patients opt for targeted versus broader gene panels. This study provides the foundations for deeper exploration of other personal factors that drive patient choice using a 'menu' approach to panel testing.

**BRCA1/BRCA2 population screening in Ashkenazi Jews: Long term impact and familial communication.** S. Lieberman<sup>1,2</sup>, A. Tomer<sup>1</sup>, A. Ben-Chetrit<sup>3</sup>, O. Olsha<sup>4</sup>, R. Beer<sup>1</sup>, A. Raz<sup>5</sup>, A. Lahad<sup>6,2</sup>, E. Levy-Lahad<sup>1,2</sup>. 1) Medical Genetics Institute, Shaare Zedek Medical Center, Jerusalem, Israel; 2) Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel; 3) Department of Obstetrics and Gynecology, Shaare Zedek Medical Center, Jerusalem, Israel; 4) Breast Unit, Dept. of Surgery, Shaare Zedek Medical Center., Jerusalem; 5) Department of Sociology, Ben-Gurion University of the Negev, Beer Sheva, Israel; 6) Department of Family Medicine, Clalit Health Services, Jerusalem, Israel.

**Background:** In Ashkenazi Jews (AJ) population screening for common (2.5%) *BRCA1/BRCA2* mutations could identify all carriers, including many (about half) lacking suggestive family history. Towards implementation, we examined the long-term impact of *BRCA* screening. **Methods:** Unaffected AJs, age  $\geq 25$  years were either self-referred (SR) or recruiter-enrolled (RE), received pre-test written information and self-reported family history (FH). Post-testing, non-carriers with significant FH and carriers received in-person genetic counseling. Psychosocial outcomes, familial communication and health behaviors were assessed using questionnaires at one week, 6 months and 2 years post-testing **Results:** We report the 2 year follow-up of 1771 participants, including 32 carriers. *Psychosocial outcomes:* RE and SR participants had similar rates of satisfaction (94%) and endorsement of population screening (91%), and similarly low stress (IES score= 4.1). Knowledge scores were higher in SR vs. RE (7.5 vs. 6.9/10,  $P < .001$ ). Among carriers, 92% expressed satisfaction and 91% endorsed population screening. Stress was higher but declined over time (IES score 13.9 vs. 19.9 at 6 months, NS). Knowledge was greater than in non-carriers (8.7 vs. 7.15/10,  $p < .001$ ). *Familial communication:* 88% of responders and 97% of carriers informed at least one relative. Satisfaction With Health Decision (SWHD) score was the only substantial predictor: communication was 6-fold higher in the highest vs. lowest score quartile ( $p < .001$ ). Of carriers' relatives, 11-27% remained uninformed. 48% of carriers' first- and second-degree relatives were tested, with higher rates in first-degree (58% vs. 26%,  $p = .0002$ ) and in female relatives (55% vs. 37%,  $p = 0.02$ ). *Health behavior:* All 25 women carriers had breast surveillance, 3/25 (12%) underwent risk-reducing bilateral mastectomy (similar to published rates in Israeli carriers). 15/16 (94%) carriers age  $> 40$  underwent Risk-reducing salpingo-oophorectomy (RRSO). Among non-carriers, mammography screening rates did not decline compared to pretest rates, and even increased in non-carriers  $> 50$  with non-suggestive FH ( $p = .003$ ). **Conclusions:** Long-term, *BRCA* screening is highly acceptable. Familial communication rates and characteristics are similar to those reported in the clinical testing setting. Non-carriers do not demonstrate false reassurance, whereas carriers universally adopted increased surveillance with the vast majority undergoing age-appropriate RRSO.

**506T**

**Cancer susceptibility mutations in very young Israeli women with breast cancer.** B. Nehoray<sup>1</sup>, L. Van Tongeren<sup>1</sup>, D. Behar<sup>2</sup>, S. Dishon<sup>2</sup>, F. Lejbkowitz<sup>2</sup>, J. Herzog<sup>1</sup>, T. Slavin<sup>1</sup>, D. Castillo<sup>1</sup>, S. Sand<sup>1</sup>, J. Weitzel<sup>1</sup>, G. Rennert<sup>2</sup>. 1) City of Hope, Division of Clinical Cancer Genomics, Duarte, CA; 2) Clalit National Israeli Cancer Control Center, Haifa, Israel.

**Background:** Germline *BRCA1* and *BRCA2* (*BRCA*) mutations are associated with an increased risk of early onset breast cancer (BC). While there is uniform testing of the *BRCA* founder mutations in Israel, extended panel testing is limited. We hypothesized that a percentage of young Israeli women who tested negative for *BRCA* Jewish founder mutations would have mutations in other breast cancer susceptibility genes, including *TP53*. **Methods:** All participants consented to an IRB-approved cancer genetics study in Israel. The study included the use of medical and family history data, and prospective biospecimens. DNA from 64 Israeli women with BC diagnosed before the age of 35 who previously tested negative for *BRCA* founder mutations was sequenced using a 767-gene custom Agilent SureSelect (Alameda, CA) kit on a HiSeq 2500. Sequencing was performed to an average of 100x read depth. All findings over 20% percent allele frequency were evaluated. American College of Medical Genetics guidelines were used to classify variants using Ingenuity Variant Analysis (Redwood City, CA). Copy number variation was evaluated by a combination of the exome hidden Markov model (XHMM) and COpy number Detection by EXome sequencing (CODEX) algorithms. **Results:** Ten participants (15%) had likely pathogenic or pathogenic variants (mutations) in known cancer predisposition genes, including non-founder mutations in *BRCA1* (2) and *BRCA2* (2), as well as *ATM* (2), *CHEK2*, *MSH2*, *MSH6*, and *MUTYH*. All mutations were within 45.7-54.4% allele fraction. One *TP53* mutation was identified. However, the allele fraction (20.4%) was lower than would be expected for a germline variant. Confirmatory Sanger sequencing did not identify the variant, indicating likely clonal hematopoiesis. Many other mutations were identified in candidate predisposition genes such as *RAD50* and *FANCF*. Copy number evaluation did not yield additional significant results. **Conclusions:** The identification of non-founder *BRCA* mutations and pathogenic variants in other susceptibility genes, supports the use of multigene panel testing in young Israeli women with breast cancer who test negative for the *BRCA* founder mutations. While we did not detect any germline *TP53* variants (1-3% expected), this may be due to regional differences and small sample size; testing is in process in a larger sample. Further studies are needed to detail the spectrum of hereditary cancer predisposition risk in young Israeli women with breast cancer.

**507F**

**Anticipated responses of genetic specialists and non-genetic specialists to unsolicited genomic secondary findings.** *K.D. Christensen<sup>1</sup>, B.A. Bernhardt<sup>2</sup>, G.P. Jarvik<sup>3</sup>, L.A. Hindorf<sup>4</sup>, J. Ou<sup>5</sup>, S. Biswas<sup>6</sup>, B.C. Powell<sup>6</sup>, R.W. Grundmeier<sup>7</sup>, K. Machini<sup>8</sup>, D.J. Karavite<sup>9</sup>, J.W. Pennington<sup>9</sup>, I.D. Krantz<sup>9</sup>, J.S. Berg<sup>9</sup>, K.A.B. Goddard<sup>10</sup>.* 1) Department of Medicine, Division of Genetics, Brigham & Women's Hospital and Harvard Medical School, Boston, MA; 2) Division of Translational Medicine & Human Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3) Division of Medical Genetics, University of Washington, Seattle, WA; 4) Division of Genomic Medicine, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 5) Department of Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA; 6) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, PA; 7) Department of Biomedical and Health Informatics, Children's Hospital of Philadelphia, Philadelphia, PA; 8) Laboratory for Molecular Medicine, Partners HealthCare Personalized Medicine, Department of Pathology, Brigham and Women's Hospital, and Harvard Medical School, Cambridge, MA; 9) Division of Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; Department of Genetics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 10) Center for Health Research, Kaiser Permanente Northwest, Portland, OR.

**Purpose** As genomic sequencing use increases, secondary findings will become more common. We compared how health care providers with and without specialized genetics training anticipated responding to different types of secondary findings. **Methods** Fifty-four physicians and genetic counselors with genomic sequencing experience reviewed laboratory reports containing five secondary findings and reported attitudes and potential clinical follow-up. Reports presented (1) a pathogenic variant in *RYR1*, (2) a pathogenic variant in *PALB2*, (3) a pathogenic variant in *CHEK2*, (4) a variant of uncertain significance in *BRCA1* in a patient with strong family history of disease, and (5) carrier status in *HFE*, *MUTYH*, and *SPG7*. Analyses compared responses from genetic specialists (clinical geneticists and genetic counselors) and physicians without specialized genetics training, and examined how responses varied by type of secondary finding. **Results** Genetic specialists scored higher than non-genetic specialists on 4-point scales assessing understandings of reports (difference=0.50,  $p<0.001$ ), and lower on scales assessing obligations about reporting (difference =-0.80,  $p<0.001$ ) and burdens of responding (difference =-0.93,  $p<0.001$ ). Nearly all attitudes differed according to what finding was reported, although genetic specialists were more sensitive to finding types than non-genetic specialists about laboratories' obligations to report ( $p<0.001$  in interaction tests). The type of secondary finding also influenced whether participants rated reviewing patients' personal and family histories, documenting findings in the medical record, and recommending familial discussions as extremely important (all  $p<0.001$ ). **Conclusion** Attitudes towards secondary findings and potential clinical responses of genetic specialists and non-genetic specialists differ greatly. Findings highlight the need to be cautious about generalizing findings from studies of genetic specialists to settings where providers are not genetic specialists, and add urgency to calls for specialty-specific approaches to supporting genomic medicine.

**Experiences and next steps in utilizing The Jackson Laboratory Clinical Knowledgebase (JAX-CKB), a relational database, for clinical and educational purposes.** *K. Sanghavi, S.E. Patterson, C.M. Statz, T. Yin, S. Mockus.* The Jackson Laboratory for Genomic Medicine, Farmington, CT.

**Statement of purpose:** Access to clinically relevant, updated, and readily available synthesized data is critical to precision medicine in cancer genomics. The Jackson Laboratory Clinical Knowledgebase (JAX-CKB) is a relational database for interpreting complex genomic profiles for clinical and educational utilization. It includes genes and variants with descriptions, relevant therapeutic and prognostic information, clinical trials, efficacy and resistance evidences supporting treatment approaches, and an application that allows a methodical search for links between data elements in the database. **Methods/Approaches:** Build of the JAX-CKB database was initiated in early 2014 and the user interface for curation was launched in mid-2014. It was validated for clinical reporting in mid-2015 and launched for open access in mid-2016 ([ckb.jax.org](http://ckb.jax.org)). The JAX-CKB continues to be used for clinical applications such as the 358 gene Cancer Treatment Profile assay and 212 gene ActionSeq™ assay, and molecular/genomic tumor boards. This database was used for provider education in an online continued medical education activity. The gene variants, efficacy evidence, and targeted therapies information are updated daily by Ph.D. staff. The clinical trials information is updated weekly. An internal survey was administered at a user-interface workshop to specifically test for user interface design elements such as the ease of navigation, search capabilities and understanding of associated content. **Summary of results:** 10/12 respondents to the internal survey found everything they were looking for in the JAX-CKB database including molecular profile, treatment approach, and connections between different areas of the database, which they found very easy to understand (11/12). As of 6/6/17, the total number of JAX-CKB website hits include 46,473 with 12,476 unique users. Average time spent on the website is 5.39 minutes. 73% of the first-time users returned to the website. The top gene searches include *TP53*, *EGFR*, *PIK3CA*, and *BRAF*. Survey results indicated the need for additional help documents related to transparency of curation methodologies. **Conclusion:** The JAX-CKB provides access to such data that empowers the global biomedical community in discovering and utilizing genomic solutions for somatic cancer conditions. Next steps include implementing a research protocol to cyclically evaluate the JAX-CKB, which would allow continuous offering of an innovative database.

**Hereditary colorectal cancer screening: A 10 year longitudinal study following an educational intervention.** J.C. Carroll<sup>1,2</sup>, K. Semotiuk<sup>2</sup>, J. Permaul<sup>2</sup>, E.M. Yung<sup>3</sup>, S. Blaine<sup>1,5</sup>, E. Dicks<sup>5</sup>, E. Warner<sup>2</sup>, H. Rothenmund<sup>6</sup>, M.J. Esplen<sup>2</sup>, J. McLaughlin<sup>10,11</sup>. 1) Family & Community Medicine, University of Toronto, Toronto, ON, Canada; 2) Family Medicine, Mount Sinai Hospital, Sinai Health System, Toronto, ON, Canada; 3) Zane Cohen Centre for Digestive Diseases Familial Gastrointestinal Cancer Registry, Mount Sinai Hospital, Toronto, ON, Canada; 4) Faculty of Medicine, University of Toronto, Toronto, ON, Canada; 5) STAR Family Health Team, O'Loane Medical Clinic, Stratford, ON, Canada; 6) Memorial University of Newfoundland and Labrador, St. John's, NL, Canada; 7) Division of Medical Oncology, Sunnybrook Odette Cancer Centre, Toronto, ON, Canada; 8) WRHA Genetics and Metabolism Program, Health Science Centre, WPG, MB, Canada; 9) University Health Network, University of Toronto, Toronto, ON, Canada; 10) Public Health Ontario, Toronto, ON, Canada; 11) Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.

**Context:** Screening reduces mortality in individuals with a family history (FH) of colorectal cancer (CRC) yet rates are suboptimal. To address this, the team developed an educational intervention consisting of a mailed CRC Risk Triage/Management Tool for family physicians (FP) and CRC information booklet for patients. **Objective:** To describe CRC screening 10 years following the intervention. **Design:** Mailed self-complete questionnaires to FPs and patients: baseline, 5, and 10 years post-intervention. **Setting:** Family practices in Ontario and Newfoundland, Canada. **Participants:** Random sample of FPs and their adult patients with a FH of CRC. Results include FPs and patients who completed all questionnaires over 10 years. **Intervention:** CRC Risk Assessment/Management Tool indicating FH criteria and appropriate screening test and timing for patients at population, low, moderate, and high risk for CRC. Patient booklet: patient stories indicating CRC risk due to FH and appropriate screening. **Outcomes:** Appropriate patient-reported CRC screening based on FH risk. Logistic regression was used to determine predictors of appropriate screening. **Results:** Of 121 FPs at baseline, 41 (34%) completed all 4 questionnaires (54% female, mean age 45). Of 208 patients, 98 (47%) completed 5 and 10 year follow up (76% female, mean age 50, 66% low/34% moderate or high risk for hereditary CRC). At the 10 year follow up, 93% of FPs reported they routinely asked patients about FH of cancer (agree/strongly agree), 71% of patients reported they discussed FH of CRC with their FP and 60% of patients reported their FP recommended CRC screening. Appropriate patient-reported CRC screening (test + timing) declined over 10 years particularly in the moderate/high risk group (baseline: 76%, 5-year: 52%, 10-year: 54%;  $p=.036$ ). Most moderate/high risk patients (~80%) underestimated their risk consistently over 10 years. At 10 years, patients reporting that their FP recommended screening were more likely to have had the appropriate test and timing (OR 5.4 95% CI 1.7, 16.7). Moderate/high risk patients were less likely to have had the appropriate test and timing (OR 0.20, 95% CI .07, 0.61). **Conclusion:** Only 65% of patients with a FH of CRC (patients most likely to benefit from screening) screened appropriately. Recommendation from the FP is an important predictor of screening.

**510F**

**The Tell Me More Study: Returning medically actionable genomic variants in the setting of a neonatal genome sequencing study.** T. DeMarco<sup>1</sup>, K. Hurley<sup>2</sup>, S. Hull<sup>3</sup>, B.E. Berkman<sup>3</sup>, E. Klein<sup>1</sup>, A. Fuller<sup>1</sup>, K. Huddleston<sup>1</sup>, B. Solomon<sup>1</sup>, F.M. Facio<sup>3</sup>. 1) Division of Medical Genomics, Inova Translational Medicine Institute, Fairfax, VA; 2) Cleveland Clinic, Cleveland, Ohio; 3) National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

The Tell Me More Study (TMM) investigated parental decision-making about enrolling newborns in genome sequencing (GS) research. This qualitative pilot study is part of the larger Inova Childhood Longitudinal Study at Inova Translational Medicine Institute, which follows offspring through the course of gestation to age 18 and provides GS to all participants. Through TMM, GS was performed concurrently for mother-father-child trios. Parents could learn about GS findings for themselves and/or for their child, deemed medically actionable under the ACMG guidelines. We report a case of a 45-year-old Asian-American male who was found to carry a deleterious *BRCA2* truncating mutation previously reported in individuals of Filipino descent. GS analysis also showed that his 3-year-old daughter carries the *BRCA2* mutation; however, the clinical team counseled the parents to defer clinical confirmatory testing to an age when she can make the decision autonomously. Thus, only the father's result was confirmed in a CLIA-certified lab. Family history collected after uncovering the *BRCA2* mutation revealed a paternal 1st cousin with breast cancer in her mid-40s. The father's unaffected parents and brother were provided genetic counseling and segregation testing, which showed paternal transmission, and revealed that his brother is a carrier. An interview at 1-month post-disclosure indicated that while the father was initially surprised by the results and was concerned about his daughter's risk, he felt that the information was empowering, allowing him and his at-risk relatives to participate in risk-reducing strategies. He reported sharing the information with relatives and a few colleagues, and intention to share it with his primary care provider. He envisioned sharing the results with his daughter when she is older and able to understand scientific principles. Despite learning this unexpected result, he did not regret his participation in the TMM study; his scientific background and interest in GS may have facilitated his positive adjustment. The father's result demonstrates that GS of infants may open another route to actionable results in adults who are not the original focus of testing. The case illustrates that people can adjust to and make use of unexpected GS results over time. However, it foreshadows new challenges in adhering to guidelines for deferral of *BRCA1/2* testing until adulthood if GS in newborns is adopted more widely. \*TMM was supported by the 2014 JEMF.

**Genetic counseling assistants in a cancer genetics clinic: Genetic counselor time utilization and impact on patient volume.** *M.L.G. Hallquist, E.P. Tricou, J.M. Savatt, H. Rocha, N. Deckard, A. Evans, A. Fan, W.A. Faucett, J. Pervola, A.K. Rahm, M. Rashkin, T. Schmidlen, M.L.B. Schwartz, J.L. Williams, M. Williams, A.H. Buchanan.* Genomic Medicine Institute, Geisinger Health System, Danville, PA.

Given steadily increasing numbers of patients seeking genetics services and the current workforce shortage of certified genetic counselors, it has become imperative that we adapt our service delivery models. One model that may increase genetic counselor efficiency while maintaining quality care is the use of a genetic counseling assistant (GCA) – a BS/BA trained assistant who has an interest in pursuing a graduate degree in genetic counseling. At Geisinger's Cancer Genetics Risk Assessment Clinic, we have delegated tasks such as triaging referrals, obtaining pedigrees, and confirming appointments to GCAs. By implementing a GCA, the goal was to maximize the time genetic counselors spent on tasks for which they are uniquely trained, such as direct patient care. This study explores the impact of GCAs on genetic counselor time utilization and patient volume. Using an online time tracking tool, genetic counselors and GCAs in the cancer genetics clinic recorded the amount of time spent on clinic-related tasks during three distinct time periods (Nov-Dec 2015, Mar-Apr 2016, Apr-May 2017). Tasks were binned into pre-appointment, direct patient care, post-appointment, or ancillary responsibilities. The genetic counselor FTE remained stable across all three time periods at 1.5 FTE, while the GCA FTE increased from baseline of no GCA, to 0.6 FTE at the second time point, to 1.3 FTE of GCA support at the third time period. Electronic medical record data were used to evaluate total numbers of patients seen (by phone or in person new appointments and results return appointments) during each tracked period. Total patients seen increased by 38% from baseline to the third time point ( $n=82$  patients at baseline, 99 at time two, and 133 at time three). This corresponds to an increase in the number of new patients seen per genetic counselor FTE from 6.3 new patients per week per FTE at baseline to 10.2 new patients per week per FTE during the most recent time period. Moreover, genetic counselor time spent on direct patient care increased three-fold from baseline to the third time period (32 hours to 63 hours to 109 hours). These data suggest that use of a GCA may allow genetic counselors to focus their expertise on direct patient care, while simultaneously increasing patient volume.

**A reporting of secondary findings in whole exome sequencing in Japan: The Project of HOPE.** *Y. Horiuchi<sup>1,2</sup>, Y. Kiyozumi<sup>2,4</sup>, H. Matsubayashi<sup>1</sup>, S. Nishimura<sup>1</sup>, K. Urakami<sup>3</sup>, S. Oonami<sup>3</sup>, M. Arai<sup>1</sup>, M. Kusuhara<sup>3</sup>, K. Yamaguchi<sup>3</sup>.* 1) Psychiatry and Behavioral Sciences Dept, Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan; 2) Genetic Counseling Dept, Shizuoka Cancer Center Hospital, Shizuoka, Japan; 3) Research institute of Shizuoka Cancer Center, Shizuoka, Japan; 4) Graduate school of Ochanomizu University, Tokyo, Japan.

Recent advantage of whole genome sequencing (WGS) and whole exome sequencing (WES) techniques are increasingly used in both clinical and research contexts. On the other hand, new ethical issues regarding the disclosure of incidental or secondary findings, i.e., results that are unrelated to the original aims of the study may be expected to arise in the genome studies. In 2013, the American College of Medical Genetics (ACMG) announced recommendations for handling incidental findings in genome sequencing and published a revised version in 2016. However, the guidelines for the secondary findings and a system of the return of results for patients have not been well established yet in Japan. In this study, we systematically constructed the genetic counseling system from clinical genome study "Shizuoka Cancer Center (SCC) the Project HOPE (High-tech Omics-based Patient Evaluation)", as a basis for initial trials in Japan. The aim of Project HOPE is to evaluate biological characteristics of cancer and diathesis of each patient by multi-omics based analyses, which integrate genomics, transcriptomics, proteomics and metabolomics. We here report the prevalence of secondary findings and the system of the return of results to patient from the HOPE study. The disclosure of secondary findings for the patients were conducted carefully and systematically in SCC. To date, 3000 cases have been analyzed and approximately 1% of the total cases were reported to be associated with hereditary cancer syndromes and approximately 1% of the total cases were reported as based on the guidelines of the ACMG. Our systematic approach will contribute to a cancer genomic medicine and serve as a useful basis for genetic counseling system in Japan. This study was approved by the Ethics Committees of Shizuoka Cancer center and Tokyo Metropolitan Institute of Medical Science.

**513F****Factors influencing sharing of genetic information: An in-depth interview study of patient who underwent cancer genetic testing in Singapore.**

*S.T. Li<sup>1</sup>, S. Sun<sup>2</sup>, D. Lie<sup>3</sup>, M. Met-Domesticci<sup>4</sup>, J. Ngeow<sup>1,4,5</sup>.* 1) Cancer Genetics Service, Division of Medical Oncology, National Cancer Centre Singapore, Singapore; 2) Division of Sociology, School of Humanities and Social Sciences, Nanyang Technology University, Singapore; 3) Office of Clinical Sciences, Duke-NUS Medical School, Singapore; 4) Oncology Academic Clinical Program, Duke-NUS Medical School, Singapore; 5) Division of Medical Oncology, National Cancer Centre Singapore, Singapore.

**PURPOSE** The uptake rate of predictive genetic testing of hereditary breast and ovarian cancer syndrome in at-risk relatives has been low in Asia, one known reason was proband's reluctance to share genetic results. This qualitative study aims to explore the factors that influence patient decision-making regarding whether or not to share their genetic test results with their at-risk relatives. **METHODS** In-depth interviews were conducted with 24 female patients with personal or family history of breast and/or ovarian cancer and received a positive, negative, or variant of uncertain significance genetic test result. Grounded theory with an inductive approach was used to identify major themes and develop a theoretical framework. **RESULTS** There were three overarching themes among the three result groups influencing the likelihood of patients sharing their genetic results: (i) family closeness; (ii) involvement of families in the testing process; and (iii) perception of low emotional impact. Presence of actionable genetic results and participant's perception of family members' acceptance increases likelihood of sharing in the positive results group. For the uncertain and negative results group, participants were less likely to disclose their genetic results if results were ambiguous or the participants perceived that there was no genetic or medical implication for their family. **CONCLUSION:** Our findings and theoretical framework provides a model of the influencing factors that involve in women's decision of sharing genetic result and highlights the important timing for the implementation of interventions to encourage or facilitate family communication of genetic results.

**514W****Uptake of polygenic risk information among women at potentially high breast cancer risk.**

John<sup>7</sup>, M. Harris<sup>8</sup>, Y. Antill<sup>9</sup>, J. Burke<sup>10</sup>, T. Roscioli<sup>11</sup>, J. Halliday<sup>12,13</sup>.* 1) Prince of Wales Clinical School, UNSW Sydney; 2) School of Psychiatry, UNSW Sydney; 3) Familial Cancer Service, Peter MacCallum Cancer Centre, Melbourne; 4) Genome.One, Darlinghurst, Sydney; 5) Sydney Medical School Northern, University of Sydney; 6) Familial Cancer Centre, The Royal Melbourne Hospital, Melbourne; 7) Clinical Genetics Service, Austin Hospital, Melbourne; 8) Family Cancer Clinic, Monash Medical Centre, Melbourne; 9) Family Cancer Clinic, Cabrini Health, Melbourne; 10) Tasmanian Clinical Genetics Service, Royal Hobart Hospital, Hobart; 11) Department of Medical Genetics, Sydney Children's Hospital, Randwick, Sydney; 12) Public Health Genetics, Murdoch Children's Research Institute, Melbourne; 13) Department of Paediatrics, University of Melbourne, Parkville, Melbourne.

**Background:** Despite increasing evidence for the utility of polygenic risk in families at high risk of breast cancer, research findings are yet to be integrated into clinical practice. This reflects the status of polygenic risk as an emerging technology and the limited evidence base on the psychosocial and behavioural outcomes of offering such testing. **Aims:** To ascertain the important psychosocial and behavioural implications of testing for polygenic breast cancer risk in the existing cohort the "Variants in Practice" (ViP) study. **Methods:** 400 women enrolled in ViP, who have either a high or low polygenic risk score (PRS), and whose personal and/or family history breast cancer remained unexplained after genetic testing for known cancer predisposition genes are being invited to participate in this study. Participants complete a baseline questionnaire assessing their knowledge of hereditary breast cancer, current breast cancer screening behaviours, psychological well-being, and intention to receive personal PRS results. **Results:** As of April 2017, 69/74 (93%) participants reported interest in receiving their PRS result, with 20/74 (27%) having received their results. The mean knowledge score among participants was 6 (out of 10), and 20% and 8 % of participants scored over the cut-offs for cancer-specific distress and general depression respectively. **Conclusion:** While, there is strong interest in receiving personal PRS result among women at high risk of breast cancer, the psychosocial and behavioural implications should be carefully considered. Data collection is ongoing, with additional data regarding uptake of results and short-term impact of receiving results to be presented.

**515T**

**Assessing the possibility of *RUNX1*, *ETV6* and *GATA2* related germline predisposition in myeloid neoplasms in a somatic cancer setting.** K. Barber, J. Bissonnette, R. Klein, J. Weisberger, J. Zhao. BioReference/GenPath, Elmwood Park, NJ.

Recently the World Health Organization (WHO) released an update to the classification of hematopoietic neoplasms with germline predisposition based on the presence of germline pathogenic variants in *RUNX1*, *ETV6* and *GATA2* (WHO, 2016). Individuals who are heterozygous for a germline *RUNX1* variant are at a 35-44% risk of myelodysplastic syndrome (MDS [614286]) or acute myeloid leukemia (AML [601626]) (Owen et al, 2008, Godley, 2014). Germline *ETV6* variants are associated with Thrombocytopenia 5 [616216], an autosomal dominant thrombocytopenia. Clinical presentation for those with germline *GATA2* variants is variable, however lifetime risk for MDS or AML is estimated to be 70%. We performed a retrospective analysis of all *RUNX1*, *ETV6* and *GATA2* variants identified on a Next Generation Sequencing panel for a myeloid neoplasm. Our goal was to determine how the new classification released by WHO would affect our strategy in reporting these variants. *RUNX1*, *ETV6* and *GATA2* variants were detected in 637 cases in our lab out of the total 7,092 myeloid cases analyzed over the last 17 months (637/7,092 = 9%). *RUNX1* variants are most commonly detected among these three genes (499/637 = 78%). The median age of all patients in this study was 71. Of the cases where a diagnosis was known, *RUNX1/GATA2/ETV6* variants were most commonly seen in AML. Of a total of 756 unique *RUNX1*, *ETV6* or *GATA2* variants reported, 67% were known disease associated variants while 33% were novel or unclear variants. Of the 507 disease associated variants, 155 were found to have an allele frequency suggestive of a possible germline variant (31%). Of the ten youngest patients (ages 6-26) identified with one of these variants, seven (70%) were detected at an allele frequency suggestive of a germline mutation (40-60% allele frequency). Based on the relatively high proportion of cases with an allele frequency suggestive of a germline variant and the significance of a germline variant, we conclude that including a statement on the final report regarding the possibility of a germline mutation is reasonable in all cases where one of these variants is detected. Germline confirmation testing should be pursued when indicated. This will allow for appropriate management of those with germline predisposition to myeloid malignancies, and would also promote testing of family members that could be at risk. In addition, this study shows the value of having genetic counseling expertise within a somatic testing lab.

**Quality Improvement Project: Shared decision making in genetic cancer risk assessment and patient barriers to risk assessment and reduction in primary care.** D.M. Person, M.B Massart, I. Campwala. University of Pittsburgh, Pittsburgh, PA.

**Introduction** Shared decision making and personalized medicine is becoming more common in primary care. It is especially valuable when considering family history for genetic cancer risk assessment as there are several risk reduction opportunities. Despite this, Genetic Cancer Risk Assessment (GCRA) has been underused in primary care (Trepanier et al 2016). Additionally, the barriers to genetic services amongst ethnic minorities have not been well characterized. We sought to evaluate the routine utilization of initial GCRA in our office and to survey patients regarding perceptions and barriers to genetic services. **Methods** GCRA was administered to 94 adult patients at our FQHC UPMC-Matilda Theiss. Patients were also asked to complete a survey about their perceptions and barriers to GCRA. Questions measured barriers based on religion, education about genetics/genetic services, family and community stigma, and medical mistrust. Survey answers were analyzed to assess the degree to which each of these barriers affects members of various patient populations. **Results** 31.91% screened positive and would be considered for additional genetic services based on GCRA. Without adjusting for socioeconomic factors, African American and Caucasian patients' answers reflected a similar education barrier to genetic services: 37.93% and 37.14%, respectively. African Americans had a greater religious barrier (19.28%) versus Caucasian patients (15.79%). 12.32% of African American patients' answers showed a possible barrier based on family/community stigma versus only 8.77% of Caucasian patients answers. Both African American and Caucasian patients selected Medical Mistrust as a significant barrier to genetic services, 41.42% and 40.81%, respectively. A t-test found that there is a significant difference in the religious barriers reported by African Americans versus Caucasian patients (p-value=0.027). Once we adjusted for socioeconomic factors we found that Medical Mistrust became a significant barrier for African American patients with a p-value of 0.047. Religion was almost significant with a p-value of 0.056. **Conclusion** Our African American patients reported a greater religious barrier to genetic services than their Caucasian counterparts. Once we adjusted for socioeconomic factors Medical Mistrust became a significant barrier for our African American patients. These findings are crucial to the continuing improvement of GCRA cultural competence and effectiveness in primary care.

**All in the Family: How family history affects diagnostic yield of hypertrophic cardiomyopathy multigene panel testing.** S.J. Martin, J. Dolinsky, L. Hoang, C. Antolik, T. Johnson, B. Dougall. Ambry Genetics, Aliso Viejo, CA.

Family history is often a predictor of disease. For hypertrophic cardiomyopathy (HCM), a family history (fhx) is seen in approximately 72% of cases in which a mutation is identified (1). To further assess the relationship between fhx of HCM and the probability of identifying a pathogenic mutation in a HCM-associated gene, we examined the family history of all probands with HCM who underwent multigene panel (MGP) testing at our diagnostic laboratory from April 2015 to June 2016. Particular emphasis was placed on analysis of *MYBPC3* and *MYH7*. Clinical history was collected from test requisitions, available pedigrees and clinical notes. Among 237 patients referred for HCM MGP testing, 32% (n=77) were positive for a mutation, the majority of which were in *MYBPC3* (n=44; 57%) and *MYH7* (n=13; 17%). Among the 57 HCM probands with positive MGP testing results who reported fhx information to our laboratory, 84.2% (n=48) reported 'some cardiac fhx.' This included 36.8% (n=21) reporting a fhx of HCM, 28.0% (n=16) reporting a fhx of sudden cardiac arrest (SCA). In addition, 15.8% (n=9) reported no cardiac fhx. Probands with mutations in *MYBPC3* had a higher frequency of reporting a fhx of HCM (14/34; 41.2%) or SCA (10/34; 29.4%), compared to probands with *MYH7* mutations, in which fhx of HCM was reported in 22.2% (2/9) of probands and fhx of SCA was reported in 22.2% (2/9) of probands. Approximately half of the *MYBPC3* mutations were either protein truncating, haploinsufficient or splice site mutations (52.2%), while the remainder (47.7%) were missense mutations, whereas *MYH7* mutations were exclusively missense alterations, consistent with the mechanism of disease for this gene. The prevalence of fhx of HCM and SCA in our cohort is lower than previously published rates of 72% and 89% (1), respectively. This may reflect ascertainment bias in previous cohorts, or an uptake of genetic testing among singleton cases of HCM in recent years. Nevertheless, these data demonstrate a role for genetic testing among sporadic or familial cases of HCM. Cardiologists and other healthcare providers should still take a thorough fhx among patients newly diagnosed with HCM. Further exploration of genotype-phenotype relationships will be valuable for better understanding the predictive value of genetic testing for HCM and may be useful in family risk counseling. 1-Genet Med. 2013 Dec;15(12):972-7. doi: 10.1038/gim.2013.44. Epub 2013 Apr 18. 2-Circ Cardiovasc Genet. 2013 Feb; 6(1): 118-131. .

**518T**

**Potential impact of statin pharmacogenetic testing in an integrated healthcare system: The Integrating Pharmacogenetics in Clinical Care (I-PICC) Study.** S.J. Miller<sup>1</sup>, C. Hau<sup>1</sup>, N. Mahajalme<sup>1</sup>, A.J. Zimolzak<sup>1</sup>, L. MacMullen<sup>1</sup>, J.L. Vassy<sup>1,2,3</sup>. 1) VA Boston Healthcare System, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Brigham and Women's Hospital, Boston, MA.

**Background:** The pharmacogenetic (PGx) association between *SLCO1B1* rs4149056 and simvastatin myopathy is well validated, but the impact of its integration into patient care is unknown. A key determinant of that impact is the pre-PGx landscape of statin use in a healthcare system. We aimed to describe the statin use in the primary care and women's health clinics of the VA Boston Healthcare System (VABHS) before the I-PICC Study, an ongoing randomized controlled trial of preemptive *SLCO1B1* genotyping. **Methods:** Eligible patients for the I-PICC Study are statin-naïve but have elevated cardiovascular disease (CVD) risk by American College of Cardiology/American Heart Association guidelines (ACC/AHA). Specifically, they are aged 40-75 and have ≥1 of the following criteria: 1) preexisting CVD, 2) diabetes, or 3) LDL cholesterol ≥190mg/dL. We used electronic health record data to quantify the patients seen in VABHS primary care and women's health in 2013-2016 who would have been eligible for the I-PICC Study. We defined diabetes and CVD from ICD codes. We determined prior and incident statin use from VA and non-VA medication orders. For each eligible patient, we defined a baseline date as the later of 1/1/2013 or the date the patient met I-PICC Study eligibility criteria. We calculated time to first statin prescription through 12/31/2016. **Results:** Of 34,254 unique patients seen at VABHS 2013-2016, 3,691 (10.8%) would have been eligible for the I-PICC Study at some time (171 [4.6%] women, 508 [13.4%] non-white). Of these, 1,827 (49.5%) had a first statin prescription during the observation period (incidence 280/1000 person-years). Of these, 911 (49.9%) were for atorvastatin (140/1000 person-years), and 689 (37.7%) were for simvastatin (106/1000 person-years). If 20% of the patients started on simvastatin had at least one copy of the C allele at rs4149056, then Clinical Pharmacogenetics Implementation Consortium guidelines for simvastatin prescribing might have guided alternative treatment for 138 (7.5%) of new statin prescriptions. **Discussion:** Preemptive *SLCO1B1* testing to guide statin initiation and avoid serious myopathy might change clinical management for 1 in 13 patients with elevated CVD risk. The I-PICC Study will examine the intended and unintended outcomes of integrating *SLCO1B1* testing, including rates of statin initiation, choice of statin, concordance with ACC/AHA guidelines, medication adherence, and documented adverse drug effects.

**519F**

**Diabetes incidence after a polygenic risk intervention: Five-year follow-up in the Genetic Counseling/Lifestyle Change for Diabetes Prevention (GC/LC) Study.** *J.L. Vassy<sup>1,2</sup>, J.B. Meigs<sup>2,3</sup>, W. He<sup>3</sup>, J.C. Florez<sup>2,3,4</sup>, R.W. Grant<sup>5</sup>.* 1) VA Boston Healthcare System, Boston, MA; 2) Department of Medicine, Harvard Medical School, Boston, MA; 3) Department of Medicine, Massachusetts General Hospital, Boston, MA; 4) Broad Institute, Cambridge, MA; 5) Division of Research, Kaiser Permanente, Oakland, CA.

**Background** Although polygenic risk scores can predict type 2 diabetes (T2D), we have shown that learning one's polygenic risk did not impact short-term weight loss or motivation for behavior change among high-risk participants in a T2D prevention program. The long-term impact of learning genetic risk on T2D incidence is unknown. **Methods** The GC/LC Study (2010-2011) was a randomized controlled trial of polygenic T2D risk counseling among adult primary care patients at one academic medical center. Participants were overweight and met at least one other metabolic syndrome criterion without a T2D diagnosis. They were randomized in a 4:1 ratio to undergo genotyping for a weighted 36-locus T2D risk score (Tested) vs. no genotyping (Control,  $n=34$ ). Tested participants in the highest (High,  $n=42$ ) and lowest (Low,  $n=32$ ) quartiles of polygenic risk (together, Intervention) were retained in the study and received their results from a genetic counselor. All participants were then enrolled in a 12-week group weight loss program. Although 33 (31%) participants lost  $\geq 5\%$  body weight, weight loss and motivation did not differ between study arms. In this 5-year follow-up study, we identified cases of incident T2D among study participants, using electronic health records (EHR) and a validated algorithm of problem list terms and billing diagnoses from  $\geq 2$  outpatient visits. We used log-rank tests to compare T2D incidence rates (with exact 95% confidence intervals) among study arms through the date T2D criteria were met or the last EHR visit through 2016. **Results** Mean baseline age was 59 (11) years; 40% were women. Follow-up data (median 6.0 years) was available on all participants. Incident T2D occurred in 5 (15%), 13 (31%), and 9 (28%) of Control, High, and Low participants, respectively. Incidence rates per 1000 person-years were: Control 27 (12-64), Low 57 (30-107), High 70 (41-120). Between-group differences in time-to-T2D were not statistically significant (Intervention vs. Control,  $p=0.08$ ; High vs. Control  $p=0.07$ ; Low vs. Control  $p=0.18$ ; High vs. Low  $p=0.63$ ). **Discussion** Disclosing and counseling about polygenic risk did not reduce long-term T2D incidence among patients at high phenotypic risk for T2D. The possibility that T2D incidence was actually higher among intervention participants (both High and Low genetic risk) merits replication and investigation of whether receipt of genetic results resulted in poorer health behaviors vs. increased T2D screening and diagnosis.

**520W**

**Acid sphingomyelinase deficiency (ASMD): Disease impact on families and caregivers.** *R. Avetisyan<sup>1</sup>, A. Hareendran<sup>2</sup>, B.J. Sanson<sup>1</sup>, S. Tan<sup>1</sup>.* 1) Sanofi Genzyme, Cambridge, MA, USA; 2) Evidera, London, UK.

**Statement of Purpose:** Acid sphingomyelinase deficiency (ASMD) is a rare, genetic, progressive, and potentially life-threatening disorder associated with significant disease burden. While the impact of ASMD on patients is known, it is also important to understand the extent of impact of the disease on the quality of life of the patients' families and caregivers. **Methods:** Qualitative research approaches were used to obtain information from the family caregivers about the disease impact on patients, as well as to explore the impact of the disease on the caregivers themselves. This research was part of a larger patient-centered study; here we report the preliminary results of the self-reported impacts of ASMD on caregivers. **Summary of Results:** The interviews included a total of 10 primary caregivers/ family members of patients with ASMD ages 2-19 years. The recruitment was conducted in the US and UK. The average age of the caregivers was 38.7 (range 33-47) years; 70% of participants were mothers of the patients. Caregivers reported a wide range of major impacts on their lives. Significant distress and emotional impact, reported at the time of diagnosis ("crushed our heart", "felt really guilty", "cried every day", "it's really stressful"), evolved throughout care for the patients and included anxiety and worries about the child's life and future. Caregivers reported impacts on physical and mental health ("back hurts" from having to move/carry the child, "a huge level of fatigue", "interrupted sleep and it's constant", "can't exercise", postponing surgery, "went into depression", "needing a consultation with a mental health practitioner"). Social impacts and impact on relationships ("affected marriage", "cause of divorce") were also reported. The caregivers also experienced financial impacts, and a number of participants reported their employment being impacted by their child's disease ("lost job" because of frequent doctor's visits, "gave up career to be more flexible", stopped working as "felt guilty didn't have time" to take care of the child). A frequently mentioned source of support for caregivers was family members and friends. **Conclusions:** These findings demonstrate substantial quality of life impacts of ASMD on the family caregivers. This research provides further evidence about the broader disease burden of ASMD, and demonstrates the extended impact that rare diseases have, not only on patients, but also on their families. Supported by Sanofi Genzyme.

**521T****Screening African Americans for *APOL1*-associated kidney disease**

**risk: Stakeholder views.** *S.M. Fullerton<sup>1</sup>, E. Umeukeje<sup>2</sup>, E. Blacksher<sup>1</sup>, C. Spigner<sup>3</sup>, J. Wilson<sup>4</sup>, K. Cavanaugh<sup>2</sup>, B. Young<sup>5</sup>, W. Burke<sup>1</sup>.* 1) Dept Bioethics & Humanities, University of Washington, Seattle, WA; 2) Vanderbilt Center for Kidney Disease, Vanderbilt University Medical Center, Nashville, TN; 3) Dept Health Services, University of Washington, Seattle, WA; 4) Dept Physiology & Biophysics and Medicine, University of Mississippi, Jackson, MS; 5) Dept Medicine (Nephrology), VA Puget Sound Health Care System and University of Washington, Seattle, WA.

**Background:** The appropriate use of genetic information in addressing racial/ethnic health and healthcare disparities is hotly debated. For example, variants of the apolipoprotein L1 (*APOL1*) gene, associated with increased risk of end-stage renal disease (ESRD), are more common in individuals with recent West African ancestry, partially explaining disproportionate rates of ESRD among African Americans compared to whites. However, the biological mechanisms linking *APOL1* variation to ESRD risk remain poorly understood, factors affecting penetrance are uncertain, and appropriate preventive measures unclear. Routine clinical screening of *APOL1* variation in patients at increased risk of kidney disease may therefore pose risks as well as benefits. It is important to consider the views of major stakeholders before such testing is widely pursued. **Methods:** As part of a larger project focused on engagement with the African-American community about *APOL1* genetic testing in research, clinical care, and kidney transplantation [R01HG007879] we conducted and analyzed semi-structured interviews with 10 kidney disease researchers, 25 clinicians (including both primary care providers and nephrologists), and 25 community members (including patients, family members, and others not directly affected by kidney disease) in Seattle, WA, Jackson, MS, and Nashville, TN. Interviews included exploration of attitudes toward routine *APOL1* screening among African Americans. **Results:** Many community members responded positively to the prospect of routine clinical screening of *APOL1*, typically based on expectations of benefit; few expressed misgivings about misuses of test information. Researchers and clinicians, in contrast, were more skeptical about the value of routine clinical screening given current uncertainties surrounding clinical utility, favoring additional research before widespread clinical implementation. Expert key informants were also more likely to identify potential risks associated with routine screening, including psychosocial impacts, costs, insurance discrimination, and other forms of stigmatization. **Conclusions:** Community member views in this study reflect a positive societal discourse about risk identification that many researchers and clinicians do not share. There is a need for both better evidence and substantive discussion between experts and the public before wide-spread screening moves forward.

**522F****Association between lower folic acid level and unbalanced neuron excitability in Chinese pediatric patients.**

*Y. Liu, X. Zhang, Y. Yu, X. Nie, X. Wang.* Pharmacy department, Beijing Children's Hospital, Beijing, China.

**Introduction:** Folic acid (FA or VB<sub>9</sub>) is an essential factor for many biochemical reactions. However, human cannot synthesis it on their own. The main source for folic acid is from one's diet. The deficiency of foliate intake would result in multiple neurological and hematological diseases. To confirm its association with different neuro-etiology, we were conducted an analysis of nine types of vitamin monitoring data from 4367 Chinese pediatric patients that visited our hospital. **Method and patient:** We collected data on nine types of vitamins (VA, VC, VD, VE, VB<sub>1</sub>, VB<sub>2</sub>, VB<sub>6</sub>, VB<sub>9</sub>, VB<sub>12</sub>) in our monitoring data from 4367 pediatric patients that visited our hospital since August 2016 to April 2017, and extracted a diagnosis related to neuropsychiatry, including 'seizure', 'epilepsy', 'convulsion', 'mental/language deterioration', 'gait disturbances', etc. to evaluate if there is any association between phenotype and one's vitamin level. The monitoring method was an electrode detection. **Result:** Patients (n=475) with unbalanced neuron excitability (seizure, epilepsy, convulsion) symptoms are significantly ( $P < 0.001$ ) associated with a lower FA level [95%CI: -8.54 to -4.09, nmol/L] when compared to healthy controls (n=882) or the remaining patients (n=2903), but no difference was found in mental/language deterioration, gait disturbance, ASD or autism symptoms (n=107). **Conclusion:** The association between neuropsychiatry and FA deficiency was established several decades ago. However, our study reflects a slightly different result via a clinical outcome, which divides these neuropsychiatry into two groups: association with all cause unbalanced neuron excitability and no association with mental developmental disorder. The intrinsic cause of this result is still under investigation.

**523W****Providing genomic medicine to the Hispanic population at the Stanford Center for Undiagnosed Diseases.**

L. Fernandez<sup>1,2</sup>, J. Kohler<sup>1,2</sup>, A. Dries<sup>1,2</sup>, D. Zastrow<sup>1,2</sup>, J. Davidson<sup>1,2</sup>, C. McCormack<sup>1,2</sup>, M. Majcherska<sup>1,2</sup>, D. Bonner<sup>1,2</sup>, D. Waggott<sup>1,2</sup>, S. Marwaha<sup>1,2</sup>, N. Friedman<sup>1,2</sup>, UDN. Members<sup>3</sup>, P. Fisher<sup>4,5</sup>, E. Ashley<sup>1,2,6</sup>, J.A. Bernstein<sup>1,4,7</sup>, M. Wheeler<sup>1,2</sup>. 1) Stanford Center for Undiagnosed Diseases, Stanford University, Stanford, California 94305-5406; 2) Division of Cardiovascular Medicine, Stanford University, Stanford, California 94305; 3) NIH Undiagnosed Diseases Network, Common Fund, Office of the Director and the National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland 20892; 4) Department of Pediatrics, Stanford School of Medicine, Stanford, California 94305-5208; 5) Department of Neurology, Stanford School of Medicine, Stanford, California 94305; 6) Department of Genetics, Stanford School of Medicine, Stanford, California 94305-5208; 7) Lucille Packard Children's Hospital Stanford, Palo Alto, California 94304.

Minority groups, including Hispanic populations, have been historically underrepresented in genomic medicine studies. The Stanford Center for Undiagnosed Diseases (CUD), a clinical site of the Undiagnosed Diseases Network (UDN) has developed tools and workflows to overcome barriers and challenges present when working with self-identified Hispanic patients, such as culture, language, limited access to internet, difficulty to request medical records to multiple health providers, and unfamiliarity with genetics and genetic research. We are addressing these challenges, facilitating enrollment and active participation of Spanish-speaking participants in our study. One of the actions we've taken to overcome these challenges, is having a fluent team coordinator who guides these families throughout all their participation in our study. Our goal is to find answers for individuals whom exhaustive clinical work-up remains unrevealing. Eighteen of the CUD's first 70 participants are of Hispanic ethnicity. We have identified a new diagnosis in six of these cases to date. We present two of these cases. Case 1 is a 10 year-old with profound developmental delay, frontal lobe intractable epilepsy, neurogenic bladder, and choreathetoid cerebral palsy. He had previous extensive imaging, metabolic and genetic testing. Trio whole exome sequencing performed through the UDN identified a mosaic pathogenic variant in the *EEF1A2* gene: heterozygous, de novo c.796C>T (p.R226W). *EEF1A2* plays an essential role in protein synthesis, and mutations have been shown to cause epileptic encephalopathy and mental retardation. Interestingly, some of his clinic findings suggest mosaicism, including asymmetry on brain MRI. Case 2 is a 7 year-old with a history of epilepsy and speech delay. Trio whole exome sequencing performed through the UDN identified a pathogenic variant in the *FGF12* gene: heterozygous, de novo c.334G>A (p.G112S). *FGF12* is involved in the positive regulation of voltage-gated sodium channel activity; mutations cause epileptic encephalopathy. Interestingly, our patient has a variant, not described in the literature so far, with the exception of one unpublished case with apparently a more severe phenotype. These two interesting cases demonstrate the importance of having a workflow to approach this population and offer them these resources. By ensuring broad access to the UDN, we can increase knowledge of the underlying mechanisms and pathways of unknown and very rare diseases.

**524T****Physicians attitudes, knowledge and barriers towards the inborn errors of the metabolism in a university hospital.**

F. Suarez<sup>1,4</sup>, M. Pedraza<sup>2,5</sup>, S. Moreno<sup>3</sup>. 1) Instituto de Genética Humana, Facultad de Medicina, Pontificia Universidad Javeriana, Bogota Colombia; 2) Servicio de Pediatría, Hospital Universitario San Ignacio, Pontificia Universidad Javeriana, Bogota Colombia; 3) Departamento de Epidemiología y Bioestadística, Facultad de Medicina, Pontificia Universidad Javeriana, Bogota Colombia; 4) Servicio de Genética, Hospital Universitario San Ignacio, Pontificia Universidad Javeriana, Bogota Colombia; 5) Clínica de Errores Innatos del Metabolismo, Hospital Universitario San Ignacio, Pontificia Universidad Javeriana, Bogota Colombia.

IEMs (Inborn errors of metabolism) are considered low-frequency diseases. Around every 1/100,000 births. However, considered together, their incidence can be close to 1/800 - 1/2500. Current knowledge on their biochemical basis allows pharmacological and nutritional treatments that change the natural history of some of these diseases. With the objective of describing knowledge of IEMs in medical specialists and residents in a University Hospital, we implemented a survey for assessing beliefs, attitudes, and barriers towards IEMs. A total of 94 physicians from Pediatrics, Internal Medicine, and Emergency room completed the survey. 75% of them had previous contact with IEMs patients, although, 64% consider that IEMs are not a common group of diseases. 90% consider that IEMs are chronic conditions, 61% consider them as degenerative diseases. 87% believes that diagnostic of IEMs can be suspect only with clinical signs. However, achieving a final diagnostic is a challenging task for 60% of physicians. 70% consider that the confirmatory laboratory results for IEMs take too long to arrive at their services. 72% believe that the HMOs impose barriers for authorizing specific test. 74% of the physicians are aware that the treatments are costly, 72% agree that current managements are not available for the majority of patients. The survey presented 4 clinical scenarios; the physicians chose if they were able to recognize the diseases and clinical signs of decompensation, 50% of the doctors in each clinical case, failed to recognize normal values of commonly used metabolites like ammonia. More than 90% of the physicians were not able to identify the clinical signs of disease decompensation and recognize no to know when to send a patient to urgent treatment. These results show that there are many misconceptions around IEMs. Improving education and training in these topics is imperative. The improvement of prognosis depends on the prompt and accurate diagnosis. Therefore physicians training must highlight the importance of recognition of important clinical signs and adequate interpretation of laboratory test. It is relevant that the physicians know that many of these diseases are not chronic but acute and mortal without treatment, which is of particular importance in countries that lack newborn screening programs. We proposed the structure of a basic program for training physician in IEMs, and some other solutions for overcoming obstacles originated from the HMOs.

**525F**

**A 25-year experience of Fragile X syndrome molecular diagnosis from a laboratory in Thailand.** P. Limprasert<sup>1</sup>, D. Tangviriyapaiboon<sup>2</sup>, O. Plong-On<sup>1</sup>, T. Sripo<sup>1</sup>, C. Charalsawadi<sup>1</sup>. 1) Department of Pathology, Faculty of Medicine, Prince of Songkla University, Hat Yai, Songkhla, Thailand; 2) Rajanagarindra Institute of Child Development, Chiangmai, Thailand.

Fragile X syndrome (FXS) is the most common form of X-linked intellectual disability (ID). To report the frequency of FXS in patients younger than 16 years referred for FXS DNA testing at a laboratory in Thailand, we retrospectively reviewed the results from previous research studies and unpublished data (293 males; 1991-1999; <https://www.ncbi.nlm.nih.gov/pubmed/11400746>) and 817 unrelated cases (771 males and 46 females) referred for FXS DNA testing at Songklanagarind Hospital during 2000-2015, to our knowledge the largest series of cases of molecular genetic FXS testing from Thailand. Overall, of the 1,064 males and 46 females tested in our laboratory, 80 males and 2 females with full mutation were identified (80/1,064 = 7.5% for males and 2/46 = 4.3% for females). The normal CGG repeats ranged from 5-47 with the two most common alleles of 29 (48.3%) and 30 (21.3%) CGG repeats. The frequencies of FXS from different cohorts and periods were all high (~7%), suggesting that patients with ID of unknown cause warrant molecular genetic testing for FXS (Table). In addition, female FXS carrier screening in the Thai population should be considered since our 25-year experience study found a high frequency of FXS. However, further studies of FXS carrier screening need to be done before implementing a population-based FXS screening policy.

Frequencies of FXS in 4 cohort studies in Thailand			
Cohort studies / Region of Thailand	Periods of samples collection	Sources	Positive FXS/ total screened cases (FXS Frequencies)
Males with ID Pediatric clinic/Southern	1991-1999	Limprasert et al 1999 and unpublished data	9/132 (6.8%) males
Males with ID Pediatric clinic/Central	1997-1999	Limprasert et al 1999 and unpublished data	12/161 (7.5%) males
Males with ID Regional child psychiatric clinic/Northern	2008-2009	This study	8/109 (7.3%) males
Children referred for FXS testing Human Genetics laboratory, University hospital/Mixed southern and central	2000-2015	This study	51/662 (7.7%) males 2/46 (4.3%) females

**Detection of genomic causes of developmental brain disorders among research participants in large-scale sequencing initiatives: Results disclosure, cascade testing, and psychosocial implications.** B. Finucane<sup>1</sup>, K. Wain<sup>1</sup>, E. Palen<sup>1</sup>, L. Kasparson<sup>1</sup>, J. Overton<sup>2</sup>, L. Habegger<sup>1</sup>, O. Gottesman<sup>2</sup>, E. Maxwell<sup>2</sup>, J. Reid<sup>2</sup>, A. Hare Harris<sup>1</sup>, C.L. Martin<sup>1</sup>, D.H. Ledbetter<sup>1</sup> on behalf of the DiscovEHR collaboration. 1) Autism & Developmental Medicine Inst, Geisinger Health System, Lewisburg, PA; 2) Regeneron Genetics Center, Tarrytown, NY.

Developmental brain disorders (DBD), including autism, intellectual disability, and schizophrenia, are clinically distinct conditions that share overlapping genomic causes, including discrete pathogenic copy number and sequence level variants. Many individuals live with symptom-based developmental and psychiatric diagnoses without ever knowing the underlying etiologies that explain their disabilities. As part of the Geisinger Health System–Regeneron Genetics Center DiscovEHR genomic sequencing initiative, we defined a set of 33 pathogenic segmental duplication-mediated copy number variants (CNVs), including deletions of 1q21.1, 22q11.2, and 15q13.3. Within a DiscovEHR cohort of 47,589 participants undergoing whole exome sequencing, we identified 386 (0.80%) with a pathogenic DBD-related CNV. The majority were adults of Caucasian background, reflective of the demographics of the overall DiscovEHR group. Most individuals had a DBD documented in their EHR but had never been genetically diagnosed. We developed a return of results (ROR) process for DBD-related genomic results, based on a broader ROR protocol already in place at Geisinger. We carefully considered the potential for negative psychological reactions to learning about a genetic DBD cause; strategies for clinical cascade testing for participants' family members; and the impact of cognitive and psychiatric symptoms on the ROR process. These challenges were balanced against the potential positive impact on medical management, as well as the perceived value to participants of having an etiological explanation for their lived experience with DBD. We completed CLIA confirmation for pathogenic DBD-related CNVs in 40 participants, and we initiated a disclosure process that included genetic counseling and family cascade testing. Participant responses were overwhelmingly positive, including poignant reactions to learning that there was a "medical reason" for cognitive and psychiatric disabilities. For some participants, identifying a genetic diagnosis resulted in important changes to medical care, including pharmacological approaches to epilepsy and psychiatric management. We conclude that identification and disclosure of causative variants is a clinically and psychologically important outcome for adults with DBD. Research and strategies for disclosure of incidentally-detected pathogenic DBD variants are needed as genomic sequencing becomes an increasingly common part of clinical care and population research.

**Maternal origin of familial 22q11.2 deletions negatively impacts FSIQ scores.** D.E. McGinn<sup>1,2</sup>, T.B. Crowley<sup>1</sup>, M. Unolt<sup>1,3</sup>, B.S. Emanuel<sup>1,4</sup>, E.H. Zackai<sup>1,4</sup>, E. Moss<sup>1</sup>, B. Morrow<sup>5</sup>, J. Vermeesch<sup>6</sup>, A. Swillen<sup>6</sup>, D.M. McDonald-McGinn<sup>1,4</sup>. 1) Children's Hospital of Philadelphia, Philadelphia, PA; 2) Davidson College, Davidson, NC; 3) La Sapienza University, Rome, Italy; 4) Perelman School of Medicine at The University of Pennsylvania, Philadelphia, PA; 5) Albert Einstein Medical College, Bronx, NY; 6) KU Leuven, Leuven, Belgium.

**Background:** Familial 22q11.2 deletions reportedly have a negative impact on full scale IQ (FSIQ) in affected offspring thought to be the result of cognitive deficits in the affected parent/assortative mating but no study has investigated differences based on parent of origin (POO) which would be useful for recurrence risk counseling. **Methods:** We retrospectively reviewed our database of 211 familial subjects with 22q11.2 deletion syndrome (22q) from 89 families followed at the Children's Hospital of Philadelphia (CHOP) for those affected offspring with a FSIQ score comparing the mean FSIQ (MFSIQ) of those with familial *de novo* deletions and maternally inherited (MI) v paternally inherited (PI) familial deletions. We then compared our findings to those from Leuven, Belgium and to *de novo* cases where POO studies (POOS) were performed in NY. **Results:** CHOP cohort: N=26 children with 22q from 23 families where 65% were inherited from an affected mother. As expected the MFSIQ (M=71.3) was statistically lower ( $p=.02$ ) than for *de novo* cases (N=342, M=76.6) but notably the MFSIQ for MI familial deletions (M=68.3) was statistically lower ( $p=.03$ ) than for PI deletions (M=76.3). Likewise in Leuven: N=26 children from 22 families where 73% were MI and the MFSIQ (M=61.4) for familial cases was lower than *de novo* (M=74.5) cases and the MFSIQ for MI deletions (M=59.8) was lower than PI deletions (M=65.9). Combining the cohorts: 67% of familial deletions were MI and the MFSIQ (M=66.4) was much lower than *de novo* cases (M=76.2). Moreover the MFSIQ for children with MI deletions (M=63.7) remained statistically lower ( $p=.03$ ) than PI deletions (M=72.0). Lastly comparing the familial cohorts to the *de novo* POOS cohort: N=57 children where the MFSIQ for maternal deletions (N=37, M=73.41) was no different ( $p=0.68$ ) than for paternal deletions (N=20, M=73.41). **Conclusion:** Here we confirm the association of lower FSIQ in familial versus *de novo* cases of 22q and report the novel finding that maternal origin of the familial deletion negatively impacts FSIQ in our American and Belgian cohorts. Confounders such as maternal comorbidities (repaired CHD, epilepsy, psychiatric illness, etc.), mitochondrial effects, socioeconomic, and level of engagement of the unaffected parent are important considerations. Regardless, a maternally inherited familial 22q11.2 deletion should now be considered a significant risk factor for poorer cognitive outcome requiring inclusion in genetic counseling.

**528F**

**The significance of KIAA2022 gene in development of early epileptic encephalopathy and intellectual disability in a girl.** S. Zhilina<sup>1,2</sup>, T. Kozhanova<sup>1,2</sup>, T. Mescheryakova<sup>1</sup>, N. Prokop`eva<sup>1</sup>, K. Osipova<sup>1</sup>, S. Aivazyan<sup>1</sup>, I. Kanivets<sup>3</sup>, F. Konovalov<sup>3</sup>, E. Tolmacheva<sup>3</sup>, F. Koschkin<sup>3</sup>, A. Prityko<sup>1,2</sup>. 1) St.Luka Scientific and Practical Center of Specialized Medical Care for Children, Moscow, Russian Federation; 2) Pirogov Russian National Research Medical University, Moscow, Russian Federation; 3) Genetic Center «Genomed», Russian Federation.

*KIAA2022* is gene of X-linked intellectual disability (MIM 300260) and pathogenic variants in gene are responsible for severe intellectual disability in boys, as well as epilepsy, postnatal growth retardation, autistic behavior, strabismus and dysmorphic facial features. The patient (girl 5 years) with diagnosis of cryptogenic epilepsy with myoclonic seizures, psycho-speech and intellectual development delay was observed in the psychoneurology department. A child was from 1 pregnancy, after a long period of infertility (the two previous marriages were infertile, 3 marriage - infertility for 4 years) and after extracorporeal fertilization; first delivery; weight - 3200 g., length - 50 cm, Apgar 8/9. The onset of the disease was in 1,5 years after the vaccination - myoclonic seizures, regress in psychomotor and speech development. EEG revealed epileptiform activity. Therapy - levothiracetam (250 mg per day). The drug was replaced with topiramate (75 mg per day). The seizures persisted in therapy. Karyotype - 46, XX. Weight 20 kg, height 108 cm. The child is hyperactive, impulsive, aggressive, poorly falling asleep, hardly speaking, acting on his own motivation, the teams are performed after multiple repetitions. There are microbrachycephaly, high line of hair growth, thin hair, thin elongated, lowered eyebrows, straight section of the eyes, short eye cracks, short eyelashes, wide base of an elongated nose with thickened nostrils; short filter, pronounced lip groove, slightly open mouth with thickened lower lip, small carious teeth, pointed chin, high-placed large, back-rotated auricles with hypoplasia of the antics. The marriage is unrelated. Parents are phenotypically healthy. The father has a healthy girl from first marriage. The previously unknown heterozygous mutation in the 3 exon of *KIAA2022* gene (chrX: 73963039A> AT, p.Asp451fs, NM\_001008537 .2) was detected by exome sequencing. The mutation was not registered in "1000 genomes", ESP6500 and ExAC. The mutation was validated in the proband by Sanger sequencing. No same mutation was in parents. The X-chromosome inactivation skewing was not determined in the study of the *AR* gene (CAG repeat, 1 exon). This clinical observation supports study of de Lange et al 2016 that mutations in *KIAA2022* gene can cause epileptic encephalopathy and intellectual disability both in boys and in girls. This is important for determining the tactics of genetic testing, medical maintenance and genetic counseling.

**529W**

**Earlier answers are better answers: Family-centered utility of genome-scale sequencing for children with intellectual disability.** *K.B. Brothers<sup>1</sup>, C.A. Rich<sup>1</sup>, K.M. East<sup>2</sup>, W.V. Kelley<sup>2</sup>, J. Huff<sup>2</sup>, K.M. Bowling<sup>2</sup>, M.D. Amaral<sup>2</sup>, C.R. Finnila<sup>2</sup>, S.M. Hiatt<sup>2</sup>, M.L. Thompson<sup>2</sup>, D. Gray<sup>2</sup>, E.J. Lose<sup>3</sup>, S. Simmons<sup>3</sup>, J. Whittle<sup>3</sup>, R.M. Myers<sup>3</sup>, N. Lamb<sup>3</sup>, G.S. Barsh<sup>3</sup>, E.M. Bebin<sup>3</sup>, G.M. Cooper<sup>2</sup>. 1) Department of Pediatrics, University of Louisville, Louisville, KY; 2) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 3) University of Alabama at Birmingham, Birmingham, AL; 4) Norton Healthcare, Louisville, KY.*

The HudsonAlpha CSER Study is a translational study of the utility of whole genome sequencing for identifying a genetic cause in children or adults with intellectual disability. To date we have enrolled 463 families. We conducted 59 parent interviews, including a total of 81 individuals, most of whom were biological mothers (69%) and biological fathers (28%). Semi-structured interviews were conducted 1 to 12 months following the return of results visit. Using a purposive sampling strategy, participants were selected to maximize diversity across four factors: race, ethnicity, whether a primary result for their child was returned, and whether a secondary result was returned to a parent. Thematic analysis was conducted using Atlas.ti software that started with a deductive theme framework which was expanded inductively based on themes encountered in interviews. Families with younger children tended to report that receiving a diagnosis for their child was very important. These families cited a range of factors that motivated their search for answers, including alleviating guilt, planning for future medical and personal care, and communicating with family, friends, teachers, therapists, and medical providers. The perceived importance of obtaining a diagnosis was comparatively decreased in families with older children, especially those with adult-aged children. Families with adult-age children tended to express acceptance about living without a diagnosis, and viewed diagnostic results primarily as informational and interesting, rather than pragmatically useful. Although many families across the age spectrum admitted to hope for a cure, parents of older children tended to report that they accepted their child as he/she is, and denied hope for a cure. Parent expectations tended to be in line with experienced utility. Families with older children identified relatively few concrete benefits from sequencing results, although families of all ages reported emotional benefits and the perception that information is valuable. These findings carry important implications for sequencing in children with rare disease, and indicate that parents may receive greater utility if sequencing is performed earlier in a child's life.

**530T**

**Early diagnosis of Usher syndrome in non-syndromic young patients with hearing loss, the importance of pretest counseling.** *M.F. van Dooren<sup>1</sup>, H.H.W. de Gier<sup>2</sup>, M.W. Wessels<sup>2</sup>, H.T. Bruggenwirth<sup>1</sup>, A.M.W. van de Ouweland<sup>1</sup>, S.G. Kant<sup>3</sup>, E.H. Hoefsloot<sup>1</sup>.* 1) Department of Clinical Genetics, Erasmus MC, Room 2018, 3000 CA, Rotterdam, Zuid Holland, the Netherlands; 2) Department of Otorhinolaryngology, Erasmus MC Sophia, Room Sp-1455, Wytemaweg 80, 3015 CN Rotterdam, the Netherlands; 3) Department of Clinical genetics, Leiden University Medical Centre, Postzone K5-R, PO box 9600, 2300 RC Leiden, The Netherlands.

Since the introduction of Next Generation Sequencing panels for analysis of hearing loss, more genetic causes of hearing loss in children have been found at a young age. In our cohort of 120 patients 21 cases (20 %) were under age of five. In this group we found four cases with non-syndromic hearing loss in which the diagnosis Usher syndrome was made using exome sequencing with a filter for 102 genes associated with hearing loss. The first patient, an 11 months old girl with bilateral sensorineural hearing loss (60-80dB) was seen on our joint ENT/genetics consultation. The inclusion of syndromic forms of hearing loss with co-morbidity in this NGS test, including possible future visual impairment was discussed prior to genetic testing. A frameshift mutation c.920\_923dup, p.His308fs and a pathogenic missense mutation c.1256G>T, p.Cys419Phe in the *USH2A* gene were found in compound heterozygosity, establishing the diagnosis Usher syndrome type 2. The second 5-years old male patient was diagnosed with congenital bilateral sensorineural hearing loss of 60dB. An unclassified variant c.12868C>T, p.Arg4290Cys and a pathogenic mutation c.17668\_17669delAT, p.Met5890fs were found in the *ADGRV1*-gen in compound heterozygosity, indicating the most likely diagnosis of Usher syndrome type 2. The third 2 years old male patient was diagnosed with congenital bilateral hearing loss of 50-55-dB. NGS analysis revealed compound heterozygosity for the c.1227G>A, p.Trp409\* and c.10525A>T, p.Lys3509\* in the *USH2A*-gen, establishing the diagnosis of Usher syndrome type 2. The fourth patient was a one year old girl who failed neonatal screening and no mutations in *GJB2/6*-gene. Using NGS two pathogenic mutations in the *USH2A* gene, c.2299delG, p.Glu767fs and c.13010C>T, p.Thr4337Met were identified. In Usher syndrome loss of vision/retinitis pigmentosa, is expected not to occur before the beginning of puberty. All patients with Usher syndrome diagnosed in our cohort were presymptomatic for visual involvement. After explaining these results to the parents, the insecurity regarding progression and severity of visual loss in future was the most important issue for the parents. As knowledge on these future problems on a very young age could be a burden for parents, pre-test counseling is essential prior to NGS analysis. However, an early diagnosis of Usher syndrome is of benefit for both clinical management of the patient and for future reproductive choices of their parents.

**Cri du Chat syndrome: Characteristics of 69 Brazilian patients.** C.A. Kim<sup>1</sup>, C.B. Mello<sup>2</sup>, L.S.E. Pimenta<sup>1</sup>, L.M. Benedetto<sup>2</sup>, E.C.N. Vaca<sup>1</sup>, R.B.F. Houry<sup>1</sup>, D.M. Befi-Lopes<sup>3</sup>, R.S. Honjo<sup>1</sup>. 1) Genetics Unit, Instituto da Criança, São Paulo, SP, Brazil; 2) Departamento de Psicobiologia - EPM/UNIFESP, São Paulo, SP, Brazil; 3) Departamento de Fonoaudiologia - USP, São Paulo, SP, Brazil.

Cri du Chat syndrome (CdCS) is a genetic syndrome caused by deletions in the short arm of chromosome 5. Although the main clinical features are well known, neurocognitive and behavioral characteristics of the phenotype are rarely described in detail in the literature. In this study we analyzed the main phenotypic features of CdCS according to parental perspective. **Methods:** A questionnaire was sent to 700 Brazilian families registered in the Brazilian Association of CdCS. The questions involved specific domains such as pregnancy and birth conditions, recurrence of the disease in the family, current major health problems, and aspects of cognitive development. **Results:** 69 questionnaires were fulfilled, regarding 42 females and 27 males, with current ages ranging from 1-41 years old (mean: 14y). Most of the parents noticed the typical cat-like cry at birth (93%). The age at diagnosis ranged from birth to 14 years old (mean: 12y). In 65% of the cases, parents reported their karyotypes were done (parental) and 49% said they did not know the recurrence risk of CdCS. The main health problems reported were: swallowing (75%) and feeding problems (75%), congenital heart disease (32%), spine abnormalities (28%), and neurological symptoms (22%). The behavioral problems were: aggressive behavior, stereotypies, anxiety, phobias and genital manipulation/masturbation. Neurodevelopmental delay was reported in most cases (96%), even though some questionnaires did not inform the milestones. Independent walk was achieved in 60%. Approximately 40% never presented expressive language and most of the patients are dependent in their daily activities. **Conclusion:** It is a pioneer initiative in the CdCS support group and the answers in the questionnaire can improve the health care assistance to these patients because it focuses the attention to the demands in a parental perspective. Besides, nearly half of the families state that they did not remember information regarding recurrence risk, which reinforces the importance of genetic counseling follow-up and the need for the expansion of Genetic services in Brazil. (Support: CNPQ).

**Over FISHing: Findings in 1400 patients with 22q11.2 deletion syndrome.** D. McDonald-McGinn<sup>1,2</sup>, T.B. Crowley<sup>1</sup>, D.E. McGinn<sup>1,3</sup>, E. Moss<sup>1</sup>, L. Katz<sup>4</sup>, O. Jackson<sup>5</sup>, M. Mascarenhas<sup>6</sup>, J.W. Gaynor<sup>7</sup>, E. Goldmuntz<sup>8</sup>, V. Deeney<sup>9</sup>, S. Sanna-Cherchi<sup>10</sup>, J. Moldenhauer<sup>11</sup>, R. Gur<sup>12</sup>, B. Morrow<sup>13</sup>, B.S. Emanuel<sup>1,2</sup>, K. Sullivan<sup>14</sup>, E.H. Zackai<sup>1,2</sup>. 1) Dept Clinical Genetics, Children's Hosp Philadelphia, Philadelphia, PA; 2) Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 3) Davidson College, Davidson, NC; 4) .Dept Endocrinology, Children's Hosp Philadelphia, Philadelphia, PA; 5) Dept Plastic and Reconstructive Surgery, Children's Hosp Philadelphia, Philadelphia, PA; 6) Dept Gastroenterology, Children's Hosp Philadelphia, Philadelphia, PA; 7) Dept Cardiothoracic Surgery, Children's Hosp Philadelphia, Philadelphia, PA; 8) Dept Cardiology, Children's Hosp Philadelphia, Philadelphia, PA; 9) Dept Orthopaedic Surgery, Children's Hosp Philadelphia, Philadelphia, PA; 10) Dept Nephrology, Columbia University, New York, NY; 11) .Dept Surgery, Children's Hosp Philadelphia, Philadelphia, PA; 12) Dept Neuropsychiatry Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 13) Albert Einstein College of Medicine, NY, NY; 14) Dept Allergy and Immunology, Children's Hosp Philadelphia, Philadelphia, PA.

**Background:** It has been a quarter since FISH studies were developed to identify the 22q11.2 deletion syndrome (22q). Formerly considered rare 22q is the most common microdeletion (~1:2000 children; 1:1000 unselected fetuses) leading to significant morbidity from multi-organ system involvement including cognitive deficits and behavioral phenotypes. Lack of recognition of the condition/lack of familiarity with current testing methods (e.g. identifying nested deletions missed by FISH) combined with phenotypic variability delays diagnosis which could improve outcomes. Early diagnosis offers medical and emotional preparedness. Careful phenotyping provides a window into understanding the genomic basis of associated conditions as evidenced by the recent description of *CRKL* (a gene within the nested LCR22C-LCR22D region) as a genetic driver of kidney development. Here we report findings on 1400 patients with 22q followed at a single center, demonstrating the value of maintaining a well characterized cohort. **Methods:** Data was abstracted for ascertainment, demographics, deletion size, associated features, familial cases and mortality. **Results:** 65% diagnosed by Genetics; 44 ascertained prenatally and delivered and followed at CHOP; 51% female; 75% White, 9% Black; 58% <18; Mean age at diagnosis - 3.8 years. Deletion size (883/1305) A-D 86%, A-B 5%, A-C 2%, B-D 4%, C-D 1%, Other 2%. Major associated features: CHD (69%) 1/2 with severe defects, palatal anomalies (68%), GI problems (66%), hypocalcemia (55%), renal anomalies (16%). Other significant features: skeletal (vertebral anomalies, scoliosis, clubfoot); CNS (idiopathic seizures, behavioral diagnoses, NTDs, polymicrogyria); autoimmune disease; GU (hypospadias, absent uterus); ENT (microtia, laryngeal web, choanal atresia, TEF); Eye (sclerocornea, ptosis); CDH; polyhydramnios; malignancies. Mean FSIQ (361/1305): 76.05 (SD 13.5). 7% familial, 88 probands and 121 relatives; 60% familial in B-D deletions; 1 somatic mosaic; 1 germline mosaic; 7 with 22q11.2DS and another disorder; 7 with autosomal recessive associated conditions (CEDNIK, Bernard Soulier, van den Edne- Gupta) unmasked by a mutation on the other allele. 4% died most often related to CHD by 5 months of age. No association was found between CHD, hypocalcemia and FSIQ. **Conclusion:** Increasing the denominator in our aging cohort better defined or confirmed previously reported figures and contributed to the observation of additional/rare associations.

**Educational approach for TSC families at LeBonheur Children's Hospital Tuberous Sclerosis Center of Excellence.** *N. Urraca*<sup>1,2</sup>, *R. Mostafavi*<sup>3</sup>, *T. Jones*<sup>1,4</sup>, *E. Pivnick*<sup>5</sup>, *J. Wheless*<sup>6</sup>, *J.J Bissler*<sup>6</sup>. 1) CFRI, Le Bonheur Children's Hospital, Memphis, TN; 2) Le Bonheur Children's Hospital Tuberous Sclerosis Center of Excellence; 3) Pediatric Genetics Division, UTHSC; 4) Pediatrics and Preventive Medicine Departments, UTHSC; 5) Pediatric Neurology Division, UTHSC; 6) Pediatric Nephrology Division, UTHSC.

**Background:** Tuberous sclerosis complex (TSC) is an autosomal dominant disorder characterized by hamartomas in several organs. Le Bonheur Children's Hospital Tuberous Sclerosis Center of Excellence (LBCH-TSCE) serves patients from all over the world. Most patients are diagnosed at outside hospitals and referred to LBCH-TSCE for specific questions. The goals of this project were to assess the patient and families level of knowledge about genetics of TSC and to test the effectiveness of our educational approach.

**Methods:** Subjects with TSC or their relatives seen at LBCH-TSCE were invited to participate. Each participant answered a 10-item questionnaire (pre-test) assessing knowledge level, completed an educational session, and received a TSC informational brochure. Six months after the same questionnaire (post-test) was administered by phone. Wilcoxon Signed Rank Test was used to test paired differences. **Results:** 23 TSC affected subjects and 44 relatives opted to participate. Almost half of participants (47.8%) reported they received genetic counseling previously. The median score for the pre-test was 6 with no significant ( $p=0.135$ ) difference between affected individuals and relatives. Median difference between the pre- and post-test was significant ( $p=0.001$ ; median 1; range -2 to 9). The difference was also significant by group: affected ( $p=0.034$ ) and relatives ( $p=0.009$ ). **Conclusions:** Providing an educational session and a TSC brochure improved participants' knowledge of the genetics of TSC. We suggest systemic implementation of educational sessions in TSC clinics. .

**534F**

**Genetic evaluation and counselling of couples who lost children affected by rare disorders.** *C. Skrypnik*<sup>1,2</sup>. 1) Molecular Genetics, Al Jawhara Center for Molecular Medicine, Arabian Gulf University, College of Medicine, Manama, Bahrain; 2) University Medical Clinics, King Abdulla Medical City.

**Background and aims:** Some lethal rare genetic disorders may lead to the death before the clinical diagnosis was clarified and confirmed by genetic testing. The aim of this study is to present the steps and the difficulties in managing, from the genetic approach, couples who lost children affected by rare genetic disorders. **Methods:** Six couples who lost children affected by a rare genetic disorder, seen by the author at the genetic evaluation and counselling sessions, were retrospectively analyzed, revising the reason for referral, family history of genetic disorders, medical reports available and existence of biological samples from the affected children, the genetic testing plan and its results.

**Results:** All couples looked to understand the recurrence risk and to find the method to avoid having another affected child. Medical reports were partially available, a clinical diagnosis assessment was made for their children but genetic testing was not performed or the result did not confirmed it. Biological samples from affected children were available only in two cases and genetic testing clarified the diagnosis for one case. Parental whole exome sequencing (WES) testing was performed for the other 4 couples and the pathogenic mutations were identified allowing a genotype-phenotype correlation. A couple was identified as carrier of two rare genetic disorders. **Conclusions:** A correct genetic evaluation of the parents and adequate genetic counselling are mandatory for choosing the right genetic testing with the highest chance to certify or clarify, postmortem, the clinical diagnosis. In the absence of biological samples from the affected children, parental WES testing is the best approach to identify the responsible genetic defect and allow adequate management. Patience, empathy and support are highly required to help them to understand complex genetic situation, make their informed decision, give their consent for testing and future investigation and handle the results, in the delicate context of the parental grief for their lost children.

**535W**

**The burden and economic impact of pediatric rare and undiagnosed genetic disease.** *N. Gonzaludo<sup>1</sup>, D. Bentley<sup>2</sup>, J.W. Belmont<sup>1</sup>, R.J. Taft<sup>1</sup>.* 1) Population and Medical Genomics, Illumina Inc., San Diego, CA, USA; 2) Population and Medical Genomics, Illumina Cambridge Ltd., Chesterford Research Park, Saffron Walden, Essex, UK.

Rare and undiagnosed genetic diseases (RUGD) affect approximately 1 in 10 people in the United States. Patients with RUGD are high utilizers of the healthcare system and often undergo years of testing before arriving at a definitive diagnosis. As the majority of rare diseases have a genetic basis and 50–75% of are thought to begin in childhood, early genetic testing in suspected individuals may represent a large national cost savings. The aim of this study was to identify the population of suspected pediatric RUGD patients most likely to benefit from genetic testing, as well as quantify their healthcare utilization and estimate their national economic burden. Using the 2012 Kids' Inpatient Database (KID), we identified discharges for pediatric patients less than 18 years old with diagnoses suggestive of RUGD, based on a curated set of ICD-9-CM codes. To capture variability in diagnoses and clinical presentations, we created minimum and maximum estimates of RUGD discharges. To establish the minimum, we selected discharges with a principal diagnosis in the set of ICD-9-CM codes that were clinically abnormal given the age at discharge. For the maximum, we considered RUGD discharges for which any diagnosis (up to 15 diagnoses per discharge) was in the set of ICD-9-CM codes. For these cohorts, we analyzed demographics, clinical characteristics, and measures of healthcare utilization, as represented by inpatient total charges and length of stay. We estimate that of the 5.85M weighted total pediatric inpatient discharges in the 2012 KID, 150,169 to 818,384, or 2.6–14% of discharges, represented suspected RUGD patients. After propensity score adjustment, total charges per inpatient discharge for neonatal RUGD patients were \$59K to \$243K higher ( $p < 0.001$ ) than those of non-RUGD, with an additional 6.6–18.6 days spent in inpatient care. Total charges per discharge for non-neonatal RUGD patients were \$38K to \$52K higher ( $p < 0.001$ ) than those of non-RUGD, with an additional length of stay of 1.8 to 2.4 days. Overall, the aggregate total charges for RUGD discharges accounted for \$14B to \$57B (11–46%) of the "national bill" for pediatric patients in 2012. Our analysis shows that pediatric RUGD patients are a significantly higher burden to the national healthcare system. While further studies are necessary, early genetic testing in this population may serve to reduce costs associated with an otherwise lengthy diagnostic odyssey.

**Lessons learned about expanded carrier screening using genome sequencing: Implications for research and practice.** *K.A.B. Goddard<sup>1</sup>, T.L. Kauffman<sup>1</sup>, C.K. McMullen<sup>1</sup>, J.A. Reiss<sup>2</sup>, C.S. Richards<sup>3</sup>, G.P. Jarvik<sup>4,5</sup>, B.S. Wilfond<sup>6,7</sup> on behalf of the NextGen project team.* 1) Center for Health Research, Kaiser Permanente Northwest, Portland, OR; 2) Department of Medical Genetics, Kaiser Permanente Northwest, Portland, OR; 3) Department of Molecular and Medical Genetics, Knight Diagnostic Laboratories, Oregon Health & Science University, Portland, OR; 4) Genome Sciences, Division of Medical Genetics, University of Washington, Seattle, WA; 5) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 6) Department of Pediatrics, Division of Bioethics, University of Washington, Seattle, WA; 7) Truman Katz Center for Pediatric Bioethics, Seattle Children's Hospital, Seattle, WA.

**Background:** This comprehensive study of preconception expanded autosomal recessive or X-linked carrier screening allowed us to assess clinical integration from multiple viewpoints. **Methods:** We performed genome sequencing and reported 728 genes/conditions for carrier status, and 148 actionable secondary findings. Women were eligible if their clinician ordered any preconception carrier screening, were not pregnant at the time of consent, and were planning a future pregnancy. **Results:** We evaluated implementation processes including reasons for declining participation, participant choice in the results to receive, and genetic counseling time to disclose results. The primary reasons for declining were lack of time or interest rather than opposition to the rationale for testing. Participants valued choice about which results to receive as a sign of respect, although most participants (95%) chose to receive everything that was offered. The results disclosure process was often lengthy, particularly visit preparation time, with a median of 64 minutes in total. Laboratory outcomes included a framework for deciding on genes/conditions to offer, an analytic pipeline for sequence interpretation, and the yield for carrier and secondary findings. Overall, 78% of participants (132 women and 54 male partners) received  $\geq 1$  carrier result (mean: 1.5/person). Three women were carriers for X-linked conditions, and all were pregnant with a male fetus at the time of results disclosure. In twelve couples, both partners were carriers for the same autosomal recessive condition. Overall, 3.4% of participants had a secondary finding (2.9% for the ACMG SF v2.0 list). Patient or health system outcomes included economic outcomes and other impacts of learning carrier status. Most participants were willing to pay substantially more than a typical copay, although this was related to income. There was no significant difference in downstream utilization between those who received genome sequencing and a randomized control group, either overall or among subcategories of utilization. There was little evidence of harm in those with a negative result ( $<25\%$  risk of having an affected child), but a small subset declined recommended care (e.g., prenatal screening in a subsequent pregnancy), perhaps due to a misunderstanding that it was not needed for them. **Conclusion:** We will discuss the implications of these findings for future clinical approaches and for future research on expanded carrier screening.

**537F**

**Data sharing to advance understanding of genetic disease: A model for data sharing agreements from the Newborn Screening Translational Research Network.** A. Brower, J. Adelberg, M. Watson. American College of Medical Genetics and Genomics, Bethesda, MD.

Exciting advances in newborn screening (NBS) and diagnostic technologies, including the use of genomics, enable identification of affected newborns prior to the onset of clinical symptoms for an ever increasing array of genetic disease. In concert with these advances, information technology tools to collect prospective clinical information to inform treatment, determine health outcomes, and understand the natural history of disease are in use by state-based NBS programs and treating clinicians. This unparalleled opportunity to diagnose a large number of genetic diseases in the newborn period, and begin to simultaneously capture longitudinal clinical data represents an incredible opportunity to accelerate the translation of findings to routine clinical care, while advancing knowledge. Realization of this vision requires the sharing of a wide variety of data across a large number of diverse institutions. To capitalize on the availability of data collected across fifty-one NBS programs and hundreds of clinical sites, the Newborn Screening Translational Research Network (NBSTRN) has designed and implemented data sharing agreements (DSA) that facilitate uploading of data to a central database. The data sharing agreement addresses data privacy and security concerns, requires responsible data stewardship for both data contributors and data users, defines data types, and outlines the process for data access and secondary use. The NBSTRN has successfully executed DSAs with a state-based NBS program, several research teams and institutions. The DSAs enable the data owner to upload phenotypic and genomic data to a central database, review and manage requests for secondary use of the data, analyze and aggregate data across data owners and projects, and disseminate findings to the research community. Currently, the number of data points available for sharing is over one million across several thousand cases affected with one of forty-six genetic conditions. We will review the DSA definitions, workflow, and present two case studies. Our successful approach to DSAs serves as a model for the sharing of clinical and genomic data across the lifespan to advance disease understanding and improve patient outcomes.

**Cases of patients and informal caregivers who decided to handle their own health condition.** V.P.F. Francisco<sup>1</sup>, S.A. Oliveira<sup>1</sup>, P. Oliveira<sup>2</sup>. 1) Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa; 2) Católica Lisbon School of Business and Economics.

Our research in the area of "user innovation" has shown that patients, and their informal or non-professional caregivers, often develop innovative solutions to help them cope with their health condition. That same stream of research also concluded that these innovative solutions often improve the quality of life of the "patient innovators" (or their caregivers) and, if shared with others living under similar conditions, can significantly impact the lives of others. Since we increasingly live and work on online collaborative environments where the user can share, search and access information in a much faster, cost effective and efficient way, we have established an award-winning platform, [www.patient-innovation.com](http://www.patient-innovation.com) aimed at empowering patients/caregivers under medical supervision and the support of two Nobel Laureates and other reputable individuals. (e.g. Patient Innovation was named Non-profit Startup of the Year and recognized by UN Secretary General Ban Ki-moon). Over 700 innovations were submitted and "screened" from a community of over 50.000 patients/caregivers from the 5 continents. In this poster we present some cases of patients and caregivers who developed innovative new solutions to help them cope with their diseases and critically discuss their similarities and differences.

**Demystifying biomedical big data analysis through a massive open online course (MOOC).** *B.R. Haddad<sup>1</sup>, P.B. McGarvey<sup>2,3</sup>, A. Kruse<sup>4</sup>, Y. Gusev<sup>1,2</sup>.*

1) Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC; 2) Innovation Center for Biomedical Informatics, Georgetown University Medical Center, Washington, DC; 3) Protein Information Resource, Georgetown University Medical Center, Washington, DC; 4) Center for New Designs in Learning & Scholarship, Georgetown University, Washington, DC.

Advances in genomics have led to the generation of massive amounts of data. However, the usefulness of these data to the basic scientist or to the clinical researcher, to the physician or ultimately to the patient, is highly dependent on understanding its complexity and extracting relevant information about specific questions. The challenge is to facilitate the comprehension and analysis of big datasets and make them more "user friendly". Towards this end we have developed a cross-disciplinary, Massive Open Online Course (MOOC), that aims to facilitate the understanding, analysis, and interpretation of biomedical big data for basic and clinical scientists, researchers, and librarians, with limited or no significant experience in bioinformatics. The 8-week course was funded by an NIH- BD2k R25 grant and was released in February 2017 on the edX platform. The course covered biomedical big data as it relates to five main areas: 1) Genomics; 2) Transcriptomics; 3) Proteomics; 4) Systems Medicine; and 5) Big Data usage in research and the clinic. Content consisted of short video lectures, interviews, and online hands-on-training on the use of various databases and analysis tools for different "omics" platforms. Students were provided with online readings and resources, and were expected to complete pre- and post-course surveys, formative assessments, and a final exam. Participation in discussion boards and other exercises was also encouraged. Over 2,000 students from over 150 countries have enrolled. We will share our experience in developing the course and discuss the pros and cons of this online approach of hands-on training in big data analysis. Quantitative data will be presented about students' demographics, motivation, and learning achievements. Themes from the discussion board and other exercises will be discussed. We plan to maintain this course as a "living resource," updating it regularly, and keeping it freely accessible. We believe that this will allow us to provide an educational opportunity to a large audience worldwide, particularly to individuals with limited access to traditional educational resources in this cutting-edge field.

**Section of Genetic Counseling at CHOP: Organizing for advocacy and professional development.** *M.H. Harr<sup>1</sup>, S. Woyciechowski<sup>2</sup>, H. Dubbs<sup>3</sup>, S. Kasperski<sup>4</sup>, S. Biswas<sup>5</sup>, A. Wilkins<sup>5</sup>, A. Melchiorre<sup>6</sup>, D.M. McDonald-McGinn<sup>6</sup>, The Section of Genetic Counseling at CHOP.* 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Cardiology, Children's Hospital of Philadelphia, Philadelphia, PA; 3) Division of Neurology, Children's Hospital of Philadelphia, Philadelphia, PA; 4) Center for Fetal Diagnosis and Treatment, Children's Hospital of Philadelphia, Philadelphia, PA; 5) Department of Pathology, Children's Hospital of Philadelphia, Philadelphia, PA; 6) Department of Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.

The Section of Genetic Counseling at Children's Hospital of Philadelphia (CHOP) was created in 2014 to provide a unified professional voice for all genetic counselors across the institution, aid in professional development and promote collaboration amongst genetic counselors. The purpose of this presentation is to provide insight into the process of formalizing the Section of Genetic Counseling at CHOP, outline our internal leadership and committee structure, and highlight accomplishments from the initial three years. Key deliverables of the Section included an institute-wide salary review that resulted in salary adjustments for new hires and employed genetic counselors, development of an enhanced career ladder for professional advancement, creation of a centralized system for student placement for observations and clinical rotations, institution of incident-to billing for genetic counselors, organization of educational and promotional activities for genetic counselors, and provision of onsite CEU opportunities. The methods and structural organization employed to achieve these deliverables will be reviewed. The Section of Genetic Counseling at CHOP currently has 44 members practicing in a wide array of disciplines including pediatric genetics, metabolic medicine, prenatal diagnosis, hereditary cancer, cardiology, neurology, internal medicine, research, and pathology. The strategies utilized by the Section have not only resulted in increased camaraderie and collaboration amongst genetic counselors, but also in increased visibility as well as recognition of the profession at the institutional level across different disciplines. Here we will offer strategies for genetic counselors, and other professionals, to identify opportunities for advocacy and professional growth, recognize potential challenges to such formal organization, and present examples of forthcoming projects within the Section which aim to advance professional development of genetic counselors across the country.

**541W**

**Genome Gateway: An online platform to increase communication between patients, providers and researchers.** A. Hott<sup>1</sup>, K. East<sup>2</sup>, W. Kelley<sup>2</sup>, M. Cochran<sup>2</sup>, D. Bick<sup>3</sup>, B. Korf<sup>4</sup>. 1) Educational Outreach, HudsonAlpha, Huntsville, AL; 2) Genomic Counseling, HudsonAlpha, Huntsville, AL; 3) Genomic Medicine, HudsonAlpha, Huntsville, AL; 4) Department of Genetics, University of Alabama-Birmingham School of Medicine, Birmingham, AL.

Genome Gateway is an online application developed to facilitate communication, education and the sharing of information between patients, the healthcare team, and clinical research teams. The purpose of the development of such a tool is three-fold: 1- to allow face-to-face patient/provider interaction to be as individualized as possible, 2- to provide a foundation for patients to understand genomic medicine evaluations and results, and 3- to create a well-organized, thorough set of educational materials that can “travel” with Genome Gateway and be utilized and customized. The development of Genome Gateway over the past 18 months has provided a clinical tool that alleviates the burden of long family history intakes, patient knowledge gaps, and pre/post-clinical visit communication. Customizable learning modules that include both written text and media, as well as, fully customizable questionnaires are delivered to individual participants tailored specifically for the participant’s needs. Additionally, secure messaging to and from participants within the application is built in, as is, the ability to create a comprehensive family history pedigree. Informed consent and other on-boarding documents are also customizable and delivered through the platform. Over 150 patients utilize Genome Gateway currently through its implementation at the Smith Family Clinic for Genomic Medicine. Evaluation of patient satisfaction with the platform, overwhelmingly rate Genome Gateway as a useful and easy to use tool that aids clinical care. Many patients report the learning material and family history as the most useful aspects of the software. Over half of diagnostic genome patients self-reported reading all assigned learning topics. Providers indicate an average time savings during the first clinical visit to be 30-45 minutes per patient compared to time spent with patients that had chosen not to use Genome Gateway. The flexibility and ease of use inherent in this software makes Genome Gateway an impactful tool in clinical genomics research studies for patients and providers. Genome Gateway will be used in the newly launched Alabama Genomic Health Initiative (AGHI) to positively impact patient satisfaction, increase access to critical learning topics, and make clinical visits more individualized. The use of Genome Gateway in a population-based genomic health study, will provide additional insight into end-user decisions on use, completion, and clinical care time savings.

**542T**

**Lumping and splitting: An age old dilemma with new age implications for disease classification.** C. Thaxton<sup>1</sup>, J. Goldstein<sup>1</sup>, K. Wallace<sup>1</sup>, M. DiStefano<sup>2</sup>, R. Ghosh<sup>4</sup>, P. Witmer<sup>5</sup>, E. Rooney Riggs<sup>6</sup>, M. Haendal<sup>7</sup>, A. Hamosh<sup>2</sup>, H. Rehm<sup>2,3</sup>, J. Berg<sup>1</sup>, *ClinGen*. 1) Department of Genetics, The University of North Carolina, Chapel Hill, NC, USA; 2) Laboratory for Molecular Medicine, Partners Healthcare Personalized Medicine, Cambridge, MA, USA; 3) Department of Pathology, Brigham & Women’s Hospital, Harvard Medical School, Boston, MA USA; 4) Baylor College of Medicine, Houston, TX, USA; 5) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD, USA; 6) Autism and Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA; 7) Monarch Initiative, OHSU, Portland, Oregon, USA.

The dilemma of categorizing and classifying scientific entities has been debated for centuries, and throughout this time several biological entities have cycled through lumping and splitting as scientific knowledge and technologies have advanced. In medical genetics, nosology — or the classification of disease — has historically approached classifying disorders based on sets of phenotypes, either lumping multiple phenotypes into a broader disease entity (i.e. syndrome) or splitting out isolated phenotypes. However, with progressive advancements in medical genetics and genomics, nosology has been turned on end. With NGS and WES sequencing technologies, we are now able to identify the underlying genetic etiologies of diseases that may have previously been “lumped” based on phenotypic presentation; these etiologies are often distinct, and systematic reclassification and re-categorization of disease entities may be necessary. The Clinical Genome Resource (ClinGen) is a resource that defines the clinical relevance of genes and variants for use in precision medicine, and has developed a system to classify the strength of a gene:disease relationship through biocuration. One challenge faced by biocurators is how to curate genes associated with several phenotypic entities: when to lump or when to split a gene:disease entity given the evidence present in the literature? To assist biocurators and establish consistency within the consortium, ClinGen has formed a task group to assemble criteria to address the lumping and splitting predicament. Our preliminary criteria include: (1) defining disease entities; (2) establishing the molecular mechanism(s) underlying the associated entities; (3) discerning the phenotype and variable expressivity; (4) and assessing clinical management. We also formulated a pre-curation process that includes assessment of disease entities and binning of genes based on one of three possible phenotypic etiologies: isolated phenotype, complex phenotype, or syndromic phenotype. This pre-curation will ultimately facilitate and streamline lumping and splitting based on our criteria. Here, we will outline the pre-curation process, our guidelines, as well as specific examples to illustrate the process of determining when to “lump” and when to “split.” Finally, we describe the implications for clinical diagnostic tools, informatics approaches, and care management to this more nuanced classification of disease entities.

**543F****Diversity and inclusion in genomic research: Why the uneven progress?**

S. Callier<sup>1,2</sup>, A. Bentley<sup>1</sup>, C. Rotimi<sup>1</sup>. 1) Center for Research on Genomics and Global Health, NHGRI, NIH, Washington, DC, US; 2) George Washington University School of Medicine and Health Sciences, Washington, DC, US.

Conducting genomic research in diverse populations has led to numerous advances in our understanding of human history, biology, and health disparities, in addition to discoveries of vital clinical significance. Conducting genomic research in diverse populations is also important in ensuring that the genomics revolution does not exacerbate health disparities by facilitating discoveries that will disproportionately benefit well-represented populations. Despite the general agreement on the need for genomic research in diverse populations in terms of equity and scientific progress, genomic research remains largely focused on populations of European descent. In this article, we describe the rationale for conducting genomic research in diverse populations by reviewing examples of advances facilitated by their inclusion. We also explore some of the factors that perpetuate the disproportionate attention on well-represented populations. Finally, we discuss ongoing efforts to ameliorate this continuing bias. Collaborative and intensive efforts at all levels of research, from the funding of studies to the publication of their findings, will be necessary to ensure that genomic research does not conserve historical inequalities or curtail the contribution that genomics could make to the health of *all* humanity.

**544W****Genetic testing in the criminal justice system: Human rights perspectives.** A. de Paor. Law, Dublin City University, Dublin, Ireland.

Genetic science and technology is advancing at a significant pace with discoveries as to the genetic basis of disease and health conditions emerging. Scientific advances are also revealing genetic details of behaviour and personality traits, including anti-social behaviour and violence. It is anticipated that behavioural genetics will develop further and will increasingly be used in various (medical and non-medical) settings, including in the criminal justice context. While much attention has been dedicated to the regulation of genetic information in commercial contexts such as employment and insurance, less focus has been dedicated to regulating genetics in the criminal justice context. This paper urges caution against the use of behavioural genetics in criminal proceedings, and argues that safeguards are needed to control the use and application of this emerging knowledge and any new technologies, and ensure appropriate awareness and education. There is a strong argument for regulating the use of genetic testing for predisposition to violence and criminality given the serious consequences for defendants and offenders. The UN Convention on the Rights of Persons with Disabilities has been used to bolster arguments for prohibiting genetic testing of persons in insurance and employment. This paper considers the potential of this Convention to inform the debate and provide a platform for discussion of the issues arising, from a disability and human rights perspective. The disability and human rights perspective is important in this debate as the absence of an appropriate regulatory framework means that it is likely that more individuals will be stigmatised and mistreated on the grounds of their genetic information in the criminal justice setting.

**545T**

**Fine-scale demography and behavior of male and female human geneticists.** *E. Glassberg<sup>1</sup>, N. Telis<sup>2</sup>, C. Gunter<sup>3,4</sup>*. 1) Department of Biology, Stanford University, Stanford, CA; 2) Department of Biomedical Informatics, Stanford University, Stanford, CA; 3) Departments of Pediatrics and Human Genetics, Emory University School of Medicine, Atlanta, GA; 4) Marcus Autism Center, Children's Healthcare of Atlanta, Atlanta, GA.

Improving the diversity of researchers in human genetics is likely to improve the diversity of problems and populations studied, subsequently decreasing health disparities of under-represented groups. One group that is under-represented in STEM is women; therefore, we wanted to quantify differences between male and female researchers in the American Society of Human Genetics (ASHG). Over the past three Annual Meetings, we collected data regarding the question-asking behavior of men and women following platform presentations. We attended live sessions and, following the meeting, used videos on the web portal to gather data about the questions posed at talks in an array of fields. For each talk, we recorded the session, the speaker, and the gender of each attendee who asked a question of the speaker. We found that, in platform presentations, female ASHG attendees tend to ask fewer questions than their male counterparts. However, analysis of abstract submissions demonstrated that the representation of women varies widely across sub-fields within ASHG (see abstract by Telis et al). In particular, we find that women are under-represented in statistical genetics and bioinformatics and over-represented in genetic counseling, genetics/genomics education, and ELSI. One might hypothesize that the relatively small number of questions from women reflects underrepresentation of women in the audiences of the talks in our dataset. We therefore used the gender ratio of poster presenters in related sub-fields to estimate the proportion of women attending each talk. We show that women are under-represented in question-askers relative to their representation in each sub-field. This is true in data collected live (bioinformatics, statistical genetics) and via webcast (cancer genetics and clinical genetics). Of note, the poster-presenter data suggest that cancer and clinical genetics are female-biased sub-fields. Together, these findings suggest that the relative lack of questions from women is robust to the overall representation of women within the sub-field of the talk. Finally, we show that women are more likely to ask questions of female speakers than they are of male speakers, though they remain less likely to ask questions of female speakers than their male counterparts. These observations from within our own professional society suggest that increasing the representation of women may be insufficient to erase gendered behavioral differences in STEM.

**546F**

**Re-writing regulation? A comparative ethics and policy study of "natural" vs. "synthetic" cells, organoids and human genomes.** *R. Isasi, S. Zuchner*. Dpt. Human Genetics, University of Miami Miller School of Medicine, Miami, FL.

The Genome Project-write aims, among other goals, to tackle current health challenges by enabling human genome-scale synthesis and editing through the development of tools, methods and foundational technologies. GP-write activities will integrate human genetics, stem cells, engineering, among other areas that had been, and continue to be, subject to particular public scrutiny. GP-write seeks to be disruptive, defying existing conceptual and technical limits. Similarly, it will significantly confront the boundaries of governing national 'policy frameworks' or 'legal systems' (i.e. norms, principles, institutions, etc.). Influenced by historical contexts, these frameworks and systems reflect ethical or moral values as well as societal priorities. Thus, an important step to support initiatives such as GP-write is to determine if the policy *status quo*, as developed and implemented, is fit-for-purpose. As GP-write is also interdisciplinary and global, the latter requires identifying and understanding differences and similarities in national approaches, as well as the ethical principles and societal values underpinning them. Consequently, central questions to be addressed are: How these policy frameworks vary across scientific disciplines and their applications? Which legal (e.g. laws, regulations) and self-regulatory measures (e.g. professional guidelines, best practices, codes of conduct, etc.) are necessary to promote responsible innovation? This presentation will identify and analyze policy and ethical approaches to the regulation of 'natural' versus engineered/synthetic human cells and organoids. By mapping the policy/ethical landscapes, we will explore their strengths and challenges, as well as their ability to adapt to scientific advances, evolving technological uptake as well as social interests. It will further assist in determining whether the issues arising in projects such as GP-write fall within, or outside, the remit of existing policy dealing with interconnected scientific fields. Our work will help elucidate the consistency of the ethical principles, social values and scientific rationale underlying the policy choices.

**547W**

**Actions and reactions to negative results from genome sequencing in a healthy preconception population.** *T. Kauffman<sup>1</sup>, S. Kraft<sup>2,4</sup>, J. Dickerson<sup>1</sup>, J. Schneider<sup>1</sup>, A. Rosales<sup>1</sup>, E. Shuster<sup>1</sup>, J. Davis<sup>1</sup>, C. McMullen<sup>1</sup>, F. Lynch<sup>1</sup>, B. Wilfond<sup>2,3</sup>, K.A.B. Goddard<sup>1</sup>* *On behalf of the NextGen study team.* 1) Center for Health Research, Kaiser Permanente, Portland, OR; 2) Department of Pediatrics, Division of Bioethics, University of Washington, Seattle, WA; 3) Truman Katz Center for Pediatric Bioethics, Seattle Children's Hospital, Seattle, WA; 4) Division of Bioethics, Department of Pediatrics, University of Washington School of Medicine, Seattle, Washington.

**Background:** As expanded carrier screening becomes increasingly widespread, it is important to understand how its clinical implementation affects the patients receiving this testing, especially for the vast majority with a negative result who are at <25% risk. **Methods:** 180 women and 71 male partners in the NextGen study received information on carrier status for 728 gene/condition pairs and 114 medically actionable secondary findings. Participants completed surveys before and after results were disclosed and a subset were interviewed 12 months after result disclosure. Surveys included questions to measure the psychosocial effect of receiving results. Interviews further explored utility and actions taken following result disclosure. Electronic medical record data was reviewed to record genetic testing (or refusal) during pregnancy both prior to and after result disclosure. Participants with a negative result have < 25% risk of having a child that could be affected by one of the tested conditions. This included individuals or couples for whom (1) the woman was not a carrier of any autosomal recessive or X-linked conditions, (2) both partners were tested but were not carriers of the same autosomal recessive condition, and (3) no individual who was tested had an autosomal dominant secondary finding. **Results:** For nearly all survey respondents, a negative result with < 25% risk had no or minimal negative emotional impact. Most reported feeling glad, or at least neutral, that they had decided to get genome sequencing, not worried about the accuracy of the test results, and unconcerned about potential implications of the results for their families or their own privacy. Interview data revealed similar findings. Utilization of primary care and mental health services did not differ between participants with a negative result at < 25% risk and usual care (no additional testing) (26% vs 29%,  $p=.72$ ). A small number of women declined recommended prenatal testing, at least one of whom declined it due to a misunderstanding that it was not needed. In the interviews, many reported feeling more confident in their family plans and relieved about a lower risk of having a child with a genetic condition. **Discussion:** There is little evidence of increased harms from genome sequencing in a healthy population for people with a negative result at < 25% risk. A small number of women may decline recommended prenatal care due to a misunderstanding that it is not needed for them.

**548T**

**All, some or none: How wanting to learn genomic results differs within a national survey sample.** *J.B. McCormick<sup>1</sup>, Y. Zhou<sup>2</sup>, K.D. Graves<sup>3</sup>, P.S. Sinicrope<sup>3</sup>, S.T. Vadaparampil<sup>4</sup>, N.M. Lindor<sup>5</sup>*. 1) Penn State University College of Medicine, Hershey, PA; 2) Georgetown University, Washington, DC; 3) Mayo Clinic, Rochester, MN; 4) Moffitt Cancer Center, Tampa, FL; 5) Mayo Clinic, Scottsdale, AZ.

**Introduction.** The volume and complexity of information derived from clinical genome sequencing presents major challenges to established genetic counseling approaches. Current efforts to inform patient choices for returning results have focused on genetics experts' efforts to bin the data into categories of actionability and severity. An alternative approach could be to determine if subgroups of patients could be "binned" according to their individual preferences for return of genomic results. **Methods:** We conducted a cross-sectional online survey with a representative sample of 895 US adults to assess perceptions and attitudes toward genomic testing for disease actionability and severity. After reading and ranking 18 hypothetical disease scenarios for disease actionability and severity, respondents indicated whether they would want to learn the results. We explored correlations with hypothetical interest in learning test results and grouped respondents according to whether they wanted to learn results for ALL, SOME or NONE of the scenarios. **Results:** The majority (70.8%) wanted all results returned and 25.7% wanted SOME results; only 3.5% wanted NONE. The profile across the ALL/SOME/NONE groups did not vary significantly by age, gender, marital status, education, having children, self-rated genetic knowledge, perceived risk for heart disease, or self-reported health status. The NONE group was more likely to be non-Hispanic White, inexperienced with genetic testing, report an average risk of cancer and have greater confidence in their decisions about genomics. Individuals in the NONE group also placed less value on healthy lifestyle and the potential importance of genetic results for self and family members. The NONE group also did not score severity or actionability as important in decision making as the SOME and ALL groups. **Conclusion:** Identifiable characteristics are evident across individuals who project wanting ALL, SOME, or NONE of hypothetically available genomic test results per this survey of a diverse US population. Results could be used to better understand the salience of genomic testing results for the lay population and help genetics care providers organize results in a way that is meaningful for their patients.

**549F****Usability of family health history tools among underserved patients.**

C. Wang<sup>1</sup>, T. Bickmore<sup>2</sup>, M. Paasche-Orlow<sup>1</sup>, T. Norkunas Cunningham<sup>1</sup>, H. Cabral<sup>1</sup>, M. Winter<sup>1</sup>, M. Campion<sup>3</sup>, D. Bowen<sup>4</sup>. 1) Boston University, Boston, MA; 2) Northeastern University, Boston, MA; 3) Stanford University, Stanford, CA; 4) University of Washington, Seattle, WA.

Efforts to improve the accessibility of electronic, computer-based family health history tools necessitate the monitoring of navigational factors that may impede their use. As part of an ongoing trial examining the validity and accuracy of computer-based family health history tools, our team sought to identify specific navigational challenges to effectively using one of two tools: VICKY: Virtual Counselor (Wang et al., 2015) and My Family Health Portrait (MFHP). Participants in the study are recruited from a single, safety net hospital in the Boston, MA area. Study participants are primarily between the ages of 45-64 (83%), African American (74%), and have less than a college degree (72%). Navigation issues were tracked by study research assistants. Navigation data is available for the initial 58 patients enrolled in the trial (29 per arm). For these initial patients, approximately 7% (2/29) did not complete VICKY and 52% (15/29) did not complete MFHP, to the point where a pedigree could be generated. In the case of VICKY, one instance was due to a technical malfunction and another instance was because the participant chose not to continue, due to fatigue from using the tool. In the case of MFHP, 7/15 (45%) patients chose not to continue because they were frustrated with the tool; 10/15 (66%) were reported to have navigation issues. Navigation issues (not mutually exclusive) included inability to enter the tool from the home screen, enter date of birth for self, and adding and saving conditions for self and relatives. Ongoing efforts are needed to monitor the usability of electronic family health history tools to ensure quality data capture by these tools, particularly among underserved patient populations who may have more limited computer literacy skills.

**550W****Why patients decline genomic sequencing studies: Experiences from the CSER consortium.**

L.M. Amendola<sup>1</sup>, J.O. Robinson<sup>2</sup>, R. Hart<sup>1</sup>, S. Biswas<sup>3,4</sup>, K. Lee<sup>2</sup>, B.A. Bernhard<sup>5</sup>, K. East<sup>6</sup>, M.J. Gilmore<sup>6</sup>, T.L. Kauffman<sup>7</sup>, K.L. Lewis<sup>8</sup>, M. Roche<sup>9</sup>, S. Scollon<sup>10</sup>, J. Wynn<sup>11</sup>, C. Blout<sup>12</sup>. 1) Medical Genetics, University of Washington, Seattle, WA; 2) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX 77030; 3) Department of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA 19104; 4) Division of Translational Medicine and Human Genetics, Department of Medicine, Perelman School of Medicine at The University of Pennsylvania, Philadelphia, PA 19104; 5) HudsonAlpha Institute for Biotechnology, Huntsville, AL 35806; 6) Department of Medical Genetics, Kaiser Permanente Northwest, Portland OR 97227; 7) Center for Health Research, Kaiser Permanente Northwest, Portland, OR 97227; 8) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, Bethesda, MD 20892; 9) Departments of Pediatrics and Genetics, University of North Carolina-Chapel Hill, Chapel Hill, NC 27599; 10) Baylor College of Medicine, Department of Pediatrics, Houston, TX 77030; 11) Department of Pediatrics, Columbia University, New York, NY 10032; 12) Division of Genetics, Department of Medicine, Brigham and Women's Hospital, Boston, MA 02115.

**Background:** Clinical and research settings are increasingly incorporating genomic sequencing (GS) technology. A better understanding of how often and why potential participants decline participation in GS research, and if there are reasons specific to GS, is essential to promoting informed decision making and identifying potential barriers to participation. The heterogeneity of populations and study designs in the National Institutes of Health funded Clinical Sequencing Exploratory Research (CSER) consortium provide a unique opportunity to explore this question in a diverse set of GS studies. **Methods:** We surveyed representatives from seven sites across the CSER consortium ascertaining the project's rates of decline and reasons potential participants declined to participate in GS research. Data were analyzed using descriptive statistics. **Results:** The decline rate for enrollment at the seven CSER sites ranged from 12-64% (median 28%), with the highest rate of decline reported by the project recruiting healthy participants for GS for reproductive carrier screening. Decline rates varied slightly across potential participants of differing ages and phenotypes. Reasons for declining GS research were reported for 1088 participants. Commonly cited reasons were similar to those reported for clinical single gene testing and non GS genetic research. Reasons included study logistics (31%), disinterest in research (16%), and privacy and discrimination concerns (13%). The potential psychological burden of pursuing and receiving results from GS has been cited as a concern in the literature; however, such impact was not cited frequently (4%) as a reason for decline. Not wanting to receive additional findings, a concern specific to GS, was also cited by a minority of potential participants (2%). **Conclusion:** Rates of decline at CSER GS study sites varied; further research is necessary to explore the impact, if any, of different participant groups and/or study protocols. Not wanting additional findings and psychological concerns related to GS did not appear to be a barrier to enrollment. Future consortia exploring GS implementation should consider using standardized collection methods to examine reasons for decline in larger populations and more diverse healthcare settings.

**551T****Prostate cancer risk follow-up among *BRCA1/2* mutation carriers in**

**Finland.** O. Kajula<sup>1,2,3</sup>, O. Kuismin<sup>2,3,4</sup>, H. Kyngäs<sup>1,2,5</sup>. 1) Research Unit of Nursing Science and Health Management, University of Oulu, Oulu, Finland; 2) Medical Research Center, Oulu University Hospital and University of Oulu, Oulu, Finland; 3) Department of Clinical Genetics, Oulu University Hospital, Oulu, Finland; 4) PEDEGO Research Unit, University of Oulu, Oulu, Finland; 5) Northern Ostrobothnia Hospital District, Finland.

**Background:** Mutations of *BRCA1/2* hereditary breast and ovarian cancer genes increase male carriers' lifetime risks for developing prostate cancer by 8.6-20 %. Thus, recommendations in genetic counseling for carriers include cancer risk follow-up procedures such as annual prostate specific antigen (PSA) test and digital rectal examination after age of 40 years old. However, despite increased risk for prostate cancer, there is no formal follow-up program for male *BRCA1/2* mutation carriers in Finland. Therefore, we have examined Finnish male *BRCA1/2* mutation carriers' the prostate cancer risk follow-ups based on their own experiences. **Methods:** Data were collected by theme interviews from Finnish male *BRCA1/2* mutation carriers ( $n=31$ ) registered in Departments of Clinical Genetics at five university hospitals in Finland. The themes were based on findings of previous studies and the data were analyzed using descriptive statistics and content analysis. **Results:** The mean age of the male *BRCA1/2* mutation carriers was 59 (range 33-82) years. Two men had been diagnosed with prostate cancer. Most of the male carriers (71 %; 22/31) had received recommendations for prostate cancer risk follow-up, and for 45 % (10/22) of those men the implementation was according to international recommendations. However, the men reported that they received inadequate information about follow-up plans in genetic counseling sessions. The men were also unsatisfied with the follow-up sessions, particularly because they felt that health-care professionals involved lacked knowledge of *BRCA1/2* and they doubted the importance of annual follow-ups. Moreover, the men worried about the continuity of prostate cancer risk follow-ups and expressed wishes that follow-ups should be organized automatically and regularly, and there should be opportunities to discuss possible problems necessary. **Conclusion:** This study shows that registered Finnish male *BRCA1/2* mutation carriers had received recommendations for prostate cancer risk follow-up. However, more attention to implementation of the surveillance is required. Departments of Clinical Genetics have an important role to play in organizing appropriate follow-ups, and findings of the study indicate needs to improve practices to provide cancer risks follow-ups in a comprehensive manner and adequate information about follow-ups in genetic counselling sessions for these carriers. Further studies are needed to explore benefits of prostate cancer follow-ups.

**552F****Sociodemographic influences on attitudes and beliefs about genetic research and services.** P.L. Bussies<sup>1,2</sup>, K. Celis<sup>1</sup>, S. Guo<sup>1</sup>, K. Czape<sup>1,2</sup>, L. Personalized medicine (PM) is individualized healthcare using multi-source information that is unique to a given person. A major source of PM is genomic information derived from ongoing clinical research. Hispanics (HI) and African Americans (AA) have been underrepresented in this research, decreasing the likelihood that PM will be clinically useful for them. Understanding the attitudes and beliefs of HI and AA about genetic research and genetic services can inform efforts to increase awareness of and participation in these activities. Our objective was to assess sociodemographic influences on attitudes and beliefs about genetic testing and genetic research among non-Hispanic whites (NHW), HI, and AA. We analyzed survey data collected from 426 individuals in South Florida (M=134/F=292; NHW=65, HI=258, AA=103). The 23-item survey collected sociodemographics (age, education, race-ethnicity, sex) and measured *genetic testing attitudes* (GTA; 4 items), *genetic research attitudes* (GRA; 4 items), *willingness to participate in genetic research* (WTP; 3 items), and *genetic knowledge* (GK; 12 items). We used univariate and multivariate methods to investigate group differences (sex, age, education, and race-ethnicity) on our dependent measures. Univariate ANOVAs (Bonferroni adjusted) showed (a) a **sex effect** in GRA ( $p=0.003$ ); (b) an **education effect** in GK ( $p<0.001$ ), as well as GRA ( $p<0.001$ ) and GTA ( $p<0.001$ ); and (c) a **race-ethnicity effect** in GTA ( $p<0.001$ ) and GRA ( $p<0.001$ ). There was no significant age effect. To model significant contributors to GRA and GTA, we performed logistic regression with sociodemographic variables as inputs. For our primary outcomes of interest, we found that education ( $p=0.005$ ) and race-ethnicity ( $p<0.0001$ ) were significant predictors of GTA while only education was a significant predictor of GRA ( $p<0.0001$ ). Using these same predictors, we did not find a significant effect in our overall model for WTP. Our results suggest that both education and race-ethnicity play important roles in determining attitudes about genetic testing and genetic research. As previously reported by other investigators, our results point to less favorable attitudes among individuals with lower education as well as among AA and HI groups. These results support the importance of studying the complex interplay of sociodemographics and attitudes about genetics and genomics in order to enhance participation in understudied populations.

**Views of experts and the public on genome editing and its issues: A literature review.** *I. Taguchi<sup>1</sup>, T. Kona<sup>1</sup>, Y. Sato<sup>1</sup>, K. Matsuura<sup>1</sup>, T. Wada<sup>1,2</sup>, S. Kosugi<sup>1,2</sup>.* 1) Department of Medical Ethics and Medical Genetics, Kyoto University Graduate School, Kyoto, Kyoto, Japan; 2) Clinical Genetics Unit, Kyoto University Hospital.

[Introduction] In 2012, the collaborative investigation team led by Professor Jennifer Doudna reported that a free genome editing using CRISPR-Cas9 was possible. They announced that National Academy of Sciences accepted the genome editing treatment for fertilized eggs only for serious genetic diseases in February, 2017. However, this ethical agreement was reached during the arguments for the basic and clinical researches. As there was a rapid shift towards the genome editing in practical use, we conducted a literature review to clarify future problems as well as grasping views of experts and the general public. [Method] We used online databases (PubMed, ICHUSHI web) to find articles using the search query: ("genome editing" OR "gene editing") AND human. The inclusion criteria for this review are below; 1) Original articles or comments with authors' opinions 2) Obtained from the published in peer-reviewed journals 3) Written in English or Japanese 4) Published during the last five years (2012.1-2017.5) [Result] There is no unified agreement on the utility of genome editing of the human germline information yet. Some experts are totally against although others agree upon its use for fertilized eggs under certain conditions such as prevention of serious genetic disorders. In the public, its use for serious illnesses was generally accepted. However, the majority of opinions were against its use in the modification of expressions unrelated to the illnesses. In addition, there was no attitude survey conducted on the public in Japan. [Discussion] Detailed investigations on uneasiness and expectation on genome editing should be carried out in Japan. It is suggested that development of the legislation and education systems corresponding to genome editing is urgently needed. In addition, it is necessary for certified genetic counselors (CGCs) to predict outlook of the public's ethical views about genome editing. Depending on its use in the future generation, CGCs need to be able to handle possible impacts of the editing flexibly.

**The Rare Genomes Project: Improving our ability to diagnose rare genetic conditions through a nationwide partnership with families.** *H. Brooks, A. O'Donnell-Luria, J. Hendrey, A. Zimmer, N. Lopez Zalba, L. Greenfield, M. Wojcik, M. Udler, S. Baxter, B. Weisburd, T. Mullen, H. Arachchi, H. Rehm, D. MacArthur.* Broad Institute of MIT and Harvard, Cambridge, MA.

More than half of all patients in the US with a suspected rare genetic disease do not currently have a formal genetic diagnosis for their disorder. Identifying all of the genes underlying rare diseases will require large-scale outreach to the rare and undiagnosed community to participate in genomic research; however, the low prevalence of rare diseases means that patients are geographically dispersed, making recruitment challenging. The Rare Genomes Project (RGP; raregenomes.org) is a direct-to-patient research study leveraging social media and online participation to dramatically increase the reach of rare disease genomic research. Patients and families are recruited through advocacy groups and social media, and directed to a simple online form to tell us about their condition. Families that meet inclusion criteria sign an electronic consent and are mailed blood or saliva collection kits. If available, archival tissue samples are collected from pathology departments. Samples are mailed overnight to our genomics platform for exome, whole genome and/or transcriptome sequencing. If we identify the genetic cause of the patient's condition, we will perform clinical validation and provide a report to the patient's family and their doctor. Families are engaged as stakeholders at each step. The first pilot study of the RGP launched in June 2017. We will describe the lessons learned from the first several hundred recruited families on the journey from social media contact through to return of clinically validated diagnoses, and details of the diagnoses made by the project to date. We will also outline key unsolved challenges in direct-to-patient genomic research, including the current regulatory barriers to the return of raw genetic data to participants, and the uncertainty around international expansion of the direct-to-patient model. We anticipate that this project will provide proof of principle of the value of a patient-engaged approach to diagnosis and gene discovery in rare disease.

**Impact of personal microbiome information on research volunteers.** C. Bloss<sup>1</sup>, E. Hyde<sup>1</sup>, R. Knight<sup>1</sup>, L. Goetz<sup>2</sup>. 1) University of California San Diego, La Jolla, CA; 2) Scripps Health, San Diego, CA.

**Introduction.** Human microbiome research has advanced rapidly, but aside from fecal transplantation for *Clostridium difficile* infection, there are currently no proven health interventions that involve manipulation of an individual's microbiome. Against this background, personal microbiome analysis has become available to individuals for a fee through both biotechnology start-up companies, as well as non-profit research programs. There has been fairly rapid uptake of the service among early adopters, with the phenomena not unlike the emergence of direct-to-consumer genetic testing companies in the late 2000s. **Methods.** A retrospective survey study of participants in the American Gut Project, a non-profit, crowdfunded and crowdsourced human microbiome research study was conducted. Respondents underwent personal microbiome analysis with return of results six months later. Survey items assessed motivations for participating and impacts of results on behavior. **Results.** A total of N=210 (64% response rate) individuals participated. General curiosity most commonly motivated individuals to seek personal microbiome analysis (80%), however, desire to improve one's health was the second most commonly cited motivation (50%). Other health-related motivations included gastrointestinal problems (GI; 35%) and "other microbiome-relevant health problems" (15%). Collectively, 133 individuals (63% of the sample) cited at least one health-related motivation. A total of 37% of respondents reported that they either made or planned to make behavioral or lifestyle changes based on their results, with change in diet (88%) or use of nutritional supplements (24%) most commonly cited among these individuals. Finally, 29% of those surveyed reported sharing or intending to share their results with their physician or health care provider. **Conclusions.** Although research has shown links between the human microbiome and a range of health outcomes, and personal microbiome analysis has become widely available through companies and non-profit research programs, the interpretation of an individual's microbiome data is still uncertain to specialized scientists, let alone practicing physicians. Despite this, findings suggest that health-related factors motivate individuals to seek personal microbiome analysis, and in some cases results may lead to changes in behavior. Further research is needed to understand the implications of these findings for the field of human microbiome science.

**Establishing variant frequencies for pharmacogenomic data in a community health system based pharmacogenomics program.** P.J. Hulick, D.L. Helseth, K. Kaul, J. Khandekar, K. Gulukota, A.A. Lemke, K.A. Mangold, N. Miller, A. Sereika, L.M. Sabatini, N.M. Parsad, D.T. Wake, H.M. Dunnenberger. NorthShore University HealthSystem, Evanston, IL.

**Purpose:** NorthShore's Pharmacogenomics (PGx) Clinic, established in March of 2015, is one of a handful of clinics nationwide which preemptively provides testing to help predict how patients will respond to a variety of widely prescribed medications. Over 500 clinic visits have occurred which has saturated capacity. The patient-centered clinical implementation served as the foundation for our broader initiative to provide seamless integration of pharmacogenomics across our health system. In November of 2016, NorthShore piloted the ability for primary care physicians to order pharmacogenomics testing directly in the clinic through a process that integrates ordering, patient consenting, resulting, and clinical decision support driven by PGx data within the electronic medical record (EMR). At the same time, a transition from several external PGx laboratories to the NorthShore Laboratory using internal developed PGx panel occurred. As part of PGX integration, an in-house variant repository (Flype), was developed to meet the needs of our growing PGX program. Crucial to monitoring the quality control of our PGX program is capturing the variant data at a population level within our hospital system. Here we report on our initial variant data for three common drug metabolizing enzymes *CYP2D6*, *CYP2C19*, and *CYP2C9* as part of our quality control initiative. These three enzymes were chosen because each laboratory tested them and there are Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines for each. The CPIC reported frequencies for a Caucasian population was chosen as the comparator given the ethnic makeup of the NorthShore population. **Summary:** Testing for 288 patients occurred at external laboratories compared to 234 patients at the internal laboratory. There was similar distribution between allele and phenotype frequencies between all populations. *CYP2D6* had the greatest number of allele variants observed in the NorthShore population, 18. *CYP2C19* is the enzyme with the most phenotypic variation with only 37% of our population being normal metabolizers. **Conclusion:** From a quality control standpoint, these were the expected findings. It is important to note that even though the variants being tested from each laboratory differ this did not translate to a major difference at the phenotype level. It is important for any large system implementing pharmacogenomics to carry out similar evaluations to identify any expected or unexpected findings.

**557T**

**Primary care physician views on direct access pharmacogenomic testing in a community health system.** A.A. Lemke, P.J. Hulick, C.G. Hutten Selkirk, A.W. Sereika, N.S. Glaser, D.T. Wake, H.M. Dunnenberger. Center for Personalized Medicine, NorthShore University HealthSystem, Evanston, IL.

Clinical pharmacogenomics (PGx) is a relatively new field with variable delivery models. In fall of 2016, a pilot program of provider-ordered, direct access PGx testing was launched that involves mailing a testing kit to the patient, obtaining a buccal sample, and returning results by mail. Through this process, clinical PGx testing can be completed at home by the patient, while still receiving supervision from the ordering provider. Little is known about how health care providers view the benefits and challenges of this type of testing. To explore issues salient to physicians, this study utilized semi-structured interviews and a brief survey to assess perspectives of 15 community primary care providers who had undergone PGx kit testing themselves, and who also had received complimentary kits for five of their patients. Participants were drawn from six community practices and all spent 51% or more of their time in patient care. The majority specialized in internal medicine and their years in practice varied. Three main themes emerged from the qualitative interviews: 1) perceived value and utility of PGx testing; 2) specific challenges to implementation in practice; and 3) provider needs going forward. Reported utility of PGx testing included avoiding medication trial and error odysseys, reducing side effects, improving medication adherence, facilitating shared decision-making, and providing patients with validation of their past medication experiences. Participants described challenges in terms of patient data privacy concerns, cost of testing, insurance coverage, and understanding complex PGx test results. Provider needs reported were more PGx education, guidance on how to address cost and insurance issues with patients, and improved clarity in the PGx results report. The survey findings indicated that most (93%) participants believed that there is "clinical utility" in PGx testing, and all strongly or somewhat agreed that undergoing self-testing improved their own understanding of PGx testing. The majority (93%) also felt that the operational logistics of implementing direct access PGx testing in their workflow seems reasonable. However, one-third (33%) did not feel confident in their ability to explain PGx results to their patients. Our study findings reveal a broadened view of the concept of clinical utility of PGx testing and the types of initiatives primary care physicians feel are needed in order to reduce barriers in PGx service delivery.

**558F**

**Pharmacogenomic counseling: Exploring participant questions about PGx test results.** T. Schmidlen<sup>1,2</sup>, A.C. Sturm<sup>2</sup>, L. Scheinfeld<sup>1,3</sup>, M.F. Christman<sup>1</sup>. 1) Coriell Personalized Medicine Collaborative, Coriell Institute for Medical Research, Camden, NJ; 2) Genomic Medicine Institute, Geisinger Health System, Danville, PA; 3) Institute for Genomics and Evolutionary Medicine, Temple University, Philadelphia, PA.

As the use of pharmacogenomic (PGx) information in healthcare increases, a better understanding of the needs of individuals receiving this information will be necessary to help guide PGx result delivery. The Coriell Personalized Medicine Collaborative (CPMC) is a prospective study investigating the utility of personalized medicine. Participants receive online genetic risk reports for 27 actionable complex diseases and 8 drug-gene pairs and can request free telephone-based genetic counseling (GC). To explore the needs of individuals receiving PGx test results, we conducted a retrospective qualitative review of inquiries from participants who requested counseling to discuss CPMC results from March 2009-February 2017. Eighty out of 690 (12%) total GC inquiries were focused on discussion of PGx results. All 80 PGx inquiries were coded and six salient themes emerged: "general help", "issues with drugs", "relevant disease experience", "what do I do now?", "sharing results" and "other drugs". Forty-three (54%) participants had general questions about their PGx results while only 7 (9%) were looking for specific guidance on dosing or drug selection. Past issues with drug side effects (n=14, 18%), dosing (n=2, 3%), and efficacy (n=3, 4%) were also mentioned. Some alluded to a personal (n=12, 15%) or family history (n=6, 8%) of diseases treated by drugs reported on in the CPMC study. Seventeen participants (21%) were interested in availability of PGx results for other non-study related drugs, while 28 (35%) asked about the impact of currently available PGx study results on other drugs. Some indicated sharing their PGx results with a doctor (n=5, 6%), and some questioned the impact of their PGx results on family members (n=5, 6%). No demographic factors predicted PGx genetic counseling requests (P>0.05). Total number of medications reported by a participant was also not predictive (P>0.05). However, number of reported medications with a corresponding PGx result was significantly associated with PGx GC requests (P<0.05). Highly engaged participants (viewed more study reports) were significantly more likely to request PGx GC (P<0.001). Our work illustrates a range of questions raised by study participants receiving PGx test results, most of which were addressed by a genetic counselor with few requiring input from prescribing providers or pharmacists. These results further support a role for genetic counselors in the team-based approach to optimal PGx result delivery.

**Implementation of precision medicine initiatives: Special considerations for underserved communities.** C.W. Brown<sup>1,2</sup>, J. Ward<sup>1,2</sup>, E. Pivnick<sup>1,2</sup>, H.J. Mroczkowski<sup>1,2</sup>, R. Mostafavi<sup>2</sup>, R. Rooney<sup>2,3</sup>, R. Joyner<sup>2</sup>, A. Ryder<sup>2,3</sup>, V. Park<sup>1</sup>, N. Urraca-Gutierrez<sup>2</sup>, LeBonheur Children's Foundation Research Institute. 1) Pediatrics/Genetics Division, University of Tennessee Health Science Center, Memphis, TN; 2) LeBonheur Children's Hospital, Memphis, TN; 3) Department of Pediatrics, University of Tennessee Health Science Center.

'Precision Medicine' promises to improve the quality of health care based in part on increasingly detailed patient information at the molecular level, thereby enhancing the precision and accuracy of diagnosis and affecting clinical management decisions. Once a precise diagnosis is established, more targeted and effective prevention, surveillance and treatment strategies can be implemented, and ineffective treatments that waste resources or can be associated with adverse outcomes can be avoided, including unnecessary procedures and medications. In addition to direct effects on medical care, genetic information can provide a diagnostic endpoint and greater sense of control, strengthen patient and family support networks that can favorably affect patient outcomes, and provide important health information that extends to family members, characteristics that challenge the conventional definition of clinical utility. At the societal level, effective genetic testing should have a favorable impact on health and allow effective health interventions throughout an entire population. However, substantial challenges occur in communities where limited resources preclude access to the 'high end' technologies that are associated with precision medicine initiatives, running the risk of creating even greater health care disparities in those communities. We describe several ongoing initiatives to address this challenge in underserved communities of Memphis, Tennessee, using a multi-faceted strategy that includes community outreach and education, partnerships with local foundations and industry, streamlining of processes to facilitate clinical DNA testing, and encouraging and facilitating participation in genomic research studies. Included in these efforts are a hospital-wide initiative to collect DNA from all patients to build a general population cohort to support genetic and genomic research; an industrial partnership, *Teaching the Genome Generation*, an educational program to implement laboratory based genomics exercises in local high schools; and other community-focused activities for genomics education. These measures are designed to help 'level the playing field' of accessibility and to minimize precision medicine disparities.

**560T**

**Integration of a tool for electronic education and consenting within primary care to enable precision prevention.** M. Moore<sup>1</sup>, M. Mboob<sup>1</sup>, K. Rageth<sup>1</sup>, M. Robinson<sup>2</sup>, K. Hood<sup>4</sup>, S. Jurgens<sup>1</sup>, M. Haendel<sup>3</sup>, C. Boerkoel<sup>1</sup>, M. Sincan<sup>1</sup>, C. Hajek<sup>1</sup>, R. Pyatt<sup>1</sup>, Monarch Initiative. 1) Imagenetics, Sanford Health, Sioux Falls, SD; 2) Micromattie Consulting Inc, Orlando, FL; 3) Oregon Health and Science University, Portland, OR; 4) HAART (HIV/AIDS Alliance for Region Two), Baton Rouge, LA.

Implementation of large scale genotyping within primary care for purposes of precision preventive medicine remains problematic; in part due to the lack of clinical resources for enrollment of patients. We hypothesized that electronic educational modules and electronic consenting can address the lack of resources and enable enrollment of patients into such genotyping protocols. To test this hypothesis, we developed an interactive, integrated consent and educational tools for enrolling individuals in pharmacogenetic and predisposition testing at the time of a visit to their primary care physician. Following refinement from feedback of the medical system, customer relations groups, and analysis of focus group responses; we launched this tool as part of a precision prevention initiative within a rural primary care setting. We present the logic underlying this process, as well as our initial results. These results include feedback from patient interaction with the electronic tools, educational initiatives to encourage patient uptake, and clinician responses.

## 561F

**The missing and the vulnerable: Developing responsible science policy for applying DNA to cross-border humanitarian causes.** *S.H. Katsanis<sup>1</sup>, L. Snyder<sup>2</sup>, A.Z. Mundorff<sup>3</sup>, S.A. Faith<sup>3</sup>.* 1) Duke Initiative for Science and Society, Duke University, Durham, NC, USA; 2) Anthropology, University of Tennessee, Knoxville, TN, USA; 3) North Carolina State University, College of Veterinary Medicine and Forensic Sciences Institute, Raleigh, NC, USA.

If scientists, humanitarians and forensic investigators were to convene today to design an international missing persons system, it likely would look very different from the systems currently in place. Within the U.S. and around the world, the current procedures for missing persons' identification using DNA are inefficient and fragmented, reliant upon law enforcement prioritization and policies borne from criminal investigations. Across borders, identifications of the deceased or displaced are mired in bureaucracy, jurisdictional regulations, and limited resources that prevent the science from being applied expeditiously to aid investigations. In addition, as concerns for border security increase, policy-makers are turning to genomics as a biometric for tracing individuals entering the country, processing refugee claims, and screening for human trafficking. We have examined the science policy as applied to cross-border cases, conducted a stakeholder analysis on DNA applications for human rights, assessed cross-border DNA database tools, and developed model language for family reference sample (FRS) collection. We have found that genetic verification of claimed relationships is required in the U.S. for some refugees and proposed legislation would expand this practice. Hundreds of human remains of unidentified migrants are found along the southern U.S. border each year and thousands of migrants are dying as they cross the Mediterranean Sea. Such high-risk migrants often lack identification documents, so DNA is an important tool for death investigators to identify human remains. Cross-border sharing of FRS DNA profiles is essential and currently ineffective, requiring the resolution of many technical, ethical, political, and administrative challenges, particularly to protect vulnerable populations from abuses of power. While guidelines and best practices have developed for handling disaster victim identifications and for identification of the missing, standard consent practices for FRS have not developed. Continuing global migration in the coming decades necessitates rethinking of the existing infrastructure to enable cross-border DNA sharing. Networking the multiple efforts around the world is a first step towards improved communication for humanitarian identifications. Careful design of a DNA database system to protect sensitive data is vital.

## 562W

**Tipping the scales: Participants make healthy dietary changes in response to direct-to-consumer genetic test results.** *S.B. Laskey, J.F. Shelton, M. Johnson, C. Wilson, R. Smith, B.L. Koelsch, The 23andMe Research Team.* 23andMe, Mountain View, CA.

The growing direct-to-consumer (DTC) genetic testing industry serves as a promising opportunity to provide personalized recommendations and empower consumers to make healthy lifestyle decisions. However, motivating behavior change is a notorious public health challenge, and the impact of DTC genetic test results on short-term and long-term behavior is still an active area of investigation. In this study, we measured self-reported dietary behavior in a subset of consented 23andMe customers who received the personalized Saturated Fat and Weight Report (SFWR), which describes the impact on BMI of an interaction between rs5082 genotype and dietary saturated fat intake. One month after publication of the SFWR, 47% of the survey participants who reported viewing their results ( $n = 17,253$ , 62% female) also reported that they were considering, planning, or had already started making dietary changes in response to the report. These participants were more likely to be female ( $p < 10^{-12}$ ), have GG genotype at rs5082 ( $p < 10^{-149}$ ), and have higher BMI ( $p < 10^{-147}$ ). In a follow-up survey six months later ( $n = 10,387$ ), 26% of participants reported having made dietary changes in response to the SFWR, including 55%, 45%, and 29% of participants who were considering, planning, or had started changes at the one-month time point, respectively. The dietary changes reported by participants were overwhelmingly healthy and aligned with the recommendations published in the SFWR. For example, of participants who reported changing dietary saturated fat intake, 94% reported eating less saturated fat in response to the SFWR. At the six-month follow-up time point, 91% and 97% of participants who reported making changes to dietary saturated fat and unsaturated fat intake, respectively, reported that they had maintained those changes. These results suggest that personalized, DTC genetic results can be a powerful motivator for positive lifestyle changes and a trusted resource for informing health and wellness decisions. Of participants who reported making dietary changes since the release of the SFWR, 66% say that the report impacted their decision. Importantly, because survey respondents may take a more proactive role in their health than non-respondents, these findings may not be generalizable to users who did not answer our surveys.

**563T**

**Genotypes associated with phenotypes: A human genetics laboratory exercise.** *D. Caporale, A. Pritchard.* Biology, University of Wisconsin-Stevens Point, Stevens Point, WI.

Within the human genome, certain genes seem to be associated with particular phenotypes. As part of a new laboratory exercise in a Human Genetics course, single nucleotide polymorphisms (SNPs) of potential interest to students were selected for assay development. Some SNPs discovered within previous studies included: 1) an APOA2 gene variant associated with weight gain when consuming saturated fatty food, 2) variants of the FGF21 and FTO genes associated with a person's preference towards sweet foods, 3) an OXTR heightened empathy variant, and 4) CYP1A2 variants associated with caffeine metabolism. We designed allele-specific primers to amplify the wild type alleles and variant alleles of these genes and others, in order for students to identify their genotypes. Computer websites were used in the following order: UCSC Genome browser to obtain gene sequences containing each SNP, NCBI PRIMER BLAST to design primer pairs, Fisher Scientific Primer Design Tool to determine the Tm compatibilities among the four primers, and BLAT to assess primer specificity within the human genome. Primers were then tested with three DNA control samples to optimize temperature profiles. After optimization, these assays were performed by students enrolled in Human Genetics. Here we report the results of the class to demonstrate the success of the assays and illustrate the genetic diversity of these genes within the class. Finally, associations between students' genotypes and phenotypes were assessed.

**564F**

**f-treeGC: Questionnaire-based pedigree chart creation software in compliance with recommendations for standardized human pedigree nomenclature.** *T. Tokutomi<sup>1,2</sup>, K. Yamamoto<sup>1,2</sup>, A. Shimizu<sup>2</sup>, M. Sasaki<sup>2</sup>, A. Fukushima<sup>1,2</sup>.* 1) Department of Clinical Genetics, School of Medicine, Iwate Medical University, Morioka, Iwate 020-8505, Japan; 2) Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Shiwa, Iwate 028-3694, Japan.

**Objective** The Tohoku Medical Megabank project aims to create a next-generation personalized healthcare system by conducting large-scale genome-cohort studies involving three generations of local residents in the areas affected by the Great East Japan Earthquake. We collected medical and genomic information for developing a biobank to be used for this healthcare system. We designed a questionnaire-based pedigree-creation software program named "f-treeGC," which enables even less experienced medical practitioners to accurately and rapidly collect family health history and create pedigree charts according to recommendations. **Methods** f-treeGC may be run on Adobe AIR. Pedigree charts are created in the following manner: 1) At system startup, the client is prompted to provide required information on the presence or absence of children; f-treeGC is capable of creating a pedigree for up to five generations. 2) An interviewer fills out a multiple-choice questionnaire on genealogical information. 3) The information requested includes name, age, gender, general status, fertility status, pregnancy status, fetal status, and physical features or health conditions of individuals over five generations. In addition, information regarding the client and the proband, and birth order information, including multiple gestation, custody, multiple individuals, donor or surrogate, adoption, and consanguinity may be included. 4) f-treeGC shows only marriages between first cousins via the overlay function. 5) f-treeGC automatically creates a pedigree chart, and the chart-creation process is visible for inspection on the screen in real time. 6) The genealogical data may be saved as a file in the password-protected original format and/or in read-only format. The created/modified date and time may be changed as required. By default, the file name automatically contains the terms typed into the entry fields, including physical features or health conditions, to enable sorting or searching from the database. **Summary** f-treeGC is fully compliant with international recommendations for standardized human pedigree nomenclature, and has a variety of uses, from genome cohort studies or primary care to genetic counseling. The present software is available for use, at no monetary cost, at the Iwate Medical University Hospital website (<http://www.iwate-med.ac.jp/hospital/clinics/medical/m26/>).

**Everything is actionable: Patient values and perceived utility of incidental genome sequencing results.** Y. Bombard<sup>1,2</sup>, M. Clausen<sup>2</sup>, C. Mighton<sup>2</sup>, S. Shickh<sup>2</sup>, E. Glogowski<sup>3</sup>, K. Schrader<sup>4</sup>, M. Robson<sup>5</sup>, A. Scheer<sup>1,2</sup>, C. Elser<sup>6</sup>, A. Eisen<sup>7</sup>, M. Evans<sup>1,2</sup>, J.C. Carroll<sup>1,8</sup>, J. Hamilton<sup>5</sup>, K. Offit<sup>8</sup>, K. Thorpe<sup>1</sup>, J. Lerner-Ellis<sup>1,8</sup>, A. Laupacis<sup>1,2</sup>. 1) University of Toronto, Toronto, ON; 2) St. Michael's Hospital, Toronto, ON; 3) GeneDx, Gaithersburg, MD; 4) BC Cancer Agency, Vancouver, BC; 5) Memorial Sloan Kettering Cancer Center, New York, NY; 6) University Health Network, Toronto, ON; 7) Sunnybrook Health Sciences Centre, Toronto, ON; 8) Mount Sinai Hospital, Sinai Health System, Toronto, ON.

**Introduction:** Genome sequencing (GS) is a driver of personalized health, facilitating diagnosis and optimized care, especially in precision oncology. One complex feature of this technology is its capacity to generate incidental results (IR), which has created much controversy. Guidelines suggest that 'medically actionable' IR should be offered to patients undergoing GS, with calls to offer additional IR based on patient preferences. Research explores patient preferences for IR in broad, often abstract terms, yet little is known about patient informed and deliberated values towards IR. Our objective was to describe patient considered values and perceived utility of receiving their IR following a deliberative, educational intervention. **Methods:** Semi-structured interviews were conducted with 15 cancer patients participating in usability testing of a decision aid (DA) designed to facilitate informed, value-based selection of incidental findings. We created an interactive, online DA ([www.genomicsadvisor.com](http://www.genomicsadvisor.com)) to guide patients' selection of IR by "binning" IR into 5 categories: (1) Medically actionable & pharmacogenetic variants, (2) Common disease SNPs, (3) Mendelian disease variants, (4) Early-onset neurological variants, (5) Carrier results. Content analysis was used to analyse the data. **Results:** Participants were enthusiastic towards GS itself, and expressed a perceived inherent value for its use in their own healthcare. All participants chose to receive some incidental findings; 9 participants selected all incidental findings. Many participants saw knowledge as empowering, and stated that the more information they had, the more actions they could take. Participants perceived all categories of IR as being "actionable," even ones defined as non-medically actionable (2, 3, 4, 5). Participants said that learning any IR could inform actions to delay disease onset, reduce symptoms, help with planning and to inform their families' future financial or reproductive planning. **Conclusion:** Despite this small sample size, participants' enthusiasm for IR suggests that uptake and use of results will be high. Many participants perceived all categories of IR to be "actionable," which creates a divergence in how patients and experts conceive IR as well as their utility and obligations for return. This divergence may cause gatekeeping challenges for providers if they are positioned to offer only medically actionable IR, and variations in access to information among patients.

**566T**

**Repatriation of out-of-country molecular testing for disorders targeted by the provincial newborn screening program: Improving access to diagnostic testing in a cost and time efficient manner in Ontario, Canada - Our first year experience.** B. Bélanger<sup>1</sup>, D.E. Bulman<sup>1,2</sup>. 1) Newborn Screening Ontario, Children's Hospital of Eastern Ontario, Ottawa, Ontario, Canada; 2) Research Institute and University of Ottawa, Ottawa, Ontario, Canada.

Newborn Screening Ontario (NSO) screens about 140 000 newborns every year in the province of Ontario, Canada. Following a positive newborn screen (NBS) result, newborns at risk for one of the multiple conditions screened have to go through diagnostic testing including molecular testing. The majority of the molecular diagnostic tests were available in laboratories outside the province, leading to additional costs and delays associated with sample transportation and prior approval by our provincial evaluation process. NSO developed a Next generation sequencing (NGS) targeted gene panel including genes associated to primary and secondary diseases targeted by the provincial NBS program. The genes targeted for interpretation can be chosen by positive screen results (i.e. elevated C5OH, PA/MMA, etc.), disease targeted, or it can be gene specific. Samples from newborns are all treated as STAT sample with a maximal turnaround time of 6 weeks (12 weeks for non-STAT samples). Within the first year of operation, our lab received 123 samples to test for the metabolic targets of newborn screening including 79 STAT samples for newborns or carrier testing for pregnant couples. All results were communicated to the ordering physician with an average turn-around time of 24.3 days between receiving a requisition and sending the report. Results were positives (2 variants) in 42% of the reports, carriers (1 variant) in 21% of the reports and negative in 38% of the reports. For at least 2 patients, the option to select interpretation by positive screen results helped us identify variants in secondary targets that would likely have been missed if only genes associated with primary targets were requested. We also received samples from older children and adults with a clinical diagnosis of a metabolic disorder, but for which genetic testing was not initially provided. The Ontario Government repatriation initiative helped us to offer a cost-effective, targeted and manageable approach for molecular diagnostic testing in newborns and families in Ontario. This additional testing by the provincial NBS laboratory helped to repatriate testing within the province and to facilitate molecular testing for health care provider, increasing accessibility for patients and family.

**Developing a genomics ready clinical workforce: From raising awareness to the establishment of a faculty of genomic medicine.** *M. Bishop, D. Callaghan, E. Miller, S. Simpson, A. McPherson, A. Pope, M. Foster, A. Seller.* Genomics Education Programme, Health Education England, Birmingham, West Midlands, United Kingdom.

By April 2018 whole genome sequencing (WGS) is expected to be commissioned for use in England's National Health Service (NHS). Health Education England's Genomics Education Programme (GEP) was established to ensure relevant staff groups are equipped in knowledge and skills to safely deliver their role in the patient pathway. While ensuring capacity and capability of the highly specialised genomic workforce is key, the greater challenge is to provide the right level of education to the wider workforce. The GEP has taken a top-down and bottom-up approach to address this issue. In 2014 the GEP established the flagship Master's programme in Genomic Medicine, delivered by 10 universities across England. The aim of this programme is to expand and extend the knowledge of trained health professionals by providing an academic grounding in genomics so they can act as clinical champions within their own specialism. To date 750 NHS professionals from all sectors of the workforce have completed at least 1 module of the Master's programme. Alumni will join the new NHS Faculty of Genomic Medicine which will serve as the centre of knowledge and expertise for genomic medicine. Concurrently, the GEP administered a cross-sectional survey of the NHS workforce ( $n=2578$ ) to identify education and training needs. Results show the majority of staff (80%) want further education in genomics, primarily on how genomics will impact their clinical role. In response to this the GEP has developed educational activities using innovative methods to raise awareness of the use of genomics in healthcare. In 2016, a 3 week Massive Open Online Course (MOOC) on WGS and its application in healthcare was launched. Over 3 iterations, the course registered >14,000 learners representing a range of professions within the NHS. Evaluation of course comments showed learners understood the use of genomic technologies and how genomics will influence their own sphere of practice. The GEP has also used social media as a tool to educate and inform different NHS staff groups through the facilitation of twitter chats. These 1 hour chats enable awareness raising and education at scale, with each chat having a total reach of >5 million. Analyses of tweet conversations show an evolution of participants' understanding of the relevance of genomics. These two approaches have ensured the GEP are responding to the learning needs of NHS staff, whilst also establishing a network of clinical champions within the NHS.

**Use of problem-based team learning to improve success of underrepresented students in an undergraduate genetics course.** *B. Bowling, E. Strome, D. Robertson.* Department of Biological Sciences, Northern Kentucky University, Highland Height, KY.

Active learning techniques in various science, engineering, technology, and mathematics courses have been shown to increase student success, particularly students coming from underrepresented backgrounds (Freeman 2014, Wieman 2014). Recent studies have begun to focus on specific ways to optimize active learning (e.g. Adams, Garcia, and Traustadottir 2016). We have implemented a model combining active learning techniques we refer to as problem-based team learning (PBTL) in which students are engaged in their learning inside and outside of class. This sophomore/junior level genetics course is required for all biology majors and a prerequisite for upper-level courses. The course includes introductory concepts in genetics and molecular biology such as DNA structure and function, gene expression and regulation, and population genetics. PBTL requires students complete readings and some online lectures prior to class and students are held accountable through individual and team readiness assessment quizzes (Michaelsen *et al.* 2004). In-class, students work collaboratively in permanent teams on application problems. We analyzed student success in the course based on risk factors including low income (as determined by Pell grant eligibility), underrepresented minority (self-reported), and first generation college student (self-reported). The average class size was approximately 50 students and those with risk factors comprised around half of the class. Four years of data with the same instructor indicate students with one or more of the risk factors were ~5 times more likely to succeed in the course (earning a C- or higher) when it was taught using PBTL than using less consistent active learning techniques. Student were also more likely to persist rather than abandon the course before and after the withdrawal deadline. Future work involves testing the efficacy of the PBTL model when adopted by other instructors in the genetics course as well as other courses within the curriculum, and further supporting underrepresented students in biology.

**569T**

**Phenotate: Crowdsourcing phenotype annotations of genetic disorders through student exercises.** *W.H. Chang*<sup>1,3</sup>, *A.X. Lozano*<sup>2,3</sup>, *M. Brudno*<sup>1,3</sup>, *G. Baynam*<sup>4,5</sup>. 1) Department of Computer Science, University of Toronto, Toronto, Ontario, Canada; 2) Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada; 3) Centre for Computational Medicine, Hospital for Sick Children, Toronto, Ontario, Canada; 4) Genetic Services of Western Australia, King Edward Memorial Hospital, Perth, Western Australia; 5) Western Australian Register of Developmental Anomalies, King Edward Memorial Hospital, Perth, Western Australia.

Creating and cataloging accurate, up-to-date, and standardized phenotype annotations for genetic diseases has tremendous clinical and research applications. In addition to providing clinicians with clear references to assist with diagnoses, especially for rare diseases, structured and computable annotations are used by algorithms to suggest a diagnosis based on a given set of phenotypes from a standardized terminology. The Human Phenotype Ontology (HPO) project provides a standardized nomenclature of phenotypes. However, the linkages between HPO and disease terminologies such as Online Mendelian Inheritance in Man (OMIM) and Orphanet Rare Disease Ontology (ORDO) are incomplete, while methods for differential diagnoses are heavily reliant on the quality of the annotations. Our project harnesses crowdsourcing, the use of large numbers of non-experts to collect high-accuracy knowledge, to generate and improve phenotype annotations between HPO and OMIM/ORDO. Phenotate is a web-based platform for undergraduate or medical students, as well as medical residents, to annotate OMIM/ORDO diseases with HPO phenotypes by completing classroom exercises. Students' responses are graded automatically against an expert-validated set of annotations for a given disease, while the ability to assign diseases without existing expert annotations expands the knowledgebase to new disorders. Annotations must reference the literature. Through these classroom exercises, new insights for a disease can be gained by observing which annotations are the most frequent, weighted by the students' grades for the exercise (a proxy of quality and reliability). The first class to use Phenotate was a second year undergraduate molecular genetics class (MGY200) at the University of Toronto in which 78 students annotated Marfan syndrome (MFS), congenital myasthenic syndrome (CMS), and Friedreich's ataxia (FA) with over 500 unique phenotypes across 72, 68, and 69 annotations, respectively. Overall, students provided more comprehensive annotations than clinicians who also submitted annotations: for MFS and FA, the most commonly entered phenotypes (ectopia lentis and dysarthria, respectively) were not present in the expert annotations, despite their relevance. Phenotate is an open platform, available for use by anyone teaching clinical genetics. Crowdsourcing annotations will enable a better understanding of genetic disorders, while offering students an educational tool that supplements their coursework.

**570F**

**The Genomics Education Partnership: Authentic big data course-based research projects for undergraduates.** *R.L. Glaser*<sup>1</sup>, *W. Leung*<sup>2</sup>, *D. Lopatto*<sup>3</sup>, *C.D. Shaffer*<sup>2</sup>, *S.C.R. Elgin*<sup>2</sup>. 1) Stevenson University, Owings Mills, MD; 2) Washington University in St. Louis, St. Louis, MO; 3) Grinnell College, Grinnell, IA.

Undergraduate research is one of the ten high impact practices (HIPs) in undergraduate education, as identified by the Association of American Colleges and Universities, that has been shown to positively impact retention and engagement. Since 2006, the Genomics Education Partnership (GEP), a collaboration of more than 100 diverse undergraduate colleges and universities and The McDonnell Genome Institute at Washington University in St. Louis (WUSTL), has provided authentic genomics research projects to undergraduate students. The GEP incorporates genomics research into the undergraduate biology curriculum to help faculty keep up with the rapid advances in the fields of genetics and genomics, and to introduce students to big data analyses. Current GEP research projects utilize comparative genomics to understand the evolution of the heterochromatic domains of the *Drosophila* Muller F element. GEP courses can be developed for any level and for multiple course settings. GEP courses can focus on the gene annotation of a recently sequenced *Drosophila* species, and/or sequence improvement, the latter involving a wet lab component. Annotation projects are designed to teach students about eukaryotic gene structure and genome organization, while introducing them to bioinformatics tools such as the UCSC genome browser. All GEP faculty have attended a training workshop at WUSTL to gain familiarity with the GEP protocols and curriculum materials. Completed student projects are submitted to WUSTL for quality control checks, after which they are pooled and the assembled data used in publications. Students who review, critique and approve the draft manuscript are eligible for co-authorship on the publication. Students enrolled in GEP courses report gains in knowledge about eukaryotic genes and genomes, and the scientific process, irrespective of institution type or course structure, with the learning gains in GEP courses being similar to those in summer research experiences. The GEP has recently developed curriculum for beginning college students, which focuses on involving freshman as well as community college students in the projects. In addition to supporting the *Drosophila* genome projects, the GEP is collaborating with the Galaxy Project to develop G-OnRamp, a platform that enables faculty researchers working with other species to develop genome browsers to aid in engaging students in genome annotation of their species of interest.

**571W****Utility of video-based education in the genetics clinic and beyond:**

**Developing alternative service delivery models.** P. Magoulas, D. Riconda, A. Lewis, H. Streff, S. Lalani, C. Shaw, A. Wallis, I. Machol, S. Chargois, L. Rosales, B. Lee. Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Education about genetic testing in a clinic setting has historically been provided by genetics specialists or other health care providers during face-to-face encounters. While this can be effective, it may not be the most efficient way to provide education in an increasingly busy and time-constrained genetics clinic environment. In addition, specialists with limited genetics training may order genetic tests for their patients without the assistance of genetics specialists. Thus, there is a greater need to educate an increasing number of patients about the nuances of genetic tests. We surmised that creating a series of educational videos to aid in the education and consenting process for certain genetic tests, such as whole exome sequencing (WES), could improve efficiency and increase patient understanding and satisfaction. The videos are meant to supplement the genetic counseling process by explaining basics of genetics, complexity of specific genetic tests, and types of results that may be returned. By providing patients standardized information, more clinician time can be spent providing answers to patient-specific concerns. Patient understanding may also be improved by viewing the video more than once. We were able to successfully integrate educational videos into the clinic workflow both during the clinic visit and outside of clinic by creating multiple internet-based platforms in which to view the videos. We also developed surveys that are completed before and after viewing the video to capture familiarity of the specific test and effectiveness of the video as an educational tool. For example, the average familiarity with WES before viewing the video was 2.05 on a Likert scale of 1 to 5 (1 = not familiar; 5= very familiar) (N=20). All of the respondents agreed that they had a better understanding of WES after viewing the video with an average score of 4.29 out of 5 (1=strongly disagree; 5=strongly agree) and that it provided a good explanation of WES (average score of 4.23). These preliminary data suggest that the video is an effective tool that increases knowledge and understanding. The utility of educational videos in both the genetics clinic and other subspecialty clinics can be an efficient mechanism to provide general education about genetic tests so that patient-specific questions and concerns can be addressed. Alternative delivery models, such as video education, will be necessary as complex testing in the genetics clinic and beyond increases.

**572T****An interactive video vignette successfully teaches pedigree analysis to undergraduates.** D.L. Newman<sup>1</sup>, L.K. Wright<sup>1</sup>, J.A. Cardinale<sup>2</sup>.

1) Gosnell School of Life Sciences, Rochester Institute of Technology, Rochester, NY; 2) Dept. of Biology, Alfred University, Alfred, NY.

Interactive Video Vignettes (IVVs) are an innovative online medium that engage users by incorporating prediction questions, data analysis and comprehension questions in an engaging and accessible way. A list of available biology-content IVVs can be found at <https://www.rit.edu/cos/interactive/>. We developed an IVV to teach students about Mendelian genetics in the context of a human disease. The storyline involves a college student working with his mother to construct their family's pedigree and decide whether or not they are at risk for Marfan Syndrome. This IVV was a little longer than most other IVVs (about 20 minutes) and incorporated many complex ideas that are known to be difficult for undergraduate students, including 1) *The relationship between genes, alleles and traits*, 2) *The genetic meaning of dominance*, 3) *Pedigree construction*, 4) *Pedigree analysis of a Mendelian trait*, and 5) *Calculating probability of inheritance*. Assessment questions that aligned with each of these concepts were developed and administered before and after students completed the IVV activity. Validation interviews were conducted to ensure assessment question clarity and to gain deeper insight into student thinking (N=14). Pre/post data and IVV usage metrics were gathered from eight classes (22-38 students per class) from three different institutions to investigate student understanding of the concepts linked to the main ideas addressed in the IVVs. All student populations studied showed improvement on the pre/post questions related to *pedigree construction*, *pedigree analysis of a Mendelian trait*, and *calculating probability of inheritance*. Our analysis also revealed that students enjoyed the activity, found the story engaging, and agreed that it enhanced their learning.

**573F**

**RGEODE: Mining big data in the high school or undergraduate biology classroom.** *K. Pirc-Hoffman*<sup>1,2</sup>, *J. Pevsner*<sup>2,4</sup>, *A.L. Norris*<sup>1,3,4</sup>. 1) Krieger School of Arts and Sciences, Johns Hopkins University, Rockville, MD; 2) Project Lead the Way (PLTW) Biomedical Science Program, Gaithersburg High School, 101 Education Blvd, Gaithersburg, MD 20877; 3) Department of Neurology, Kennedy Krieger Institute, 707 N. Broadway, Baltimore, MD 21205; 4) Department of Neuroscience, Johns Hopkins School of Medicine, 725 N. Wolfe St, Baltimore, MD 21205.

Despite the emerging role of big data in science today, bioinformatics is absent in most high school biology classrooms. Some science-focused curricula have integrated bioinformatics, but to a very limited extent. Given that data and tools are freely available online, an internet-enabled computer is all that is required to learn and perform bioinformatics analyses. Here we present R GEO Data Explorer (RGEODE), a gene expression module to facilitate integration of bioinformatics into the high school or introductory college biology classroom. To assist teacher-implementation, RGEODE is a complete module that includes resources for both the teacher and students. These resources include tutorial PowerPoint presentations, pre- and post-quizzes, student worksheets, and an example RGEODE analysis. Through the lesson sequence, students: (1) gain content knowledge of how eukaryotic genes are regulated and expressed, (2) learn basic R programming, and (3) implement R programming for gene expression analysis of a GEO microarray experiment. Field testing of the RGEODE module was conducted with a group of Project Lead the Way (PLTW) Biomedical Science students (n = 33) at Gaithersburg High School (Montgomery County, Maryland). The student cohort included both juniors (88%) and seniors (12%), with a slight sex-bias (64%) for self-identified females. Student knowledge content scores on gene expression increased an average of 10% from pre-quiz to post-quiz. The majority of students self-reported an increased interest in bioinformatics after the activity (80%). The challenges to implementation were technical in nature, notably restricted permissions and limited hard drive space on the school-provided laptops. Students who used their own laptops did not face these challenges. As a result, the module has been adapted to circumvent such challenges, through use of alternative implementation methods, including online web apps and pre-loaded USBs for students. RGEODE is a complete bioinformatics activity module appropriate for high school and introductory undergraduate biology classes. RGEODE leverages freely available gene expression data from NCBI GEO ([www.ncbi.nlm.nih.gov/geo/](http://www.ncbi.nlm.nih.gov/geo/)), analysis tools in R, and best practices from field testing. The RGEODE module complements existing high school curricula, including PLTW Biomedical Science (MI 3.1.4-5, BI capstone), NGSS (HS-LS-1-1), and AP Biology Framework (3.A.1.e).

**574W**

**No one's genome is more interesting than your own: Understand Your Genome® through experiential education.** *E. Ramos, M.A. McGinniss, J. Esposito, E. Thorpe.* Illumina, Inc., San Diego, CA.

**Background** Clinical whole genome sequencing (cWGS) continues to gain acceptance as the cost of sequencing decreases and studies demonstrating clinical utility are highlighted. Despite the accelerating pace of adoption, there are limited education options about cWGS available to a broad population. To address growing interest, the Understand Your Genome® (UYG) program was created to improve understanding, awareness, and engagement around cWGS via an experiential educational forum. **Methods** Full participants received physician-mediated cWGS through the CLIA-certified, CAP-accredited Illumina Clinical Services Laboratory, which included clinical interpretation of variants found in ~1690 genes associated with more than 1200 genetic disorders, access to their genome in an online visualization tool, and attendance to an educational symposium. A "watch and learn" option was introduced starting in November 2015 for symposium attendance only. At registration, attendees were asked questions about their professional backgrounds, understanding of genomics, and their motivations for attending the UYG program. Beginning in 2016, participants were surveyed immediately following the conference. Participants of 10 symposia completed identical surveys, and responses were tallied and analyzed. **Results** As of May 2017, 1932 individuals participated in one of 35 programs and 1437 had cWGS. 264 individuals completed the survey for a completion rate of 40% (range of 13-63%). Across these 10 symposia, 64% of participants responded that their interest in genomics had increased significantly. For the 3 programs that had the most diverse attendee background with lower genomic and medical literacy, 78%, 88% and 89% reporting a significant increase in interest. >82% reported an increase in their understanding of genomics, biology and common diseases, how genomics affects them, the clinical utility of genomics, and how genomics is being applied to improve patient care. 89% rated their experience as excellent or very satisfied. **Conclusion** A review of survey data from individuals participating in an experiential education program report increased interest in genetics, understanding of multiple facets of clinical genomics, and intent to continue engagement with their genomes. As the price of cWGS continues to drop, these data suggest that experiential education may support engagement and genomics education for a diverse population, including community genomics initiatives like the All of Us Study.

**575T**

**Breakthroughs and barriers in secondary/post-secondary partnerships designed to promote research in molecular genetics, human genetics and GMOs.** T.N. Turley-Stoulig<sup>1</sup>, A. Anderson<sup>2</sup>, A. Bertaut<sup>1</sup>, A. Call<sup>2</sup>, C. Carolina<sup>2</sup>, A. Hartley<sup>2</sup>, C. Hudspeth<sup>1</sup>, K. Humble<sup>1</sup>, I. Juarez<sup>1</sup>, T. Leonard<sup>2</sup>, N. Lorena<sup>1</sup>, M. McCormick<sup>2</sup>, D. Newton<sup>2</sup>, K. Phan<sup>1</sup>, J. Pursell<sup>2</sup>, R. Rieger<sup>1</sup>, C. Taylor<sup>1</sup>, H. Williams<sup>1</sup>, A. Ulloa<sup>1</sup>, H. Ulloa<sup>1</sup>, T. Tinney<sup>2</sup>. 1) Department of Biological Sciences, Southeastern Louisiana University, Hammond, LA; 2) Northshore Technical Community College, Lacombe, LA.

The field of genetics and associated technologies are advancing at a rapid pace, creating a great need to interest students in genetics for future study and better educate the general population to foster a better understanding of advancements being made and genetic services available. The purpose of this study was to increase genetics-based knowledge and comprehension, increase awareness of genetics technologies and research and encourage study in genetics and STEM disciplines in general for a range of students at progressive levels. Four high schools participated during the 2016-17 year following a pilot program the previous year with one participating high school. We used an innovative, multi-dimensional approach involving a university/community college partnership coupled with outreach that spans the fields of genetically modified organisms (GMOs) and human genetics by bringing laboratory techniques of both disciplines into classrooms of high school students, exposing them to genetics-based materials they would otherwise not encounter. A series of primer modules were used to educate students in basic genetics and train them in DNA isolation, PCR and GMO analysis through a series of practical modules. Instructional modalities included animations and hands-on techniques. The study spanned the academic year and involved training of undergraduate students from Southeastern Louisiana University who then taught Northshore Technical Community College students. The undergraduate cohorts then team-taught high school students in their high school classrooms and on the undergraduate campuses. Primer modules covered basic genetics concepts, human genetic disease, GMOs, and modern laboratory techniques. Practical modules provided laboratory extensions for conducting GMO experiments using techniques discussed in primer modules. Challenges were largely associated with attrition of community college students. We plan to modify the program in the future using feedback from community college students and greater involvement of community college faculty in an effort to increase retention. Results at all student levels indicated an increase in student understanding of genetics concepts and stronger interest in the study of cells and/or genes in the future. We conclude that this "ladder of learning" approach enhances the educational experience of community college, university and high school students in a unique and invaluable way and may be applied to other programs.

**576F**

**Effectiveness of a dedicated rotation in genomics, genetic medicine, and undiagnosed diseases for internal medicine residents.** M. Wheeler<sup>1,2</sup>, L. Geng<sup>2,3</sup>, J. Kohler<sup>1,2</sup>, P. Levonian<sup>4</sup>, R. Wittles<sup>1,3</sup>, J. Hom<sup>2,5</sup>, J. Ford<sup>4,5</sup>. 1) Division of Cardiovascular Medicine, Stanford University, Palo Alto, CA; 2) Center for Undiagnosed Diseases, Stanford University, Stanford, CA; 3) Internal Medicine Training Program, Department of Medicine, Stanford University, Stanford, CA; 4) Department of Genetics, Stanford University, Stanford, CA; 5) Division of Medical Oncology, Stanford University, Stanford, CA; 6) Division of General Internal Medicine, Stanford University, Stanford, CA.

Though genetics and genetically driven therapies are gaining importance in the care of adult patients, formal graduate medical education in genetics and genomics has not been a routine part of the internal medicine residency curriculum. To address this educational gap, we developed a rotation to provide targeted genetics and genomics education for internal medicine residents at Stanford University. The two-week rotation included subspecialty inherited diseases clinics with practitioners in medical oncology, cardiovascular disease, neurology, and medical genetics. In addition, residents participated in sessions with advanced practice members of the clinics including genetic counselors, physician-scientists, and nurse specialists. To complement the clinical educational component, residents attended clinical conferences focused on genetic diseases and were introduced to the Center for Undiagnosed Diseases (CUD), a clinical site of the Undiagnosed Diseases Network. Under the supervision of physician members of the CUD, residents could participate in the clinical evaluation of patients referred to the CUD. We surveyed participants to assess their experience in the rotation, their genetic literacy prior to and after the rotation, and to compare knowledge gained during the rotation with the educational experiences in other internal medicine residency rotations. Survey respondents identified increases in genetic literacy, new appreciation of genetic counseling, importance of family history taking, availability and affordability of genetic testing, and utility of genetics for clarifying diagnosis. Residents started with a wide range of genetic literacy, from a single course in medical school to doctorate in computational genomics; despite this diversity, all participants gained additional knowledge and described the rotation as a valuable addition to their graduate medical education. Exposure to the CUD was cited as a valuable addition, as was the opportunity to focus on diagnosis and to delve deeply into a challenging case. As graduate medical education continues to evolve, our experience demonstrates that integration of genetics and genomics into the training of internal medicine residents is feasible, effective, and desired by trainees. Similar rotations more broadly implemented may be a viable intermediate to existing joint training programs in internal medicine and medical genetics.

**577W**

**Perspectives and barriers to adoption of infobutton-related technologies for genomic medicine.** L.V. Rasmussen<sup>1</sup>, S.J. Aronson<sup>2</sup>, J.J. Connolly<sup>3</sup>, G. De Fio<sup>4</sup>, R.R. Freimuth<sup>5</sup>, J.J. Murray<sup>6</sup>, D.B. Pet<sup>7</sup>, J.F. Peterson<sup>7</sup>, B.H. Shirts<sup>8</sup>, M.S. Williams<sup>9</sup>, C.L. Overby<sup>9,10</sup>. 1) Department of Preventive Medicine, Northwestern University, Chicago, IL; 2) Partners HealthCare, Boston, MA; 3) The Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA; 4) Department of Biomedical Informatics, University of Utah, Salt Lake City, UT; 5) Department of Health Sciences Research, Mayo Clinic, Rochester, MN; 6) Department of Internal Medicine, Meharry Medical College, Nashville, TN; 7) Vanderbilt University School of Medicine, Nashville, TN; 8) Department of Laboratory Medicine, University of Washington, Seattle, WA; 9) Genomic Medicine Institute, Geisinger Health System, Danville, PA; 10) Department of Medicine, Johns Hopkins School of Medicine, Baltimore, MD.

**Background** Infobuttons – context-sensitive links embedded in electronic health record (EHR) systems or patient portals – can connect providers and patients to more relevant information resources for complex medical topics, including genomic medicine. Little is known about individual and institutional perspectives on infobutton implementation. **Methods** A survey was developed by the electronic Medical Records and Genomics (eMERGE) consortium's Infobutton sub-group to assess perceptions about infobuttons, the OpenInfobutton software (OIB), ClinGen EHR toolkit (CG), and two eMERGE-developed systems (DocUBuild [DUB] and MyResults.org [MR]). The survey was distributed to several major consortium-driven initiatives that are focused on implementing genomic medicine: ClinGen, CPIC, CSER, DIGITizE, eMERGE, GA4GH, IGNITE, and ISCC. **Results** In total, 25 unique responses from 19 institutions were received. The majority of respondents did not have infobuttons enabled for genomic content at their institution (n=16, 64%), and did not have or were not aware of plans to expand their availability (n=20, 80%). Respondents generally agreed they felt knowledgeable about infobuttons (n=17, 68%), but less so for specific software platforms (OIB: n=11, 44%; CG: n=5, 20%; DUB: n=8, 32%; MR: n=9, 36%). Regarding experiences and opinions about specific software systems, responses in the survey were optional, and 24 respondents completed at least one question about their experiences with and opinions about OIB, 20 about CG, 19 about DUB and 19 about MR. For two software systems (CG, DUB), respondents were mixed neutral (NT) and in agreement (AG) on the impact the systems would have on improving infobutton adoption (CG: NT=8/20 [40%], AG=9/20 [45%]; DUB: NT=9/19 [47.4%], AG=7/19 [36.8%]). For these systems, the largest perceived adoption barrier was lack of adaptability to local needs (CG=8, DUB=6, MR=6), with other perceived barriers including system complexity, and lack of ability to conduct a small-scale trial. **Conclusion** Institutions involved in genomic medicine initiatives are not widely using infobuttons for genetic results, but do anticipate benefits from recent projects focused on infobutton implementation and adoption. More importantly, perceived barriers are noted toward adoption, which system developers may proactively address.

**578T**

**Evaluating nonresponse bias in a longitudinal study of healthy adults receiving genome sequencing.** S.D. Crawford<sup>1</sup>, M.D. Linderman<sup>2,3</sup>, M. Ball<sup>4</sup>, M.A. McGinniss<sup>4</sup>, J. Esposito<sup>4</sup>, E. Ramos<sup>4</sup>, R.H. Young<sup>1</sup>, R.C. Green<sup>5,6,7,8</sup>, PeopleSeq Consortium. 1) SoundRocket, Ann Arbor, MI; 2) Department of Computer Science, Middlebury College, Middlebury, VT; 3) Open Humans Foundation, Boston, MA; 4) Illumina, Inc., San Diego, CA; 5) Division of Genetics, Brigham and Women's Hospital, Boston, MA; 6) Broad Institute of MIT and Harvard, Cambridge, MA; 7) Harvard Medical School, Boston, MA; 8) Partners HealthCare Personalized Medicine, Cambridge, MA; 9) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY.

The PeopleSeq Consortium is a multi-site longitudinal study designed to measure medical, behavioral and economic outcomes after elective sequencing of ostensibly healthy individuals. The study design consists of a pre-test survey (fielded prior to sequencing report disclosure), a post-test survey (fielded approximately three months following report disclosure), and annual follow-up surveys thereafter. Participants are recruited via email invitations, and nonresponders are reminded to participate via a series of follow-up emails. In an ongoing recruitment, approximately 1,437 individuals have been invited to participate. Approximately 513 have participated, giving us a response rate of ~36%. Nonresponse is only problematic if those who do not respond are different than those who do respond, resulting in a nonresponse induced bias. Current best practices in survey research suggest that response rates are not a good proxy for data quality, and that other information is needed to evaluate the potential for nonresponse bias at the case or item level. Individuals who undergo personal genome sequencing at one of the collaborating sites are eligible for inclusion in the PeopleSeq Consortium so the study is in a unique position to know a little bit about all eligible participants. As such, aggregate and individual data, including basic demographics and other measures of interest in evaluating possible nonresponse bias, can be obtained about both nonresponders and responders. In our study, these data include gender/sex, race/ethnicity, age, education, adoption status, and employment field. By analyzing the differences between responders and nonresponders on these measures, we can build an understanding for how nonresponse may or may not be introducing a bias in our study. These data will be the first data on nonresponse in a study of outcomes from personal genome sequencing of ostensibly healthy individuals who have had healthy sequencing. Understanding the potential for bias in this way also enables us to assess the overall quality of the data that is collected. We will discuss the likely impact response rate increasing efforts may have on any possible bias we detect.

**579F**

**MyCode participants' research priorities for precision health.** *E. Huang<sup>1</sup>, A.K. Rahm<sup>2</sup>, C. Flansburg<sup>2</sup>, J.K. Wagner<sup>2</sup>.* 1) Lafayette College, Easton, PA; 2) Geisinger Health System, Danville, PA.

**Introduction:** Participant engagement has previously been identified as a key component to long-term success of precision health initiatives, whether such initiatives are at a national scale such as the All of Us Research Program or a regional scale such as the MyCode Community Health Initiative. Building communities, including participants in research design and implementation decisions, providing access to information, and reporting findings from such research and innovation projects foster durable, trusted relationships and shared investment in our biomedical future. **Methods:** An online survey was administered to MyCode participants to elicit their input on environmental data to be integrated with genomic and electronic health record data in precision health projects conducted at Geisinger Health System. The survey collector was open from June 7 to July 31, 2016, and a total of 77,629 participants were invited to the survey (62,629 using the MyGeisinger patient portal were recruited online and a random sample of 15,000 not using MyGeisinger were recruited via postcard). Content analysis was performed on free-text responses submitted. **Results:** A total of 6,091 participants responded (7.8% response rate) and submitted 9,815 free-text responses to a question eliciting suggestions for health outcomes, medical conditions, or topics for prioritized study. Respondents emphasized the study of causes of disease and health conditions and not just their cures; treatments and diagnostics; or prevention. While cancers were most prominent among specific conditions, the most popular medical specialties covering respondents' suggestions were, in ranked order, neurology, gastroenterology, and immunology. Environmental aspects suggested focused on water quality, fracking impacts, air quality, genetically modified organisms, and exposures to asbestos, radon, and lead. Respondents suggested a few interesting unexpected topics for study, including the health effects of technology usage. **Conclusions:** Participant engagement requires considerable institutional commitment, dedicated resources, and recognition of the value in shared decision-making. Empowering participants to shape research priorities is one way to remind participants of their enrollment in longitudinal projects, build mutual respect, manage expectations for progress, and promote shared scientific vision. Next steps are to integrate these results into future plans for MyCode.

**580W**

**A conceptual framework for genome sequencing: Adaptation of the Theory of Planned Behavior.** *L. Hull<sup>1</sup>, J. Vassy<sup>1,2,3</sup>.* 1) VA Boston Healthcare System, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Brigham and Women's Hospital, Boston, MA.

The outcomes of whole-genome or whole-exome sequencing depend on the quality of the decision-making process; these outcomes may include patient understanding of sequencing results, psychological impact of results, changes in behavior in response to sequencing, healthcare utilization and cost, and decisional satisfaction and regret. The decision to pursue sequencing is complicated given that the results may be inconclusive or contain additional information unrelated to the original reason for sequencing. Therefore, true informed consent for sequencing depends on a patient's understanding of its risks and benefits. Many studies have explored the motivations and concerns of patients undergoing sequencing; however, a framework to approach how patients assess the risks and benefits of sequencing, and ultimately decide whether and how they pursue sequencing, has not been formally described. We performed a narrative review in which we synthesized the themes elicited in previous work regarding the decision to pursue or decline sequencing, mapping these to the Theory of Planned Behavior (TPB) model. We found several descriptive, qualitative, mixed-methods, and survey-based studies that have evaluated the motivations and concerns of individuals pursuing sequencing; however, only one study specifically focused on the concerns of sequencing study decliners. Participants' motivations and concerns have stemmed from personal, altruistic, and family-related considerations. Trust in providers and research institutions were high among individuals participating in studies, but may not be representative of the larger population. Intention to pursue sequencing was high and did not change after informed consent among well-educated study enrollees. We conclude that further study is needed of more diverse cohorts of individuals both pursuing and declining sequencing, to better understand their decision-making process. Additional areas of study could include studying trust and barriers to participating in sequencing, especially among sequencing decliners. The effects of informed consent as a possible modifier of initial intention to pursue sequencing should be evaluated in populations with lower baseline enthusiasm or lower education levels. Given, these findings, we propose a theoretical framework, derived from the TPB, to conceptualize how patients approach the decision to pursue or decline sequencing; this framework helps to highlight areas for future investigation.

**581T****Special considerations for genomic sequencing research in the United States Air Force: Development of the MilSeq Project.**

*M.D. Maxwell<sup>1</sup>, J. Vassy<sup>2</sup>, C. Gardner<sup>3</sup>, C. Blout<sup>4</sup>, S. Pereira<sup>5</sup>, M. Mehlman<sup>6,10</sup>, E. Parasidis<sup>11</sup>, K. Christensen<sup>1</sup>, J.O. Robinson<sup>5</sup>, A. McGuire<sup>5</sup>, M. Lebo<sup>6,7,8</sup>, M. De Castro<sup>2</sup>, R. Brenner<sup>9</sup>, B. Morgan<sup>4</sup>, R. Green<sup>1,6,8,12</sup>.* 1) Department of Medicine, Brigham and Women's Hospital, Boston, MA; 2) Air Force Medical Genetics Center and Molecular Diagnostic Laboratory, Keesler AFB, MS; 3) Air Force Medical Support Agency, Falls Church, VA; 4) 59th Medical Wing, Joint Base San Antonio – Lackland AFB, TX; 5) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 6) Harvard Medical School, Boston, MA; 7) Department of Pathology, Brigham and Women's Hospital, Boston MA; 8) Partners Personalized Medicine, Boston, MA; 9) The Law-Medicine Center, Case Western Reserve University School of Law, Cleveland, OH; 10) Biomedical Ethics, Case Western Reserve University School of Medicine, Cleveland, OH; 11) Moritz College of Law and College of Public Health, Ohio State University, Columbus, OH; 12) The Broad Institute of MIT and Harvard, Cambridge, MA.

**Purpose** The Genetic Information Nondiscrimination Act (GINA) of 2008 protects against health insurance and employment discrimination among civilians who undergo genomic sequencing (GS), but does not apply to active-duty military personnel. Although the military routinely performs select carrier screenings and incorporates protections afforded by the National Defense Authorization Act (NDAA) of 2008, we aim to explore a range of considerations unique to GS in the military. **Methods** In collaboration with United States Air Force (USAF), we have developed a pilot research protocol, the MilSeq Project, in which GS will be performed on 75 ostensibly healthy, active-duty Airmen. Pathogenic and likely pathogenic variants as well as autosomal recessive carrier status will be reported to Airmen participants by USAF healthcare providers who have received brief genomics training and are supported by a genetic counselor. Relevant pharmacogenomic variants and disease-associated risk alleles will also be reported. Reports will be permanently incorporated into the Airmen's military medical record after disclosing results. To maximize the safety of the research protocol, we examined the applicability of GINA, NDAA, other federal regulations, and basic human subject research rights to the military population. **Results** Special considerations for genomic research in the military include: 1) institutional considerations, as the military operates within a hierarchical rank structure which can influence a service member's voluntary participation in research; 2) the potential for adverse career outcomes, as medical records can be reviewed when evaluating assignments and promotions, with injury prevention and duty disruption as primary concerns. Therefore, Airmen in certain military occupational specialties may be deemed unfit for duty or discharged if determined to be at risk or symptomatic of certain genetic conditions. However, based on current literature, a variant that could impact an Airman's career is expected to be found in less than 1% of individuals who receive GS. These considerations are clearly delineated in the MilSeq Project informed consent process. **Conclusion** The implementation of GS in the military includes considerations that are distinct from a civilian cohort and therefore data are not directly comparable. We have developed a protocol for the MilSeq Project that is sensitively designed to begin collecting reliable outcome data regarding the use of GS in the military.

**582F****"It's not an easy language for me to understand": Australians' expectations of support from health professionals for interpretation of personal genomic test results.**

*S. Metcalfe<sup>1,2</sup>, C. Hickerton<sup>1</sup>, R. Tytherleigh<sup>1</sup>, J. Savard<sup>3</sup>, E. Tutty<sup>1</sup>, C. Gaff<sup>1</sup>, K. Gray<sup>3</sup>, A. Middleton<sup>4</sup>, A. Newson<sup>4</sup>, A. Nisselle<sup>1,2</sup>, E. Stackpoole<sup>1</sup>, B. Terrill<sup>1</sup>, E. Turbitt<sup>1</sup>, B. Wilson<sup>8</sup>.* 1) Genetics Education and Health Research and Dept Paediatrics, Murdoch Childrens Research Institute and The University of Melbourne, Parkville, Melbourne, Victoria, Australia; 2) Australian Genomics Health Alliance; 3) The University of Sydney, Sydney, NSW, Australia; 4) The Walter & Eliza Hall Institute and Melbourne Genomics Health Alliance, Parkville, Melbourne, Victoria, Australia; 5) The University of Melbourne, Parkville, Melbourne, Victoria, Australia; 6) Wellcome Trust Sanger Institute, Hinxton, UK; 7) Garvan Institute of Medical Research, Sydney, NSW, Australia; 8) University of Ottawa, Ottawa, Ontario, Canada.

**Background.** Australians can order personal genomic tests (PGT) directly from companies online, via medical professionals or alternative health practitioners. PGT companies claim to provide information about an individual's health (including nutrition/genomic wellness/fitness) and/or ancestry. Surveys of Australian genetic health professionals (GHPs) have shown an increase from 11.3% (2011) to 51.1% (2017) seeing clients about PGT, raising concerns about the impact on publicly-funded health services. Many are not comfortable discussing PGT results and some services now refuse to do this. **Aim.** To explore Australians' interest in PGT and their expectations of support for result interpretation. **Methods.** The online GeNIOz survey was available to the public from April 2016 to May 2017. Quantitative data were analysed descriptively in STATA. Qualitative interviews were also conducted and coded independently using thematic analysis. **Results.** 2,806 Australians attempted and 2,393 fully completed the survey. 22.5% (572/2,538) had genetic testing, with 15.1% having had a medical/health-related PGT, while another 32.0% considered such a test, and 10.7% had ancestry testing. All respondents were asked about whom they would approach to help them understand their health-related test results: 77.7% selected general practitioners (GPs), 57.4% selected GHPs, and 7.5% selected alternative health practitioners. Furthermore, 55.8% selected GPs and 44.2% selected GHPs, even for non-health related tests. Some interviewees who had ancestry testing discussed downloading their raw data to conduct further analysis using online programs or companies, including to obtain health information, occasionally taking these results to a health practitioner for interpretation. Other interviewees had *MTHFR* and other 'genomic wellness' tests and some turned to alternative health practitioners for support. **Conclusion.** In our sample, 47.1% Australians have either had or are interested in having a personal genomic test for health-related reasons, including testing for 'genomic wellness', as marketed in Australia. Their views regarding from whom they would seek support to interpret these tests have workforce implications, not only for genetic health services which are traditionally publicly funded with a medical focus, but also for GPs and alternative health practitioners (naturopaths/nutritionists) who often have limited understanding of these types of tests and their clinical significance.

**583W**

**The duty to warn at-risk relatives: The experience of genetic counselors and medical geneticists.** *T.J. Perry, M.B Farmer, C.B. Hurst, G. McGwin, N.H. Robin.* University of Alabama at Birmingham, Birmingham, AL.

Most genetic counselors and medical geneticists will experience patient refusal to warn an at-risk relative. When faced with such a situation, conflicting laws, professional guidelines, and ethical obligations may lead to confusion regarding whether a clinician has a duty to warn their patient's relatives of genetic risk. Dugan, et al. (2003) and Falk, et al. (2003) surveyed genetic counselors and medical geneticists, respectively, to examine their clinical experiences with the conflict of duty to warn versus patient confidentiality. This issue has become increasingly relevant as the actionability and breadth of genetic test results has significantly increased since 2003, and pertinent federal laws have been implemented which did not exist at the time of those past studies. Using a modified and merged version of the Dugan and Falk surveys, we sought to understand if interim changes in the field of medical genetics have led to shifts in how clinicians are experiencing, and therefore reacting to, patient refusal to inform at-risk relatives. Compared to the majority of clinicians surveyed by Dugan and Falk, only 30% (77/258) of medical geneticists and genetic counselors believed they had a duty to warn their patients' relatives of genetic risk. However, neither profession was less likely to seriously consider notifying at-risk relatives without patient consent than in the previous studies. Of those who considered warning an at-risk relative, two genetic counselors and no medical geneticists actually proceeded with notification of an at-risk relative without patient consent. Only 8% (21/259) of participants believed professional guidelines effectively address the issue of duty to warn. Of those who felt current guidelines do not address the issue, 60% were not aware of relevant American Society of Human Genetics guidelines. Similar to the results of Dugan and Falk, the majority of medical geneticists (59% 30/51) and almost half of genetic counselors (46%, 95/206) experienced patient refusal. Yet awareness of federal and state laws which regulate the disclosure of genetic information to at-risk relatives remains surprisingly low. These results suggest that because the conflict of duty to warn remains a common experience among genetics professionals, educational resources are needed to facilitate informed decision making. Furthermore, participants' opinions of current policies and clinical decisions may guide future policies and professional positions.

**584T**

**A legal analysis of the loss of chance doctrine in the context of genomics and precision medicine.** *J. Wagner.* Geisinger Health System, Danville, PA.

Genetic professionals have long been concerned about legal liability, including liability risks that might attach when decisions are made to return or alternatively withhold data or results from individuals to whom those pertain. Professional organizations have statements and recommendations regarding what to return and when. Labs do not routinely reanalyze data or recontact individuals with updated information as genomic science and technology advances, and there is general consensus that researchers do not have duties to look for or report all findings. Nevertheless, when broad genomic research is conducted where participants are also patients and when institutional policy or research protocol stipulates data or results will be withheld (regardless of rationale), there are concerns about when and how individuals might ultimately learn this information and whether the discovery will be too late to avoid (1) the progression of a condition for which prevention or treatment was available or (2) unnecessary harms such as ineffective treatments for which substitutes were available. The loss of chance doctrine is a legal theory available in some states that, in the context of medical malpractice but not research, enables a plaintiff to recover from a defendant whose breach of duty reduced the chance of a favorable outcome (such as a delayed diagnosis or treatment resulting in diminished chance of recovery or survival). There is a paucity of critical analysis of this legal doctrine, despite acknowledgement by some of its relevance to the genetics field. Even the American Law Institute has not yet taken a position despite the doctrine's first court appearance 50 years ago. A systematic search of cases invoking the loss of chance doctrine was performed using Thomson Reuters Westlaw in Spring 2017. Cases identified were briefed using standard legal research methodologies (i.e., analysis of parties, facts, history, holding, principles, and rationales). 862 cases were identified, including 681 state and 181 federal and including 70 in PA, NJ, & DE (states in US 3rd Cir). This legal doctrine is poorly understood and manifested differently across jurisdictions within the medical malpractice context. In light of the legal uncertainty and given the perceived burdens making ongoing reanalysis and recontact of all participants infeasible, adoption of policies to provide prompt and broad data access to patient-participants as a risk mitigation strategy should be considered.

**Medical relevant findings from whole exome sequencing for apparently healthy individuals in physical examination of Chinese people.** Z. Xia<sup>1</sup>, S. Han<sup>1</sup>, D. Chen<sup>1</sup>, W. Yuan<sup>1</sup>, N. Li<sup>1</sup>, S. Wang<sup>1</sup>, M. Qi<sup>1,2,3</sup>. 1) School of Medicine, Zhejiang University, Hangzhou, Zhejiang province, China; 2) James Watson Institute of Genome Sciences; 3) Department of pathology and laboratory Medicine, University of Rochester, NY, USA.

**Background:** Whole exome sequencing (WES) has been proved to be a very powerful approach to identify new disease genes and molecular diagnosis of unknown clinical cases. However, limited studies reported on if this approach could provide useful information and should be offered to the apparently healthy people. **Methods:** WES was performed on 2 patients with clinical findings and 29 self-claimed 'healthy' individuals at an Illumina HiSeq platform. 1493 genes were analyzed for 303 monogenic disorders including inherited cancers, cardiac arrhythmias, high prevalent genetic diseases, inborn errors of metabolism, age-related diseases, neuromuscular diseases, skin disorders, and eye diseases. Variants of pathogenic, likely pathogenic as well as variants of unknown significance (VUS) were reported according to the current ACMG guidelines. Genetic counseling was provided. **Results:** One pathogenic mutation consistent with the clinical diagnosis, a VUS matched to family history, and 112 susceptible variants were identified and reported. Seventy-five pathogenic or likely pathogenic (P/LP) variants in 56 genes occurred 102 times in 30 individuals who might or would be affected. Thirty-six P/LP variants appeared 45 times (34 gene, 22 individuals) in autosomal recessive carriers. One X-linked recessive pathogenic variant appeared in 2 unrelated female carriers. **Conclusions:** This study suggests that WES for apparently healthy people, will enable effectively physicians to take appropriate measures for disease diagnosis, prevention and treatment in their patients. It will also help these individuals to prevent the genetic disease passed down to their offspring.

**586W**

**How Filipino parents cope with having a child with Maple Syrup Urine Disease.** M.R. Tumalak<sup>1</sup>, C.D. Padilla<sup>1</sup>, M.Y. Laurino<sup>1</sup>, E.S. Regalado<sup>2</sup>, A.V. Legaspi<sup>3</sup>, E.R. Ventura<sup>4</sup>. 1) University of the Philippines-Manila, Manila, Philippines; 2) University of Texas Health Science Center, USA; 3) Bow Valley College, Canada; 4) University of the Philippines-Diliman, Quezon City, Philippines.

**Introduction:** In the Philippines, maple syrup urine disease (MSUD) is the most common inborn error of metabolism (IEM). A family may experience stress, anxiety, sorrow, or feelings of helplessness when a child is diagnosed to have a genetic disorder that may lead to chronic care and disability. An illness in a child affects not only the child, but the whole family as well. **Methods:** The phenomenological approach was used in this study, in order to capture the coping experience of the participants. A total of 12 parents were interviewed using a semi-structured set of questions. **Result:** Knowledge of MSUD, the coping strategies used and their advice for other parents were considered to be part of their coping mechanism in the diagnosis of the disease in their child. The families used different coping strategies, such as information seeking, acceptance of their fate, and strengthening their belief in God, for them to be able to adapt to their situation. **Conclusion:** The findings of this study describe the different coping processes used by the families. It will help form policies and guidelines for genetic counseling of MSUD patients and their families in the Philippines. This aims to assist families in coping with the diagnosis and improve outcomes of affected children.

**587T**

**Experience and specialty impact processes for interpretation and clinical application of genetic test results.** C. Berrios<sup>1</sup>, E. Hurley<sup>2</sup>, I. Thiffault<sup>1</sup>, L. Zellmer<sup>1</sup>, C. Saunders<sup>1</sup>, S. Soden<sup>1</sup>, K. Goggin<sup>2</sup>, L. Willig<sup>1</sup>, E. Farrow<sup>1</sup>. 1) Center for Pediatric Genomic Medicine, Children's Mercy, Kansas City, MO; 2) Division of Health Services and Outcomes Research, Children's Mercy, Kansas City, MO.

Significant efforts have been made in recent years to standardize laboratory classification of genetic variants, including the publication of guidelines by professional societies. However, the impact of genetic testing on patient care ultimately depends on the clinician's interpretation of results. Clinician interpretation and application of results can be highly variable. To date, little is known about clinicians' cognitive processes and behaviors that may explain this variability. This study explores how clinicians across diverse specialties review and interpret genetic test results. We surveyed clinicians who return test results to patients/families regarding frequency of returning results, investigation of differing variant classifications, and resources used. A subset of participants completed in-depth interviews about their approach to reviewing lab reports, interpreting variants, applying findings, and communicating results to patients/families. Of the 93 survey respondents, 33% returned genetic results > 3x/month and 46% did so < 1x/month. Behaviors in investigating results varied, but for variants of uncertain significance (VUS) a majority "sometimes/frequently/always" sought laboratory or genetic specialist consultation (80.7%) and conducted additional research (74.1%). Clinicians who less frequently returned results were more likely to seek consultation ( $\chi^2(2)=6.87$ ,  $p=0.032$ ) or conduct additional research ( $\chi^2(2)=10.64$ ,  $p=0.005$ ) on pathogenic variants. All participants were equally likely to use PubMed and OMIM, with a minority accessing other resources. Those who frequently returned results were more likely to use HGMD ( $\chi^2(2)=9.18$ ,  $p=0.010$ ) and ClinVar ( $\chi^2(2)=25.15$ ,  $p<0.001$ ). Follow-up interviews ( $n=24$ ) corroborate survey findings regarding frequent investigation of VUS and differences in resources used. Providers with specialty or significant experience in genetics referenced more detailed discussions of VUS with patients and, in some cases, reinterpretation of a laboratory variant classification for clinical care. Reinterpretation was influenced by representative and availability heuristics, trust in the laboratory and institutional resources, and confidence in clinical expertise. Our results reveal divergent processes in clinician interpretation of genetics results based on specialty and experience. Further study of factors influencing clinical variant interpretation are needed to improve standardization of genomic medicine.

**588F**

**A comparison of international policies on CRISPR and gene modification technologies and the risk of lag in Canadian science.** Z. Master<sup>1</sup>, P. Bedford<sup>2</sup>. 1) Alden March Bioethics Institute, Albany Medical College, Albany, NY; 2) Centre for Commercialization of Regenerative Medicine, Toronto, ON.

CRISPR/Cas gene editing technology has been touted to have widespread applications to human health because of its accuracy in genome modification and ease of use. While many scientific societies and national and international organizations have drafted statements and policies in an attempt to promote research, the situation remains unclear on the permissibility of germline gene modification research using CRISPR under Canadian legislation. Compared with the U.S. and U.K., Canada's law on genome modification may be considered restrictive. Under appropriate ethical oversight, research involving germ cell gene editing is authorized by the European Academies Science Advisory Council and the National Academies of Sciences, Engineering, and Medicine. A group of Canadian scholars contend that the Assisted Human Reproduction Act (AHRA) is ambiguous, and have interpreted the legislation to prohibit the use of CRISPR technology on human embryos. We interpret the policy to permit the use of CRISPR under specific conditions, but agree that clarification from Health Canada is required before moving forward. Based on our analysis of the AHRA, Parliamentary debates and previous policy reports, we argue that CRISPR research might be permissible using surplus embryos where appropriate evidence demonstrates negligible likelihood of transmission to descendants or when researchers do not intend to transfer embryos to induce pregnancy. Canadian legislation contains a germline prohibition focused on the transmission of genes to future descendants. An examination of the legislative history shows that the intent behind the prohibition was to prevent genetically modified children and concerns at the time did not focus on research using surplus embryos. We also contend that CRISPR technology may be allowed in cases where gametes used to create embryos focus on studies intended to improve assisted reproductive technologies as Canadian legislation permits the creation of embryos for such purposes. Aligned with some national policies, Canada could permit germline editing under appropriate ethical safeguards while prohibiting germline modification to future generations. Clear direction is required from Health Canada on interpreting the legislation as international trends will compel Canada to make more permissible legislative amendments or risk a lag in Canadian science and innovation regarding the use of gene modifying technologies.

**589W**

**What determines value for genomics-informed healthcare? Evidence from a discrete choice experiment.** D. Regier<sup>1,2</sup>, D. Veenstra<sup>3</sup>, A. Basu<sup>3</sup>, S. Jagori<sup>3</sup>, J. Carlson<sup>3</sup>. 1) ARCC-CCR, BC Cancer Agency, Vancouver, British Columbia, Canada; 2) School of Population and Public Health, University of British Columbia; 3) Pharmaceutical Outcomes Research and Policy Program, Department of Pharmacy, University of Washington.

**Introduction:** The uptake of precision medicine has been varied. Evidence that enumerates individuals' preferences is needed to inform the worth of precision medicine interventions and future research agendas. **Objective:** To determine the impact of genomic information, scientific uncertainties, cost, and health outcomes on preference-based utility and willingness to pay (WTP) for genomics-informed healthcare. **Methods:** We used a sequential mixed methods approach. Qualitative research with patients identified the following attributes as important: type of genetic test, penetrance, medical expert agreement on changing medical care based on genomic information, quality of life, life expectancy with statistical uncertainty on outcomes, and cost. The discrete choice experiment method was used to enumerate preference-based utility and value. The target population was a sample of the American lay public. Analyses allowed for preference heterogeneity to characterize individual-level utility. **Results:** The lay public (n=101) stated strong positive utility for increasing levels of medical expert agreement and moderate disutility for quantity of life gains with a high degree of statistical uncertainty. Average WTP to receive genomics-guided care where identified disorders had high-penetrance, a high level of medical expert agreement, improved quality of life, and improved quantity of life by 3 months with a high degree of statistical certainty was \$1700 (95% CI, \$1029,2371). WTP decreased to \$1231 (95% CI 532,1929) when the uncertainty around quantity of life gains significantly increased. **Discussion:** The value of precision medicine technology to the public is significantly influenced by medical expert agreement and the degree of scientific uncertainty surrounding health outcomes. These findings can be used to project the economic value of and demand for genomics-guided health care, as well as inform a translational genomics research agenda.

**590T**

**Measuring health outcomes in telegenetics.** J. Stock<sup>1</sup>, D. Maeise<sup>2</sup>, S. Mann<sup>3</sup>, M. Lyon<sup>2</sup>, A. Keehn<sup>2</sup>, D. Flannery<sup>2</sup>, M. Watson<sup>2</sup>. 1) Seattle Children's, Seattle, WA, USA; 2) American College of Medical Genetics and Genomics, Bethesda, MD, USA; 3) Hawaii Department of Health, Honolulu, HI, USA.

**Purpose** To improve access to genetic services, the National Coordinating Center (NCC) for the seven Regional Genetic Networks (RGNs) supports the use of telegenetics – genetic services delivered through interactive video conferencing. In 2017, work began on a menu of health outcome measures for genetic services. The goal is to standardize the collection of data about genetic services; to describe the value of genetic services to insurers, other funding sources, and healthcare decision-makers, as well as families; and to assess the similarities or differences in patient health when genetic services are provided via interactive videoconferencing or as in-person visits. This performance measurement work complements the current NCC/RGN set of common evaluation data elements to assess telegenetic visit characteristics; provider and family satisfaction; provider and family time and travel costs; and family experience. **Methods** The NCC Telegenetics Workgroup developed a *Framework for Health Outcomes Measurement in TeleGenetics* that includes descriptions of telemedicine models, genetic services interventions, and outcome types (individual patient, family, health system). A literature review was conducted by Seattle Children's medical librarian using Medline and PsychInfo from 2006 forward. The search found 78 abstracts that measured outcomes after the provision of interactive video conferencing for health purposes between a provider and patient. Abstracts which measured only satisfaction were excluded. Two surveys conducted by the NCC found low rates of interactive video conferencing utilization by genetic professionals (18%-35.7%). **Results** With too few clinical geneticists and genetic counselors; geographic disparities in the distribution in genetic professionals; and patient distance to genetic services, telegenetics is a potential solution to current access barriers. Performance measures that encompass prenatal counseling, cancer genetics, newborn screening follow-up and disease management are needed to evaluate changes in access to services for patients with genetic conditions, especially the medically underserved. Through technical assistance to promote the use of telemedicine, the NCC seeks input from genetic specialists and affected individuals and their families to make for meaningful outcomes measures. The NCC at the American College of Medical Genetics and Genomics is funded by the Health Resources and Services Administration UH9MC30770-01-00..

**Reproductive decision making process, medical concerns and special needs of preimplantation genetic diagnosis (PGD) users: Lessons from qualitative and quantitative analysis.** S. Zuckerman<sup>1,2</sup>, S. Gooldin<sup>3</sup>, B. Savitsky<sup>4</sup>, G. Altarescu<sup>1,2</sup>. 1) Shaare Zedek Medical Center, Jerusalem, Israel; 2) Hebrew University - Hadassah Medical School, Jerusalem, Israel; 3) Hebrew University - The Department of Sociology and Anthropology, Jerusalem, Israel; 4) Hebrew University- The Braun School of Public Health, Hadassah Medical Center, Jerusalem, Israel.

PGD is an accepted procedure for prenatal diagnosis (PND), worldwide. It may eliminate some of the obstacles related to conservative options of PND, but can raise personal, social and moral questions. The psychosocial aspects of the technology have been discussed among experts and were evaluated among various population groups. Yet, only scant empirical data focused on PGD users' experiences. A combined methodology was used to investigate PGD's implications on its users: qualitative analysis of semi-structured in-depth face-to-face interviews with 43 PGD users, representing variety of population's sub-groups. On the basis of the interviews, a detailed closed web-based questionnaire was developed. Univariate and multivariate adjustment was performed on data obtained from 155 PGD users in different stages of the procedure. PGD is considered a preferable diagnostic procedure for 139 (95%) subjects. Nevertheless, 71 (47 %) reported a complex decision-making process. Perceived advantages are: assurance of the embryo's unaffected status from the beginning of the pregnancy (48%), thus avoiding the need for pregnancy termination (33%) and invasive prenatal tests (20%). Perceived disadvantages focused on the medical actions involved (63%) and the delay in time between the first counseling and the PGD procedure itself (52%). Other future needs included improving the communication with medical staff (47%) and implementing emotional support (29%). The study indicates special needs of respondents from minority groups and distinct genetic, as well as socio-economic, backgrounds. Subjects introduce permissive moral stand regarding different PGD uses but made a clear distinction between medically justified applications to unjustified social and aesthetic uses. This interdisciplinary qualitative and quantitative analysis of a large sample of PGD users will deepen the insights of the special needs of this particular group and can form a basis for development of counseling and guidance programs of future PGD users. Furthermore, it will also help foster a public debate concerning medical, ethical, sociological and economic aspects of the technology.

**592W**

**Next-generation sequencing experience: Impact of early diagnosis of Usher syndrome.** C. Wright<sup>1</sup>, A. Brown<sup>1</sup>, M. Albert, Jr.<sup>3</sup>, A. Mukherjee<sup>4</sup>, G. McGwin<sup>4</sup>, C. Hurst<sup>1</sup>, J. Smith<sup>2</sup>, N.H. Robin<sup>1</sup>. 1) Department of Genetics, University of Alabama at Birmingham, Birmingham, AL; 2) Hearing and Speech Dept, Children's of Alabama Birmingham, AL; 3) Retina Consultants of Alabama Birmingham, AL; 4) Department of Biostatistics, University of Alabama at Birmingham, AL.

**Purpose:** The aim of this study was to assess the parental psychosocial implications, such as emotions and coping, of earlier diagnosis of USH via genetic testing compared to parents of children who were diagnosed later via ophthalmologic findings. **Method:** Thirty-six participants were recruited through an online posting on the Usher Syndrome Coalition website. Two comparison groups were formed based on the method of diagnosis (i.e. genetic diagnosis vs. ophthalmologic diagnosis). Semi-structured interviews were recorded and transcribed. Comparison, using thematic and statistical analysis, of psychosocial impact on parents of children diagnosed early (genetic testing) and later (ophthalmologic findings) was completed. **Results:** There were no statistically significant differences in emotions between the two groups of participants, suggesting that earlier diagnosis via genetic testing does not lead to increased anxiety or psychosocial issues for parents. Additional themes identified from parent interviews and their application to patient care are described. **Conclusions:** Earlier diagnosis of Usher syndrome via genetic testing does not cause a more harmful emotional impact than later diagnosis via ophthalmologic findings. In fact, there are multiple benefits to earlier diagnosis via genetic testing. Earlier diagnosis allows parents to emotionally process and prepare the child for independence throughout life.

**593T**

**Targeted genomic screening in unselected adults.** *K.R. Muessig<sup>1</sup>, K. Kuczynski<sup>2</sup>, P. Himes<sup>1</sup>, M. Gilmore<sup>1</sup>, S. Westaway<sup>1</sup>, B.C. Powell<sup>2</sup>, J.S. Berg<sup>2</sup>, J. Cadigan<sup>2</sup>, K. Weck<sup>2</sup>, J. O'Daniel<sup>2</sup>, K. Foreman<sup>2</sup>, K.A.B. Goddard<sup>1</sup>, J.P. Evans<sup>2</sup>, G.E. Henderson<sup>2</sup>.* 1) Center for Health Research, Kaiser Permanente NW Portland, OR; 2) University of North Carolina at Chapel Hill, Chapel Hill, NC.

Background: Targeted genomic screening in unselected adults has not been widely studied. 1-2% of adults in the US unknowingly carry pathogenic, highly penetrant variants that confer high risk for severe but preventable disease. Before we implement screening for adults, we must answer questions about the true prevalence of genetic conditions in unselected populations, acceptance of genetic counseling, penetrance of conditions ascertained by screening, and adherence to recommended clinical follow up. Methods: We recruited individuals at a research biobank at Kaiser Permanente Northwest [KPNW] (N=650) and a primary care practice at UNC-Chapel Hill (N=436). The study used online consent, survey, and interview procedures. Joiners agreed to genomic screening for 17 genes related to 11 medically actionable conditions. 262 of those approached were enrolled. Joiners who screened positive were offered their choice of an in-person or phone appointment with a genetic counselor to disclose results. During results disclosure, the genetic counselor recommended clinical follow up actions, and placed the result in the electronic medical record. Results: The GeneScreen test identified 15 positive screening results; 14 were CLIA-confirmed; 1 was not confirmed per participant request. Confirmed results included pathogenic or likely pathogenic variants for 6 conditions including variants in *HFE* (N=7, 2 C282Y homozygotes, 5 C282Y/H63D); *KCNQ1* (N=2), *BRCA2* (N=1), *LDLR* (N=2), *RET* (N=1), and *RYR1* (N=1). The 14 participants with CLIA-confirmed positive results (10 KPNW+ 4 UNC) were offered genetic counseling to learn their test result. Four attended a visit in-person and 10 requested a phone call. Nine participants declined referrals for clinical follow up with Genetics; however, of the 9, three wanted to follow up with their PCP, and one accepted a referral to cardiology. Among the 10 KPNW participants, several had prior knowledge about their condition (N=5); most preferred results over the phone (N=4). This was also true for participants who had signs or symptoms prior to joining (N=2). Conclusion: Although participants invited to join the study were not selected due to phenotypic characteristics, some self-selected on the basis of prior personal or family history of the targeted conditions. The results disclosure process and willingness for clinical follow up is influenced by pre-existing signs or symptoms of the condition or prior knowledge of the molecular diagnosis.

**594F**

**Burkitt lymphoma and skeletal dysplasia.** S.L. Campbell<sup>1,2</sup>, J. Flores<sup>1,2,3</sup>, R. Antony<sup>1,2,4</sup>, B.A. Speckhart<sup>2</sup>, E. Bugaieski<sup>1,2</sup>, K.S. Fernandez<sup>1,2,5</sup>. 1) Department of Pediatrics, University of Illinois College of Medicine at Peoria, Peoria, IL; 2) Children's Hospital of Illinois at OSF-Medical Center, Peoria, IL; 3) University of Utah School of Medicine, Pediatric Genetics Division, Salt Lake City, UT; 4) University of California Davis, Sacramento, CA; 5) Valley Children's Hospital, Madera, CA.

**BACKGROUND:** Cartilage-hair hypoplasia (CHH) is an autosomal recessive chondrodysplasia with short stature, sparse hair and defective cell-mediated immunity. It is caused by mutations in the ribonuclease mitochondrial RNA processing (*RMRP*) gene. Cancer incidence is 7-fold higher in patients with CHH than in the general population, especially non-Hodgkin lymphoma (NHL) and basal cell carcinoma in the third and fourth decade of life. **OBJECTIVE:** To report the association of skeletal dysplasia and Burkitt lymphoma in a young adult female. **DESIGN/METHOD:** Case Report. **RESULTS:** An 18-year old Amish female with disproportionate short stature presented to our center for management of Burkitt lymphoma. She had presented a week earlier with lymphadenopathy, fevers, night sweats, and weight loss for 2-4 weeks. A tonsillar biopsy was consistent with mature B-cell lymphoma. On exam, her height was three feet associated with spine involvement and brachydactyly, mild bowing of the legs, normal size head without frontal bossing, fine and sparse hair. She had normal intelligence. Her pattern of dysmorphisms was suggestive of CHH (parents declined genetic testing). She had extensive cervical, occipital, and submandibular lymphadenopathy and splenomegaly felt across the midline. Repeat biopsy confirmed Burkitt lymphoma with *Myc* rearrangement. PET-CT scan showed widespread disease involving cervical lymph nodes, spleen, iliac bone and bone marrow. Treatment with standard-intensity FAB/LMB therapy (group C) with the addition of Rituximab was initiated. She had an incomplete response to COP (~80% reduction of tumoral masses) but achieved complete remission after COPADAM1. She is 16-months off therapy without evidence of disease. **CONCLUSIONS:** While the association between CCH and NHL has been established we are unclear as to the specific mutation in our patient. Immunodeficiency related to *RMRP* mutation could have been the driver for tumorigenesis. On the other hand, fibroblast growth factor receptor 3 (*FGFR3*), a glycoprotein belonging to the tyrosine kinase receptor family, is a regulator of bone growth and gain of function germline mutations of the *FGFR3* gene result in congenital skeletal dysplasias such as hypochondroplasia/achondroplasia. *FGFR3* overexpression can be oncogenic and cooperate with *Myc* in B-cell lymphomas development. We hope to increase awareness of skeletal dysplasias and cancer predisposition in the pediatric population.

**595W**

***RB1* gene mutations in retinoblastoma patients from Central America.** M. Dean<sup>1</sup>, E. Torres Gonzalez<sup>1</sup>, L. Garland<sup>2</sup>, G. Bendfeldt<sup>1,3</sup>, V. Giron<sup>4</sup>, C. Garrido<sup>4</sup>, H. Lou<sup>2</sup>, P. Valverde<sup>4</sup>, M. Barnoya<sup>2</sup>, M. Castellanos<sup>4</sup>, G. Mejia<sup>5</sup>, R. Ortiz<sup>5</sup>, S. Luna-Fineman<sup>4,6,7</sup>. 1) Laboratory of Translational Genomics, NCI, Gaithersburg, MD; 2) Leidos Biomedical Research, Inc., National Laboratory for Cancer Research, Gaithersburg, MD; 3) Universidad de San Carlos Medical School, Guatemala City, Guatemala; 4) Unidad Nacional de Oncología Pediátrica, Guatemala City, Guatemala; 5) Hospital La Mascota, Managua, Nicaragua; 6) Stanford University, Stanford, CA; 7) Pediatric Hematology/Oncology/SCT/ Cancer Bio, Stanford University School of Medicine, Stanford, CA.

Previous analysis of 327 consecutive cases at a pediatric referral hospital in Guatemala revealed that retinoblastoma accounts for 9.4% of all cancers and the estimated incidence is 7.0 cases/million children, higher than the United States or Europe. The number of familial cases is low, and there is a striking disparity in indigenous children due to late diagnosis, advanced disease, rapid progression and elevated mortality. Complete *RB1* sequencing of germline DNA from 73 retinoblastoma patients from Guatemala (n=66), Nicaragua (n=6), and Honduras (n=1) identified 21 patients with pathogenic mutations. The mutations were nearly all predicted null alleles, 43% nonsense, 29% frameshift and 24% splice site mutations. Twelve of the mutations have not been previously reported. Pathogenic mutations were identified in 75% (9/12) of the bilateral cases, versus 13% of the unilateral cases (X<sup>2</sup>=17, P=10E-5). One unilateral case was found to be mosaic (19%) for an R552X mutation, and another unilateral case with a c.55\_56delGA mutation has a sibling with retinoblastoma. There was no significant difference in gender between cases with and without mutations, and 78% of the children with mutations in Guatemala were Mestizos versus 60% of WT subjects (not significant). The higher incidence of retinoblastoma in Guatemala is associated with a lower rate of bilateral disease (24%) than all US cases (31%) or US Hispanic cases (39%, X<sup>2</sup>=10, P=0.0016) in the SEER database. However, this could be related to a higher mortality (82%) in bilateral indigenous cases. There is no difference in the percentage of cases diagnosed before 1 year of age (51% in Guatemala vs. 50% in the US). An early diagnosis program could identify cases at an earlier age and improve the outcome of retinoblastoma in this diverse population, and a pilot educational poster program resulted in early diagnoses.

**596T****Male breast cancer susceptibility due to FANCM mutation: A case report.**

R. Janavicius<sup>1,2</sup>. 1) Vilnius University Hospital Santara Klinikos, Vilnius, Lithuania; 2) State Research Institute, Innovative Medicine Center.

Male breast cancer (MBC) is a rare, poorly understood disease. Germline susceptibility to MBC is substantial and is mostly confined to *BRCA2/BRCA1* genes mutations, however majority familial MBC has no known genetic basis. Recently, with the broader application of NGS, newer female breast cancer (FBC) susceptibility genes were established. Interestingly, a vast majority of FBC susceptibility genes are related to Fanconi anemia pathway. FANCM was recently identified as a moderate FBC predisposition gene, with the preponderance to triple negative BC. However, the contribution of these genes to MBC is still understudied. Case report. 66 yrs old male patient was referred for VULSK Oncogenetic Unit due to MBC diagnosed at the age of 65 (pT1cN0M0, ductal carcinoma G2, ER-98%, PR-90%, HER2(FISH)(-)). Family history showed prostate cancer in paternal uncle (dx 87). As part of routine comprehensive genetic testing, the patient underwent 96 cancer genes TruSight Cancer NGS testing panel on MiSeq (Illumina). Truncating FANCM (NM\_020937) gene mutation c.5101C>T (p.Gln1701\*) was identified; no other pathogenic/likely pathogenic genes mutations were revealed. During predictive testing, healthy daughter carrier (age 29) was identified. Discussion: From the newly identified FBC genes to date, only PALB2 was associated with possible MBC risk. No clear FANCM involvement in MBC susceptibility was demonstrated in published studies; only one MBC case (untested) was noted in a family with FANCM c.5791C>T mutation from Spain. Conclusion: FANCM c.5101C>T in MBC patient is reported for the first time, highlighting potential contribution of FANCM to MBC susceptibility. Funding: Lithuanian Research Council, SEN18/2015.

**Beyond the NMD boundary: Characterizing the phenotypes of C-terminal *CDH1* mutations.** K. Krempely, C. Espenschied, I. Lu, A. Chamberlin, R. Karam. Ambry Genetics, Aliso Viejo, CA.

The nonsense-mediated mRNA decay (NMD) pathway is an mRNA surveillance system that degrades transcripts containing premature termination codons (PTC) located approximately 50 nucleotides upstream of the last exon-exon junction. Transcripts containing C-terminal PTCs located downstream the 50 nucleotide "NMD boundary" are not targeted for decay, potentially coding for truncated proteins retaining partial function. Therefore, one must be cautious when interpreting C-terminal truncating variants. *CDH1* truncating mutations cause Hereditary Diffuse Gastric & Lobular Breast Cancer (OMIM 137215). *CDH1* transcripts containing C-terminal PTCs downstream the NMD boundary have been shown experimentally to escape NMD; consequently, breast and gastric cancer risks associated with these truncations should be carefully evaluated. The aim of this study was to characterize and report *CDH1* C-terminal truncating alterations identified downstream of the NMD boundary in a large diagnostic laboratory cohort of ~400,000 *CDH1* alleles. Using molecular evidence, structural information, and clinical data, we characterized the most C-terminal *CDH1* pathogenic and likely pathogenic alterations in our cohort. The most C-terminal truncation we identified was p.E836\* (c.2506G>T); it was confirmed *de novo* in an individual diagnosed with lobular breast cancer at 54 years of age who did not meet the International Gastric Cancer Linkage Consortium diagnostic criteria (IGCLC negative). Other truncations identified in this region include c.2398delC (p.R800Afs\*16), c.2430delT (p.F810Lfs\*6), and c.2490dupG (p.L831Afs\*4), all seen in families meeting IGCLC criteria. We also identified, in an IGCLC negative family, a nonstop variant of unknown significance predicted to extend the protein by 29 amino acids (c.2647T>C (p.\*883Qext\*29)). Due to the uncertainty surrounding the functional impact of these alterations, clinical and molecular evidence proved essential in determining their pathogenicity. Characterization of the most C-terminal *CDH1* pathogenic truncation increases our understanding of the sequences located beyond the NMD boundary, resulting in improved classification of alterations in this clinically actionable gene.

**Prevalence of the *UGT1A1\*28* polymorphism in a population-based African American breast cancer cohort: A pilot study.** A. Starlard-Davenport<sup>1</sup>, A. Smith<sup>1</sup>, G. Vidal<sup>2,3</sup>, J. Cordero<sup>1</sup>, R. Cordero<sup>1</sup>, R. Blue<sup>4</sup>, C. Simpson<sup>1</sup>, A. Stanfill<sup>5</sup>, B. Lyn-Cook<sup>5</sup>. 1) Department of Genetics, Genomics and Informatics, College of Medicine, University of Tennessee Health Sciences Center, Memphis, TN 38163; 2) Division of Hematology/Oncology, College of Medicine, University of Tennessee Health Science Center, Memphis, TN 38163; 3) The University of Tennessee West Cancer Center, Memphis, TN 38163; 4) Department of Acute and Tertiary Care, College of Nursing, University of Tennessee Health Science Center, Memphis, TN 38163; 5) Division of Biochemical Toxicology, FDA National Center for Toxicological Research, Jefferson, AR 72079.

**Background and Objectives:** Inherited variations in UDP-glucuronosyl-transferase (*UGT*) genes involved in estrogen metabolism are associated with an increased breast cancer risk in primarily non-Hispanic white and Chinese populations. *UGT1A1* is a major enzyme that conjugates estrogens and their metabolites, thus preventing estrogen-mediated mitosis and mutagenesis. *UGT1A1* is polymorphic. The *UGT1A1\*28* promoter polymorphism is characterized by the presence of an additional TA repeat in the TATA sequence of the *UGT1A1* promoter, ((TA)7TAA, instead of (TA)6TAA). Homozygous ((TA)7/(TA)7) and heterozygous ((TA)6/(TA)7) *UGT1A1\*28* genotypes are associated with reduced *UGT1A1* expression and transcriptional activity. The objective of this study was to assess the prevalence of *UGT1A1\*28* polymorphisms in a population-based African American cohort of women with and without breast cancer. **Methods:** Saliva specimens were collected from African American women with a history of breast cancer (cases (n=70)) and controls (n=120) recruited through community-based participatory events and West Cancer Center in Memphis, TN between May 2016 to April 2017. Women age 18 and above were included in the study. Saliva was collected using Oragene®-OG-500 DNA Self-Collection kits. DNA was isolated using DNA Genotek's Prep-It L2P DNA isolation kit. The *UGT1A1\*28* polymorphism was identified from PCR amplified and purified DNA. Purified PCR products (351 bp) were bidirectional sequenced using forward or reverse primers. *UGT1A1* genotypes were assigned based on the number of TA repeats for each allele (i.e., 6/6, 6/7, 7/7, or 7/8). This study was approved by the UTHSC Institutional Review Board. **Results:** Homozygous *UGT1A1\*28* ((TA)7/(TA)7) genotypes were detected in 24% of women. Most women (41%) were heterozygous for the ((TA)6/(TA)7) genotypes while 20% of women had the wildtype *UGT1A1\*28* ((TA)6/(TA)6) genotype (where no polymorphism was detected). Of women with breast cancer, 53% were heterozygous for the ((TA)6/(TA)7) genotypes whereas only 19% carried the wildtype genotype. **Conclusions:** The results suggest that homozygous and heterozygous *UGT1A1\*28* promoter polymorphisms are prevalent among African American women. Recruitment of African American women to participate in our research study is ongoing to determine whether screening for the *UGT1A1\*28* promoter polymorphism may be useful to identify women with reduced estrogen metabolism rates and greater susceptibility to breast cancer.

**599T**

**Muir-Torre syndrome presenting with juvenile astrocytoma.** G.E. Tiller, S. Jeddi, J. Goff, E. Parkhurst. Dept Genetics, Kaiser Permanente, Los Angeles, CA.

Astrocytomas are primary brain tumors which may arise due to somatic or germline mutations in a number of genes, including p53, NF1, BRCA1, and the MMR genes associated with Lynch syndrome. We describe a 24 year old Hispanic male who was diagnosed with a frontal lobe astrocytoma (anaplastic ganglioglioma, WHO grade III) at 17 years of age, followed by the development of acute lymphoblastic leukemia at age 18 years. Family history was negative for central nervous system, endometrial and colorectal cancers, although his mother was diagnosed with non-Hodgkins lymphoma at age 59 years. A 20-gene cancer panel implemented on the patient revealed a germline MSH6 mutation (c.1168-1170delGATinsAA); immunohistochemical analysis of the brain tumor with anti-mismatch repair protein antibodies revealed absent staining for MSH6. Colonoscopy revealed no polyps. Parental testing revealed that the 74 year old father carried the mutation as well. He recently had 2 sebaceous adenomas removed, in which subsequent IHC testing revealed absent staining for MSH6. He has been referred for screening colonoscopy, and it has been recommended that his older son and daughter receive genetic counseling and testing. Among 184 Kaiser Permanente patients with personal and/or family history of Lynch syndrome-associated malignancies as well as MMR gene mutations, only three were identified with primary brain tumors: astrocytoma at 17 years (MSH6), glioblastoma at age 57 years (MSH2), and glioblastoma at age 75 years (MLH1). The present case illustrates two key points: the utility of cancer gene panels in patients with juvenile brain tumors, and the value of cascade testing despite negative family cancer history.

**600F****In-frame germline deletion of exons 23 and 24 results in DICER1**

**syndrome.** M. Apellaniz-Ruiz<sup>1,2</sup>, L. de Kock<sup>1,2</sup>, N. Sabbaghian<sup>1</sup>, M. Wu<sup>1,2</sup>, F. Guaraldi<sup>3</sup>, L. Ghizzoni<sup>3</sup>, G. Beccuti<sup>3</sup>, W.D. Foulkes<sup>1,2,4,5</sup>. 1) Lady Davis Institute, Segal Cancer Centre, Jewish General Hospital, Montreal, Quebec, Canada; 2) Department of Human Genetics, McGill University, Montréal, Québec, Canada; 3) Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, University of Turin, Turin, Italy; 4) Program in Cancer Genetics, Department of Oncology and Human Genetics, McGill University, Montréal, Québec, Canada; 5) Department of Medical Genetics, Research Institute of the McGill University Health Centre, Montréal, Québec, Canada.

**Introduction:** *DICER1* syndrome is a rare human disease (OMIM #601200) associated with a predisposition to several rare phenotypes, including pleuro-pulmonary blastoma, cystic nephroma, Sertoli-Leydig cell tumor (SLCT) and multinodular goiter (MNG), among other manifestations. Patients with this syndrome have been shown to harbour an unusual combination of a widely-distributed, generally-truncating germline *DICER1* mutation, coupled with a somatic missense mutation located in exons 24 or 25 which partially encode the RNase IIIb domain. Here we describe a large family with remarkable history of MNG and SLCT, carrying an in-frame germline *DICER1* deletion.

**Objective:** We aimed to study the genetic background of this large pedigree and to further explore the impact of the identified germline mutation.

**Methods:** DNA from blood and tumor samples was analyzed for *DICER1* mutations. Multiplex ligation-dependent probe amplification (MLPA) assay was used to screen for germline *DICER1* duplications or deletions. cDNA was synthesized from RNA from LCLs to characterize the expression of *DICER1* alleles. In addition, *DICER1* targeted capture and/or Sanger sequencing of RNase IIIa and IIIb domains was performed on tumor DNA. **Results:** MLPA showed that 8 of the 15 tested family members carried a germline *DICER1* in-frame deletion (c.4207-41\_5096+1034del). mRNA transcripts with the deletion were not eliminated by nonsense-mediated mRNA decay and were expressed in the cDNA of the patients. Thus, individuals carrying the deletion would express a protein devoid of exons 23 and 24. Additional second somatic hotspot mutations were found in the tumors from 4 of the *DICER1* germline deletion carriers from whom tissue was available. **Conclusion** Most patients with *DICER1* syndrome have a germline loss of function *DICER1* mutation on one allele, and usually lose both the RNase IIIa and IIIb catalytic domains. Here, for the first time, we have shown that the expression of an almost full-length *DICER1* protein in which the RNase IIIa domain and two (1810, 1813) of four metal-ion binding amino acids in the RNase IIIb domain remain intact, is not sufficient to prevent tumorigenesis.

**Improving variant classification by incorporating pre-curated gene-specific knowledge into hereditary cancer multi-gene panel testing.** H. Kang, C. Pardo, J. Thusberg, K. Erhard, R. Quintana, S-H. Wang, I. Wilson, K. Ouyang, M. Anderson. Invitae Corporation, San Francisco, CA.

Multi-gene panel testing in the diagnosis of inherited disease is routinely recommended in the clinic and broadly provided by genetic testing laboratories. As panels and tested genes grow in number, novel variant observations also increase. To guide the interpretation of a variant during multi-gene panel testing, our laboratory developed Sherlock, an objective evidence- and point-based variant classification framework. Although truncating variants, splice-site variants, and large copy number variations are often de facto pathogenic, variants truncating in the last exon of a gene (i.e., expected to escape nonsense-mediated decay), causing in-frame gross deletions or duplications, and occurring in the initiator codon are not necessarily pathogenic. When clinical or functional data are unavailable, our framework is designed to query whether a variant impacts critical functional domains and structural residues, pre-defined pathogenic variants, or the molecular mechanism for a gene. To improve variant classification for approximately 130 hereditary cancer genes, we established a database for this key information. Herein, we demonstrate our approach with a series of novel or rare variants identified during the clinical diagnostic testing of hereditary cancer genes. For *FH* and *VHL*, which utilize two alternative initiating ATGs that generate different protein isoforms, the interpretation of novel truncating variants between the two methionines can be confusing without gene-based rules. For the functionally and structurally well-characterized *BRCA1*, *BRCA2*, and *CHEK2*, our approach is important in pre-determining whether in-frame gross deletions and duplications occur in functionally critical domains or in exons in which naturally occurring alternative transcripts have been reported. For *POLE* and *POLD1*, in which loss-of-function missense variants in specific domains have been established as the disease-causing mechanism, our approach is useful in excluding novel truncating variants from de facto pathogenic classification. For *CDKN1C*, with its highly repetitive sequence, we have pre-defined rules to exclude commonly detected variants within the PAPA domain. Finally, we present a nonsense variant in the last exon of *TMEM127*, in which the classification was established with clinical data because studies of the protein functional domains are limited. Our approach demonstrates that pre-curated, gene-specific knowledge is essential for variant classification.

**602T**

**Evaluation of QIAGEN Clinical Insight as a content resource for variant curation in a CLIA laboratory.** K. Karimi<sup>1</sup>, S. Cox<sup>1</sup>, K. Moyer<sup>1</sup>, P. Kang<sup>1</sup>, E. Evans<sup>1</sup>, S. Tanenbaum<sup>2</sup>, D. Richards<sup>2</sup>. 1) Counsyl, South San Francisco, CA; 2) QIAGEN, Redwood City, CA.

Counsyl performs an expanded carrier screen for >175 recessive diseases and a panel of up to 36 genes for hereditary cancer risk assessment. Our CLIA laboratory utilizes NGS to analyze all exons for panel genes, excluding some regions with high homology, and a comprehensive curation workflow is used to interpret the clinical impact of detected variants. Automated proprietary software initially classifies variants with high population frequency or which have not been reported. Remaining variants undergo curation by PhD scientists and genetic counselors before approval by board-certified laboratory directors. Pathogenicity is assessed using ACMG guidelines and is based on published case and functional studies, variant databases, population frequency, conservation, and in silico predictors. Identification of articles mentioning a variant is crucial for accurate appraisal of pathogenicity, and Counsyl searches variant databases, an in-house library, and online. We investigated QIAGEN QCI as a solution for reducing manual searches, with quantitative and qualitative assessment of variant coverage. QIAGEN Clinical Insight (QCI) is a clinical decision support platform that provides manually curated clinical case evidence with computed ACMG classifications and a comprehensive bibliography of articles. Articles describing variants in the relevant genes are identified through natural language processing of abstracts and PubMed annotations. Full texts are reviewed by scientists that have undergone training, and data is entered into a web-based curation tool. QIAGEN uses third party User Acceptance Testing to validate high-level coverage and accuracy to comply with quality targets. For 1,919 variants curated by Counsyl, we evaluated reference overlap with QCI and whether additional QIAGEN references would alter classifications. We found QCI coverage to be comprehensive, containing 89.3% of article-variant pairs identified by Counsyl, and an additional 13,938 article-variant pairs for the evaluated variants. The vast majority of our classifications (98.8%) were unaltered, thus demonstrating the benefits of adopting QCI for reference selection, while validating the efficacy of our previous workflow. With initial integration, QCI has significantly increased curation efficiency, as evidenced by ~75% time savings in a reference search process that can take up to 45 minutes. More time-intensive methods can now be focused on variants nearer evidence thresholds.

**603F**

**Genotoxic chemotherapies and radiotherapy contribute to the development of multiple primary tumors in patients with Li-Fraumeni syndrome.** E. Kasper<sup>1</sup>, E. Angot<sup>2</sup>, E. Colasse<sup>3</sup>, L. Nicol<sup>3</sup>, J-C. Sabourin<sup>2</sup>, S. Adriouch<sup>4</sup>, Y. Lacombe<sup>5</sup>, C. Le Clezio<sup>1</sup>, S. Raad<sup>1</sup>, Y. Zerdoumi<sup>1</sup>, T. Frebourg<sup>1</sup>, J-M. Flaman<sup>1</sup>, G. Bougeard<sup>1</sup>. 1) Normandie Univ, UNIROUEN, Inserm U1245 and Rouen University Hospital, Department of Genetics, Normandy Centre for Genomic and Personalized Medicine, Rouen, France; 2) Normandie Univ, UNIROUEN, Inserm U1245 and Rouen University Hospital, Department of Pathology, Normandy Centre for Genomic and Personalized Medicine, Rouen, France; 3) PICTUR – Small Animal Imaging, Rouen University, Rouen, France; 4) Normandie Univ, UNIROUEN, Inserm U1234, Rouen University, Rouen, France; 5) Animal Facility, Faculty of Medicine and Pharmacy, Rouen University, Rouen, France.

Li-Fraumeni syndrome (LFS), due to *TP53* germline mutations, is one of the most severe predispositions to cancer, characterized by an early age of onset and a broad tumor spectrum. We recently reported in LFS patients a very high incidence of multiple primary cancers (MPC), above 40%, including secondary tumors in radiation fields. Considering these clinical observations and the mechanism of anti-cancer treatments we speculated a link between these treatments and the development of MPC in LFS patients. To address this question, we first adapted to mouse cells the p53 genotoxicity assay previously developed in our laboratory and based on the p53-transcriptional response to DNA damage in human lymphocytes. We showed that most of classical anti-cancer treatments, except spindle poisons, are genotoxic in mouse like in human cells. We then evaluated the *in vivo* genotoxicity of treatments using a LFS mouse model. *Trp53* KO<sup>-/-</sup>, *wt*<sup>-/-</sup> and *wt/wt* mice were exposed to X-rays or to various anti-cancer drugs: a mitotic spindle poison (Docetaxel), and a topoisomerase inhibitor (Etoposide). Mice treated with NaCl were used as control group. Tumor development was monthly monitored using whole-body MRI, and histopathological analysis was performed to confirm the presence of tumors. We analyzed a total of 208 mice. X-rays and Etoposide were shown to accelerate tumor development in *Trp53*<sup>-/-</sup> and *wt*<sup>-/-</sup> mice (OR=6.46, p-value=1.24.10<sup>-3</sup> and OR=3.91, p-value=5.76.10<sup>-4</sup>, respectively), unlike Docetaxel which was devoid of effect on tumor development kinetics. This study provides evidence that genotoxic chemotherapies and radiotherapy contribute to MPC development in LFS patients. Therefore, in germline *TP53* mutation carriers, radiotherapy should be avoided whenever possible and surgical treatment prioritized. Diagnosis laboratories should be able to perform fast analysis of *TP53* before radiotherapy in clinical situations strongly suggestive of LFS such as very early-breast cancer < 31 years of age, and non-genotoxic treatments should be considered in the future to reduce the risk of MPC.

**604W**

**FLCN gene pathogenic variants in individuals presenting with lung cysts without pneumothorax, skin features or renal tumours typical of Birt-Hogg-Dube syndrome: A case series and review of the literature.** K. Kohut<sup>1</sup>, I. Vlahos<sup>1</sup>, R. Aul<sup>1</sup>, K. Snape<sup>1,2</sup>, H. Hanson<sup>1,2</sup>. 1) Clinical Genetics, St George's University Hospital NHS Foundation Trust, London, United Kingdom; 2) St George's University of London, London, United Kingdom.

**Background:** Birt-Hogg-Dube syndrome (BHDS) is an autosomal dominant, highly penetrant condition caused by a pathogenic variant in the *FLCN* gene. Clinical features include skin fibrofolliculomas, pulmonary cysts often resulting in spontaneous pneumothorax and certain renal tumours, often bilateral and multifocal. Genetic testing is typically initiated in probands with  $\geq 5$  fibrofolliculomas, facial angiofibroma histologically confirmed and not linked to another syndromic cause, multiple/bilateral chromophobe, oncocytic, and/or hybrid renal tumors or renal tumours with a family history of renal tumour, or personal and family history of pneumothorax. **Case series:** We describe two cases in which an *FLCN* pathogenic variant was found in individuals under investigation by the respiratory team whose radiological work-up identified lung cysts suggestive of BHDS, in the absence of any other features of the condition. One was a 37 year-old man who presented with chest pain. CT chest identified thin-walled pulmonary cysts involving all lung zones. He had no obvious renal cysts and no family history. He did not have a formal diagnosis of BHDS-related skin features, but on review in Genetics he was referred to dermatology to determine if some lumps on his face, neck and upper back could constitute fibrofolliculomas. The second case was a 46 year-old woman who was under review after developing left lower lobe bullae post pneumonia. CT demonstrated cystic lung disease with a "stacked" appearance, which has been described in BHDS. She had no renal cysts, family history or skin features of BHDS. Both cases had some intrafissural cysts, which are unusual in other cases of cystic lung disease. **Results:** These two cases exemplify the possibility to identify BHDS based on isolated presentation of lung cysts. **Conclusions:** Health professionals in genetics, general practice and respiratory/thoracic specialities including radiology should be aware of the possibility of BHDS in individuals with lung cysts, and refer to genetics for assessment and genetic testing of the *FLCN* gene. Careful questioning about personal and family history as well as a detailed examination could help to distinguish between BHDS and other conditions presenting with lung cysts. A diagnosis of BHDS will identify the need for further dermatological and renal follow-up, as well as at-risk family members who should be screened. This could lead to earlier diagnosis and improved prognosis.

Breast and/or ovarian cancers (BOC) are among the most common cancers in women across the world. In the Indian population, healthcare burden due to BOC has been steadily rising, thus stressing the need for early detection, surveillance and disease management measures. However, the burden attributable to inherited mutations is not known. We sequenced 1010 unrelated patients and families from India with an indication of BOC, using the TruSight Cancer panel which includes 14 genes strongly associated with risk of hereditary BOC (HBOC). Genetic variations were identified using the Strand NGS software and interpreted using the StrandOmics platform. We were able to detect mutations in 304 (30.1%) cases, of which, 55 mutations were novel. Majority (84.5%) of the mutations were detected in the *BRCA1/2* genes as compared to non-BRCA genes (15.5%). When the cases were stratified on the basis of age at diagnosis (AAD) and family history of cancer, the highest detection rate of 72% was observed in patients with AAD below 40 years and with first degree family member(s) affected with BOC. Our findings indicate that in the Indian population, there is a high-prevalence of mutations in the high-risk breast cancer genes: *BRCA1*, *BRCA2*, *TP53* and *PALB2*. In India, socioeconomic inequality limiting access to treatment is a major factor towards increased cancer burden; therefore incorporation of a cost-effective multi-gene test will be helpful in ensuring widespread implementation of genetic screening in the clinical practice for HBOC.

**Cancer following radiotherapy for primary cancers in Li-Fraumeni syndrome patients.** L. Oba<sup>1</sup>, P.P. Khincha<sup>2</sup>, J.T. Loud<sup>1</sup>, L. Morton<sup>1</sup>, S.A. Savage<sup>1</sup>, M.I. Achatz<sup>1</sup>. 1) Clinical Genetics Branch, DCEG, National Cancer Institute, NIH, Bethesda, MD; 2) Radiation Epidemiology Branch, DCEG, National Institution, NIH, Bethesda.

Li-Fraumeni syndrome (LFS) is a rare autosomal dominant hereditary cancer predisposition syndrome associated with early age of onset, and a high lifetime risk of multiple primary malignancies. Approximately 70% of individuals with LFS have a germline *TP53* mutation. *In vivo* studies have shown that *Trp53* heterozygous mice are radiation-sensitive and likely to develop a second cancer after exposure to ionizing radiation. These findings, along with reports of second malignancies occurring in the radiation field of LFS patients treated with ionizing radiation, led to the recommendation to minimize radiation exposure in germline *TP53* mutation carriers. The Li-Fraumeni Syndrome Study, a longitudinal cohort study conducted by the Clinical Genetics Branch, National Cancer Institute, evaluated the association of previous radiotherapy for cancer treatment with the onset of a second cancer in the area exposed to ionizing radiation. Medical charts were reviewed of 68 LFS patients (14 males and 54 females) who carried a germline *TP53* mutation. Of these 68 patients, 27 developed one primary cancer and 41 had two or more primary cancers. Twenty-four patients of 68 were treated with therapeutic radiation, 15 of whom developed a subsequent primary malignancy. Of the 15, seven patients (five breast cancers and two sarcomas) developed a new primary malignancy within the field of radiation. The subsequent malignancies developed were spindle cell sarcoma of the chest in three patients, breast cancer in two patients, adenocarcinoma of the lung in one patient and glioblastoma in one patient. After radiation exposure, the median time to the appearance of a subsequent cancer in those seven patients was four years (range from 1-42 years). In summary, 29% of LFS patients treated with radiation therapy developed a cancer within the radiation field of therapeutic radiation. This analysis demonstrates the importance of larger studies on radiation treatment exposure in LFS patients to determine the risk of radiation-induced cancers, and the importance of minimizing radiation exposure in *TP53* germline mutation carriers.

**Germline mutations in DNA repair genes are overrepresented in children and young adults with rhabdomyosarcoma: A discovery and validation cohort study.** T. Wegman-Ostrosky<sup>1</sup>, N. Light<sup>2</sup>, E.L. Young<sup>3</sup>, H.C. Chen<sup>4</sup>, Y.Y. Chi<sup>5</sup>, D. Hall<sup>6</sup>, D.S. Hawkins<sup>7</sup>, J. Kim<sup>8</sup>, P.J. Lupo<sup>9</sup>, R. Patidar<sup>10</sup>, A. Shlien<sup>2,10</sup>, S. Skapek<sup>6</sup>, M. Tyagi<sup>10</sup>, J. Wei<sup>10</sup>, X. Wen<sup>9</sup>, J.D. Schiffman<sup>3</sup>, J. Khan<sup>9</sup>, D. Malkin<sup>2,10</sup>, D.R. Stewart<sup>1</sup>. 1) Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, Natio, Rockville, MD; 2) Genetics and Genome Biology Program, The Hospital for Sick Children, University of Toronto, Toronto, Canada; 3) Dept. of Pediatrics and Huntsman Cancer Institute, University of Utah, Salt Lake City, UT, USA; 4) University of Florida, Gainesville, FL, USA; 5) Children's Oncology Group, Monrovia, CA, USA; 6) Seattle Children's Hospital, Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA, USA; 7) Dept. of Pediatrics, Baylor College of Medicine, Houston, TX, USA; 8) Dept. of Pediatrics, University of Texas Southwestern Medical Center, Dallas, TX, USA; 9) Genetics Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD, USA; 10) Department of Pediatrics, The Hospital for Sick Children, University of Toronto, Toronto, Canada.

**Intro.** Rhabdomyosarcoma (RMS) accounts for 3% of all pediatric cancer and is the most prevalent soft tissue tumor in childhood and adolescents. The etiology of RMS remains largely unknown; it is reported that hereditary factors account for 7-33% of RMS. We sought to determine the prevalence of pathogenic germline genetic variation in RMS patients unselected for family history. **Methods.** All samples were ascertained from the D9902 correlative biology study of the Children's Oncology Group. Germline whole-exome sequencing (WES) was conducted at the National Cancer Institute (NCI) on the discovery cohort (n=121); whole-genome sequencing (WGS) was conducted at SickKids on the validation cohort (n=122). WGS is underway on another 150 samples. WES was performed on 598 cancer-free adult controls from NCI studies. Analysis on 137 cancer-predisposition genes from the combined COSMIC germline and Rahman lists focused on those with previously annotated dominant inheritance. We reviewed variants with a MAF <0.05%. Truncating and canonical splice-site variants were considered pathogenic (P); missense variants with CADD >20 and evidence of pathogenicity in ClinVar or HGMD-DM (after literature review) were considered likely pathogenic (LP). P/LP frequency in each cohort was compared with controls using the Fisher's exact test. **Results.** The NCI and Toronto cohorts were comparable in age, gender and histologic type. In the NCI cohort, 12 P/LP variants were identified (10%; P=0.009) in *ATM*, *DICER1*, *FLCN*, *MSH6*, *NF1*, *PTPN11*, *RB1*, *RET*, *TP53* and *SDHA*. In the Toronto cohort, 13 P/LP variants were identified (11%; P=0.004) in *ATM*, *BRCA2*, *CHEK2*, *EXT2*, *HRAS*, *NF1*, *RB1*, *RET*, and *TP53*. Genes with P/LP variation common to both cohorts were *ATM*, *NF1*, *RB1* and *TP53*. In the controls, there were 23 P/LP variants (4%) in *ATM*, *BRCA2*, *CHEK2*, *EXT2*, *HRAS*, *MSH6*, *RET*, and *TP53*. **Conclusion.** We observed a significant excess of pathologic germline variation in RMS in multiple established cancer predisposition genes. WES and WGS explained only a minority of risk in sporadic RMS. Some genes (*NF1*, *RB1*, *PTPN11*, *TP53*, *DICER1*) underlie syndromes known to be associated with RMS, whereas others (*BRCA2*, *CHEK2*, *MSH6*, *SHDB*) merit additional validation in larger cohorts. Our results suggest that germline genetic testing may be of clinical utility for patients with sporadic RMS, and that pathogenic variants in DNA repair pathway genes may be broadly relevant to the etiology of these cancers.

**608T**

**Unexpected cancer-predisposition gene mutations in Cowden syndrome and Bannayan-Riley-Ruvalcaba syndrome patients without underlying germline *PTEN* mutations.** L. Yehia<sup>1,4</sup>, Y. Nji<sup>2</sup>, K. Sesock<sup>1</sup>, F. Niazi<sup>1</sup>, B. Fletcher<sup>1</sup>, J. Chen<sup>1</sup>, T. LaFramboise<sup>1,3,6</sup>, C. Eng<sup>1,3,5,6</sup>, 1) Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH; 2) Center for Clinical Genomics, Cleveland Clinic, Cleveland, OH; 3) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH; 4) Department of Pathology, Case Western Reserve University, Cleveland, OH; 5) Taussig Cancer Institute, Cleveland Clinic, Cleveland, OH; 6) Germline High Risk Focus Group, CASE Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH.

Patients with *PTEN* hamartoma tumor syndrome (PHTS), which encompasses Cowden/Cowden-like syndrome (CS/CS-like) and Bannayan-Riley-Ruvalcaba syndrome (BRRS) characterized by germline *PTEN* mutations, benefit from *PTEN*-enabled cancer risk assessment and clinical management. *PTEN* wildtype patients (~50%) remain at an increased risk of developing certain cancers. Existence of germline mutations in other known cancer susceptibility genes has not been previously explored in these patients, with implications for different medical management. We conducted a 4-year multicenter prospective study (2011-2015) of incident patients with features of CS/CS-like and BRRS without *PTEN* mutations. Whole-exome sequencing and targeted analysis were performed including 59 clinically actionable genes from the American College of Medical Genetics and Genomics (ACMG) and 24 additional genes associated with inherited cancer syndromes. Germline mutation spectrum and frequencies were compared to The Cancer Genome Atlas (TCGA), including 6 apparently sporadic cancer types associated with PHTS. Pathogenic or likely pathogenic cancer susceptibility gene alterations were found in 13 of 87 (14.9%) CS/CS-like and BRRS patients and included *MET* (n=6), *MUTYH* (n=1), *RET* (n=1), *TSC2* (n=1), *BRCA1* (n=1), *BRCA2* (n=1), and *HRAS* (n=1). We found concordant genotype-phenotype associations in 5 (38.5%) patients. Neither proband age at consent, nor personal/family history of cancer predicted the presence of pathogenic germline mutations. Mutations were only found in 119 of 3152 (3.7%) patients from TCGA apparently sporadic PHTS component cancers (OR=4.08, 95% CI 2.07-7.52, p=1.87x10<sup>-4</sup>). Our findings demonstrate that broad multigene testing in the context of genetic counseling should be considered in *PTEN* wildtype CS/CS-like and BRRS patients due to the enrichment and clinical actionability of the identified and unexpected mutated cancer genes. Finding non-canonical gene mutations in CS/CS-like and BRRS patients might alter medical management.

**609F**

**Clinical and genetic analysis of patients with hamartomatous polyposis syndromes.** J. Oh, H.T. Kim, J.W. Kim. Department of Laboratory Medicine & Genetics, Samsung Medical Center, Sungkyunkwan University School of medicine, Seoul, South Korea.

**Background:** Peutz-Jeghers syndrome (PJS) is an autosomal dominant inherited disorder characterized by hamartomatous polyps in the gastrointestinal tract and germline mutation of the serine threonine kinase 11 (*STK11*) gene are known to be the leading cause of PJS. Also, multiple hamartomatous polyps can be found in the patients with mutation of the *SMAD4* gene and patients with mutations of *STK11* and *SMAD4* are known to have a tendency of younger. In this study, we examined the largest sample size in the *STK11* gene on Asian patients to date. **Methods:** Patients referred to molecular genetic center of Samsung medical center for genetic study of the *STK11* and *SMAD4* between January 2006 and May 2017 were examined in this study. An analysis of the *STK11* and *SMAD4* gene was performed in 70 patients and 12 patients, respectively. We sequenced the coding regions and intron-exon boundaries of the *STK11* and *SMAD4* gene and obtained clinical data from electronic medical records. We also conducted a meta-analysis in the *STK11* and *SMAD4* gene on East Asian patients based on literature search results. **Results:** Genetic abnormalities were observed in 30% of patients (21/70 patients) in the *STK11* gene and 17% (2/12 patients) in the *SMAD4* gene. Twenty different variants including eight frameshift, five nonsense, five missense and three aberrant splicing were found in 21 patients in the *STK11* gene. Pathogenic variants were found most frequently in exon 1 (8/21) and other pathogenic variants were scattered throughout the *STK11* gene. Seven novel variants that were not recorded in the *STK11* databases were identified: c.232A>G, c.233A>C, c.239\_240del, c.443del, c.598-2A>G, c.652\_667del, c.884\_891dup. **Conclusions:** In previous studies, the type of the *STK11* gene variants reported in Korean patients was mostly missense, but our study showed high rate of truncating variant similar to other studies. Since mutation of the *STK11* and *SMAD4* gene is associated with the disease of childhood and increases risk of cancer at multiple sites, screening of the *STK11* and *SMAD4* gene variants on patients with hamartomatous polyposis syndrome is very important to identify individuals with suspected patients. **Key Words:** Peutz-Jeghers syndrome, Polyposis, *STK11*, *SMAD4*, Korean.

**610W**

**WGS in pediatric neuroncology patients shows a preponderance of germline Mendelian disease gene mutations.** *M. Bainbridge<sup>1</sup>, S. Nahas<sup>1</sup>, L. Famaes<sup>1</sup>, D. Dimmock<sup>1</sup>, D. Malicki<sup>2</sup>, M. Bondy<sup>3</sup>, S. Chowdhury<sup>1</sup>, S. Kingsmore<sup>1</sup>, J. Crawford<sup>1</sup>, R. Wechsler-Reya<sup>4</sup>.* 1) Institute for Genomic Medicine, Rady Children's Hospital, San Diego, CA; 2) Rady Children's Hospital, San Diego, CA; 3) Baylor College of Medicine, Houston, TX; 4) Sanford-Burnham Medical Research Institute in La Jolla, CA.

Pediatric central nervous system (CNS) cancers are rare but devastating tumors with poorly understood, likely genetic, etiology. Here we present results from a neuro-oncology pilot project at Rady Children's Institute for Genomic Medicine combined with a previous study of 200 familial glioma cases. We employed high coverage whole genome tumor (120x) normal (40x) sequencing with somatic variant detection at a minimum of 5% allele frequency combined with CNV and methylation arrays to rapidly interrogate pediatric CNS tumors. At data cutoff, we identified germline tumor predisposition mutations in *NF1*, *DICER*, *FANCA*, and *VCP*. In the last case the patient had a metastatic lesion in the CNS from an apparent unidentified primary osteosarcoma. This patient also had a known pathogenic mutation in the autosomal dominant gene causative for Paget's disease [MIM: 167320], *VCP*, a bone over-growth disorder associated with increased risk of osteosarcoma. The patient with *DICER1* mutation also had a splicing mutation in *PTCH1*, the cause of Basal cell nevus syndrome [MIM: 109400] and Holoprosencephaly 7 [MIM:610828]. We examined a cohort of ~200 familial glioma cases with WGS and observed a single highly deleterious (CADD > 30) missense mutation in *PTCH1*, whereas no similar variants in *PTCH1* was found in a control cohort of >1000 samples. In another patient with no known causative germline mutations we observed syndromic findings including encephalopathy, speech delay and growth hormone deficiency. In this patient, we discovered a likely pathogenic missense mutation in *SMARCA4*, the cause of Coffin-Siris Syndrome 4 [MIM:614609] and rhabdoid tumor predisposition syndrome 2 [MIM:613325]. Disruption of *SMARCA4* function in this patient may, therefore, explain syndromic findings or account for predisposition to tumor formation. In addition, molecular findings in one case completely altered clinical treatment: Reclassifying the tumor from a pineoblastoma to high grade glioblastoma and, owing to a mutation in *H3F3A* (p.Lys27Met), permitting the patient to enroll in a clinical trial. These results demonstrate the value of WGS sequencing in identifying critically important molecular findings in pediatric patients with CNS tumors. The identification of rare, deleterious mutations in known Mendelian genes underscores the hypothesis that genes which are critical for embryological brain development may contribute to predisposition to cancer of the CNS.

**611T**

**Identification of three novel loss of function mutations within APC, the causal gene for classical familial adenomatous polyposis.** *A. Gupta<sup>1</sup>, S. Macklin<sup>2</sup>, A. Sigafos<sup>2</sup>, K. Clark<sup>2</sup>, F. Vairo<sup>1</sup>, P. Atwal<sup>3</sup>, E. Klee<sup>1</sup>.* 1) Center for Individualized Medicine, Mayo Clinic, Rochester, MN; 2) Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN; 3) Clinical Genomics, Mayo Clinic, Jacksonville, Florida.

**Statement of purpose:** Familial adenomatous polyposis (FAP) is characterized by multiple adenomatous colorectal polyps developing in the second decade of life, which if left untreated lead to colorectal cancer by the third or fourth decade of their life, and contribute to 1% of colorectal cancer cases. Classical FAP is caused by germline mutations in the Adenomatous polyposis coli (*APC*) gene which are inherited in an autosomal dominant manner. To date, a total of 1795 mutations have been identified within *APC* as listed on Human Gene Mutation Database (HGMD), of which there are 332 nonsense, 97 missense, 112 splice site substitutions, 8 regulatory, 731 small deletions, 315 small insertions/duplications, 46 small indels, 129 gross deletions, 12 gross insertions/duplications and 13 complex rearrangements. Notably a substantial number of these are loss of function (LOF) mutations. This study reports three novel LOFs identified within *APC*. **Methods:** Genomic DNA was extracted from whole blood of the patients. DNA of these patients was tested using Invitae colorectal cancer gene panel consisting of 12 genes including *APC*. Sequence changes as well as deletions/duplications were evaluated. **Results:** A likely pathogenic duplication of exons 3-11 was identified in one patient. Reports of large gross duplications spanning several exons within *APC* are relatively rare, and only one study (Kerr et al., 2012) has reported two such mutations, of which one was a large duplication of the 5'UTR and exons 2-15 and the other was a large duplication spanning exons 4-11, and both were identified in only one patient each. A potential cryptic splice site mutation, classified as a Variant of Unknown Significance (VUS) (c.221-5T>G) was identified in another patient. The most likely consequence of this mutation is the shifting of acceptor splice site upstream by 5 bps according to various splice prediction programs. This may lead to an insertion of 4 bps, causing a frameshift and subsequent truncation (p.E74Vfs\*2) after two amino acid residues. Another patient was found to have a pathogenic 2 bp deletion (c.421\_422delAG), also leading to a frameshift and subsequent truncation (p.R141Vfs\*6). As mentioned above, a large number of splice site mutations and small deletions within this gene have been previously implicated with FAP. **Discussion:** The three novel mutations identified within *APC* in this study contribute to the existing vast database of germline mutations already known for FAP.

## 612F

**Functional characterization of germline *TMEM127* mutations in familial pheochromocytoma.** S.K. Flores, Y. Deng, Y. Qin, P.L. Dahia. Dept. of Medicine, The University of Texas Health Science Center at San Antonio, San Antonio, TX.

**Background:** Germline mutations in the transmembrane (TM) protein-encoding gene, *TMEM127*, have been associated with pheochromocytomas (PHEOs), highly hereditary tumors of neural crest origin. *TMEM127* is a tumor suppressor that localizes to endo-lysosomal membranes and negatively regulates mTOR signaling. However, the functional relevance and clinical significance of germline *TMEM127* mutations have not been well defined. Investigating the *TMEM127* mutation spectrum and the related mutant phenotypes can provide insights into *TMEM127* function and allow for better interpretation of genetic screening results and surveillance of affected and at-risk individuals.

**Purpose:** The aim of this study was to characterize the functional consequences of germline *TMEM127* mutations detected in patients with PHEOs by determining the subcellular localization and protein stability of the resulting mutant *TMEM127* proteins. **Methods:** Nine *TMEM127* missense mutations and two frameshift mutations were selected for characterization. GFP-tagged wild-type (WT) and mutant *TMEM127* plasmids were generated and transiently transfected into HEK293FT cells. Confocal images of GFP signals were taken 48 hours post-transfection. Cell pellets were collected at 24, 48 and 72 hours post-transfection for Western blot analysis and probed for *TMEM127*, GFP and B-actin (as loading control). Band intensity was calculated using ImageJ. **Results:** Missense mutations (N=5) and frameshift mutations (N=2) that occurred within or disrupted putative TM domains resulted in mutant proteins with a diffuse, cytoplasmic pattern indicative of loss of membrane localization. Missense mutations (N=4) located outside of putative TM domains resulted in mutant proteins with a punctate pattern similar to that of WT *TMEM127* indicative of retention of membrane localization. All mutant proteins with a diffuse, cytoplasmic pattern showed a markedly decreased abundance when compared with the WT *TMEM127*. **Conclusion:** Membrane localization of *TMEM127* is necessary for its stability and, likely, for its tumor suppressor function. Loss of membrane localization is associated with mutations disrupting putative TM domains. Thus, TM-associated mutations are likely to lead to loss of function. It is conceivable that mutations, where the mutant protein retains membrane localization, may impair other function(s) of *TMEM127*, such as binding to an associated protein, and will require further investigation.

## 613W

**Systematic characterization of germline variants in endometrial carcinoma from the DiscovEHR study.** J.E. Miller<sup>1</sup>, R.P. Metpally<sup>2</sup>, T.N. Pearson<sup>1</sup>, S.B. Krishnamurthy<sup>2</sup>, V.R. Dasari<sup>2</sup>, D.R. Lavage<sup>2</sup>, A.M. Cook<sup>2</sup>, A.L. Smith<sup>2</sup>, J. Nash<sup>2</sup>, D.J. Carey<sup>2</sup>, M.D. Ritchie<sup>1,3</sup>, D. Kim<sup>1,3</sup>, R. Gogo<sup>2</sup> on behalf of the DiscovEHR collaboration. 1) Biomedical & Translational Informatics Institute, Geisinger Health System, Danville, PA; 2) Weis Center for Research, Geisinger Medical Center, Danville, PA; 3) Huck Institute of the Life Sciences, Pennsylvania State University, University Park, PA.

Endometrial cancer (EMCA) is one of the most common cancers among women in the world. Currently, there is a need to identify which genes contain potentially pathogenic germline variants among EMCA patients. The Geisinger Health System (GHS) has the unique opportunity to address this problem using the DiscovEHR cohort which includes whole-exome sequencing on over 50,000 consenting patients, 300 of whom were diagnosed with EMCA. Here, a bioinformatics pipeline was developed to annotate rare variants that are potentially pathogenic using ClinVar, HGMD (Human Gene Mutation Database) and VEP (Variant Effect Predictor). Potentially pathogenic variants in EMCA participants (N = 300) were compared to potentially pathogenic variants present in non-cancer controls (N = 2120, female participants older than 80 with no history of cancer) and other hormone related cancers (N = 1486, OHRC, e.g. ovarian and breast cancer) cohorts to identify which genes and variants are unique in EMCA. Twenty-six genes had a greater burden in EMCA relative to the non-cancer controls. Of the 26 genes with potentially pathogenic variants, only 2 also had an increased burden in the OHRC cohort, suggesting the 24 genes identified may help distinguish participants with EMCA from those with non-EMCA cancer or no cancer. Additionally, comparing GHS to the cancer genome atlas (TCGA) EMCA germline data illustrated there were 91 genes with potentially pathogenic variation and 55 unique potentially pathogenic variants that were present in both studies. Thus, similar germline variation can be observed in unique EMCA cohorts and could help prioritize genes and variants to investigate for future work. In summary, this systematic characterization of potentially pathogenic germline variants provides new insights for distinguishing those diagnosed with EMCA from those with non-EMCA cancer or no cancer.

**614T**

**The HBV receptor gene *SLC10A1* is frequently down-regulated in hepatocellular carcinoma and is associated with poor survival.** *P. An, C.A. Winkler.* Basic Research Laboratory, Center for Cancer Research, National Cancer Institute, Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD.

Sodium taurocholate cotransporting polypeptide (NTCP, *SLC10A1*) was recently identified as the cell-entry receptor for Hepatitis B virus (HBV). *SLC10A1*, exclusively expressed in the basolateral membranes of hepatocytes, is physiologically responsible for hepatic uptake of sodium-dependent bile salts. *In vitro* and animal experiments show that down-regulation of *SLC10A1* reduces HBV replication. Chronic HBV infection is a major risk factor to development of hepatocellular carcinoma (HCC). However, the clinicopathological role of *SLC10A1* in HCC is largely unknown. In this study, we investigated the expression and prognostic value of *SLC10A1* in HCC by integrating and meta-analyzing eight gene expression datasets (n=1200) derived from Gene Expression Omnibus (GEO) and The Cancer Genome Atlas (TCGA) data sets. We assessed *SLC10A1* gene expression difference between tumor and normal tissues, and its correlation with overall patient survival with Kaplan-Meier method. The expression level of *SLC10A1* was markedly decreased in HCC tumor tissues compared with corresponding normal tissues in 6 out of 8 datasets (meta-p-value <0.0001, fold change 1.03-9.6). Interestingly, differential expression was observed in both HBV-positive and HBV-negative HCCs, suggesting that other mechanisms than HBV receptor function of *SLC10A1* underlie the observed expression differences. Furthermore, in the TCGA HCC dataset, low expression in tumor tissue was associated with poor survival (Log-rank p-value <0.001). We postulate that decreased *SLC10A1* may lead to over-accumulation of bile acids, which is potentially cytotoxic to hepatocytes, causing liver inflammation and regeneration. In summary, the *SLC10A1* gene is down-regulated in liver cancers and is associated with poor prognosis. The intriguing role of *SLC10A1* in HCC tumorigenesis warrants further investigation. (Funded by the National Cancer Institute under Contract HHSN261200800001E).

**615F**

**Germline variants in mismatch repair genes are associated with microsatellite instability in sporadic tumors.** *A.R. Buckley<sup>1,2</sup>, H. Carter<sup>3,4,5</sup>, O. Harismendy<sup>6</sup>, N.J. Schork<sup>2</sup>.* 1) Biomedical Sciences Graduate Program, University of California, San Diego, La Jolla, CA, United States of America; 2) Human Biology Program, J. Craig Venter Institute, La Jolla, CA, United States of America; 3) Division of Medical Genetics, Department of Medicine, University of California San Diego, La Jolla, CA, United States of America; 4) Moores Cancer Center, University of California San Diego, La Jolla, CA, United States of America; 5) Cancer Cell Map Initiative (CCMI), University of California San Diego, La Jolla, CA, United States of America; 6) Division of Biomedical Informatics, Department of Medicine, University of California San Diego, La Jolla, CA, United States of America.

Cancer research to date has largely focused on somatic genetic aberrations, whereas the contribution of germline variation is controversial. While the role of germline variation in cancer susceptibility has been clearly demonstrated in rare familial cancer predisposition syndromes and in *BRCA*-associated cancers, it is arguable that inherited variation can additionally shape tumor growth and influence tumor phenotypes in sporadic cancers. Microsatellite instability (MSI) is a tumor phenotype characterized by expansion or contraction of repetitive microsatellite sequence elements due to somatically-acquired defects in the mismatch repair (MMR) machinery, either through somatic mutation or promoter hypermethylation. We hypothesize that deleterious germline variants in MMR pathway genes can similarly contribute to tumor MSI. To test this hypothesis, we called germline variants on 5,365 individuals spanning 17 cancer types from The Cancer Genome Atlas (TCGA) and studied their contribution to previously characterized somatic MSI. Using a rare variant burden approach, we tested the association between germline variants and somatic MSI accounting for somatic mutation and promoter hypermethylation of 225 genes involved in DNA repair. We found that germline loss of function (LOF) variants in the MMR pathway are significantly associated with an increased number of somatic MSI loci. This association was multiple-hypothesis corrected significant at both the pathway level and for *PMS2* and *PNKP* individually. Importantly, in some instances we observed that somatic LOF mutations, germline LOF variants, and somatic promoter hypermethylation have a similar effect size. Our results demonstrate that germline variation can influence somatic phenotypes to the same degree as somatic mutation, highlighting the need to integrate germline variants in cancer analyses.

**Genetic polymorphisms of *CD40* ligand gene and susceptibility to cervical cancer.** *T. Chang<sup>1</sup>, Y. Yang<sup>2,4</sup>, Y. Lee<sup>1,3,5</sup>, T. Chen<sup>2</sup>, W. Lin<sup>1</sup>, C. Lin<sup>1</sup>.* 1) Med Res Dept, Mackay Memorial Hosp, New Taipei, Taiwan; 2) Gynecology and Obstetrics Dept, Mackay Memorial Hosp, Taipei, Taiwan; 3) Pediatrics Dept, Mackay Memorial Hospital, Taipei, Taiwan; 4) Gynecology and Obstetrics Dept, Taipei Medical University, Taipei, Taiwan; 5) Pediatrics Dept, Taipei Medical University, Taipei, Taiwan.

Although human papillomavirus (HPV) infection is the main cause of cervical cancer, the host immunogenetic background also plays an important role in the development of cervical cancer. CD40 ligand (CD40L, also known as CD154 or gp39), a type II transmembrane protein, is primarily expressed on activated T cells and critical in T cell immunity. This study aims to investigate if variants of the *CD40L* gene are associated with cervical cancer in Taiwanese women. The  $-3459$  A/G and CA dinucleotide repeat polymorphisms were genotyped in 518 cervical squamous cell carcinoma (CSCC) patients and 508 age/sex matched healthy controls. The presence and genotypes of HPV in CSCC patients were also determined. We found no significant association between any polymorphisms or haplotypes examined and CSCC risk. In addition, no significant association was observed between HPV-16 positive CSCC patients and controls. Our findings provide no support for the hypothesis that specific *CD40L* polymorphisms are associated with CSCC susceptibility in Taiwanese women.

**617T**

**The progression of global gene expression in melanoma: From normal skin to metastatic disease.** *L. Cordeiro, O. Lupi.* UNIRIO, Rio de Janeiro, RJ, Brazil.

Cutaneous melanoma is the most deadly form of skin cancer and its worldwide incidence has been increasing at a rate higher than of any other tumor over the last several decades. In 2017, over 87000 new cases of melanoma will be diagnosed in the United States, making it the fifth cancer in incidence, and more than 10000 deaths will be attributed to the disease. While five-year survival rates have been improving, it can be lower than 15% in advanced cases, despite major advances in the treatment of metastatic disease in the last decade. High-throughput molecular techniques have been key to the development of such novel systemic therapies and will most likely play a major role in melanoma research. We systematically mined public gene expression data and built a unique dataset of over 700 samples, with expression measures of over 12000 genes, of normal skin, primary and metastatic melanoma. We analyzed the progression of changes in global gene expression from normal skin (N) to primary melanoma (P) and from primary to metastatic melanoma (M) and found 1429 differentially expressed genes in the N-P transition and 405 differentially expressed genes in the P-M transition. Moreover, 111 and 132 genes are consistently up and downregulated, respectively, in both N-P and P-M transitions, indicating that certain molecular changes take place at the outset and are maintained throughout advanced stages of the disease. Several genes were upregulated more than ten fold from normal skin to metastatic melanoma – *SPP1*, *GDF15*, *BCL2A* and *SERPINE2* – while some were downregulated by more than 95% – *SERPINB5*, *CST6*, *PERP*, *SLURP1* and *HOPX*. Pathway enrichment analysis uncovered distinctive patterns of changes in global expression in each transition. In the N-P transition, several immune-related pathways are activated – antigen processing and presentation, immune-related signaling and inflammatory response – as well as the p53 signaling pathway. In the P-M transition, the immune-related pathways and the p53 signaling pathway remain strongly activated and though cell cycle pathways seemed somewhat perturbed in the N-P state change, it is clear that these changes became statistically stronger in the P-M transition. Also, the deregulation of epithelial–mesenchymal transition pathways observed in the P-M transition is a known hallmark of metastatic disease.

**CDKN2A germline polymorphisms demonstrate parallel associations of disease risk and clinical outcome in melanoma patients.** S. Fang<sup>1</sup>, Y. Wang<sup>1</sup>, M. Ross<sup>1</sup>, J. Gershenwald<sup>1</sup>, J. Cormier<sup>1</sup>, R. Royal<sup>1</sup>, J. Reveille<sup>2</sup>, Q. Wei<sup>3</sup>, C. Amos<sup>4</sup>, J. Lee<sup>1</sup>. 1) University of Texas MD Anderson Cancer Center, Houston, TX; 2) The University of Texas Health Science Center at Houston; 3) Duke University School of Medicine; 4) Dartmouth College.

Germline mutations of the *CDKN2A* gene account for 1-2% of sporadic cases of melanoma and up to 40% of familial melanoma; furthermore, the *CDKN2A* region represents the strongest melanoma risk locus in genome-wide association studies (GWAS). A recent investigation has suggested that melanoma patients with high-penetrance *CDKN2A* germline mutations have worse melanoma-specific survival compared to patients with *CDKN2A* wild-type status. We therefore sought to evaluate associations between *CDKN2A* germline polymorphisms and both melanoma risk and patient outcomes. Previous studies have reported significant associations between melanoma susceptibility and multiple SNPs in the 9p21 region adjacent to *MTAP* and flanking *CDKN2A*, of which 9 SNPs were genotyped in the MD Anderson GWAS cohort of 1804 melanoma patients and 1026 normal controls, with a total of 818,237 genotyped SNPs and a median follow-up for the melanoma patients of 8.3 years. We evaluated these 9 SNPs for their associations with melanoma risk and melanoma-specific survival. The results indicated that 6 of 9 SNPs were significantly associated with melanoma risk ( $P < 0.05$ ). The A allele of the SNP rs4636294 in *CDKN2A* was associated with increased melanoma risk (odds ratio [OR]=1.23,  $P=0.0002$ ) and increased risk of melanoma-related death (hazard ratio [HR]=1.22,  $P=0.0135$ ). After adjustment for age, sex and disease stage at presentation, this SNP remained associated with increased risk of melanoma-related death (HR=1.20,  $P=0.0281$ ). Similarly, the C allele of rs2218220 was associated with increased melanoma risk (OR=1.23,  $P=0.0002$ ) and increased risk of melanoma-related death in both univariate (HR=1.22,  $P=0.0141$ ) and multivariable analysis (HR=1.20,  $P=0.0285$ ). Finally, the G allele of rs935053 was associated with increased melanoma risk (OR=1.25,  $P=0.000049$ ) and increased risk of melanoma-related death in univariate (HR=1.22,  $P=0.0144$ ) and multivariable analysis (HR=1.22,  $P=0.0151$ ). These associations suggest that common variants in the tumor suppressor gene *CDKN2A* may influence not just melanoma risk but also, in parallel fashion, the risk of melanoma-related death. Thus, common *CDKN2A* polymorphisms may act, similarly to rare high-penetrance mutations, in controlling not just melanoma risk but also disease severity. Additional investigation is indicated to confirm these findings in an independent cohort and to evaluate alterations in *CDKN2A* expression and function associated with these polymorphisms.

**Association of cytokine polymorphisms with gastric cancer prognosis in Santiago, Chile.** P. Gonzalez-Hormazabal<sup>1</sup>, M. Musleh<sup>2</sup>, S. Romero<sup>1</sup>, V.G. Castro<sup>1</sup>, M. Bustamante<sup>3</sup>, J. Stambuk<sup>4</sup>, F. Izquierdo<sup>4</sup>, R. Pisano<sup>4</sup>. 1) Human Genetics Program, Institute of Biomedical Sciences, University of Chile; 2) Department of Surgery, University of Chile Clinical Hospital; 3) Department of Surgery, School of Medicine at Eastern Campus, University of Chile; 4) San Juan de Dios Hospital.

Chile has one of the world's highest mortality rate from gastric cancer. Polymorphisms in cytokine gene has been associated with gastric cancer, but little is known about their role in prognosis for this disease. We aimed to investigate the association of 12 polymorphisms in eight cytokine genes (IL-1B, IL-8, IL-17A, IL-17F, IL-32, TNF, IL1-RN, and IL-10) with overall survival in 165 gastric cancer patients from Santiago, Chile, who received gastrectomy between December 2010 and August 2014. Mean survival time was 35.5 months (minimum 0.3 months, maximum 75.9 months). TaqMan assay was used to genotype the polymorphism. We used Stepwise Cox regression to select the polymorphisms and clinicopathological variables to be included in the Cox proportional hazard model. Our results suggest that rs1143627 (*IL1B* -31T>C) and rs4073 (*IL8* -251A>T) are associated with poor survival ( $p=0.037$  and  $p=0.010$ , respectively). Hazard Risk (HR) for rs1143627 TC or CC genotypes and rs4073 AT or TT genotypes was 1.33 [1.02 – 1.74] and 1.31 [1.07 – 1.63], respectively, both adjusted for age, sex, TNM score and tumor size. In conclusion, rs1143627 and rs4073 polymorphism are associated with poor overall survival of gastric cancer. Further larger studies are needed to validate our findings. Grant support: Fondo Nacional de Desarrollo Científico y Tecnológico, Chile. FONDECYT #1151015.

**Multi-gene hereditary cancer panel testing for *BAP1*.** S. Hiraki, L. Susswein, J. Bissonnette, Y. Wang, RT. Klein, KS. Hruska. GeneDx, Gaithersburg, MD.

**Statement of Purpose:** *BAP1* is a recently identified cancer predisposition gene associated with an increased risk of uveal melanoma, cutaneous melanoma, mesothelioma, clear cell renal cell carcinoma (RCC), and other cancers. However, the full phenotypic spectrum and penetrance of the gene has yet to be delineated. Our aim was to describe the spectrum of *BAP1* variants identified in our clinical testing cohort, and to characterize the clinical phenotype of individuals with *BAP1* pathogenic and likely pathogenic variants (collectively denoted PV). **Methods:** Results of *BAP1* testing were reviewed for individuals undergoing next-generation sequencing and deletion/duplication analysis of *BAP1* as a single-gene test, targeted variant test, or as part of a custom multi-gene hereditary cancer panel of up to 61 genes between January 2016 and March 2017. Personal and family histories, as well as the spectrum of variants identified, were assessed for those who carried a *BAP1* PV.

**Results:** Of 835 individuals whose testing included *BAP1*, 7 unique *BAP1* PV were identified in 13 individuals. All of the variants identified were loss-of-function and included 3 nonsense, 2 frameshift, and 2 canonical splice variants. Six individuals had panel testing for 2-44 genes, 2 individuals had single-gene *BAP1* testing, and 5 individuals from 2 unrelated families had targeted testing for a known familial PV. One individual who underwent panel testing also had a known PV in the family. Ten of the 13 PV carriers had phenotypes consistent with *BAP1*, including clear cell RCC (5), melanoma (3), and dysplastic nevi (2). The remaining 3 were unaffected, 2 of whom were under the age of 25 years and had targeted variant testing. Family histories included melanoma in 3 cases, one of which was uveal, and renal cell carcinoma in 3 cases. **Conclusions:** All *BAP1*-positive individuals had a clinical presentation consistent with *BAP1* tumor predisposition in terms of personal and/or family histories. For individuals with characteristic *BAP1*-associated tumors, adding this gene to a testing panel may identify variants that could influence future screening.

**621F**

**Role of *HOXB13* in breast and ovarian cancer: Preliminary data from a laboratory-based multigene panel testing cohort.** C. Horton, H. LaDuca, J. Grzybowski, C. Gao. Clinical Diagnostics, Ambry Genetics, Aliso Viejo, CA.

**Background:** The p.G84E alteration in *HOXB13* has been associated with an increased risk for prostate cancer in male carriers. While the phenotypic spectrum in carriers unselected for personal or family history of prostate cancer has not been well studied, predisposition to breast or ovarian cancers in females has been suggested. Here we aim to evaluate the role of p.G84E in predisposition to breast and ovarian cancer using a clinical laboratory cohort. **Methods:** De-identified molecular results and clinical histories were retrospectively reviewed for 33146 individuals who had multigene panel testing (MGPT) that included analysis of the *HOXB13* p.G84E locus. The frequency of *HOXB13* p.G84E was compared between non-Finnish European (NFE) MGPT cases and NFE controls from the Exome Aggregation Consortium (ExAC). **Results:** Eighty-nine individuals were *HOXB13* p.G84E carriers (0.27% of 33146), including nine with a mutation in a second gene. The most common cancers reported in p.G84E carriers were female breast (42 of 70; 60%), ovarian (3 of 70; 4.3%), and prostate (2 of 10; 20%). The frequency of p.G84E was significantly higher in NFE prostate probands than the ExAC NFE controls (1.35%; OR 4.4 p=0.03), but not in NFE female breast (0.35%; OR 1.1 p=0.5) or ovarian (0.16%; OR 0.5 p=0.4) probands. Individuals with family history of prostate cancer were more likely to carry p.G84E than those without (OR 2.43 p=5.06e-05) and the effect was strengthened in individuals with two or more family members with prostate cancer compared to those with no family history (OR 3.2 p=0.002). In contrast, individuals with family history of breast or ovarian cancer were not more likely to carry p.G84E than those without family history of these cancers. **Conclusions:** Although breast and ovarian cancer were among the most common cancers in p.G84E carriers, the mutation rate in these probands was not increased compared to the general population. Therefore, the preponderance of breast and ovarian cancer likely reflects the nature of this laboratory cohort rather than a risk association. The impact of prostate cancer family history on *HOXB13* mutation frequency highlights the importance of including prostate cancer when collecting family history regardless of the primary cancer indication for testing. The results of this study reinforce the association between *HOXB13* and prostate cancer; however, more data is needed to determine if female carriers are at increased risk to develop cancer. .

Peters: on behalf of CCFR, CORECT and GECCO. 1) Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Moffitt Cancer Center, Tampa, FL; 3) University of Michigan, Ann Arbor, MI; 4) National Cancer Institute, Bethesda, MD; 5) CHU Nantes, Nantes, France; 6) German Cancer Research Center, Heidelberg, Germany; 7) University of Virginia, Charlottesville, VA; 8) Massachusetts General Hospital, Boston, MA; 9) Mount Sinai Hospital, Toronto, ON, Canada; 10) Ontario Institute for Cancer Research, Toronto, ON, Canada; 11) The University of Melbourne, Melbourne, Australia; 12) University of Hawaii Cancer Center, Honolulu, HI; 13) University of Utah Health Sciences Center, Salt Lake City, UT; 14) University of Washington, Seattle, WA; 15) USC Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA.

Colorectal cancer (CRC) is a heterogeneous disease, consisting of biologically and clinically distinct subgroups that can affect prognosis and drug response. Yet, to date, CRC GWAS have assumed a genetically homogeneous case group, mainly because comprehensive molecular profiles are not readily available for well-powered samples. Recently, it has been established that primary tumor site is correlated with molecular subtype, and prognosis. The proximal, right-sided colon has a different embryonal origin than the distal, left-sided colon and the rectum, and right-sided tumors more frequently have microsatellite instability, the CpG island methylator phenotype, and *BRAF*<sup>V600E</sup> mutations. By contrast, left-sided tumors have higher frequencies of *APC*, *KRAS*, and *TP53* mutations. In this study, we explored whether genetic risk factors differ between CRC case subgroups defined by primary tumor site. We performed whole-genome sequencing of 1,961 CRC cases and 981 controls, and subsequently imputed these haplotypes into 11,895 CRC cases and 14,659 controls that are part of the Colorectal Cancer Family Registry (CCFR) and the Genetics and Epidemiology of Colorectal Cancer Consortium (GECCO). Stratified GWAS revealed a genome-wide significant common SNP signal associated specifically with proximal colon cancer risk (rs1800734;  $P=1.3e-9$ ; 4,349 cases) at the *MLH1* gene, which frequently harbors causative mutations in Lynch syndrome (OMIM #609310). When comparing effects at known CRC risk loci between tumor sites, we found strong differences at several loci, e.g., for rs3087967 at *COLCA1/COLCA2*, odds ratios were 1.18 (95% CI: 1.11-1.24;  $P=4.0e-9$ ) based on 6,344 left-sided tumor cases, and 1.02 (95% CI: 0.96-1.08;  $P=0.49$ ) based on 4,344 right-sided tumor cases. To quantify the shared genetic basis, we performed bivariate GREML analysis as implemented in GCTA. We estimated the genetic correlation  $r_g$  to be 0.74 (95% CI: 0.45-1.00). A likelihood ratio test for rejecting the hypothesis that  $r_g = 1$  approached significance ( $P=0.055$ ). On the underlying liability scale, the heritability was estimated to be 0.068 (95% CI: 0.046-0.091) and 0.080 (95% CI: 0.050-0.102) for left- and right-sided tumors, respectively. We are currently expanding this analysis to >60,000 CRC cases and controls. Additionally, we will use the BUHMBOX statistic to test whether the shared genetic basis can be explained by subgroup heterogeneity such that risk alleles are shared by only a subset of all cases.

## 623T

**Birth order affects risk of multiple lymphoid cancers in lymphoid cancer families.** S.J. Jones<sup>1,2</sup>, O.S. Uvarov<sup>3</sup>, D. Salema<sup>3</sup>, J. Connors<sup>4</sup>, A. Brooks-Wilson<sup>2,3</sup>. 1) Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada; 2) Canada's Michael Smith Genome Sciences Centre, British Columbia Cancer Agency, Vancouver, British Columbia, Canada; 3) Department of Biomedical Physiology and Kinesiology, Simon Fraser University, Burnaby, British Columbia, Canada; 4) Centre for Lymphoid Cancers, BC Cancer Agency, Vancouver, British Columbia, Canada.

The hygiene hypothesis proposes that an early life environment that has a relative lack of early exposure to microorganisms and infectious disease inhibits a child's immune system from maturing optimally. Consequently, such individuals are more susceptible to atopic disorders, including allergies and autoimmune diseases, as well as some lymphoid cancers including Hodgkin lymphoma (HL), acute lymphocytic leukemia, and possibly non-Hodgkin lymphoma (NHL). Birth order and family size relate to the hygiene hypothesis, as they are likely to affect exposure to infectious diseases, with low birth order and smaller families correlating with higher risk of immune-related disorders. We examined sibships within 182 families with a history of lymphoid cancer. Birth order and other information was collected from telephone interviews and questionnaires, from multiple family members whenever possible. 380 sibships with 481 lymphoid cancer cases were examined. We hypothesized that early life factors in these families would support the hygiene hypothesis. An inverse relationship between birth order and lymphoid cancer diagnosis was observed for all types of lymphoid cancers together ( $p$ -value <0.0001), as well as for NHL ( $p$ -value <0.0001), chronic lymphocytic leukemia ( $p$ -value = 0.0069), and multiple myeloma ( $p$ -value = 0.0011) separately, but was not significant for HL ( $p$ -value = 0.2265), possibly due to small sample size. The observed inverse relationship between birth order and risk of lymphoma is supportive of the hygiene hypothesis, and that childhood exposures to infectious disease may play a role in risk of multiple types of lymphoid cancers. The familial nature of the cancers studied here implies a role of shared genetic and/or environmental factors. The current observation implies that such effect(s) may be modified by lifestyle factors that correlate with birth order, and could lead to identification of lifestyle factors that protect against lymphoid cancers even in the familial context.

**Rare DNA repair gene mutations predispose to young onset and lethal prostate cancer in the UK.** Z. Kote-Jarai<sup>1</sup>, DA. Leongamornlert<sup>1</sup>, EJ. Saunders<sup>1</sup>, S. Wakerell<sup>1</sup>, I. Whitmore<sup>1</sup>, T. Dadaev<sup>1</sup>, C. Cieza-Borrella<sup>1</sup>, K. Govindasami<sup>1</sup>, MN. Brook<sup>1</sup>, DV. Conti<sup>2</sup>, RA. Eeles<sup>1</sup>. 1) Oncogenetics, The Institute of Cancer Research, London, London, United Kingdom; 2) Keck School of Medicine, USC, Los Angeles, CA, US.

Prostate cancer (PrCa) is the most common solid tumour in men in the Western world. There is substantial evidence that PrCa predisposition is due both to common and rare germline variation. We screened 167 genes from DNA damage response and repair pathways, within a UK based cohort of young onset cases (diagnosed at <65 years) and controls. Samples were sequenced using a custom Agilent SureSelectXT bait library and Illumina HiSeq technology and processed using a BWA/GATK 2.8 pipeline. Following sample QC, data was analysed from 1,285 PrCa cases and 1,163 controls, with mean target coverage of 76x. We identified 5,086 single nucleotide variants (SNVs) and 175 indels. 233 unique protein truncating variants (PTVs) with MAF <0.5% in controls were found in 97 genes of the screening panel. The total proportion of PTV carriers in cases was higher than in controls (14.5% vs. 11.6%,  $P = 0.036$ ). This enrichment was greater within the previously reported BROCA gene set of 22 tumour suppressor genes (4.5% vs 2.2%,  $P = 2.5 \times 10^{-3}$ ) and subset of *ATM*, *BRCA1*, *BRCA2* and *CHEK2* (3.7% vs. 1.4%,  $P = 3.1 \times 10^{-4}$ ). To identify genes which distinguish PrCa cases from controls within our sample set, we calculated the OR for each gene with at least 2 carriers of PTVs. This analysis selected 21 genes with OR  $\geq 1.5$ ; men with PTVs in these were 3.6-fold more likely to have PrCa ( $P = 4.29 \times 10^{-10}$ ). We subsequently compared lethal PrCa cases (cause of death PrCa,  $n = 183$ ) to indolent cases (Gleason score  $\leq 6$ ,  $n = 563$ ) to evaluate genes associated with poor clinical prognosis. 8 genes had OR  $\geq 1.5$  for lethal PrCa, 7 of which overlapped the predisposition gene set (*ATM1*, *CHEK2*, *BRCA2*, *GEN1*, *MSH2*, *MSH5* & *POLD1*). Within our cohort, carriers of PTVs in the lethal PrCa gene set were 3.9-fold more likely to die from PrCa (11.5% vs. 3.2%,  $P = 6.20 \times 10^{-5}$ ). The union of these gene sets provides a 22 gene panel of which only 6 genes overlap with the BROCA panel. 7.8% of men diagnosed <65yrs with PrCa carried a PTV in this gene set compared to 2.3% of controls. These findings will help facilitate the development of a PrCa specific sequencing panel with both predictive and prognostic potential.

**Genome-wide scan of single-nucleotide polymorphisms associated with prostate cancer specific death.** W. Li<sup>1</sup>, D. Sjoberg<sup>2</sup>, E. Vertosick<sup>3</sup>, A. Dahlin<sup>3</sup>, O. Melander<sup>3</sup>, D. Ulmert<sup>4</sup>, H. Lilja<sup>5,6,7</sup>, R. Klein<sup>1</sup>. 1) Icahn Institute for Genomics and Multiscale Biology and Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY USA; 2) Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, NY USA; 3) Lund University, Lund, Sweden; 4) Molecular pharmacology program, Sloan Kettering Institute, New York, NY USA; 5) Departments of Laboratory Medicine, Surgery, and Medicine, Memorial Sloan Kettering Cancer Center, New York, NY USA; 6) Nuffield Department of Surgical Sciences, University of Oxford, Oxford, UK; 7) Department of Translational Medicine, Lund University, Malmö, Sweden.

While over 100 SNPs are associated with risk of prostate cancer diagnosis, SNPs associated with prostate cancer specific mortality remain to be identified. We used GWAS to find single nucleotide polymorphisms (SNPs) predictive of prostate cancer specific death. This study used a time-to-event survival analysis based on 11,506 men aged 45-73 in Malmö, Sweden accepting participation during 1991-96. In the Malmö Diet and Cancer (MDC) study, 1053 men were diagnosed with prostate cancer of whom 245 died from the disease by December 31, 2014. Men diagnosed with prostate cancer were genotyped genome-wide and all common variants were imputed using 1000 Genomes data. Stage and grade at diagnosis and outcome information was obtained from the Swedish Cancer Registry, the National Prostate Cancer Registry of the Southern Region, and cause of death obtained from the Causes of Death Registry at the National Board of Health and Welfare in Sweden, a reliable source on the cause of death from prostate cancer. We conducted a genome-wide association study using Cox proportional hazards model, adjusted for age at diagnosis and stage and grade at diagnosis. Top candidate SNPs were further studied using eQTL analysis and explored in other prostate cancer cohorts. We tested each of 6,126,633 SNPs for association with prostate cancer specific survival. Two of SNPs tested in this analysis reached genome-wide significance ( $p < 5 \times 10^{-8}$ ): rs73055188 ( $p = 5.27 \times 10^{-9}$ , per-allele HR = 2.27, 95% CI 1.72–2.98) located in the *AOX1* gene and rs35105661 ( $p = 1.10 \times 10^{-8}$ , per-allele HR = 2.03, 95% CI 1.59–2.59) located in the *HERC4* gene. Additionally, 10 candidate SNPs with  $P < 1 \times 10^{-6}$  were found. eQTL study shows that rs73055188 is correlated with *AOX1* gene expression level, which is associated with biochemical recurrence of prostate cancer. Our GWAS identified several SNPs associated with prostate cancer specific death. Multiple lines of evidence showed that *AOX1* gene is related to prostate cancer progression. These putative associations suggest that GWAS may be useful in identifying SNPs and genes associated with clinical outcome in prostate cancer.

**Analysis of circulating tumor cells in multiple myeloma patients reveals mutations in proto-oncogenes and tumor suppressor genes of NF- $\kappa$ B, Ras/MAPK, and PI3K/Akt pathways.** D.S. Manjegowda<sup>1</sup>, A.M. Veerappa<sup>2</sup>. 1) Department of Biomedical Science, Nitte University Centre for Science Education and Research, Nitte University, Paneer Campus, Deralakatte, Mangalore, Karnataka, India; 2) Department of Genetics and Genomics, University of Mysore, Manasagangotri, Mysore, Karnataka, India.

Multiple myeloma (MM), a malignancy of plasma cells, is characterized by widespread genomic heterogeneity and, consequently, differences in disease progression and drug response. The characterization of circulating tumor cells (CTCs) may represent a non-invasive method to capture relevant mutations present in plasma cell clones. Here, we conducted a study, to analyze the genomic landscape of CTCs in five MM patients. We performed whole-exome sequencing in sorted CTCs and compared their mutational profile. The disease pathway analysis was performed to identify driver and passenger gene mutations. Present investigation revealed several deleterious and damaging driver gene mutations in *MLL3*, *BRCA2*, and *LTB* contributing towards early initiating mutagenic events leading to plasma cell immortalization and disease initiation. This loss of genomic integrity led to accumulation of additional translocation mutations involving *RAG1*, *IGH* and *IGK*. This transposition occurred near to an enhancer present 149 kb upstream enhancing the production of *IGK*. The molecular events driving and sustaining the cancer identified crucial genomic alterations in genes such as *KRAS*, *DIS3*, *NANOG*, *FLT3*, *IL6*, *JAG1* and *MAP3K1*. Secondary mutations in *KRAS*, a proto-oncogene and member of MAPK signaling pathway, was found causing continuous proliferation and differentiation of cells leading to MM. These genes belong to NOTCH, wntless (WNT), and nuclear factor-kappa B (NF- $\kappa$ B), Ras/MAPK, phosphatidylinositol3-kinase/Akt (PI3K/Akt) pathways and mutations in genes of these pathways contribute towards activation of oncogenic pathways. These mutations were found to precede, succeed or jointly initiate several stages of activations in oncogenic pathways contributing towards sustained activation in MM cells.

The rapid introduction of massive parallel sequencing into clinical genetics services is enabling the screening of multiple breast cancer susceptibility genes in one assay at reduced cost for women who are at increased risk of breast (and other) cancer. These gene panels now typically include a large number of genes but only a few of these genes have established clinical validity. These tests therefore pose considerable challenge to clinical genetic services, as very little is known about the breast cancer risk associated with any of the observed genetic variation. Accumulated research on *BRCA1* and *BRCA2* mutation carriers now means that these women can be offered personalized risk assessment, targeted treatment regimens and informed decision making about the use of chemo-preventive agents, bilateral salpingo-oophorectomy, mammography, risk reducing mastectomy, magnetic resonance imaging (MRI) and other screening modalities. This information is lacking for high-risk women (as defined on family history) who are not found to carry an identifiable mutation in *BRCA1* or *BRCA2*. These women represent about 80% of those tested. Some evidence has been accumulated to enable improved management for women found to carry mutations in *PALB2*, *ATM* and *CHEK2*, and their families. The community now needs similar information about the larger number of genes that are being tested routinely on gene panels to provide the evidence-base from which clinical management and genetic counseling can be provided. We are conducting a large nation-wide study of 10,000 Australian women at high-risk of breast cancer who have tested negative for mutations in *BRCA1* and *BRCA2*. We are performing targeted sequencing of *BRCA1*, *BRCA2*, *PALB2*, *TP53*, *ATM*, *MLH1*, *MSH2*, *MSH6*, *PMS2*, *BARD1*, *BRIP1*, *CDH1*, *CHEK2*, *MRE11A*, *RAD50*, *NBN/NBS1*, *MUTYH*, *NF1*, *PTEN*, *RAD51C*, *STK11*, *FANCM*, *RECQL*, *RAD51D* and will present the spectrum of genetic variation observed in these genes. The BRA-STRAP study will enable i) Australian population-based specific estimates of mutation prevalence and penetrance and ii) pooling with similar data from other international efforts including BRIDGES (European Commission) and CARRIERS (NIH). This work will enable the evidence-based translation of new genetic information and a new genetic testing model into clinical practice.

**Genome-wide association study to identify the novel biomarker for response to tamoxifen.** H. Ohnishi<sup>1,2</sup>, I. Endo<sup>1</sup>, S. Nakamura<sup>3</sup>, T. Ishikawa<sup>4</sup>, M. Kubo<sup>5</sup>, C. Udagawa<sup>6</sup>, G. Kutomi<sup>6</sup>, Y. Sagara<sup>7</sup>, Y. Hasegawa<sup>8</sup>, H. Zaha<sup>9</sup>, H. Takei<sup>10</sup>, H. Zembutsu<sup>1</sup>. 1) Cancer Precision Medicine Center, Cancer Institute, Tokyo, Japan; 2) Department of Gastrointestinal Surgery, Graduate School of Medicine, Yokohama City University, Yokohama, Japan; 3) Division of Breast Surgical Oncology, Department of Surgery, Showa University School of Medicine, Tokyo, Japan; 4) Department of Breast Surgery, Tokyo Medical University, Tokyo, Japan; 5) RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; 6) 1st Department of Surgery, Sapporo Medical University, Sapporo, Japan; 7) Department of Breast Surgery, Sagara Hospital, Kagoshima, Japan; 8) Department of Breast Surgery, Hirosaki Municipal Hospital, Hirosaki, Japan; 9) Department of Breast Surgery, Nakagami Hospital, Okinawa, Japan; 10) Department of Breast Surgery, Nippon Medical School, Tokyo, Japan.

Purpose: Although many association studies of genetic variants with the clinical outcomes of breast cancer patients receiving adjuvant tamoxifen therapy have been reported, genetic factors determining individual response to tamoxifen are not fully understood. To identify novel genetic markers for response to tamoxifen, we conducted a genome-wide association study (GWAS). **Material and Methods:** We enrolled 347 pathologically diagnosed with estrogen receptor (ER)-positive (> 10%), human epidermal growth factor receptor 2 (HER2)-negative, invasive breast cancer patients receiving preoperative tamoxifen monotherapy for 14–28 days. Ki-67 response in breast cancer tissues after tamoxifen therapy was used as a surrogate marker for response to tamoxifen. We performed a GWAS using 275 patients with the Illumina HumanOmniExpressExome-8-v1-2 (Illumina), and 72 patients were used for a replication study. **Results:** In the GWAS, the top 100 single nucleotide polymorphisms (SNPs) which revealed the smallest *P* values showed possible associations with Ki-67 response (*P* value =  $3.55 \times 10^{-4}$  to  $8.44 \times 10^{-6}$ ). We selected 74 SNPs of the top 100 SNPs, after considering linkage disequilibrium (LD;  $r^2 < 0.8$ ), for a replication study. Furthermore, a combined result of the GWAS and replication study revealed stronger association of three SNPs with Ki-67 response than the result of GWAS (SNPA;  $P_{\text{combined}} = 8.34 \times 10^{-6}$ , SNPB;  $P_{\text{combined}} = 1.64 \times 10^{-5}$ , and SNPC;  $P_{\text{combined}} = 2.03 \times 10^{-5}$ ). To further characterize the three SNPs, we imputed genotypes of SNPs that were not genotyped in the GWAS but are located within 500 kb upstream or downstream of the three SNPs. In this study, we finally identified three SNPs (SNPD on chromosome 4;  $P_{\text{combined}} = 5.69 \times 10^{-6}$ , SNPE on chromosome 6;  $P_{\text{combined}} = 1.64 \times 10^{-6}$ , and SNPF on chromosome 10;  $P_{\text{combined}} = 9.77 \times 10^{-6}$ ) possibly associated with Ki-67 response. We examined the combined effects of the three SNPs by classifying patients into three groups on the basis of the total number of risk alleles of these three SNPs, and found that the number of risk alleles of these three genes had cumulative effects on Ki-67 response after tamoxifen therapy ( $P_{\text{combined}} = 1.86 \times 10^{-15}$ ). **Conclusions:** Our results could contribute useful information for identifying biomarkers for predicting response to tamoxifen therapy in patients with breast cancer.

## 629T

**Gene environment interactions in the context of lobular breast cancer.** C. Petridis<sup>1,2</sup>, M.A. Simpson<sup>1</sup>, R. Roylance<sup>3</sup>, E.J. Sawyer<sup>1</sup>. 1) Medical and Molecular Genetics, King's College London, London, United Kingdom; 2) Research Oncology, King's College London, London, United Kingdom; 3) UCLH NHS Foundation Trust, University College London, United Kingdom.

Invasive lobular breast cancer (ILC) is the second most common histological subtype of breast cancer accounting for approximately 15% of all invasive cases. A pre-invasive lesion, lobular carcinoma *in situ* (LCIS) is also present in approximately 60% of these cases. We have previously shown that there is a significant overlap in the genetic predisposition of ILC and the most common invasive ductal carcinoma (IDC) but there are also distinct associations. It has also been shown that the majority of the environmental risk factors have similar associations between the two subtypes but that the use of hormone replacement therapy is more strongly associated with ILC compared to IDC. The aim of this study was to assess whether there is any of an interaction between breast cancer susceptibility loci and use of HRT in ILC. 12 single nucleotide polymorphisms (SNPs) previously found to be associated with ILC were genotyped using the iCOGS platform (cases) and KASP genotyping technology (controls), in postmenopausal women (406 cases and 481 controls) from the GLACIER study. Seven SNPs reached a corrected level of significance ( $P < 0.0042$ ) and were included in the analysis. Three loci show some evidence of interaction with HRT: rs704010, *ZMIZ1* ( $P = 0.0065$ ); rs865686, 9q31.2 ( $P = 0.019$ ) and rs2981582, *FGFR2* ( $P = 0.03$ ). For rs704010, 10:79081391, *ZMIZ1* and rs865686, 9:108126198, 9q31.2 the risk increased for homozygous carriers of risk allele in the presence of HRT (rs704010: OR of HRT for carriers of 2 risk alleles = 1.82 (1.06, 3.11)). In contrast for rs2981582, 10:121592803, *FGFR2* the risk conferred by the risk allele was observed only in the group of individuals who have not used HRT. None of these interactions were deemed significant after correcting for multiple testing, however these interactions warrant further investigation with a larger sample set.

**Oral findings of cancer predisposition conditions: “Red flags” that dental, oral and craniofacial providers should recognize for early diagnosis, referral and management.** A.M. Pham<sup>1,2,3</sup>, P.A. Sanchez-Lara<sup>1,2,3</sup>, L.T. Odone<sup>1,2,4</sup>, D.D. Yamashita<sup>1,2,4</sup>. 1) Children’s Hospital Los Angeles, Los Angeles, CA; 2) Center for Craniofacial Molecular Biology, Los Angeles, CA; 3) Keck School of Medicine, University of Southern California, Los Angeles, CA; 4) Ostrow School of Dentistry, University of Southern California, Los Angeles, CA.

In this paper, we highlight the presentation of a recent 7-year-old Hispanic female patient who presented to the oral surgery clinic for evaluation of her multiple distal tongue papillary nodules. She had a history of chronic constipation, mild intellectual disability, seizures and a negative family history. On exam she had ten 3mm papillary nodules on the distal 1/3 of her tongue and two pea-sized buccal prominences at the inner edge of the oral commissure. She had a narrow face, prominent lips, mild periorbital and conjunctival erythema. Biopsy of the nodules confirmed that they were papillary neuroomas, which supported the concern for MEN2B. Subsequent screening test for calcitonin and genetic analysis for the *RET* gene confirmed our diagnosis. Multiple endocrine neoplasia type 2B (MEN2B) is a rare congenital disorder that involves high risk for development of medullary carcinoma of the thyroid (MTC), pheochromocytoma, and parathyroid adenoma or hyperplasia. We also highlight several other recent patients with typical and atypical oral presentations of other cancer predisposition syndromes. Although the cases highlighted in this series are not an exhaustive list, several features identified should be considered “red flags” that trigger prompt referral for confirmation, counseling and management.

Lee Moffitt Cancer Center & Research Institute; 4) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 5) Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute.

Testicular Germ Cell Tumor (TGCT) is the most common cancer affecting men aged 15–45. More than 230,000 US men are living with the disease. No highly penetrant genetic has been identified in TGCT, despite high estimated heritability. Sons and brothers of TGCT cases have 4–6-fold and 8–10-fold risk increases, respectively. Linkage and candidate gene studies have been uninformative, with the exception of a modest association with *PDE11A* inactivating mutations and the Y-deletion “*gr/gr*.” GWAS studies, however, have revealed almost 40 independently associated loci, involving pathways unique to germ cell tumors (germ cell development, sex determination), in addition to pathways associated with other cancer types (DNA damage response and telomere length). This study aimed to identify candidate germline variants with a role in TGCT predisposition. We performed exome sequencing on 221 probands with TGCT who also had either a first- or second-degree family history of TGCT, or bilateral TGCT. Variants were considered of interest if they were: rare (MAF<0.01 ExAC European non-Finnish population); missense, frameshift, or stop mutation; assessed as deleterious in MetaLR and MetaSVM; and heterozygous. Several genes presented three or more pathogenic mutations throughout the cohort. These genes included *TYR* and *OCA2*, important for tyrosine metabolism, and of particular interest given that TGCT almost exclusively affects white men. Variants were found in several genes related to hypogonadism and fertility, including *WDR11* and *PROK2*. Pathway analysis showed significant over-representation of variants in three pathways: KREB zinc fingers ( $p=1.08E-18$ , FDR=1.23E-07), ABC transporters ( $p=2.20E-18$ , FDR=2.92E-15), proteins related to collagen deposition and remodeling ( $p=8.21E-09$ , FDR= 1.09E-5). The latter are of particular interest, given that collagen remodeling drives descent, and maldescent (cryptorchidism) is one of the best-defined TGCT risk factors. Association was independent of whether the patients were clinically cryptorchid (Fisher’s exact t-test  $p=0.637$ ). These data suggest that heritability of TGCT is genetically highly heterogeneous, concordant with existing models based on GWAS findings. Our findings suggest novel associations of TGCT predisposition with ABC transporters, collagen remodeling genes, and zinc fingers.

The lifetime risk to develop colorectal cancer (CRC) is ~4.5% and doubles with one affected 1<sup>st</sup> degree relative and increases with additional affected 1<sup>st</sup> degree relatives. There are ~16 major genes known to be associated with high penetrance CRC or polyposis (CRC/P). Although ~25% of all CRC/P cases appear familial, current genetic testing fails to identify a causal genotype in ~80% of those cases. There are likely other genes underlying heritable high penetrance CRC/P that have not been validated and are not on current genetic testing panels. To test for evidence of novel CRC/P associated loci we evaluated 178 candidate genes nominated by linkage, GWAS, or involvement in DNA repair. We compared the number of rare (minor allele frequency < 0.005), potentially disruptive variants (PDVs: stop gain, splice acceptor/donor change, frameshift) found in 83 unexplained CRC/P cases and 2440 controls. Cases included individuals from the University of Washington Clinical Sequencing Exploratory Research NEXT Medicine study (N=51) and Family Polyposis Study (N=10), ascertained from patients referred to medical genetics, and from the Women's Health Initiative (N=22). European ancestry controls were selected from the Exome Sequencing Project, and were not known to have any Lynch [MIM 120435] associated cancers. All participants were verified to have European ancestry and did not have identifiable pathogenic or likely pathogenic variants in any CRC/P associated gene. Multiple sequencing platforms were used as the data were ascertained from multiple sites and at different times. Sequences for each participant were aligned to the whole genome and jointly genotyped using Genome Analysis Tool Kit. As the target regions differed, we analyzed regions covered by all targets and with >90% genotype rate. We found a significant association between case status and rare PDV presence: 19% of cases versus 12% of controls with ≥ 1 PDV in the 178 genes considered (OR=1.7, p=0.04). PDVs were found in 15 genes for cases and 92 genes for the larger control group. As the number of burden tests is large, no gene met test-wide statistical significance (p<2.8e-4). However, logistic regression, adjusting for ancestry and sequencing center/target, indicated 3 genes had suggestive evidence for association with CRC/P: *BRIP1* (OR=36, p=0.003), *NTHL1* (OR=37, p=0.0016), and *RECQL* (OR=20, p=0.008). In summary, these data support the existence of additional genes that underlie high penetrance CRC/P.

**633F**

**Identification of novel prostate cancer susceptibility loci in Finnish population.** C. Sipeky<sup>1</sup>, T.L.J. Tammela<sup>2</sup>, A. Auvinen<sup>3</sup>, C. PRACTICAL<sup>4</sup>, J. Schleutker<sup>1,5</sup>. 1) Institute of Biomedicine, University of Turku, Turku, Finland; 2) Faculty of Medicine and Life Sciences, University of Tampere, Tampere, Finland; 3) Faculty of Social Sciences, University of Tampere, Tampere, Finland; 4) Prostate Cancer Association Group to Investigate Cancer Associated Alterations in the Genome (PRACTICAL); 5) Tyks Microbiology and Genetics, Department of Medical Genetics, Turku University Hospital, Turku, Finland.

Prostate cancer (PrCa) is the second most prevalent cancer in men worldwide, with 420,000 new cases and with over 100,000 annual deaths (2012). PrCa has a significant heritable component, with genetic factors accounting for 58% of the risk. Accordingly, genome-wide association studies (GWAS) identified 104 low penetrance PrCa susceptibility loci to date, predominantly in populations of mixed European ancestry. However, effect allele frequencies (EAF) and strength of association (Odds ratio, OR) are often variable across populations. Our aim is to identify common PrCa susceptibility alleles specific for Finnish population. Therefore, we conducted an analyses of >200,000 single nucleotide polymorphisms (SNPs) in 2764 PrCa cases and 2401 controls of Finnish origin. Germline DNA samples were genotyped within the Collaborative Oncological Gene-Environment Study (COGS) using Illumina iSelect custom SNP genotyping platform. Statistical analyses of unconditional case-control logistic regression model was performed by using PLINK software. After FDR adjustment altogether 160 variants remain significant on GWAS level (p<5x10<sup>-8</sup>). The PrCa associated signals are concentrated on chromosomes (chr) 7, 8, 11, 17, 19, and in close proximity to one another on the same chr. The strength of association varies between 0.59-1.86. In our study we identified 101 risk variants on chr 8, 11, 17 (OR 1.24-1.86) and 59 protective variants on chr 7, 8, 17, 19 (OR 0.59-0.80). The OR 1.86 is the highest by now found in GWAS studies examining common SNPs in non-familial cases. Our data suggests that chromosome 11 seem to be risk conferring, whereas chromosomes 7 and 19 possess protective variants. The results facilitate population risk stratification for screening, clinical studies, treatment choices and functional research of prostate cancer in Finnish population.

**634W****Co-heritability between aggressive and non-aggressive prostate cancer:**

**Are germline risk loci the same for all prostate cancers?** C.G. Tai<sup>1</sup>, N.C. Emami<sup>1,2</sup>, T.J. Hoffmann<sup>1,3</sup>, L.C. Sakoda<sup>4</sup>, E. Jorgenson<sup>4</sup>, L.A. Habel<sup>4</sup>, J. Shan<sup>4</sup>, D.K. Rantunga<sup>4</sup>, C.R. Chao<sup>5</sup>, N.R. Ghai<sup>6</sup>, D. Aaronson<sup>6</sup>, J. Presti<sup>6</sup>, C. Schaefer<sup>7</sup>, N. Risch<sup>1,3,4</sup>, S.K. Van Den Eeden<sup>4,7</sup>, J.S. Witte<sup>1,3,7</sup>. 1) University of California, San Francisco (UCSF), San Francisco, CA; 2) Program in Biological and Medical Informatics, UCSF, San Francisco, CA; 3) Institute for Human Genetics, UCSF, San Francisco, CA; 4) Division of Research, Kaiser Permanente Northern California, Oakland, CA; 5) Department of Research and Evaluation, Kaiser Permanente Southern California, Pasadena CA; 6) Department of Urology, Kaiser Oakland Medical Center, Oakland, CA; 7) Department of Urology, UCSF, San Francisco, CA.

**Introduction:** There is considerable debate over whether germline genetic risk loci for overall prostate cancer confer susceptibility for aggressive prostate cancer phenotypes. Previous studies of aggressive prostate cancer have been unable to replicate many of the same genetic associations previously found for overall prostate cancer, of which the majority is non-aggressive. But often these studies have limited sample size and thus likely underpowered. In this analysis we aim to evaluate the degree to which risk loci are shared between aggressive and non-aggressive prostate cancer and to estimate the genetic correlation between the two phenotypes. **Methods:** We conducted our analysis using a subset of unrelated individuals of European ancestry from the Kaiser Permanente Genetic Epidemiology Research on Aging (GERA) cohort which included 3,501 prostate cancer cases (1,090 aggressive and 2,411 non-aggressive) and 24,664 controls. Aggressive phenotypes were prostate cancer cases with high Gleason score, early age at diagnosis (less than 55 yrs), or biochemical recurrence. Using the method implemented in GCTA v1.26.0 we conducted a bivariate restricted maximum likelihood estimation of the genetic covariance between aggressive and non-aggressive prostate cancer using controls without prostate cancer as the referent for both phenotypes. Genetic relationship matrices were built using a set of LD-pruned SNPs filtered based on minor allele frequency, call rate, missingness between cases and controls, and 1000 Genomes allele frequency. **Results:** SNP heritability for aggressive and non-aggressive prostate cancer was 0.19 (SE = 0.07) and 0.26 (SE = 0.06), respectively. The genetic correlation between these two phenotypes was estimated to be  $r_G = 1.0$  (SE = 0.27). Using imputed SNP data, the heritability estimates increased to 0.25 (SE = 0.10) and 0.35 (SE = 0.09) for aggressive and non-aggressive prostate cancer, respectively, while the genetic correlation remained the same  $r_G = 1.0$  (SE = 0.26). **Conclusions:** Although there may be some genetic risk loci specific to aggressive prostate cancer, it seems many of the loci previously found for overall prostate cancer are also risk loci for aggressive prostate cancer.

**635T****A rare variant in GOLM1 predisposes to cutaneous malignant melanoma.**

C. Teerlink<sup>1</sup>, C. Huff<sup>2</sup>, J. Stevens<sup>3</sup>, S. Holmen<sup>3,4</sup>, K. Trombetti<sup>2,4</sup>, D. Grossman<sup>2,5</sup>, J. Farnham<sup>6</sup>, J. Wen<sup>6</sup>, J. Facelli<sup>7</sup>, L. Meyer<sup>6,8</sup>, J. Zone<sup>5</sup>, S. Leachman<sup>9</sup>, L. Cannon-Albright<sup>1,9</sup>. 1) Dept Internal Medicine, Univ Utah Sch Med, Salt Lake City, UT; 2) Department of Epidemiology, University of Texas MD Anderson Cancer Center, Houston, TX; 3) Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; 4) Department of Surgery, University of Utah School of Medicine, Salt Lake City, UT; 5) Department of Dermatology, University of Utah School of Medicine, Salt Lake City, UT; 6) Utah Department of Health, Salt Lake City Utah, UT; 7) Department of Biomedical Informatics, University of Utah School of Medicine, Salt Lake City, UT; 8) George E. Wahlen Department of Veterans Affairs Medical Center, Salt Lake City, UT; 9) Department of Dermatology, Oregon Health and Science University, Portland, OR.

**Statement of purpose:** Significant linkage of cutaneous malignant melanoma (CMM) to chromosome 9q21 was previously reported in a Danish pedigree resource and confirmed in Utah high-risk pedigrees. Sequence data was analyzed to identify the responsible predisposition gene. **Methods:** Whole exome sequencing of pairs of related CMM cases from two pedigrees with evidence of 9q21 linkage was performed to identify the responsible predisposition gene. **Results:** A rare non-synonymous variant in Golgi Membrane Protein 1 (*GOLM1*), (rs149739829, S307L, chromosome 9:88,650,378 base pair (hg19)) shared in both carriers in one linked pedigree was observed. Segregation of this variant in additional CMM-affected relatives of the index carriers was confirmed. A significant excess of carriers of the variant was observed among 491 unrelated Utah CMM cases compared to 207 population non-cancer controls (OR=9.7, p=0.0045). This significant excess was validated in an independent set of 1,534 CMM cases and 1,146 population controls from Texas, (OR=2.5, p=0.015). Multiple other pedigrees segregating this variant have been identified; protein prediction modeling suggests large changes in the cytoplasm region shown to bind EGFR and other RTK proteins. **Conclusion:** These findings suggest that *GOLM1* is a CMM predisposition gene.

**636F**

**Association of TLL1 variant with hepatocellular carcinoma developed after eradication of hepatitis C virus.** K. Tokunaga<sup>1</sup>, K. Matsuura<sup>2</sup>, H. Sawai<sup>1</sup>, Y. Kawai<sup>3</sup>, K. Kojima<sup>3</sup>, M. Nagasaki<sup>3</sup>, Y. Tanaka<sup>2</sup>, Japanese Genome-Wide Association Study Group for Viral Hepatitis. 1) Dept Human Genetics, Univ Tokyo, Grad Sch Med, Tokyo, Japan; 2) Dept Virology & Liver Unit, Nagoya City University, Grad Sch Med Sci, Nagoya, Japan; 3) Dept Integrative Genomics, Tohoku Univ, Tohoku Med Megabank Org, Sendai, Japan.

The risk of developing hepatocellular carcinoma (HCC) does not completely disappear even after the eradication of hepatitis C virus (HCV) by anti-viral therapy. We aimed to identify host genomic variations associated with HCC development after achieving sustained virological response (SVR) in chronic hepatitis C (CHC) patients. We conducted a genome-wide association study (GWAS) in 456 Japanese patients who achieved SVR by interferon-based therapy, followed by a replication analysis for 79 candidate SNPs in an independent set of 486 patients. A SNP located within the intron of *TLL1* (rs17047200) on chromosome 4, showed a strong association with developing HCC at a genome-wide level of significance when the results of GWAS and the replication stage were combined (odds ratio = 2.4,  $P = 2.7 \times 10^{-8}$ ) in the allele frequency model. Multivariate analysis showed that the *TLL1* variant was an independent risk factor of developing HCC (hazard ratio = 1.9,  $P = 0.002$ ) as well as male gender, elder age, lower platelet count, albumin level, and higher post-treatment  $\alpha$ -fetoprotein level. In combination of the risk genotypes with distinct other factors, we could propose each prediction model for HCC development in patients with mild and advanced hepatic fibrosis. The *TLL1* expression analyses showed that mRNA levels in human stellate cells increased according to their activation; those in liver tissues of an animal model with hepatic fibrosis and CHC patients increased according to hepatic fibrosis progression. We suggest that the genetic testing of *TLL1* variant would be useful for implementing personalized surveillance of HCC after achieving SVR.

Schleutker<sup>9</sup>. 1) Biocenter Oulu, Faculty of Biochemistry and Molecular Medicine, University of Oulu, Oulu, Finland; 2) Institute of Biomedicine, University of Turku, Turku, Finland; 3) Department of Pathology, MCW Cancer Center, Medical College of Wisconsin, Milwaukee, USA; 4) State Key Laboratory of Medical Molecular Biology, Center for Bioinformatics, Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Peking Union Medical College, Beijing, China; 5) Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden; 6) School of Life Science, Shandong University, Jinan, China; 7) Department of Pathology, Oulu University Hospital, Oulu, Finland; 8) Medical Research Center, University of Oulu, Oulu, Finland; 9) Tyks Microbiology and Genetics, Department of Medical Genetics, Turku University Hospital, Turku, Finland.

Genome-wide association studies have identified the rs11672691 intronic variant in the long non-coding RNA gene *PCAT19* at 19q13 associated with aggressive prostate cancer (PCa). In the current study, we observe a significant association of rs11672691 with additional features indicative of clinically aggressive disease including high tumor stage, PSA progression and the development of castration-resistant PCa in a cohort of 2738 PCa patients. Yet, the underlying molecular mechanisms by which rs11672691 impacts PCa severity remain totally unknown. Here we find that rs11672691 resides in an enhancer element and alters the binding site of homeodomain transcription factors including HOXA2, a novel oncogenic transcriptional regulator with prognostic potential in PCa. HOXA2 displays preferential binding to the aggressive PCa-associated G allele of rs11672691, and regulates the expression of rs11672691-associated genes *PCAT19* and *CEACAM21* that are revealed by an eQTL analysis of four independent data sets with over 1000 prostate samples. Furthermore, *PCAT19* regulates *CEACAM21* expression, and rs11672691 enhancer forms a long-range chromatin interaction with *CEACAM21* promoter region. Suppression of *PCAT19* or *CEACAM21* inhibits PCa cell growth and metastasis. *CEACAM21* upregulation correlates with PCa progression and relapse. Strikingly, CRISPR-Cas9-mediated single nucleotide editing indicates that rs11672691 directly impacts the expression of *PCAT19* and *CEACAM21*, and PCa cellular properties. Importantly, clinical data indicate that the PCa patients carrying the GG genotype of rs11672691 have increased risk of biochemical relapse and decreased metastasis-free survival. In addition, *CEACAM21* expression has obvious prognostic value in the PCa patient group with GG genotype compared with those carrying GA or AA genotype of rs11672691. Together, these results demonstrate the biology and clinical implications of rs11672691 in association with aggressive PCa, and lay the ground work for future translation of this finding to the clinic.

**Cisplatin induced gene expression in lung and ovarian cancer cell lines reveal tissue specificity.** S.W. Williams, A.G. Thornburg, A.L. Stark. University of Notre Dame, Notre Dame, IN 46556.

Lung and ovarian cancers are two of the most prevalent and deadly forms of cancer. Despite extensive research into the nature of these types of cancer individually, broader relationships between the cancers are not as well understood. Cisplatin, a platinum based drug, is used in the treatment of both lung and ovarian cancers. The drug works by attaching to and disrupting DNA in dividing cells, inducing apoptosis. We sought to gain a more complete understanding of the relationship between lung and ovarian cancer by examining the expression profiles of genes in cisplatin treated cell lines. We utilized the Expression Atlas, a continually developing database of gene expression information created by the European Bioinformatics Institute to identify genes with significant expression changes (fold change greater than 5) following cisplatin treatment in ovarian cancer cells. We then evaluated those genes in comparably treated lung cancer cells. Interestingly, MMP12 exhibits a fold change of 7.1, with an adjusted p-value of 2.056E-07, in ovarian cancer cells treated with cisplatin. Despite MMP12 being identified as expressed in lung tissue, we found that this gene exhibits no expression in cisplatin treated lung cancer cells suggesting a difference in how cisplatin-induced gene expression is different in these distinct cancer tissues. MMP12 has been implicated in numerous lung phenotypes including COPD and emphysema, further pointing to fundamental differences between ovarian and lung cancer. Further understanding chemotherapy induced gene expression in different cancer cells can lead to important therapy improvements for patients.

**No association between 135G>C polymorphism of *RAD51* and colorectal cancer in Iranian population.** N. Yazdanpanahi<sup>1</sup>, R. Salehi<sup>2</sup>, S. Kamali<sup>2</sup>. 1) Department of Genetics, Falavarjan Branch, Islamic Azad University, Isfahan, Iran; 2) Department of Genetics and Molecular Biology, School of Medicine, Isfahan University of Medical Sciences, Isfahan, Iran.

**Introduction:** Colorectal cancer (CRC) is of the most frequent cancers and accounts as the second leading cause of death from cancers in the world. The gene *RAD51* involves in double-strand breaks repair of DNA. Genetic variants within this gene could affect the potential of DNA repair and susceptibility to various tumors such as CRC. The current study evaluated the association of *RAD51* 135G>C polymorphism with sporadic CRC in a subgroup of Iranian population. **Materials and Methods:** One hundred patients with sporadic CRC and 100 controls were investigated from two referral centers in Isfahan. Genotyping for the *RAD51* 135G>C was carried out using polymerase chain reaction-restriction fragment length polymorphism assay. **Results:** No significant association between the *RAD51* 135G>C and sporadic CRC (odds ratio = 0.86, 95% confidence interval = 0.464–1.595) was revealed. The frequency of genotypes and also alleles of the mentioned polymorphism were not significantly different between case and control groups ( $P = 0.2$  and  $0.4$ , respectively). **Conclusion:** The results suggest that *RAD51* 135G>C probably has not a crucial role in Iranian CRC risk and is not a crucial potential risk factor in molecular diagnostics of mentioned disease among Iranian population.

## 640W

**Functional evaluation of the correlation of gene expression changes in pathogenesis and platinum chemotherapy in lung and breast cancer cell lines.** M.L. Yoder, A.L. Stark. University of Notre Dame, Notre Dame, IN 46556.

Gene expression can be altered by many factors including developmental changes and drug treatment. We sought to investigate whether induced gene expression changes between cancer pathogenesis and chemotherapy response could be correlated. We interrogated the Expression Atlas created by the European Bioinformatics Institute for genes with a significant ( $p < 10^{-10}$ ) expression change in A549 and other lung cancer cell lines. We identified 171 genes that met that threshold. The gene with the largest fold change (8 fold induction) was ALDH1A1 ( $p = 4.9E-13$ ). Interestingly, there has been a correlation established between ALDH1A1 and cancer pathogenesis in breast cancer so we decided to further follow-up on this gene and others from the list. Because cisplatin is a chemotherapeutic used to treat both lung and breast cancer, we wanted to assess the gene expression changes after cisplatin treatment. We exposed lung (A549) and breast (MCF7) cancer cells to 5  $\mu$ M cisplatin and collected pellets at 2, 4, 6, 24, and 48 hours after exposure. We utilized quantitative RT-PCR to determine the log-fold change of ALDH1A1 and other genes from the list. Further experimentation is necessary to validate the significance of these findings, however, these results point to a promising new avenue to identify genes' whose expression modification could improve treatment response.

**A genetic analysis of the change in prostate-specific antigen concentrations over time.** S. Rashkin<sup>1</sup>, T. Hoffmann<sup>1,2</sup>, L. Sakoda<sup>3</sup>, E. Jorgenson<sup>3</sup>, L. Habel<sup>4</sup>, J. Shan<sup>5</sup>, D. Ranatunga<sup>3</sup>, C. Chao<sup>4</sup>, N. Ghai<sup>4</sup>, D. Aaronson<sup>6</sup>, J. Presti<sup>6</sup>, C. Schaefer<sup>3</sup>, N. Risch<sup>1,2,3</sup>, S. Van Den Eeden<sup>3,6</sup>, J. Witte<sup>1,2</sup>. 1) Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA; 2) Institute for Human Genetics, University of California San Francisco, San Francisco, CA; 3) Division of Research, Kaiser Permanente Northern California, Oakland, CA; 4) Department of Research and Evaluation, Kaiser Permanente Southern California, Pasadena, CA; 5) Department of Urology, Kaiser Oakland Medical Center, Oakland, CA; 6) Department of Urology, University of California San Francisco, San Francisco, CA.

Prostate-specific antigen (PSA) measures have been used to screen for prostate cancer as increased PSA concentrations are indicative of prostate cancer. However, PSA concentration can vary between individuals due to various factors, leading to only moderate accuracy of PSA testing with a universal threshold. It has been proposed that PSA screening for prostate cancer can be improved by incorporating information from genetic markers influencing PSA concentrations independent of prostate cancer to determine individual-specific screening thresholds. Studies have been conducted examining the relationship between PSA concentrations and genetic variation, but most use PSA levels measured at a single point in time or simplify longitudinal measurements to a single summary statistic. However, knowledge of how genetics affects PSA concentrations over time may better aid in determining a personalized screening threshold for an individual by incorporating how PSA is likely to change for an individual over time independent of prostate cancer to determine if an increase in PSA over time falls within normal bounds for that individual. Here, we explore the genetic basis of changes in PSA over time in Kaiser Permanente health plan members. A previous GWAS in this dataset (28,503 non-Hispanic white Kaiser Permanente health plan members and 18,615 men from replication cohorts) compared each SNP to the median PSA level over time (an average nine measures per man) and found multiple SNPs associated with PSA levels, many of which were not associated with prostate cancer. We now extend this analysis by examining how genetics affects change in PSA over time. First, we model PSA using a linear mixed effects model, adjusting for age at each measurement and principle components, with a random intercept and slope term to model within-person variation in baseline PSA and change in PSA as age increases. We then use the random slopes as the outcome for a GWAS. Preliminary results indicate that, while most significant SNPs are replicating previous results, there may be novel findings associated with change in PSA but not median PSA, including one on 17p12. Additionally, there are some SNPs that were previously associated with median PSA that are not significant in our analysis, indicating that they may be related to baseline PSA rather than changes in PSA over time.

**Characterization of global molecular architecture and regulatory mechanisms underlying hepatocellular carcinoma.** *H.M. Natri, M. Wilson Sayres, K. Buetow.* Center for Evolution and Medicine, School of Life Sciences, Arizona State University, Tempe, AZ.

Cancer is a complex disease shaped by diverse gene-by-gene and gene-by-environment effects. While genome-wide association studies have generated numerous associations between variants and complex traits, the underlying mechanisms connecting these variants to phenotypes are largely unknown. The majority of known loci associated with complex diseases are located in noncoding regions and are thus likely to affect disease risk by altering gene regulation. Expression quantitative trait locus (eQTL) analysis has emerged as an important tool for translational medicine by enabling the identification of causal variants affecting complex diseases. Detection of eQTLs and epistatic effects between loci requires the calculation of a large number of associations. Multiple-testing creates a computational challenge which has limited the number of detected eQTLs and construction of genetic networks underlying complex diseases. Hepatocellular carcinoma (HCC) is the second leading cause of cancer death worldwide. HCC is influenced by genetic susceptibility, environmental factors such as infections, metabolic syndrome, and alcohol use, and shaped by numerous biological processes, resulting in a high degree of genetic and transcriptional heterogeneity. HCC incidence in the US has doubled in the last 3 decades, attributable to increased rates of obesity. HCC exhibits sex bias in occurrence with 2.1-fold higher rate in HBV+ males, 1.9-fold in HCV+ females, but equal rates in individuals with metabolic syndrome. While sex bias in cancer is partly attributed to sex-specific differences in risk behaviors and environmental exposure, the relationship of these differences to sex as a biological variable has not been systematically investigated. Moreover, most eQTL studies as yet have failed to explore the role of sex-specific impacts of regulatory variants. Here, we utilize an integrative systems genetic approach to investigate the mechanisms involved in HCC. By sex-specific analyses of genotypic, transcriptomic, and phenotypic data from TCGA, GTEx, and ICGC datasets, we produce a detailed outlook on the role of inherited and somatic genetic variation and gene regulation in HCC. We use a Hadoop Big Data framework and multiple mapping algorithms for efficient and robust identification of both cis and trans-eQTLs. We present a characterization of regulatory networks underlying HCC occurrence and susceptibility, highlighting the role of sex-specific impacts of genetic variants.

**Molecular characterization of Brazilian patients with hereditary breast and ovarian cancer syndrome: What can we find beyond BRCA1 and BRCA2 genes?** *S.C.S. Carvalho<sup>1</sup>, D.B. Brotto<sup>1</sup>, R. Torrieri<sup>2</sup>, L.A. Teixeira<sup>1,2</sup>, L.F. Araujo<sup>1</sup>, J.R. Praça<sup>3</sup>, K.C. Peronni<sup>3</sup>, T.O. Anjos<sup>3</sup>, W.A. Silva Jr.<sup>2,3</sup>.* 1) Department of Genetics, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, SP, Brazil; 2) Center for Medical Genomics at General Hospital of the Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, SP, Brazil; 3) Regional Blood Center at General Hospital of the Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, SP, Brazil.

The Hereditary Breast and Ovarian Cancer Syndrome (HBOC) is characterized by families with breast and/or ovarian cancer inherited in an autosomal dominant manner and it comprehends almost 10% and 15% of all cases of breast and ovarian cancer, respectively. The *BRCA1* and *BRCA2* genes were associated with high risk of hereditary breast and ovarian cancer with a prevalence of pathogenic mutations of 20-30% in HBOC cases, leading to a 20-fold increase in risk. Many studies identified other genes, although less penetrant, associated with an increased risk to HBOC. Genetic screening in other genes than *BRCA1/BRCA2* in the Brazilian population has shown mutations in *TP53* (p.R337H), *CHEK2* (c.1100delc) and *PTEN* (microdeletions) genes, accounting for 4,16% of the evaluated cases. Thus, this study aimed to characterize the mutational profile of HBOC patients based on the screening of 21 genes associated with DNA damage repair (homologous and mismatch repair), including *BRCA1* and *BRCA2*, in a Brazilian cohort. Using a targeted gene sequencing panel for mutation screening in 94 patients of Southeast Brazil, it was identified 726 point mutations and small insertions/deletions. Almost 28% were mutations located in coding regions and affecting splicing regions and 16,7% were probably pathogenic mutations found in 20 of the 21 analyzed genes. The five top mutated genes were *BRCA1*, *BRCA2*, *CHEK2*, *PALB2* and *PMS2*. The prevalence of pathogenic mutations in *BRCA1* and/or *BRCA2* was 57,44% with one case presenting CNVs in *BRCA2*. This group of patients was younger (the oldest one were diagnosed with 37 years old) than the non-*BRCA* mutated group, displayed higher tumor grades and comprised the major number of deaths (70%) and metastatic (61,5%) cases, with almost 68% being triple negative breast cancer cases. The prevalence of pathogenic mutations in other genes than *BRCA1* and *BRCA2* was 33%, in which 9,57% of the cases did not present any mutation in *BRCA1/BRCA2* genes. In these non-*BRCA* mutated cases it was found pathogenic mutations in *PMS2* and 3 novel mutations in *BRIP1*, *ATR* and *RAD50* genes. Only 2 of 94 samples were not mutated in any gene of the panel and both will proceed to exome analyses. Although all these mutations are in process of Sanger validation, we suggest in advance that other genes than *BRCA1/BRCA2* may contribute to HBOC phenotype in 1/3 of the Brazilian cohort. The next steps will focus on functional characterization of these mutations on the DNA repair kinetics.

**Fine-mapping analysis of 152 breast cancer risk loci from OncoArray and iCOGS data.** L. Fachal<sup>1</sup>, H. Aschard<sup>2</sup>, J. Allen<sup>3</sup>, D. Barnes<sup>3</sup>, J. Beesley<sup>4</sup>, M. Ghoussaini<sup>5</sup>, S. Khar<sup>6</sup>, J.S. Carroll<sup>6</sup>, V.N. Kristensen<sup>6</sup>, G. Chenevix-Trench<sup>4</sup>, A.C. Antoniou<sup>7</sup>, J. Simard<sup>7</sup>, P. Kraft<sup>8</sup>, D.F. Easton<sup>1,3</sup>, A. Dunning<sup>1</sup>, the Consortium of Investigators of Modifiers of *BRCA1/2*, the Breast Cancer Association Consortium. 1) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, UK; 2) Department of Genomes and Genetics, Center for Bioinformatics, Biostatistics and Integrative Biology, Institut Pasteur, Paris, France; 3) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK; 4) Cancer Division, QIMR Berghofer Medical Research Institute, Brisbane Australia; 5) Cancer Research UK, Cambridge Institute, University of Cambridge, Cambridge, UK; 6) Department of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital Radiumhospitalet, Oslo, Norway; 7) Genomics Centre, Centre Hospitalier Universitaire de Québec-Université Laval Research Centre, Quebec city, Canada; 8) Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, Massachusetts, USA.

One hundred and fifty-two breast cancer risk loci have been discovered through genome-wide association studies (GWAS). For most, the causal variants and the mechanisms underlying these associations remain unknown. To identify candidate causal variants and better understand how these loci affect carcinogenesis, we combined association data for all known susceptibility regions with *in-silico* genomic feature annotation. Genotypes for 639,121 variants across these regions were determined using the custom iCOGS and OncoArray platforms, or estimated by imputation, in 84,642 cases and 88,937 controls of European ancestry from the Breast Cancer Association Consortium (BCAC). Using stepwise multinomial logistic regression, we identified independent signals specifically associated with ER-positive (ER+) or ER- breast cancer risk, or associated with both subtypes. We also determined the credible causal variants within each signal, and whether these variants overlapped with transcription factor (TF) binding sites, histone marks, DNase hypersensitivity sites (DHS) (ENCODE, IHEC, GEO), or TF motifs (Factorbook, JASPAR), specifically in breast tissue. Across the 150 confirmed loci, we identified 196 independent association signals. Seventy-nine loci contained two or more independent signals. Sixty-seven signals were more strongly associated with ER+ disease and 28 with ER- disease. We also conducted a meta-analysis between the ER- specific BCAC GWAS and the Consortium of Investigators of Modifiers of *BRCA1/2* (CIMBA) GWAS of 9,439 unaffected and 9,369 affected *BRCA1* mutation carriers; based on this meta-analysis we identified 10 additional signals. For ER+ disease, we found significant enrichment of binding sites for 21 different TFs, including FOXA1, GATA3, and ESR1; and histone marks H3K27ac and H3K4me1 in ER+ breast cancer cell lines coincident with the positions of the candidate variants. For ER- disease, the most significantly enriched annotation is DHS in mammary epithelial tissue, indicative of open chromatin. Empirical Bayes fine-mapping analyses incorporating enriched functional annotations were able to refine association signals and identify individual SNPs with high posterior probability of causality (>95%) in 17 regions, including those near *FGFR2*, *MAP3K1*, and *TERT/CLPTM1L*. Our results suggest significant overlap of credible causal variants with active gene regulatory elements and binding sites for certain TFs in a subtype specific manner in breast cancer.

**645F**

**Gene expression imputation identifies novel candidate genes and susceptibility loci associated with risk of cutaneous squamous cell carcinoma.** N.M. Ioannidis<sup>1,2</sup>, W. Wang<sup>1</sup>, E. Jorgenson<sup>3</sup>, M.M. Asgari<sup>3,4</sup>, A.S. Whittemore<sup>1,5</sup>. 1) Department of Health Research and Policy, Stanford University School of Medicine, Stanford, CA; 2) Department of Genetics, Stanford University School of Medicine, Stanford, CA; 3) Division of Research, Kaiser Permanente Northern California, Oakland, CA; 4) Department of Dermatology, Massachusetts General Hospital, Boston, MA; 5) Department of Biomedical Data Science, Stanford University School of Medicine, Stanford, CA.

Cutaneous squamous cell carcinoma (cSCC) is a common and costly form of skin cancer, with risk factors including fair skin pigmentation and exposure to ultraviolet radiation. Recent genome-wide association studies (GWASs) have identified genetic susceptibility loci for cSCC, although the roles of some loci in disease pathogenesis remain unclear. Examining associations between cSCC risk and imputed gene expression levels in GWAS subjects has the potential to identify candidate causal genes at these previously associated loci, as well as to identify genes in novel cSCC associated loci for further study. We imputed expression levels of autosomal genes in blood and skin tissue of 6,891 cSCC cases and 54,566 controls participating in the Genetic Epidemiology Research in Adult Health and Aging (GERA) cohort of the Kaiser Permanente Northern California healthcare system. We identified 19 loci containing 33 genes whose imputed expression levels differed between cSCC cases and controls in at least one tested tissue type at a false discovery rate < 10%. Many of these genes are located in novel cSCC susceptibility loci that were not identified in previous GWAS analyses. In addition, several associated genes located in previously associated loci had not been previously considered as candidate causal genes. Thus, our results suggest novel genetic mechanisms contributing to cSCC risk and illustrate the ability of gene expression imputation methods to identify previously undiscovered susceptibility loci from GWAS datasets. Our work also illustrates several limitations in interpreting results based on gene expression imputation that are relevant to future studies of other complex traits.

**Novel susceptibility loci associated with *BRCA*-negative *BRCA*-like breast cancer (“*BRCAX*”) for Korean women.** J.Y. Lee<sup>1</sup>, J. Kim<sup>2</sup>, J.W. Lee<sup>2</sup>, S.W. Kim<sup>3</sup>, S.H. Ahn<sup>2</sup>, J.L. Hopper<sup>4</sup>, J. Sung<sup>1</sup>. 1) Department of Epidemiology, Graduate School of Public Health, Seoul National University, Seoul, South Korea; 2) Department of Surgery, Asan Medical Center, Seoul, South Korea; 3) Department of Surgery, Daerim St.Mary's Hospital, Seoul, South Korea; 4) Centre for Molecular, Environmental, Genetic and Analytical Epidemiology, University of Melbourne, Carlton, Victoria, Australia.

**INTRODUCTION:** “*BRCAX*” refers breast cancer types mimicking those with *BRCA1/2* gene mutation carriers, but genetic screening for *BRCA* genes found to be non-significant tests. In Korea, breast cancer cases with very early onset (age <40) or signs suggesting strong genetic background are allowed to conduct *BRCA* gene test covered by National Health Insurance. Burden from the *BRCAX* spectrum cases is higher for Asians than Westerners. Around 10% of examined were reported to have significant *BRCA1/2* mutations. Usual suspects include unknown rare genes with high penetrance, epigenetics, or interactions between already known loci. In this study, we report initial findings from a genome-wide search for new candidate genes explaining *BRCAX* spectrum cancer. **METHODS:** 1,505 of *BRCAX* cases from Korean Hereditary Breast Cancer (KOHBRA) study and 5,979 control women from Korean Genome and Epidemiology Study (KoGES) were analyzed using genome-wide SNP/SNV panels (>3.3 million markers after imputation). Asian women's cases from the Breast Cancer Association Consortium (BCAC) were used for replication. **RESULTS:** From initial analysis, we have identified 17 loci approaching suggestive significance level ( $10^{-3}$ ) including 6 known and 11 novel regions. Three novel loci (*PDE7B*, *UBL3* and *SLC39A11*) were replicated for high-risk Asian women's breast cancer cases from the BCAC (1,482 cases and 3,612 controls). A candidate variant is located on intron of *PDE7B*. Evidences that this variant alters gene expression of *PDE7B* in several tissues and is involved in regulatory functions were observed. Moreover, effect size of known susceptibility genes seemed different from general breast cancer cases. To compare the impact of identified loci for *BRCAX*, we estimated a portion of familial relative risk (%FRR) for breast cancer explained by known and novel variants. Sum of %FRR for *BRCAX* cases was increased from 25.0% to 27.6% by addition of new loci. For known and novel variants which showed significant association results for both datasets, sum of %FRR for *BRCAX* cases (9.57%) was higher than that of breast cancer cases with unknown mutation status for *BRCA* genes (6.50%). **CONCLUSIONS:** We have identified several novel loci that might explain the *BRCAX* cases. Our findings suggest new candidate genes exist and might be used for screening test. **ACKNOWLEDGEMENT:** Data of breast cancer cases were provided by Korean Hereditary Breast Cancer (KOHBRA) and Breast Cancer Association Consortium (BCAC).

**Melanoma genetics: Larger sample size identifies novel loci and enables causal inference.** S. Macgregor<sup>1</sup>, U. Liyanage<sup>1</sup>, J.S. Ong<sup>1</sup>, M. Iles<sup>2</sup>, D.T. Bishop<sup>2</sup>, M.T. Landi<sup>3</sup>, P.A. Kanetsky<sup>4</sup>, F. Demenais<sup>5</sup>, A. Goldstein<sup>3</sup>, A. Cust<sup>6</sup>, M.H. Law<sup>1</sup>, *Melanoma genetics consortium*. 1) Statistical Genetics, QIMR Berghofer Medical Research Institute, Brisbane, Australia; 2) University of Leeds, Leeds, UK; 3) National Cancer Institute, National Institutes of Health, Bethesda, Maryland, USA; 4) H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida, USA; 5) Institut National de la Santé et de la Recherche Médicale (INSERM), UMR-946, Genetic Variation and Human Diseases Unit, Paris, France; 6) Sydney School of Public Health, The University of Sydney, Sydney, Australia.

We conducted a genome wide association study (GWAS) meta-analysis comprising 17569 cutaneous melanoma cases and 28006 controls from Australia, Europe and the United States. Haplotype Reference Consortium data was used to allow imputation of rarer variants, allowing us to identify, at genomewide levels of significance, the intermediate penetrance melanoma risk variant in *MITF* initially found via sequencing in families. Furthermore, due to increased sample size, we identified 5 loci not previously detected. The peak SNP at each new locus lies within or near *KIAA0390*, *CDH1*, *GPRC5A*, *DMTN* and *GPR37*. Confidence in determination of which is the key gene (or genes) varies by locus. The *GPR37* hit is a common variant (minor allele frequency~0.25) which is immediately adjacent to the gene *POT1*, a telomere biology gene previous found to harbor rare loss of function variants conferring melanoma risk. For both *KIAA0390* and *DMTN*, the lead SNP altered gene expression levels. We applied a functional enrichment approach using fgwas to test which tissues were most relevant to the peak SNPs. Enrichment was largest for DNase-I hypersensitive sites in melanocytes, with enrichment also seen in other tissues including skin fibroblasts and thymus. We also used the GWAS data to conduct Mendelian Randomization to evaluate the role of 8 putative risk factors in melanoma risk. Our power to draw strong causal inferences was high for height, obesity, cholesterol and fatty acid levels. For height, we showed that a predicted 10cm increase in height led to a 14% increase in melanoma risk ( $P=0.02$ ), consistent with observational study estimates. For obesity, cholesterol and fatty acid levels we could rule out all but very small effects of these risk factors on melanoma risk. Our power was lower for vitamin D levels, waist hip ratio, coffee and alcohol consumption; these traits were not significantly related to melanoma risk but at current sample sizes we can only rule out these traits having a large effect on melanoma risk. By October 2017 we anticipate increasing our sample size by several thousand cases; this will increase the number of novel loci as well as strengthening our causal inferences. In this analysis of over 45,000 samples, we identified several novel loci conferring melanoma risk and used Mendelian randomization to draw strong inferences regarding causality of some modifiable risk factors.

Despite its efficacy as a curative agent in testicular cancer, cisplatin can result in severe, often permanent toxicities, including tinnitus. Treatment of tinnitus is limited to palliative behavioral modifications and attenuation of associated anxiety and stress. We performed a novel genome-wide association study of cisplatin-induced tinnitus in 835 well-characterized testicular cancer survivors (Median age at assessment: 38 ± 10 (SD) years; median cumulative dose of cisplatin: 400 mg/m<sup>2</sup>). There are no external quantitative means to assess tinnitus clinically, therefore, we assessed it as a binary response to the question derived from the validated Scale for Chemotherapy-Induced Neurotoxicity: "Have you suffered in the last 4 weeks from: Ringing in your ears?", with "not at all" (662) respondents as controls, and "Quite a bit" or "Very much" (173) as cases, excluding "a little bit" respondents (467). We observed a significant association between tinnitus and cisplatin dose by 100mg/m<sup>2</sup> [OR: 1.36, *p* = 0.01], age by decade [OR: 1.28, *p* = 0.003], noise exposure [OR: 1.7, *p* = 4x10<sup>-6</sup>], vertigo [OR: 6.4, *p* = 1.4x10<sup>-7</sup>], use of psychotropic medication (anxiolytics/antidepressants) [OR: 2.4, *p* = 0.003], and difficulty hearing in crowds [OR: 7.9, *p* < 10<sup>-6</sup>]. Nearly 7.3 million SNPs passed quality control in 835 genetically European individuals. Imputed SNP dosages and covariates including age, noise exposure, cisplatin dose, and 10 genetic principal components were logistically regressed on tinnitus. Intronic SNPs with *p* < 1.0x10<sup>-5</sup> were observed in several genes that are associated with hearing loss, neurodegenerative and anxiety disorders. The top signal (*p* = 1.5x10<sup>-8</sup>) was the variant rs7606353, about 14kb upstream of *OTOS*; a gene involved in cochlear development and implicated in vestibular disease. Other implicated genes include *OR6B3*, *DPYSL2*, as well as *PPFIBP1*, a gene also associated with tinnitus in Vanderbilt BioVU (*p* = 0.002; 105 cases, 7899 controls). Gene set enrichment analysis revealed that the ten most enriched biological processes (FDR *q* < 0.15) are neurological in origin, including central nervous system axonogenesis (*q* = 0.04). Heritability was assessed using GCTA, revealing potential polygenic architecture (*h*<sup>2</sup> = 0.57±0.48, *p* = 0.10). Discovering new links between tinnitus, genetic predispositions and interactions with cisplatin therapies can pave the way for more effective preventative strategies or novel treatment options for cancer survivors.

**649W****Genetic association analysis of advanced neoplasia in a colon cancer screening cohort.**

*X. Qin<sup>1,2</sup>, E.R. Hauser<sup>1,2</sup>, A. Stone<sup>3</sup>, W.C. Carter<sup>3</sup>, D. Humphries<sup>4</sup>, M.C. O'Leary<sup>5</sup>, T.S. Redding<sup>1</sup>, Z.F. Gellad<sup>1,2</sup>, D. Provenzale<sup>1,2</sup>, D. Lieberman<sup>5,6</sup>.* 1) VA Cooperative Studies Program Epidemiology Center, Durham VA Health Care System, Durham, NC; 2) Duke University, Durham, NC; 3) VA Pharmacogenomics Analysis Laboratory, Central Arkansas Veterans Healthcare System, Little Rock, AR; 4) Massachusetts Veterans Epidemiology Research and Information Center, VA Boston Healthcare System, Boston, MA; 5) VA Portland Health Care System, Portland, OR; 6) Oregon Health & Science University, Portland, OR.

Numerous advances have been made in identifying genetic risk factors for colon cancer through the analysis of large case-control studies. Fewer studies have been performed to identify genetic factors for cancer precursors, i.e. adenomatous polyps, which are identified and removed during colonoscopy. Understanding which genetic variants increase risk in progression from cancerous precursors to cancer could result in better risk stratification of individuals at risk of colon cancer. We developed a biorepository for the Department of Veterans Affairs (VA) Cooperative Studies Program Study #380 (CSP 380) "Prospective Evaluation of Risk Factors for Large (≥1cm) Colonic Adenomas in Asymptomatic Subjects." CSP 380 is a longitudinal study of 3121 participants aged 50-75 enrolled for screening colonoscopy from 1994-1997. Follow-up using the VA electronic health records is continuing. The biorepository includes 815 individuals with blood (lymphocytes and/or serum), DNA, and/or normal rectal tissue samples. Approximately 170 of these individuals have stored polyp samples frozen at the time of the baseline colonoscopy. To date approximately 1700 archived polyp samples (formalin or Bouin's fixed) have been obtained, representing a longitudinal tissue resource from repeat colonoscopies. Our initial genetic association study has three goals: 1) evaluate association of previously identified colon cancer SNPs in genetic risk of advanced neoplasia; 2) evaluate association of variants in genes differentially expressed in colon cancer from The Cancer Genome Atlas (TCGA) project; and 3) perform a GWAS analysis using DNA from the baseline blood samples. Advanced neoplasia at baseline, defined as at least one tubular adenoma ≥10 mm, adenoma with villous histology, adenoma with high-grade dysplasia, or invasive cancer, was identified in approximately 26% of individuals in the biorepository. Initial power calculations give 80% power for odds ratios of 1.4 at an alpha of 0.05 (colon cancer candidate SNPs), 1.5 at an alpha of 0.0001 and 1.8 at genome-wide significance assuming a minor allele frequency of 0.10. Genotyping with the Illumina Infinium Omni2.5-8 GWAS chip is complete with excellent genotyping quality and will be available for collaborative research. Information on the CSP 380 data and biorepository, study forms and data dictionary is available at <a href="https://www.research.va.gov/programs/csp/cspect/initiatives.cfm">https://www.research.va.gov/programs/csp/cspect/initiatives.cfm</a>.

**Genome-wide association study identifies novel loci for mammographic breast density.** *W. Sieh<sup>1</sup>, J.H. Rothstein<sup>1</sup>, J.A. Lipson<sup>2</sup>, S.E. Alexeeff<sup>3</sup>, L. Sakoda<sup>3</sup>, R. McBride<sup>4</sup>, R. Graff<sup>4</sup>, N. Achacoso<sup>3</sup>, V. McGuire<sup>2</sup>, D.L. Rubin<sup>2</sup>, A.S. Whittemore<sup>2</sup>, L.A. Habel<sup>3</sup>.* 1) Icahn School of Medicine at Mount Sinai, New York, NY; 2) Stanford University School of Medicine, Stanford, CA; 3) Division of Research, Kaiser Permanente Northern California, Oakland, CA; 4) University of California, San Francisco, CA.

**Purpose:** Mammographic density is a strong risk factor for breast cancer. Most of the variation in mammographic density is explained by hereditary factors that remain largely unknown. We conducted a genome-wide association study to identify novel loci for mammographic density. **Methods:** This study included 24,192 non-Hispanic white women genotyped on the Affymetrix Axiom European array as part the Research Program on Genes, Environment and Health (RPGEH). All women were 40 years or older and underwent screening with full-field digital mammography at 37 Kaiser Permanente clinics throughout Northern California. Density measurements were obtained by a single radiological technologist using Cumulus on the processed images. In Stage 1, 20,311 women imaged using Hologic machines were analyzed. In Stage 2, 3881 additional women imaged using GE machines were analyzed independently. Meta-analysis was performed using METAL. **Results:** Combined analysis of Stages 1 and 2 identified 37 loci associated with dense area ( $n = 24$ ), non-dense area ( $n = 15$ ) or percent dense area ( $n = 16$ ) with  $p$ -values  $< 5 \times 10^{-8}$  and concordant associations in Stages 1 and 2. Interestingly, alleles at 2 loci were associated with dense area and non-dense area in the same direction, and consequently were not significantly associated with percent dense area. Among the 37 loci, 10 overlapped with known susceptibility alleles for breast cancer and 8 were previously known to be associated with mammographic density. **Conclusions:** Mammographic density is a complex trait influenced by polygenic and environmental factors. We found evidence that some loci have pleiotropic effects on the amount of dense and fatty tissue in the breast, and many loci are also associated with breast cancer. Further analyses are needed to identify potentially functional variants, and biological pathways that may be involved in mammographic density.

**651F**

**Phenome wide association study of breast cancer genetics reveals novel association with seborrheic keratosis.** *J. Liu<sup>1</sup>, Z. Ye<sup>2</sup>, J. Mayer<sup>2</sup>, B. Hoch<sup>2</sup>, S. Hebbing<sup>1</sup>.* 1) Department of Human Genetics, Marshfield Clinic Research Foundation, Marshfield, WI; 2) Biomedical Informatics Research Center, Marshfield Clinic Research Foundation, Marshfield, WI.

**Background:** The phenome-wide association study (PheWAS) is an innovative and complementary approach to genome-wide association study (GWAS) with particular advantages in identifying disease susceptibility loci using a disease independent approach. The genetic etiology of breast cancer is very complex including both common and rare genetic variants contributing significantly to disease risk. We hypothesized that the PheWAS approach may be utilized to comprehensively study breast cancer genetics and identify novel gene-disease relationships. **Methods:** We evaluated associations between 48,953 genetic variants in 65 breast cancer candidate genes with 7,457 phenotypes in a cohort of 11,000 subjects linked to extensive electronic health record data at Marshfield Clinic. The study population is homogenous with 77% of participants claiming German ancestry. Association testing was conducted by Firth analysis. **Results:** Multiple statistically significant ( $p < 1.37E-10$ ) SNP-disease pairs were identified including expected associations between *TCF7L2* and type II diabetes, along with multiple novel SNP-disease pairs. For example, a novel association between variant rs10069690 on gene *TERT* and Seborrheic Keratosis ( $p = 9.29E-13$ ) was identified. Furthermore, when restricting analysis to only 172 variants previously defined as GWAS significant SNPs for breast cancer, we further identified a statistically significant association between *FTO* and obesity ( $p = 1.36E-08$ ) and suggestive association between *FRY* and arthropathy ( $p = 6.30E-06$ ). **Conclusions:** The PheWAS approach has proven to be a powerful method to discover and rediscover SNP-disease associations. This PheWAS study confirmed the associations between breast cancer genes and obesity and type II diabetes, and further emphasizes the genetic variants associated with breast cancer have pleiotropic properties.

**Profiling of genomic alterations of mitochondrial DNA in gingivobuccal oral squamous cell carcinoma indicates that somatic mutations modulate prognosis in patients.** A. Palodhi, S. Ghosh, N.K. Biswas, A. Basu, P.P. Majumder, A. Maitra, *India Project Team of the International Cancer Genome Consortium*. National Institute of Biomedical Genomics, Kalyani, West Bengal, India.

**Statement of Purpose:** Gingivobuccal Oral Squamous Cell Carcinoma (OSCC-GB) is of high prevalence in many lower and middle income countries, including India where this cancer type is primarily driven by the wide-spread use of chewing tobacco. We have undertaken high resolution genomic investigations of the mitochondria in patients of OSCC-GB from India in order to elucidate the role of mitochondrial genome in initiation and progress of this disease. We expect our findings to be useful for patient classification with respect to disease progress. **Methods:** Mitochondrial DNA sequence data was generated from paired tumor and blood from 89 OSCC-GB patients using Illumina HiSeq 2500 and Ion Torrent PGM at high depth (>2500X). BWA-MEM was used to align the sequence data to the mitochondrial reference sequence (rCRS-revised Cambridge Reference Sequence). VarScan2 was used to detect somatic and germline variants in the mtDNA. The fold change in mtDNA copy number in tumour DNA compared to DNA from paired adjacent normal tissue was measured by Real Time PCR. Information on mitochondrial transcripts were extracted from whole transcriptome RNA-Seq data generated from paired tumor and adjacent normal tissue RNA using the Tuxedo set of tools. **Results:** The major highlights of our findings are: (i) We found that a significantly higher (*Chi-sq test*,  $P=0.01$ ) proportion of OSCC-GB patients who harbor somatic non-synonymous mutations in mitochondrial genes coding for respiratory Complexes III, IV and V have lymph node metastasis compared to the other OSCC-GB patients. (ii) The somatic mutation signature 5'-TCN-3'>5'-TTN-3' was overrepresented (*Chi-sq test*,  $P=0.0018$ ) in the mitochondrial genomes, which is different from the tobacco related mutation signature in the autosomal genome previously reported in OSCC-GB. (iii) mtDNA copy number in tumor tissue was observed to be reduced than that in adjacent normal tissue in a significant (*Mann-Whitney test*,  $P<0.000001$ ) number of OSCC-GB patients. Additionally, patients with somatic mutations in mitochondrial coding genes, presented lower expression of mitochondrial transcripts (*Two sample unpaired t-test*,  $P=0.05$ ). Overall, we conclude that somatic mutations in mitochondrial DNA might influence prognosis in gingivobuccal oral cancer and the results suggest that such information might be useful in gaining clinical insights in the progress of the disease.

**Prognostic inherited genetic variation in non-small cell lung cancer.** F. Abbas Aghababazadeh, X. Wang, B. L. Fridley. Biostatistics and Bioinformatics, Moffitt Cancer Center, Tampa, FL.

**Background:** Lung cancer is a common and severe disease which ranks the top among cancers worldwide in terms of mortality for both men and women. Environmental exposures, such as tobacco smoking, contribute to over 80% of lung cancer deaths. However, in a small percent of cases, germline single nucleotide polymorphisms (SNPs) have been shown to contribute to the risk of developing non-small cell lung cancer (NSCLC), particularly in families with strong family histories for NSCLC. Much research has been conducted to determine prognostic somatic mutations and drug-able mutations, thus leading to targeted therapies for NSCLC. However, little research has been reported on genetic variation and their impact on survival following diagnosis of NSCLC. Therefore, we set out to determine genetic variation related to overall survival (OS) in two major subtypes of NSCLC using data from the TCGA; lung squamous cell carcinoma (LUSC) and lung adenocarcinoma (LUAD). **Methods:** Genome-wide genetic data from the TCGA for subjects with confirmed diagnosis of lung cancer were downloaded along with clinical features such as age, smoking status, race, stage of the disease and overall survival (OS) status. Under each lung cancer subtypes, quality control (QC) and population stratification estimation were applied, followed by the testing for association of each SNP marker; under an additive genetic model; with OS was modeled with Cox proportional hazard regression models, while adjusting for age of diagnosis, stage, and population stratification. Meta-analysis was then completed to combine the results across the two cancer subtypes.

**Results:** 411 LUAD and 317 LUSC patients were included in the analyses on 676766 and 766758 SNPs, respectively. The median survival time (MST) for patients corresponding to the each subtype LUAD and LUSC were 20.6 and 19.1 months, respectively. For the analysis of LUAD, we observed two SNPs with  $p$ -value  $< 10^{-4}$ . Meta-analysis is on-going to combine the results from the two independent genome-wide association studies. **Conclusion:** Future research is needed to understand the genetic variation that relates to the etiology and progression / outcome of this deadly cancer, and how environmental factors by modify these effects. Additional pharmacogenomics studies are also needed to determine genetic variations- either inherited (germline), acquired (somatic), or both - that contributed to toxicity or response to commonly used therapies for NSCLC.

**Replication study and functional analysis identify a novel gene associated with gemcitabine-induced leukopenia/neutropenia.** C. Udagawa<sup>1,2,3</sup>, Y. Teratake<sup>1</sup>, H. Ueno<sup>4</sup>, H. Okamura<sup>5</sup>, T. Okusaka<sup>4</sup>, H. Yamano<sup>5</sup>, K. Hirayama<sup>5</sup>, N. Nakamura<sup>5</sup>, H. Zembutsu<sup>1,2</sup>. 1) Cancer Precision Medicine Center, Cancer Institute, Tokyo, Japan; 2) Division of Genetics, National Cancer Center Research Institute, Tokyo, Japan; 3) New Business Development Life Science Group, Toyo Kohan Co., Ltd., Tokyo, Japan; 4) Hepatobiliary and Pancreatic Oncology Division, National Cancer Center Hospital, Tokyo, Japan; 5) Research and Development Center Life Science Group, Toyo Kohan Co., Ltd., Yamaguchi, Japan.

Gemcitabine is used for the treatment of patients with various tumors. The use of gemcitabine is often limited by unpredictable dose-limiting hematological toxicities. Genetic factors are thought to be one of the causes of individual variability in the leukopenia/neutropenia observed in cancer patients who received gemcitabine therapy. In our previous studies, we identified four novel SNPs associated with gemcitabine-induced severe leukopenia/neutropenia (combined  $P = 1.27 \times 10^{-6} - 5.98 \times 10^{-6}$ , odds ratio (OR) = 2.60 – 34.00). To identify a genetic marker(s) for gemcitabine-induced leukopenia/neutropenia, which could be feasible for routine clinical use, we conducted a replication study by genotyping the four single nucleotide polymorphisms (SNPs) using 171 patients treated with gemcitabine monotherapy, and a combined study in a total of 345 patients, including 119 patients with at least grade 3 leukopenia/neutropenia and 226 controls. We identified two loci significantly associated with gemcitabine-induced leukopenia/neutropenia (SNPA in *AERG1*,  $P_{\text{fisher}} = 7.24 \times 10^{-4}$ , odds ratio (OR) = 3.11; SNPB in *AERG2*,  $P_{\text{fisher}} = 1.22 \times 10^{-2}$ , OR = 2.39). Combined analysis indicated a strong association of the SNPA in *AERG1* with gemcitabine-induced leukopenia/neutropenia (combined  $P = 3.35 \times 10^{-8}$ , OR = 3.68), and possible association of the SNP B in *AERG2* with the leukopenia/neutropenia (combined  $P = 3.85 \times 10^{-6}$ , OR = 3.01). Furthermore, we confirmed that cell death on dose-dependent manner was observed after treatment of gemcitabine and that mRNA expression level of *AERG1* was significantly increased by dose escalation of gemcitabine in cell lines (MCF7 and HS-5). To investigate the functional role of this gene, we examined the relationship between expression level of *AERG1* and gemcitabine-induced toxicity. We further investigated the effect of *AERG1* on cell viability and growth after gemcitabine treatment by shRNA-mediated knockdown system. We observed the resistance to the apoptosis in *AERG1* knocked down cells compared to the control cells. Although further investigation is required to clarify the effect of the SNP on gemcitabine-induced myelosuppression, our results suggested that *AERG1* might contribute to gemcitabine-induced apoptosis.

**655W**

**Risks of melanoma in melanoma-prone families with and without *CDKN2A/CDK4* mutations over four decades.** A.M. Goldstein<sup>1</sup>, D.E. Elder<sup>2</sup>, M. Curry<sup>2</sup>, M.C. Fraser<sup>1</sup>, V. Pichler<sup>1</sup>, D. Zimetkin<sup>4</sup>, X.R. Yang<sup>1</sup>, M.A. Tucker<sup>1</sup>. 1) Human Genetics Program, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD; 2) Department of Pathology, University of Pennsylvania, Philadelphia, PA; 3) Information Management Services, Inc., Silver Spring, MD; 4) Westat, Inc., Rockville, MD.

We assessed the risks of melanoma over four decades in American melanoma-prone families. From 1976-1989, eligibility criteria included documented invasive cutaneous melanoma (CM) in two living family members. After 1990, this criterion was changed to three living members with documented CM because of increased CM incidence. We clinically evaluated 1226 members of 56 families and followed them prospectively. All families were tested for mutations in *CDKN2A* and *CDK4*; 29 were mutation positive (Mut+) and 27 mutation negative (Mut-). We compared the rates of invasive CM, both first and second, by family mutation status to population rates in the Surveillance, Epidemiology, and End Results (SEER) program. For estimation of CM risk by calendar period, we divided the time into three intervals: prior to study initiation in 1976, 1976-1989, and 1990+. For estimating CM risk by study participation, we divided time into a retrospective period before the participant's first clinical exam (including initial exam) and a prospective period after initial exam. Comparing the three calendar periods, the risk of first CM decreased slightly. Chiefly, risks in the 1990+ period were lower than risks in 1976-1989 (13.0 vs 30.8 for all; 7.8 vs 15.3 for Mut-, 15.6 vs 38.6 for Mut+). Also, the risks of CM after first exam were approximately one third the risks prior to the first exam, in both Mut+ (12.7 vs 34.6) and Mut- (5.4 vs 16.2) families. Among CM patients, the risk of a second melanoma was increased 10-fold in all families; the risk was somewhat higher in Mut+ families versus Mut- families. Cumulative risks of first melanoma for both Mut+ and Mut- families were significantly different from those in SEER over the same period. All families had earlier onset and substantially higher risk than the general population with Mut+ families having earliest onset and highest risk. Similarly, risks of second CM were significantly elevated in all, Mut+, and Mut- families. Second CM risks in these families were, however, similar to general population risks in SEER from parallel periods suggesting that given susceptibility and exposure to develop one melanoma, individuals continue to be at risk and need surveillance, whether or not they carry a high-risk mutation. In this family-based study spanning four decades, the prospective risk of melanoma has decreased substantially in both Mut+ and Mut- families, during a period when melanoma risk in the general population has rapidly increased.

**656T****Impact of interaction between single nucleotide polymorphisms (SNPs) in neural repair genes and patient characteristics on cognitive outcomes in patients with hematological malignancies treated with hematopoietic cell transplantation (HCT).** *N. Sharafeldin<sup>1</sup>, A. Bosworth<sup>2</sup>, S.K. Patek<sup>3</sup>, Y. Chen<sup>2</sup>, P. Singh<sup>1</sup>, X. Wang<sup>3</sup>, L. Francisco<sup>1</sup>, S.J. Forman<sup>4</sup>, F.L. Wong<sup>3</sup>, S. Bhatia<sup>1</sup>.*

1) Institute for Cancer Outcomes and Survivorship, University of Alabama at Birmingham, Birmingham, AL; 2) Population Sciences, City of Hope, Durate, CA; 3) Department of Mathematics, University of North Texas, Denton, TX; 4) Hematology and Hematopoietic Cell Transplantation, City of Hope, Duarte, CA.

Neural repair genes have been previously linked to cognitive impairment in neurodegenerative diseases such as Alzheimer's disease and in association with chemotherapy-induced cognitive decline in cancer patients. The aim of this study was to explore the association between SNPs on neural repair genes *APOE*, *TOMM40*, and *BDNF* and cognitive impairments after hematopoietic cell transplantation (HCT). We also aimed to examine the impact of interactions between candidate SNPs and key demographic and clinical factors on cognitive impairment. In a prospective cohort of 277 hematologic cancer patients treated with autologous or allogeneic HCT (median age 52.2y; 58.5% males; 68.6% non-Hispanic whites [NHW]), cognitive function was assessed using standardized neuropsychological testing at pre-HCT, 6 months, 1, 2, and 3 years post-HCT. Most common primary diagnoses were non-Hodgkin lymphoma (30.1%) and acute myeloid leukemia (24.7%). We calculated a Global Deficit Score representing the overall performance across all tests in the neuropsychological test battery, and used it in generalized estimating equation models as a binary indicator of cognitive impairment. We identified significant associations between cognitive impairment post-HCT and age  $\geq 50$ y at HCT (OR=3.0, 95%CI: 1.6-5.7,  $p=0.001$ ), male sex (OR=2.6, 95%CI: 1.5-4.6,  $p=0.001$ ), race other than NHW (OR=2.8, 95%CI: 1.5-5.2,  $p=0.001$ ), and low cognitive reserve (OR=5.9, 95%CI: 3.2-10.7,  $p<0.0001$ ). Analysis involved 14 candidate SNPs across the 3 genes, LD pruning was used to identify number of independent tests (6 tests) yielding a  $p$ -value threshold of 0.0083 using Bonferroni correction for multiple testing. There were no statistically significant SNP main effects, however, we identified significant interactions between rs1519479 on *BDNF* gene and age  $\geq 50$ y at HCT (OR=0.2, 95%CI: 0.1-0.6,  $p=0.006$ ); between rs10835210 on *BDNF* gene and race other than NHW (OR=5.5, 95%CI: 1.7-18.1,  $p=0.005$ ); and between rs1160985 on *TOMM40* gene and low cognitive reserve pre-HCT (OR=10.4, 95%CI: 2.3-47.5,  $p=0.003$ ). There were no significant interactions between sex and any of the candidate SNPs. These results suggest a significant effect of age, race, and cognitive reserve on cognitive impairment in HCT recipients and that the effect of SNPs on neural repair genes may be modified by these factors.

Chan School of Public Health, Boston, MA; 11) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, UK; 12) Division of Molecular Pathology, The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, The Netherlands; 13) Division of Psychosocial Research and Epidemiology, The Netherlands Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, The Netherlands.

**Background:** Breast cancer genome-wide studies have identified 181 single nucleotide polymorphisms (SNPs), many of which have shown differential associations by estrogen receptor (ER) status, or have been identified in ER-negative/triple negative (TN) specific scans. Because multiple clinicopathological tumor features are correlated with each other, additional analyses are needed to identify specific tumor features driving the observed heterogeneity. **Methods:** Analyses included 106,571 cases and 95,762 controls of European descent participating in 81 studies of the Breast Cancer Association Consortium. Genotypes for 181 previously identified risk SNPs were determined using genome-wide arrays. Subtypes were defined based on ER, progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2). We used a two-stage polychotomous logistic regression to perform a global test that simultaneously tests subtype heterogeneity defined by one or more tumor marker. The model was also used to test for heterogeneity by specific markers adjusting for the others, and to efficiently handle missing data on tumor markers via an Expectation-Maximization algorithm. **Results:** Of 181 known risk SNPs, 86 had a  $P$  value for the global test for heterogeneity  $<0.05$ , and 43 had  $P < 3 \times 10^{-4}$  (corresponding to a Bonferroni corrected  $P < 0.05$ ). Of these 43 SNPs, 20 had a  $P_{\text{het}} < 0.05$  for marker-specific tests for heterogeneity only for ER: 15 of which were primarily associated with ER-positive and 5 with ER-negative disease. Two SNPs located in 9q31.2 and 10q26.12 had  $P_{\text{het}} < 0.05$  only for PR and were associated with PR-positive but not PR-negative disease. One SNP located in 6q25/*ESR1* showed  $P_{\text{het}} < 0.05$  only for HER2 and was more strongly associated with HER2-positive than negative disease. The remaining 20 SNPs showed  $P_{\text{het}} < 0.05$  for more than one marker: five of them were primarily associated with TN disease and the rest of other marker combinations. Ongoing analyses incorporating information on tumor grade and histology while accounting for ER, PR and HER2 may provide further insights into the underlying heterogeneity of SNP associations. **Conclusion:** We have identified novel evidence of heterogeneity for breast cancer SNPs by tumor subtypes defined by ER, PR, and HER2. The two-stage regression method is an efficient and systematic approach for identifying heterogeneous associations between SNPs and disease subtypes defined by multiple, correlated disease characteristics.

**658W**

**Development of breast cancer risk prediction for the UK population using the UK Biobank dataset.** *K. Alajmi, A. Lophatananon, K. Muir.* University of Manchester, Manchester-UK, United Kingdom.

Several risk prediction models have been developed to estimate the likelihood of developing breast cancer based on specific risk factors in currently healthy individuals within a specific period of time. The majority of these models are however not user-friendly, do not focus on modifiable factors entirely and are not specifically designed for the general public. Our research group is developing an individualised risk prediction model for breast cancer focussing on the modifiable risk factors using the UK Biobank data. A nested case-control study within the 273,467 female participants is being used to develop the model. Two models have been built based on the menopausal status (Pre (64,116 subjects) and post menopause (196,948)). Backward stepwise logistic regression was used to fit the model using the significant risk factors from the univariate regression analyses. Moreover, calibration and discrimination were performed in both models. Additionally a cross validation approach of 10 folds was used to test the internal validation. For model external validation, we will further seek external validation in other Caucasian cohorts. The model provides risk scores derived from the presence or absence of specific risk factors and will be compared to the general public score. The model will allow people to modify their risk profile with appropriate prevention measures. The main goal of the model is to be used in cancer education and prevention. The preliminary results from pre and post-menopause models show moderately good calibration and discrimination (ROC=0.691) among pre-menopausal females. While in the post-menopausal model it was well calibrated and moderately discriminated with an (ROC 0.6882). Further risk factors (SNPs) will be identified and assessed for causality using a Mendelian Randomisation approach (SNPs as surrogate of exposures) and genetic predisposition will also be included in the model with the aim of improving the performance of the model. In conclusion, we are developing an individualised breast cancer risk prediction model for the UK population based on the modifiable risk factors. The model will enable us to educate and to design appropriate interventions tailored to the individual with the aim of assisting them to make appropriate changes to modify their cancer risk profile.

**Integrative genomic analyses revealed candidate susceptibility genes in GWAS identified loci for colorectal cancer risk.** *J. Bao<sup>1,2</sup>, X. Shu<sup>1</sup>, J. Wang<sup>3</sup>, W. Wen<sup>1</sup>, J. Long<sup>1</sup>, Q. Cai<sup>1</sup>, Q. Liu<sup>3</sup>, W. Zheng<sup>1</sup>, X. Guo<sup>1</sup>.* 1) Division of Epidemiology, Vanderbilt University Medicine Center, Nashville, TN, USA; 2) College of life Science, Fujian Agriculture and Forestry University, Fuzhou, Fujian, China; 3) Center for Quantitative Sciences, Vanderbilt University School of Medicine, Nashville, TN, USA.

Genome-wide association studies (GWAS) have identified approximately 50 loci associated with colorectal cancer (CRC) risk. However, the gene and biological mechanisms underlying these observed associations are largely unknown. We conducted a cis-expression quantitative trait loci (cis-eQTL) analysis for all GWAS-identified single nucleotide polymorphisms (index SNPs) and their flanking genes ( $\pm$  1 MB region), in three publically available datasets including normal and/or colorectal cancer tissue samples from the Genotype-Tissue Expression (GTEx) (N = 169), The Cancer Genome Atlas (TCGA) (N = 242), and Colomics project (N = 144). Applied the Benjamini-Hochberg adjusted  $P < 0.05$  in at least one of three datasets, eQTL analysis revealed that 19 index SNPs are significantly linked with expression levels of 32 genes, suggesting they may be candidate susceptibility genes for CRC. Among them, nine were previously reported as candidate genes linked to six index SNPs, and 23 genes linked to 15 index SNPs are newly identified. To further investigate the possible underlying biological mechanisms, we performed an integrative analysis of Chromatin Immunoprecipitation Sequencing (ChIP-seq), DNase I hypersensitive sites sequencing (DNase-seq), and chromatin-interaction data from various genomic resources that were generated from multiple cell types, including CRC cells, to examine the chromatin interactions between promoter/enhancer regions of all SNPs in strong linkage disequilibrium (LD,  $R^2 > 0.8$ ) with index SNPs and promoter regions of the identified candidate susceptibility genes. Our result suggested that approximate 60% of these genes including five previously reported and 14 novel genes showed evidence of the chromatin interactions with the regions of functional SNPs (located in promoter/enhancer regions). A functional enrichment analysis using Ingenuity Pathway Analysis (IPA) revealed that the most enriched network for these target genes are related to lipid metabolism and cancer function. Our study revealed several novel candidate genes for CRC risk and shed lights on biological mechanisms for CRC carcinogenesis.

**660F****Genome-wide association study of Waldenström macroglobulinemia identifies novel loci.**

Waldenström macroglobulinemia (WM) is a unique subset of lymphoplasmacytic lymphoma (LPL) that is defined by the presence of an LPL infiltrate in the bone marrow together with a monoclonal IgM protein in the serum. Although WM/LPL has been estimated to have high heritability, the genetic basis for WM predisposition remains unknown. To identify susceptibility loci for WM, we conducted a two-stage genome-wide association study (GWAS) in over 500 WM/LPL cases and 4,300 controls of European ancestry. In stage 1, 217 WM cases and 3,798 controls were genotyped on the Illumina Omni Express or Illumina Omni2.5 platforms and passed quality control filters. The data were imputed using the Haplotype Reference Consortium panel and analyzed using logistic regression. Eleven promising loci ( $P < 5.0 \times 10^{-7}$ ) were selected for replication in 312 WM/LPL cases and 564 controls. Two novel loci were convincingly replicated in stage 2 ( $P < 1.2 \times 10^{-5}$ ) and were genome-wide significant in the combined analysis of both stages: 6p25.3 (*EXOC2*, OR = 21.14,  $P = 1.36 \times 10^{-6}$ ) and 14q32.13 (intergenic near *TCL1*, OR = 4.90,  $P = 8.74 \times 10^{-10}$ ). A possible second signal with weak linkage disequilibrium to the first variant ( $r^2 = 0.002$ ) was observed at 14q32.13, but did not reach genome-wide significance ( $P = 3.16 \times 10^{-6}$  after conditioning on the first signal). Both loci are located near genes of particular interest for WM/LPL. Dysregulated *TCL1* expression in B cells enhances cell proliferation and survival, leading to cell transformation, and it is aberrantly expressed in WM. *EXOC2* interacts with Ras proteins to mediate oncogenic RAS signaling, which is critical for cancer cell survival and proliferation. In laboratory experiments, we found that cells transduced with the *EXOC2* variant allele reporter pCS-EGFP-3'G showed significantly increased EGFP fluorescence compared to the wildtype, suggesting the variant is associated with increased *EXOC2* protein levels. Cells harboring the *EXOC2* variant allele were also observed to have significantly increased cell proliferation compared to wildtype cells. We further discovered that the *EXOC2* variant abrogates a miRNA binding site, possibly contributing to gene expression changes for NF- $\kappa$ B pathway constituents. Together these two new, relatively high penetrant loci explain ~3.9% of the familial risk, significantly increasing our understanding of the genetic susceptibility of WM/LPL and pointing to possible biological pathways that may be important for risk.

**661W****Evaluation of the impact of rare variants on glioblastoma susceptibility.**

R. Bohlender, Y. Yu, H. Zhao, C. Huff. Epidemiology, MD Anderson Cancer Center, Pearland, TX.

Glioblastoma (GBM) is a deadly disease, with a 5-year survival rate of only 5%. GBM has a strong familial component, with an estimated heritability of up to 66%. However, only 6% of the excess familial risk of GBM is accounted for by known genetic risk factors. We conducted a whole-exome sequencing case-control study involving 324 GBM cases of European ancestry from The Cancer Genome Atlas (TCGA) and 3507 controls of European ancestry from the National Database for Autism Research (NDAR) to investigate sources of risk. We used the Variant Annotation, Analysis, and Search Tool (VAASST) to conduct a case-control association analysis. VAASST is a gene-based test, which leverages variant level information about phylogenetic conservation and amino acid substitution to prioritize variants likely to influence protein function. Due to differences in sequencing platforms, laboratory preparation, and capture technologies, we observed high levels of Type I error inflation. We used the Cross Platform Association Toolkit (XPAT), which is designed to control for cross-platform artifacts in association studies with heterogeneous sequencing datasets. Using XPAT, we observed consistency between empirical and observed  $p$ -values to alpha levels of 0.005. Two genes previously implicated in GBM as susceptibility and somatic driver genes, TP53 and EGFR, were nominally statistically significant ( $p = 7.4 \times 10^{-4}$  and  $3 \times 10^{-3}$ , respectively). To estimate the risk of GBM conferred by rare variants, we calculated gene-level odds ratios for the following variant categories: All rare variants (minor allele frequency  $< 0.005$ ), rare likely gene-disrupting (LGD) variants (insertion of premature stop codon, frameshift, or splice-site variant), and rare missense variants predicted to be potentially damaging by both PolyPhen2 and VAASST. Effect size estimates for EGFR (OR = 3.290 (1.312, 8.251)) and TP53 (OR = 6.546 (1.557, 27.516)) are nominally significant. We observed an excess of rare LGD variants in *RAD50* (OR = 5.439, (0.993, 29.812);  $p = 0.0153$ ), suggestive of a role in GBM risk. *RAD50* is a part of the MRN protein complex, involved in double stranded break repair, and has been previously associated with breast cancer risk. We report the full results from our case-control analyses, and provide an initial assessment of somatic-germline interaction in GBM at EGFR, TP53, and *RAD50*. The results from this work yield new insights into the impact of rare genetic variation on GBM susceptibility.

**Familial-aggregation of somatic mutations in lung cancers.** *Y. Chang<sup>1,2</sup>, M. Lee<sup>3</sup>, H. Chen<sup>4</sup>, S. Su<sup>5</sup>, G. Chang<sup>6,7</sup>, H. Chen<sup>2</sup>.* 1) Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, Taipei, Taiwan; 2) Institute of Statistical Science, Academia Sinica, Taipei, Taiwan; 3) Institute of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan; 4) Graduate Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan; 5) Center of Biotechnology, National Taiwan University, Taipei, Taiwan; 6) Division of Chest Medicine, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; 7) Comprehensive Cancer Center, Taichung Veterans General Hospital, Taichung, Taiwan.

Genetic variations plays import role in lung cancer, especially somatic mutations. Somatic mutations in epidermal growth factor receptor (*EGFR*) have great impact on tumor progression and treatment strategy. Patients with familial history of lung cancer are more susceptible to lung cancer. The familial-aggregation of somatic mutations is seldom investigated. In this study, we sequenced 143 genes for 27 lung cancer patients from 13 families. These 143 genes are well established oncogene or tumor suppressor, and relevant to clinical trials. The sequenced sites are about 2661 base pairs (bp) with average sequence depth 1655X (range 1005X-2208X). We identified 570 single nucleotide variants (SNVs) in 99 genes. These 570 SNVs could group 21 out of 27 patients into correct families (77.78%) in cluster analysis. The percentage of somatic mutations shared among a family (co-mutation) is 77.99% (range 60.02%-88.08%, p-value  $2.2 \times 10^{-16}$  estimated from Cochran-Mantel-Haenszel test). Additionally, among the identified 570 SNVs, 222 somatic SNVs (%) in 70 genes were not observed in Taiwanese populations. Co-mutation rates were observed significant different between family members both having *EGFR*-positive lung cancers and at least one members with *EGFR*-negative lung cancers (21.50% versus 42.10%, p-value of t-test is 0.0427). These results indicated that somatic mutations in lung cancer had the property of familial-aggregation and family members both having *EGFR*-positive lung cancers had lower co-mutation rate.

**Classification of lung adenocarcinoma using optimized support vector machines applied to gene expression data.** *J.S. Diaz<sup>1,2</sup>, A.C. Gonzaga<sup>2</sup>.* 1) Faculty of Medicine and Health, University of Leeds, Leeds, West Yorkshire, United Kingdom; 2) Department of Physical Science and Mathematics, University of the Philippines Manila, Manila, Philippines.

**Introduction:** Lung cancer has been identified as a major health issue for both developed and developing countries. Non-small-cell lung carcinoma (NSCLC) is the most common type of lung cancer accounting to 85 to 95 % of lung cancer cases with adenocarcinoma as common form. Early diagnosis of lung cancer is important to provide the patients with more timely treatment preventing spread and worsening of the disease. To classify lung cancer patients on the basis of gene expression data, this study used two types of response variables namely 1. Normal and Cancer(Binary) and 2. C1, C2, C3, C4, CM and G1 (multiclass). **Methods:** The 12600 genes in the dataset were initially filtered based on the top ranking genes in terms highest variability. The cut-off is 50 standard deviation units leaving 3312 genes used in the next step of analysis. Support vector machines optimized by genetic algorithm were used to model patient class. **Results:** Results indicate that almost all lung cancer patients were correctly classified by the model at 99% accuracy rate while 94% accuracy rate was observed for normal patients. Overall, the accuracy rate observe for this classification analysis is 96.3 % with 2 genes in the model. Maximal overlap wavelet transformation was applied to the data set using filters of the Daubechies (*DB or db*) class and checked the classification performance versus the analysis without the transformation. Five wavelet filters namely db2, db4, db6, db8 and db10 at eight levels (1-8) were tested. It was found out that in general, models using maximal overlap wavelet transforms of the data were able to classify patients accurately at a rate ranging from 94.1% to 98.75 % composed of 13 to 50 features (functions of genes). For the multiclass problem, it was found out that selected wavelet transforms were able to classify adenocarcinoma patients accurately at a rate of 93.22 to 99.58% and outperformed the model without using the wavelet transform of the data. **Conclusion:** Maximal overlap wavelet transformation improves classification accuracy of the genetic algorithm optimized support vector machines but selected more number of genes as compared with analysis without the transformation. Therefore, if the primary consideration is simplicity in terms of number of genes to consider in decision making, method without the transformation is recommended. On the other hand, allowing some increase in the number of genes in the model leads to more accurate classification.

**664W****Whole-genome DNA methylation profiling in breast cancer by the Illumina MethylationEPIC array and the TruSeq EPIC sequencing platforms.**

C. He<sup>1</sup>, G. Jiang<sup>2</sup>, H. Lin<sup>2</sup>, N. Lin<sup>2</sup>, A. Shendure<sup>1</sup>, J. Wan<sup>2</sup>, Y. Liu<sup>2</sup>. 1) Cancer Prevention and Control Program, University of Kentucky Markey Cancer Center, Lexington, KY; 2) Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN.

The Illumina MethylationEPIC array (EPIC-array) has been widely used to profile genome-wide DNA methylation in human samples using hybridization techniques. The new Illumina TruSeq Methyl Capture EPIC sequencing (EPIC-seq) leverages the power of next-generation sequencing (NGS) technology and aims to providing much higher resolution data. We empirically compared whole-genome DNA methylation profiling from the two platforms (EPIC-array and EPIC-seq) in our breast cancer study and critically evaluated the performance of the two platforms in identifying differentially methylated CpG sites and islands that were associated with breast cancer risk. We showed that EPIC-Seq covered much more CpG sites within the same region, on average, 1,485,036 CpG sites compared to 155,862 CpG sites by array profiling (about 9.5-fold higher). When we compared the difference of CpG methylation ( $\beta$ ) between breast tumor and normal samples, we found that in general  $\Delta\beta$  showed high consistence between two approaches in terms of both CpG sites and CpG islands. However, EPIC-seq tended to have larger  $\Delta\beta$  compared to EPIC-array in two extremes of the distribution. Despite the high consistency for the differentially methylated sites and regions, we observed that EPIC-Seq provided higher measures in the variation of the beta value (wider dynamic range) comparing to EPIC-Array technology, particularly around the extreme hypo- and hyper-methylation regions (beta value is close to 0 and 1). These results suggested that EPIC-seq had a higher sensitivity in distinguishing methylation difference and may lead to identification of more DNA methylation sites and regions associated with breast cancer risk.

**665T****Fine mapping of the 6q25 breast cancer risk locus among Latinas**

**reveals additional variants associated with risk.** J. Hoffman<sup>1</sup>, L. Fejerman<sup>2</sup>, D. Hu<sup>2</sup>, P. Lott<sup>3</sup>, S. Huntsman<sup>2</sup>, E.M. John<sup>4,5</sup>, G. Haiman<sup>10</sup>, E. Ziv<sup>6</sup>, COLUMBUS Consortium. 1) Department of Epidemiology & Biostatistics, University of California, San Francisco, San Francisco, CA; 2) Department of Medicine, Institute for Human Genetics, Helen Diller Family Comprehensive Cancer Center, University of California, San Francisco, San Francisco, CA; 3) University of California, Davis, Davis, CA; 4) Cancer Prevention Institute of California, Fremont, CA; 5) Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA; 6) Instituto Nacional de Salud Pública, Cuernavaca, México; 7) Universidad del Tolima, Ibagué, Colombia; 8) City of Hope Comprehensive Cancer Center, Duarte, CA; 9) Kaiser Permanente Northern California, Oakland, CA; 10) University of Southern California, Los Angeles, CA.

Introduction: Numerous loci have been identified by genome-wide association studies (GWAS) for breast cancer (BC), but the majority have been identified in populations of European and Asian ancestry. We have conducted a GWAS of BC in Latinas and have previously identified at least one locus at 6q25 associated with risk. Here we report on fine mapping at the 6q25 locus in this population. Methods: For discovery we used data from 2396 cases and 7468 controls. We included Latina BC cases and controls from the San Francisco Bay Area Cancer Study (SFBACS), Northern California BC Family Registry (NCBCFR) (942 cases and 699 controls), Kaiser Research Program on Genes Environment and Health cohort (225 cases and 3576 controls), Multiethnic cohort (MEC) (520 cases and 2491 controls), and the Cancer de Mama (CAMA) Study (709 cases and 702 controls). All datasets were imputed to the Haplotype Reference Consortium (HRC). We performed association analysis using logistic regression and adjusted for genetic ancestry by means of principal components analysis. For replication, we used a subset of the CAMA study without GWAS data (310 cases and 464 controls), Latina BC cases (1148) from the Clinical Cancer Genetics Research Network and matched controls (387), and samples from a Colombian study (954 cases and 769 controls). Replication samples were genotyped by Taqman probes except for the Colombian study, which was imputed to the HRC. Results: We identified 34 SNPs that were genome-wide significant ( $p < 5e-8$ ) at 6q25. The top SNP, rs140068132, previously identified in our GWAS as a Latina specific SNP, was associated with a strong protective effect for the minor allele, with an odds ratio (OR) of 0.58 per allele ( $p = 1.6e-12$ ). Of the remaining SNPs, 21 were in high to moderate LD ( $r^2 > 0.5$ ) with rs140068132 and 7 SNPs were in low LD ( $r^2 < 0.2$ ). Of these 7 SNPs, 4 were in near perfect LD, characterized by rs851984 (OR 1.26,  $p = 1e-8$ ), which had previously been reported in GWAS of Caucasians and Asians. Another 3 SNPs, characterized by rs3778609 (OR 0.75,  $p = 2e-8$ ), were in low LD with rs140068132 and other previously reported SNPs. This SNP replicated in a combined analysis of additional studies (OR 0.89,  $p = 0.039$ ). Summary: We have performed fine mapping at 6q25 in Latinas and have identified one novel genome-wide significant block of SNPs. This result supports the notion that multiple variants within 6q25 contribute to breast cancer risk, some of which are population specific.

**Prevalence of cancer predisposition gene mutations among unselected pancreatic cancer patients.** C. Hu<sup>1</sup>, S.N. Hart<sup>2</sup>, E. Polley<sup>2</sup>, R. Gnanolivu<sup>2</sup>, J. Na<sup>2</sup>, K.Y. Lee<sup>2</sup>, W.R. Bamlet<sup>2</sup>, K.G. Chaffee<sup>2</sup>, R.R. McWilliams<sup>2</sup>, G.M. Petersen<sup>2</sup>, F.J. Couch<sup>1,2</sup>. 1) Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 2) Health Sciences Research, Mayo Clinic, Rochester, MN; 3) Oncology, Mayo Clinic, Rochester, MN.

Early detection and intervention offers the possibility of improved survival for individuals diagnosed with pancreatic cancer (PC). In the absence of biomarkers predicting the presence of PC, individuals with genetic predisposition to this disease have the greatest potential for improved survival. Several PC predisposition genes such as BRCA2, PALB2, and ATM have been identified through family-based studies. However, the relevance of all known cancer predisposition genes to PC, and the risks of PC associated with mutations in established PC predisposition genes are not known. Here we evaluated the largest cohort to date of unselected PC patients subjected to hereditary cancer panel testing for the prevalence and risks of mutations in cancer predisposition genes. Germline DNA from 3030 unselected PC patients enrolled in a prediagnostic rapid ascertainment cohort at Mayo Clinic from 2000 to 2016. A customized 37 gene (1733 primer pairs) Qiaseq multiplex PCR-based panel along with Hiseq4000 paired-end sequencing was used to identify germline variants. Pathogenic variants were combined by gene and compared to mutation frequency in ExAC reference controls to estimate associations with PC. A total of 171 pathogenic mutations and 8 CNVs in established PC predisposition genes were found in 6.04% of patients: ATM (2.46%), BRCA2 (2.05%), BRCA1 (0.64%), PALB2 (0.50%), CDKN2A (0.40%). Multiple pathogenic variants in the CHEK2 (1.08%), PMS2 (0.28%), MSH6 (0.23%), MLH1 (0.22%), and TP53 (0.20%) cancer predisposition genes were identified in another 2.01% of patients. Pathogenic mutations in ATM, PALB2, BRCA1, BRCA2, CDKN2A, and MLH1 were associated with moderate or high risks (odds ratio (OR): 2.0-6.0) of pancreatic cancer, whereas mutations in CHEK2 and MSH6 were associated with lower risks (OR<2.0). Overall, mutations in cancer predisposition genes were found in up to 8% of unselected pancreatic cancer cases. Importantly, not all patients with mutations met hereditary cancer testing criteria defined by the American College of Gastroenterology and National Comprehensive Cancer Network. Together these findings suggest that refinement of the guidelines for clinical genetic testing may be needed.

Hereditary mutations in cancer-susceptibility genes are responsible for tumor development in limited but clinically important subgroup of breast cancer (BC) patients. The carriers of hereditary mutations face a high life-time risk of cancer, which often develops at an early age. Tailored care improving life expectancy in these high-risk individuals requires an unequivocal identification of causative mutations in hundreds of known cancer-susceptibility genes. We have designed the multigene targeted next-generation sequencing panel CZECA (CZEch CAncer paNel for Clinical Application) enabling simultaneous analysis of 219 cancer susceptibility or candidate genes that we used for the analysis of 744 high-risk BC patients. The primary analysis revealed 238 truncating (indels, nonsense, splicing, and large genomic rearrangements) germline variants in 78 genes that affected 210 (28.2%) patients. Over half of truncating variants was identified in only seven genes, that included mutations in *BRCA1* (in 6.6% of analyzed patients), followed by mutations in *BRCA2* (3.6%), *PALB2* (2.0%), *CHEK2* (1.3%), *PMS1* (0.9%), *RECQL* (0.8%), and *ATM* (0.7%). Seven patients carried a combination of two truncating variants in these genes. Only a single truncating germline variant was detected in 48 genes that in majority coded for DNA repair proteins. The mean age of all truncating variant carriers, carriers of mutations in seven the most frequently altered genes and carriers of mutations in other 71 genes were nearly identical. However, the mean ages at BC diagnosis (ranging between 39.8 – 60.0 years) differed among carriers of mutations in the most frequently mutated genes. The analysis show that mutations in the most frequently altered genes affected 113/744 (15.2%) patients, but other 13% patients carried mutations in other BC susceptibility or candidate genes. We are aware that the further studies will need to be performed in order to characterize biological importance and clinical significance of variants in non-conventional BC susceptibility genes. However, the early age of BC diagnoses in carriers of variants in these genes warrants such effort. The data obtained from analyzed patients will be used for the development of national-wide database of genotypes and associated phenotypic characteristics for diagnostic purposes. **Results of *BRCA1/2* testing in 1339 high risk Israeli patients with breast and/or ovarian cancer who were tested negative for the founder mutations.** *I.M. Kedar<sup>1</sup>, S. Hartmayer<sup>1</sup>, N. Ginzach<sup>1</sup>, L. Bazak<sup>1</sup>, M. Lifshitz-Kalis<sup>1</sup>, N. Magal<sup>1</sup>, L. Basel-Salmon<sup>1</sup>, E. Reinstein<sup>2,4</sup>, T. Shapira<sup>2</sup>, R. Bernstein Molho<sup>3</sup>, Y. Goldberg<sup>1,2</sup>.* 1) Recanti Genetics, Rabin Medical Center, Petah Tikva, Israel; 2) Macabbi Health Services; 3) Department of genetics and Department of Oncology, Tel Aviv Medical Center, Ichilov Hospital, Tel Aviv, Israel; 4) Department of Genetics, Meir Medical Center, Kfar Saba, Israel.

**Introduction:** We report results of *BRCA1/2* testing in 1339 Israeli breast or ovarian cancer patients who were referred for comprehensive gene testing.

**Methods:** During the years 2014-2017 patients who had at least 10% chance of being a *BRCA1/2* carrier by various probability models (BRCAPRO, PENNII or Boadicea) and were tested negative for founder mutations, were offered *BRCA1/2* full sequencing. Non-Ashkenazi patients also had deletion/duplication testing. Patients from ethnic groups with unknown founder mutations were referred directly to sequencing. **Results:** Fifty-three patients (4%) carried a pathogenic or likely pathogenic variant. Sixty-six (5%) had variants of unknown significance. Four of the carriers (8%) had various gene rearrangements.

Overall, we identified 46 different pathogenic variants in 53 patients. One likely pathogenic mutation was detected in 4 unrelated Arab patients from the same village. Four variants occurred twice in unrelated patients. 3% of full Ashkenazi Jews, 9% of half Ashkenazi Jews, and 2% of the Non-Ashkenazi Jews had a non-founder mutation. Most of the carriers (92%) had family history of cancer.

**Conclusions:** Detection rate of a *BRCA1/2* mutation was lower than expected by probability models in the various Jewish ethnic subgroups. There was a relatively high rate of 16% *BRCA1/2* carriers among Arab patients. This is the first comprehensive report of the yield of *BRCA1/2* sequencing in the Israeli population. Mapping the *BRCA1/2* variant spectrum in the local population should be used to further facilitate and guide *BRCA1/2* testing and interpretation. These findings also suggest that different probability models should be used for patients tested negative for founder mutations.

**Whole exome sequencing reveals genes with elevated germline rare variants burden in myeloid malignancy patients.** *S. Li, S. Grandhi, C. Bosworth, J. Wang, Z. Li, T. LaFramboise.* Genetics and Genome Sciences, Case Western Reserve University, Cleveland, OH.

Myeloid malignancy is a clonal disorder which is found in hematopoietic stem or progenitor cells. Because genetic changes can contribute to the disease by disturbing key aspects in cells such as self-renewal, proliferation and differentiation, it is important to know which genes are associated with myeloid malignancy in order to increase our understanding, assess disease risk, and develop therapeutic strategies to treat the disease. However, there has been no significant genetic association reported through genome wide association studies (GWAS) for myeloid malignancy. As GWAS has typically focused on common variants, the association of rare variants and susceptibility to myeloid malignancy remains unclear. We have analyzed germline whole-exome sequencing data from a total of 850 myeloid malignancy patients. We first explored the truncating and disruptive rare variants in genes that are found to have crucial roles in cancer development or known to be frequently mutated in myeloid malignancy patients. We found that there are a number of cancer causing genes which are having rare but disruptive variants. We then conducted rare variant association tests and observed that some genes have elevated rare variant burden in myeloid malignancy patients. We also saw a number of genes showing higher-than-expected numbers of patients harboring both germline and somatic disruptions in the same gene. Lastly, we looked at the read depth ratio of reference and alternate alleles in tumor cells for regions that have elevated rare variant burden in the matched normal cell. We observed that regions which bearing rare variants tend to selectively remain in tumors. This may suggest that retaining those regions can have an advantageous effect on tumor progression by unmasking the effect of germline rare variants. Our results show that inherited rare variants can be crucial for susceptibility to myeloid malignancy.

**Large rearrangement analysis in *GREM1* and the identification of novel deletions and duplications.** D. Mancini-DiNardo, E. Mundt, T. Judkins, J. Holladay, K.R. Bowles, B.B. Roa. Myriad Genetic Laboratories, Inc., Salt Lake City, UT.

**Background:** Duplication of the *GREM1* regulatory region leading to changes in expression has been reported in patients with Hereditary Mixed Polyposis Syndrome (HMPS), a rare condition that has been identified in a small number of families to date. A 40kb duplication in the *GREM1* upstream regulatory region was reported as an Ashkenazi Jewish founder mutation in HMPS families. Individuals with HMPS develop multiple colorectal polyps of varied types at young ages and have a significantly increased risk for colorectal cancer. Here we report on our laboratory's experience with genetic testing for *GREM1* large rearrangements (LRs) as part of a hereditary cancer panel. **Methods:** *GREM1* was incorporated into multi-gene pan cancer panel testing in July 2016. Next generation sequencing (NGS) dosage analysis was designed to detect LRs in *GREM1* and the upstream region overlapping the adjacent gene *SCG5*. All LRs were confirmed using MLPA. The 40kb duplication was further confirmed by breakpoint-specific PCR and sequencing analysis. LRs in *GREM1* detected between July 2016 and May 2017 were assessed here. **Results:** Seven unique *GREM1* LRs (4 deletions, 3 duplications) were detected in 26 individuals. The only previously reported LR detected here is the 40kb duplication, which spans a region upstream of the *GREM1* 5'UTR and includes exon 2 of the adjacent *SCG5* gene. Two other duplications have also been detected, which extend beyond the endpoints of the founder duplication. The 40kb duplication is classified as pathogenic because of the collective supporting data; however, the pathogenicity of the other two duplications and four deletions has not been established. Therefore, those LRs are currently classified as variants of unknown significance. **Conclusions:** LR analysis of *GREM1* in this population has demonstrated more variations than previously reported. As such, care must be taken in the analysis and interpretation of LRs involving *GREM1*. Assessment of the regions upstream and downstream of *SCG5* exon 2 is critical to distinguishing between similar duplications, which may differ in clinical significance. Proper identification and interpretation of LRs detected in *GREM1* is essential to appropriate clinical management.

**Identification of genetic variants associated with lung cancer risk among European and African Americans with COPD.** V.L. Martucci<sup>1,2</sup>, Y. Bradford<sup>3</sup>, W.J. Blot<sup>4,5</sup>, P.P. Massion<sup>6,7</sup>, M.C. Aldrich<sup>1,2,4</sup>. 1) Department of Thoracic Surgery, Vanderbilt University School of Medicine, Nashville, TN; 2) Department of Thoracic Surgery, Vanderbilt University Medical Center, Nashville, TN; 3) Biomedical and Translational Informatics Program, Geisinger Health System, Danville, PA; 4) Division of Epidemiology, Vanderbilt University Medical Center, Nashville, TN; 5) International Epidemiology Institute, Rockville, MD; 6) Division of Allergy, Pulmonary and Critical Care Medicine, Vanderbilt University Medical Center, Nashville, TN; 7) Veterans Affairs Medical Center, Nashville, TN.

Chronic obstructive pulmonary disease (COPD) is an established risk factor for lung cancer (LC). Candidate genes contributing to risk of each disease have been identified in independent investigations of COPD and LC. Yet genetic variants associated with LC among individuals with concomitant COPD and among African Americans (AA) remain understudied. The goal of this study was to identify genetic variants contributing to LC development among European American (EA) and AA individuals with COPD. We conducted a nested case-control study of COPD and LC cases (N=257) and COPD controls (N=342) among ever smokers from the Southern Community Cohort Study, a large prospective cohort of EAs and AAs in the Southeastern US. Samples were genotyped using the Affymetrix UK Biobank Axiom Array. After quality control assessment, a total of 363,487 SNPs and 125 cases/151 controls remained for AAs and 363,512 SNPs and 125 cases/151 controls remained for EAs. Candidate genes were selected based on prior associations with COPD, LC, and/or tobacco use. Biofilter software was used to identify all SNPs within the candidate genes (+/-10 kb) (N=4,127 SNPs). In AAs, the three most significant results were rs76641146 (OR=2.06, 95% CI: 1.33-3.19) and rs7276417 (OR=1.86, 95% CI: 1.24-2.80) in the *DSCAM* region on chromosome 21 and rs11080470 (OR=0.54, 95% CI: 0.37-0.79) in the *FAM38B* region on chromosome 18. In EAs, the most significant results were rs7237913 (OR=2.03, 95% CI: 1.37-2.99) and rs600695 (OR=0.54, 95% CI: 0.37-0.78) in the *LAMA1* region on chromosome 18 and rs12495100 (OR=0.48, 95% CI: 0.31-0.74) in the *RBMS3* region on chromosome 3. All four gene regions have been previously associated with LC, primarily in European populations, and all except *FAM38B* have been associated with smoking. However, none of these regions passed multiple testing correction using a false-discovery rate (FDR) of 15%. Focused analyses of candidate SNPs from prior GWAS of LC, COPD, or smoking identified a statistically significant association with LC among EA (after applying a FDR correction) with a prior smoking-associated SNP rs9365334 (OR=2.47, 95% CI: 1.54-3.97) in *PARK2* on chromosome 6q26. *PARK2* has been implicated as a tumor suppressor gene in prior studies of LC. While genetic variants may contribute to LC risk among individuals with comorbid COPD, larger sample sizes in diverse populations are needed to confirm or refute potential associations.

Genome-wide association studies (GWAS) have successfully uncovered multiple germline variants contributing to the risk of specific subtypes of non-Hodgkin lymphoma (NHL); however, much of the heritability remains unknown, even after considering all common SNPs simultaneously as predictors and estimating the variance explained. Thus far, little consideration has been given to the potential role of recessive genetic effects on disease risk. Interest in examining runs of homozygosity (ROHs) across the genome, as one aspect of recessive genetic inheritance, has grown in recent years. Identification of ROHs in an outbred population may provide insight into the contribution of recessive effects on disease risk. We evaluated the association between genome-wide homozygosity and NHL risk by estimating the fraction of ROHs (FROH) across the autosomes in eight previously conducted GWAS of NHL of European ancestry, including 2,761 chronic lymphocytic leukemia (CLL) cases, 3,715 diffuse large B-cell lymphoma (DLBCL) cases, 2,563 follicular lymphoma (FL) cases, and 720 marginal zone lymphoma (MZL) cases and up to 7,287 controls. Identified ROHs were a minimum of 1.5 megabases in length. We performed logistic regression to estimate odds ratios and 95% confidence intervals for the association of FROH with risk of NHL subtype, controlling for age, sex, and top ten principal components of ancestry. Regression results for each NHL subtype by study were combined using fixed-effect meta-analysis. Preliminary results indicate a positive association between FROH and risk of CLL ( $\beta = 23.8$ , 95% CI = 13.1-34.4,  $p = 1.19 \times 10^{-6}$ ), corresponding to an OR of 1.27 for every 1% increase in FROH. We also observed a positive association between FROH and risk of FL ( $\beta = 12.9$ , 95% CI = 2.31-23.5,  $p = 0.017$ ), corresponding to an OR of 1.14 for every 1% increase in FROH. We did not find evidence to support an association between FROH and risk of DLBCL ( $p = 0.15$ ) or MZL ( $p = 0.13$ ). Our findings indicate a role for recessive genetic effects in the etiologies of CLL and FL. These results may help explain some of the missing heritability of these complex diseases. More in-depth analyses of specific regions of homozygosity may lead to additional insight into genetic susceptibility to both CLL and FL.

**Whole-genome sequencing analysis of HPV31 and HPV35 reveals variability in cervical cancer risk.** M. Pinheiro<sup>1</sup>, Y. Xiao<sup>1</sup>, M. Yeager<sup>1,2</sup>, M. Cullen<sup>1,2</sup>, J.F. Boland<sup>1,2</sup>, R. Burk<sup>4,5</sup>, Z. Chen<sup>6</sup>, K. Yu<sup>1</sup>, N. Wentzensen<sup>1</sup>, M. Steinberg<sup>1,2</sup>, S. Bass<sup>1,2</sup>, L. Burdett<sup>1,2</sup>, T. Raine-Bennett<sup>3</sup>, T. Lorey<sup>3</sup>, P.E. Castle<sup>4</sup>, M. Schiffman<sup>1</sup>, L. Mirabello<sup>1</sup>. 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, MD; 2) Cancer Genomics Research Laboratory, Leidos Biomedical Research, Inc., Frederick, MD; 3) Regional Laboratory and Women's Health Research Institute, Division of Research, Kaiser Permanente Northern California, Oakland CA; 4) Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY; 5) Departments of Pediatrics, Microbiology and Immunology, and Obstetrics & Gynecology and Women's Health, Albert Einstein College of Medicine, Bronx, NY; 6) Department of Microbiology, The Chinese University of Hong Kong, Hong Kong.

**Background:** High-risk human papillomavirus (HPV) infection causes virtually all cervical cancers. HPV31 and HPV35 are attributed to ~4% and 2% of cervical cancers worldwide, respectively. They are the closest genetically related to HPV16, the most carcinogenic type causing ~60% of cancers. Within each HPV type there are Evolutionary-derived variant lineages, which are linked to strong differences in carcinogenicity for HPV16, but this is not known for HPV31 and HPV35. We do not know why HPV types and variant lineages differ profoundly in risk of cancer, but viral genetic variation is likely part of the answer. We conducted the largest case-control study of HPV31 and HPV35 genetic associations with risk of cervical precancer/cancer using HPV whole-genome sequencing data. **Method:** 2,073 HPV31 and 608 HPV35 cervical cell specimens from the NCI-KPNC PaP study were whole-genome sequenced using custom Ion AmpliSeq panels. The cohort included CIN2 (HPV31: 438; HPV35: 179) and CIN3 precancer (HPV31: 342; HPV35: 94) and cancer (HPV31: 7; HPV35: 1) cases, compared with controls with benign infections ( $\leq$ CIN1; HPV31: 1,286; HPV35: 334). Logistic regression models were used to estimate CIN3/cancer (CIN3+) risk among HPV variant lineages, each individual SNP, and to determine if race/ethnicity modified risk. Burden tests assessed the combined effects of rare variants (MAF<0.03). **Results:** HPV31 A and B lineages had higher risks of CIN3+ compared to the C lineage (OR=1.7, 95%CI=1.2-2.3; OR=1.6, 95%CI=1.1-2.4, respectively); the A2 sublineage had the highest risk (OR=2.1, 95%CI=1.2-3.6). Risks were not modified by a woman's race/ethnicity ( $P>0.1$ ). Eighty-nine individual SNPs were significantly associated with CIN3+ ( $P<0.05$ ), 27 of which mapped to the viral regulatory region (URR) which regulates both viral replication and transcription (strongest SNP, OR=5.3, 95%CI=1.7-16.7). Rare non-silent SNPs in the L1 gene were significantly more frequent in the controls (Burden  $P=0.03$ ). For HPV35, there was a statistically significant difference among lineages by a woman's race/ethnicity ( $P=2.8 \times 10^{-6}$ ). African-American women had a higher risk of CIN3+ compared with European women if infected with A2 (OR=11.7, 95%CI=1.2-114). For A1, European women had a higher risk (OR=3.4, 95%CI=1.1-10.2). Individual SNP analyses revealed 8 SNPs associated with CIN3+ ( $P<0.05$ ). **Conclusion:** HPV31 and HPV35 genetic variation influences risk of cervical cancer, and HPV35 risk is modified by a woman's race.

## 674T

**Height and body mass index as modifiers of breast cancer risk among 22,588 carriers of *BRCA1* or *BRCA2* mutations: A Mendelian randomization study.** F. Qian<sup>1</sup>, J. Mitchell<sup>2</sup>, G. Chenevix-Trench<sup>3</sup>, M.A. Rookus<sup>4</sup>, O.I. Olopade<sup>5</sup>, T. Rebbeck<sup>6</sup>, D. Huo<sup>6</sup> on behalf of Consortium of Investigators for the Modifiers of *BRCA1/2* (CIMBA). 1) Department of Medicine, University of Chicago, Chicago, IL; 2) Division of Gastroenterology, Hepatology and Nutrition, Children's Hospital of Philadelphia, Philadelphia, PA, USA; 3) Department of Genetics, QIMR Berghofer Medical Research Institute, Brisbane, Australia; 4) Department of Epidemiology, Netherlands Cancer Institute, Amsterdam, The Netherlands; 5) Department of Epidemiology, Dana Farber Cancer Institute, Boston, MA, USA; 6) Department of Public Health Sciences, University of Chicago, Chicago, IL, USA.

**Background** Inheritance of *BRCA1/2* mutations confers a high life-time risk of breast cancer, and there are potential modifiers of this risk. Prospective cohort studies and Mendelian randomization analysis have shown height and body mass index (BMI) to affect breast cancer risk in the general population, but it remains unclear whether these associations are causal in *BRCA1/2* mutation carriers and their respective strengths. **Methods** We used the Mendelian randomization method to evaluate the association between height/BMI and breast cancer in the Consortium of Investigators for the Modifiers of *BRCA1/2* (CIMBA), consisting of 14,676 *BRCA1* and 7,912 *BRCA2* mutation carriers, with 11,451 cases of breast cancer. We created a height genetic score (height-GS) using 586 height-associated genetic variants and a BMI-GS using 93 BMI-associated genetic variants, weighted by their respective effect estimates in previous genome-wide association studies. We modeled the association between each GS as an instrumental variable and breast cancer risk using Cox proportional hazards models. **Results** We found body height was positively associated with breast cancer risk (hazard ratio [HR]: 1.07 per 10 cm increase in height, 95% confidence interval [CI]: 1.01–1.12;  $P=0.01$ ) and BMI was inversely associated with breast cancer risk (HR: 0.95 per 5 kg/m<sup>2</sup> increase in BMI, 95% CI: 0.92–0.98;  $P=0.001$ ). The height-GS explained 13.4% of the variation in height and the BMI-GS explained 2.6% of variation in BMI. The height-GS was positively associated with breast cancer risk, though this was not statistically significant (HR: 1.06 per 10 cm increase in genetically predicted height, 95% CI: 0.98–1.15;  $P=0.13$ ). The BMI-GS was found to be inversely associated with breast cancer risk (HR: 0.91 per 5 kg/m<sup>2</sup> increase in genetically predicted BMI, 95% CI: 0.83–0.99;  $P=0.04$ ). We found similar results when evaluating the pooled HR of individual height or BMI-associated genetic variants using an inverse-variance fixed-effects meta-analysis. The associations were similar for *BRCA1* and *BRCA2* carriers. **Conclusion** The observed associations between height/BMI and breast cancer risk in *BRCA1/2* carriers corroborate findings from prior studies in the general population. Under Mendelian randomization assumptions, these associations could be interpreted as causal. Further studies are warranted to elucidate the precise biological pathways that mediate the relationship between height/BMI, *BRCA1/2*, and breast cancer.

## 675F

**A cis-eQTL genetic variant of the cancer-testis gene *CCDC116* is associated with risk of multiple cancers.** N. Qin<sup>1,2,3</sup>, C. Wang<sup>1,2,3</sup>, Q. Lu<sup>1,2,3</sup>, T. Huang<sup>1,2,3</sup>, J. Dai<sup>1,2,3</sup>, H. Ma<sup>1,2,3</sup>, G. Jin<sup>1,2,3</sup>, C. Wu<sup>4</sup>, D. Lin<sup>4</sup>, H. Shen<sup>1,2,3</sup>, Z. Hu<sup>1,2,3</sup>. 1) Department of Epidemiology and Biostatistics, Nanjing Medical University, Nanjing, Jiangsu, China; 2) State Key Laboratory of Reproductive Medicine, Nanjing Medical University, Nanjing, Jiangsu, China; 3) Jiangsu Key Lab of Cancer Biomarkers, Prevention and Treatment, Collaborative Innovation Center for Cancer Medicine, Nanjing Medical University, Nanjing, Jiangsu, China; 4) State Key Laboratory of Molecular Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China.

Recent studies have found that cancer-testis (CT) genes, which are expressed predominantly in germ and cancer cells, may be candidate cancer drivers. Because of their crucial roles, genetic variants of these genes may contribute to the development of cancer. Here, we systematically investigated the association of common variants in CT genes and their promoters for the risk of lung cancer in our initial GWAS (2,331 cases and 3,077 controls), followed by *in silico* replication using additional 10,512 lung cancer cases and 9,562 controls. We found a significant association between rs3747093 located in the *CCDC116* promoter and lung cancer risk (OR=0.91,  $P_{meta}=7.81 \times 10^{-6}$ ). Although *CCDC116* was expressed at lower levels in somatic tissues compared to the testis, the protective allele A of rs3747093 was associated with decreased *CCDC116* expression in many normal tissues, including the lung ( $P=8.1 \times 10^{-13}$ ). We subsequently genotyped this variant in another four commonly diagnosed cancers (gastric, esophageal, colorectal and breast cancers), as we found expression quantitative trait locus (eQTL) signals for rs3747093 and *CCDC116* in their corresponding normal tissues. Interestingly, we observed consistent associations between rs3747093 and multiple cancers (gastric cancer: OR=0.85,  $P=2.21 \times 10^{-4}$ ; esophageal cancer: OR=0.91,  $P=2.57 \times 10^{-2}$ ; colorectal cancer: OR=0.80,  $P=1.85 \times 10^{-6}$ ; breast cancer: OR=0.87,  $P=1.55 \times 10^{-3}$ ). Taken together, the A allele of rs3747093 showed significant protective effects on cancer risk (OR=0.88,  $P_{pool}=6.52 \times 10^{-13}$ ) in an Asian population. Moreover, our findings suggest that low abundance expression of CT genes in normal tissues may also contribute to tumorigenesis, providing a new mechanism of CT genes in the development of cancer.

**676W**

**Multiple-gene sequencing revealed novel mutation characteristics beyond BRCA1/2 in Chinese women with familial breast cancer.** Y. Shi<sup>1</sup>, W. Li<sup>1</sup>, Y. Deng<sup>1</sup>, L. Yang<sup>1</sup>, T. Zhou<sup>1</sup>, X. Li<sup>1</sup>, Y. Wu<sup>1</sup>, Q. Zhi<sup>1</sup>, Y. Yu<sup>1</sup>, H. Weng<sup>1</sup>, Z. Lan<sup>1</sup>, D. Zhao<sup>1</sup>, H. Qin<sup>1</sup>, G. Sun<sup>1</sup>, M. Swift<sup>2</sup>, B. Xu<sup>3</sup>. 1) TopGene Tech Co., Ltd, Guangzhou, Guangdong, China, China; 2) Top Medical (Europe) Co., Ltd. Green Pastures, Stockport, SK4 3RA, United Kingdom; 3) Department of Medical Oncology at the Cancer Hospital and Institute, Chinese Academy of Medical Sciences(CAMS), and Peking Union Medical College(PUMC) in Beijing, China.

**Background:** Germline mutations on BRCA1/2 are predisposing risk for a woman to develop breast or/and ovarian cancer. However, mutations on BRCA1/2 genes could not account for all the familial breast cancers. As a result, mutations on other genes which is associated with familial breast or/and ovarian cancer should be considered. **Methods:** In this study, a total of 412 Chinese women patients with familial primary breast cancer were enrolled from 56 Chinese hospitals. A pre-designed multiple-gene panel (22 genes including BRCA1/2) was used to enrich target sequences. PE150 sequencing reads were produced by NextSeq CN500 platform. Germline mutations were identified by strict bioinformatics method and were further validated by Sanger sequencing. For each validated variant, an in-house developed method which is superior to previous reported methods was used to evaluate its clinical effect. **Results:** 71 out of 412 patients (17.23%) were identified carrying at least one deleterious mutation (classified as likely pathogenic or/and pathogenic). Among these 71 patients, 49(69.01%) carried BRCA1/2 mutations, 14(19.72%) carried MMR mutations, 3(4.23%) carried PALB2 mutations and the remaining 5 patients each carried mutation from RAD50 (1.41%), ATM (1.41%), CHEK2 (1.41%), PTEN (1.41%), TP53 (1.41%). Of all the deleterious mutations, one likely pathogenic mutation identified as BRCA1: c.5470\_5477delATTGGGCA(NM\_007294) causing frameshift at codon 1824 in one patient (proband(III.2)) was also found in other 4 family members from the same pedigree. For the remaining 70 patients with deleterious mutation(s), 69 (98.59%) out of it, same mutation(s) in proband could be found in at least one other family member in the same pedigree. In addition to the above, our results also showed that about 3% patients were concluded as carrying mutation(s) with "Uncertain Significance (VUS)" on BRCA1/2 genes, while 10% patients were identified with VUS mutations on non-BRCA1/2 genes. **Conclusions:** Multiple-gene sequencing technology has been confirmed as an efficient solution for identifying novel mutation characteristics beyond BRCA1/2 gene in Chinese women with familial breast cancer. In our study population, about 40% susceptible mutations occurred in non- BRCA1/2 gene which broaden the mutation spectrum for familial breast cancer in Chinese women. In the future, independent research in large sample size of patients is worth conducting to investigate non-BRCA1/2 genes.

**677T**

**Genetic variants in the 8q24 region are associated with prostate cancer risk in Mexican men.** B. Silva<sup>1</sup>, R.A. Aragon<sup>2</sup>, G. Castillo<sup>3</sup>, O.S. Frausto<sup>3</sup>, D.I. Ibarra<sup>2</sup>, M.B. Calao<sup>2</sup>, E. Torres<sup>2</sup>, E. Macias<sup>2</sup>, K. Penuelas<sup>4</sup>, M.A. Bermudez<sup>4</sup>. 1) Immunogenetics, CIBIN-IMSS, Monterrey, NUEVO LEÓN, México; 2) UMAE 25, IMSS, Monterrey, NUEVO LEÓN, México; 3) HG Z33, IMSS, Monterrey, NUEVO LEÓN, México; 4) Molecular Biology, CIBIN-IMSS, Monterrey, NUEVO LEÓN, México.

Prostate cancer (PCa) is the second most common cancer diagnosed in males in the developed world. Several independent genetic association studies identify single nucleotide polymorphisms (SNPs) within the 8q24 region as a risk factor for PCa. The case control study was performed in a Mexican male population from the Mexican Social Security Institute (IMSS) consisting of 185 patients with biopsy confirmed adenocarcinoma of the prostate and abnormal serum prostate-specific antigen (PSA) and 384 male volunteer controls older than 45 years who had no history of PCa. We selected 4 SNPs at 8q24, those most strongly associated with PCa risk in several studies (rs 16901979C/A, rs6983267G/T, rs1447295 C/A, rs7837328 G/A), and they were genotyped by 5' exonuclease TaqMan assays. Statistical analysis was performed using: Epi Info V-7, HWE calculator and SNP Stats software. We found significant association between PCa and three SNPs in 8q24, the rs16901978 AC genotype (OR=2.21; 95% CI=1.3-3.7, Pc=0.01), rs1447295 AC genotype (OR=2.07; 95% CI=1.37-3.13, Pc=0.002), and rs7837328 AG genotype (OR=1.64; 95% CI=1.14-2.34, Pc=0.03). Pairwise linkage disequilibrium (LD) analysis was conducted. We found evidence of strong LD (D' greater than 0.5) within the 8q24 SNPs. Haplotype analysis revealed haplotypes containing the risk alleles, confer high risk to PCa. In conclusion, our study established the association between SNPs in 8q24 with increased susceptibility to PCa in Mexican male population. However, more validation studies and functional assays should be performed to prove true effect in the susceptibility to disease.

**678F****Genetic variation and gastric cancer susceptibility in Western Honduras.**

G. Tavera<sup>1</sup>, R.L. Dominguez<sup>3</sup>, J. Bartlett<sup>1</sup>, B.G. Schneider<sup>2</sup>, C.B. Cherry<sup>2</sup>, D.A. Israel<sup>2</sup>, J. Romero-Gallo<sup>2</sup>, M.B. Piazuelo<sup>2</sup>, R.M. Peek<sup>2</sup>, K.T. Wilson<sup>2</sup>, S.M. Williams<sup>1</sup>, D.R. Morgan<sup>2</sup>. 1) Department of Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland, OH; 2) Division of Gastroenterology, Hepatology, and Nutrition, Vanderbilt University, Nashville, TN; 3) Hospital de Occidente, Santa Rosa de Copán, Copán, Honduras.

Gastric cancer is the third leading cause of cancer mortality, and the leading infection-associated cancer. Central America has one of the highest global incidences and mortality rates of gastric cancer in the world (mortality-to-incidence ratio of 0.82). We analyzed samples from gastric biopsies taken from a population-based, case-control study in rural Western Honduras (n = 672 cases and 722 controls), to evaluate 94 single-nucleotide polymorphisms (SNPs) in distinct inflammatory and nutritional genes that may be implicated in the development of gastric cancer. Quality control excluded 11 SNPs with a minor allele frequency of less than 0.05 and one SNP was removed, which was out of Hardy–Weinberg equilibrium ( $p < 1.0 \times 10^{-16}$ ). Initial association tests identified rs1927914 on chromosome 9, in the toll-like receptor-4 (TLR4) gene and the C allele with gastric cancer risk ( $p = 0.000674$ ; OR = 1.31). This SNP has been associated with risk of prostate cancer in multiple studies. The SNP rs530537 on chromosome 11, in the caspase-1 gene (CASP1), with the A allele, was associated with mild protection from gastric cancer risk ( $p = 0.000925$ ; OR = 0.78). Caspase-1 is involved in protein cleavage of inflammatory cytokines. Further analysis will be performed exploring the existence of potential gene networks. Identification of SNPs related to inflammatory and nutritional processes may point to mechanisms of pathogenesis and targets for therapy and preventative screening for gastric cancer.

**A model averaging approach for improved *in silico* variant prediction.** Y. Tian, S. Li, M.H. Black, A. Elliott, H.M. Lu, D. Qian. Bioinformatics and Computational Biology, Ambry Genetics, Aliso Viejo, CA.

A variety of *in silico* scores are currently utilized in missense variant assessment as evidence of pathogenicity. A Bayesian Integrated Evaluation method was developed to leverage the information from these scores, in which *in silico* predictors are initially selected manually or by stepwise regression. However, the models produced often contain uninformative predictors and do not quantify their gene-specific importance. A robust and stable gene-specific model is needed to calibrate information from *in silico* tools. Using data from 129,691 patients who underwent genetic testing at a single diagnostic laboratory in 2012-2016, we assembled a collection of 1,292 missense variants in 8 genes (*BRCA1*, *BRCA2*, *CDH1*, *TP53*, *MLH1*, *MSH2*, *MSH6* and *PMS2*), each classified according to a five-tier classification system per ACMG guidelines. Nine *in silico* scores (Polyphen2, SIFT, Grantham, CADD, AGVGD, MutationAssessor, phastCons, phyloP and REVEL) were collected for all variants. Gene-specific Model Averaging Logistic Regression (GMALR) models were trained on known classified variants using the nine *in silico* scores as predictors. We assessed each predictor using relative variable importance (RVI) defined as the sum of Akaike weights over all candidate models (range 0 to 1). The predicted rate of variants of unknown significance (VUS), positive predictive value (PPV), negative predictive value (NPV), and coefficient mean squared error (MSE) with 10-fold cross validation, were compared for GMALR vs. Gene-specific Stepwise Logistic Regression (GSLR) models. GMALR results indicated that the relative importance of each *in silico* predictor varied by gene. For example, AGVGD, CADD, phyloP and REVEL had the highest RVI in *BRCA1*, while MutationAssessor, phastCons and phyloP had the highest RVI in *BRCA2*. Predicted VUS rates were 39.5% and 45.2% for GMALR and GSLR models respectively; PPV and NPV were ~99% for both models. Thus, GMALR reduced the predicted VUS rate and had similarly low misclassification rates compared to GSLR. GMALR models also improved model robustness by a meaningful margin compared to GSLR models; mean  $\pm$  SD of MSE across all genes was  $1.7 \pm 1.2$  and  $5.0 \pm 4.9$  for GMALR and GSLR models, respectively. Our results underscore the improved prediction performance and model robustness of the GMALR approach when evaluated in the context of *in silico* variant prediction and as compared to stepwise regression methods such as GSLR.

**SNP-SNP interactions associated with prostate cancer aggressiveness in African Americans.** *H. Tung, H. Lin.* Biostatistics, LSU Health New Orleans, New Orleans, LA.

African American (AA) men tend to have a higher incidence rate of prostate cancer (PCa) and are also more likely to have aggressive PCa. Although single nucleotide polymorphisms (SNPs) associated with PCa aggressiveness in AAs have been reported, impact of SNP-SNP interactions are under studied. The study objective is to identify SNP-SNP interactions and build a prediction model to predict aggressive PCa in AAs. A total of 1,933 PCa patients from the Multiethnic Cohort (MEC) Study were included. We evaluated 5,064 SNPs in the four pathways (angiogenesis, mitochondria, miRNA, and androgen metabolism). PCa aggressiveness is defined as prostate cancer with a Gleason score  $\geq 8$ /undifferentiated or regional/distant SEER staging. All models were adjusted for study site and the first four principal components for population stratification. SNP main effects associated with PCa aggressiveness were evaluated using logistic regressions. For SNP-SNP interactions, the SNP Interaction Pattern Identified (SIPI), a novel statistical method, was used. SIPI take advantages by considering the inheritance modes (additive, dominant, recessive), code direction and the non-hierarchical models structure. None of these SNP findings reached the stringent the Bonferroni significant level. The promising SNP main effects ( $p$ -value $<1 \times 10^{-3}$ ) and SNP-SNP interaction pairs ( $p$ -value $<1 \times 10^{-6}$ ) were candidates for building the prediction model. The model with the identified SNP-SNP interactions has a good discrimination ability for PCa aggressiveness than the one without these interactions. The values of area under the Receiver Operating Characteristic curve (AUROC) are  $>0.8$  and  $0.65$ , respectively. Among 12 SNPs and 56 SNP pairs in the final model, the most important SNP is rs3789889 in *SYK*, which was shown as the main effect and was involved in several leading interaction terms. The top SNP interaction pair is rs3789889 in *SYK* and rs7358800 in *COL4A2* ( $p=9.3 \times 10^{-9}$ ). *SYK* has been reported to be a candidate kinase target for the treatment of advanced prostate cancer previously. This study demonstrated that SNP-SNP interactions may have an important impact on predicting PCa aggressiveness in AAs.

**DNA methylation reveals distinct signatures in profiling tumor-infiltrating immune cells.** *X. Wang<sup>1</sup>, C. Liang<sup>2</sup>, L. Wang<sup>3</sup>.* 1) Department of Biostatistics and Bioinformatics, Moffitt Cancer Center and Research Institute, Tampa, FL; 2) Yale University; 3) University of Texas MD Anderson Cancer Center.

**Introduction:** Immunotherapy has produced promising results in treating cancers. Further understanding of the crosstalk between tumor and its immune microenvironment is likely to have an immediate impact on therapeutic intervention as well as the development of markers of drug resistance. One main difficulty in quantifying the components of tumor microenvironment is that currently there are considerable technological and analytical barriers to assessing and measuring tumor immunity in situ. **Methods:** The TCR-regions were sliced from RNA-seq bam files from all TCGA major cancer types. The CDR3 sequences were identified and annotated, and the diversity of TCR repertoire was then calculated and normalized. We use Tumor Immune Estimation Resource to estimate relative abundance of major tumor-infiltrating immune cell types (i.e., CD8 T cell, CD4 T cells, B cells, neutrophils, macrophages, and dendritic cells) from RNA-seq data. The penalized regression together with stability selection procedure (1000 runs) was employed to detect top epigenetic markers that are associated with immune phenotypes. Because it is hard to apply elastic net method directly to the all the features in the methylation arrays, we developed a novel methylation feature screening procedure based on the distance correlation (DC-SIS) to get a smaller set of informative features. The advantage of DC-SIS is that it does not require model specification for responses and it can be used directly to screen grouped predictor variables. **Results:** We applied our integrated deconvolution method and observed that methylation panel provides a strikingly accurate prediction of immune cell abundance, especially in estimating T cells and dendritic cells (with  $r>0.9$ ), as well as the diversity of TCR repertoire. The results were benchmarked with existing NanoString immune panel and flow cytometry data in a local skin cancer data set. We also demonstrated the potential of using methylation panel to explore T cell exhaustion profiles. Results from this project suggest that the DNA methylome adds a new dimension to the pan-omic snapshot of cancer immunity and tumor microenvironment, and the identification of driver epigenetic events would potentially promulgate a novel paradigm for immunotherapy of cancer.

**Risk factors associated with primary cutaneous melanoma of the scalp and neck.** S.V. Ward<sup>1,4</sup>, R.P. Wood<sup>1</sup>, J.S. Heyworth<sup>2</sup>, M.J. Millward<sup>2</sup>, I. Orlov<sup>1</sup>, P.A. Kanetsky<sup>5</sup>, M. Berwick<sup>6</sup>, N.E. Thomas<sup>7</sup>, C.B. Begg<sup>4</sup>, E.K. Moses<sup>1</sup>. 1) Centre for Genetic Origins of Health & Disease, University of Western Australia, Perth, Western Australia, Australia; 2) School of Population and Global Health, University of Western Australia, Perth, Western Australia, Australia; 3) School of Medicine and Pharmacology, University of Western Australia, Perth, Western Australia, Australia; 4) Department of Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York, New York; 5) Department of Cancer Epidemiology, H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida; 6) Department of Internal Medicine, University of New Mexico Cancer Center, University of New Mexico; 7) Department of Dermatology, University of North Carolina, Chapel Hill, North Carolina.

**Background:** Scalp and neck melanoma (SCNM) has a lower survival rate and worse prognosis than melanoma of other anatomic sites. Various prognostic and demographic risk factors for SCNM have been identified but little is known about other factors associated with melanoma at this site. This study aimed to investigate the phenotypic, environmental and genetic factors associated with SCNM, compared to all other anatomic sites of melanoma (OSM). **Methods:** Two large, population based collections of melanoma cases formed the sample for this study; the Western Australian Melanoma Health Study (WAMHS, n=1200) and the international Genes, Environment and Melanoma study (GEM, n=2943). Pooled analyses in all cases used logistic regression models, adjusted for study centre, to investigate the non-genetic factors associated with SCNM vs. OSM. Genetic association analyses between anatomic site and 34 single nucleotide polymorphisms (SNPs) from known melanoma susceptibility loci were also performed. Participants from the WAMHS formed the discovery sample, with significant associations validated in the GEM study. An exploratory genome wide association study (GWAS) was also conducted in the WAMHS, to identify potential novel variants associated with SCNM. **Results:** Females had a significantly decreased odds of SCNM (OR= 0.52, 95% CI: 0.39–0.68), as did those who had used a sunbed more than once (OR=0.63, 95% CI: 0.42–0.92). A borderline association for an increased odds of SCNM was observed in those older than 70 years (OR= 1.02, 95% CI: 1.00–1.05) and with a higher degree of weekend sun exposure in childhood (OR= 1.07, 95% CI: 1.002–1.15) and adolescence (OR= 1.06, 95% CI: 1.00–1.13). An initial associations was observed between SNP rs45430 (*MX2* gene) and a decreased odds of SCNM but after adjustment for multiple testing, no SNPs remained significantly associated in the candidate gene analyses. Suggestive results for the association of SCNM with novel SNPs were observed in the GWAS, including a peak on chromosome 12 in the *UBC* (rs7309653: p=5.44 x 10<sup>-7</sup>, rs7135151: p=1.14 x 10<sup>-7</sup>) and *RNU6-927P* (rs7304293: p=3.87 x 10<sup>-6</sup>) genes. **Conclusions:** Novel associations were identified between environmental risk factors and SCNM. Known melanoma risk SNPs may not play a role in the site-specific development of melanoma but other, potentially novel genomic loci were identified. These results now require validation in an independent population.

**683T**

**Tumor profiling of separated carcinomatous and sarcomatous components from uterine carcinosarcoma biopsies provides insights into their development.** Z. Weber<sup>1,2</sup>, Y. Liu<sup>3,4</sup>, F.A. San Lucas<sup>5</sup>, A. Deshpande<sup>6</sup>, R. Sulaiman<sup>6</sup>, M. Fagerness<sup>6</sup>, N. Flier<sup>6</sup>, J. Sulaiman<sup>6</sup>, C. Davis<sup>1</sup>, J. Fowler<sup>1</sup>, G. Davies<sup>1</sup>, D. Starks<sup>6</sup>, L. Rojas-Espaillet<sup>6</sup>, P. Scheet<sup>1</sup>, E. Ehli<sup>1</sup>. 1) Avera Institute for Human Genetics, Sioux Falls, SD; 2) University of South Dakota, Sanford School of Medicine, Sioux Falls, SD; 3) Graduate School of Biomedical Sciences, University of Texas at Houston Health Science Center, Houston, TX; 4) University of Texas MD Anderson Cancer Center, Houston, TX; 5) Weill Cornell Graduate School of Medical Sciences, New York, NY; 6) Avera Cancer Institute, Sioux Falls, SD.

**Motivation:** Uterine carcinosarcoma (UCS) is a rare and aggressive form of uterine cancer. It is bi-phasic, exhibiting histological features of both malignant epithelial (carcinomatous) and mesenchymal (sarcomatous) elements. Studies have indicated that UCS arises from sarcomatous differentiation of high-grade carcinoma while others have suggested a bi-clonal nature. Given these differences, we sought to separate the carcinoma and sarcoma elements of UCS to try to understand their molecular differences and gain further insights into how these tumors develop. **Method:** We macrodissected carcinomatous, sarcomatous, and normal cells from formalin fixed paraffin embedded (FFPE) uterine samples of 10 UCS patients. SNP microarrays and deep sequencing (~6000x) of 26 cancer genes were performed. RNA-sequencing was also performed to quantify gene expression. Allelic imbalance (AI), mutation and gene expression profiles were compared between carcinomatous and sarcomatous components. **Results:** AI profiling suggests that sarcomatous samples have higher genomic aberration loads compared to their carcinomatous counterparts, while mutation profiling indicates that carcinomatous and sarcomatous components share similar mutated gene patterns. Two of 10 patient tumors exhibited strong evidence of intra-tumor heterogeneity, showing mutation and AI profile differences between their paired-tumor compartments. These potentially more aggressive tumors were classified to be mesenchymal-like through gene expression profiling. **Conclusion:** For the first time, we investigate differences between the carcinomatous and sarcomatous components of UCS from multiple molecular perspectives including AI, mutation and gene expression profiling. From these perspectives, both carcinomatous and sarcomatous components share similar profiles suggesting that they originated from a single clone. Where differences can be identified, carcinomatous aberrations appear to be a subset of those found in sarcomatous tumor profiles, with sarcomatous samples having elevated aberration loads. This suggests that the sarcomatous cells originated and evolved from the carcinomatous cells.

**Rare germline variants in known cancer predisposition genes in sporadic chordoma.** Y. Xiao<sup>1</sup>, B. Zhu<sup>1</sup>, K. Jones<sup>1,2</sup>, A. Vogt<sup>1,2</sup>, L. Burdette<sup>1,2</sup>, W. Luo<sup>1,2</sup>, B. Zhu<sup>1,2</sup>, B. Hicks<sup>1,2</sup>, N. Freedman<sup>1</sup>, S. Chanock<sup>1</sup>, D. Parry<sup>1</sup>, A. Goldstein<sup>1</sup>, X. Yang<sup>1</sup>. 1) Human Genetics Program, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health; 2) Cancer Genomics Research Laboratory, Leidos Biomedical Research, Frederick National Laboratory for Cancer Research, Frederick, MD, USA.

Chordoma is a rare bone cancer that occurs in the skull base and spine with an incidence rate less than 0.1 per 100,000 in the United States. We previously identified germline *T* gene duplications as a major susceptibility mechanism in familial chordoma. Common and rare germline variants in the *T* gene were also found to be associated with both familial and sporadic chordoma. However, underlying genetic susceptibilities for the majority of chordoma cases remain unknown. To systematically characterize rare germline variants in established cancer predisposition genes in chordoma, we extracted whole exome sequencing (WES) data from 133 unrelated sporadic chordoma cases recruited from the United States and Canada for 114 known cancer predisposition genes. Rare variants were defined as <0.1% in the 1000 Genomes Project, Exome Sequencing Project, and  $\leq 2$  families from our in-house database of 1,000 cancer-prone control families. Among the 114 known cancer predisposition genes, we identified 172 rare nonsynonymous variants of which 13 are loss-of-function (LOF) variants. To assess the overall genetic burden of rare germline variants, we performed a rare variant burden test (SKAT statistics) comparing the chordoma cases to 598 unrelated population controls from two cohort studies (Cancer Prevention Study [CPS]-II and Prostate, Lung, Colorectal and Ovarian Screening Trial [PLCO]) that were sequenced using the same platform as the chordoma cases. Cases had increased frequencies of rare germline variants for *MET*, *UROD*, *ERCC4*, *TRIM37*, and *BRCA2* compared to controls (p-value < 0.01). After Bonferroni correction, the *MET* gene remained significant (p-value <  $4 \times 10^{-4}$ ). Of particular interest, a missense variant in *MET* (chr7:116397716) was shared by 4 chordoma cases but none of the controls. This variant, which was not reported in any public or in-house control datasets, is predicted to be deleterious by all 13 *in silico* programs we evaluated. Our results suggest that rare germline variants in *MET* may be associated with susceptibility to sporadic chordoma.

**685W**

***BRIP1*, *RAD51C*, and *RAD51D* ovarian and breast cancer associations observed in a multi-gene panel testing cohort.** L. Yackowski, L.R. Susswein, K.J. Arvai, R.I. Torene, M.L. Marshall, S.R. Solomon, P.D. Murphy, R.T. Klein, K.S. Hruska. GeneDx, Gaithersburg, MD.

**Statement of Purpose:** This analysis examines the association of ovarian (OC) and breast (BC) cancer with pathogenic or likely pathogenic variants (collectively, PV) in *BRIP1*, *RAD51C*, and *RAD51D* in a cohort of patients undergoing multi-gene hereditary cancer panel testing. The association of these genes with OC has been well-studied and results are consistent with an increased risk. The BC association with these genes, however, is tenuous and needs further study. **Methods:** We performed a retrospective case-control study to assess whether cancer risk was associated with each gene. Cases were women with BC or OC referred for panel testing including up to 62 genes. Controls were reportedly healthy mothers of individuals referred for whole exome sequencing. We reviewed genetic testing results and personal cancer history for both groups. Women with more than one PV in these or another gene were excluded from the analysis. Adjusted odds ratios (ORs) were generated by multivariate logistic regression analysis controlling for age. **Results:** Ovarian cancer: *BRIP1*, *RAD51C*, and *RAD51D* are associated with a statistically significant increased risk of ovarian cancer (Table 1).

Table 1

Gene	Ovarian Cancer Cases	Controls	OR (95% CI)	p-value
<i>BRIP1</i>	0.7% (32/4296)	0.1% (16/12887)	3.14 (1.46-6.95)	0.004
<i>RAD51C</i>	0.7% (31/4285)	0.05% (6/12887)	13.10 (5.09-38.81)	<0.0001
<i>RAD51D</i>	0.4% (17/4282)	0.02% (3/12887)	11.16 (2.61-63.35)	0.003

Breast cancer: *BRIP1*, *RAD51C*, and *RAD51D* are associated with a statistically significant increased risk of breast cancer (Table 2).

Table 2

Gene	Breast Cancer Cases	Controls	OR (95% CI)	p-value
<i>BRIP1</i>	0.3% (89/30047)	0.1% (16/12887)	1.93 (1.10-3.59)	0.029
<i>RAD51C</i>	0.1% (45/30003)	0.05% (6/12887)	2.72 (1.18-7.43)	0.030
<i>RAD51D</i>	0.1% (31/29993)	0.02% (3/12887)	4.06 (1.29-18.13)	0.032

**Conclusions:** Pathogenic variants in *BRIP1*, *RAD51C*, and *RAD51D* are well-established with respect to OC risk and are further confirmed in this cohort. Although recent *BRIP1* case-control data show no evidence of an increased risk for BC, earlier reports suggest an increase in BC risk. This study supports a modestly increased BC risk with *BRIP1* PV in a large, independent cohort. For *RAD51C* and *RAD51D*, the consensus in the literature is that PV seem to be rare in BC-only families. In this case-control study, we observed a statistically significant association with BC risk and *RAD51C* and *RAD51D* PV. These results add to the rapidly evolving knowledge of cancer risks associated with PV in *BRIP1*, *RAD51C*, and *RAD51D*.

**686T**

**Rare germline variants in the promoter region of *CDKN2B* may cause melanoma predisposition.** R. Yang<sup>1</sup>, P. Hyland<sup>1</sup>, J. Choi<sup>1</sup>, A. Vu<sup>1</sup>, Y. Xiao<sup>1</sup>, K. Jones<sup>1,2</sup>, A. Vogt<sup>1,2</sup>, L. Burdette<sup>1,2</sup>, B. Zhu<sup>1,2</sup>, M. Yeager<sup>1,2</sup>, B. Hicks<sup>1,2</sup>, N. Freedman<sup>1</sup>, L. Beane-Freeman<sup>1</sup>, S. Chanoock<sup>1</sup>, T. Andersson<sup>2</sup>, M. Tucker<sup>1</sup>, K. Brown<sup>1</sup>, A. Goldstein<sup>1</sup>. 1) div Cancer Epidemiology & Genetics, NCI/NIH, Bethesda, MD; 2) Frederick National Laboratory for Cancer Research, Frederick, MD.

Approximately 10% of cutaneous malignant melanoma (CMM) cases occur in a familial setting and known high-risk CMM genes (*CDKN2A* being the most frequent one) account for melanoma risk in less than 40% of melanoma-prone families. To identify additional high-risk susceptibility genes for familial CMM, we performed whole exome sequencing in germline DNA from 144 CMM patients/obligate gene carriers from 76 American melanoma-prone families. We identified two rare missense variants in *CDKN2B* that showed cosegregation with CMM in two families. The first variant (g.22008763 C>T), with a frequency of  $3.6 \times 10^{-5}$  in the Exome Aggregation Consortium (ExAC) among non-Finnish Europeans, was seen in 6 of 7 sequenced CMM patients in a family with a total of 13 CMM patients. The second variant (g.22008767 C>G), which was not reported in any public database or in-house controls, was seen in all 3 patients (including a pair of identical twins) sequenced in a smaller family. We subsequently sequenced the entire coding region of *CDKN2B* in 795 CMM cases and 807 matched controls from two cohort studies (Prostate, Lung, Colorectal and Ovarian Screening Trial and Agriculture Health Study) and found a third *CDKN2B* variant that was present in a single CMM patient. This variant (g.22008772 G>C) was also not reported in any database or any controls we sequenced. All three variants are located only a few bases away from each other and within the intronic region of the major *CDKN2B* transcript expressed in melanocytes. Based on experimental data from the NIH Epigenomics Roadmap project and ENCODE, these variants map to a CpG island and an active promoter in normal primary melanocytes and skin fibroblasts as well as open chromatin in different cell lines. Most interestingly, these variants locate to a canonical motif and DNA footprint for CCCTC-binding factor (CTCF) in melanoma cell lines. Moreover, preliminary results from a semi-quantitative CTCF binding assay using variant or wild-type *CDKN2B* constructs and melanoma cell extracts showed that both variants found in families had reduced CTCF binding compared to the wild-type. CTCF has an important role in regulating chromatin architecture suggesting that the germline *CDKN2B* variants may alter CTCF regulatory function and gene expression important for melanoma predisposition in both familial and sporadic CMM. However, future functional studies are needed to establish the link between these variants and melanoma susceptibility.

**687F**

**Combining weak signals by rank truncated products of p-values with application to detection of simultaneous closely-spaced mutations in cancer genomes.** D. Zaykin<sup>1</sup>, F. Hu<sup>1</sup>, L.J. Klimczak<sup>1</sup>, D. Gordinin<sup>1</sup>, O. Vsevolozhskaya<sup>2</sup>. 1) NIEHS, Durham, NC., USA; 2) U of Kentucky.

Methods for combining top ranking statistics or P-values are useful for analysis of high dimensional genomics data, because they aggregate top ranking signals into a single score and at the same time adjust for multiple comparisons. The Rank Truncated Product method (RTP) by Dudbridge and Kolemán (2003) gained popularity in many extensions, including its adaptive versions, where the number of top-ranking P-values is varied to maximize power. However, all previously known theoretical forms of the RTP distribution are unwieldy, involve complicated multiple integration, and result in page long equations. We developed several new ways of evaluating the RTP distribution that greatly simplify the analytic form of the combined P-value, down to a single line of R code. Our approach leads to new powerful methods for combining top-ranked, possibly correlated statistics. We applied our methods to analysis of spatial distribution of mutations caused by single-strand (ss) DNA specific APOBEC cytidine deaminases in cancer genomes. These mutations often occur simultaneously and in close proximity to each other, i.e., in clusters. Clusters formed by APOBEC mutagenesis in ss DNA would have only C or only G mutated in a given strand (C- or G-coordinated). Simultaneous mutations in transient long stretches of ss DNA in a cluster are unlikely to be broken by somatic recombination or genome rearrangements, therefore allele frequencies of mutations within a cluster are expected to be the same. Analysis using our methods confirms that allele frequencies within C- or G-coordinated clusters are closer to each other compared to frequencies within other cluster types.

## 688W

**Significance of secondary genetic findings in a large prospective population sample.** K. Kristiansson<sup>1,2</sup>, P. Salo<sup>1,2</sup>, V. Salomaa<sup>1</sup>, P. Jousilahti<sup>1</sup>, H. Kääriäinen<sup>1</sup>, M. Perola<sup>1,2,3</sup>. 1) National Institute for Health and Welfare, Helsinki, Finland; 2) Institute for Molecular Medicine Finland, University of Helsinki, Helsinki, Finland; 3) University of Tartu, Estonian Genome Centre, Tartu, Estonia.

**Introduction:** Genetic studies are encouraged to return secondary findings from clinically important genes to the study participants. The rare but highly penetrant mutations in these genes typically lead to serious consequences, such as cancer or serious heart dysrhythmia, but there are known medical interventions with potential life-saving value. Although classified as pathogenic in web-based databases, the impact of most risk variants at a population level remains unclear. **Material and Methods:** We studied variation in 59 genes of the American College of Medical Genetics and Genomics (ACMG) secondary findings recommendation. Impact of the risk variants on clinical outcomes was evaluated in 25-74 year old FINRISK study participants (N~23 000) using up to 23 years of follow-up. The variants, genotyped with genome-wide microarrays and imputed using population specific reference panel, were analyzed in time-to-event and logistic regression models. **Results:** The expected number of risk allele carriers for 75 ACMG risk variants varied between 4 and 300 based on publicly known allele frequencies and similar numbers were seen in FINRISK. Although some variants associated with increased risk of an event during follow up (e.g. carriers of a risk variant in a cardiomyopathy associated gene had a 3.7 times higher risk of heart failure compared to non-carriers in Cox survival analysis ( $p=0.0014$ )), for a large majority we observed no clinical significance. **Conclusions:** Before secondary findings from clinically important genes are returned to study participants, the significance of the variants needs to be carefully evaluated at a population level.

## 689T

**A esophageal adenocarcinoma susceptibility locus at 9q22 also confers risk to esophageal squamous cell carcinoma by regulating the function of BARX1.** C.W. Yan<sup>1,2</sup>, Y. Ji<sup>3</sup>, T.T. Huang<sup>1</sup>, Y. Gao<sup>4</sup>, Y.Y. Gu<sup>1</sup>, Q. Qi<sup>1</sup>, H.X. Ma<sup>1</sup>, G.F. Jin<sup>1,2</sup>. 1) Department of Epidemiology and Biostatistics, School of Public Health, Nanjing Medical University, Nanjing, China; 2) Jiangsu Key Lab of Cancer Biomarkers, Prevention and Treatment, Collaborative Innovation Center for Cancer Medicine, Nanjing Medical University, Nanjing, China; 3) Department of Cardiothoracic Surgery, The Affiliated Wuxi People's Hospital of Nanjing Medical University, Wuxi, China; 4) Department of Medical Oncology, The Affiliated Huaian First People's Hospital of Nanjing Medical University, Huai'an, China.

A genome wide association study (GWAS) identified genetic variants at 9q22 significantly associated with the risk of esophageal adenocarcinoma (EAC)/ Barrett's esophagus (BE), which were different from those loci discovered by previous GWAS on esophageal squamous cell carcinoma (ESCC). It is important to evaluate whether these susceptibility loci for EAC/BE are also implicated in ESCC development. In the current study, we analyzed genetic variants at 3p13, 9q22, 16q24 and 19p13 in a case-control study including 2139 ESCC patients and 2463 cancer-free controls in a Chinese population, and further characterized the function relevance of genetic variants by functional assays. We found that the G allele of rs11789015 at 9q22 as compared with A allele, was significantly associated with a decreased risk of ESCC with a per-allele odds ratio of 0.77 (95%CI, 0.65-0.90;  $P=1.38 \times 10^{-3}$ ), whereas the other three loci were not associated with ESCC risk. We further found that rs11789015-G allele correlated with decreased mRNA levels of *BARX1*. Dual-luciferase reporter gene assay revealed that the A > G change at rs11789015 significantly decreased the promoter activity of *BARX1*. Both the mRNA and protein levels of *BARX1* were significantly higher in ESCC tumor tissues compared with the corresponding normal tissues. Moreover, the deletion of *BARX1* substantially reduced ESCC cells growth, migration and invasion. In conclusion, these results suggest that genetic variants at 9q22 are associated with the risk of both EAC/BE and ESCC, possibly by regulating the function of *BARX1*.

**690F**

**Detection of epigenetic field defects using weighted epigenetic distance-based method.** Y. Wang<sup>1</sup>, A. Teschendorff<sup>2</sup>, M. Widschwendter<sup>2</sup>, S. Wang<sup>1</sup>. 1) Department of Biostatistics, Columbia University, New York, NY; 2) Department of Women's Cancer, University College London, London, UK.

Detecting molecular alterations early in carcinogenesis is important for cancer early detection. One common approach in detecting early molecular alterations, known as field defects, is to compare normal tissues from healthy individuals to the normal tissues adjacent to tumors. Due to its important role in many biological processes and cancer progression, studies have identified epigenetic field defects, notably early DNA methylation alterations using current EWAS (epigenome-wide association studies). Here we propose a complementary approach based on characterization of similarity/dissimilarity of DNA methylation of a set of individuals at multiple CpG sites on a gene or a genetic region. This similarity-based approach has been proven to be powerful in genome-wide association studies (GWAS) and gene expression studies, but hasn't been investigated in epigenetics. We propose a weighted epigenetic distance-based regression on gene or genetic region with several site-level weights considered: (1) p-value testing for mean differences between normal tissues from healthy individuals to the normal tissues adjacent to tumors; (2) site-level correlation capturing average correlation to the rest of the sites on this gene. We demonstrated the superior performance of the proposed weighted distance-based method over non-weighted version and standard site-level EWAS method. Application to DNA methylation data of breast cancer from Gene Expression Omnibus (GEO) comparing normal tissues adjacent to tumors and normal tissues from independent age-matched cancer-free women shows that many novel epigenetic field defects in breast cancer across the genome that were not previously reported and were missed by standard EWAS method in this analysis are cancer-related.

**Genome-wide interaction study of smoking behavior and non-small cell lung cancer risk in Caucasian population.** Y. Li<sup>1</sup>, X. Xiao<sup>1</sup>, Y. Han<sup>1</sup>, O. Gorlova<sup>2</sup>, D. Christiani<sup>2</sup>, M. Johansson<sup>3</sup>, J. McKay<sup>3</sup>, P. Brennan<sup>3</sup>, R. Hung<sup>4</sup>, C. Amos<sup>1</sup> OncoArray Consortium. 1) Biomedical Data Science Department, Dartmouth College, United States; 2) School of Public Health, Harvard University, United States of America; 3) Genetic Cancer Susceptibility Group, International Agency for Research on Cancer, France; 4) The Lunenfeld-Tanenbaum Research Institute, Division of Epidemiology, Dalla Lana School of Public Health, University of Toronto, Canada.

Non-small cell lung cancer (NSCLC) is the most common histological type of lung cancer. Both environmental and genetic risk factors contribute to lung cancer carcinogenesis. Here, we conducted a genome-wide interaction analysis between SNPs and smoking status (never vs ever smokers) in a European-descent population. We adopted a two-step analysis strategy in the discovery stage: we first conducted a case-only interaction analysis to assess the relationship between SNPs and smoking behavior using 13,336 NSCLC cases. Candidate SNPs with p-value less than 0.001 were further analyzed using a standard case-control interaction analysis including 13970 controls. The significant SNPs with p-value less than  $3.5 \times 10^{-6}$  (correcting for multiple tests) from the case-control analysis in the discovery stage were further validated using an independent replication dataset comprising 5377 controls and 3054 NSCLC cases. We further stratified the analysis by histological subtypes. Two novel SNPs, rs6441286 at gene *IL12A-AS* (chr13q25.33) and rs17723637 at gene *ZNF462* (chr9q31.2), were identified. The interaction odds ratio and meta-analysis p-value for these two SNPs were 1.24 with  $6.96 \times 10^{-7}$  and 1.37 with  $3.49 \times 10^{-7}$ , respectively. Additionally, interaction of smoking with rs4751674 at gene *AFAP1L2* (chr10q25.3) was identified in squamous cell lung carcinoma with an odds ratio of 0.58 and p-value of  $8.12 \times 10^{-7}$ . This study is by far the largest genome-wide SNP-smoking interaction analysis reported for lung cancer. The results from our study reinforce that gene-smoking interactions play important roles in the etiology of lung cancer and account for part of the missing heritability of this disease.

**692T****Type 2 diabetes susceptibility variants contribute to breast cancer risk.**

*M.H. Black, S. Li, B.A.J. Sarver, A. Elliott, H.M. Lu.* Bioinformatics and Computational Biology, Ambry Genetics, Aliso Viejo, CA.

Type 2 diabetes mellitus (T2DM) is a known risk factor for breast cancer (BC), but whether the conditions share a common genetic etiology remains to be elucidated. Analyses to date have focused mainly on T2DM GWAS-identified intronic or intergenic variants. Recently, exome analysis in ~100,000 individuals detected 21 coding variants predisposing to T2DM. We performed whole exome sequencing in 9,639 BC cases and 3,988 controls, among patients referred for genetic testing at a single laboratory in 2012-2015, and leveraged this vast collection of genotype and phenotype data to investigate the contribution of these coding variants to risk for and clinical features of BC. We also used 1000 Genomes (G1K) as a reference population to confirm our findings. All models were conducted within genetically inferred G1K-defined populations and adjusted for sex and 3 ancestry PCs. Among Europeans (n=7,235 BC, 2,666 controls), *PPARG* P12A Pro (RAF=94.2%) was associated with BC at genome-wide significance ( $OR_{adj}=1.49$ ,  $p=3.9 \times 10^{-10}$ ). BC was also associated with *PPIP5K2* S1207G (RAF=2.5%,  $p=2.4 \times 10^{-6}$ ), *PAM* D563G (RAF=3.0%,  $p=9.5 \times 10^{-6}$ ) and *ASCC2* V123I (RAF=93.8%,  $p=8.0 \times 10^{-4}$ ). P12A was significantly associated with HR<sup>+</sup>, HR<sup>-</sup>, and HER2<sup>-</sup> BC. D563G and S1207G were significantly associated with HER2<sup>-</sup> and V123I with HER2<sup>-</sup> BC only. P12A results comparing cases to G1K (n=501) were consistent ( $OR_{adj}=1.78$ ,  $p=1.5 \times 10^{-6}$ ). Risk estimates from G1K comparisons for the other 3 variants were nearly identical to those from internal controls, but not significant due to sample size. Among Mexicans, Central and South Americans (n=809 BC, 768 controls, 334 G1K), *PPARG* Pro (RAF=94.3%) was associated with BC compared to controls ( $OR_{adj}=1.98$ ,  $p=1.9 \times 10^{-6}$ ) and G1K ( $OR_{adj}=1.90$ ,  $p=0.001$ ). Among South Asians (n=105 BC, 99 controls, 479 G1K), *PPARG* Pro (RAF=95.9%) was linked to BC in comparisons with G1K ( $OR_{adj}=3.38$ ,  $p=0.003$ ); internal control sample size was too small for risk estimation. No associations were detected among Africans (n=968 BC, 293 controls, 639 G1K) or East Asians (n=522 BC, 162 controls, 502 G1K). Results were similar when excluding males and/or those carrying cancer gene mutations. Genetic risk scores assessing cumulative effects across 21 variants were not associated with BC in any racial/ethnic group. These data suggest that *PPARG* P12A and other T2DM coding variants confer risk for BC and its clinical subtypes, with potentially important implications for clinical screening and management.

**693F****Novel approach to construction of causal gene regulatory network.**

*R. Jiao<sup>1</sup>, Z. Hu<sup>2</sup>, M. Xiong<sup>1</sup>.* 1) Biostatistics, University of Texas Health Science Center, Houston, TX; 2) School of Life Science, Fudan University, Shanghai, China.

The popular methods for construction of gene regulatory networks are correlation analysis, independent tests and Bayesian networks. Correlation analysis is unable to discover regulatory direction. The independent tests and Bayesian networks, these traditional causal inference only can identify up to Markov equivalence class and cannot find the unique causal solutions or unique gene regulatory network. To uniquely discover the causal relationships and causal gene regulatory networks, novel functional additive noise models (ANMs) for causal inference where smoothing spline regression was used to fit the functional model have been developed and applied to construction of causal gene regulatory network. The proposed ANMs were applied to Wnt signaling pathway with RNA-Seq of 145 genes measured in 447 tissue samples. Fifty most significant causal relations were selected to test detection power that was defined as the proportion of correctly inferred paths, given that the paths in the KEGG pathway database were taken as the true paths. For comparison, the score-based linear structural equation models (SEMs) with integer programming (IP) and Glasso were also included in the analysis. Given directed paths in KEGG, results showed that 38% of detected paths by the ANM agreed with the paths in the KEGG, while SEMs only reached 22% accuracy. Given both directed and undirected paths, the results showed that the ANM could reach 46% accuracy in path detection while SEMs and Glasso could only reach 29% and 24% respectively. The ANM outperformed the score-based linear SEMs and the Glasso algorithms.

## 694W

**Rate of reclassification of cancer genetic variants differs by race/ethnicity, depending on gene.** L.R. Van Tongeren<sup>1</sup>, T.P. Slavin<sup>1</sup>, C.E. Behrendt<sup>2</sup>, I. Solomon<sup>3</sup>, C. Rybak<sup>3</sup>, B. Nehoray<sup>3</sup>, L. Kuzmich<sup>3</sup>, M. Niell-Swiler<sup>3</sup>, K. Blazer<sup>3</sup>, S. Tao<sup>3</sup>, K. Yang<sup>3</sup>, J. Culver<sup>3</sup>, S. Sand<sup>3</sup>, D. Castillo<sup>3</sup>, J. Herzog<sup>3</sup>, S.W. Gray<sup>3</sup>, J.N. Weitzel<sup>4</sup>. 1) City of Hope, Division of Clinical Cancer Genomics, Duarte, CA; 2) City of Hope, Department of Information Sciences, Duarte, CA; 3) City of Hope, Integrative Genomics Core, Duarte, CA; 4) University of Southern California Norris Comprehensive Cancer Center, Cancer Genetics Program.

**BACKGROUND:** Efforts are ongoing to improve interpretation of cancer genetic tests, especially for racial/ethnic minority populations, whose genetic tests disproportionately indicate variants of uncertain significance. We hypothesized that rate of variant reclassification differs for individual racial/ethnic minorities relative to non-Hispanic Whites (NHW). Because *BRCA* genes have been studied most extensively, we considered whether findings differed by gene. **METHODS:** We studied participants enrolled with informed consent from two sites in the Clinical Cancer Genomics Community Research Network from 9/96-12/16. Participants self-identified as primarily Hispanic White, NHW, Asian, African or Native American. Non-Benign variants in actionable genes were followed for reclassifications through 2/17 or until reclassification to Benign. Duplicate within-family reports (same laboratory, gene and variant) were excluded. A log-linked generalized linear model of reclassifications over years of follow-up tested 4 categories of minority race/ethnicity, taking into account interaction by gene (*BRCA* vs non-*BRCA*) and correlation among tests at the same laboratory. The model adjusted for covariates (laboratory, year, and test result as a time-dependent variable) and multiple hypothesis testing. **RESULTS:** Of N=1,817 tests studied, 315 (17%) were reclassified at least once (maximum 3 times), for a total of 359 reclassifications in 10,508 years. Median time to first reclassification was 3.58 years. Rate of reclassification differed significantly from NHW for 3 of 4 racial/ethnic minorities, but only for non-*BRCA* tests. (Table)

Table. Covariate-Adjusted* Ratio (95% CI) of Reclassification Rates.			
Race/Ethnicity	Non- <i>BRCA</i> Variants	<i>BRCA1</i> or <i>BRCA2</i>	Holm p
African American	2.45 (1.61-3.74)	1.45 (0.96-2.19)	0.006
Asian American	0.76 (0.63-0.91)	1.12 (0.97-1.30)	0.034
Hispanic White	1.73 (1.59-1.89)	1.15 (1.02-1.30)	<0.001
Native American	1.91 (0.42-8.64)	0.80 (0.17-3.76)	0.903
Non-Hispanic White		1.21 (1.09-1.34)	

\*Rate ratios shown are adjusted for laboratory, result and year of original test.

**CONCLUSIONS:** For non-*BRCA* variants only, reclassification rates were higher for Hispanic and African American, and lower for Asian American, than NHW tests. Higher rates of reclassification may stem from efforts to improve representation of racial and ethnic minorities in reference genomic databases. However, that improvement does not appear to extend to variants found among Asian Americans.

## 695T

**Genes associated with pancreatic cancer predict survival and prognosis.**

A. Gonzalez-Reymundez<sup>1</sup>, S.Y. Lunt<sup>2</sup>, A.I. Vazquez<sup>1</sup>. 1) Department Epidemiology & Biostatistics, Michigan State University, East Lansing, MI; 2) Department of Biochemistry and Molecular Biology, Michigan State University, MI.

Pancreatic cancer, which causes >40,000 deaths per year in the U.S., has a dismal 5-year survival rate of ~7%. Despite some improvements in patient care, the survival rate for most pancreatic cancer patients at the time of diagnosis is less than one year, and our ability to predict which patients will benefit from surgery and treatment remains inadequate. One of the main limitations for predicting patient response to surgery and treatment is the poorly understood molecular basis of pancreatic cancer. Here, we address the challenge of predicting pancreatic cancer survival and prognosis by identifying key genes that differentiate tumor grade and patient survival. To achieve this goal, we used a homogenous sample of pancreatic cancer patient data from TCGA, consisting of primary ductal pancreatic ductal carcinomas from white Caucasian individuals, all having received a Whipple procedure and without history of prior malignancies or metastasis (n=103: 44 and 59 females and males, respectively; 60 and 43 alive and deceased patients at the moment of the last follow up, respectively). We first determined the association between gene expression with tumor grade and survival at six months via multiple logistic regression models, using the patient's age, gender, tumor stage, and log transformed RNA reads by 13511 genes (Affymetrix HT Human Genome U133A Array), as predictors. We further sub-selected de-regulated genes in terms of their predictive power by applying a forward variable selection coupled with a linear discriminant analysis. We found several genes that were previously confirmed to be involved in pancreatic cancer: *PVRL1* (involved on cell-cell contacts; its downregulation is associated with poor prognosis and tumor proliferation), *ESAM* (involved on cell aggregation; frequently up-regulated in intestinal type gastric cancer), and *RNASEN* (maintenance at adult pancreatic acinar cells; involved on *KRAS*-driven pancreatic neoplasia; regulates differentiation and viability during mouse pancreatic cancer initiation). We also found several novel genes with functions that could potentially be linked with pancreatic cancer: *GABRA1* (downregulation associated with insulin secretion), *METAP1* (required for normal progression through cell cycle), and *CAMTA2* (potential tumor repressor). Our results suggest these genes are good candidates for further studies on target therapy.

**Efficient gene-by-treatment interactions test to develop predictive biomarkers on genome-wide studies using multidimensional hierarchical mixture models.** *T. Otani*<sup>1,2</sup>, *H. Noma*<sup>2,3</sup>. 1) Risk Analysis Research Center, The Institute of Statistical Mathematics, Tachikawa, Tokyo, Japan; 2) CREST, Japan Science and Technology Agency, Tachikawa, Tokyo, Japan; 3) Department of Data Science, The Institute of Statistical Mathematics, Tachikawa, Tokyo, Japan.

In the development of molecular diagnostics for optimizing individualized treatment, efficient exploration of predictive biomarkers is of particular importance to predict responses to therapeutics effectively. In this assessment, an efficient test of gene-by-treatment interactions is crucial, because conventional statistical analyses for detecting interaction effects based on standard regression models lack sufficient statistical power especially on large-scale genome-wide studies. In this study, we illustrate an efficient multi-subgroup gene screening method using a multidimensional semi-parametric hierarchical mixture model and an optimal discovery procedure (ODP) developed to overcome this issue, with application to breast cancer and stroke randomized clinical trials with genomic data. This method reveals the underlying effect size distribution of disease-related genes across treatment and control groups via empirical Bayes estimation under the hierarchical mixture model. Then, based on the optimal gene ranking and posterior probabilities of association for each gene derived from the fitted model, disease-related genes are detected by the ODP with control of false discovery rate levels. We applied this method to randomized clinical trials with molecular data to detect interactions between single nucleotide polymorphisms (SNPs) and treatments, and detected new 6 SNPs being associated with progression-free survival in breast cancer patients and new 3 SNPs being associated with homocysteine levels in blood that are strongly associated with the risk of stroke. We present estimated effect size distributions which could provide a clue for understanding biological mechanisms of diseases, detected disease-related SNPs with their characteristics, and a result of genomic annotation of those using publicly available tools and databases for biological investigation and for validation of the method. Also, we provide a comparison of efficiency with the conventional statistical analyses for detecting gene-by-treatment interactions based on the standard regression models.

**697W**

**Two susceptibility variants associated with osteosarcoma in the HLA class II region.** *C. Zhang*<sup>1,2</sup>, *K. Walsh*<sup>2,1</sup>. 1) Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA; 2) Department of Neurological Surgery, University of California, San Francisco, San Francisco, CA.

Osteosarcoma is the most commonly diagnosed primary malignant bone tumor in adolescents and young adults. A genome-wide association study previously identified a risk variant in *GRM4* (6p21.3), approximately 1 Mb from the human leukocyte antigen (HLA) class II region. Although they detected additional signals in the HLA class II region, the risk variant in *GRM4* was on a separate haplotype block. Therefore, further analyses were necessary to determine whether there is an independent risk locus in the HLA class II region. We performed genetic analyses of HLA class II genes on chromosome 6 in 207 cases and 696 controls using dried newborn bloodspots stored by the California Department of Public Health. Genotype data were generated with the Affymetrix Axiom Array supplemented with ~18,000 additional probes across the MHC region. We imputed HLA alleles using a reference panel of 5,225 individuals in the Type 1 Diabetes Genetics Consortium who underwent high-resolution HLA typing via next-generation sequencing. All subjects were of European-ancestry, and case-control comparisons were adjusted for population stratification using ancestry-informative principal components. Using four-digit classical HLA alleles, which distinguish HLA gene variants at the amino acid level, 27 commonly observed HLA class II alleles (frequency > 0.05) were analyzed, and three highly correlated variants were associated with osteosarcoma risk. The most significantly associated variant in the discovery dataset, *HLA-DQB1\*02:01* (OR=0.51,  $P=0.003$ ), was replicated in an independent dataset of non-overlapping 657 osteosarcoma cases and 1183 controls from dbGaP (OR=0.70,  $P=0.018$ ) (OR<sub>meta</sub>=0.62,  $P_{meta}=1.5E-4$ ). The meta-analysis also revealed a second independent signal at *HLA-DQA1\*01:01* (OR<sub>meta</sub>=1.33,  $P_{meta}=0.001$ ). Both HLA class II association signals are independent of the *GRM4* variant identified in the prior genome-wide association analysis, and showed no linkage disequilibrium ( $r^2 < 0.01$ ). Our findings suggest a role for HLA class II variants in contributing to the risk of osteosarcoma. Additional work is needed to clarify potential causal mechanisms underlying these associations.

## 698T

**HPV16 genomic insights into cervical carcinogenesis: Viral oncogene E7 conservation is critical to carcinogenesis, and relation to human APOBEC3 activity.** L. Mirabello<sup>1</sup>, M. Yeager<sup>2</sup>, K. Yu<sup>3</sup>, G. Clifford<sup>2</sup>, B. Zhu<sup>1</sup>, Y. Xiao<sup>1</sup>, M. Cullen<sup>1</sup>, J.F. Boland<sup>1</sup>, N. Wentzensen<sup>1</sup>, T. Raine-Bennett<sup>3</sup>, Z. Chen<sup>4</sup>, S. Bass<sup>5</sup>, L. Song<sup>1</sup>, M. Steinberg<sup>1</sup>, L. Burdett<sup>1</sup>, M. Dean<sup>1</sup>, D. Roberson<sup>1</sup>, T. Lorey<sup>6</sup>, S. Franceschi<sup>7</sup>, P.E. Castle<sup>8</sup>, J. Walker<sup>8</sup>, R. Zuna<sup>8</sup>, R.D. Burk<sup>8,9</sup>, M. Schiffman<sup>1</sup>.

1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, MD; 2) Infections and Cancer Epidemiology Group, International Agency for Research on Cancer (IARC), Lyon, France; 3) Women's Health Research Institute, Division of Research, Kaiser Permanente Northern California, Oakland, CA; 4) Department of Microbiology, The Chinese University of Hong Kong, Hong Kong; 5) Regional Laboratory, Kaiser Permanente Northern California, Oakland, CA; 6) Department of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY; 7) University of Oklahoma Health Sciences Center, Oklahoma; 8) Departments of Pediatrics, Microbiology and Immunology, and Obstetrics & Gynecology and Women's Health, Albert Einstein College of Medicine, Bronx, NY.

**Objective:** To determine if HPV16 genetic variation influences risk of cervical precancer and cancer, and if there is a relation to the antiviral activity of human APOBEC3 cytidine deaminases, we conducted a large case-control study of HPV16 genomes from a total of 5,720 women. **Methods:** HPV16 genomes were sequenced from 3,215 cervical samples from NCI-KPNC PaP Cohort women (1,107 controls [≤CIN1], 906 CIN2 precancer, 1,093 CIN3 precancer, 109 cancer), and each HPV16 SNP and the combined effects of rare nonsynonymous variants in each viral gene region were evaluated for associations with risk of precancer/cancer (CIN3+). We replicated these findings by HPV16 genome sequencing 996 samples from a cross-sectional U.S. SUCCEED population and 1,509 invasive cancers collected internationally by IARC. HPV16 mutation signatures were evaluated to determine if observed variants matched an APOBEC3-induced signature. **Results:** Forty-nine SNPs were associated with CIN3+, two SNPs located in the regulatory region (URR) were strongly associated with a reduced risk and remained significant after adjustment for multiple tests (OR 0.04,  $P=1.6 \times 10^{-9}$ ; OR 0.06,  $P=7.2 \times 10^{-5}$ ). Unexpectedly, controls had significantly more HPV16 nonsynonymous/nonsense variants throughout the genome (Beta of -0.13/mutation,  $P=6.5 \times 10^{-67}$ ) compared to cases. Strikingly, the oncogene, E7, was devoid of non-silent variants in precancers/cancers compared to higher levels in the controls ( $P=1.0 \times 10^{-67}$ ); we confirmed this in cancers from around the world and E7 was significantly less variable than all other gene ORFs in cancers, even compared to the other oncogene E6 ( $P=6.1 \times 10^{-3}$ ). In a mutation signature analysis, 24% of variants were potentially induced by APOBEC3 in all samples, and these variants were not evenly distributed across the HPV16 genome. Controls had significantly higher numbers of APOBEC3-induced variants compared to precancer cases ( $P=5.6 \times 10^{-5}$ ), particularly in E7 ( $P=0.009$ ), consistent with an antiviral mechanism; whereas, cancer cases had a uniquely high level of APOBEC3-induced variants ( $P=0.004$ ), which may be related to their longer infection time and activation of APOBEC in cancer. **Conclusions:** There is evidence of APOBEC3 editing throughout the HPV16 genome related to infection outcome. Our data indicate that strict conservation of E7, which disrupts Rb function, is critical for HPV16 carcinogenesis, presenting a highly specific target for etiologic and preventive research. .

## 699F

**Proteomics and genomics integration to predict ovarian cancer survival.**

U. Ozbek<sup>1</sup>, C. Conley<sup>2</sup>, J. Peng<sup>2</sup>, P. Wang<sup>1</sup>. 1) Icahn School of Medicine at Mount Sinai, New York, NY; 2) University of California at Davis, Davis, CA.

Ovarian cancer is the fifth leading cause of cancer death. It's estimated that there will be 22,440 new cases and 14,080 deaths of ovarian cancer in the US in 2017. To improve the treatment of ovarian cancer patients, it is of great importance to accurately identify the patients with relatively low survival. In this study, our goal is to integrate multiple omics data sets, including DNA copy number alterations (CNA), mRNA expressions, and protein expression profiles, using network analysis tools to derive gene expression signatures useful to predict survival outcomes of ovarian cancer patients. We hypothesize that genes (1) being influenced by CNA events, (2) serving as hub nodes in gene regulatory networks, and (3) impacting activities of many proteins, shall play important roles in shaping the cell phenotypes and are particularly useful for predicting patients' survival. To test this hypothesis, we first construct a regulatory network of CNAs and mRNA expressions based on genomic profiles of 293 ovarian cancer samples from The Cancer Genome Atlas (TCGA) using a newly developed statistical tool, spaceMap, a conditional graphical model, which learns the conditional dependency relationships between two types of nodes through a penalized multivariate regression framework. Based on the inferred regulatory network, we identify a collection of hub genes that are influenced directly by CNA and are interacting with a large number of other genes. We then select a subset of these genes whose expressions also appeared to have a big impact on global protein activities based on both mRNA and proteomics profiles of 100 ovarian tumors from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) study. In the end, we demonstrate that these selected genes are in general more informative to predict patient survival outcome. We expect such a strategy could lead to better prediction models for disease outcome in clinical practice. The candidate genes identified from the analysis could also lead to novel drug targets to improve the patient disease outcome.

**Survey of microRNA SNPs identifies novel breast cancer susceptibility loci in a case-control population-based study of African American women.** J. Bensen<sup>1</sup>, M. Graff<sup>1</sup>, K. Young<sup>1</sup>, P. Sethupathy<sup>2</sup>, J. Parker<sup>3</sup>, C. Pecot<sup>4</sup>, K. Currin<sup>1</sup>, S. Haddad<sup>5</sup>, E. Ruiz-Narvaez<sup>3</sup>, C. Haiman<sup>4</sup>, C-C. Hong<sup>5</sup>, L. Sucheston-Campbell<sup>6</sup>, Q. Zhu<sup>5</sup>, S. Liu<sup>5</sup>, S. Yao<sup>5</sup>, E. Bandera<sup>6</sup>, L. Rosenberg<sup>2</sup>, K. Lunetta<sup>2</sup>, C. Ambrosone<sup>2</sup>, J. Palmer<sup>2</sup>, M. Troester<sup>2</sup>, A. Olshan<sup>1</sup>. 1) University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Cornell University, Ithaca, NY; 3) Boston University, Boston, MA; 4) University of Southern California, Los Angeles, CA; 5) Roswell Park Cancer Institute, Buffalo, NY; 6) Rutgers University, New Brunswick, NJ.

**BACKGROUND:** MicroRNAs (miRNAs) regulate gene expression and influence cancer. Primary transcripts of miRNAs (pri-miRNAs) are poorly annotated and little is known about the role of germline variation in miRNA genes and breast cancer (BC). We sought to identify germline miRNA variants associated with breast cancer risk and tumor subtype among African American (AA) women. **METHODS:** Genotyping and imputed data from four studies of breast cancer in AA women were combined into a final data set containing 224,188 miRNA gene SNPs for 8,350 women; 3,663 cases and 4,687 controls. Primary miRNA sequence was identified for 566 miRNA genes expressed in ENCODE Tier 1 cell types and human pancreatic islets. Association analysis was conducted using logistic regression for BC status overall and by tumor subtype. **RESULTS:** A novel breast cancer signal was localized to an 8.6kb region of 17q25.3 by 4 SNPs (rs9913477, rs1428882938, rs28585511, and rs7502931) and remained statistically significant after multiple test correction (OR (95%CI) = 1.44 (1.26, 1.65); p-value=3.15x10<sup>-7</sup>; FDR=0.03). Primarily ER positive and PR positive cases drive this signal. These SNPs reside in a genomic location that includes both the predicted primary transcript of non-coding miRNA gene *MIR3065*, and first intron of the gene coding for brain-specific angiogenesis inhibitor 1-associated protein 2 (*BAIAP2*). Additionally, miRNA associated SNPs on chromosomes 1p32.3, 5q32, and 3p25.1 were the strongest signals for hormone receptor, luminal vs. basal and her-2 enrichment status, respectively. A second phase of genotyping (1,397 BC cases, 2,418 controls) that included rs9913477 was used for replication and meta-analysis. Replication of this 17q25.3 SNP confirmed its positive association with BC (OR (95%CI) = 1.16 (1.12, 1.76); p-value=3.56 x 10<sup>-1</sup>). Furthermore, when meta-analyzed with the original data set, the association of rs9913477 with BC (OR (95%CI) = 1.39 (1.31, 1.57); p-value=4.28x10<sup>-7</sup>) remained significant. **CONCLUSION:** Germline genetic variation in this region indicates that *MIR3065* may play an important role in BC development and heterogeneity among AA women. Further investigation to determine the potential functional effects of these SNPs is warranted. This study contributes to our understanding of BC risk in AA women and highlights the complexity in evaluating variation in gene-dense regions of the human genome.

## 701T

**Mosaic truncating *PPM1D* mutations are age-related but lack a strong association with breast cancer risk.** T.A. Myers<sup>1</sup>, M.J. Machiela<sup>1</sup>, C. Hautman<sup>2</sup>, R. Koster<sup>1</sup>, W. Figg<sup>1</sup>, L. Jessop<sup>1</sup>, L.M. Colli<sup>1</sup>, M. Garcia-Closas<sup>1</sup>, S.J. Chanock<sup>1</sup>. 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Rockville, MD; 2) Cancer Genomics Research Laboratory, Leidos Biomedical Research Inc., Frederick National Laboratory for Cancer Research, Frederick, MD.

Mosaic protein truncating variants (PTVs) in exon 6 of the protein phosphatase, Mg<sup>2+</sup>/Mn<sup>2+</sup> dependent 1D (*PPM1D*) gene in blood-derived DNA have been associated with breast and ovarian cancer risk. Recent studies in patients with ovarian cancer have suggested mosaic *PPM1D* PTVs are selected for by chemotherapy and may not confer cancer risk. Our aim was to perform ultra-high depth (>2,500x target coverage) sequencing of the *PPM1D* mutation cluster region to evaluate whether *PPM1D* PTVs are associated with breast cancer risk or if these mutations were selected for by cancer treatment. We investigated blood-derived DNA from 1,734 breast cancer cases and 1,129 controls from the Polish Breast Cancer Study (PBCS), a breast cancer case-control study from Poland, and 2,158 breast cancer cases and 1,932 controls from the Prostate Lung Colorectal and Ovarian Cancer Screening Trial (PLCO), a prospective trial in the United States. We performed multiplex amplicon PCR using two sets of target-specific primers designed to amplify the mutation cluster region (MCR) in exon 6 of *PPM1D* and incorporate Illumina adapter overhang sequences. Low-cycle PCR was performed to add Illumina sequence adapters and dual indices to the amplicons allowing for pooling of 384 samples per Illumina MiSeq run. Data analysis was performed by the MiSeq Reporter 2.6.2.3 PCR Amplicon Workflow and variants were called using the Illumina Somatic Variant Caller, designed to detect low-frequency mutations below 5%. All samples were required to pass a minimum QC filter of 250x coverage across 80% of the MCR for subsequent analysis. Detected *PPM1D* PTVs were independently validated using a Nextera XT library preparation protocol. In total, we identified 50 of 6,953 (0.9%) women with a mosaic *PPM1D* PTV variant frequency between 1.0% and 30.6%. A higher frequency of mosaic *PPM1D* PTVs was observed with increasing age ( $P_{trend}=0.005$ ); however, there was no significant difference in variant frequency between breast cancer cases and controls (OR=1.44, 95% CI=0.81-2.59, P-value=0.22). Furthermore, we found no significant effects of treatment prior to blood collection (e.g., chemotherapy, radiation or hormone exposure) or smoking on risk of developing *PPM1D* PTVs. Our study indicates *PPM1D* PTVs are present in women from two studies of breast cancer and suggests frequencies increase with age, but finds limited evidence supporting a strong association between *PPM1D* PTVs and breast cancer risk or related treatments.

**Gender differences in germline mutations in bladder cancer participants from the DiscovEHR study.** L. Bang<sup>1</sup>, M. Shivakumar<sup>1</sup>, D. Lavage<sup>2</sup>, T. Garg<sup>3,4</sup>, D. Kim<sup>1,5</sup> on behalf of the DiscovEHR collaboration. 1) Biomedical and Translational Informatics Institute, Geisinger Health System, Danville, PA; 2) Phenomics Core, Geisinger Health System, Danville, PA; 3) Department of Urology, Geisinger Health System, Danville, PA; 4) Department of Epidemiology and Health Services Research, Center for Health Research, Geisinger Health System, Danville, PA; 5) The Huck Institutes of the Life Sciences, The Pennsylvania State University, University Park, PA.

Sex-related differences in bladder cancer are clinically well-known and merit further genetic characterization. Bladder cancer affects men more frequently than women (3:1); however, women are diagnosed at higher stages and have worse overall survival. Of urologic cancers in The Cancer Genome Atlas (TCGA), bladder cancer had the most differences by sex and extensive sex-biased molecular signatures. The DiscovEHR study, a cohort with electronic health records (EHR) linked to the MyCode biobank of Geisinger Health System, provided whole exome sequencing (WES) and SNP array data for consented patients. We examined a cohort diagnosed with urothelial carcinoma (N=355) as well as an age, sex, and smoking status matched non-cancer control cohort (N=710). The influence of rare germline variants (MAF<0.05) from WES data on differential presentation of bladder cancer based on sex was characterized by rare-variant binning and applying a dispersion-based test using Bin-KAT, adjusting for age and smoking status. Rare germline variants in *ARSD* and *CCNI2* were significantly associated with sex-related discrepancies in bladder cancer occurrence. Females with bladder cancer were more likely to have variants in *CCNI2* than males (Bonferroni-corrected P =0.045); males with bladder cancer were more likely to harbor mutations in *ARSD*, a pseudoautosomal X-chromosome gene (Bonferroni-corrected P = 0.0032). This association with *ARSD* was separately confirmed in SNP array data for the same cohort of patients, with common missense variant *rs211653* within *ARSD* being suggestively significant (P = 2.0x10<sup>-6</sup>) in males with bladder cancer as compared to females. *ARSD* is a gene in the sulfatase family involved in X-linked skeletal dysplasia and warfarin metabolism; significant differential activity of Arylsulfatase A in patients with genitourinary tract disorders such as bladder cancer has been found previously. Our results demonstrate that germline mutation analysis in an unselected hospital-based cohort improve our understanding of the etiology of sex disparities in bladder cancer. A larger DiscovEHR cohort in the future will support the replication of these results.

**Integrative Bayesian group bridge regularization analysis in multiple heterogeneous high-dimensional survival data.** Y. Li. School of Statistics, Shanxi University of Finance & Economics, Taiyuan, China.

In the analysis of survival data in high-throughput genomic studies, results generated in the analysis of a single dataset may suffer a lack of reproducibility because of small sample sizes. Integrative analysis provides an effective way of pooling information across multiple independent studies with comparable designs, and can be more effective than single-dataset analysis and meta-analysis. In this study, we conduct integrative bayesian group bridge regularization analysis for the sparsity structures of multiple heterogeneous high-dimensional survival data. Our study also advances from the existing studies by conducting systematic simulations and direct comparisons of multiple methods. The proposed approach can effectively accommodate heterogeneity among multiple studies and identify markers with consistent effects across studies. You may contact the author (during and after the meeting) at liyi@sxufe.edu.cn.

**Inflated genome-wide *de novo* mutation rate in carriers of *TP53* germline mutations.** X. Pan<sup>1,2</sup>, J. Bojadzieva<sup>1</sup>, E. Dodd<sup>1</sup>, B. Li<sup>3</sup>, D. Wheeler<sup>1</sup>, V. Johnson<sup>2</sup>, L. Strong<sup>1</sup>, W. Wang<sup>1</sup>. 1) MD Anderson Cancer Center, Houston, TX; 2) Texas A&M University, College Station, TX; 3) Vanderbilt University, Nashville, TN; 4) Baylor College of Medicine, Houston, TX.

Germline mutations are the driving force behind genome evolution and etiology of diseases. It has been well established that the number of *de novo* germline mutations is positively correlated with the age of the father. However, it remains largely unknown what factors other than perhaps paternal age would affect the initiation and accumulation of germline mutations. This question is particularly important for Li-Fraumeni Syndrome (LFS), a cancer predisposition syndrome mostly caused by germline *TP53* mutations, in which there is an unusually high prevalence of *de novo* mutations (7-20%). To investigate this issue, we generated whole-genome sequencing data (at a 30x read depth) from five quartets of LFS probands, healthy siblings and their parents, and tried to compare the genome-wide *de novo* mutation number between the probands and their healthy siblings. We selected all available *de novo* probands who had unaffected siblings within close age range (1-4 years) in order to reduce the age difference between the paired proband and sibling as much as possible. All the *de novo* probands had at least two types of cancer, the most common being osteosarcoma and breast cancer. None of the siblings or parents of probands had any record of cancer. We applied the *de novo* mutation calling software Polymutt and additional stringent filters to identify genome-wide *de novo* mutations in the 5 probands with *TP53* mutations and 5 healthy siblings. As a result, we observed that in three of the five families, the number of *de novo* SNVs differed widely between the probands and their siblings (53 vs. 36, 48 vs. 19 and 54 vs. 34), while in the other two there was no difference (44 vs. 45 and 36 vs. 33). Overall, the probands had significantly higher *de novo* mutation number than their normal siblings ( $p = 0.035$ , paired t-test). This suggests the possibility that factors other than the age of the father may have a strong impact on the *de novo* mutation number within families, and that these factors may put individuals at increased risk for deleterious mutations.

**Detection of signal regions in whole genome genotyping and sequencing association studies using scan statistics.** Z. Li<sup>1</sup>, X. Lin<sup>1,2</sup>. 1) Biostatistics Dept, Harvard T.H. Chan School of Public Health, Boston, MA; 2) Statistics Dept, Harvard University, Cambridge, MA.

Large scale Whole-genome sequencing (WGS) studies, such as the TOPMed and Genome Sequencing Programs, are currently being conducted to identify susceptible rare variants associated with human diseases or traits. The classical single-marker association analysis for rare variants has limited power and SNP-set based analysis are commonly used in analyzing rare variants. A major challenge in analyzing WGS data is how to handle non-coding variants. These existing SNP-set based tests for rare variant analysis, such as burden and SKAT, require to pre-specify gene regions and hence are not directly to WGS data, as analysis units and window sizes (if a moving window method is used), are not well defined and unknown in WGS analysis, because of a large number of non-coding variant regions. We propose a scan statistic based method to optimal detect association signal segment sizes and locations by scanning the genome continuously. The proposed method accounts for the LD among genetic variants, and allows for signal regions to have both causal and neutral variants, and causal variants whose effects can be in different directions. The proposed procedure properly controls for family-wise error rates. Through analysis of simulated data, we showed that the proposed scan procedure can effectively detect association signal regions. We applied the proposed method to analyze WGS datasets to identify the genetic regions that are associated with heart- and blood-related traits. .

**A novel Bayesian multiple testing approach for region-based analysis of next generation sequencing (NGS) data.**

*J. Xu<sup>1,2</sup>, W. Xu<sup>1,3</sup>, R. Hung<sup>1,2</sup>, G. Liu<sup>1,3</sup>, L. Briollais<sup>1,2</sup>.* 1) Dalla Lana School of Public Health, University of Toronto, Toronto, Canada; 2) Lunenfeld-Tanenbaum Research Institute, Mount Sinai Hospital, Toronto, ON, Canada, Canada; 3) University of Health Network, Princess Margaret Cancer Centre, Toronto, ON, Canada.

The discovery of rare genetic variants through Next Generation Sequencing (NGS) is becoming a very challenging issue in the human genetic field. We have recently proposed a novel region-based statistical test based on a Bayes Factor (BF) approach to assess evidence of association between a set of rare variants located on this region and a disease outcome. Gene-based inference can be performed using permutation testing. For genome-wide inference (i.e. multi-regions test), we introduce a Bayesian False Discovery Rate (BFDR) control procedure inspired by the work of Efron (2005). In this setting, it is critical to estimate the null distribution of the BF for the non-associated regions. We used an empirical estimate of the null distribution and studied its properties by simulation and analytically. In particular, we showed that the choice of priors can impact seriously the BFDR procedure. Our BF approach has been applied to a study of lung cancer from Toronto including 262 cases and 261 controls with whole exome sequencing data. We applied the BFDR control procedure to >13.7K genes and estimated the FDR for the top 5, 10 and 20 genes to be respectively, 2.9%, 7.5% and 12.8%. Our top genes included for example TERT and TLR6. In conclusion, the use of empirical Bayes priors along with a Bayesian control of FDR offer a comprehensive framework to make genome-wide statistical inference about the important chromosomal regions associated with the disease of interest in the context of NGS data.

Clinical germline genetic testing of cancer predisposition gene panels is now widely used to identify women at increased risk for breast cancer. The identification of pathogenic mutations in established predisposition genes, such as *BRCA1* or *BRCA2*, may result in improved risk management of breast cancer for tested patients and their family members through tailored screening, prophylactic surgeries, or chemoprevention. The efficacy of these clinical interventions shows the promise of identifying pathogenic mutations in predisposition genes. However, the utility of results from hereditary cancer panel testing of genes other than *BRCA1* and *BRCA2* has been limited because the levels of risk for breast cancer associated with mutations in several of the panel genes have not been clear. Recent studies of women eligible for clinical hereditary panel testing have likely overestimated the risks associated with mutations in each gene because of the presence of genetic modifiers associated with a family history of breast and/or ovarian cancer. Here we report interim results from the "CAnceR Risk Estimates Related to Susceptibility" (CARRIERS) study, which aims to estimate breast cancer risks associated with mutations in hereditary cancer panel genes in the general population. CARRIERS involves sequencing all coding sequence and splice consensus sites from 37 cancer predisposition genes along with 126 common genetic risk factors for breast cancer in 40,000 breast cancer cases and 35,000 matched controls from cohort-based nested breast cancer studies and population-based case-control studies. We will report associations with risk of breast cancer for individual pathogenic mutations and combined mutations in each gene, as well as interactions with strength of family history. Population-based risk estimates for breast cancer for each of the hereditary cancer panel genes will be useful for risk management of patients and for development of breast cancer risk prediction models.

## 708F

**Clinicopathological and prognostic significances of EGFR, KRAS, BRAF and PI3KCA mutations in biliary tract cancer.** *H. Lee<sup>1</sup>, S. Kang<sup>1</sup>, T. Park<sup>2</sup>, J. Kim<sup>2</sup>.* 1) hematology-oncology, Ajou university school of medicine, Suwon, Gyeonggido, South Korea; 2) pathology, Ajou university school of medicine, Suwon, Gyeonggido, South Korea; 3) biochemistry, Ajou university school of medicine, Suwon, Gyeonggido, South Korea.

Biliary tract carcinomas (BTCs) are more common in Korea in western countries. It is more difficult to treat. Epidermal growth factor receptor (EGFR) is a therapeutic target for the cancer. Mutations of the EGFR gene and the activation of its downstream pathways, including KRAS and BRAF, is important for targeted therapy. This study aims to analyze the EGFR, KRAS, BRAF and PI3KCA mutations in BTCs and their association with clinical outcomes. Paraffin-embedded specimens containing 113 resected BTCs at the Ajou University Hospital between 2009 and 2013 were analyzed. The exons 18-21 of EGFR gene, the codon 12, 13 and 61 of KRAS gene, BRAF V600E, and PI3KCA mutation were analyzed by cobas 4800. We tested the correlation between these mutations and the overall survival, tumor location, stage, and lymphocyte numbers at diagnosis in BTCs. There is no mutation of EGFR and BRAF mutation in BTC patients. 23(20.3%) BTC patients had the codon 12, 13 of KRAS mutation, 12(10.6%) patients had the codon 61 of KRAS mutations while 7 (6.1%) patients had PI3KCA mutations. Factors influencing survival on univariate analysis were tumor positive margin, lymphocyte, perineural invasion and bilirubin level. On multivariate analysis, tumor positive margin and perineural invasion were independent prognostic factors. A correlation between KRAS mutations and survival tend to be observed( $p=0.051$ ). PI3KCA mutation was not correlated with survival( $p=0.956$ ). EGFR and BRAF mutations are not shown in BTCs. KRAS mutation showed 34 patients (31%) and 7 (6.1%) patients had PI3KCA mutations. Tumor positive margin and perineural invasion were independent prognostic markers in BTCs.

## 709W

**Evolutionary genomic analysis of a longitudinal series of prostate cancer bone metastases and xenografts from one patient revealed selection of progressively therapy resistant metastatic clone.** *T. Gaasterland<sup>1,3,4</sup>, M. Muldong<sup>2</sup>, A. Gallegos<sup>3,4</sup>, C. Wu<sup>2,5</sup>, T. Mendoza<sup>2,5</sup>, W. Zhu<sup>2,5</sup>, L. Edsall<sup>1,3</sup>, M. Liss<sup>6</sup>, A. Kullidjian<sup>2,7</sup>, C. Jamieson<sup>2,5</sup>.* 1) Institute for Genomic Medicine, University of California San Diego, La Jolla, CA; 2) Moores Cancer Center, University of California San Diego, La Jolla, CA; 3) Scripps Institution of Oceanography, University of California San Diego, La Jolla, CA; 4) Bioinformatics and Systems Biology Program, University of California San Diego, La Jolla, CA; 5) Urology, Department of Surgery, University of California San Diego, La Jolla, CA; 6) Department of Urology, University of Texas Health Sciences Center, San Antonio, TX; 7) Department of Orthopedic Surgery, University of California San Diego, La Jolla, CA.

Background: Prostate cancer (PrCa) metastasizes to bone in 50-90% of patients with advanced disease, yet little is known about genome-wide alterations in these metastases. To understand genome changes and progressive therapy resistance, we examined genome variation and gene expression in a 3-year longitudinal series of surgical PrCa bone metastasis (mets) samples and xenografts derived from the same patient. Methods: Surgical specimens collected during orthopaedic repair surgery resulted in a longitudinal sample series including blood, mets 1 (post-ADT, radiation), mets 2 (+10.5 mon. post-ADT, radiation, docetaxel), mets 3 (++12 mon. post-abiraterone, radiation, cabazitaxel). Intra-femoral xenograft mouse model PCSD1 was established from mets 1. We used copy number variation (CNV) from SNP arrays (Affymetrix Oncoscan), whole exome sequencing (WES), and gene expression from all samples to examine longitudinal changes, impact of treatment, and xenograft genome integrity. Results: CNV profiles of mets 1 and a low passage PCSD1 xenograft revealed extensive alterations highly conserved in both, with copy number gains across the majority of the genome and scattered regions of loss. In contrast, comparison of CNV profiles for mets 1 and 2 showed significantly different patterns with some regions of conservation. Unexpectedly, CNV profiles were highly conserved between mets 2 and high passage PCSD1 xenografts derived from mets 1. Whole exome analysis identified shared and unique point mutations across all samples. Phylogenetic dendrogram analysis of these mutations together with CNV profiles indicated reduced heterogeneity over time, and selection of one sub-population both in patient samples and xenografts. WES also identified germline alterations in DNA repair genes (BRCA2, ATM and CHEK2) and tumor suppressor genes (TP53, PTEN). Treatment of the xenograft model with anti-androgen bicalutamide induced expression of a neuronal gene signature. Conclusions: CNV and WES revealed that selection of a similar therapy-resistant sub-population occurred in both patient metastases and xenografts derived from the same patient, providing the first direct evidence that a therapy-resistant sub-clone was already present in early metastasis. Analysis of surgical metastases at different stages of treatment and progression in this patient provides a foundation to profile genomic diversity in recurrent bone metastatic PrCa.

**The early evolutionary signatures of clonal hematopoiesis leading to blood based cancers and cardiometabolic conditions.** K. Skead<sup>1</sup>, S. Abelson<sup>2</sup>, J. Wang<sup>2,3</sup>, M. Minden<sup>2,3</sup>, L. Shlush<sup>2,4</sup>, J. Dick<sup>2,5</sup>, P. Awadalla<sup>1,5</sup>. 1) Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 2) Princess Margaret Cancer Centre, Toronto, Ontario, Canada; 3) Department of Medical Biophysics, University of Toronto, Toronto, Ontario, Canada; 4) Weizmann Institute of Science, Rehovot, Israel; 5) Department of Molecular Genetics, University of Toronto, Toronto, Ontario, Canada.

Population aging has emerged as a major factor influencing patterns of health and shifting disease profiles. Recent studies have shown that hematopoietic stem cells (HSCs) accumulate somatic mutations over time as a function of regular aging. Certain private mutations confer a slight fitness advantage causing particular HSCs to undergo clonal expansions and contribute disproportionately more to the mature blood cell pool in addition to impacting disease susceptibility in a process referred to as clonal hematopoiesis. Most notably, these clonal expansions have been found to associate with blood-based cancers and various cardiometabolic conditions. However, clonal hematopoiesis has been observed in individuals both in the absence of a disease diagnosis and as a precursor state to disease development; a phenomenon termed clonal hematopoiesis of indeterminate potential (CHIP). As such, there is a clear need to capture and characterize the evolutionary trajectory from normal blood cell composition, through to CHIP and, more significantly, disease state clonal hematopoiesis. For the purposes of this study, we have leveraged two large population cohorts, the Canadian Partnership for Tomorrow Project (CPTP) and the European Prospective Investigation into Cancer and Nutrition (EPIC) study, to identify incidental cases of cardiometabolic conditions, hematological cancers, "healthy" CHIP and corresponding biological samples collected prior to diagnosis. Following targeted deep sequencing and the genomic characterization of the pre-hematological cancer, pre-cardiometabolic and "healthy" CHIP samples, we are using a Bayesian approximation approach to construct quantitative evolutionary framework with which to assess the forces shaping the accumulation of somatic mutations in blood, and interpret site frequency spectrums with respect to clonal expansions and clinical outcomes. Effectively, we will discern early stage patterns of clonal hematopoiesis indicative of 1) hematological cancers, 2) cardiometabolic conditions, from 3) "healthy" CHIP, that is, benign clonal patterns not found to be a precursor state to disease. Ultimately, this study provides a platform through which we are able to explore the predictive utility of clonal hematopoiesis in order to differentiate individuals more likely to be susceptible to age associated diseases in addition to functioning as an earlier diagnostic tool.

**711F**

**Similar frequency of ACMG-59 gene secondary findings in a large whole exome sequenced cancer cohort and ethnicity-matched controls.** J. Kim<sup>1</sup>, M. Wang<sup>2,3</sup>, W. Luo<sup>2,3</sup>, M.M. Gaudet<sup>4</sup>, S.M. Gapstur<sup>4</sup>, B. Zhu<sup>2,3</sup>, A.M. Goldstein<sup>1</sup>, D.R. Stewart<sup>1</sup>, NCI DCEG Cancer Genomics Research Laboratory, NCI DCEG Cancer Sequencing Working Group. 1) Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 2) Cancer Genomics Research Laboratory, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 3) Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD; 4) Epidemiology Research Program, American Cancer Society, Atlanta, GA.

**Intro.** The frequency of pathogenic (P) or likely pathogenic (LP) secondary findings (SF) in ACMG-59 genes is 1-3%, largely from clinical laboratories and analysis of publicly available databases. We investigated the frequency of ACMG-59 SF variants in a large, heterogeneous, family-based cancer-research cohort and in cancer-free ethnicity-matched controls. **Methods.** Whole exome sequencing was conducted on 1320 cases and 994 cancer-free controls from a variety of cancer-based studies. Examination of ethnicity-informative variants ensured comparable case/control population structure. We matched capture region and read depth for case-control comparisons. Pathogenicity of ACMG-59 variants (MAF < 1%) was determined using InterVar (a semi-automated application of ACMG/AMP Guidelines) and a hotspot-, ClinVar-, HGMD-DM- and LoF-based tiering scheme (tier 1: most pathogenic). **Results.** Using InterVar, in the 24 ACMG-59 cancer genes, we observed 6 P/LP unique variants (22 total; 2.2%) in controls and 5 P/LP unique variants (27 total; 2.0%) in cases (P=0.77). In the 35 ACMG-59 non-cancer genes, we found 9 P/LP unique variants (9 total; 0.9%) in controls and 12 P/LP unique variants (18 total; 1.0%) in cases (P=0.34). There were 696 unique VUS in cases and 590 unique VUS in controls. Alternatively, using the tiering scheme, in the 24 ACMG-59 cancer genes, we found 76 unique tier 1 variants (146 total, 15%) in controls and 78 tier 1 variants (229 total, 17%) in cases (P=0.09). However, 52% of tier 1 variants had conflicting P/LP status between ClinVar and HGMD-DM. No significant differences were observed in the ACMG-59 non-cancer genes. Similar results were observed when restricting the analysis to 1 cancer patient/pedigree. **Discussion.** Using InterVar, a conservative method, overall, we observed ~3% P/LP variants and no significant differences in P/LP variant frequencies between cancer cases and controls for both ACMG-59 cancer and non-cancer genes. Similarly, there were no significant differences in tier 1 variant frequencies in cases and controls. We acknowledge limited power inherent in studying rare variants, especially for single genes. For both methods used, the large number of VUS require detailed database and literature review, a time- and labor-intensive process hampered by the difficulty in interpreting conflicting P/LP determinations. Our data suggest that resolving numerous VUS will likely impose a significant burden on the return of ACMG-59 SF.

**712W**

**Genetic diversity and rare mutations in the Puerto Rican population.** *E.J. Torres Gonzalez<sup>1</sup>, W. Wolfsberger<sup>2</sup>, T.K. Oleksyk<sup>2</sup>, M. Dean<sup>1</sup>*. 1) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Gaithersburg, MD; 2) Caribbean Genome Center, University of Puerto Rico at Mayaguez, PR.

Modern Puerto Ricans are an admixture of African, European and Native American ancestral populations. Previous studies such as 1000 Genomes have reported on common mutations and the distribution of admixture in the island. To identify rare (<1 %) and potentially disease-related mutations we carried out exome sequencing of a diverse Puerto Rican sample set. From a collection of 673 individuals from 66 municipalities we selected 120 individuals from 10 municipalities, based on either high expected European, African or Native American genetic ancestry. A preliminary analysis yielded some known disease mutations in the population, such as Phenylketonuria (PKU), G6PD deficiency, Stargardt macular dystrophy (STGD), Familial hypercholesterolemia (FH), HFE-associated hereditary hemochromatosis, Familial Mediterranean fever (FMF), Sickle-cell disease (HbS), and the Duffy and Diego blood groups. Variant calling was carried out with GATK and LoFreq. These samples will be joined to 107 individuals from the 1000Genomes (PUR population) and 2 targeted sequencing panels.

**713T**

**Functional role of intragenic methylation in alternative splicing in cancer.** *Y. Lee, D. Kim, S. Han*. Biomedical Informatics, University of Utah, Salt Lake City, UT.

**Background:** DNA methylation in promoter regions leads to transcriptional silencing, such as of tumor suppressor genes in cancer. However, the functions of DNA methylation in the gene body (intragenic, i.e. exons and introns) have not yet been completely elucidated. Recently, hypermethylation has been implicated in enhancing exon recognition by recruiting methyl—CpG—binding protein (MECP2) to hypermethylated sites. In this study, we examined intragenic methylation in splicing regulatory elements (SREs: exonic splicing enhancer (ESE), exon splicing silencer (ESS), intronic splicing enhancer (ISE), intronic splicing silencer (ISS)) as a mechanism to understand how epigenetic factors contribute to alternative splicing events in cancer. **Hypothesis:** Methylation patterns of SREs are involved in directing alternative splicing events in cancer. **Methods:** We developed a splicing decision model to identify actionable methylation loci potentially affecting splicing events (i.e. exon skipping) among CpG sites in putative intragenic SRE regions. We used DNA methylation and RNA—seq data for breast and lung cancer samples and normal cases from The Cancer Genome Atlas (TCGA). We additionally used hyper- and hypomethylation data published in Selamat et. al (2013) as an independent lung cancer dataset. To identify regions hyper— and hypomethylated in cancer, we performed an unpaired t-test for differential methylation status (beta value) between cancer and normal cases. Multiple testing was accounted for by controlling the false discovery rate ( $p < 0.05$  with  $FDR < 0.1$ ). **Results:** We investigated whether specific patterns of methylation were enriched in SRE regions affecting exon skipping. We found that for breast cancer samples, differential methylation status was enriched in SRE regions but not in non—SRE regions. Particularly, hypomethylation in cancer showed a greater enrichment in ESE regions with putative exon skipping events. Similar results were observed in the both the TCGA lung cancer cases and an independent lung cancer dataset. These data suggest that hypomethylation in SRE regions may cause failure to recruit MECP2, therefore leading to exon skipping. **Conclusion:** Our study suggests that intragenic methylation status is important for splicing regulation and may improve our understanding of how intragenic epigenetic markers play a role in gene regulation by affecting alternative splicing.

**Systematic evaluation of copy number variations: Towards rational personalized cancer therapy.** S. Appenzeller<sup>1</sup>, A. Gesierich<sup>2</sup>, A. Thiem<sup>1,2</sup>, A. Hufnagel<sup>3</sup>, H. Kneitz<sup>2</sup>, A. Rosenwald<sup>4</sup>, R. Bargou<sup>1</sup>, M. Goebeler<sup>2</sup>, S. Meierjohann<sup>2</sup>. 1) Comprehensive Cancer Center Mainfranken, University Hospital Würzburg, Würzburg, Germany; 2) Department of Dermatology, Venereology and Allergology and Skin Cancer Center, University Hospital Würzburg, Würzburg, Germany; 3) Department of Physiological Chemistry, University of Würzburg, Würzburg, Germany; 4) Institute of Pathology, University of Würzburg, Würzburg, Germany.

With the identification and functional characterization of an increasing number of tumor oncogenes, the inhibitor pools of pharmaceutical companies have significantly increased in the last decades. Nowadays, numerous inhibitors e.g. targeting a large number of kinases are either approved by FDA and EMA or are currently evaluated in clinical trials. However, usage of these inhibitors is largely restricted to tumors, which carry a defined single activating somatic mutation, e.g. BRAF (p.V600E/K) in melanoma or EGFR (p.L858R) in non-small cell lung carcinoma. Copy number variations, such as deletions or amplifications of tumor-relevant genes, are rarely investigated, although they may be of relevance and potentially targetable by pharmacological intervention. We used targeted deep panel sequencing to identify genetic alterations in melanoma. We used DNA isolated from paired tumor and fresh-frozen blood (as non-pathological control) samples in order to be able to detect somatic single nucleotide variants (SNVs) as well as somatic copy number variations (CNVs) in a panel of more than 50 melanoma relevant genes. While the detection of somatic mutations and small indels using targeted panel sequencing was feasible, CNV detection turned out to be challenging with the restricted genomic information of the gene panel. This is mainly due to the fact that thresholds for calling a CNV are largely undefined and existing bioinformatic tools give unsatisfactory and conflicting results. To address this issue, we developed a bioinformatic pipeline, which is able to reliably identify CNVs even from small sequencing panels. The results were evaluated and confirmed using an array-based assay, the current gold standard for CNV analysis. This analysis will be a valuable diagnostic and prognostic device, which can be used in the clinical setting for personalized therapy decisions at comparatively low cost.

**Single-molecule resolution of haplotype-specific, megabase-scale and complex oncogenic rearrangements in metastatic cancers.** S. Greer<sup>1</sup>, B. Lau<sup>2</sup>, J. Chen<sup>1</sup>, C. Xia<sup>1</sup>, H. Ji<sup>1,2</sup>. 1) Oncology, Stanford University, Stanford, CA; 2) Stanford Genome Technology Center, Stanford University, Stanford, CA.

Resolution of complex structural variants (SVs) remains one of the last major challenges of NGS data analysis, despite the ubiquity and significance of SVs in both normal and disease genomes. SVs are difficult to resolve due to the inability of short sequencing reads to span across complex rearrangements, leading to resolution only by indirect evidence. To address this challenge, we have developed a method that leverages barcoded sequence reads derived from single molecules to resolve complex genomic structures without the need for assembly. With this methodology, we have resolved complex rearrangements involving multiple classes of SVs over a range of many megabases which are not evident even with long read sequencing technologies. We have successfully resolved complex rearrangements at megabase scale across many types of malignancies, including diffuse gastric cancer, colorectal cancer, and cholangiocarcinoma. All of this was accomplished at single molecule accuracy and was possible even in samples with tumor fractions of less than 30%. Our initial analysis involving metastatic samples from a patient with primary diffuse gastric cancer has been published and highlights our ability to identify unique rearrangement motifs that have undergone segmental duplication. Further, clustered somatic rearrangements could be assigned to specific parental haplotypes. This was possible without the need for long read sequencing. Further, we used haplotype-informed local assembly to validate haplotype-specific rearrangement motifs. We boosted the performance of assembling tumor-specific SVs by the bioinformatic extraction of somatic regions at single molecule resolution. Sequence assembly thus yielded approximately 100 kilobase contigs that confirmed the results of our SV resolution method. Overall, we demonstrate the utility of SV resolution and assembly to improve our understanding of genomic instability in the context of cancer genome analysis.

**NGSEA: Network-augmented Gene Set Enrichment Analysis.** *H. Han, S. Lee, I. Lee.* Biotechnology, Yonsei University, Seoul, South Korea.

Gene set enrichment analysis (GSEA) is a widely used computational method to test a statistical association between a gene set and rank-ordered expression signatures. Despite the popularity, there are shortcomings in this method. For examples, perturbation of disease genes in the patient would give expression signature of the responsive genes rather than the causal genes, resulting in limited associations between the patient expression signature and the relevant disease. Furthermore, the mixed signature of up- and down-regulations for the same disease gene set could diminish the statistical significance of the association between the expression signature and the disease. To overcome such limitations, we present a modified GSEA, network-augmented GSEA (NGSEA), which uses re-ranked signature genes based on differential expressions of neighbors in a functional gene network. In this method, genes with differentially expressed neighbor genes are more weighted. We found NGSEA performed better than GSEA in identifying associations between KEGG disease pathways and expression signatures derived from the patient with a relevant disease. NGSEA also shows higher performance than GSEA in identifying drugs for patients with relevant diseases, suggesting that NGSEA can be applied to drug repositioning. With these results, we demonstrated that incorporating information of gene functional networks can improve the GSEA. NGSEA should be a useful resource, as network-augmented scoring allows us to identify disease-related gene sets which were undetectable with expression signatures only.

**Methodologies for FMS-like tyrosine kinase (FLT3) internal tandem duplication (ITD) detection from two types of next generation sequencing data such as whole exome sequencing and amplicon sequencing.** *D. Kim<sup>1</sup>, Y. Hong<sup>2</sup>, Y. Koh<sup>3</sup>, K. Ahn<sup>4</sup>, J. Shin<sup>2</sup>, H. Yun<sup>2</sup>, S. Yoon<sup>2,1</sup>.* 1) Seoul National University Cancer Research Institute, Seoul National University College of Medicine, 101 Daehagro, Jongno-gu, Seoul 110-799, Korea; 2) Development Group, Healthcare Analytics Team, Samsung SDS, SDS Tower West Campus 11F, Olympic-ro 35-gil, Songpa-gu, Seoul 138-240, Korea; 3) Department of Internal Medicine, Seoul National University Hospital, 101 Daehagro, Jongno-gu, Seoul 110-744, Korea; 4) Functional Genome Institute, PDXen Biosystem Inc. Hwarang Ro, KIST venture town, Seoul, Republic of Korea.

We developed new ITD detection algorithm (ITDetect) and applied two type of next generation sequencing data based on capture library construction method (WES) and PCR amplification (amplicon sequencing). ITDetect is based on BWA and is specified for ITD detection including FLT3-ITD. We validated and compared result of ITDetect with other ITD detecting algorithms using nested polymerase chain reaction (PCR) method. In 81 acute myeloid leukemia patients with WES data, FLT3-ITD was positive in 11 patients (13%) when called with ITDetect, all of whom were validated with nested PCR. Meanwhile FLT3-ITD was positive only in 7/81 patients by conventional PCR. The concordance rate of ITDetect and nested PCR was 95% (77/81). ITDetect showed better ITD detection performance when compared with previously reported ITD callers. In large AML cohort (n=213), patients who were positive for FLT3-ITD with nested-PCR but not with conventional PCR had shorter survival outcomes than patients who were negative for FLT3-ITD with nested PCR, suggesting clinical significance of sensitive FLT3-ITD detection. We also performed amplicon based sequencing in separated AML cohort (n=41) and applied ITDetect and Pindel. In this cohort, Pindel was shown better performance than ITDetect. Among 5 FLT3-ITD positive patients in 41 AML cohort, 2 of them were FLT3-ITD positive with ITDetect but, 4 of them were FLT3-ITD positive with Pindel. In conclusion, It is very careful when ITDetect is applied for amplicon based sequencing data. Amplicon based sequencing data was shown irregular soft clipping reads, because amplicon based sequencing is logically likely to include PCR error. However, we developed more sensitive detection methods for FLT3-ITD based on WES data that is clinically meaningful and low performance will be overcome after optimizing for amplicon sequencing data.

**Genomic analysis of PDX sequencing data.** *J. Kim, S. Kim, A. Choi, S. Lee.* Ewha Womans University, Seoul, South Korea.

PDX mouse model is an emerging platform to test treatment responses for cancer patients in preclinical setup, thus providing ample opportunities to realize the personalized and precision medicine. Detailed histological and molecular characterization is essential to confirm the compatibility of PDX mice with the patient tumor. We have established 220 PDX models representing 180 lung cancer patients and generated whole exome and transcriptome sequencing data. Ideally, trio samples of patient normal, patient tumor, and mouse tumor tissues are required to identify somatic mutations in PDX mouse that are concordant with patient tumor. Here we describe computational pipelines for analyzing deep sequencing data for PDX mice. First, we present a procedure for determining the compatibility between PDX mice and the patient tumors based on intricate mapping and accurate detection of somatic variants. Resulting somatic variants and copy number variations (CNVs) were compared in 70 cases with trio samples. We classified the PDX mice as good models when >10% of somatic variants in patient tumor sample were replicated in the PDX mice. We obtained 40 good models out of 70 cases (success rate of 57%). The CNV profiles of patient and PDX tumors were similar in successful cases. Next, we developed a computational pipeline to identify somatic mutations for exome sequencing data of PDX mouse when patient normal or tumor data were missing. Extensive filtering processes were used to remove mouse-originated mutations and germline mutations. We tested our pipeline for 70 trio cases of lung cancer, and demonstrated that we could retrieve most of genuine somatic mutations without too much of false positives without patient reference tissues. Our results highlight the power, cautions, and limits of PDX sequencing data.

**A tailored topic model integrates both nucleotide context and genomic location heterogeneity in mutational process profiling.** *S. Li, M. Gerstein<sup>1,2,3</sup>.* 1) Computational Biology and Bioinformatics, Yale University, New Haven, CT; 2) Department of Molecular Biophysics and Biochemistry, Yale University, New Haven, CT; 3) Department of Computer Science, Yale University, New Haven, CT.

Multiple endogenous and exogenous mutational processes modify cancer genome and leave distinct fingerprints over time, including somatic alterations both before the cancer initiation and during cancer development. Noticeably, they exhibit characteristic genomic location preferences and mutational nucleotide context biases. In a generative model, multiple latent processes generate mutations drawing from their corresponding nucleotide context distributions ("mutation signature"). By sequencing cancer sample, we observe mutations accumulated from mixed mutation processes that are unevenly operative in different regions of the genome. Several mutation processes have been recognized by both computational and experimental studies and associated with known etiologies. Mutation is the cornerstone of tumorigenesis and understanding the fundamental underlying processes helps gain insights of cancer initiation and development. One key issue is to disentangle the mixed mutational processes in cancers mutation profiles. Previous work assumed these processes are evenly distributed when learning them, although post-analysis found they show genomic location preference. Here we propose a topic model that organically encodes mutation heterogeneity of both genomic location and mutational nucleotide context. Our model allows mutational processes smoothly evolving as dictated by the genomic location and features. Each mutational process has a characteristic nucleotide context distribution to reflect the underlying chemical and biological biases. Additionally, to avoid the nucleotide context complexity blowing up exponentially, our model parsimoniously builds the context tree by pruning less informative subtrees. By simultaneously learning mutational processes from both genomic features and nucleotide context, our model leads to robust and biologically interpretable mutational processes inference. Moreover, consolidating these two dimensions of heterogeneity gives us a chance to better portray mutational processes and investigate the vibrant interplay between them. We demonstrated the performance of our model on both simulated data and real world cancer data.

**Copy number segmentation with left-to-right hierarchical Dirichlet process hidden Markov model and segment clustering.** *K. Liao<sup>1</sup>, W. Hsieh<sup>2</sup>.* 1) Department of Computer Science, National Tsing-Hua University, Hsinchu City, Taiwan; 2) Institute of Statistics, National Tsing-Hua University, Hsinchu City, Taiwan.

Hidden Markov model (HMM) is a powerful statistical tool and is often used to analyze copy number data. A limitation of the standard HMM is that the number of states is fixed. Although the number of states can be selected using model selection methods such as Bayesian information criterion, they are mostly computationally expensive and there is no consensus on the optimum method (Harati Nejad Torbati et al., 2016). Hierarchical Dirichlet process hidden Markov model (HDPHMM) is a variant of hidden Markov model which allows unbounded number of states. The number of states can be automatically decided with Gibbs sampling methods. However, standard HDPHMM only allows ergodic structure with time-homogeneous state transition probability and this leads to relatively uniform lengths of segments with the same state. We developed a variant of HDPHMM called left-to-right HDPHMM with segment clustering (LRC-HDPHMM), which allows the same state to change state transition probability over time. Our method is based on a variant of HDPHMM called LR-HDPHMM which implements non-ergodic structure by disabling state transition from right to left. Although LR-HDPHMM is free from relatively uniform segment length, the same state cannot be revisited again. We solved this problem by clustering segments using another Dirichlet process which generates the state space of interest. Simulation study showed that LRC-HDPHMM is better than the standard HDPHMM in that it allows relatively variable lengths of segments with the same state. We applied our method to the analysis of subclonal copy number data. Compared to other HMM-based methods, our model has more flexible state transition probability and allows unbounded number of subclones and copy number. Furthermore, our method can be easily extended to jointly analyze multiple samples from the same tumor.

**Heterogeneous deconvolution of mixed tumor expression - DeMix-Py.** *R. Liu<sup>1,2</sup>, W. Wang<sup>3</sup>, C. Huang<sup>4</sup>, H. Zhu<sup>1</sup>.* 1) Department of Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX; 2) Department of Statistics, Rice University, Houston, TX; 3) Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX; 4) Department of Biostatistics, UNC at Chapel Hill, Chapel Hill, NC.

**Introduction:** Tumor samples normally contain non-unique tissues such as immune or healthy tissues, which leads to estimation error of gene expression signatures associated with cancer diagnosis and main therapy. The existence of mixed tumor samples consequentially affects gene expression profiling commonly performed under RNAseq and based transcriptomics. The physical purification is generally infeasible, therefore, in silico dissection of mixed tumor samples is an expecting tool that needs to be precedent to analyze gene expressions. **Methods and Results:** We present a frequentist model (DeMix-Py) applicable for RNAseq data follow a negative-binomial distribution. In DeMix-Py, the gene expressions are assumed to be observable from both unmatched pure normal tissue samples and mixed tumor tissue samples (mixtures of tumor tissue and health tissue), where the normal tissue and tumor tissue are assumed to follow the negative-binomial (NB) distribution. In order to estimate the mixture proportion and the parameters in NB distribution, our DeMix-Py proposes a three-step strategy: (i) estimating parameters in NB distribution for normal tissues; (ii) estimating the mixture proportion and parameters in NB distribution for tumor tissues; and (iii) calculating the normal tissue expression and tumor tissue expression. Simulation studies show that DeMix-Py performs well in both deriving the mixture proportion of tumor tissue in various gene expression datasets and calculating the tumor tissue expression for each gene samples with extremely heterogeneity. Moreover, DeMix-Py outperforms the existing Bayesian method in term of computational complexity for large-scale data analysis. **Conclusion:** The proposed frequentist DeMix-Py method provides an effective deconvolution way of mixed tumor expression. It is a natural route that offers uncertainty measures for proportions through posterior inference.

**Identification of germline copy number variations (CNVs) using targeted sequencing data on 6q in hereditary lung cancer families.** D. Mandal<sup>1</sup>, D. Tran<sup>1</sup>, K. Wood<sup>1</sup>, A. Musolf<sup>2</sup>, M. Badoo<sup>3</sup>, M. de Andrade<sup>4</sup>, C. Gaba<sup>5</sup>, P. Yang<sup>6</sup>, M. You<sup>6</sup>, M. Anderson<sup>7</sup>, A. Schwartz<sup>8</sup>, S. Pinney<sup>8</sup>, C. Amos<sup>9</sup>, J. Bailey-Wilson<sup>2</sup>. 1) Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) National Human Genome Research Institute, National Institutes of Health, Baltimore, MD; 3) Tulane Cancer Center, New Orleans, LA; 4) Mayo Clinic, Rochester, MN; 5) University of Toledo Dana Cancer Center, Toledo, OH; 6) Medical College of Wisconsin, Milwaukee, WI; 7) University of Cincinnati College of Medicine, Cincinnati, OH; 8) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 9) Geisel School of Medicine, Dartmouth College, Lebanon, NH.

Family history is a significant risk factor for lung cancer (LC). About 10% of lung cancer cases (22,000 cases per year in the U.S.) have at least one first-degree relative affected with lung cancer, and 25% of cases have at least one first- or second-degree affected relative. Previous multipoint linkage analyses of hereditary lung cancer families ( $\geq 3$  LC cases/family) collected by the Genetic Epidemiology of Lung Cancer Consortium detected significant linkage to the 6q25 region. To identify germline genetic variants, targeted sequencing of 6q23-6q27 was obtained. Using these sequencing data we have performed analyses to identify germline copy number variations (CNVs). CNVs have been reported on lung cancer cell lines and somatic samples; however, no germline specific CNVs have been reported in high-risk LC families. The objective of the present study is to detect germline CNVs from the targeted sequencing data in hereditary lung cancer (HLC) families that might be responsible for increased lung cancer susceptibility in these families. In addition to identifying CNVs, transmission of germline CNVs in these families will be detected in multiple generations using targeted sequencing data on affected and informative unaffected family members in future. The nine most informative high-risk HLC families ( $\geq 4$  LC cases/family) on whom we have targeted sequencing data included 25 affected and 55 informative unaffected family members. Phenotype, genotype, and smoking data are available on all family members. A CNV-specific algorithm incorporated in CANOES (<http://www.columbia.edu/~ys2411/canoes/>) was used in order to successfully call and identify germline CNVs. To confirm, CNVs were then visualized independently using Integrative Genomics Viewer (IGV). We have identified germline CNVs on five genes, including *EYA4*, *PARK2*, *RGS17*, *ARID1B*, and *NOX3*, in four LC families. These genes were identified earlier as candidates using either linkage analysis of the HLC families or by targeted sequencing analysis of 6q23-25. CNVs on these genes are present in more than one HLC family. Our findings suggest that the identified genes warrant further investigation to unveil functional mechanisms in the HLC families. In the long run, identification and hereditary transmission of these germline CNVs might be useful in conjunction with the identification of other genomic variants in the detection of high-risk individuals with multiple cases of lung cancer in the families.

**ViFi: Virus integration and fusion identification in tumor samples.** N. Nguyen, V. Deshpande, J. Luebeck, V. Bafna. Computer Science and Engineering, University of California, San Diego, La Jolla, CA.

Viral infection followed by integration into the human genome has been shown as a driver of tumorigenesis, particularly in cervical cancer and hepatocellular carcinoma (HCC). Detecting viral integrations from NGS technology, however, is a challenging task. One problem hindering existing tools is separating out true integrations from false positives integrations. For example, integrations from the Hu et al., Nat. Genet. 2015 study have been challenged as false positives integrations as a result of sequencing artifacts (Dyer et al., Nat. Genet. 2015). We developed Virus Integration and Fusion Identification (ViFi), a tool for detecting viral integrations from WGS data and human-virus fusion mRNA from RNASeq data. ViFi uses a combination of reference-based mapping and phylogenetic modeling to identify viral reads, and incorporates the mappability scores to reduce false positive detections. The end result is a tool that can accurately detect viral integrations, even when the viruses are highly mutated or are not found in the reference genomes. We present a comparison of ViFi to a competing tool, VERSE, on both simulated and biological datasets with experimentally verified integrations. In a simulation study, both ViFi and VERSE have high precision and recall on the easy model conditions. However, on the hardest model condition where the integrated virus is only 65% similar to the closest related reference virus, the use of phylogenetic modeling allows ViFi to accurately detect viral integrations with a precision and recall of 88%, while VERSE fails to detect any integration. On the biological datasets, ViFi detects an additional integration compared to VERSE. We applied ViFi to 68 cervical cancer samples with matched WGS and RNA-Seq data. We found integrations in 51 samples, of which 49 contained fusion mRNA sequences. Importantly, genomic segments with integrations had increased expression of nearby human mRNA (2.5 fold increase), with significantly higher expression when human-viral fusion mRNA are present (5.5 fold increase). Surprisingly, we found that integration also results in the expression of proximal LTR and LINE elements (3.5 to 5.3 fold increased expression when fusion mRNA is present). Guided by previous results that implicate fusion HBV-LINE1 with increased tumor susceptibility in HCC (Lau et al. Cancer Cell 2014), our findings highlight the need to explore the roles of LINE and LTR elements in HPV pathogenesis in cervical cancer.

**Expanding GEMINI to annotate and prioritize subclonal mutations in heterogeneous tumors.** *T. Nicholas*<sup>1,2</sup>, *B. Pedersen*<sup>1,2</sup>, *X. Huang*<sup>1,2</sup>, *Y. Qiao*<sup>1,2</sup>, *G. Marth*<sup>1,2</sup>, *A. Quinlan*<sup>1,2</sup>. 1) Human Genetics Department, University of Utah, Salt Lake City, UT; 2) USTAR Center for Genetic Discovery, University of Utah, Salt Lake City, UT.

DNA sequencing has unveiled extensive tumor heterogeneity in several different cancer types, with many exhibiting substantial clonal substructures. Considerable genetic variation exists within individual tumors and between metastatic sites from shared phylogenies, highlighting ongoing tumor growth and evolution. These differences can be further magnified over time by selective pressures introduced by different treatments. Properly identifying and tracing this variation throughout the expansion and progression of a tumor represents a significant challenge. Furthermore, being able to prioritize and focus on mutations most likely to contribute to tumor evolution or that could serve as potential therapeutic targets represents an ongoing problem, but is crucial towards determining possible clinical care. GEMINI is an effective tool for exploring genetic variation by enabling the querying of multiple genome annotations into a single database. Here we describe our progress towards an adaptation to the GEMINI framework that is more ideally suited for the complex patterns of genetic variation inherent to the study of tumor heterogeneity across multiple tumor biopsies. This is accomplished by enhancing GEMINI variant annotation to include tumor clonal specifications. Additionally, by incorporating existing tools and databases that facilitate the interpretation of cancer mutations (e.g., CIVIC, DGIdb, VEP, CRAVAT) into the GEMINI framework, the identification of mutations that may be driving clonal evolution is simplified. The advances to the GEMINI framework that we are developing will better enable cancer scientists and research oncologists to discern genetic details, at a clonal level, of how a tumor evolves over time, and better interpret these mutations in the context of potential patient care.

**725T**

**Identification and characterization of novel oncogene candidates in invasive breast carcinoma.** *D.G. Piqué*<sup>1,2</sup>, *J.M. Greally*<sup>2</sup>, *J.C. Mar*<sup>1,3</sup>. 1) Dept. of Systems and Computational Biology, Albert Einstein College of Medicine, Bronx, NY; 2) Dept. of Genetics, Albert Einstein College of Medicine, Bronx, NY; 3) Dept. of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY.

Invasive breast carcinoma (IBC) is the most common cancer in women worldwide. The overexpression of certain oncogenic mRNA isoforms, such as an *ERBB2* isoform that skips exon 16, drives resistance to the anti-cancer therapeutic trastuzumab and promotes the development of metastatic breast lesions. One characteristic of an oncogenic mRNA isoform is that it is highly expressed in a subgroup of tumors relative to normal tissue. However, both the prevalence and regulation of oncogenic mRNA transcript isoform expression in RNA-sequencing (RNA-seq) data from breast tumors remain largely unknown. Here, a novel statistical approach was developed for identifying oncogene candidate mRNA isoforms (OCs) based on the observation that oncogenes are overexpressed in a subset of tumors relative to normal tissue. From applying our approach to RNA-seq data from 113 paired tumor-normal breast tissue samples from TCGA, we identified five OCs, two of which have known roles in oncogenesis. In addition, several mRNA isoforms of the well-known breast cancer oncogene *ERBB2* share statistical properties with a theoretical OC, which shows that our statistical approach reflects patterns of known oncogene expression. To understand the factors that drive the overexpression of OCs in certain breast tumors, multivariate logistic regression that incorporated both clinical and molecular covariates such as DNA methylation and copy number variation (CNV) was conducted. Our results suggest that DNA methylation, particularly within introns, is a major factor associated with the overexpression of the full-length isoform of *CBX2*, an oncogene candidate that was identified using our method and that promotes metastasis in prostate cancer. *CBX2* overexpression in primary breast tumors was associated with the upregulation of mRNA isoforms involved in cell cycle-related processes, consistent with its potential role as an oncogene. Due to the low levels of *CBX2* mRNA expression in normal adult female tissue and availability of *CBX2* chromodomain inhibitors, pharmacologic inhibition of *CBX2* activity may serve as a therapeutic target in aggressive subtypes of breast cancer. The identification of oncogene candidates based on mRNA expression profiles between tumor and normal samples may yield fundamental insights into the molecular regulation of transcriptional programs in cancer and uncover new therapeutic targets to treat aggressive subtypes of cancer.

**Pathogenicity of Mutation Analyzer (PathoMAN): A fast, automation of germline genomic variant curation in clinical sequencing.** V. Ravichandran, K. Offit, J. Vijai. Clinical Genetics Service, Memorial Sloan Kettering Cancer Center, New York, NY.

Multiplexed gene sequencing for clinical testing, generates large number of genetic variants. The guidelines for variant curation provided by the ACMG requires the aggregation of multiple lines of genomic data evidences from diverse sources and familiarity with the scientific literature and publicly available databases. We know of no computational tools that automates this, which would provide uniformity to the process and significantly speed up the interpretive process. We present *Pathogenicity of Mutation Analyzer (PathoMAN)*, a tool that automates germline genomic variant curation from clinical sequencing. PathoMAN aggregates multiple tracks of genomic, protein and disease specific information from public sources such as ClinVar, ExAC, UniProt, 1000 genomes, dbNSFP and locus specific databases. Variant and gene specific annotations are used to classify per ACMG rubric. We analyzed 2500 manually curated and classified, high quality variants in 180 genes from three large, recently published studies to quantify the performance of PathoMAN. The dataset consisted of 242 pathogenic/likely pathogenic (P/LP), 1272 benign/likely benign (B/LB) and 1261 variants of uncertain significance (VUS). We report the summary of PathoMAN classifications in 4 categories: concordance, discordance, discovery and loss of resolution when contrasted against the manual curation. As new data, we present the automated curation of 76 cancer predisposition genes using PathoMAN for the gNOMAD dataset, useful for gene burden tests. For the 3 published datasets on cancer, PathoMAN achieves an average of 75% and 60% concordance and 1.5% and 0.1% discordance for P/LP and B/LB respectively. PathoMAN resolves 12% of reported VUS as P/LP or B/LB. Although the average false positive rate was <3%, the lack of resolution of 30% of the variants, reflected the absence of evidence available in the public databases to classify genomic variants as pathogenic or benign based on the ACMG guidelines. We describe the bottlenecks to automation of variant curation and propose new standards. We propose, a new code scheme for 5 ACMG classes that were not utilizable in the present scenario, which we hope will be used by the community to enhance the utility of the ACMG guidelines. In addition, the algorithm provides clinical and research labs to perform rapid identification of pathogenicity calculation of variants discovered and could be a valuable tool for quick turnaround of clinical and research results.

**Weighted similarity network fusion through integrating genomic functional annotation.** P. Ruan<sup>1</sup>, S. Wang<sup>2</sup>. 1) Department of Statistics, The George Washington University, Washington, DC; 2) Department of Biostatistics, Mailman School of Public Health, Columbia University, New York, NY.

Recent technology developments have made it much easier to collect various kinds of genome-wide data, which provides scientists a great chance to utilize the information from different data sources to solve complex problems such as classification of diseases subtypes or identification of disease related genes. Many data-integration methods have been developed to meet such needs. Among these methods, similarity network fusion method, which effectively fuses the similarity networks of samples for each data sources into one fused network, has shown great potential for capturing similarities of samples and further identifying disease subtypes. Here, we propose a weighted similarity network fusion method, which adds weights to similarity networks by integrating genomic functional annotations, thereby improving the method's performance of disease subtypes classification. With information combined from gene expression and DNA methylation when both weighted by genomic functional annotations, we classified cancer subtypes more accurately across multiple TCGA (the Cancer Genome Atlas) cancer datasets than existing data-integration approaches. Further investigation on survival data confirmed the improved cancer subtype classifications.

**728T****Telomere length dynamics from whole genome sequencing using Telomeasure in progressing and non-progressing Barrett's esophagus.**

*J.M. Shelton<sup>1</sup>, T.G. Paulson<sup>2</sup>, M. Shah<sup>1</sup>, K. Arora<sup>1</sup>, R. Sanghvi<sup>1</sup>, X. Li<sup>2</sup>, C.A. Sanchez<sup>2</sup>, K. Oman<sup>2</sup>, B. Hubert<sup>2</sup>, B. Riley-Gillis<sup>1</sup>, E. Venturini<sup>1</sup>, A. Corvelo<sup>1</sup>, N. Robine<sup>1</sup>, D.M. Oschwald<sup>1</sup>, P. Galipeau<sup>2</sup>, B.J. Reid<sup>2</sup>.* 1) New York Genome Center, 101 Avenue of the Americas, New York, NY 10013, USA; 2) Fred Hutchinson Cancer Research Center PO Box 19024, Mailbox C1-157 Seattle WA 98109.

Barrett's esophagus (BE) is a generally benign metaplasia that develops as a protective adaptation to chronic acid reflux, but 5-10% of BE patients progress to esophageal adenocarcinoma (EAC) [1]. Because EAC is resistant to multiple treatment options [2] and currently has a poor patient survivorship [3], understanding the transition from BE to EAC would allow for better surveillance and treatment strategies. It has been hypothesized that telomere shortening may be involved in the development of chromosomal instability and the transition to EAC [4], but telomere dynamics have not been well characterized prior to a diagnosis of EAC. To identify differences in telomere length between EAC progressors and non-progressors, we performed whole-genome sequencing of esophageal epithelium from two groups of BE patients; forty who progressed to EAC and 40 with stable benign BE, matched by follow-up time. Purified BE epithelium from two locations in the esophagus and from a minimum of two times points, along with constitutive blood samples were collected and sequenced. To determine average telomere length in each sample, we developed a novel method – Telomeasure – that uses chromosome arm-level coverage to infer the number of telomeres and alignment to mock-human telomeres to estimate telomeric DNA content. Despite showing a strong correlation with estimates from a previously published tool (TelSeq [4]), Telomeasure is less affected by sequencing errors, variation in read length, and higher degrees of genomic instability, a frequent occurrence in BE samples. Consistent with previous studies, BE samples have in general shorter telomeres compared to their matching normal controls, which likely reflect higher cell turnover in the reflux-exposed esophagus. EAC progressors show significantly higher variability in telomere length and in telomere lengthening/shortening rate between T1 and T2 timepoints compared to non-progressors. Additionally, several telomere-associated genes were predominantly mutated in progressor samples. Copy number variants overlapping TERT, BCOR, RB1, CCNE1, TP53 and PDGFRA and mis-sense mutations in ASF1B, RTEL and TP53 were almost exclusively found in progressor samples. These results demonstrate the utility of Telomeasure for characterizing telomere dynamics from whole genome sequence data. [1] doi:10.1038/nrc2773 [2] doi: 10.1101/gr.214296.116. [3] doi: 10.1097/JTO.0b013e3182397751 [4] doi: 10.1038/ncomms6224. [5] doi: 10.1093/nar/gku181.

**729F****Practical noninvasive biomarkers: Identification of blood gene signatures for diagnosis of lung cancer.** *B. Song<sup>1,2</sup>, L. Shi<sup>1,2</sup>, Z. Yi<sup>1</sup>, W. Zhang<sup>1</sup>.*

1) Department of Medicine, Icahn School of Medicine at Mt. Sinai Hospital, New York City, NY; 2) Horace Mann High School, Bronx, NY.

Lung cancer is a leading cause of cancer related death with almost 160,000 deaths in the United States per year. One factor that significantly decreases a patient's chance of survival is late diagnosis, as there are minimal therapeutic treatments that are effective in late stage lung cancer. Even early in cancer development, however, lung cancer manifests itself with several distinctive genetic and genomic signatures. One of these is abnormal expression of genes which can affect cell growth and proliferation. Current studies of these focus on cancer tissues that require invasive biopsies from tumors. The approach presented in this study looked for mRNA biomarkers for lung tumor tissue that could be found in the blood, allowing for diagnosis from a simple blood test even at an early stage of the cancer development. Robust meta-analysis was performed to analyze mRNA expression profiles in blood from lung cancer patients. Using a training set of 4 mRNA expression lung cancer datasets with a total of 646 patients, 152 meta-genes were significantly over or under expressed in cancer patients compared to healthy individuals, many of these having functions in intracellular signaling cascades and glycerolipid metabolic processes. When these were compared to 2308 metagenes identified from lung tumor tissue expression profiles in 7 datasets with a total of 1636 patients, they yielded 33 overlapping metagenes. These 33 metagenes could effectively diagnose lung cancer status with an average AUC of 0.878 in the training set. They were validated in an independent lung cancer cohort with an average AUC of 0.939. The metagenes were also then applied in a cox regression model with patient survival data, and were shown to produce significant association with prognosis in 4 datasets ( $p=0.00406-2.68 \times 10^{-8}$ ). The blood biomarkers that were identified in this study could be a breakthrough that allows for development of an effective and quick assay for early diagnosis of lung cancer in a non-invasive and cost-effective manner.

**Identification of somatic tumor-only variants on 1120 solid tumor cases through intelligent variant filtration.** S. Van Vooren<sup>1</sup>, T. Stockley, PhD, FCCMG, FACMG<sup>2</sup>, M. Sukhai, PhD<sup>2</sup>, S. Kamel-Reid, PhD, FACMG<sup>2</sup>. 1) Agilent Technologies, Santa Clara, CA; 2) Genome Diagnostics, University Health Network, Toronto, Canada.

Tumor molecular profiling by next-generation sequencing (NGS) aims to use information on somatic tumor-specific variants to direct cancer treatment. A significant challenge in tumor molecular profiling is identifying tumor-specific variants in the presence of germline variants which are also identified during tumor testing. The majority of germline variants are benign changes not contributing to the cancer occurrence, although rare germline cancer predisposition variants may also be identified during the testing of tumor tissue. In order to identify true somatic tumor-specific variants, a common approach is the sequencing of both tumor and normal tissue (often peripheral blood), with variants from each tissue source used to classify variants as either somatic or germline. However paired tumor-normal testing leads to increasing costs due to the need to test both tissue sources. In addition paired tumor-normal testing may identify potentially unwanted incidental germline cancer predisposition variants. In this study, we present a solution that can improve the identification of somatic tumor-specific variants obtained from NGS testing of tumor tissue only, without the need to sequence normal tissue for comparison to germline variants. We evaluate the use of the Agilent Alissa platform (formerly Cartagenia Bench Lab NGS) to implement the lab's filtration strategy and assess performance of the approach on 1120 solid tumor cases for which paired tumor-normal NGS variant results were available at the Genome Diagnostics Lab at the University Health Network.

**Integrated somatic mutation detection from tumor-normal sequencing data using multiple calling methods.** Y. Wang, J. Li. Department of Human Genetics, University of Michigan, Ann Arbor, MI.

Multiple computational methods have appeared for calling somatic mutations based on next-generation sequencing data of matched tumor-normal pairs. The idea underlying most of these methods is to identify new alleles in the tumor sample or altered allele frequencies in the tumor that are statistically robust given the sequencing depth. However, several commonly adopted methods, such as *Mutect*, *Varscan* and *Strelka*, often detect very different sets of somatic variants. We sought to understand the source of such differences and found that some of these methods failed to consider the case of loss-of-heterozygosity (LOH), thus could not report Ref/Ref (or Alt/Alt) genotype in the tumor when the normal is Ref/Alt. Others relied on the Ref/Ref as the baseline genotype and failed to call the Ref/Alt in the tumor when the normal is Alt/Alt. Further, many of these methods assumed no tumor-normal mixing and would not leverage read count data to detect quantitative differences between the normal and tumor allele frequencies. We used an in-house exome sequencing data for a T-N pair at an average depth of 300X to compare *Mutect*, *Varscan*, and *Strelka*, and characterized their striking differences in the category of variants detected and their different cutoff values. We have since established a unified approach that combines the respective strengths of these methods. Our approach is to create a union list of called variants from these methods, combined with a parallel series of calls based on T-N swapping, and re-test the T-N allele frequencies using the Fisher's Exact test. The results thus obtained covered a much more complete catalog of somatic variants in all possible T-N allelic combinations and detected changes that occurred only in a fraction of the cells. Our approach is superior to those that simply combines multiple variants lists by majority vote, as it is built on the actual underlying allele count differences. Its sensitivity is directly linked to allele frequency alterations and the sequencing depth and averted the problem that different methods have distinct sensitivities and sometimes incomplete consideration of possible mutation types.

**Access and discover pathways from Pathway Commons.** *J.V. Wong<sup>1</sup>, I. Rodchenkov<sup>1</sup>, O. Babur<sup>2</sup>, A. Luna<sup>2,4</sup>, E. Demir<sup>2</sup>, C. Sander<sup>2,4</sup>, G. Bader<sup>1</sup>.* 1) Department of Computational Biology, University of Toronto, Toronto, Ontario, Canada; 2) Department of Computational Biology, Oregon Health & Science University, Portland, OR; 3) Dana-Farber Cancer Institute, Boston, MA; 4) Department of Cell Biology, Harvard Medical School, Boston, MA.

Pathway Commons ([www.pathwaycommons.org/](http://www.pathwaycommons.org/)) serves researchers by integrating data from public pathway and interaction databases and disseminating it in a uniform fashion. The knowledge base is comprised of metabolic pathways, genetic interactions, gene regulatory networks and physical interactions involving proteins, nucleic acids, small molecules and drugs. Alongside attempts to increase the scope and types of data, a major focus has been the creation of user-focused tools and resources that facilitate access, discovery and application of existing pathway information to facilitate day-to-day activities of biological researchers. For those wishing to browse and discover pathways within the collection, we offer a web-based 'Search' application that enables users to query by keyword and visualize ranked search results. 'PCViz' is a web tool that accepts gene names and returns a customizable interaction network visualization based upon pathway data resources. These complement existing desktop software add-ons linking Pathway Commons to the Cytoscape (CyPath2) network analysis tool and the R (paxtoolsr) programming language. To facilitate analysis and interpretation of experimental data - for instance, enrichment studies that distill pathway alterations from underlying gene expression changes - pathway data file downloads can be directly used in software tools such as Gene Set Enrichment Analysis. For those wishing to learn more about pathway resources and analysis, an online 'Guide' includes case studies and guided workflows. Ongoing development of web apps will enhance the accessibility to pathways and integrate support for visualization and interpretation of experimental data.

**733W**

**Identification of germline copy number variations (CNVs) using whole-exome sequencing data in Caucasian and African American men with hereditary prostate cancer.** *K. Wood<sup>1</sup>, D. Tran<sup>1</sup>, M. Baddoo<sup>2</sup>, M. DeRycke<sup>3</sup>, S. Riska<sup>3</sup>, S. McDonnell<sup>3</sup>, D. Schaid<sup>3</sup>, S. Thibodeau<sup>3</sup>, D. Mandal<sup>1</sup>.* 1) Department of Genetics, LSU Health Sciences Center, New Orleans, LA; 2) Tulane Cancer Center, New Orleans, LA; 3) Mayo Clinic, Rochester, MN.

Prostate cancer (PCa) is the 2nd leading cause of cancer-specific deaths among American men, and there is a significant racial disparity between African American (AA) and Caucasian (CAU) affected men, with AA men having a 60% higher incidence rate than their CAU counterparts. Due to limited genomic data on AA men with PCa, no ancestry specific genetic variants have been detected to date. So far, somatic copy number variations (CNVs) have been documented in PCa tumors, but changes in CNV have not been studied in germline DNAs from hereditary PCa (HPC) cases, which accounts for approximately 15% of PCas. The goal of the present study is to identify germline CNVs in whole exome sequencing (WES) data on cases from HPC families ( $\geq 3$  PCa affected/family) and population controls. We hypothesize that rare germline CNVs in actionable genes contribute to higher incidence of PCa in AA HPC men. We have WES data on 13 affected cases from 13 independent HPC families and 10 population controls. Of the 13 cases, 11 are CAU and 2 are AA, with the age at diagnosis ranging from 51 to 75 years. A CNV-specific calling algorithm, CANOES (<http://www.columbia.edu/~ys2411/canoes/>), was used to successfully detect germline CNVs by modeling read counts using a precise distribution. To confirm, CNVs were then visualized independently using Integrative Genomics Viewer (IGV). CANOES called 466 germline CNVs on CAU, 303 of which were confirmed using IGV; 18 of them are located within cancer-related genes. Seven of those cancer-related genes harboring germline CNVs were also previously shown to be associated with PCa tumors, including *GSTM1*, *DMBT1*, *GSTT1*, *POTEM*, *UGT2B17*, *MTUS1* and *PTGER*. Four of the 7 germline CNVs in cancer-related genes were found only among the CAU HPC cases and not in the controls. CANOES called 132 germline CNVs from the AA WES datasets, 30 of which were confirmed using IGV, and 3 of those were within cancer-related genes. Two of these 3 germline CNVs were within genes that have previously been associated with PCa tumors in CAU, including *SPAG11A* and *CKMT1B*. The preliminary analysis in our dataset shows no overlap between germline CNVs identified in AA and CAU, further suggesting that ancestry plays a significant role in PCa health disparity. Documentation of these CNVs in PCa tumors emphasizes the importance of studying these genes further. In general, the identification of germline CNVs within HPC families will facilitate PCa screening in the future.

**Optimal design of single cell studies for detecting and quantifying clonal subpopulations.** *J. Yu<sup>1</sup>, C. Li<sup>1</sup>, O. De La Cruz C.<sup>2</sup>* 1) Department of Population and Quantitative Health Sciences, Case Western Reserve University, Cleveland, OH; 2) Department of Mathematical Sciences, Kent State University, Kent, OH.

**Motivation.** Cancer cell populations often evolve, generating distinct clonal subpopulations. Characterizing the clonal structure of a tumor is valuable for understanding the biology of the disease. Recent advances in single-cell DNA sequencing technologies enable the characterization of clonal architecture in heterogeneous cell populations. In studies of clonal detection with single-cell sequencing, there is usually a trade-off between the number of cells assayed and sequencing depth per cell. This study aimed to provide a guideline for determining the optimal number of cells and sequencing depth needed for clonal detection. **Methods.** We mimicked experimental designs with various numbers of cells and overall sequencing depths by subsampling cells and paired reads from a tumor single-cell sequencing dataset for 6 patients with childhood acute lymphoblastic leukemia (Gawad et al, 2014). We repeated the subsampling 5 times and results were averaged over the 5 replicates. **Results. 1)** Our results suggest that the number of cells has a higher impact on clustering results than sequencing depth, and that under a fixed sequencing budget, more cells with lower depth tend to yield the correct number of clusters with higher probability, as well as lower misclassification rate. **2)** To evaluate how low the depth can be without losing information on clone detection, we identified the depth at which  $\geq 80\%$  of the mutants present in a cell can be detected in  $\geq 90\%$  of the cells. We used an exponential model to fit data for each cell. Our results show that the depth needed for mutant detection varies from patient to patient, ranging from 30X to 88X. **3)** We also evaluated a few potential factors affecting the robustness of clustering results. We found that detection of a small clone tends to require a high number of cells and relatively high depth, that large clones tend to be split into two clusters at a low depth, and that results tend to be more sensitive to reduction in number of cells and depth when the clustering is driven by relatively few somatic mutations.

**735F**

**Evaluating relationships between pseudogenes and genes: From pseudogene evolution to their functional potentials.** *Y. Zhang, T. Johnson, S. Yu, K. Huang.* Department of Biomedical Informatics, College of Medicine, The Ohio State University, Columbus, OH.

Pseudogenes are fossil relatives of genes. They have long been thought of as "junk DNAs", since they do not code proteins in normal tissues. Although most of the human pseudogenes do not have noticeable functions,  $\sim 20\%$  of them exhibit transcriptional activity. There has been evidence showing that some pseudogenes adopted functions as lncRNAs and work as regulators of gene expression. Furthermore, pseudogenes can even be "reactivated" and translated into proteins in some conditions, such as cancer initiation. All the above have shown that pseudogenes could have functional potentials in the genome. In this study, we developed a novel approach integrating graph analysis, sequence alignment and functional analysis to evaluate pseudogene-gene relationships in human genome: (a) Find candidate regulatory target genes. Two known transcriptional level regulatory mechanisms of pseudogenes are RNA interference, and transcription products serving as competitive miRNAs binding targets. Both of these two mechanisms rely on sequence similarity between the pseudogenes and regulatory target genes. It is intuitive to find the candidate target genes by sequence similarity. Thus, we built a database of pseudogene-gene (PGG) families. Each family contains one or multiple pseudogenes and homologous genes (potential target genes) as members. We have developed the approach for constructing PGG families using sequence alignment and network analysis, and we are optimizing the pipeline for efficient compute performance using GPUs. (b) Detect key mutation signatures within each family. This database will also provide a resource for identifying mutation signatures that switch on/off the function of pseudogenes. For example, loss-of-function mutations that silenced pseudogenes, or frameshift mutations that coded abnormal peptides. (c) Infer functional annotations of pseudogenes. Functional annotations (e.g. GO terms) will be overlaid on the PGG networks, and functions of pseudogenes will be inferred from known annotations of its neighbors (i.e. other nodes in the same network). In summary, evaluating the relationships between pseudogenes and their gene counterparts could help us reveal the evolutionary path of pseudogenes and associate pseudogenes with functional potentials. It also provides an insight into the regulatory networks involving pseudogenes with transcriptional and even translational activities.

**Prediction of genome-wide DNA methylation in locus-specific repetitive elements.** Y. Zheng<sup>1,2</sup>, B. Joyce<sup>1</sup>, L. Liu<sup>1</sup>, Z. Zhang<sup>1</sup>, W. Kibbe<sup>3</sup>, W. Zhang<sup>1</sup>, L. Hou<sup>1</sup>. 1) Center for Population Epigenetics, Northwestern University, Chicago, IL; 2) Division of Health and Biomedical Informatics, Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL; 3) Center for Biomedical Informatics and Information Technology, National Cancer Institute, Rockville, MD.

DNA methylation in repetitive elements (RE) suppresses their mobility and maintains genomic stability, and decreases in it are frequently observed in tumor and/or surrogate tissues. Averaging methylation across RE in the genome is widely used to quantify global methylation. However, methylation may vary in specific RE and play diverse roles in disease development, thus averaging methylation across RE may lose significant biological information. The ambiguous mapping of short reads by and high cost of current bisulfite sequencing platforms make them impractical for quantifying locus-specific RE methylation. Although microarray-based approaches (particularly Illumina's Infinium methylation arrays) provide cost-effective and robust genome-wide methylation quantification, the number of interrogated CpGs in RE remains limited. We report a random forest-based algorithm (and corresponding R package, *REMP*, available in Bioconductor) that can accurately predict genome-wide locus-specific RE methylation based on Infinium array profiling data. We validated its prediction performance using alternative sequencing and microarray data. Testing its utility with The Cancer Genome Atlas data demonstrated that our algorithm offers more comprehensively extended locus-specific RE methylation information that can be readily applied to large human studies in a cost-effective manner. We found that hypomethylated RE loci in cancer may play a role in transcription activation, potentially impair chromatin stability, and regulate key cancer-related pathways. Specifically, we observed a significant positive correlation between intronic locus-specific RE methylation and the host gene expression, which supported the hypothesis that DNA methylation in intronic regions may potentially silence RE to maintain a gene's efficient transcription. Locus-specific RE methylation also achieved significantly higher power than global methylation in discriminating tumor from normal tissues (area under the ROC curve = 98.3% vs 74.1%, respectively,  $p < 0.001$ ), which underscored the valuable information added by our algorithm. Our work has the potential to improve our understanding of the role of global methylation in human diseases by leveraging methylomic data from large-scale human studies and identify novel RE loci that may exert important biological and pathological effects for cancer early detection and diagnosis.

**Incorporating multiple NGS read features enables detection of transposon insertions across the genome.** A. Zimmer, A. Robertson, Z. Mahkovec, G. Mishne, J. van den Akker. Color Genomics, Burlingame, CA.

Large insertions can disrupt coding sequences and gene function. Genomic insertions can arise from multiple sources, including errors in homologous recombination and the transposition of mobile elements (transposons). Transposons, genetic elements that can transpose from one location to another, make up a large fraction of the human genome. While the majority of transposons have lost the ability to be transposed, some are still active and several such variants with clinical relevance have been published, including a Portuguese founder mutation in *BRCA2* (c.156\_157insAlu). Detecting insertions, and transposon insertions in particular, poses several technical challenges in capture-based NGS panels: (i) large insertions are a major disruption to the genomic sequence and can affect the hybridization between targeting probes and the sample DNA; (ii) a transposon inserted sequence is present many times in the genome, causing problems with alignment (iii) the inserted sequence is generally longer than NGS reads, so no reads span the inserted sequence; (iv) transposon insertions often include A-rich linker sequences which cause sequencing artifacts. Here, we describe the development of a novel method to identify insertions in NGS data. Our algorithm to detect structural variants is based on reads where one end aligns to the region of interest, but the other does not, i.e. soft-clipped reads. For positions where there are a significant number of soft-clipped reads at the same location, we compute several features of the reads and the locus which can be used to distinguish true insertions from NGS artifacts. The most important features were: number of soft-clipped reads, fraction of soft-clipped reads, sequence agreement of the soft-clipped reads, GC content of the locus, sequence uniformity of the locus, number of reads supporting a nearby large indel, and number of inverted reads. A second step uses local assembly to estimate the inserted sequence; for insertions at the size of an Alu element (~300 bp), this is typically sufficient to uniquely identify the exact element in public databases. We validated this method by sequencing samples identified from the 1000 Genomes data set that carry insertions in the genes of the Color Test. In conclusion, this caller is able to identify large insertions based on a single breakpoint and independent of the inserted sequence. It can therefore be used to call insertions across the genome.

**738F**

**A novel algorithm to identify somatic copy-number alterations which delivers high accuracy in targeted resequencing of cancer genes from tumor specimens.** *F.M. De La Vega<sup>1,2</sup>, S.A. Irvine<sup>2</sup>, K. Gaastra<sup>2</sup>, Y. Pouliot<sup>2</sup>, R.T. Koehler<sup>2</sup>, D. Mendoza<sup>2</sup>, P. Cavales<sup>2</sup>, A. Vilborg<sup>2</sup>, L. Trigg<sup>2</sup>.* 1) Stanford University School of Medicine, Stanford, CA, USA; 2) TOMA Biosciences, Foster City, CA, USA; 3) Real Time Genomics, Ltd., Hamilton, New Zealand.

Next-generation, deep sequencing of gene panels is being adopted as a diagnostic test to identify actionable mutations in samples from cancer patients. Targeted sequencing involves positive selection of gene exons typically involving PCR at some stage in the protocol. PCR creates GC-content and length biases that skew the representation of DNA fragments within the sequenced library. Combined with the small counts of reads in some of the targeted exons, this results in reduced sensitivity to the identification of copy number alterations (CNA). Here we present a novel CNA calling algorithm optimized for targeted resequencing data delivering high sensitivity and specificity by comparing test data to a negative control or to a model constructed from normal samples. Coverage is corrected for G+C content, a median normalization is applied, and the Mumford-Shah energy function is used for segmentation. We benchmarked and validated this algorithm with both simulated data and with real sequencing data obtained with an oligonucleotide-selective sequencing (OS-Seq) enrichment assay for a 130-cancer gene panel with minimal PCR bias. We sequenced to a >1,000X on-target median depth a set of cancer cell lines with orthogonally verified CNAs and a new reference material comprised of synthetic CNA sequences spiked on a well-known Genome-in-a-Bottle cell line background (SeraCare, Inc). A distinctive feature of our method is its ability to filter raw calls to a specified sensitivity and specificity trade-off by selecting empirical score thresholds based on the analysis of the reference datasets. We show that we can detect all true hemizygous deletions and amplifications from about 0.6 to more than 150 excess copies over the diploid background, with a FDR <5% across the 130 genes in the panel. We find an excellent correlation ( $r^2=0.97$ ) between the copy number estimated by our method and the results from digital droplet-PCR assays. We compared our calls with those from the CNVkit and VEGAWES programs using ROC curve analysis. Our results show that our CNA caller outperforms these other programs in terms of ROC area under the curve and overall accuracy. To our knowledge this stringent evaluation with an absolute ground truth from defined reference materials has never been performed to evaluate NGS CNA algorithms and assays. We suggest that our benchmarking protocol could be used to validate clinical sequencing analysis pipelines that provide CNA calls.

**739W**

**AmpliconArchitect: On the fine structure of focal amplifications in cancer.** *V.B. Deshpande<sup>1</sup>, J. Luebeck<sup>2</sup>, M. Bakhtiari<sup>1</sup>, N. Nguyen<sup>1</sup>, K.M. Turner<sup>2</sup>, P.S. Mische<sup>3,4,5</sup>, V. Bafna<sup>1</sup>.* 1) Department of Computer Science and Engineering, University of California at San Diego, La Jolla, California 92093, USA; 2) Bioinformatics and Systems Biology Program, University of California, San Diego, La Jolla, California 92093, USA; 3) Ludwig Institute for Cancer Research, University of California at San Diego, La Jolla, California 92093, USA; 4) Moores Cancer Center, University of California at San Diego, La Jolla, California 92093, USA; 5) Department of Pathology, University of California at San Diego, La Jolla, California 92093, USA.

Focal amplifications or amplicons are copy number(CN) gains of small portions of the genome, as opposed to large-scale aneuploidies. We recently showed that extrachromosomal DNA (ecDNA) drives oncogene amplification and tumor growth in as many as 40% of all human cancer (Turner et al, Nature 2017). ecDNA breaks the eukaryotic norm of tumor evolution and is interconvertible with intrachromosomal amplification as homogeneously staining regions (HSRs). Amplicons often undergo multiple rearrangements and understanding their structure sheds light on the nature of ecDNA. However, traditional structural variant callers are incapable of analyzing and representing the complex structures. We present AmpliconArchitect (AA), a tool which predicts the structure of complex focal amplifications from whole genome sequencing of cancer samples. AA performs CN-aware detection of amplified regions and rearrangements to construct a breakpoint graph and decomposes the graph into cycles. Finally, AA provides an interactive visualization of the cycles in the genomic context to explore all candidate amplicon structures. AA accurately predicted complex structures in 960 diverse simulations with 85% accuracy even at low sequencing coverage ( $\geq 1\times$ ). We applied AA to 117 samples from 13 cancer subtypes and found 157 amplicons in 55 samples. We compared their distribution with the CN gains from 3919 SNV array samples from TCGA. Amplicon size ( $\mu\approx 1.8\text{Mbp}$ ) and CN ( $\mu\approx 3.6$ ), each, showed exponential distributions. Amplicons containing multiple genomic regions were larger than localized amplicons ( $p<5e-4$ ). FISH analysis of 37 amplicons showed that while ecDNAs tend to be smaller (<5Mbp) with high CN (up to 200) and HSRs can be larger (up to 20Mbp), there was no clear separation in their distributions as expected from their interconvertible nature. Amplicon structure was preserved across biological replicates and cancer subtypes were enriched for specific oncogenes. In a second study, analyzing 69 cervical cancer samples infected with human papillomavirus (HPV), we found HPV integration into human genome in 56 samples and 61 chimeric human-viral amplifications in 42 samples. While there is oncogene enrichment, these cases form a small portion of the amplicons. A majority of the amplicons have "bifocal" circular integration as opposed to the intuitive notion of viral integration at a single cut site, suggesting human-viral chimeric ecDNAs containing segments from multiple chromosomes.

**740T****Tumor mutation burden (TMB) as a marker for DDR and IO combination.**

Z. Lai<sup>1</sup>, R. McEwen<sup>2</sup>, D. Hodgson<sup>2</sup>, B. Dougherty<sup>1</sup>, J.C. Barrett<sup>1</sup>, J. Dry<sup>1</sup>. 1) AstraZeneca, Waltham, Ma; 2) AstraZeneca, Cambridge, UK.

Both immune checkpoint inhibitors (IO therapies) and PARP inhibitors have been shown to greatly benefit patients in certain cancers, though many patients eventually relapsed to the therapies. There are growing evidences that TMB might be a tumor agnostic marker for predicting IO therapy responses. Deficiencies in DDR (DNA Damage Response) can lead to damaged DNA un-repaired or mis-repaired, which would contribute to increasing tumor mutation burden. Tumors with certain DDR deficiencies, such as BRCA1 and BRCA2 mutations, have been shown to be sensitive to PARP inhibitors, both pre-clinically and clinically. We hypothesize that patients with DDR deficiencies, defined as those harboring germline or somatic mutations in HRR (Homologous recombination repair) genes, will have higher TMB and more immune active, and can potentially receive greater benefit from the combination of DDR and IO therapies. We investigated the relationship between DDR deficiencies and TMB across TCGA (The Cancer Genome Atlas) disease cohorts, as well as some internal datasets from DDR clinical studies. In addition, we also examined the relationship between TMB and immunoscores, which quantify the in situ immune infiltrate and have been demonstrated to be a prognostic factor. We found across many cancer types, patients with DDR deficiencies have significantly higher TMB and higher immunoscores. The result supports that TMB is a potential marker for selecting patients for DDR and IO combination therapy.

**741F****Genomic instability phenotypes in multidimensional genomic cancer studies.** B.N. Lasseigne, S.J. Cooper, G.M. Cooper, R.M. Myers. HudsonAlpha Institute for Biotechnology, 601 Genome Way, Huntsville, AL.

The ability to infer molecular signatures from various genomic data sets can aid in prioritizing future experiments and provide biological insight into disease-associated pathways and mechanisms. In particular, chromosomal instability (CIN, altered chromosome number and structure) and the CpG island methylator phenotype (CIMP, widespread altered promoter methylation) are molecular phenotypes representing distinct cancer etiologies and chemotherapy responses. These genomic instabilities also demonstrate overlapping information content across data types because gross alterations in one feature set results in consistent changes in others (e.g. CIN is linked to widespread DNA hypomethylation and characteristic gene expression changes). In this proof of concept study in kidney cancer (n=291), we compared several definitions each of CIN (total number of breakpoints, number of genes with significant CNV, percent of bases with CNV, or total functional aneuploidy) and DNA methylation instability (the raw number of CpGs methylated, percent of CpGs methylated in CpG islands, shores or non-islands, and the density of methylated CpGs to non-methylated CpGs), characterizing their relationship to each other and clinical phenotypes like patient survival. Our results suggest these metrics are capturing distinct biological properties to a considerable extent. For example, we show that CIN better predicts long-term surviving patients (p=0.0559) while DNAm instability better predicts non-surviving patients (p=0.00017). Additionally, using machine learning methods we predict both CIN (LASSO model ROC AUC=0.866) and DNAm instability (LASSO model ROC AUC=0.8817) status from gene expression data alone. Our findings will facilitate prioritization of experiments in future studies, improve interpretation of these instability signatures for both basic biology and clinical use, and allow their inference from each of the major genomic data types.

**742W****Predictive, discriminative versus associated or prognostic biomarker? Comparisons of discriminant, predictive and association and network analysis methods for mass spectrometry data from ovarian cancer.** Y. Liang<sup>1</sup>, A.G. Kelemen<sup>2</sup>, H. Zhang<sup>3</sup>.

1) Department of Family and Community Health, University of Maryland, Baltimore, Baltimore, MD; 2) Department of Organizational Systems and Adult Health, University of Maryland, Baltimore; 3) Department of Pathology, Johns Hopkins Medical Institutions, Baltimore.

Ovarian cancer is the deadliest gynecologic malignancy with majority patients diagnosed in later stage. Antineoplastic therapeutics is vital to treating serious ovarian patients but have heterogeneous responses. Mass spectrometry (MS) based proteomic technologies have enabled global expression profiling at the protein level to examine the linkages between glycoproteins and ovarian cancer as a network and to determine which glycoproteins linked to cancer subtypes. However, there are various key challenges analyzing MS glycoproteome data such as small/weak effects, heterogeneity, high percentage missing, skewness, which make most algorithms and modeling based approaches not applicable. In this study, we conduct multi-stage and multilayer systematic analysis of MS glycoproteins from ovarian tumor sample obtained from the Clinical Proteomic Tumor Analysis Consortium (CPTAC) and The Cancer Genome Atlas (TCGA). One hundred twenty two samples from 9606 proteins are analyzed, and ovarian status is defined based on the putative homologous recombination deficiency (HRD) (67 HRD positive, 55 non-HRD/negative). Multilayer systematic analysis include 1) statistical process control for correcting technical variations and examine heterogeneity; 2) missing data imputations with SVD; 3) two-way regression based sliding window analysis for identifying the significant and predictable biomarkers; 4) Discriminative analysis and neural network approach for discriminative power and predictive accuracy; 5) Ovarian subtype identification using clustering analysis (mixture model, HC, PCA); 6) Correlation network comparisons and visualization (Cytoscape); and pathway and function analysis (Ingenuity pathway analysis) for validating the findings and understanding key mechanisms. Results reveal a marked difference when select the glycoproteins based on predictive, discriminative, associative or prognostic biomarkers, indicating the subtypes of proteomic profiles with functional differences and distinct subpopulations within ovarian patients. The proposed sequential multilayer approaches provide different perspective of the important biomarkers linked to the important biological processes influencing the ovarian progression, heterogeneity, and efficacy of platinum therapeutics and drug resistance, which are validated with associated pathway and function analysis.

**743T****Tissue-specific feature of whole genome sequencing aids tissue-mapping in plasma.** H. Liang<sup>1,2</sup>, X. Zhou<sup>1,2</sup>, S. Qiao<sup>1,2</sup>, G. Xie<sup>1,2</sup>, X. Shi<sup>1,2</sup>, X. Zhao<sup>1,2</sup>, K. Wu<sup>1,2</sup>, F. Li<sup>1,2</sup>, H. Liang, F. Li. 1) BGI-Shenzhen, Shenzhen 518083, China; 2) China National Genebank-Shenzhen, BGI-Shenzhen, Shenzhen, 518083, China.

Tissue-specific genome polymorphism generated during histodifferentiation marks tissues with different patterns which requires mass whole genome sequencing data to mine. With plenty of samples of multiple kinds of tissues provided by public genomic databases, The Cancer Genome Atlas (TCGA) and International Cancer Genome Consortium (ICGC) represented, we use statistical methods to mine those potential tissue-specific patterns, basing on which we structure a model to track samples' origin with their sequencing data, and then try to apply this model on cDNA to evaluate the risk of suffering tumor under the conception that as the tumor's growth will accelerate cell apoptosis, the extra DNA fragments released into plasma during this period would take tissue-specific signals, through detecting those patterns we can find the subclinical damage of the relevant tissue. We test multiple kinds of tissues, the result shows great accuracy in both tests of tissue and plasma. Our model detects the niduses of most patients with their plasmas correctly, besides with the low false positive of misjudging health controls, suggests that our model has great potentiality on early cancer screening.

**744F**

**Discovering resistance mechanisms of mutant *NRAS* melanoma towards MEK inhibitor treatment from patient derived tumors.** G. Moriceau, W. Hugo, RS. Lo. Division of Dermatology, UCLA.

Despite the recent improvements of targeted therapies and immunotherapies in metastatic human melanoma, primary and acquired resistance arises and limits patient survival benefit. Development of combinations based on these foundational therapies should yield further survival benefits in the near future. MEK inhibitor monotherapy has limited clinical activity against *MUTNRAS* melanoma but can serve as a foundation for rational combinations. In this context, we investigate the genetic/non-genetic and immune mechanisms of acquired MEKi resistance in *MUTNRAS* melanoma through analyzing pre- and post-tumors (with a total of 15 tumors) from seven *MUTNRAS* melanoma patients. To enable mechanistic study, we also generated >20 patient derived xenograft (PDX) MEKi-resistant tumors from two different *MUTNRAS* melanoma patients. These PDX tumors were treated with MEKi at three different dosages to study the correlates of different resistance mechanisms with multiple MEKi dosing. We utilized the nCounter® Vantage 3D™ Assays to analyze two slides from each patient-derived and PDX tumor: one for immune RNA profiling and another for Protein Solid Tumor Assay for FFPE. We combine the data from this analysis with whole exome data (with patient-matched normals) from the same set of tumor tissues. A cross-samples comparison using the nCounter Vantage 3D Assays provides systematic assessment of genetic, immune subset and protein changes associated with MEKi resistance within actual patient tumors. These observations will be validated both *in vitro* (using isogenic pairs of *MUTNRAS* cell lines pre-/post-MEKi resistance) and *in vivo* (using the PDX and PDX derived cell lines).

**Access, visualize and analyze pediatric genomic data on St Jude Cloud.** S. Newman<sup>1,6</sup>, X. Zhou<sup>1,6</sup>, C. McLeod<sup>1,6</sup>, G. Wu<sup>1</sup>, E. Sioson<sup>1</sup>, S. Wang<sup>1</sup>, J.R. Michael<sup>1</sup>, A. Patel<sup>1</sup>, A. Frantz<sup>1</sup>, T. Chang<sup>1</sup>, R.I. Davidson<sup>2</sup>, S. Ma<sup>4</sup>, I. McGuire<sup>2</sup>, N. Robison<sup>2</sup>, E. Suh<sup>2</sup>, L. Tanner<sup>2</sup>, J. McMurry<sup>2</sup>, K. Perry<sup>2</sup>, M. Rusch<sup>1</sup>, J.R. Downing<sup>1,5</sup>, J. Zhang<sup>1</sup>. 1) Department of Computational Biology, St Jude Children's Research Hospital, Memphis, TN; 2) Department of Information Services, St. Jude Children's Research Hospital, Memphis, TN; 3) Microsoft Research, Redmond, WA; 4) DNAnexus, Mountain View, CA; 5) Department of Pathology, St Jude Children's Research Hospital, Memphis, TN; 6) Contributed Equally.

Cloud computing is poised to revolutionize genomics as it facilitates secure sharing and collaborative analysis of huge datasets. Many pediatric diseases are rare and, as data and expertise are widely dispersed, a central focus for sharing and collaboration will be vital for pediatric oncology research moving forward. Our new cloud platform, built in collaboration with DNAnexus, centers around three core concepts: Data, Tools and Visualization. First, we make all data from the Pediatric Cancer Genome Project (PCGP) securely available having remapped it to the *GRCh38* reference genome using a highly optimized BWA/GATK pipeline powered by Microsoft Azure. The initial data offering is comprised of approximately 700 tumor/germline whole genome pairs from common and rare pediatric cancers. Non-identifiable data can be accessed immediately whereas raw data can be securely obtained through a one-time streamlined access request procedure. We next offer highly optimized cloud-based implementations of our extensively validated analysis pipelines. This allows users to quickly and privately run complex workflows on their own data regardless of computational expertise. Our initial workflows include differential gene expression, structural variant prediction, neoepitope prediction, variant annotation and pathogenicity classification. Users may upload their own data and build a "virtual" cohort integrated with PCGP data or reanalyze PCGP data using their own tools and workflows. Data and results can be securely shared inside of the platform. We provide innovative cohort-level visualizations for data mining including protected access browsing of germline variants, and open access interactive browsing of somatic variants, copy number abnormalities, and structural alterations. These interactive visualizations allow investigators to drill down on interesting loci to identify new gene variants potentially linked to a disease. Of particular interest are the thousands of non-coding somatic and germline variants detected in PCGP samples. We overlay ATAC-seq data to help users assess the chromatin state of potential regulatory non-coding variants. By bringing analytic tools to the world's largest set of pediatric genomics data, St Jude Cloud will enable innovative genomic analysis, data sharing and development of new methods that will further our knowledge of pediatric cancer and support precision medicine initiatives across the globe.

**Expression variability is associated with breast tumour subtype.** *J.F. Pearson<sup>1</sup>, G.A.R. Wiggins<sup>2</sup>, M. Black<sup>3</sup>, A. Dunbier<sup>3</sup>, L.C. Walker<sup>1</sup>.* 1) Biostatistics and Computational Biology Unit, University of Otago Christchurch, Christchurch, New Zealand; 2) Department of Pathology, University of Otago Christchurch, New Zealand; 3) Department of Biochemistry, University of Otago Dunedin, New Zealand.

Inherited mutations in *BRCA1* are associated with greater risk of developing breast and ovarian cancers. *BRCA1* is important for several functions in cells throughout the body, however mutations in *BRCA1* are strongly associated with breast and ovarian cancer with only minor effects in other tissues. Approximately, 70% of *BRCA1*-related breast tumours display a basal-like phenotype (eg. high grade and oestrogen receptor negative), although the gene networks that are critical for the mechanism remain unclear. Gene expression studies have extensively interrogated breast cancers, including tumours from *BRCA1* mutation carriers, however results from these studies lack consensus, with inconsistency in candidate genes and pathways. Importantly, these studies have focused on differentially expressed genes by comparing the mean of each group and determining statistical significance. We demonstrate the application of an alternative approach, which is to assess expression data using differential variability analysis, thereby discovering genes with a significant difference in variance between two sample groups. Expression data from 74 familial breast cancers and a 2116 sporadic breast cancer meta-cohort were interrogated for gene expression variability. We found that basal tumours and *BRCA1* related tumours showed 39.9% (95% CI 39.4-40.3%) and 13.2% (95% CI 12.6-13.7%) increased global variability, respectively. Differential variability analysis identified gene sets that were enriched in pathways associated with epithelial cell function and development. Furthermore, we identified two genes, *PAX6* and *FOXA1*, involved in these pathways with significantly greater expression variability in basal or *BRCA1* related tumours, in both study cohorts. These findings are novel and suggest epithelial cell development pathways may be more tightly regulated in non-basal and non-*BRCA1* related tumours.

**747F**

**Transcriptome-based classification of primary melanoma identifies tumor subtypes that predict outcome in stage I.** *R. Thakur<sup>1</sup>, J. Nsengimana<sup>1</sup>, J. Laya<sup>2</sup>, M. Lauss<sup>2</sup>, A. Filla<sup>1,3</sup>, S. O'Shea<sup>1</sup>, M. Chan<sup>1</sup>, G. Jönsson<sup>2</sup>, D.T. Bishop<sup>1</sup>, J. Newton-Bishop<sup>1</sup>, J.H. Barrett<sup>1</sup>.* 1) Section of Epidemiology and Biostatistics, University of Leeds, Leeds, United Kingdom; 2) Department of Oncology and Pathology, University of Lund, Lund, Sweden; 3) National Heart and Lung Institute, Imperial College London, London, United Kingdom.

The 5-year disease-specific survival rate for AJCC (American Joint Committee on Cancer) stage I melanoma patients is around 95%, while for stage IV it is only ~15%. Even though most stage I patients survive their disease, some do not, and the desire is therefore to identify prognostic biomarkers in addition to clinical predictors within stage I melanoma. Previous transcriptome analyses from metastatic melanoma (mainly stage IV) have generated molecular classification schemes for identifying tumor classes that predict outcome. However, when these schemes were applied to primary melanomas from the Leeds cohort (n=702), the molecular classes showed different predictive properties across tumor stages (interaction P=0.03), failing to offer prognostic value in stage I tumors. In this study, a robust consensus-based PAM (Partitioning Around Medoids) method was used to cluster whole genome transcriptomes from 702 primary melanomas from the Leeds melanoma cohort (34% stage I, 51% stage II, 15% stage III). Seven distinct tumor classes were identified based on cluster separation and a number of other criteria. The 7 classes showed a strong association with outcome after adjusting for AJCC stage. When stratified by stage, in stage I tumors the 7 classes still showed borderline evidence of association with survival (P=0.06), and one particular class was strongly predictive of poor outcome (HR= 6.7, 95% CI: 1.4-31.7, P=0.016). Differentially expressed genes across the 7 classes were identified, and biological pathway enrichment was explored using ReactomeFIViz. The class with the worst prognosis was associated with upregulation of pathways related to cell cycle and downregulation of immune response pathways, whilst the inverse of this was observed in the best survival group. In keeping with previously reported studies, tumors from the worst survival group were histologically thicker, more frequently ulcerated and had more mitoses. The clinical relevance of the tumor classes was validated using an independent cohort of 223 primary melanomas. In conclusion, tumor classes derived from gene expression have been identified of demonstrated prognostic value, and importantly these are pertinent in stage I melanoma. These classes could serve to improve clinical decision-making and allow patient treatment to be tailored according to prognosis.

## 748W

**A novel framework for tumor classification which uses sufficient dimension reduction for feature selection and Bayesian networks for integrating CT image and epigenomic.** Y. Wang, M. Xiong, N. Lin. University of Texas Health Science Center at Houston, Houston, TX.

Next generation of genomic, sensing and image technologies will produce deeper and deeper genomic, epigenomic, imaging and phenotypic data with millions of features. They are increasingly used for disease prediction and prevention, especially for cancer. Discovering biomarkers from miRNA-seq and methylation-seq profiles is a high-dimensional, small sample size problem in machine learning. A fundamental question is how to efficiently extract epigenomic variants of clinical utility and to develop novel unified approach to classification analysis of epigenomic data. The developed sufficient dimension reduction, multitask feature selection algorithms for large-scale machine learning will offer a powerful tool for developing a general framework for efficiently and jointly extracting genomic and epigenomic variants of clinical utility and shift paradigm for cancer marker selection from independent, rank-based selection to powerful systematically and jointly genome-wide searching selection. Using Bayesian network to develop novel and highly discriminating algorithms for combining miRNA, methylation and imaging classifiers will substantially improve our ability to accurately detect cancer. We applied the proposed methods to TCGA ovarian cancer data set with 112 samples (80 tumor tissue samples and 32 tumor free samples) for ovarian cancer prediction. The results showed that the average prediction accuracy for each individual dataset is 74% for the CT image dataset, 69% for the mi-RNA dataset, 72% for the DNA Methylation dataset. After using Bayesian Network to combine different types of the datasets, the average prediction accuracy increased to 79%.

**Multiregion high-depth whole exome sequencing of matched primary and metastatic tumors revealed inter- and intra-individual genomic heterogeneity and polyclonal seeding in colorectal cancer metastasis.** Q. Wei<sup>1</sup>, Z. Ye<sup>2</sup>, X. Zhong<sup>3</sup>, L. Li<sup>4</sup>, C. Wang<sup>2,6</sup>, R. Myers<sup>2</sup>, J. Plazzo<sup>5</sup>, A. Yan<sup>2</sup>, S. Waldman<sup>4</sup>, X. Chen<sup>2</sup>, B. Jiang<sup>5</sup>, B. Li<sup>1</sup>, H. Yang<sup>2</sup>. 1) Department of Molecular Physiology and Biophysics, Vanderbilt University, Nashville, TN 37235, USA; 2) Department of Medical Oncology, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA 19107, USA; 3) Department of Medicine, Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN 37235, USA; 4) Department of Pharmacology and Experimental Therapeutics, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA 19107, USA; 5) Department of Pathology, Thomas Jefferson University, Philadelphia, PA 19107, USA; 6) Department of Environmental Health, School of Public Health, Nantong University, Nantong, Jiangsu 226000, China.

**Purpose:** Colorectal cancer (CRC) has high prevalence and mortality in many developed countries. Distant metastasis accounts for about 90% of CRC deaths. Intratumor heterogeneity (ITH) has been extensively identified in many solid malignancies; however, ITH in primary and metastatic CRC tumors, as well as the primary to metastatic tumor evolution are largely underexplored.

**Patients and Methods:** We conducted high-depth whole exome sequencing in multiple regions of matched primary and metastatic tumors from four CRC patients. Using a total of 28 tumor, normal, and lymph node samples, we analyzed inter- and intra-individual heterogeneity, inferred the subclonal architecture of each tumor, and depicted the subclonal evolutionary route from primary to metastatic tumors for each patient. **Results:** CRC has significant inter-individual heterogeneity but relatively limited intra-individual heterogeneity. Genomic landscapes were more similar within primary, metastatic or lymph node tumors than across these types. Remarkably, all metastatic tumors inherited multiple genetically distinct subclones from primary tumors, supporting a polyclonal seeding mechanism for metastasis. Nonetheless, metastatic tumors exhibited less ITH than primary tumors, indicating that single-region sequencing may be adequate to identify important metastasis mutations to guide treatment. Analysis of one patient with the trio of primary, metastatic, and lymph node tumors supported a mechanism of synchronous parallel dissemination from the primary to metastatic tumors that were not mediated by lymph nodes. **Conclusion:** In CRC, metastatic tumors have different but less heterogeneous genomic landscapes than primary tumors. CRC has a polyclonal seeding mechanism which suggests that different subclones migrate to distant organs and promote metastasis. These findings demonstrated the rationale and feasibility for identifying and targeting primary tumor-derived metastasis-potent subclones for the prediction, prevention, and treatment of CRC metastasis. .

**The Seven Bridges Cancer Genomics Cloud: Enabling discovery from petabyte-scale human genomic data resources.** *E.H. Williams, G. Kaushik, E. Lehnert, R. Malhotra, A. Sethi, Z. Onder, B. Davis-Dusenbery.* Seven Bridges, Cambridge, MA.

Next-generation sequencing has catalyzed the generation of petabytes of genomic data from thousands of patients, creating immense research opportunities but also immense challenges related to organizing, sharing, and analyzing large and often heterogeneous data volumes. The Cancer Genome Atlas (TCGA) network alone has produced more than 2.5 petabytes of data. Downloading the complete TCGA dataset to a local data store can take several weeks or more, and integrated analysis requires resources available only to a limited number of researchers with access to large institutional compute clusters. With the aim of democratizing access to TCGA data, the National Cancer Institute in 2015 launched the Cancer Genomics Cloud Pilots program to colocate data and the computational resources necessary for its analysis in the cloud. Funded by this program, the Seven Bridges Cancer Genomics Cloud (CGC; [cancer-genomics-cloud.org](http://cancer-genomics-cloud.org)) is a customizable and scalable data access and analysis platform that connects users via the web to extensive public datasets, including TCGA, the Simons Genome Diversity Project, and the Cancer Cell Line Encyclopedia, and enables collaborative, reproducible analysis across both public and private cohorts. The CGC also gives users access to a public toolkit containing nearly 250 common analytical tools and workflows, and additional resources including the open-source CGC Software Development Kit and Data Cruncher facilitate custom tool prototyping and deployment on the platform. Since its launch in early 2016, more than 1700 researchers from more than 150 institutions in 30 countries have used the CGC to deploy more than 5,000 applications and perform more than 80,000 analyses, representing almost 100 years of computation time. To demonstrate how the CGC can help researchers unlock insights into the relationship between genomics and human health, we will present data analysis case studies - beginning with raw sequencing reads and ending with population-scale genomic and clinical data that can be fed into statistical models for biomarker discovery - conducted through this secure, compliant cloud environment. For example, we will show how to generate biomarkers for TCGA cancer types using machine learning in Python and R to classify cancer subtypes from gene expression data that has been reprocessed using gold-standard RNA sequencing workflows described in the Common Workflow Language.

**CliP: Fast subclonal architecture reconstruction from whole-genome sequencing data.** *K. Yu<sup>1</sup>, S.J. Shin<sup>2</sup>, H. Zhu<sup>1</sup>, W. Wang<sup>2</sup>, the Evolution and Heterogeneity Working Group of the Pan-Cancer Analysis of Whole Genomes Initiative.* 1) Department of Biostatistics, University of Texas MD Anderson Cancer Center, Houston, TX; 2) 1. Department of Bioinformatics and Computational Biology, The University of Texas MD Anderson Cancer Center, Houston, TX.

**Introduction:** Tumors as well as various human tissues usually consist of different subpopulations (subclones) that are characterized by somatic mutations. The composition of such subpopulations may affect disease prognosis and treatment efficacy. And understanding the subclonal structure helps infer the evolutionary history of cells which can further guide the discovery of driver mutations such as those in cancer studies. Currently most subclonal reconstruction methods are Dirichlet Process (DP) based, requiring expensive computing since MCMC algorithm is commonly adopted to solve the problem, and careful post-processing due to the fact that the number of clusters scales with number of single nucleotide variations (SNVs) in the DP setting. **Methods and Results:** We present CliP (Clonal structure identification through penalizing pairwise difference), a fast and minimum post-processing algorithm for calling subclonal structures using whole-genome sequencing data. CliP deterministically solves a penalized likelihood problem, making execution much faster. In a simulated sample with 15,000 SNVs, it takes CliP less than 1 hour to finish the subclonal reconstruction, which is about 100 times faster than other methods. CliP is also capable of handling sequencing data at low coverages (30X-60X). Based on 125 simulated samples, CliP showed comparable prediction performance with DP-based methods. In the application to ICGC whole-genome sequencing data from 2,703 tumor samples from 39 cancer types, CliP provided results within 4 days and was able to analyze the hypermutator (>100,000 SNVs) samples correctly. **Conclusion:** We have proposed CliP, a fast and accurate subclonal reconstruction method that requires minimum post-processing. It is especially suitable for quickly processing large cohort containing thousands of whole-genome sequencing data to analyze cancer heterogeneity and their evolutionary histories.

## 752T

**Dissecting tumor-immune system interaction in non-small cell lung cancer using TCGA data.** X. Yu, X. Wang. Department of Biostatistics and Bioinformatics, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL.

Immunotherapies have recently revolutionized the treatment of diverse types of cancer, including non-small cell lung cancer (NSCLC). While treatment with PD-1 blockers induce durable response in approximately 20% of patients with advanced NSCLC, majority of patients still fail to response or do not derive substantial clinical benefits. Efforts have been made to study the tumor-immune interaction and to develop predictive genomic markers for immune checkpoint blockage in varied cancer types. Recent studies have linked the higher response rate to elevated mutational load or predicted class-1 neoantigens, increased CD8+ tumor infiltrating lymphocytes (TILs) and clonally expanded T-cell populations. However, much less is known about how the interaction between tumor and immune system impact NSCLC patient outcome. In this work, we comprehensively studied the association between tumor genomic landscape, immunogenicity, and composition of the tumor immune microenvironment in TCGA NSCLC patients utilizing a wide range of computational genomic tools. We found that the mutational load and neoantigen burden were not significantly associated with immunogenicity or TIL pattern. Using the gene expression measured from RNAseq, we were able to identify makers only associated with high mutation low cytolytic activity. In addition, strong correlations were observed between tumor cytolytic activity, T cell receptor (TCR) diversity and TIL compositions, however a group of patients who have high T-cell infiltrating and low immunogenicity showed the worst survival, regardless of their mutational burden, indicating a potential target group for PD-1 axis blocker treatment. .

## 753F

**RADAR: A RNA binding protein regulatory network resource for cAncer Research.** J. Zhang<sup>1,2</sup>, J. Liu<sup>1,2</sup>, D. Lee<sup>2</sup>, L. Lochovsky<sup>1,2</sup>, M. Gerstein<sup>1,2,3</sup>. 1) Molecular Biophysics & Biochemistry, Yale University, New Haven, CT; 2) Program in Computational Biology & Bioinformatics, Yale University, New Haven, CT; 3) Department of Computer Science, Yale University, New Haven, CT.

In the cell, numerous RNA binding proteins (RBP) interact with single or double stranded RNAs to play a series of critical post-transcriptional regulatory roles. Malicious regulatory activities of these RBPs, either from abnormal expression of RBPs or disruption of binding sites by mutations, may affect various types of RNA processing and result in aberrant expressions of target genes. Hence, it is important to investigate how regulatory changes of RBPs are associated with phenotype alterations in various diseases, such as cancer. However, currently, there is no systematic assessment of RBP regulatory networks in various cell types. Hence, we collected 318 RBP binding profiles from public data and endeavored to make it a suitable resource for cancer research. Specifically, we first investigated the functional importance of the RBP binding sites by studying their selection constraints from single-nucleotide polymorphisms (SNPs). We identified categories of RBP binding sites to be significantly enriched with rare SNPs, even to a degree similar to the coding regions, strongly indicating that they are playing important roles in gene regulation. We then set up a high-confidence RBP regulatory network by linking RBP binding profiles from multiple experiments with gene annotations. To pinpoint key RBPs that shape tumor-specific expression patterns, we performed differential expression analysis in 24 cancer types using data from TCGA data and evaluated the regulation power of each RBP by investigating their target gene expression changes. Specifically, we identified several RBPs, such as DDX55 and SUB1, to significantly drive tumor-to-normal differential expression. In addition, we performed a de novo motif scan on each RBP binding profile and compared it with RBPs reported from previous investigations using SELEX experiments. The majority of our discovered RBP motifs are in concordance with previous results, indicating the high quality of the binding profiles we collected. Based on these motifs, we further examined the RBP motif gain and loss events in multiple cancers and assigned their significance by comparing them against robustly simulated somatic variants. As a culmination of our efforts, we release our tool, RADAR, for prioritizing and inferring RBP's regulatory potential for cancer research. It is aimed to interpret patient gene expression profiles using our identified RBP network and evaluate the RBP regulatory changes introduced by somatic mutations.

**Domain retention in transcription factor fusion genes and its biological and clinical implications: A pan-cancer study.** Z. Zhao<sup>1,2</sup>, P. Kim<sup>1</sup>. 1) School of Biomedical Informatics, University of Texas HSC Houston, Houston, TX; 2) Human Genetics Center, School of Public Health, University of Texas HSC Houston, Houston, TX.

Genomic rearrangements involving transcription factors (TFs) can form fusion proteins resulting in either enhanced, weakened, or even loss of TF activity. Functional domain (FD) retention is a critical factor in the activity of transcription factor fusion genes (TFFGs). A systematic investigation of FD retention in TFFGs and their outcome (e.g. expression changes) in pan-cancer has not been done yet. Here, we examined the FD retention status in 386 TFFGs across 13 major cancer types and identified 151 TFFGs involving 95 TFs that retained functional domains. To measure the potential biological relevance of TFs in TFFGs, we introduced a major active isofusion index (MAII) and built a prioritized TFFG network using both MAII scores and the observed frequency. Interestingly, the four TFFGs (*PML-RARA*, *RUNX1-RUNX1T1*, *TMPRSS2-ERG*, and *SFPQ-TFE3*) having the highest MAII scores showed 50 differentially expressed target genes (DEGs) in fusion-positive versus fusion-negative samples. Gene set enrichment tests of these DEGs revealed genes involved in tumorigenesis-related processes in each cancer type. *PLAU*, which encodes plasminogen activator urokinase and serves as a biomarker for tumor invasion, was found to be consistently activated in the samples with highest MAII scores. Among the 50 DEGs, 21 are drug targetable and 14 are expressed in acute myeloid leukemia (AML) samples. Accordingly, we constructed an AML-specific TFFG network, which included 38 DEGs in *RUNX1-RUNX1T1* or *PML-RARA* positive samples. In summary, this pan-cancer study revealed several critical TFFGs and their potential target genes, and provided insights into the clinical implications of TFFGs.

**Integrative approach to cancer driver gene discovery from somatic mutations.** S. Zhao, X. He, M. Stephens. Human Genetics, University of Chicago, Chicago, IL.

Knowledge of driver genes whose mutations lead to tumor-genesis is important for understanding the mechanisms of cancer and for identifying promising drug targets. Despite intensive sequencing and computational efforts, our knowledge of driver genes in most tumor types remain far from complete. Computational methods are essential to leverage cancer sequencing data to identify driver genes. Existing methods typically rely on some pattern of somatic mutations in the genes: driver genes would have more somatic mutations than expected, or the mutations in driver genes are more likely to be deleterious and spatially clustered. Nevertheless, most existing methods would utilize one feature a time. In this work, we develop a novel integrative approach for driver gene discovery that incorporates multiple features of driver genes in a single framework. As part of our approach, we come up with a mixed effect model to capture the baseline mutation rates, that incorporates both global features predictive of mutation rates and local variations of mutation rates. Our model also allows us to put more emphasis on more deleterious mutations (e.g. nonsense mutations) when evaluating the mutational burden of a gene. Finally, our model is designed to reward genes with mutations that are closely clustered. We evaluate our approach using TCGA data, and we found that in almost all tumor types, it outperforms MutSigCV, the current leading method for driver gene discovery.

**756F**

**Identification of tissue-specific regulatory networks.** *M. Bilow, E. Eskin.* Computer Science, UCLA, Los Angeles, CA.

A great number of gene-regulatory networks and pathway analyses have been performed, beginning with the advent of microarray technology 20 years ago, and these number and complexity of these networks continues to grow. Many of these analyses have been performed in a single tissue only, for example blood or brain, and this has resulted in the publication of gene interaction networks that are insufficiently general. The Gene-Tissue Expression Project has changed this by sampling from many tissues belonging to the same individual. This advance makes it possible to identify tissue-specific regulatory networks and fit a Bayesian network to this data. The Bayesian network has three primary components: tissue-transcript effects: the influence by each tissue on the quantity of each transcript; variant-specific effects: relationships between each genetic variant and each transcript; and transcript-transcript interactions: networked causal relationships between transcripts. Our algorithm follows an expectation-maximization paradigm and is able to provide confirmation and evidence for multi-tissue gene regulatory networks, many of which extend previously-known gene networks.

**757W**

**A comprehensive characterization of tumor profiles using custom SureSelect targeted panels.** *A. Ashutosh, A. Vadapalli, L. Forsmark, H. Tao, C. Lecocq, L. Niu, A. Khare, B. Arezi, G. Amparo, M. Ramaiah, M. Ruvolo, C. Pabon, J. Ghosh, J. Jin, D. Roberts.* Diagnostics and Genomics (DGG), Agilent Technologies, Santa Clara, CA.

Somatic copy number variations (CNV) play a critical role in oncogenesis and in tumor progression. However, due to tumor heterogeneity and plurality of clones in tumors, the problem becomes complex. Additionally, aberration size, copy number and prevalence vary widely within and across tumor types. Further, formalin fixed paraffin embedded (FFPE) tissues present additional experimental challenges such as poor sample quality, crosslinking, and deamination. Traditional molecular profiling of cancer samples (e.g. FISH and SNP arrays) is gradually being replaced by next-generation sequencing (NGS) since in addition to detecting CNVs, it provides a way for rapid characterization of single nucleotide variations, short insertions and deletions, and translocations in a single assay. Until now CNV detection has been with either whole exome or large gene NGS panels containing hundreds of genes. Several current computational approaches for estimating both copy number and cancer clone fraction work better on large panels, exomes or WGS than they do on small panels. In this abstract, we address the challenge of detecting copy number variations at both gene and chromosome scales with NGS using small gene panels. The success of the analysis method is tied to the strategic selection of Agilent SureSelect probes that cover not only the coding regions of the genes of interest but also span the surrounding regions to provide additional allelic copy number information. This analysis utilizes either a matched normal or standard control DNA to compute read depth ratios. The aberrant regions are identified by jointly segmenting the read depth ratios and SNP allele frequencies. The clonal structure is discerned by evaluating two Bayesian cancer models in a hierarchical manner. The contribution of the major aberrant clone is separated out by the first model and a more detailed second model provides a refined clonal structure if present. We validate the results by an orthogonal technique-(FISH), samples with known aberrations and dilution series experiments for sensitivity. As an example, we show detection of 3 copies of MET at 20% tumor fraction and 16 copies of ERBB2 at 2%.

## 758T

**GATK4 adds germline and somatic copy number variant plus somatic SNV and indel calling.** S.H. Lee, *Data Sciences and Data Engineering (DSDE) Team*. The Broad Institute of MIT and Harvard, Cambridge, MA.

The Genome Analysis Toolkit software is well established for germline SNP and indel discovery from whole genome (WGS) and exome short-read sequencing data. The command-line-interface program has 46K users worldwide<sup>1</sup> and offers comprehensive support through extensive documentation<sup>2</sup>, an active online forum<sup>3</sup>, and interactive workshops<sup>4</sup>. Major version 4 (GATK4) is re-engineered to compute and scale more efficiently. It is completely open source<sup>5</sup> and has new and improved collections of computational tools towards (i) somatic copy number variant discovery, (ii) somatic SNV and indel calling with an enhanced Mutect2, (iii) germline copy number variant discovery (experimental workflow), and (iv) germline SNP and indel calling with HaplotypeCaller. We will focus on the newer workflows (i–iii). Additionally, we will touch briefly upon functionality and resources that enable researchers to study large genomic data. For example, GATK4 supports use of the GenomicsDB datastore<sup>6</sup> towards scalable analyses. This functionality, contributed by collaborators at Intel Health and Life Sciences, enables calling on large datasets exemplified by the joint variant calling of 15K WGS samples that resulted in the gnomAD resource<sup>7</sup>. In addition, the GATK4 engine supports Apache Spark parallelization of compute for faster results, and can directly read from and write to Google Cloud Storage. Finally, resources include the Cromwell and WDL pipelining solution that enables reproducibility of analyses as well as easy parallelization of compute, e.g. scattering across samples and over genomic intervals<sup>8</sup>.

## 759F

**Detecting pathogenic structural variants with long-read PacBio SMRT Sequencing.** A.M. Wenger, L. Hickey, Y. Li, B. Lerch, P. Peluso, J. Korlach. Pacific Biosciences, Menlo Park, CA.

Most of the basepairs that differ between two human genomes are in intermediate-sized structural variants (50 bp to 5 kb), which are too small to detect with array comparative genomic hybridization or optical mapping but too large to reliably discover with short-read DNA sequencing. Long-read sequencing with PacBio Single Molecule, Real-Time (SMRT) Sequencing platforms fills this technology gap. PacBio SMRT Sequencing detects tens of thousands of structural variants in a human genome with approximately five times the sensitivity of short-read DNA sequencing. Effective application of PacBio SMRT Sequencing to detect structural variants requires quality bioinformatics tools that account for the characteristics of PacBio reads. To provide such a solution, we developed pbsv, a structural variant caller for PacBio reads that works as a chain of simple stages: 1) map reads to the reference genome, 2) identify reads with signatures of structural variation, 3) cluster nearby reads with similar signatures, 4) summarize each cluster into a consensus variant, and 5) filter for variants with sufficient read support. To evaluate the baseline performance of pbsv, we generated high coverage of a diploid human genome on the PacBio Sequel System, established a target set of structural variants, and then titrated to lower coverage levels. The false discovery rate for pbsv is low at all coverage levels. Sensitivity is high even at modest coverage: above 85% at 10-fold coverage and above 95% at 20-fold coverage. To assess the potential for PacBio SMRT Sequencing to identify pathogenic variants, we evaluated an individual with clinical symptoms suggestive of Carney complex for whom short-read whole genome sequencing was uninformative. The individual was sequenced to 9-fold coverage on the PacBio Sequel System, and structural variants were called with pbsv. Filtering for rare, genic structural variants left six candidates, including a heterozygous 2,184 bp deletion that removes the first coding exon of *PRKAR1A*. Null mutations in *PRKAR1A* cause autosomal dominant Carney complex, type 1. The variant was determined to be *de novo*, and it was classified as likely pathogenic based on ACMG standards and guidelines for variant interpretation. These case studies demonstrate the ability of pbsv to detect structural variants in low-coverage PacBio SMRT Sequencing and suggest the importance of considering structural variants in any study of human genetic variation.

### Integrated search for multi-omics data using extended GA4GH Genomics

**API.** S. Kawano<sup>1</sup>, Y. Suzuki<sup>2</sup>, S. Sugano<sup>3</sup>. 1) Database Center for Life Science, Joint Support Center for Data Science Research, Research Organization of Information and Systems, Kashiwa, Chiba, Japan; 2) Department of Computational Biology, Graduate School of Frontier Sciences, The University of Tokyo, Kashiwa, Chiba, Japan; 3) Department of Medical Genome Sciences, Graduate School of Frontier Sciences, The University of Tokyo, Kashiwa, Chiba, Japan.

In recent years, diagnosis using genome sequence information has been a major method for rare diseases and cancers. It is important that these information are efficiently shared between hospitals in order to find similar patients and help medical treatment. Global Alliance for Genomics and Health (GA4GH), which is an international collaboration accelerating health-data sharing, provides several tools such as Genomics API, Beacon, and Matchmaker Exchange in order to share the genomic and phenotypic information. The GA4GH tools mainly focuses on single nucleotide variants (SNVs) in genotypic information. However, other factors such as epigenome (DNA methylations and histone modifications measured by bisulfite sequencing (BS-seq) and chromatin immunoprecipitation sequencing (ChIP-seq), respectively), transcription start sites (TSS) identified by TSS-seq, and amounts of gene expression determined by RNA-seq (hereinafter collectively called multi-omics) also affect phenotypes. It is convenient to be able to search not only SNVs but also multi-omics data at the same time in order to obtain more detailed information about relationships between genomic information and phenotypes. Here, we chose Genomics API to integrate multi-omics data. Because the Genomics API does not support to multi-omics data, we extended its data model: we defined extra classes such as BS-seq, ChIP-seq, TSS-seq, and RNA-seq in addition to the variant class. As sample datasets, we used multi-omics data including SNVs data measured from 26 lung cancer cell lines, and forcibly converted them into Variant Call Format (VCF) files. The VCF files were loaded into a Genomics API repository for searching. As a result, multi-omics data was searchable in an integrative way. For example, our API returned a list of SNVs, DNA methylation sites, and histone binding sites etc. from a specific region (e.g. 10000 - 15000) on a specific chromosome (e.g. chr.1). Application of this API enables correlation analysis as well as similarity search between samples (patients) using multi-omics data. In conclusion, we extended the standard technology provided by GA4GH while ensuring compatibility, and enabled integrated search of multi-omics data.

## 761T

### MicroRNA eQTL analysis in pancreatic cancer with efforts towards

**functional validation.** A. Jermusyk<sup>1</sup>, L. Rost<sup>1</sup>, M. Zhang<sup>1</sup>, R. Atrah<sup>1</sup>, J.W. Hoskins<sup>1</sup>, B. Zhu<sup>2</sup>, W. Xiao<sup>3</sup>, I. Collins<sup>1</sup>, N. Chatterjee<sup>3,4</sup>, J. Shi<sup>2</sup>, L. Amundadottir<sup>1</sup>. 1) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, Maryland 20892, USA; 2) Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, Maryland 20892, USA; 3) Division of Bioinformatics and Biostatistics, National Center for Toxicology Research, FDA, Jefferson, Arkansas 72079, USA; 4) Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland 21205, USA.

MicroRNAs (miRNA) are small, non-coding RNAs of about 21 nucleotides in length that bind the 3' UTR region of messenger RNAs (mRNAs) preventing translation and causing destruction of the mRNA. The roles of individual miRNAs in cancer remains to be fully uncovered. Our aim in the current study is to identify miRNAs whose expression is genetically regulated in pancreatic cancer. We performed a miRNA eQTL analysis using data from TCGA pancreatic cancer tumor samples (n=115) and employing the linear regression program, Matrix eQTL. After determining significant SNP-gene pairs through running 100 permutations of our analysis and establishing a FDR of 10%. At a *P*-value threshold of  $P < 8.5e-7$  (FDR<0.1), two SNP-gene pairs were significant; miR-577 and rs35182026, and miR-3130-1 and rs10664575. We then predicted the mRNAs they potentially regulate using predictive binding databases. We investigated mRNAs that were consistently reported in multiple prediction packages and possibly involved in cancer. Based on these analyses: *GOLFPH3*, *TFAP2A*, and *HOXA1* are probable targets of miR-577 and *FAS*, *SIM1*, and *RAB14* are probable targets of miR-3130-1. We then assayed the expression of two of the most significant miRNAs with eQTLs (miR-3130-1 and miR-577) in 30 pancreatic cancer cell lines in order to select cell lines to overexpress and downregulate these miRNAs. We identified IMIMPC-2, MiaPaCa-2, and AsPC-1 as ideal cell lines to overexpress and/or downregulate miR-577 and miR-3130-1. We will up- and downregulate these two miRNAs in these cell lines and then assess the expression of the predicted target mRNAs. Ultimately, we are working towards determining whether we can verify the miRNA-mRNA binding predictions, and determine what are the implications of these binding events for cancer. We have identified miRNA eQTLs in pancreatic cancer tissues and are working towards identifying their target mRNAs. We hope to uncover the relevance of these miRNA in pancreatic cancer biology through overexpression and downregulation, and examine the resulting phenotypic effects.

**Designing for success: The right CRISPR design strategies for the right experiment.** *L. Brody, N. Humphryes-Kirilov, V. Dillard, R. Doyle.* Desktop Genetics, 28 Hanbury Street, London, E1 6QR, United Kingdom.

CRISPR design is a complex multivariate problem. The weight of each variable differs depending on the experiment under consideration. Current methods of designing CRISPR experiments are based on a single-variable, resulting in poor experimental outcomes. Our current scoring methods were tested and validated using an sgRNA library of over 3,500 sgRNAs in essential genes with a variety of predicted sgRNA activities and specificities. The predicted 'good' sgRNAs achieved significantly higher read depletion for essential genes, with fewer failing sgRNAs, compared to sgRNAs that didn't meet the scoring criteria. Our scoring algorithm incorporates multiple published observations for choosing effective sgRNAs, which differs from other CRISPR tools that tend to focus on one factor such as sgRNA sequence or specificity. In addition, we have incorporated variant databases which provide a basis for the investigation of the molecular and cellular activity of genetic variation, which is increasingly important for understanding the mechanistic function of the human genome. At Desktop Genetics, we have developed a CRISPR design platform accounting for genomic variants including single nucleotide polymorphisms, small insertions/deletions, translocations and copy number variants. Using NGS data and our optimized CRISPR design rules, we demonstrate a bespoke methodology for *in vitro* functional assays in cultured human cells of a defined genotype. We show how model-specific genomes in conjunction with customizable guide RNAs can be used to precisely target genomic sites of interest to induce loss-of-function mutations and validate predicted variant function. This may provide a unique approach for downstream variant interpretation and interrogation of their role in the pathogenesis of rare and common genetic diseases.

**Whole genome sequencing signatures for early detection of cancer via liquid biopsy.** *B.G. Kermani.* Crystal Genetics, Inc., Los Altos, CA.

The enthusiasm around early detection of cancer using next-generation sequencing (NGS) has placed this goal in the spotlight, particularly in the recent years. Liquid biopsy is often defined as the modus operandi for early detection, as taking biopsies from the actual organs is not practical for a wide-spread screening test. Liquid biopsy comprises cell-free tumor DNA (ctDNA) and circulating tumor cell (CTC) approaches. While ctDNA is more popular, mostly due to the ease of operation, it suffers from low signal-to-noise ratio (SNR). CTC, on the other hand, provides the ability to interrogate single cells with high SNR. However, finding such cells, especially at the earlier stages of cancer, has been challenging. In addition to the targeted gene panels, whole exome sequencing (WES) and whole genome sequencing (WGS) have been considered in the past, for CTC applications, albeit primarily on prognosis (and not diagnosis). The common ideas hinge upon correlating the count of the CTCs or the discovered copy number variations (CNVs) with the state of the disease or lack thereof. In this work, our approach has been focused on using WGS for cancer diagnosis, although other NGS modalities may also be considered. We have identified proprietary signatures that have shown promise in identifying cancer versus normal tissues, in specific cancer types such as breast cancer. Some of these signatures have certain properties that would make them portable to the CTC domain. Since most of publicly available data on CTC work has been on metastatic cancers, we have shown that some signatures hold for such data. Moreover, considering the error modes of CTCs, e.g., allele dropout (ADO), there appears to be a path to maintain the integrity of some of these signatures, although less efficiently, in CTCs from the earlier stages of cancer. Currently, based on limited data, our approach has shown promise at the WGS tissue level, with a detection rate of ~90% for Stage I and Stage II of breast cancer. In order to calculate the upper-bound on the sensitivity of this method using liquid biopsy, the tissue-derived number would have to be multiplied by the detection rate of the CTCs, which is currently low to medium, depending on the technology and the cancer type. However, as the CTC detection rate improves, given the R&D efforts in this area, we anticipate that this method would gain more significance in the early detection of cancer.

Cho<sup>1,9</sup>, The Million Veteran Program, Department of Veterans Affairs Office of Research & Development.* 1) Massachusetts Veterans Epidemiology Research and Informatics, VA Boston Healthcare System, Boston, MA, USA; 2) Department of Biostatistics, Boston University School of Public Health, Boston, MA 02118, USA; 3) Radiological Imaging and Informatics Group, Department of Radiological Sciences, David Geffen School of Medicine, UCLA, LA, CA, 90024 USA; 4) School of Medicine, Boston University, Boston, MA 02118, USA; 5) Department of Medicine, VA Western New York Healthcare System, Buffalo, NY 14203; 6) Department of Internal Medicine, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, Buffalo, NY 14203, USA; 7) CERC, VA Healthcare System, West Haven, CT; 8) School of Medicine, Yale University, New Haven, CT; 9) Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; 10) Department of Biomedical Informatics, Jacobs School of Medicine and Biomedical Sciences, University at Buffalo, Buffalo, NY 14203, USA.

**Background:** We identified a large, curated source population of U.S. veterans with non-small cell lung cancer (NSCLC). This enables us to a) train text-based machine learning case-finding algorithms, and b) derive correlations between genetic variants, comorbidities, exposures, and cancer presentation. Identification of this cohort will support accurate, timely screening patients and building prediction algorithms from structured and unstructured data, to drive better clinical care. We evaluated structured medical codes (ICD codes) for phenotypes to compare to curated cases in the cancer registry (CR), which includes histology data. We also identified the subset of patients in the Million Veteran Program (MVP). The cohort is categorized by tumor stage at diagnosis, allowing us to test initial workflow and algorithms, as well as validate genetic tools relative to known susceptibility loci (eg, *ALK*, *EGFR*, *KRAS*, Chr. 15,6,5), comorbidities (eg, COPD), and exposures (eg, smoking). **Methods:** Patients with early (stage I and II) and late (III and IV) stage onset of cancer at diagnosis were identified in the national corporate data warehouse (CDW) and CR. We used the CMS chronic disease data warehouse definitions of >20 ICD codes, with >1 encounter observed in an electronic health record, to identify subjects in both CDW and MVP. Data were integrated with date of diagnosis, date of first treatment, histology, stage, and primary tumor type from the CR. We included only patients with adenocarcinoma, squamous cell carcinoma, or large cell carcinoma specified. We excluded patients who had conflicts in stage or histology, and we only included patients once if described in the CR multiple times. **Results:** Using the CMS definition, we identified 399,504 distinct patients within the CDW, and 14,435 in MVP. Whereas, queries of the manually curated CR identified 211,899 patients, of whom 6,206 are in MVP. We found a significant difference ( $p < 0.001$ ) in mean time to treat NSCLC patients diagnosed at early (52.8 days) versus late (41.8 days) stage. **Conclusion:** By integrating clinical data with a manually curated CR, we have identified a large cohort of NSCLC subjects, including thousands with germline variants and survey data collected. We also demonstrate a difference by stage in time to the first course of treatment. This vetted cohort allows the correlation of susceptibility genes, comorbidities, and exposures to clinical presentation (stage and histology).

**Somatic mutation identification through haplotype discrepancy in tumor-only sequencing without matched normal DNA.** *W. Chen, G. Wu, S. Wang, J. Wen.* St. Jude Children's Research Hospital, Memphis, TN.

The major interests in cancer research is to identify mutations that are of clinical importance, especially tumor-specific (somatic) alterations that help disease prognosis, diagnosis and treatment. To achieve high specificity, matched normal/germline samples are always required to distinguish somatic mutations from human germline variants. However, very often the matched normal specimens are not available, limiting our ability to take advantage of larger cohort to detect recurrent somatic mutations. The challenge becomes more significant for rare tumors that might harbor novel driver mutations. To analyze the tumor-only samples, currently there are two approaches. The first approach relies on large human polymorphism databases to eliminate germline variants and cancer mutation databases to recognize somatic mutations. The second approach utilizes the fact that most tumor specimens contain normal cell contamination that cannot be removed in surgery, and compute the likelihood of somatic status by assessing the variant allele frequency deviation. Both approaches, however, use indirect evidences from either unmatched samples or statistical inferences, which cannot validate the true state of somatic mutations. To capture direct evidences of somatic mutations, we described a novel approach called SMITH (somatic mutation identification through haplotype) that utilizes the nature of normal contamination in tumor samples and the barcode feature in 10x Genomics Chromium data to call haplotypes in tumor-only sequencing. We hypothesized that variants with >2 reliable haplotypes are from somatic origins, otherwise from germline origins. We evaluated our approach using one low grade pediatric diffuse astrocytoma. First, the paired tumor and normal samples were sequenced using Illumina WGS. Using paired analytical approach, we identified 58 somatic mutations to serve as positive control and 1949 rare germline variants as negative control. We then sequenced the tumor sample using the Chromium platform, and applied SMITH. Out of the 58 somatic mutations, 51 were successfully classified as somatic, while only 2 out of the 1949 germline variant were mis-classified as somatic by SMITH (precision=96.2%, recall=87.9%). Overall these results suggest that SMITH is an effective approach capturing direct evidence for somatic mutations, and highlighting its potential application including, but not limited to, tumor-only somatic mutation or sub clonal somatic mutation discovery.

**Leveraging protein coding gene expression profiles to accurately impute lncRNA transcriptome of uncharacterized samples.** A. Nath, P. Geleher, R.S. Huang. Medicine, University of Chicago, Chicago, IL.

Long non-coding RNA's (lncRNAs) play an important role in gene regulation and are increasingly being recognized as crucial mediators of disease pathogenesis. Accurate profiling of the lncRNA transcriptome however remains a challenge owing to significantly lower expression compared to protein coding genes (PCGs). Thus, unlike PCGs, high-quality lncRNA transcriptome data remains sparsely available for a vast array of phenotypes. Here we propose a lncRNA expression imputation (LEXI) framework to reconstruct the lncRNA transcriptome of uncharacterized samples using their PCG profiles. LEXI is based on learning patterns of PCGs associated with each lncRNA across a diverse cohort of samples, and then imputing lncRNA transcriptome profiles in the uncharacterized sample. Specifically, we developed LEXI by evaluating the performance of various machine-learning algorithms benchmarked in a cross-validation study across a cohort of cancer cell lines. Furthermore, we demonstrate that LEXI accurately imputes lncRNA profiles not only in cell lines, but in cancer and normal tissues as well with models generated using independent RNAseq and microarray datasets. The goal of LEXI is to harnesses the enormous wealth of publicly available PCG expression data and enable discovery of novel lncRNA associations in various phenotypes, including disease susceptibility, prognosis and drug sensitivity. As a proof of concept, we corroborated differential expression patterns of oncogenic lncRNAs *MALAT1* and *HOTAIR* in human cancers. These results suggest that indeed LEXI can enable profiling of lncRNA expression in various uncharacterized samples and therefore allow follow-up exploration of lncRNA function.

**Subtype-specific expression of long noncoding RNAs in b-cell acute lymphoblastic leukemia.** C. Nodzak<sup>1</sup>, J. Wen<sup>1</sup>, G. Centoducatte<sup>2</sup>, J.A. Yunes<sup>2</sup>, X. Shi<sup>1</sup>. 1) Bioinformatics and Genomics, University of North Carolina at Charlotte, Charlotte, NC; 2) Laboratorio de Biologia Molecular, Centro Infantil Boldrini, Campinas, Sao Paulo, Brazil.

Precursor B-cell acute lymphoblastic leukemia (ALL) is a hematological cancer that commonly afflicts children and adolescents. One of the first subtypes of ALL described was the Philadelphia chromosome positive (Ph+) ALL, characterized by the reciprocal translocation between the long arms of chromosomes 9 and 22 with an expressed fusion product of the BCR and ABL1 kinases. Many other subtypes of ALL have been defined by various other gene fusion products (ETV6/RUNX1, TCF3/PBX1, AF4/MLL, among others) and abnormal ploidy levels. Recently, a poor prognosis type of ALL, known as Philadelphia-like (Ph-like), was defined by clustering with the (Ph+) ALL samples in global gene expression analysis. Long noncoding RNAs (lncRNAs) are known to play a role in the regulation of genes involved in multiple physiological processes and recent findings have continued to provide evidence that aberrant expression of these molecules can affect genes implicated in aspects of cancer hallmarks. Here, using data from the NCI-TARGET initiative we investigated subtype-specific co-expression networks between lncRNAs and mRNA across ten ALL subtypes followed by enrichment analysis to identify pathologically associated pathways. From the same source, a subset of Ph-like samples with matched RNA-seq and SNP 6.0 arrays were then tested for allele specific effects at heterozygous sites within these networks using an FDR corrected binomial test on the allelic ratios of uniquely mapped reads. The findings from our analysis show subtype-specific lncRNA expression in ALL, as well as an allelic effect on genes that belong to co-expression networks with lncRNAs in the Ph-like subtype.

**The NantOmics Pharmacogenomics Test: An integrative panomic approach to pharmacogenomics screening.** C. Schwartz<sup>1</sup>, J. Little<sup>1</sup>, C. Vaske<sup>1</sup>, S. Benz<sup>1</sup>, P. Soon-Shiong<sup>3</sup>, S. Rabizadeh<sup>2</sup>, J.Z. Sanborn<sup>1</sup>. 1) NantOmics, Santa Cruz, CA; 2) NantOmics, Culver City, CA; 3) NantWorks, Culver City, CA.

Numerous cancer therapies contain pharmacogenomics warnings on their FDA labels, yet pharmacogenomics screening is not yet used in routine clinical practice. Pharmacogenomics testing can be used to tailor therapies to the patient's genotype to reduce the chance of drug-induced toxicities, improve patient outcomes and reduce treatment costs. Here we present the NantOmics pharmacogenomics test, which uses whole genome (DNA) and whole exome sequencing data from FFPE tumors and matched normal samples to predict and advise physicians of possible toxicities. Using FDA labels and guidelines from the Clinical Pharmacogenomics Implementation Consortium (CPIC), we developed a clinical pharmacogenomics panel including 46 markers in 11 genes linked to toxicities from 14 cancer therapies, in addition to a research panel of 13 gene-drug pairs reported in primary literature. The test screens for both germline and somatic variants to determine how an oncology patient will respond to potential therapies in the clinical setting. The test was run on over 890 patient samples, 96.5% of which contained a variant in at least one gene from our panel. Furthermore, 8% of patients had genomic variants that could have resulted in severe or life threatening drug toxicities. For all alleles in our clinical panel, we observed similar allele frequencies to those reported in the ExAC database. Our test was validated on a cohort of patients previously genotyped by an independent CLIA-validated PCR-based panel, as well as on a set of synthetic data. Our validation studies demonstrated that the test is able to detect each variant in our panel, and is able to correctly determine patient genotype in all studied cases. Given the high number of patients with potential treatment-altering genomic variants, these results underscore the need for pharmacogenomics screening for oncology patients in a clinical setting.

**769W**

**Cepip: Context-dependent epigenomic weighting for prioritization of regulatory variants and disease-associated genes.** J. Wang<sup>1</sup>, M.J. Li<sup>2,3,4</sup>, Z. Liu<sup>3,5</sup>, B. Yan<sup>3</sup>, Z. Pan<sup>3</sup>, D. Huang<sup>4</sup>, Q. Liang<sup>4</sup>, D. Ying<sup>3</sup>, F. Xu<sup>3</sup>, H. Yao<sup>3</sup>, P. Wang<sup>1</sup>, J.P.A. Kocher<sup>1</sup>, Z. Xia<sup>3,5</sup>, P.C. Sham<sup>3</sup>, J.S. Liu<sup>2</sup>. 1) Department of Health Sciences Research and Center for Individualized Medicine, Mayo Clinic, Scottsdale, AZ 85259, USA; 2) Department of Statistics, Harvard University, Cambridge, Boston, MA 02138-2901, USA; 3) Center for Genomic Sciences, The University of Hong Kong, Hong Kong SAR, China; 4) Department of Pharmacology, School of Basic Medical Sciences, Tianjin Medical University, Tianjin, China; 5) Department of Anaesthesiology, The University of Hong Kong, Hong Kong SAR, China.

It remains challenging to predict regulatory variants in particular tissues or cell types due to highly context-specific gene regulation. By connecting large-scale epigenomic profiles to expression quantitative trait loci (eQTLs) in a wide range of human tissues/cell types, we identify critical chromatin features that predict variant regulatory potential. We present cepip, a joint likelihood framework, for estimating a variant's regulatory probability in a context-dependent manner. Our method exhibits significant GWAS signal enrichment and is superior to existing cell type-specific methods. Furthermore, using phenotypically relevant epigenomes to weight the GWAS singlenucleotide polymorphisms, we improve the statistical power of the gene-based association test.

**770T**

**Negative binomial model-based clustering: Discover novel molecular subtypes of ovarian cancer.** Q. Li, J.R. Noel-MacDonnell, D. Koestler, E.L. Goode, B.L. Fridley. 1) Department of Biostatistics and Bioinformatics, Moffitt Cancer Center, Tampa, FL; 2) Department of Health Services and Outcomes Research, Children's Mercy Hospital, Kansas City, MO; 3) Department of Biostatistics, University of Kansas Medical Center, Kansas City, KS; 4) Department of Health Sciences Research, Mayo Clinic, Rochester, MN.

Unsupervised clustering refers to the grouping of subjects and/or genomic features based on their similarity and represents one of the widely applied methods in analysis of high-throughput 'omic data. A variety of unsupervised clustering methods have been proposed for RNA-Seq count data, however most of the methods currently applied do not capture the over-dispersed nature of this data. We propose a Negative Binomial Model-Based (NBMB) method to cluster samples based on RNA-Seq data using a modified Expectation-Maximization algorithm, and is available in an R package named *NB.MClust*. Results from an extensive simulation study found that NBMB without transform outperforms Gaussian Mixture Model (GMM) with different transformations, based on Adjusted Rand Index (ARI). When sample size is N=150 or larger, ARI of NBMB is better than or equal to that of GMM in over 95% of simulated datasets, half of which show strictly better ARI in NBMB. We further assessed the ability of transcriptome wide NBMB clustering to determine molecular subtypes using two tumor RNA-Seq studies of epithelial ovarian cancer (EOC), the first from Mayo Clinic and the second from TCGA. We compared the cluster assignments from NBMB to the existing "CLOVAR" classifier. In both datasets, NBMB discovered similar but slightly distinct clusters or subtypes based on the CLOVAR classifier. Three of NBMB subtypes in TCGA data were associated with progression-free survival. In order to clarify prognostic relevance, future work would apply NBMB clustering on more EOC tumors and integrating NBMB-based subtypes with known prognostic factors.

**Identification of potential LREA regions in prostate cancer cell lines using multi-omic analysis features of Strand NGS software.** P. Karuna, S.K. Sivamani, S. Ramachandru, S.C. Cherukuri. Strand Life Sciences Pvt. Ltd, Bangalore, Karnataka, India.

Epigenetic gene deregulation in cancer commonly occurs through chromatin repression and promoter hypermethylation of tumor-associated genes. However, this mechanism of the epigenetic-based gene activation in carcinogenesis is still poorly understood. Here, using Strand NGS bioinformatics software, we provide an illustrative example by integrating gene expression, chromatin and DNA methylation genome-wide profiles in prostate cancer and were able to identify 35 LREA (long-range epigenetic activation) domains that harbor 251 genes, including multiple gene families, and tumor-related genes. As a part of this study, we re-analyzed the publicly available datasets GSE38685. This study highlights the identification of LREA regions by Expression profiling, Methylation profiling, Genome variation profiling, and Genome binding by high throughput sequencing in an efficient and powerful way using Strand NGS. The clustering analysis of these activated domains showed significant enrichment in several gene families, including the *MAGE*, *UGT2*, and *KLK* families and the differential expression of the gene clusters were identified. The Genome binding analysis and the methylation analysis were performed to assess whether these activated gene clusters also exhibit epigenome changes. In prostate cancer cells, the entire *KLK* family shows a remarkable feature of switching between the gain of the repressive histone modifications H3K9me2 and H3K27me3 along with loss of active Histone modifications H3K9ac and H3K4me3. We also found examples of CpG island methylation specifically at the *KLK* locus that resulted in transcriptional activation. An overlay of the Expression, Methylation, and the ChIP-Seq data using WikiPathways displayed that *KLK* genes play a vital role in the Prostate cancer signaling pathway. Our results clearly demonstrate that cancer-specific DNA methylation of CpG islands contribute to deregulation of promoter usage, and can result not only in gene repression but also in cancer associated gene activation.

**772W**

**Matched tumor/germline samples aid in detecting genomic instability in multiple myeloma using linked-read whole genome sequencing without the need for high molecular weight DNA.** C. Ashby, M.A. Bauer, A. Mikulasova, O.W. Stephens, R.G. Tytarenko, F.E. Davies, G.J. Morgan, B.A. Walker. Myeloma Institute, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

**Introduction:** Multiple Myeloma is a hematological malignancy of plasma cells in the bone marrow characterized by translocations, copy number aberrations and mutations. However, the interaction of these events has not been fully explored due to technological inadequacies. We sought to gain new understanding by using 10X Genomics linked-read whole genome sequencing (WGS). However, archived myeloma DNA samples do not meet the high molecular weight (HMW) recommendation by 10X Genomics. **Materials and Methods:** 32 pairs of tumor and germline samples from myeloma patients were analyzed using 10X Genomics WGS, of which 27 had known translocations involving the Ig loci. Sequences were aligned to hg38 using Longranger (v2.1.0). A novel algorithm was developed to detect somatic translocation events by statistically comparing shared barcodes across identified breakpoints between tumor and germline. Similarly, normalized depth and barcode ratio, haplotype and B allele frequency comparison was used for copy number variant detection. **Results:** Samples had a median molecule length (ML) of 25 kb, with only 7 of the 64 (11%) having the 10X Genomics recommended ML. Samples were sequenced to a median depth of 43.7x. Longranger's structural variant (SV) caller identified a median of 105 SV calls per sample but, when compared with germline, only a median of 22 were somatic events (range 3-145). Of these somatic events, a median of 6 (27%) had less than 2 supporting split and/or paired reads (as reported by Longranger), suggesting that they would not have been detected using standard WGS. There was a median of 5 (range 1-20) inter- and 14 (range 1-142) intra-chromosomal SVs. Of the 27 samples with expected Ig rearrangements, copy number breakpoints or SVs were detected in 24 (89%). Nine had an event that did not pass filter, but were verified by lack of overlapping barcodes in the germline sample. Of the discrepant samples, one had lower ML and mean depth (7 kb;32x) and one had lower mean depth (34x). Interestingly, two samples with lower ML had copy number events at the expected translocation breakpoint. **Conclusions:** Assisted by matched control sample, even low MW samples have sufficient barcodes to find somatic SV events revealing that the genome of myeloma is heterogeneous with each sample showing a wide range of SVs. It is clear that the linked read approach will help characterize the wide variance of genome instability in myeloma, and this in turn may impact outcome.

**773T**

**Expression-based Variant Impact Phenotyping (eVIP) for determination of somatic mutation function in cancer.** A. Berger<sup>1</sup>, L. Jerby<sup>2</sup>, A. Regev<sup>2</sup>, J. Boehm<sup>2</sup>, A. Brooks<sup>3</sup>. 1) Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Broad Institute of MIT & Harvard, Cambridge, MA; 3) UC Santa Cruz, Santa Cruz, CA.

Variants of unknown significance (VUS) pose a major challenge to the implementation of precision medicine. A bottleneck in functional characterization of genetic variants is the development of optimized and highly tailored assays for each gene of interest. We hypothesized that functionally impactful genetic changes will directly or indirectly affect the cellular transcriptional program, and gene expression profiling might therefore represent a general and scalable assay for characterization of mutation function. To test this hypothesis, we generated an open reading frame (ORF) library of 194 missense or in-frame indel variants in 53 different genes. The mutations selected were somatic variants observed in primary lung adenocarcinomas. The library was introduced into human lung cell lines via lentiviral transduction. 96 hours after transduction, transcriptional signatures were generated by L1000 profiling. We built a publicly-available computational pipeline, eVIP, that compares wild-type and mutant transcriptional signatures to classify mutations as impactful (gain-of-function, change-of-function, loss-of-function) or likely neutral. eVIP identified 69% of the mutations as impactful, versus 31% as likely neutral. eVIP correctly classified 21 known oncogene mutations as impactful and identified dozens of never-characterized gain- and loss-of-function mutations. We performed two complementary screens to determine the effect of the variants on drug resistance and xenograft tumor formation phenotypes. We validated rare, oncogenic variants in *ARAF*, *BRAF*, *EGFR*, *ERBB2*, *KRAS*, and *RIT1*, and identified small molecule MEK inhibitors as able to reverse the phenotypes induced by these rare variants. To adapt eVIP to a pooled screen format, we sought to apply eVIP to single-cell RNA sequencing data. Ten wild-type or mutant ORFs were used to generate a pooled population of A549 cells. Single-cell RNA-seq transcriptional profiles were highly correlated to the bulk signatures generated by L1000, demonstrating the promise of single-cell RNA-seq to significantly expand eVIP throughput by enabling pooled screens. Here we present eVIP as a generalizable method for characterization of genetic variants that requires no prior knowledge of gene function. Continued high-throughput functional characterization of mutations should illuminate the role of VUS in cancer and other diseases.

**Fix-C: A novel experimental and computational method for structural variation detection and *in silico* long range phasing from FFPE tumor tissue.** H.A. Costa<sup>1</sup>, M. Blanchette<sup>2</sup>, C.D. Bustamante<sup>1,3</sup>, R.E. Green<sup>4</sup>, P.D. Hartley<sup>5</sup>, C. Kunder<sup>5</sup>, N. Putnam<sup>2</sup>, B. Rice<sup>2</sup>, C. Troll<sup>2</sup>, J.L. Zehnder<sup>5</sup>. 1) Department of Genetics, Stanford University School of Medicine, Stanford, CA, 94305 USA; 2) Dovetail Genomics, LLC, Santa Cruz, CA, 95060 USA; 3) Department of Biomedical Data Science, Stanford University School of Medicine, Stanford, CA, 94305 USA; 4) Department of Biomolecular Engineering, UC Santa Cruz, Santa Cruz, CA, 95064 USA; 5) Department of Pathology, Stanford University School of Medicine, Stanford, CA, 94305 USA.

**Introduction:** The clinical management and therapy of many solid tumor malignancies is dependent on the utilization of genomic tools for comprehensive detection of medically actionable or diagnostically relevant genetic variation. However, a principal challenge in tumor sequencing is the use of archival formalin-fixed paraffin-embedded (FFPE) tissue which produces highly fragmented low-molecular weight nucleic acid. This sub-optimal input specimen, coupled with the short read nature of DNA and RNA next-generation sequencing protocols, proves challenging to generate long-range (Mbp+) genomic sequence data that are able to accurately and robustly provide information on underlying large-scale structural variation and phasing from these specimens. **Methods:** As a proof-of-principle we have developed a Hi-C chromosome conformation capture methodology for FFPE tissue called "Fix-C" which yields phased read pairs spanning distances up to full chromosomes and enables unambiguous structural variation detection and variant phasing in archival specimens. We have applied our method to 15 clinical lung adenocarcinoma and sarcoma specimens spanning a broad range of tumor purity for structural variation fusion detection and somatic variant phasing. **Results:** Our method achieves a 100% concordance rate with concurrent FISH testing, which is currently used as the clinical gold standard. Additionally, this global structural detection approach enables unbiased whole-genome perspective for structural variation detection, and identifies novel structural events in our cohort missed by FISH and traditional RNA and DNA sequencing on these specimens. Lastly, our novel approach allows us to produce long phased sequences from FFPE tissue with an N50 of 132 megabases (full chromosome scale) in these specimens—enabling accurate and haplotype-aware somatic mutation phasing. **Conclusions:** Here we present a novel sequencing approach that leverages the genome scale structural resolution of Hi-C with the throughput of traditional Illumina sequencing methods. By *in silico* analysis we are able to reconstruct long allele haplotypes from fragmented FFPE specimens, and demonstrate the ability to identify known and novel structural events in tumor tissue. This advance is a paradigm shift in FFPE nucleic acid analysis and will enable high-detailed resolution of global structural variation underlying solid tumor malignancies while simultaneously allowing unambiguous somatic variant phasing.

## 775W

**Using liquid biopsies for low frequency variant detection and tissue-of-origin exploration.** K. Cunningham, J. Lenhart, A. Wood, S. Sandhu, C. Schumacher, L. Kurihara, V. Makarov, T. Harkins. Swift Biosciences, Ann Arbor, MI.

Liquid biopsy assays enable non-invasive profiling of circulating, cell-free DNA (cfDNA) and circulating tumor cell DNA to assist in early-stage diagnosis of disease and monitoring treatment response. Since high sequencing depth is required to profile cfDNA variants, most liquid biopsy assays use targeting to cost-effectively achieve deep coverage of target loci for pathogenic variant detection as low as 1% allelic fraction. An assay that produces uniform, comprehensive coverage from low DNA quantities is critical for obtaining the necessary sensitivity. We developed a liquid biopsy workflow for low frequency variant detection from 10 mL of blood combined with Accel-NGS<sup>®</sup> library preparation. In addition, we explored whether methylation patterns of cfDNA possess information about the tissue-of-origin. Whole blood samples were collected in Streck Cell-Free DNA BCT<sup>®</sup> vials from patients with late stage cancer and cfDNA was extracted with the Promega Maxwell RSC. A total of 10 ng cfDNA was used to make an Accel-NGS 2S Hyb library followed by hybridization capture using IDT xGen<sup>®</sup> Pan Cancer probes. Molecular barcodes were incorporated to label each library molecule uniquely prior to amplification. Sequencing was performed to a minimum of 8000X mean bait coverage. In parallel, 10 ng cfDNA samples were used as input to the Accel-NGS Methyl-Seq Kit to study methylation patterns. Extraction yielded 8-32 ng cfDNA with a size peak of 170 bp and a mean qPCR integrity score of 0.22, characteristic of high quality cfDNA lacking cellular DNA. The Accel-NGS 2S Hyb Kit exhibited 90% conversion with cfDNA, providing highly complex libraries with uniform target coverage (>99% of bases covered >100X). Molecular barcodes enabled removal of PCR duplicates while preserving fragmentation and strand duplicates to maximize coverage. Sensitive and precise detection of variants was achieved down to 0.5% allele frequency. In addition, using whole genome bisulfite sequencing (WGBS) and *a priori* knowledge of differentially methylated regions characteristic of different human tissues, we identified predominant tissue sources of cfDNA in blood. We developed a liquid biopsy workflow for low frequency variant detection from clinically relevant quantities of cfDNA and a WGBS workflow showing the epigenetic status of cfDNA can be used to identify tissue-of-origin. Together, these approaches provide powerful methods for detecting, identifying, and monitoring disease.

**Obtaining high quality transcriptome data from formalin-fixed, paraffin-embedded diagnostic prostate tumour specimens.** *L.M. FitzGerald<sup>1,2</sup>, C.H Jung<sup>3</sup>, E.M Wong<sup>4</sup>, J. Joo<sup>4</sup>, J.A. Gould<sup>5</sup>, V. Vasic<sup>5</sup>, J.K. Basset<sup>6</sup>, N. O'Callaghan<sup>7</sup>, T. Nottle<sup>6</sup>, J. Pedersen<sup>6</sup>, G.G. Giles<sup>2,7</sup>, M.C. Southey<sup>2,4</sup>.* 1) Cancer, Genetics and Immunology, Menzies Institute for Medical Research, Hobart, Tasmania, Australia; 2) Cancer Epidemiology and Intelligence Division, Cancer Council Victoria, Melbourne, VIC, 3004; 3) Melbourne Bioinformatics, University of Melbourne, Parkville, VIC, 3010; 4) Department of Pathology, The University of Melbourne, Parkville, VIC, 3010; 5) Monash Health Translation Precinct, Medical Genomics Facility, Hudson Institute of Medical Research, Clayton, VIC, 3168; 6) TissuPath Specialist Pathology, Mount Waverley, VIC, 3149; 7) Centre for Epidemiology and Biostatistics, School of Global and Population Health, The University of Melbourne, Melbourne, VIC, 3010.

Prognostic genomic biomarkers that can be measured at diagnosis to aid choice of treatment options are unavailable for most common cancers. This has been due in part to the poor quality and quantity of available diagnostic specimens and to limitations in genomic technologies. Recent technical advances now provide the ability to perform high density molecular genetic analyses using suboptimal biological specimens. Here we describe the optimisation of a gene expression assay for use with formalin-fixed, paraffin-embedded (FFPE) diagnostic prostate cancer (PrCa) specimens. We applied the Ion AmpliSeq Transcriptome Human Gene Expression Kit (AmpliSeq Kit) to RNA samples extracted from 36 tumour-enriched and 16 adjacent normal tissues (AD<sub>JNT</sub>) from 37 FFPE PrCa specimens over a series of eight pilot studies, incorporating protocol modifications in studies 2 to 5. Data quality was measured by 1) the total number of mapped reads; 2) the percentage of reads that mapped to AmpliSeq target regions (OnTarget%); 3) the percentage of genes on the AmpliSeq panel that had a read-count  $\geq 10$  (TargetsDetected%); and 4) a comparison of the gene read-count distribution of the prostate tissue samples with the median distribution of control cell line-derived RNA samples. Modifications incorporated into pilot study 5 provided high quality gene expression data equivalent to that from control cell line-derived RNA samples. These modifications included the use of freshly cut slides for macrodissection; increased tissue section thickness (8 $\mu$ m); RNA extraction using the RecoverAll Total Nucleic Acid Isolation Kit for FFPE (ThermoFisher); 18 target amplification cycles; and processing six samples per chip. Preliminary Differential Gene Expression (DGE) analysis on TMM normalised data from 15 AD<sub>JNT</sub> and 26 prostate tumour samples identified 2,630 differentially expressed genes (FDR  $< 0.01$ ), of which 1,275 were up-regulated and 1,355 were down-regulated. A modified protocol for the AmpliSeq Transcriptome Human Gene Expression Kit can generate high quality, transcriptome data from suboptimal FFPE-derived RNA. This protocol will facilitate the discovery of prognostic biomarkers for cancer by allowing researchers to exploit previously under-utilised diagnostic FFPE specimens.

**777F**

**Digital gene expression from low sample input: Highly multiplexed and robust profiling of formalin-fixed paraffin-embedded (FFPE) and fresh frozen samples from as little as 1 ng of RNA using the nCounter® Platform.** *D. Hanson, M. Bailey, L. Dennis, M. Eagan, N. Elliot, G. Meredith, S. Warren, A. White.* NanoString Technologies, Seattle, WA.

Gene expression analysis from tissue biopsies and formalin-fixed paraffin-embedded (FFPE) samples are an industry standard and invaluable to scientists who seek to answer biological questions in the fields of translational and biomarker research. However, one of the major challenges faced by scientists and clinicians is one of sample conservation. Researchers working with samples of low RNA content, biopsies with limited tissue amounts or rare cell types are often faced with the difficult choice of how to run multiple analytical tests and generate as much biologically relevant data as possible from limited available sample material. Furthermore, samples such as FFPE are often degraded or crosslinked due to fixatives used in the tissue archival process. For this reason, it is important for molecular technologies to not only be able to generate quality data but to do so while consuming the least amount of sample possible. NanoString's nCounter System is an automated platform that, by using a digital molecular barcoding technology, enables counting of unique transcripts within a sample. The standard nCounter protocol recommends RNA inputs of 100 ng for successful expression profiling. Here we demonstrate a method using a pre-amplification approach upfront of the nCounter workflow that significantly reduces RNA input requirements 10 to 100-fold depending on sample type. RNA extraction was performed on a sample set containing both F/F (fresh/frozen) and FFPE samples from spleen, brain, lymph node and tumor tissues. Samples were profiled on the nCounter across NanoString gene expression panels using both 100 ng of un-amplified input RNA with the standard workflow, and either 1 ng (F/F) or 10 ng (FFPE) RNA with the Low RNA Input workflow. Profiles were generated from all samples and the overall number of genes detected showed high concordance ( $r > 0.85$ ) between samples prepared using the standard (un-amplified) and Low RNA Input (amplified) methods. The data presented demonstrates successful validation of a Low RNA Input nCounter workflow enabling a 10x-100x reduction in sample input while maintaining robust expression profiling with an increased sensitivity of detection of low expressing genes.

**Multiplexed molecular characterization of non-small cell lung cancer PDX models with NanoString's nCounter® Vantage 3D™ DNA:RNA:Protein Solid Tumor assay.** *D. Hinerfeld<sup>1</sup>, S. Airhart<sup>2</sup>, A. White<sup>1</sup>, T. Hood<sup>1</sup>, C. Bult<sup>2</sup>.*

1) Nanostring Technologies, Seattle, WA; 2) The Jackson Laboratory, Bar Harbor, ME.

**Background:** While significant progress has been made in the development of targeted and immune-based therapies, non-small cell lung cancer (NSCLC) frequently acquires resistance resulting in disease progression and ultimately death. Decreasing this high mortality rate requires the development of new therapeutic strategies and rational combinations of new and existing drugs. Part and parcel of these efforts is development of biomarkers that can predict both efficacy and potential side effects of these novel NSCLC therapies. Patient Derived Xenografts (PDX) are powerful models for pre-clinical research into therapeutic efficacy and mechanism of action. However, drug studies in PDX models are time consuming and resource intensive. Leveraging these models to gain a deeper understanding of the heterogeneity of the PDX tumors as well as the molecular determinates of therapeutic response or resistance adds significant value beyond determining the change to tumor volume alone. **Methods:** Somatic variants in 25 different clinically actionable genes as well as the expression of 770 cancer-relevant RNAs plus 26 proteins and phosphoproteins were simultaneously analyzed in twelve NSCLC models using the NanoString Vantage 3D research assay. This new multi-analyte technology for mutational status and gene expression was validated against previous DNA and RNAseq analysis of all tumors. **Results:** NanoString SNV and indel calls revealed consistent results when comparing to the DNAseq data for the primary patient tumor and the PDX model. For all twelve tumors, the average correlation between the RNAseq (frozen) and NanoString (FFPE) analysis was  $R^2$  of  $0.62 \pm 0.05$ , which is similar to what has been previously reported, particularly considering the difference in sample type. The expression profile of 26 proteins and phospho-protein targets reveals heterogeneity in pathway activation across the different models. **Conclusion:** Even amongst samples with the same driver mutations, there is significant heterogeneity in both RNA and protein expression. This heterogeneity is particularly interesting with respect to two PDX lineages of a single patient tumor where the simultaneous analysis of RNA and protein reveals clues into their observed differences in sensitivity to treatment with erlotinib.

**Development of a lysate-based multiplex proteomics platform using nCounter.** *J. Lee<sup>1</sup>, G. Demirkan<sup>2</sup>, G.K. Geiss<sup>2</sup>, C.P. Vellano<sup>1</sup>, B. Filanoski<sup>2</sup>, Y. Lu<sup>1</sup>, Z. Ju<sup>2</sup>, S. Yu<sup>1</sup>, H. Guo<sup>1</sup>, L. Bogatzki<sup>2</sup>, W. Carter<sup>2</sup>, R. Meredith<sup>2</sup>, S. Warren<sup>2</sup>, Z. Ding<sup>1</sup>, A.A. Sahin<sup>4</sup>, J.M. Beechem<sup>2</sup>, G.B. Mills<sup>1</sup>.* 1) Systems biology, UT MD Anderson Cancer Center, Houston, TX; 2) NanoString Technologies, Inc., Seattle, WA; 3) Bioinformatics and computational biology, UT MD Anderson Cancer Center, Houston, TX; 4) Pathology, UT MD Anderson Cancer Center, Houston, TX.

Comprehensive understanding of the functional proteome has helped characterize many cancers and identified treatment regimens that translate to improved outcomes. Integration of genomics and transcriptomic with functional proteomics will provide the most information for understanding cancer biology and improving patient outcomes. Recent protein measurement technologies have expanded in plexity; however, accurate protein measurement using antibody-based multiplex methods is still challenging due to signal amplification steps, which decreases robustness and accuracy. In this study, we developed multiplex DNA-oligo-labeled antibody panels and associated nitrocellulose or ELISA plate-based protocols for lysate samples based on the digital nCounter technology that assesses single molecules without amplification. Targets encompassed major cancer signaling proteins and phospho-proteins, with an emphasis on breast cancer markers. We implemented a rigorous pipeline to validate barcoded antibodies using Western blotting, ELISA and cross-platform comparison with Reverse Phase Protein Array (RPPA), an orthologous high-throughput proteomics technology. Results from the antibody panel were highly reproducible both in technical and biological replicates ( $r = 0.99$  and  $0.92$  respectively) using lysate samples from multiple cancer cell lines with different perturbations. Importantly there was no evidence for "batch effects" across samples sets caused by non-biological factors ( $r = 0.99$ ). To assess potential clinical utility, we processed lysates from frozen breast cancer patient tumors and demonstrated accurate breast cancer subtyping. Taken together, we show highly quantitative utility for protein measurement in relevant conditions. Importantly, the multiplex proteomics platform is highly suited to the clinical setting due to its robustness and reproducibility. .

**780F****Functional validation of pleiotropic susceptibility loci for breast and ovarian cancer using chromosome conformation capture technology.**

J. Plummer<sup>1</sup>, S. Kar<sup>2</sup>, Q. Li<sup>3</sup>, M. Freedman<sup>3</sup>, P. Pharoah<sup>2</sup>, S. Gayther<sup>1</sup>. 1) The Center for Bioinformatics & Functional Genomics, Department of Biomedical Science, Cedars Sinai Medical Center, CA; 2) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, UK; 3) Department of Medical Oncology, Dana-Farber Cancer Institute, The Eli and Edythe L. Broad Institute, Cambridge, MA.

Breast and ovarian cancers share common etiologies and similar genetics, such as mutations in *BRCA1/2* are responsible for most multi-case breast/ovarian cancer families. This shared genetic liability is also manifested in terms of common genetic susceptibility variants that suggests widespread pleiotropic effects on both cancer types. Previous GWA and cis-eQTL analyses identified *RCCD1* as a likely candidate gene for both breast and ovarian cancer risk (Cancer Discovery 2016). Chromosome conformation capture (3C) methods are powerful tools to identify physical interactions between target genes and risk-associated SNPs. We have used circularized chromosome conformation capture (4C) assays in both breast and ovarian normal (MCF10A and FT246) and cancer cell lines (BT549, MCF7 and UWB1.289, KURA-MOCHI) to identify interactions between the *RCCD1* promoter and possible candidate causal variants at the 15q26 pleiotropic risk locus. Of interest, rs763280402 and rs774617992 showed 4C interactions with the *RCCD1* promoter in cancer cells. Given regulatory elements are the likely functional targets of most risk-associated alleles, we used regulatory feature annotation (Statehub) to show both variants lie in predicted enhancers of normal breast cells (HMEC), a likely functional target. In fact, ovarian cancer patients who have high *RCCD1* expression ( $P < 0.004$ ) show prolonged survival curves (KM Plotter). These findings demonstrate that using an integrated functional genomics to comprehensively evaluate interactions of a given breast and ovarian cancer risk locus can identify candidate susceptibility genes for both cancer types.

**781W****Hereditary predisposition to asynchronous bilateral breast cancer:**

**Going beyond BRCA1, BRCA2 and PALB2.** M. Tischkowitz<sup>1</sup>, E. Fewings<sup>1</sup>, J. Redman<sup>1</sup>, M. Goldgraben<sup>1</sup>, J. Hadfield<sup>2</sup>, P. Concannon<sup>3</sup>, J. Bernstein<sup>4</sup>, D. Conti<sup>5</sup>, A. Larionov<sup>1</sup>, The WECARE Consortium. 1) University of Cambridge, Cambridge, United Kingdom; 2) Genomics Core, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom; 3) Genetics Institute and Department of Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL, United States; 4) Department of Epidemiology and Biostatistics, Memorial Sloan-Kettering Cancer Center, New York, NY, United States; 5) Division of Biostatistics, Department of Preventive Medicine, University of Southern California, Los Angeles, CA, United States.

**Background:** BRCA1/2-negative asynchronous contralateral breast cancer (CBC) is associated with familial history, suggesting a heritable component in CBC beyond the BRCA1/2 mutations. However, no datasets have yet been generated to study germline variants associated with BRCA1/2-negative CBC. **Methods:** DNA extracted from blood was obtained from 256 CBC and 256 matched unilateral breast cancer (UBC) patients of European ancestry enrolled in the Women's Environmental Cancer and Radiation Epidemiology (WECARE) study. Women with *BRCA1*, *BRCA2* or *PALB2* mutations were excluded. Whole exome sequencing (WES) was performed using Illumina library preparation and sequencing technologies. VCF files were generated following GATK Best Practices workflow. Rare variants were aggregated per gene and statistical associations were assessed using SKAT R package. Trends in crude allelic frequencies (AFs) were evaluated by comparing AFs in CBC, UBC and non-Finish European cases from 1-thousand genomes project. **Results:** 235 CBC and 245 UBC were successfully sequenced to ~60x average depth on targets. Focused analysis in established breast cancer genes suggested that *ATM* and *CHEK2* showed crude AFs trends consistent with CBC association. Small sample and effect sizes precluded exome-wide detection of candidate genes that would pass multiple testing-correction in SKAT analysis. Combining results from the SKAT analysis, the crude AFs assessments and manual prioritising by biological functions allowed for the selection of candidate genes, which could be used for further genotyping in a larger cohort or for experimental validation. **Conclusion:** The study reports a new WES dataset for the identification of candidate genes potentially associated with asynchronous contralateral breast cancer.

## 782T

Gastric cancer is the second leading cause of cancer-related deaths worldwide. Approximately 1,000,000 individuals are diagnosed with gastric cancer annually worldwide, resulting in 800,000 deaths. Gastric cancer is a highly heterogeneous disease and novel therapeutic regimens based on the genomic data from gastric cancer are still limited. We have successfully generated 69 patient-derived xenograft (PDX) mouse models from Korean gastric cancer patients using immunodeficient NSG mice. These PDX models cover different types of gastric cancers, including the diffuse, intestinal, and mixed types based on the Lauren classifications. We performed whole-exome sequencing and RNA-seq on 47 primary gastric cancer patient samples and their corresponding PDX tumor samples. Systemic analysis and comparison of the mutational profiles in the primary and PDX samples indicated that the mutational process is preserved throughout tumor growth in the mice, and in most tumors, this is due to the CpG→TpG mutation mechanism. The gene expression patterns were also highly conserved between the primary and corresponding PDX tumors, with expression-based TCGA subtype classifications being maintained. Consistent with the loss of immune-related functions and human stroma in the PDX establishment, expression signatures associated with immune-related and stromal cell function were decreased in the PDX tumors compared with the matched primary tumors. In addition, we observed the development of 27 human EBV-Diffuse large B-cell lymphoma (DLBL) during the engraftment of gastric cancer into the immunodeficient mice and analysis of these tumors are ongoing. The PDX models established in this study will become important resources for studies of tumor heterogeneity, clonal evolution, drug sensitivity and resistance, molecular pathogenesis of EBV-induced DLBL lymphoma as well as the development of novel target therapy for gastric cancer precision medicine.

## 783F

**Comparative analysis between gene expression profile and genomic profile in adrenocortical carcinoma samples.**

F.P. Fortes<sup>1,2</sup>, L.M. Canto<sup>2</sup>, H. Kuasne<sup>2</sup>, F.A. Marchi<sup>2</sup>, K.C. de Andrade<sup>1,2</sup>, S.R. Rogatto<sup>3</sup>, M.I. Achatz<sup>1</sup>. 1) Division of Cancer Epidemiology and Genetics- DCEG, National Cancer Institute/ National Institutes of Health (NCI/NIH), Bethesda, MD; 2) International Research Center (CIPE)- AC Camargo Cancer Center, São Paulo, São Paulo, Brazil; 3) Department of Clinical Genetics, Vejle Hospital, SLB, University of Southern Denmark, Vejle - DK.

Li-Fraumeni syndrome (LFS) is a cancer predisposition disorder that increases the risk of developing tumors at an early age as well as multiple primary tumors. Pathogenic germline *TP53* mutations are the underlying cause of LFS. In Southern and Southeastern Brazilian population the syndrome is present in 0.3% due to the presence of a founder mutation, p.R337H *TP53*. This mutation was initially described as tumor-specific, predisposing individuals to adrenocortical carcinoma (ADR). ADR is a rare neoplasm worldwide, but pediatric ADR is 10-15 times more incident in p.R337H mutation carriers. To date, the factors that lead to the development of ADR in some carriers of *TP53* germline mutations while others carriers remain asymptomatic remain unclear. Our hypothesis is that the presence of the p.R337H mutation may not be sufficient for ADR development. The aim of this study was to evaluate the copy number alterations (CNA) of ADR patients who were either positive (N=3) or negative (N=4) for p.R337H mutation, and to compare the results with global gene expression analysis data from our group. Analysis of gains and losses was evaluated by CytoScan HD Array (Affymetrix, Santa Clara, CA, USA). Analysis of global gene expression was evaluated by microarray (4x44K, Agilent Technologies). Genomic alterations that distinguished tumors that were positive for the p.R337H mutation from those that were negative for it were identified using Fisher's exact test, where regions with  $p < 0.05$  were regarded as statistically significant. For the gene expression analysis, Student's t-test was used to evaluate differences between p.R337H-positive and p.R337H-negative groups. There were 25 alterations involving chromosomes 1, 10, 11, 12 and 17. Most alterations were located on chromosomes 12 (11/25) and 17 (9/25). A total of 25 genes were identified as having altered transcript expression. Of these, 17 presented gain and increased expression when comparing positive vs. negative cases, and eight presented loss and decreased expression for the same analysis. Despite the small sample size, ADR patients who were positive for the p.R337H mutation presented a lower level of genomic instability than p.R337H-negative. This data suggests that patients with the p.R337H mutation may present a carcinogenic process that is distinct from that of patients without mutations in the *TP53* gene.

**Using NGS to detect mutations below 1% allele frequency in circulating cell free DNA and associated tumors.** A. Wood, S. Sandhu, V. Kelchner, J. RoseFigura, J. Lenhart, L. Kurihara, V. Makarov, T. Harkins. Swift Biosciences, Ann Arbor, MI.

The use of circulating, cell-free DNA (cfDNA) for early detection and monitoring of disease is rapidly growing. This necessitates accurate variant detection at and below 1% allele frequencies due to a low population of tumor DNA within cfDNA samples. Reliable, low-frequency variant detection by next-generation sequencing (NGS) is challenging due to non-specific background noise from PCR and sequencing errors. We have employed molecular identifiers (MIDs) to uniquely label individual DNA molecules prior to amplification, facilitating the distinction of true variants from PCR and sequencing errors. MID incorporation also results in increased data retention by removing PCR duplicates while preserving fragmentation and sister strand duplicates. Here, we have applied MIDs to both our Accel-NGS® 2S whole genome library prep followed by hybridization capture with various cancer panels, and to our Accel-Amplicon™ library prep that uses multiplex PCR ideal for small panels that are amenable to deep sequencing. To validate this technology, we performed low frequency spike-in experiments at 1% and 0.5% with genomic DNA as well as various cfDNA samples. 2S libraries were prepared and hybridization capture was performed with an 800kb pan cancer panel. Libraries were sequenced to greater than 8000x coverage and a consensus sequence was generated with BMFtools. All known variants present at 1% and 0.5% allele frequencies were maintained in the resulting data. Further, true variants were preserved while PCR and sequencing errors were removed, demonstrating improved specificity using MIDs. We also validated variant calling below a 1% allele frequency using the Accel-Amplicon *EGFR* Pathway Panel with MIDs. After validation of our MID technology, libraries were prepared with cfDNA and tumor samples from individuals with ovarian, liver, stomach, and colon cancers. Libraries were sequenced to a minimum of 13,000x coverage, and we determined data retention after de-duplication with and without the use of MIDs. We observed a significant increase in data retention that led to a 2 to 5-fold increase in coverage using MIDs. Variant calling identified pathogenic mutations in all cfDNA samples, including those present in a corresponding tumor sample when available. This study highlights the ability of MID technology to enable variant detection at and below 1% allele frequencies, critical to track known variants and identify novel pathogenic mutations in cfDNA samples.

**785T**

**Functional integration of genomic and transcriptomic data using Strand NGS explains drug resistance in basal cell carcinoma.** S. Kapoor, S. Ramachandrala, S.C. Cherukuri. Strand Life Sciences Pvt. Ltd, Bangalore, Karnataka, India.

Understanding a phenomenon as complex as cancer needs a comprehensive understanding and interpretation of the integrative events at genomic, transcriptomic, and proteomic levels. Currently, NGS has brought a major change in the way multifaceted diseases like cancer are perceived and treated. Just understanding and interpreting the data for base level changes or expression level changes is not enough to decode a disease like cancer. Therefore, simultaneous and integrated comprehension of the events is the need of the hour as it can provide an insight into the biological processes operational in complicated diseases, and this would be instrumental in planning and providing personalized cure to the affected individuals. Strand NGS is an integrated NGS data analysis tool that has strong analysis workflows and allows one to perform integrated analysis of various omics data. This tool has analysis and interpretation capability called MOA (Multi-omic analysis) which allows one to integrate results across different experiment types as well as multiple organisms. The visualization of experimental data overlaid on curated pathways or literature derived networks allows one to get an exhaustive picture of the biologically significant happenings. Using publicly available genome and transcriptome NGS data set GSE58377, we demonstrate integrated analysis in Strand NGS in an attempt to explain the Drug resistance in basal cell carcinoma and explore the plausible approaches for treating basal cell carcinomas (BCCs). Using Strand NGS we could find various SNPs and CNVs in genes *TP53*, *PTCH1*, and *SMO* in resistant BCCs. This case study emphasizes on the need of integration of sequence variation data with expression data to understand and interrogate biological problems like cancer that could be helpful in diagnostics, precision medicine, and might lead to discovery of cancer biomarkers. This study highlights the competence of Strand NGS in carrying out such analyses in a single tool with ease and providing clinicians and researchers with fast and accurate results, excellent visualizations, and allowing them to comprehend their data further by carrying out downstream analysis of their NGS data.

**DNA repair improves sequencing accuracy in FFPE DNA samples.** *F. Stewart, C. Song, P. Liu, L. Chen, L. Ettwiller, E. Dimalanta, T. Davis, T. Evans.* New England Biolabs, Inc., Ipswich, MA.

Targeted cancer therapy based on genomic alterations can be remarkably effective. Currently, cancer genome profiling using next generation sequencing (NGS) is routinely applied in cancer therapies to guide personalized treatment. The accuracy of this profiling directly impacts therapeutic choices and the outcomes of patient care. Although samples of blood and other bodily fluids are being actively explored for early disease diagnosis and treatment monitoring, DNA isolated from FFPE samples is currently the main source for NGS-based genetic profiling. However, sequencing DNA from FFPE samples is challenging due to limited quantities and poor quality, a result of DNA damage incurred during fixation and storage of the tissue sample. We previously showed that false positive variants are abundant and can account for a major fraction of identified somatic variations in publicly available datasets (Chen, L., et al., *Science* 2017). These false positive variants show signs of mutagenic DNA damage. We further demonstrated that enzymatic DNA repair increases sequencing quality by lowering damage-induced background noise. Therefore, enzymatic DNA repair has the potential to improve sequencing accuracy, avoiding incorrect somatic variant calls and consequently reducing incorrect diagnostic conclusions, especially from damaged FFPE DNA samples. In this study, we have optimized a second generation of FFPE DNA repair enzyme mix (v2) that is specifically designed to work on the most abundant types of DNA damage in FFPE samples. FFPE DNA isolated from tumor samples were treated with or without the DNA repair enzyme mix v2 prior to library preparation. Target enrichment of a panel of 151 cancer genes was performed, and deep sequencing data was obtained for variant analysis. A subset of candidate variants identified by sequencing was further validated using droplet digital PCR (ddPCR) assay. The original FFPE DNA input was also analyzed using ddPCR to confirm the variant calls detected via deep sequencing. Both deep sequencing and ddPCR showed no difference in high frequency variant abundance between the control and repair groups. However, the number of false positive variant calls was reduced in the repair group. ddPCR results from the original FFPE DNA samples confirmed the real positive variant calls in the repair group. Our data demonstrates that DNA repair significantly increases sequencing accuracy without altering the frequency of actual mutations in tumor samples.

**Longitudinal integrative omics of rituximab treatment on primary B cells.** *L.R.K. Brooks, G.I. Mias.* Michigan State University, East Lansing, MI.

We will present results from our investigation of longitudinal profiling in primary B-cells following their perturbation through treatment with Rituximab (RTX). RTX is a monoclonal antibody anticancer drug, targeting the B cell marker CD20, used to treat different types of blood cancers. This project aims to further investigate RTX's pathway of action, the possible gene interactions precipitated by RTX treatment within B cells, and changes in cell signaling mediated by exosomes following multiple time points after RTX treatment. Our approach employs the integration of transcriptomic and proteomic molecular components derived from treated and untreated cells, and uses the dynamics to classify temporal responses and deduce inter- and intra- cellular interactions over time. Primary B cells cultured in serum free media were treated and followed over time. Following drug treatment, cells were assayed over multiple time points (6 and 24) in the span of 24 hours including the RTX treatment. At each time point, RNA and protein were extracted and prepared for RNA-Sequencing and mass spectrometry proteomics respectively. Additionally, for 6 time points exosomes were extracted from the media (secreted from the cells) and exosomal small RNA was prepared for sequencing. The data were analyzed using our MathlOmics framework to identify temporal trends and statistically significant overrepresentation of KEGG pathways and gene ontology (GO) terms. Our findings indicate activation of genes, showing specific patterns of activation, and corresponding over-representation ( $p < 0.01$ ) in the Nuclear Factor Kappa B (NFkB) signaling pathways, Fc gamma R-mediated phagocytosis and PI3K-AKT pathway, including many genes involved in apoptotic processes, negative regulation of cell proliferation and extracellular exosomes. Overall our time series profiling approach identified known and novel gene and protein expression responses of B cell populations to RTX, and allowed us to construct interaction networks of the different molecular components. The focus on NFkB signaling pathway shows clear response following drug treatment, and offers an example of the method's utility. Finally, our approach is generalizable to any treatment and dynamic monitoring of cells. LRKB is supported by a Michigan State University Mavis Richardson Travel Grant. GIM and research in this investigation were supported by the National Human Genome Research Institute (NHGRI) under grant number R00 HG007065.

**Use of Bionano Optical Maps to identify medically-relevant genomic variation.** A.W.C. Pang, J. Lee, S. Chan, W. Andrews, T. Anantharaman, A. Hastie, H. Cao. Research and Development, BioNano Genomics, San Diego, CA.

Structural variation (SV) detection is fundamental to understand genetic diseases. While karyotyping and conventional molecular detection approaches are robust, they can be manually intensive, biased towards targeted loci, and cannot determine the copy number of long repeats. Bionano Genomics® with its Saphyr™ System offers an unbiased and sensitive method to detect large variants. Bionano's next-generation mapping (NGM) technique, relies on NanoChannel arrays to linearize DNA, image DNA with high resolution and haplotype-aware *de novo* assemble megabase long optical maps. This method can capture over 4,000 insertions and deletions (>1kbp), translocations and inversions in a human sample. We introduce here a software pipeline that analyses Bionano SV calls to identify candidate disease-associated SVs. To do so, the software searches for high-confidence calls, and evaluates quality scores of the assembly, alignments, and SVs detected. To further ascertain relevant candidates, it filters the remaining calls with over 443,000 SVs collected from 144 individuals with no observable disease phenotypes, and compares them with calls from disease-specific databases. Using this pipeline, whose total runtime takes only a few hours, we can efficiently select the few dozens of SVs for further analysis. We ran specimen from individuals with hematological malignancies, applied the candidate-finding pipeline, and identified known rearrangements such as the t(9;11)(q21.3;q23.3) in acute myeloid leukemia AML and t(9;22)(q34.12;q11.23) in chronic myeloid leukemia CML. Moreover, we uncovered novel mutations ranging in size from a small 4.2kbp insertion disrupting an ALL gene *CNOT3* to a large 9.6Mbp deletion at 17q25. Also, we applied NGM on rare and currently undiagnosed diseases. Using a family-based study design, we looked for rare or *de novo* SVs in affected individuals. In one quartet family, we identified a 174kbp heterozygous deletion shared by the two affected children and the carrier father. This deletion overlaps *ATCD3*, a member of the ATP binding cassette gene family. Also, in one affected sample, we detected a rare 364 kbp heterozygous inversion, which was also inherited from the father. Further experimental validation of these candidate SVs and comparison with the phenotypes are needed to establish disease-association. In conclusion, Bionano maps can significantly aid the discovery of functional SVs, and improve our understanding of the mechanisms of diseases.

**Familially-inherited fusion genes as a new-class of cancer predisposition genes.** D. Zhuo. SplicingCodes.com, Biotailor Inc, Palmetto Bay, FL.

Genetic predisposition to cancer has been well documented for several centuries and has initially observed via unusual cancer occurrences of familial clusterings. Studying cancer-prone families has lead to identify over 100 Mendelian cancer predisposition genes. However, All these CPGs are derived from known genes carrying point mutations and none of them are derived from gene fusion. Recently, by systematic analysis of RNA-seq data of glioblastoma, prostate cancer, lung cancer, breast cancer, multiple myeloma, and lymphoma from different regions of the World, we have found that *KANSARL* (*KANSL1-ARL17A*) fusion transcripts are detected in are rarely detected in the tumors of individuals from Asia or Africa. In contrast, they exist in 30 - 52% of the tumors from North Americans cancer patients. Further analyses have revealed that *KANSARL* is a familially-inherited fusion gene is specific to 28.9% of the population of European ancestry origin. Therefore, we have confirmed that *KANSARL* is the first cancer predisposition fusion gene associated with genetic backgrounds of European ancestry origin. Our "Big Data" approaches, we have identified hundreds of thousands fusion transcripts generated by copy number variations (CNVs), inversions, duplications, deletions and read-through. Since many of these genetic alternations are familially-inherited, the familially-inherited fusion genes may be much more common and widespread. Familially-inherited fusion genes contribute genetic predisposition of cancer and other human complex diseases. Large-scale and systematic validations of these potential familially-inherited fusion transcripts will be discussed.

**The identification of biomarkers for EGFR-TKI-induced interstitial lung disease through whole genome sequencing analysis.** *H. Zembutsu*<sup>1,2</sup>, *C. Udagawa*<sup>1,2</sup>, *H. Horinouchi*<sup>3</sup>, *Y. Ohe*<sup>3</sup>. 1) Cancer Institute, Tokyo, TOKYO, Japan; 2) National Cancer Center Research Institute; 3) National Cancer Center Hospital.

The drug-induced interstitial lung disease (ILD) are one of the critical issues of chemotherapy for patients with cancer because the mortality of this adverse event is extremely high. The incidence of EGFR-TKI-induced lung injury is more common in Japan (3.98%) than in many other countries (0.3% in USA), and the EGFR-TKI-associated ILD mortality rate is reported to be about 33%-50%. Hence, the predictive marker for EGFR-TKI-induced ILD is expected to be developed to prevent the tragedy for the patients with cancer, however, it is not yet available. Until today, no association study has identified genetic marker for EGFR-TKI-induced ILD. In this study, we carried out whole-genome sequencing (WGS) to identify not only common-variants but also rare-variants related to EGFR-TKI-induced ILD using 27 cases who had been diagnosed as having EGFR-TKI-induced ILD from clinical information and CT image by radiologist or respiratory oncologist independently. More than four million single nucleotide variants (SNVs) and >1 million insertion-deletion (INDEL) were called in each sample after quality check. We perform association study between these genetic variants in 27 EGFR-TKI-induced ILD cases and those in general population (control; 1000 Genomes Project data). In this association study, > 9 million variants called by the WGS were tested by Fisher's exact test for the three genetic models (allelic, dominant and recessive mode). More than 29,000 variants showed minimum adjusted  $P < 0.1$  in the three modes. Four INDELS (2 insertions and 2 deletions) showed strong association with EGFR-TKI-induced ILD ( $P < 1.92 \times 10^{-50}$ ). These findings suggest that these genetic variants may contribute to variation in development of EGFR-TKI-induced ILD. Validation study of these findings may allow for the identification of patients at increased risk of EGFR-TKI-induced ILD and inform the use of an alternative to EGFR-TKI and/or the clinical management of this toxicity.

**Novel sequencing adapters resolve index-hopping with unique, dual-matched barcoding and enable low frequency mutation detection with consensus analysis.** *M. Light*<sup>1</sup>, *M. McNeill*<sup>1</sup>, *K. Lai*<sup>1</sup>, *K. Giorda*<sup>1</sup>, *K. Shah*<sup>1</sup>, *S. Groenewold*<sup>2</sup>, *M. Jarosz*<sup>1</sup>. 1) Research and Development, Integrated DNA Technologies, Redwood City, CA; 2) Research and Development, Integrated DNA Technologies, Coralville, IA.

Rapid growth in next generation sequencing throughput is driving demand for higher sample multiplexing and enabling applications that require deeper sequencing. Historically, combinatorial indexing has been used to increase multiplexing capacity during hybridization capture and sequencing using a minimal number of sample barcodes (8-i5 indices x 12-i7 indices for 96 samples). This combinatorial approach is vulnerable to sample cross-talk, where a single index misassignment causes a read from one sample to be assigned to another sample. There are many sources of sample cross-talk, such as adapter cross-contamination, sequencing or PCR errors, and index hopping during multiplexed capture or cluster amplification. A set of adapters with unique, dual-matched sample barcodes have been developed to filter out mis-assigned barcodes. Further, molecular tags (UMIs) have been incorporated for *in silico* error correction. This combination of dual-matched indices and UMIs enables highly accurate low-frequency variant detection. Libraries were made using custom adapters (described above) and commercially available library construction kits, and enriched using the IDT xGen® AML Panel. To highlight the utility of dual-matched indices, index hopping was measured for capture pools of 1, 4, 8, and 16 libraries using the frequency of mismatched index 1 and index 2 sequences. The baseline rate of barcode mismatches was low for single-plex captures (0.09%) but increased with higher multiplexing (up to 0.39% for 16 samples). Next, consensus analysis error correction was demonstrated using a 1% mixture of Coriell DNA samples NA12878/NA24385 (25 ng input, 0.5% minimum allele frequency) to model low-frequency mutations. A 75-kb custom xGen Lockdown® Panel was used for target enrichment, and libraries were sequenced on the Illumina MiSeq® sequencer. Sensitivity and positive predictive value (PPV) were assessed across the Genome in a Bottle high-confidence region (35 kb) with a variant calling threshold of 0.2%. UMI consensus analysis combined with mutation-specific thresholds for oxidative damage improved the PPV for low-frequency (<1%) variants from 28% to 96% while retaining a sensitivity of 87% for true positives. This consensus approach was then used demonstrate error correction in formalin-fixed, paraffin-embedded (FFPE) and cell-free derived tumor DNA.

**Highly efficient double-stranded molecular tagging empowers improved accuracy of ultra-low frequency mutation detection.** *J. Wang, K. Lai, K. Giorda, M. Jarosz.* Integrated DNA Technologies, Redwood City, CA.

Molecular diagnostics for precision medicine are becoming a reality due to rapid advances in next generation sequencing. Yet the development of non-invasive methods to detect and monitor tumors during treatment using liquid biopsies spotlights the challenges remaining for ultra low-frequency (<17%) mutation detection of circulating tumor DNA. These subclonal mutations are difficult to distinguish from low-level errors introduced during sample preparation, target enrichment, and sequencing. Molecular barcoding strategies, which tag both strands on input DNA molecules, allow for exquisite error correction, but these adapters are challenging to manufacture and their low library conversion efficiency have limited their utility for clinical research. IDT has developed unique duplex adapters that are compatible with standard library preparation methods but offer significantly higher library conversion for low input samples. Mixtures of Coriell DNA samples NA12878 and NA24385 were used to model low-frequency mutations (1.0–0.1% minimum alternative allele frequencies). Novel complementary unique molecular index (UMI) adapters were used with standard library conversion kits to generate libraries. Target enrichment libraries were prepared with a custom 75 kb IDT xGen® Lockdown® panel and sequenced on MiSeq®, NextSeq® and/or HiSeq® sequencing platforms (Illumina). Using 25 ng input, library conversion efficiency was comparable for standard and UMI adapters, with ~1,400X and ~1,500X de-duplicated coverage, respectively. Our analysis pipeline generated consensus reads based on duplicate read base agreement, sequencer base quality, and top and bottom strand observations. Consensus reads were used for variant calling with a 0% threshold with VarDict. Sensitivity (true positive rate) and positive predictive value (PPV) were measured across the genome in a bottle high confidence region (35 kb portion of custom panel). Standard adapters provided 90% sensitivity for variants >0.2% but called >5,000 false positive variants for a PPV of just 5%. In contrast, duplex UMI adapters and consensus analysis had excellent sensitivity of >90% but contained no false positives for 100% PPV. Duplex UMI adapters virtually eliminate false positive errors. Unparalleled accuracy for ultra low-frequency variant calls at 0.1% allele frequency combined with highly efficient library conversion will provide robust tools for more sensitive diagnostics and improved patient care.

**New methods for high-throughput nucleic sequencing and diagnostics using a thermostable group II intron reverse transcriptase (TGIRT).** *C.D. Wu, Y. Qin, J. Yao, R.M. Nottingham, A.M. Lambowitz.* Institute for Molecular and Cellular Biology, Department of Molecular Biosciences, The University of Texas at Austin, Austin, TX.

We have developed new methods for high-throughput RNA and DNA sequencing based on the use of thermostable group II intron-encoded reverse transcriptases (TGIRTs). TGIRT enzymes have higher fidelity and processivity than commonly used retroviral reverse transcriptases, along with a novel template-switching activity that enables attachment of sequencing adapters to nucleic acid template sequences without tailing or RNA ligation. The latter activity enables RNA-seq library construction from small amounts of degraded RNA samples, such as FFPE tumor slices or cell-free (cf) RNAs in human plasma, in <2 h. Validation of the method using fragmented human reference RNAs with ERCC spike-ins demonstrated advantages compared to the widely used TruSeq v3 method, including higher strand-specificity, more uniform 5'-to 3'-gene coverage, and detection of more splice junctions, particularly near the 5' ends of genes, even from fragmented RNAs. Importantly, TGIRT-seq enables the quantitative profiling of small non-coding (nc) RNAs in the same RNA-seq as protein-coding and long ncRNAs and gives full-length, end-to-end reads of tRNAs and other structured small ncRNAs, neither of which is possible with other RNA-seq methods. TGIRT-seq of cfRNAs in human plasma revealed RNA fragments derived from protein-coding genes and lincRNAs, as well as tRNAs, Y RNAs and most other classes of structured small ncRNAs, with many tRNAs being full-length transcripts rather than fragments as reported previously. In a separate study, TGIRT-seq of RNAs present in highly purified HEK-239T cell exosomes in collaboration with the Schekman lab (UC Berkeley) showed that the predominant membrane-encapsulated RNA cargos are full-length tRNAs and other small ncRNAs, along with smaller amounts of spliced mRNAs, which can vary with cell type. Finally, TGIRT single-stranded (ss) DNA-seq of cell-free DNA in human plasma enabled analysis of (i) nucleosome positioning, (ii) transcription factor occupancy, (iii) DNA methylation sites, and (iv) tissues-of-origins comparably to conventional ssDNA-seq methods, but with a more streamlined workflow that enables precise mapping of DNA ends. Current efforts focus on the use of TGIRT-seq for analysis of patient primary tumor tissues, PBMCs, and plasma samples for diagnostic applications.

**Cell cycle specific copy number profiling from parallel single cell genomics and transcriptomics.** R. Rahbari<sup>1</sup>, M. Teng<sup>1</sup>, I. Macaulay<sup>2</sup>, P. Kumar<sup>2</sup>, T. Voets<sup>3</sup>. 1) WellcomeWellcome Trust Sanger Institute, Hinxton, CB10 1SA, UK Trust Sanger Institute, Cambridge, Cambridgeshire, United Kingdom; 2) Earlham Institute, Norwich Research Park, Norwich, NR4 7UZ, UK; 3) Laboratory of Reproductive Genomics, Department of Human Genetics, KU Leuven, Leuven, Belgium.

Current large-scale single-cell genome sequencing projects have delivered novel insight in intra-tumour subclonal architectures, acquired somatic mutations in normal tissue as well as in diseases such as neurological disorders. However, in these studies, the genetic composition of the cells is often studied without considering confounding biological factors imposed by the cell cycle status. In this study, we have utilised the powerful parallel Genomic and transcriptomic single cell sequencing method (G&T-seq1) to build a novel approach for cell-cycle specific copy number profiling. We demonstrated that DNA-replication perturbs conventional single-cell DNA copy number analysis, leading to the detection of focal read depth differences across the genome that may be interpreted as false structural DNA imbalances, but in fact oscillate according to the DNA replication program. Following single-cell G&T-seq, we identified the cell state of each single cell based on their transcriptomic profile. This cell cycle state classification then informed our single-cell DNA copy number analysis pipeline in order to normalise DNA read depth signals of S-phase cells against those from G1-phase cells, exposing the early and late DNA replication domains of the S-phase cell. In addition, comparing the DNA copy number profiles of the cells in "early" S-phase to those in "late" S-phase, revealed variation in replication timing between cells of the same type, which may be due to stochastic origin firing in individual cells. Further, this method can help in better understanding of links between DNA replication timing and other cellular processes, including transcription, DNA-mutational burden, genome instability and the aetiology of genetic disease. Key words: Single cell, cell type, replication timing, CNV profiling Reference: 1. Macaulay, I.C. *et al.* G&T-seq: parallel sequencing of single-cell genomes and transcriptomes. *Nat Methods* **12**, 519-22 (2015).

**795F**

**A novel NGS target enrichment technology: Improved speed, selectivity, and uniformity.** J. Pel. Boreal Genomics, Vancouver, BC, Canada.

Targeted Next Generation Sequencing (NGS) has become common practice in many research and clinical applications, as a faster, cheaper, and often simpler approach to equivalent depth whole-genome or whole-exome sequencing. Target capture methods are especially useful when covering large regions beyond the capacity of multiplexed PCR, such as multi-gene liquid biopsy panels. Current target capture methods, however, typically have long, multi-day workflows that limit their utility in a clinical setting. In addition, small panels (below ~100kb), typically have high off-target capture rates, resulting in an increased cost of sequencing to reach a desired depth of coverage. We have developed a novel library construction method that replaces typical multi-day 'PCR-capture-PCR' workflows with a single 'PCR/capture' step. This approach, which uses physically linked probes and primers, reduces the time and complexity of the workflow, eliminating long capture and clean-up steps and enabling the capture to be completed in less than a day with minimal hands on time. Additionally, PCR and capture are combined in such a way that off-target DNA is reduced due to multiple capture stages, reducing the cost of sequencing. Performance of multi-gene cancer panels using cfDNA is presented, along with variant detection and estimates of cost reduction.

**Cryptic forms of mutant splicing detected by cBROCA.** S. Casadei<sup>1</sup>, S. Gulsuner<sup>1</sup>, M.K. Lee<sup>1</sup>, J.B. Mandell<sup>1</sup>, B.H. Shirts<sup>3</sup>, C.C. Pritchard<sup>3</sup>, M.-C. King<sup>1,2</sup>, T. Walsh<sup>1</sup>. 1) Medical Genetics Dept, University of Washington, Seattle, WA; 2) Genome Sciences Dept, University of Washington, Seattle, WA; 3) Laboratory Medicine Dept, University of Washington, Seattle, WA.

Mutations that alter splicing most frequently lead to exon skipping or introduction of new splice sites, but can also result in intron retention, activation of pseudoexons, or degeneration of exonic sequence. *In silico* tools flag variants that may alter splicing, but are less able to predict sequences of mutant transcripts or their relative abundance. To detect and characterize unconventional mutant transcripts, we used cBROCA, our targeted RNA sequencing approach, to sequence cDNA from patient LCLs for 41 cancer genes. Because cBROCA targets the entire locus of each gene, all transcripts are detected and their relative abundance can be determined. In families severely affected with breast or ovarian or colon cancer, we quite frequently encounter examples of unusual consequences of splice mutations. For example, *BRCA1* c.4185(+1) insAdel21 was predicted to disrupt a canonical splice site and to lead to skipping of exon 12, which is small, inframe, and expendable. However, analysis by cBROCA indicates that most transcripts from this mutant allele retain the 402bp intron 11, which includes multiple truncation codons. A second example is *ATM* c.5674(+1)G>T, which leads to both skipping of a small inframe exon and retention of 1645bp intron 36 with multiple truncation codons. A very different example is *APC* c.532(-1000)delGT, which was revealed by cBROCA analysis to disrupt an intronic splicing silencer, leading to exonification of 165bp of previously intronic DNA and a premature stop. In our experience, RNA sequencing using cBROCA enables discovery and quantitative characterization of splice mutations of all classes, including relative abundance of multiple different transcripts from the same mutant allele. Supported by the Komen Foundation, by NIH R35CA197458, and by NIH R01CA175716.

**Exome sequencing reveals a novel germline gain-of-function *EGFR* mutation in a young adult with bilateral adrenocortical carcinoma.** S. Akhavanfar<sup>1,2</sup>, L. Yehia<sup>1,3</sup>, I. Smith<sup>1</sup>, T. Romigh<sup>1</sup>, C. Eng<sup>1,2,4,5,6</sup>. 1) Genomic Medicine Institute, Cleveland Clinic, Cleveland, OH; 2) Department of Molecular Medicine, Lerner College of Medicine, Case Western Reserve University School of Medicine, Cleveland, OH; 3) Department of Pathology, Case Western Reserve University School of Medicine, Cleveland, OH; 4) Taussig Cancer Institute, Cleveland Clinic Foundation, Cleveland, OH; 5) Department of Genetics and Genome Sciences, Case Western Reserve University School of Medicine, Cleveland, OH; 6) CASE Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH.

Adrenocortical carcinoma (ACC) is a rare endocrine tumor with poor overall prognosis and slight predilection for females. Five-year survival is approximately 38% if the tumor is confined to the adrenal gland and 7% in the presence of distant metastasis. In children, ACC is commonly associated with inherited cancer syndromes, predominantly Li-Fraumeni syndrome, with 50-80% of childhood ACC harboring *TP53* germline mutations. ACC in adolescents and young adults are rarely due to germline *TP53* mutations. Other less common germline mutated genes in ACC include *IGF2*, *PRKAR1A* and *MEN1*. The majority of sporadic ACC tumors occur in adults and their somatic mutations occur mainly in the same genes as germline mutations. We are interested in the subset of patients with clinical features of inherited ACC but who are wild-type for all known germline mutated genes. As part of a larger prospective case-series of the whole-exome sequencing of fifty children, adolescents and young adults with rare tumors, we found a novel missense heterozygous variant in the gene encoding C-terminal tail of epidermal growth factor receptor (*EGFR* [OMIM 131550]; p.Asp1080Asn) in a 21-year-old female with bilateral ACC. This patient was wild-type for known ACC germline mutations including in *TP53*. We functionally confirmed that *EGFR* p.Asp1080Asn variant is an activating gain-of-function mutation which causes increased phosphorylation of EGFR at Tyr1045 position. Increased phosphorylation of ERK1/2 was also observed, confirming the activation of downstream signaling pathways by this mutation. While our observation should be validated through a larger series, it suggests that *EGFR* can be an underlying germline predisposition factor for ACC, especially in young adults. Importantly, identifying a targetable gene for ACC has the potential to improve molecular diagnosis and treatment of this disease, which is known to have limited therapeutic options.

**Trans-eQTLs in prostate cancer risk.** *M. Bicak, M. Middha, R.J. Klein.* Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai Hospital, New York, NY.

GWAS successfully identified numerous prostate cancer risk SNPs to date. However we still lack understanding of how such SNPs function to alter an individual's risk of prostate cancer, which is further hindered by insufficient sample sizes. We conducted eQTL association analysis on tumor and normal datasets from multiple cohorts to test if prostate cancer risk SNPs are correlated with gene expression changes in nearby and remote genes by using linear regression. Meta-analysis was applied to resulting cis and trans-eQTLs to increase the power to detect risk loci that are shared among different cohorts. As a result, previously unreported cis-eQTLs were found, such as NOTCH4 and rs30967026. Furthermore, 66 trans-eQTLs were found at an FDR of 5%, for which some SNPs seem to be trans-eQTLs for many genes, suggesting to be prostate cancer associated trans-eQTL hotspots. These include: (i) SNPs that are at loci for prostate-secreted proteins, such as rs10993994 (MSMB) and rs17632542 (KLK3/PSA), as well as (ii) SNPs that are at loci with transcription factors, such as rs12653946 which is confirmed as cis-eQTL with IRX4; rs1512268 which is near NKX3-1, a transcription factor known to play a role in prostate cancer; and rs339331 which has been shown to associate with RFX6 activity. Ongoing work is performing mediation testing and causal inference analysis to predict if the expression changes of the trans-eQTLs are mediated through cis-eQTLs.

**Interrogating key RECQL4 related genomic and epigenomic alterations in osteosarcoma.** *H. Horn, P. Meltzer.* Genetics Branch, Center for Cancer Research, National Cancer Institute, Bethesda, MD.

Osteosarcoma is the most common type of bone cancer (or malignancy), affecting children and adolescents. One of the key hallmarks of OS is the high rate of structural and copy number variation. The DNA helicase RECQL4 is required for normal osteoblast formation and mutations in RECQL4 have been associated with osteosarcoma pathogenesis. In this study, we investigate the underlying mechanisms of RECQL4 deficiency by detecting genomic and epigenomic alterations in two OS cell lines; one in-house RECQL4 deficient and one highly rearranged osteosarcoma cell line. Both cell lines were sequenced using 10x linked-read, whole-genome and exome sequencing technologies. The combination of multiple sequencing platforms allowed us to accurately discover and validate a comprehensive catalogue of RECQL4 related rearrangements. One step further, genomic information was integrated with methylation ChIP-seq data towards detection of enhancer associated epigenomic rearrangements. Our holistic approach of combining multiplatform genome sequencing together with epigenomic information has provided us a comprehensive characterization of RECQL4 related rearrangements with possible clinical impact in osteosarcoma.

**Ion AmpliSeq™ TERT promoter sequencing.** *J.M. Kilzer, S. Wang, M. Manivannan, A. Broomer, A. Kraltcheva, D. Mazur, C. Van Loy, M. Andersen.* Thermo Fisher Scientific, Carlsbad, CA.

TERT promoter mutations are highly recurrent in over 50 cancer types. Two independent hotspot mutations, TERT C228T and C250T, in this region have been identified as the most common point mutations in several tumor types. Studies suggest that identification of TERT promoter mutations might be used as potential clinical biomarkers for predicting survival rates for some cancers. However, this region has been shown to be challenging to sequence for both forward and reverse strands. Herein, we describe the design optimization of a TERT promoter assay for use in highly multiplexed target amplification reactions to generate libraries for analysis with the Ion Torrent™ NGS platform. In this study, 16 amplicon primer designs of sizes ranging from 125-200bp were generated to target the TERT promoter region containing two known hotspot mutation sites. These designs were combined with larger Ion AmpliSeq™ DNA research panels to generate highly multiplexed libraries. Libraries were used for template preparation on the Ion Chef™ Instrument and subsequently sequenced using the Ion S5™ System. Multiple options were tested to determine optimal conditions for TERT assay performance, including changes to templating reagents, multiple chip types, and changes in nucleotide flow order during sequencing. The resulting sequencing data was used to evaluate coverage of known common point mutations by each design for each condition tested. We generated several primer designs targeting common point mutations in the TERT promoter region that resulted in improved amplicon coverage using the Ion S5™ System. Sequenced strand bias ranged from 99% forward reads for poorest performers to as low as 57% for best performers. End-to-end read through of reverse reads was significantly improved from as low as 0% up to 53% in two of the 16 amplicons tested. Comparison of available Ion system options demonstrated a large range in performance, though trends were similar between amplicons across all platforms. Optimal results were generated using Ion 530 chips in combination with modifications to the Ion Chef™ template preparation chemistry and an alternative nucleotide flow order for all amplicons. In conclusion, we were able to generate and identify new amplicon designs that demonstrated a significant improvement over prior results. In combination with optimized Ion system conditions, these amplicons resulted in 62% and 60% forward reads and 55% and 51% reverse reads reading end-to-end.

## 801F

**The role of antioxidants in the context of carcinogen induced chromosome aberrations.** *Y.C. Li, Z.C Hung.* Department of Biomedical Sciences, Chung Shan Medical University, Taichung, Taiwan.

As we know generally, the antioxidant is considered as an agent for cancer prevention because it would scavenge the ROS (reactive oxygen species) which cause DNA damage and turn to initiate the development of cancer. Several studies showed that chewing betel nut were associated with the high risk of oral cancers. Arecoline is a major alkaloid in betel nut and suggested as a probably carcinogen because it had been evidenced to cause DNA damage, cell death, and ROS. However, it is unclear whether scavenging ROS by antioxidants could prevent carcinogen itself inducing DNA damage. In this study, we would establish the kinetic relation of arecoline-induced toxicities including DNA damage, cell death, and ROS and to further understand the role of antioxidants in the context of arecoline induced DNA damage. We analyzed the chromosome aberrations (CAs), ROS and cell death under CHO-K1 cells treated with arecoline alone or combination with antioxidants in different concentration and duration. We observed arecoline cause CAs in four stages as dose- and time-dependent manner. At the beginning, arecoline would directly cause primary CAs. Secondary CAs occurred following time and can be inhibited by GSH. Once CAs over a threshold, CAs would induce ROS and then ROS would cause the tertiary CAs and cell cycle arrest. After CAs and ROS accumulated a certain amount, the cell death initiated and then caused the fourth stage of CAs. In our study, we also found that antioxidants, like catalase, inhibited the ROS induced tertiary CAs via scavenging ROS but neither primary nor secondary CAs. Taken together, it suggested that ROS was induced under CAs over a threshold and then cause cell death to prevent abnormal cells with CAs alive. Moreover, the antioxidant can only prevent ROS induced CAs, but not arecoline (a carcinogen) itself induced CAs. In turn, the cells with CAs are survival at antioxidants treatment. The survival aberrant cells would be a high risk factor of carcinogenesis. Therefore, it should be more carefully evaluated for the use of antioxidant in cancer prevention.

**HPV16 integrated genomic and molecular characterization of cervical cancer in Guatemala.** *H. Lou<sup>1</sup>, J. Boland<sup>2</sup>, W. Zhou<sup>3</sup>, J. Mitchell<sup>3</sup>, D. Roberson<sup>3</sup>, L. Garland<sup>1</sup>, M. Herrera<sup>4</sup>, D. Wells<sup>1</sup>, J. Troyer<sup>1</sup>, F. Pinto<sup>2</sup>, S. Bass<sup>3</sup>, X. Zhang<sup>3</sup>, M. Yeager<sup>3</sup>, E. Gharzouzi<sup>2</sup>, M. Dean<sup>4</sup>.* 1) LTG-DCEG, NCI-Leidos Biomedical Research, Inc., Gaithersburg, MD, USA; 2) Instituto de Oncología, Guatemala City, Guatemala; 3) CGRL-DCEG, NCI-Leidos Biomedical Research, Inc., Gaithersburg, MD, USA; 4) LTG-DCEG, NCI, Gaithersburg, MD USA.

Viral integration into the host genome is a characteristic genetic event in cervical carcinogenesis. HPV integration occurs into different genomic locations within the vicinity of important cancer related genes, in some tumors. Here, we compared HPV16 integration frequencies in 96 Guatemalan cervical cancer patients by capture of HPV DNA on Nimblegen array and DNA sequencing. A total of 65 % (62/96) of the cervical cancer had detectable HPV16 integration. HPV16 can be divided into four main subtypes including A, B, C and D, differing in the high conserved L1 sequence by less than 10%. HPV16 subtype A showed a higher rate of integration than D2 and D3. HPV16 and its subtype A subjects have a significantly younger age in integrated cervical cancer patients. Patients with HPV16 subtype D2 are younger than subtype A. The analysis of the HPV integrated cervical cancer patients and *PIK3CA* mutations demonstrate that there is a significantly older age in HPV16 integrated patients with *PIK3CA* mutations as compared to without *PIK3CA* mutations. HPV integration sites were identified in 62 patients. At least 13 genes including *GAPDH*, *LRP1B*, *MACROD2*, *NAALADL2*, *GLI2*, *WWOX*, *BCL11B*, *INPP4B*, *CSMD1*, *PGAP3-ERBB*, *PTPN13* and *FHIT* were reported in previous studies. In addition, we found HPV16 integrated into the promoter of host *IRF4* (interferon regulatory factor4) that plays an important role in the regulation of the interferon response to virus infection and is as an oncogenic biomarker for hematological malignancies. Our data indicated that the age, specific HPV16 subtype and somatic *PIK3CA* mutations are associated with viral integration in HPV16 positive cervical cancers and the genes at the specific sites of viral integration may play important roles in cervical cancer progression and metastasis.

**Effects of 744ins20 - ter240 *BRCA1* mutation on breast/ovarian carcinogenesis and role of curcumin in telomerase inhibition.** *M. Pongsavee.* Department of Medical Technology, Faculty of Allied Health Sciences, Thammasat University, Patumthani, Thailand.

Breast cancer is correlated with high estrogen level. *BRCA1* gene mutation increases risk of hereditary breast/ovarian carcinogenesis. Telomerase can protect telomere shortening. Curcumin is a yellow component in *Curcuma longa* Linn and has antioxidant properties. Study the effect of 744ins20 - ter240 *BRCA1* mutation at exon 10 about DNA repair function by MTT dye reduction and study about Telomerase inhibition caused by curcumin with Telomerase activity assay and Trypan blue exclusion assay were done. The results showed that this mutation caused DNA repair defect ( $P < 0.05$ ) and curcumin could inhibit telomerase function and affected cancer cell progression. 744ins20 - ter240 *BRCA1* mutation involved in DNA repair defect and curcumin could inhibit telomerase function. .

**Rhesus macaques with mutations in MLH1 and MSH6 develop Lynch syndrome colorectal cancers.** *M. Raveendran<sup>1</sup>, R. Alan Harris<sup>1</sup>, B. Dray<sup>2</sup>, P. Gillespie<sup>2,3</sup>, D. Brammer<sup>2,4</sup>, S. Gray<sup>2</sup>, L. Williams<sup>2</sup>, D. Muzny<sup>1</sup>, R. Gibbs<sup>1</sup>, C. Abee<sup>2</sup>, J. Rogers<sup>1</sup>.* 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 2) MD Anderson Cancer Center, ME Keeling Center for Comparative Medicine, Bastrop, TX; 3) Eli Lilly & Co, Indianapolis, IN; 4) University of Houston, Houston, TX.

Colorectal cancer (CRC) is among the most common forms of human cancer. Lynch syndrome is a hereditary form of CRC caused by mutations in any of four genes involved in DNA mismatch repair (*MLH1*, *MSH2*, *MSH6* and *PMS2*). In humans, lifetime risk of both colorectal and endometrial cancer is dramatically increased in heterozygotes with these mutations. We identified a series of genealogically related rhesus macaques (*Macaca mulatta*) exhibiting CRC near the ileocecal junction or in the ascending colon, proximal to the hepatic flexure, as in human Lynch syndrome. Histopathological exams of resected tumors found invasive colonic adenocarcinomas with desmoplastic features. We performed a series of genetic analyses to test the hypothesis that this is a model of Lynch syndrome. Sanger sequencing of *MLH1* in affected animals found several carrying a 2-base pair deletion in the *MLH1* promoter. In vitro analyses show this promoter mutation significantly reduces *MLH1* expression in human SW480 cell lines. Whole genome sequencing of 16 affected macaques identified a premature stop codon in *MLH1* in 3 individuals carrying the 2 bp deletion. Other affected animals not carrying *MLH1* mutations are heterozygous for a missense mutation in *MSH6* that is scored by CADD as probably damaging. Ten of the 16 CRC affected animals we sequenced carry identifiable damaging mutations in *MLH1*, *MSH6* or both, establishing this as a genetic model of Lynch syndrome, with equivalent cancers attributable to spontaneous mutations in genes that cause Lynch syndrome in humans. These studies are part of a larger program designed to discover new disease models through whole genome sequencing in rhesus macaques. Five hundred thirty macaques have been sequenced using Illumina. Genotype calling employs GATK with annotation through Ensembl VEP. We have identified 72,746,387 unique SNVs. The average SNVs per macaque individual is 9,476,124, substantially more than in humans. Predicted variants include 8,556 stop codons gained, 1,346 stops lost, 340,104 missense and 65,707 splicing variants, as well as 17,286,051 small indels (1 to 60bp). Rhesus macaques provide many important animal models of human disease. The documentation of Lynch syndrome in this species underscores the value of naturally occurring functional genetic variation as a resource for development of genetically equivalent translational models.

**Detection of viral sequences and integration sites in HPV-positive (HPV+) recurrent/metastatic head and neck cancer (RMHNC) patients.** *D. Thach, G. Sulkowski, M. Ahmad, R. Iyer, J. Deeken.* Inova Translational Medicine Institute, Inova, Fairfax, VA.

**Background:** The cause for the rising incidence of HPV+ HNC remains unexplained, and while patients can be cured by combined modality treatment, more than 1 in 4 patients will suffer recurrence. Understanding the basis for recurrence risk with respect to virus sublineages and their interactions with the host genome could be critical to personalizing initial treatment. Previously, we have genotyped virus sublineages via SNP markers and also found an unexpected high rate of *TP53* mutations in our cohort. Here, we detect viral lineages via whole genome sequencing, and searched for their sites of integration into the host genome. **Methods:** FFPE DNA from resected recurrent tumors of HPV+ RMHNC patients were analyzed for viral sequences and integration into the host genome. The Accel-NGS 2S kit was used to prepare whole tumor libraries that were sequenced on the Illumina HiSeq 2500. VirusFinder2.0 was used to detect viral sequences by searching non-human reads against a database of known virus genomes. Detected viruses were further analyzed for chimeric reads supporting their sites of integration into the host genome.

**Results:** Recurrent tumors from 3 patients were analyzed. High quality HPV16 contigs of sizes 7614, 8445, and 1269 were detected in all 3 samples, and the contigs were more than 99% identical to known HPV isolates. The spiked-in positive control, phiX DNA, was detected as well. No HPV contigs were detected in a negative control tumor; instead a 1399 contig with 99.9% identity to HHV-4 was detected. In all samples and controls, low quality contigs of unexpected viruses were repeatedly detected, suggesting background sequence homologies or reagent contamination. Novel HPV16 integration sites was found at *3q26.33*, disrupting *LINC01206*, a long intergenic non-protein coding RNA of unknown function in the host. The breakpoints in the HPV16 genome was in the E1, L1, and upstream of E6 genes. **Conclusions:** We have detected and sequenced HPV genomes in recurrent tumors, and have found novel integration sites disrupting a host lincRNA, which are unlikely to be inhibited by new-targeted therapies. More research is needed to identify viral-tumor integration and mutational profiles based on viral integration to optimize precision medicine strategies.

**An integrative detection and analysis of structural variation in cancer genomes.** J. Xu<sup>1</sup>, J. Dixon<sup>2</sup>, V. Dileep<sup>3</sup>, Y. Zhan<sup>4</sup>, F. Song<sup>1</sup>, V. Le<sup>2</sup>, G. Yardimci<sup>5</sup>, A. Charkraborty<sup>6</sup>, D. Bann<sup>1</sup>, Y. Wang<sup>1</sup>, C. Ernst<sup>6</sup>, S. Hadjur<sup>6</sup>, D. Odom<sup>6</sup>, J. Stamatoyannopoulos<sup>7</sup>, J. Broach<sup>1</sup>, R. Hardison<sup>1</sup>, F. Ay<sup>8</sup>, W. Noble<sup>8</sup>, J. Dekker<sup>9</sup>, D. Gilbert<sup>6</sup>, F. Yue<sup>1</sup>. 1) Penn State University, Hershey, PA; 2) Salk Institute for Biological Studies; 3) Florida State University; 4) University of Massachusetts; 5) University of Washington; 6) La Jolla Institute for Allergy and Immunology; 7) Altius institute for Biomedical Sciences; 8) University College London; 9) University of Cambridge; 10) University of Massachusetts Medical School.

Structural variants can contribute to oncogenesis through a variety of mechanisms, yet, despite their importance, the identification of structural variants in cancer genomes remains challenging. Here, we present an integrative framework for comprehensively identifying structural variation in cancer genomes. For the first time, we apply next-generation optical mapping, high-throughput chromosome conformation capture (Hi-C), and whole genome sequencing to systematically detect SVs in a variety of cancer cells. Using this approach, we identify and characterize structural variants in up to 29 commonly used normal and cancer cell lines. We find that each method has unique strengths in identifying different classes of structural variants and at different scales, suggesting that integrative approaches are likely the only way to comprehensively identify structural variants in the genome. Studying the impact of the structural variants in cancer cell lines, we identify widespread structural variation events affecting the functions of non-coding sequences in the genome, including the deletion of distal regulatory sequences, alteration of DNA replication timing, and the creation of novel 3D chromatin structural domains. These results underscore the importance of comprehensive structural variant identification and indicate that non-coding structural variation may be an underappreciated mutational process in cancer genomes. .

**Functional characterization of a novel prostate cancer candidate gene at 2q37 in normal human prostate cell line.** C. Cieza-Borrella<sup>1</sup>, S. Wakerell<sup>1</sup>, I. Whitmore<sup>1</sup>, Q. Karlsson<sup>1</sup>, E. Saunders<sup>1</sup>, R. Eeles<sup>1,2</sup>, Z. Kote-Jarai<sup>1</sup>. 1) The Institute of Cancer Research, London, UK; 2) The Royal Marsden Hospital NHS Trust, London, UK.

Prostate Cancer (PrCa) is the most frequently diagnosed cancer among men in developed countries. The effectiveness of PSA screening remains controversial and new molecular biomarkers are needed to improve screening and clinical management of disease. Genome Wide Association studies and consequent fine-mapping analyses, identified four independent association signals at 2q37 represented by intronic and coding variants in the *NGEP/ANO7* gene. This gene encodes a cell membrane protein involved in cell-cell signalling and only expressed in prostate tissue. To investigate its role in PrCa we knocked out *NGEP/ANO7* in the diploid human epithelial prostate cell line RWPE-1 using CRISPR/Cas9 technique by transfecting cells with Cas9 protein and three different sgRNAs using Lipofectamine RNAiMAX. We also overexpressed this gene using a pCMV6-AC-GFP TrueORF vector. RNA and protein expression of the clones were checked by rt-qPCR and western blot. *NGEP* knockout, overexpressed and non-transfected clones were seeded in 3D cultures and their response to various stimuli was measured. Our results show that only those clones with both alleles knocked out resulted in complete loss of *NGEP* mRNA expression. A homozygous in-frame deletion of 24bp found in exon 1, within the N-terminal cytoplasmic tail, resulted in loss of *NGEP* mRNA expression compared to the 'no gRNA/Cas9 only' and 'non-transfected' control clones. This CRISPR'd clone forms spheroids which are smoother and more compact in appearance. It possesses a significantly reduced rate of spheroid proliferation and initial results suggest that it may also be more resistant to staurosporine induced apoptosis than the non-CRISPR'd cells. To assess the differential expression of other genes when repressing or overexpressing *NGEP* we will show results of RNAseq from positive clones. Our observations so far indicate that *NGEP/ANO7* plays a key role in prostate cells' physiology and analyses are ongoing to elucidate the biological mechanisms behind its function.

**808W****Optical mapping reveals a higher level of chained fusion events in human cancer.**

V.M. Hayes<sup>1,2</sup>, A.T. Papenfuss<sup>3</sup>, D.C. Petersen<sup>1</sup>, D.M. Thomas<sup>1</sup>, E.K.F. Chan<sup>1</sup>. 1) Human Comparative and Prostate Cancer Genomics, Garvan Institute of Medical Research, Darlinghurst, Sydney, NSW, Australia; 2) Central Clinical School, University of Sydney, Camperdown, NSW, Australia; 3) Bioinformatics Division The Walter and Eliza Hall Institute of Medical Research, Melbourne, Victoria, Australia; 4) Cancer Division, Garvan Institute of Medical Research, Darlinghurst, Sydney, NSW, Australia.

Chromosomal rearrangements are common in cancer, with potential to drive cancer progression and treatment response. These rearrangements can be complex, resulting in fusions of multiple chromosomal fragments as well as derivation of supernumerary chromosomes, such as neochromosomes. These fusion events may be driven by single or combination of processes, leading to the observed molecular and clinical complexity. Liposarcomas for example, are characterized by neochromosome formation, mostly likely a result of chromothripsis and hundreds of cycles of breakage-fusion-bridge amplifications. Short read sequencing is largely unable to assay all regions of the genome and generally unable to resolve relationships between distant rearrangements (e.g. chained rearrangements). In this study we show the utility of optical mapping using the Bionano Genomics next generation mapping technology to directly observe complex chained fusion events in a well-characterized liposarcoma cell line 778. From a total of 2,486 structural variations over 1Kb in length, we describe 778 as significantly translocated, observing a total of 151 chromosomal translocations. Importantly, we identified 101 fusion-specific genome maps harboring 282 large complex rearrangements, including 117 inter-chromosomal translocations and capturing much of the previously described neochromosomes. Using these large intact genome maps (range 189 Kb to 6.2 Mb) we were able to reconstruct optical maps of chained fusions, including the order, orientation, content and size of rearranged fragments. We show that optical mapping resolves fusion events marked by large intervals, revealing a higher level of chained rearrangements than detectable by sequencing alone. Furthermore, our data supports evidence for a single catastrophic genomic event early during the evolution of 778, followed by additional random, plausibly stepwise, rearrangement processes. We conclude that optical mapping is an important complement to deep sequencing for detecting and reconstructing complex genomic rearrangements.

**809T****Comprehensive whole-genome analysis of the primary ENCODE cell line K562.**

B. Zhou<sup>1</sup>, S. Byeon<sup>2</sup>, J. Arthur<sup>3</sup>, X. Zhang<sup>1</sup>, X. Zhu<sup>1</sup>, R. Pattni<sup>1</sup>, S. Ho<sup>1</sup>, N. Ben-Efraim<sup>1</sup>, C. Urban<sup>1</sup>. 1) Department of Psychiatry and Behavioral Sciences and Department of Genetics, Stanford University School of Medicine, 3165 Porter Drive, Palo Alto, CA, 94304, USA; 2) School of Computer Science and Engineering, Pusan National University, Building 313 Room 308, 2 Busandaehak-ro 63 beon-gil, Geumjeong-gu, Busan 609-735, South Korea; 3) Department of Statistics, Department of Biomedical Data Science, Bio-X Program, Sequoia Hall, 390 Serra Mall, Stanford University, Stanford, CA 94035, USA; 4) Department of Health Sciences Research, Center for Individualized Medicine, Mayo Clinic, 200 1st Street S.W., Rochester, MN 55905, USA.

K562 is an immortalized myelogenous leukemia cell line derived from a 53-year-old female, one of the three tier-one cell lines of ENCODE, and one the premier cell lines used for CRISPR/Cas9 large scale gene editing screens. As such it is a major 'work horse' cell line that is frequently used in many laboratories around the world. However, although transcriptomic and epigenomic characteristics of K562 are extensively studied and documented, the genome sequence has never been determined and higher order structural features were only cursorily known. We performed deep short-insert whole genome sequencing, long-insert mate-pair sequencing, 10X Genomics linked-read sequencing, and used a combination of novel and established computational tools to call and catalog a wide spectrum of genomic variants: single nucleotide variants (SNVs, copy number corrected), small deletions and insertions (indels), phased SNP haplotype blocks, large copy number variants (CNVs) by chromosomal region, retrotransposon insertions, and structural variants (SVs), many of which are phased and a significant fraction of which are the result of complex genomic rearrangements. A subset of the SVs were validated using a combination of PCR and Sanger sequencing. In addition, we obtained karyotyping and performed genomewide microarray analysis using highdensity oligonucleotide arrays to validate the large CNVs resolved by our deep whole-genome sequencing based approach. The sequencing data and variant calls will be released through the ENCODE Portal. We imagine that they may be useful for a wide variety of purposes, e.g. for projects that use this cell line for CRISPR screens, where knowledge of the SNVs can extend the number of editing targets while knowledge of aberrant copy numbers will allow for the avoidance of non-diploid regions; or for studies that carry out in-depth analyses of the vast amount of ENCODE epigenomics data available for the K562 cell line, e.g. to determine whether a potential or known regulatory sequence element has been altered by SNVs, indels, retroinsertions or a gain or loss of copies of that given element and whether this can be correlated with signal changes on the epigenomic or transcriptome level. Furthermore, this study may serve as a technical example for advanced, integrated whole genome sequence and structure analysis beyond standard short read/short-insert whole-genome sequencing.

## 810F

**De novo inference of enhancer-gene networks in diverse cellular contexts reveals the long-range regulatory impact of disease-associated variants.** *J. Wang<sup>1</sup>, P. Greenside<sup>2</sup>, A. Kundaje<sup>2</sup>, M. Kellis<sup>3</sup>.* 1) Computational Mathematics, Science and Engineering, Michigan State University, East Lansing, MI; 2) School of Medicine, Stanford University, Stanford, CA; 3) Computer Science and Artificial Intelligence Lab, Massachusetts Institute of Technology, Cambridge, MA.

Non-coding variants implicated in genome-wide association studies (GWAS) are enriched in enhancer elements active in disease-relevant cellular contexts. Identifying context-specific target genes and downstream pathways affected by enhancers harboring regulatory variants remains a challenge. We developed a novel mixed-membership probabilistic model that leverages the modular dynamics of gene expression and enhancer chromatin state across 56 diverse human cell types and tissues from the Roadmap Epigenomics Project to infer highly-connected, tissue-specific enhancer-gene networks. Chromatin conformation maps and expression QTLs validate the superior accuracy and tissue-specificity of our predicted networks compared to existing approaches. While half of the predicted links involve elements less than 50 kilobases apart, only a third associate enhancers with their nearest genes. Linked enhancers significantly improve tissue-specific regression models of gene expression. Distal co-association of regulatory sequence motifs suggests synergistic regulation of genes by multiple enhancers with a key role for protein-protein interactions between lineage-specific transcription factors in mediating enhancer-promoter interactions. Networks of cooperating enhancers with shared motif composition and target genes are depleted of disease-associated variants, suggesting regulatory buffering mechanisms. We demonstrate the utility of our context-specific enhancer-gene links to predict putative target genes, biological processes and pathways of non-coding variants associated with diverse traits and diseases, including colorectal cancer. Subsets of our predictions also demonstrate promising functional relevance in mouse breast cancer experiments.

## 811W

**Exosomes in cancer: Small vesicular transporters for cancer development and metastasis, biomarkers in cancer therapeutics.** *A. Abak<sup>1</sup>, E. Sakhinia<sup>2</sup>, A. Abhari<sup>3</sup>.* 1) Tabriz University of Medical Sciences and Department of Biochemistry and Clinical Laboratory, Division of Medical Genetics, Faculty of Medicine, Tabriz University of Medical Sciences, Tabriz, Iran, Email: Atefeh.abak@gmail.com; 2) Tuberculosis and Lung Disease Research Center and Department of Biochemistry and Clinical Laboratory, Division of Medical Genetics, Faculty of Medicine, Tabriz University of Medical Sciences, Golgasht Street, Tabriz, Iran; 3) Department of Biochemistry and Clinical Laboratory, Division of Clinical Biochemistry, Faculty of Medicine, Tabriz University of Medical Sciences, Golgasht Street, Tabriz, Iran.

Cancer progression is a multistep procedure in which exosomes play substantial roles. Exosomes are small, lipid bilayer membrane vesicles of endocytic origin with a diameter of 40-100 nm. They can transport bioactive molecules such as mRNAs, proteins, DNA fragments, and non-coding RNAs from a donor cell to recipient cells, causing of the change of genetic information and reprogramming of the recipient cells. Many diverse cell types such as mesenchymal cells, immune cells, and cancer cells release exosomes. Increasing evidence illustrates that cancer derived exosomes which may contribute to the tumor initiation, tumor progression, metastasis, and drug resistance. Exosomes are secreted nanovesicles that play significance roles in cell-cell communication through shuttling proteins and nucleic acids to recipient cells and tissues. In this review, we discussed multiple mechanisms related to biogenesis, load, and shuttle of exosomes. Also we illustrated the multifaceted roles of exosomes in cancer development, tumor immunology, angiogenesis, and metastasis. Exosomes may act as the promising biomarkers for the prognosis of various types of cancers which suggested a new pathway for anti-tumor therapy of exosomes and progress exosome-based cancer diagnostic and therapeutic programs. Our objective was to meta-analysis systematically Review the literature from 2005 to 2017 with the terms "exosome" and "cancer", which included breast cancer, pancreatic cancer, gastric cancer, colorectal cancer, hepatocellular carcinoma, prostate cancer, bladder cancer, papillary thyroid carcinoma, glioblastoma, melanoma and leukemia. Inclusion Criteria is all the study designs relating to topic of interest, containing different cell lines, tissue specimens of several cancers, plasma samples of different cancer patients, using different methods (qRT-PCR and Western blotting). Exclusion criteria are any articles that not related to role of exosomes in cancer.

**Epigenetic regulation of *POLG1* in breast cancer.** *P. Bajpai<sup>1</sup>, B. Singh<sup>1</sup>, K.K. Singh<sup>1,2,3</sup>*. 1) Department of Genetics, University of Alabama at Birmingham, Birmingham, Alabama, 35294, USA; 2) Department of Genetics, Departments of Pathology, Environmental Health, Center for Free Radical Biology, Center for Aging and UAB Comprehensive Cancer Center, University of Alabama at Birmingham, Birmingham, Alabama, 35294, USA; 3) Birmingham Veterans Affairs Medical Center, Birmingham, Alabama, 35294, USA.

Nuclear-encoded polymerase POLG1 performs critical function of mtDNA replication and repair in mitochondria. We have previously reported that reduction of mtDNA content induces cancer progression. Methylation-dependent alterations in genes expression are associated with cancer progression. Since alteration in *POLG1* expression impacts mitochondrial DNA (mtDNA), which in turn leads to decreased mitochondrial OXPHOS, one of the most common phenotypes of cancer cells, we wanted to address the role of *POLG1* methylation status in cancer progression. We analyzed mRNA expression of *POLG1* in non-neoplastic human breast epithelial cells MCF-12A and human breast cancer cell lines MCF-7 and MDA-MB-231, and Rho<sup>0</sup> (mtDNA depleted) cells. A very low expression of *POLG1* was observed Rho<sup>0</sup> and MDA-MB-231 cells compared to non-neoplastic breast cell line MCF-12A. To address whether the *POLG1* expression is epigenetically regulated, we treated MDA-MB-231 cells with 5-aza-2'-deoxycytidine (5-aza), an inhibitor of DNA methylation. Treatment of MDA-MB-231 cells with increasing dose of 5-aza increased expression of *POLG1* in a dose dependent fashion. 5-aza treatment increased expression of mitochondria-encoded genes of mitochondrial OXPHOS complex as well as mitochondrial respiratory activity. 5-aza treatment-mediated increase in *POLG1* expression increased growth rate and reduced matrigel invasion capacity of MDA-MB-231 cells. To further confirm the hypothesis, we analyzed the effect of *POLG1* mediated mtDNA depletion on nuclear epigenetic changes by employing a dominant negative POLG1 D1135A mutation in a doxycycline inducible Tet-on MCF-7 cells. We observed mtDNA depletion impacts nuclear genome, and the reversal of mtDNA mediated effects on nuclear genome when mtDNA is reversed back to control level after growing POLG1 D1135A MCF-7 cells for further 6 days in absence of doxycycline. We will be further studying the effect of 5-aza in modulating methylation status of *POLG1* promoter region. Our results indicate that *POLG1* is epigenetically regulated, and its methylation status alter mitochondrial functions which can potentially affect the tumorigenic properties of the breast epithelial cells and could serve as important signature marker.

**In-depth analysis of genomics and epigenomics identifies a novel susceptibility lncRNA *GCLET* for gastric cancer.** *M. Du<sup>1,2</sup>, J. Lu<sup>1,2</sup>, G. Ma<sup>1,2</sup>, H. Chu<sup>1,2</sup>, Y. Ge<sup>1,2</sup>, W. Shao<sup>1,2</sup>, S. Li<sup>1,2</sup>, R. Zheng<sup>1,2</sup>, N. Tong<sup>1,2</sup>, G. Jin<sup>3</sup>, Z. Hu<sup>3</sup>, H. Shen<sup>3</sup>, M. Wang<sup>1,2</sup>, Z. Zhang<sup>1,2</sup>*. 1) Department of Biostatistics, Nanjing Medical University, Nanjing, Jiangsu, China; 2) Department of Environmental Genomics, Jiangsu Key Laboratory of Cancer Biomarkers, Prevention and Treatment, Collaborative Innovation Center for Cancer Personalized Medicine, Nanjing Medical University, Nanjing, Jiangsu, China; 3) Department of Epidemiology, Nanjing Medical University, Nanjing, Jiangsu, China.

**Background:** Genome-wide association studies (GWASs) have identified several loci dramatically associated with gastric cancer risk, but it seldom reported the specific mechanism of susceptibility gene for gastric cancer.

**Methods:** We implemented an integrative methodology as a part of the "post-GWAS" strategy for gastric cancer including distributional annotation of genetic variants, gene-set analysis of GWAS data and *in silico* analysis along with functional studies. **Results:** By the validation of three-stage and multi-ethnic populations, we identified a significant association between rs3850997 at a long noncoding RNA (lncRNA) Gastric Cancer Low-Expressed Transcript (*GCLET*) and gastric cancer risk ( $P = 5.34 \times 10^{-7}$ ). It is mainly attributed to the allele-specific effect of rs3850997 on transcription factor CTCF binding affinity and thus on the expression levels of *GCLET*. Additionally, it was demonstrated that *GCLET* as a biomarker with higher expression could significantly predict better clinical progression and outcome of gastric cancer. Furthermore, *GCLET* could elevate *FOXP2* expression by competing with miR-27a-3p.

**Conclusion:** These findings suggest that the in-depth analysis by integrating genomics and epigenomics could further investigate the etiology and pathology of cancers.

**Clinical relevance of non-coding A-to-I RNA editing in multiple human cancers.** T. Gu<sup>1</sup>, A. Fu<sup>2</sup>, M. Bolt<sup>3</sup>, K. White<sup>3</sup>. 1) Interdisciplinary Center for Biotechnology Research, University of Florida, Gainesville, FL; 2) Department of Statistical Science, Institute for Bioinformatics and Evolutionary Studies, Center for Modeling Complex Interactions, University of Idaho, Moscow, ID; 3) Institute for Genomics and Systems Biology, The Department of Human Genetics, The University of Chicago, Chicago, IL.

RNA editing is a post-transcriptional process that alters the nucleotide sequences of certain transcripts, in vertebrate most often converting adenosines (A) to inosines (I). Recently multiple studies have implicated RNA editing in cancer development and progression. However, most studies have focused on re-coding RNA editing events, which change the amino acid sequence of proteins but constitute only a small percentage of A-to-I RNA editing events. The function and clinical relevance of the majority of non-coding RNA editing events in cancers have not been systematically examined. We identified 3,788 non-coding A-to-I RNA editing events of high confidence from four human cancers (liver hepatocellular carcinoma, LIHC; lung adenocarcinoma, LUAD; kidney renal clear cell carcinoma, KIRC; and thyroid carcinoma, THCA). For each tumor type, hundreds to thousands of the non-coding RNA editing events showed significant differential editing (DE) efficiency between tumor and normal samples. These DE sites have distinct profiles across the four cancer types, and most (2,357; 62%) of the non-coding events we observed are at 3'UTRs and enriched at microRNA (miRNA) seed regions (key element for miRNA to recognize their targets). In kidney cancer, which has the largest uncensored survival data among the four cancer types, ninety four DE sites are significantly associated with patient survival. Using sparse regression and bootstrapping methods, we identified 3'UTR RNA editing sites that can affect gene expression, either independent of or through working with miRNAs. We validated the 3'UTR RNA editing sites in transcripts from the *CWF19L1* and *F11R* genes and the edited sites can result in increased protein levels. Furthermore, we demonstrated the alterations of the two genes' expression affect the proliferation of human embryonic kidney cells (HEK293T). These results indicate that 3'UTR editing sites may affect their host gene expression, and thus impacting cell proliferation.

**Epigenetic regulation of the Runx2 gene in lung cancer.** A. Herreno<sup>1</sup>, A. Ramirez<sup>1</sup>, G. Giraldo<sup>1</sup>, O. Moreno<sup>1</sup>, A. Cañas<sup>2</sup>, M. Montecino<sup>3</sup>, A. Rojas<sup>2</sup>. 1) Instituto de Genética, Pontificia Universidad Javeriana, Bogotá, Colombia; 2) Unidad de neumología-Hospital Universitario San Ignacio, Bogotá, Colombia; 3) Centro de Investigaciones Biológicas, Facultad de Ciencias Biológicas y Facultad de Medicina, Universidad Andrés Bello, Santiago, Chile.

Lung cancer is one of the most common causes of cancer death in the world causing 1.6 million deaths per year. This disease can be developed by genetic, epigenetic and environmental factors, among others. In Colombia for 2015, Globocan has estimated an average of 5433 diagnosed, with a mortality rate of 92.3%. In recent years, the influence of specific lineage transcription factors in pathologies such as cancer has been demonstrated. In this regard, it has been reported that the transcription factor Runx2, master regulator of osteoblastic differentiation, can actively participate in processes of progression, survival and transition mesenchymal epithelium in different types of cancer. The expression of *Runx2* is regulated by the presence of covalent modifications mediated by the WDR5/MLL/UTX complex. We selected 31 samples of lung tissues of patients who attended Hospital Universitario San Ignacio for the study of lung lesions suspected of malignancy with indications for pulmonary biopsy obtained from thoracoscopy and tomography-guided fine needle aspiration from 2016 to 2017. In this work demonstrates an increase in the expression of the *Runx2* gene at the level of mRNA and protein by RT-PCR and WB respectively in subjects diagnosed with lung cancer type NSCLC. This deregulation in the expression of Runx2 is related to changes in the levels of enrichment of the enzymatic complex WDR5 / MLL/ UTX and is related with the presence of covalent modifications of activating histones in the P1 promoter of Runx2.

**Molecular mechanisms underlying serrated polyps: Comprehensive DNA methylation analysis reveals new targets in the serrated neoplasia pathway.** V. Khammad<sup>1</sup>, N. Zhuchenko<sup>2</sup>, T. Lysytsyna<sup>2,3</sup>, I. Abramov<sup>2</sup>, I. Sapozhnikova<sup>1</sup>, E. Khammad<sup>1</sup>, O. Zaitseva<sup>1,2</sup>. 1) Medical Rehabilitation Center, Ministry of Health of Russian Federation, Moscow, Russian Federation; 2) I.M. Sechenov First Moscow Medical University, Moscow, Russian Federation; 3) Engelhardt Institute of Molecular Biology, Moscow, Russian Federation.

**Background:** Most cases of colorectal cancer (CRC) originate from identifiable precursor lesions. Fearon and Vogelstein described adenomatous polyps as the principal pre-neoplastic lesions leading to CRC. However, recently recognized «serrated pathway» represents a heterogeneous group of polyps with characteristic serrated morphology some of which exhibit a significant risk of neoplastic progression. Our aim was to investigate DNA methylation in serrated polyps (SPs) and achieve a better understanding of their role in colorectal carcinogenesis. **Methods:** We performed comprehensive genome-scale DNA methylation profiling in 76 sporadic CRCs with corresponding normal mucosa, 35 sessile serrated polyps (SSPs) and 48 traditional serrated adenomas (TSAs) using the Illumina HumanMethylation450 BeadChip. Gene expression profiling was also performed using the Illumina whole-genome DASL HT Assay. **Results:** Our genome-wide methylation study showed that differentially methylated loci were highly enriched for CpG islands in gene promoter regions: CRCs and SSPs exhibited higher methylation levels compared to TSAs ( $p < 0.0001$ ). Methylation-mediated transcriptional silencing of various genes belonging to the  $\beta$ -catenin/Wnt pathway (SFRP family genes, DKK3, WIF1, CDX2, MCC, WNT5a) was the most frequent molecular abnormality identified in TSAs (21/48; 44%) and CRCs (33/76; 43%). This finding suggests that aberrant DNA methylation has a huge impact on Wnt-driven tumorigenesis in TSAs. Moreover, SOX-Wnt interactions may also be involved in malignant transformation of TSAs. Three key genes of the SOX family: SOX7, SOX17 and SOX9, also known as suppressors of the hyperactive  $\beta$ -catenin activity, were downregulated through promoter hypermethylation in TSAs (11/48; 23%, 7/48; 15% and 4/48; 8%). The disruption of p53 and RB tumor-suppressor signaling pathways by epigenetic inactivation of IGFBP7 and CDKN2A occurred predominantly in SSPs (13/35; 37%) and was observed in some cases of CRC (10/76; 13%). Finally, we discovered that increased methylation of CpG islands in MLH1 occurred more frequently in SSPs (24/35; 69%) than in tumor specimens (9/76; 12%) and TSAs (3/48; 6%). **Conclusions:** Our data suggests that microsatellite instability, CpG island methylator phenotype high and inactivation of IGFBP7 and CDKN2A play a key role in neoplastic progression in SSPs, while TSAs are more likely to develop cancer through methylation-mediated deregulation of the  $\beta$ -catenin/Wnt signaling pathway.

**Differential DNA methylation aspect of L1-chimeric transcripts in various cancers.** S. Kim, S. Mun, K. Han. Nanobiomedical Science, Dankook University, Cheonan, Chungnam, South Korea.

Transposable elements (TEs) have contributed to the genomic structural variations which were lead to primate evolution. TEs are classified in to LINE, SINE, ERV, and SVA. Among these elements, LINE-1s (L1s) make up ~17% of the human genome, with a total of about 520,000 copies. Approximately 1,800 copies of human-specific L1s are integrated into genome after the divergence of human and chimpanzee lineages. Although the major of L1s are inactive, some human-specific L1s are still active in the human genome. L1s are a *cis*-regulatory elements and contain bidirectional internal promoters within the 5' untranslated region (UTR). L1 promoters contribute the transcriptome diversity and differential expression of nearby genes. The gene expression is regulated by the methylation of CpG islands in the 5'UTR of L1s. In this study, we characterized the L1-chimeric transcripts and analyzed methylation status of L1 promoter. First, we collected 150 L1-chimeric transcripts generated from L1 antisense promoters by referring to previous studies. Through manual inspection, we identified 60 L1-chimeric transcripts derived from 48 L1 antisense promoters that may serve as alternative promoters. We performed reverse transcription-PCR to analyze their expression patterns in matched cancer-normal tissue pair (gastric, colorectal, lung, breast, liver, prostate, breast, ovary, uterus, and kidney). Furthermore, we analyzed relative gene expression using real-time PCR and investigated correlation between methylation status of DNA and its expression. Here, we suggest that DNA methylation of L1 antisense promoter could affect the differential gene expression between cancer and normal tissues.

**The effect of expression of glycosylation genes, regulators, and targets on cancer cell line sensitivity to drug treatment.** *J. Krushkal<sup>1</sup>, Y. Zhao<sup>1</sup>, C. Hose<sup>2</sup>, A. Monks<sup>2</sup>, J.H. Doroshow<sup>1,3</sup>, R. Simon<sup>1</sup>.* 1) Division of Cancer Treatment and Diagnosis, National Cancer Institute, Rockville, MD 20850; 2) Molecular Pharmacology Laboratory, Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, MD 21702; 3) Division of Cancer Treatment and Diagnosis and Center for Cancer Research, National Cancer Institute, Bethesda, MD 20892.

Glycosylation pathways are vital for cell functioning. In cancer, many glycosylation processes are profoundly altered, affecting malignant cell growth, functioning, and interaction with surrounding environment. Due to their importance in cancer development, progression, dissemination, and treatment, glycosylation components are increasingly being targeted in cancer therapy and used as cancer biomarkers. We used time course gene expression data for the NCI-60 cancer cell lines treated with eleven antitumor agents (bortezomib, cisplatin, dasatinib, doxorubicin, erlotinib, gemcitabine, paclitaxel, sirolimus, sorafenib, sunitinib, and toptotecan) to analyze the transcriptional response of 179 genes involved in biochemical glycosylation pathways or encoding glycosylation targets, regulators, and components of cancer pathways affected by glycosylation. For each cancer drug, concentration, and time after treatment, we identified glycosylation genes with a concerted response, defined as those genes in which the expression of the vast majority of the cell lines changed in the same direction (upregulation or downregulation). Expression of 145 glycosylation genes was affected by at least one antitumor agent in a concerted manner. While many genes responded in a concerted manner to multiple agents, the direction and magnitude of their transcriptional responses were specific to individual drugs. Pretreatment expression levels of several candidate genes, e.g., *EXT1*, *NRP1*, *GALNT10*, *GNPTAB*, and *SIGLEC6*, were significantly correlated with chemosensitivity to dasatinib and erlotinib. Drug treatment induced transcriptional changes in many genes. Some of these changes were correlated with chemosensitivity to antitumor agents with different mechanisms of action. Such genes participate in *N*- and *O*-glycosylation, fucosylation, biosynthesis of poly-*N*-acetylglucosamine, removal of misfolded proteins, binding to hyaluronic acid and other glycans, and cell adhesion. Examples of such genes include *C1GALT1C1* (*COSMC*), *FUCA1*, *SDC1*, *MUC1*, and members of the *MGAT*, *GALNT*, *B4GALT*, *B3GNT*, *MAN*, and *EDEM* gene families. We provide a catalog of concerted expression changes of glycosylation genes, ligands, targets, and regulators in response to treatment by different agents, and list the genes associated with chemosensitivity. These genes may be targeted in combination therapy in order to enhance the treatment effects. Funded by NCI Contract No. HHSN261200800001E.

**Motif disruption domains lead to cancer gene expression rewiring.**

*F.C. Lamaze<sup>1</sup>, A. Chateigner<sup>1</sup>, H.A. Edgington<sup>1</sup>, A. Ang Houle<sup>1</sup>, M.J. Fave<sup>1</sup>, P. Awadalla<sup>1,2</sup>, PCAWG-3.* 1) Informatics Program, Ontario Institute for Cancer Research, Toronto, Ontario; 2) Department of Molecular Genetics, University of Toronto, Toronto, Ontario.

Recent advances in sequencing studies have exposed numerous potentially high-impact and, in some cases, actionable somatic variants in protein-coding regions across several tumor types. Yet, 95% of these somatic mutations lie in the non-coding fraction of the genome. Studies of noncoding variation implicate disease-associated loci are commonly located in noncoding regions, and are recurrent in regulatory regions. There is much evidence to suggest that a proportion of somatic single nucleotide variants (SNV) in cancer may have transcriptional regulatory mechanisms. Yet, the functional characterization of non-coding SNV, with respect to gene regulation during tumorigenesis, is a challenge. Somatic non-coding mutations rarely overlap among patients, which necessitates large sample sizes to detect associations. We analysed somatic mutations called from whole-genome sequencing and RNA sequencing from 2881 tumors across the Pan-Cancer Analysis of Whole Genomes to identify and functionally characterize mutation accumulation and its impact on gene dysregulation in cancer. We identified 1,507,105 million motif disruption domains (MDDs) of median size 1.2kb across 40 cancer types, which we characterized as pan-cancer targets for recurrent mutation accumulation. The top 1% of motif disruption scores capture binding sites of transcription factors (TFs) and cofactors known to bind to promoter, enhancer and insulator regions, for example pioneer TFs (FOXA and GATA), chromatin remodeler binding sites (EP300) and CTCF (CCCTC-binding factor). These MDDs may deregulate gene expression in cancer-specific and pan-cancer patterns by disrupting transcription factor binding sites in regulatory and insulator elements. Disruption is most recurrent across individuals at MDDs in conserved open chromatin, revealing potential functional drivers. This accumulation of somatic variants targeting regulatory and structural elements in MDDs generates gene expression dysregulation during tumorigenesis. We believe this work will improve our ability to classify tumoral and non-tumoral tissue samples by identifying pan-cancer and cancer-specific mutational signatures with substantive functional impact on the regulation of genes and pathways that could reveal new therapeutic targets.

**Effect of DNA methylation on expression of drug response genes.** *J.M. Oh<sup>1</sup>, I.W. Kim<sup>1</sup>, S. Kim<sup>2</sup>*. 1) College of Pharmacy and Research Institute of Pharmaceutical Sciences, Seoul National University, Seoul, South Korea; 2) Department of Bioinformatics and Life Science, Soongsil University, Seoul, South Korea.

**Backgrounds:** Pharmacogenomics focuses on the influence of individual genetic variations on drug response and is helping to pave the way toward safer and more effective treatments for patients. Individual differences in drug response are associated with genetic and epigenetic variability. DNA methylation can affect drug response by altering the expression of genes encoding drug-metabolizing enzymes, transporters, and targets. To identify DNA methylation loci for drug response genes, we investigated DNA methylation and RNA expression profiles of drug response using the Cancer Genome Atlas data. **Methods:** Important pharmacogenomic-related genes were searched on the Pharmacogenomics Knowledge Base and the US Food and Drug Administration Table of Pharmacogenomic Biomarkers in Drug Labels. DNA methylation and RNA expression profiles of drug response genes were selected from colon adenocarcinoma and kidney renal clear cell, liver hepatocellular, and lung squamous cell carcinomas. We identified DNA methylation sites in each sample to obtain  $\beta$ -value levels for all probes. The M-value was calculated by the following equations:  $M\text{-value} = \log_2\{\beta\text{-value}/(1 - \beta\text{-value})\}$  and this M-value was used for a statistical analysis. A Pearson's correlation analysis was used to identify DNA methylation loci related to differential gene expression after adjusted by tissue types. The distance matrix for DNA methylation variables in normal samples was constructed using the Euclidean distance and was visualized by multidimensional scaling analysis. **Results:** We found DNA methylation loci in drug response genes contributed to different DNA methylation levels in various normal tissues that correlated with their RNA expression levels. Additionally, the different methylation levels of DNA methylation loci in drug response genes were related to their differential expression in normal and tumorigenic kidney, liver, colon, and lung tissues. **Conclusions:** DNA methylation profiles of drug response genes in normal and tumor tissues may play a role in determining individual variations in drug response.

**Evaluation of circulating cell free DNA in bisulfite sequencing applications.** *M. Poulin, J. Xu, R. Drennan, S. Miller, A. Meyer, L. Yan*. EpigenDx, Hopkinton, MA., USA.

Circulating cell free DNA (cfDNA) has become a highly sought-after analyte in both the research and clinical communities. Its use in detecting and evaluating biomarkers for various diseases and its non-invasive isolation make it extremely versatile. However, the isolation, quantification and limited quantities give rise to many technical issues for use as a routine product in diagnostic medicine. We have been isolating cfDNA from serum and plasma for DNA methylation analysis using both pyrosequencing and next-generation bisulfite sequencing. Because the cfDNA must be bisulfite treated prior to either sequencing method, we have analyzed the quantity and quality of cfDNA from different volumes of serum, following both isolation and bisulfite treatment. Quantities of DNA were examined using real-time PCR quantification assays that can assess both unmodified and bisulfite treated DNA at very low levels. Results will be presented for the quantification of cfDNA isolated from various samples and volumes of serum both before and after bisulfite treatment. The quality and utility of the bisulfite treated DNA was analyzed using a targeted NextGen bisulfite sequencing (tNGBS) panel of 18 cancer related genes containing approximately 200 CpG sites; APC, BRCA1, CDKN2A, CST6, DAPK1, ESR2, ETS1, FOXP3, GSTP1, HIST1H3C, HOXB4, IKZF2, ITGAL, MLH1, RARB, RASGRF2, RUNX3, SOX17, TMEFF2. Results were also validated using pyrosequencing assays and will be presented for the different samples and different serum starting material. These results will help to evaluate isolated cfDNA prior to bisulfite sequencing protocols and establish optimal volumes of serum that need to be processed for these downstream applications.

**Genetic polymorphism and gene expression of SHH & PI3K gene in ameloblastoma.** *H. Singh, AB. Urs.* Oral Pathology, Maulana Azad Institute of Dental Sciences, BSZ Marg, MAMC Complex, New Delhi, New Delhi, India.

**Background & Aim:** Ameloblastoma is a benign and local aggressive odontogenic tumor. SHH plays a pivotal role in epithelial mesenchymal interaction to induce many cellular changes while PI3K has an important role i.e. cellular quiescence, proliferation, cancer, and longevity in the pathogenesis of Ameloblastoma through PI3K/AKT/mTOR signalling pathway. The study was designed to evaluate the gene expression and gene polymorphism of SHH and PI3K gene. **Materials & Methods:** The present study was a prospective preliminary study, which was carried out in 30 patients of confirmed ameloblastoma cases. Biopsy was taken with patient's consent. Genomic DNA was extracted for polymorphism of SHH and PI3K gene by polymerase chain reaction to assess genetic alteration and Immunohistochemistry technique respectively. **Results:** Mutations were found in Eight cases for PI3K, of these 5 cases had mutations in exon 9 (62.5%) in E542 and E545 region and 3 in exon 20 (37.4%) in H1047. No SHH gene polymorphism was detected in tumor. No differences were noted in the frequency and type of mutations analyzed by sex, age, or histologic features. The gene expression of SHH & PIK3CA was significantly higher in tumor epithelial cells. **Conclusion:** These results suggest that common genetic variations in these pathways may modulate risk and clinical outcomes of ameloblastoma. Further replication and functional studies are needed to confirm these findings. It will be of benefit to the patient, if we target the mutation or aberrant protein products at the appropriate time by intervention of précised therapy.

**MiRNA profiling of pre-cancerous and cancerous condition of stomach by next-generation sequencing.** *J. Skieceviciene<sup>1</sup>, S. Juzenas<sup>1</sup>, V. Salt-eniene<sup>1</sup>, R. Steponaitiene<sup>1</sup>, G. Kiudelis<sup>2</sup>, L.V. Jonaitis<sup>2</sup>, L. Venclauskas<sup>3</sup>, A. Ivanauskas<sup>3</sup>, A. Tamelis<sup>3</sup>, G. Hemmrich-Stanisak<sup>4</sup>, M. Hubenthal<sup>4</sup>, A. Franke<sup>4</sup>, L. Kupcinskas<sup>1,2</sup>, J. Kupcinskas<sup>1,2</sup>.* 1) Institute for Digestive Research, Lithuanian University of Health Sciences, Kaunas, Lithuania; 2) Dept of Gastroenterology, Lithuanian University of Health Sciences, Kaunas, Lithuania; 3) Dept of Surgery, Lithuanian University of Health Sciences, Kaunas, Lithuania; 4) Institute of Clinical and Molecular Biology, Christian-Albrecht-University Kiel, Kiel, Germany.

Gastric cancer (GC) is a leading cause of cancer related death worldwide. Therefore, molecular biomarkers for early non-invasive diagnostics of this malignancy are of major interest. Deregulation of miRNAs has been observed virtually in all major types of cancer. The aim of this study was to determine miRNA expression profile in tissue and plasma of patients with GC and atrophic gastritis (AG). High-throughput miRNA profiling of 20 GC, 18 AG and 26 controls was performed using small RNA-seq approach and differentially expressed miRNAs were defined. Highly significantly deregulated miRNAs were selected (criteria: corrected p-value < 0.01, and fold change > 2, expression level in plasma (read count sum > 5)) for validation by Taq-Man low-density array in replication group of 39 GC, 40 AG and 40 controls. Validated miRNAs (FDR adjusted p-value < 0.01 and fold change > 2.0) were further analysed in plasma samples of the study group (60 GC, 60 AG and 60 controls). The study was approved by the bioethical research committee (No BE-2-10). Small RNA-seq revealed: (i) 110 differentially expressed miRNAs in GC group compared to HC group; (ii) 17 differentially expressed miRNAs in AG compared to HC; (iii) 76 differentially expressed miRNAs in GC compared to AG. In the validation analysis 21 miRNA present in plasma and meeting other criteria were selected for validation study. The expression levels of 8 out of 21 miRNA in GC and 2 out of 21 miRNA in AG compared to normal tissue showed significant differential expression to the same direction as in profiling study. The expression level of miRNA in GC compared to AG was statistically different 5 out of 21 miRNA. The expression levels of validated miRNAs were further analyzed in plasma samples. The expression levels of hsa-miR-148a-3p and hsa-miR-375 showed significant down-regulation in GC plasma; while hsa-miR-223-3p was significantly up-regulated (FDR adjusted p < 0.05). No miRNA expression differences were observed in plasma of AG patients. In conclusion, miRNA expression profiling revealed: (i) 8 deregulated miRNAs in GC tissue, (ii) two deregulated miRNAs in AG tissue, (iii) five miRNAs were different in GC compared to AG. Evaluation of miRNAs as non-invasive biomarkers in GC plasma revealed differential expression of hsa-miR-148a-3p, hsa-miR-375 and hsa-miR-223-3p.

**Epigenetics modification and gene expression studies upon human amniotic fluid stem cells treated with chemotherapeutic drugs.** *P. Upadhyaya<sup>1</sup>, D. Di Tizio<sup>1</sup>, P. Ballerini<sup>1</sup>, I. Antonucci<sup>1,2</sup>, L. Stuppia<sup>1,2</sup>.* 1) Department of Psychological, Health and Territorial Sciences, Laboratory of Molecular Genetics, School of Medicine and Health Sciences, G. d'Annunzio University, Chieti-Pescara, Italy; 2) Stem Tech Group, Center for Aging Studies (CESI), G. d'Annunzio University, Chieti-Pescara, Italy.

**BACKGROUND:** Although testicular cancer (TC) has one of the highest cure rates of all cancers with an average five-year survival rate of 95%, following the treatment with chemotherapeutic reagents, it leads to infertility in some of the patients (30%). In the recent years, it has been reported in the literature that human Amniotic Fluid-derived Stem Cells (hAFSCs) show characteristics similar to pluripotent cells of the epiblast and therefore could be considered ideal candidate to generate in vitro germ cells. The purpose of this particular study was to investigate the epigenetic modifications of hAFSCs during treatment with the chemotherapeutic drugs Bleomycin, Etoposide and Cisplatin (BEP regime). **METHODS:** hAFSCs were cultured for up to 7 consecutive passages and at 5<sup>th</sup> and 7<sup>th</sup> passages Cisplatin, Bleomycin and Etoposide were added into the culture medium. From the dose-response curve, the optimal time of treatment was found to be 48 hours and the IC<sub>50</sub> of Cisplatin, Bleomycin and Etoposide was found to be 5 µM, 50 µM and 100 µM, respectively. Then, the hAFSCs were treated with the respective IC<sub>50</sub> concentration and a concentration 10 times less (i.e. 5 and 0.5 µM for Cisplatin; 50 and 5 µM for Bleomycin; 100 and 10 µM for Etoposide) for epigenetics as well as expression studies. **RESULTS:** Expression analysis by Quantitative PCR showed the increase of expression of pluripotency-associated genes ( Oct-4, SOX2, c-Myc, KLF4 and c-Kit) in the cells treated with the chemotherapeutic drugs as compared to the control. Finally, Global DNA methylation experiments have demonstrated a gradual demethylation of DNA in cells treated.

**CONCLUSION:** The chemotherapeutic agents used for the treatment of testicular cancer were found to be acting epigenetically on the DNA of hAFSCs. The results obtained suggest that BEP regime remove methyl group from the DNA and the expression studies of pluripotent markers support this epigenetic data. In future, hAFSCs could be used in disease modelling of infertility to study mutagenic and epigenetic effects of the drugs.

**Integrating chromatin and expression variation in statistical fine-mapping.** *M. Roytman<sup>1</sup>, G. Kichaev<sup>1</sup>, B. Pasaniuc<sup>1,2,3</sup>.* 1) Bioinformatics IDP, University of California Los Angeles, Los Angeles, California, USA; 2) Department of Pathology and Laboratory Medicine, Geffen School of Medicine, University of California Los Angeles, Los Angeles, California, USA; 3) Department of Human Genetics, Geffen School of Medicine, University of California Los Angeles, Los Angeles, California, USA.

Recent efforts to characterize how genetic variation impacts intermediate molecular phenotypes have yielded thousands of SNPs that associate with local and distal histone modifications -- termed histone quantitative trait loci (hQTLs). Chromatin states that are defined by combinations of histone marks are in turn, known to associate with changes in gene regulation. Furthermore, recent studies have identified many eQTLs that co-localize with molecular QTLs, implying there may exist a shared genetic influence on epigenetic traits and gene expression. Therefore, one proposed mechanism where regulatory variants may affect gene expression and thereby cause disease is through changes in chromatin state. Here we introduce new frameworks that models the hierarchical relationships between genome, epigenome, and gene expression to predict both the causal SNP and the causal epigenetic mark within a gene region. Our model naturally allows for multiple causal variants and marks to further improve accuracy. We extend our approach to incorporate interaction effects on the histone-expression level, which will allow us to identify cases where two marks influence expression concordantly rather than independently.

**826W****Mismatch repair-associated mutations reprogram the colorectal cancer enhancer epigenome.**

*S. Hung<sup>1</sup>, A. Saiakhova<sup>1</sup>, D. Neu<sup>1</sup>, Z. Faber<sup>1</sup>, C. Bartels<sup>1</sup>, G. Dhillon<sup>1</sup>, M. Kalady<sup>2</sup>, S. Markowitz<sup>1,2</sup>, P. Scacheri<sup>1</sup>.* 1) Department of Genetics and Genome Sciences, Case Western Reserve University, Cleveland, OH; 2) Department of Medicine, Case Western Reserve University, Cleveland, OH; 3) Lerner Research Institute, Cleveland Clinic, Cleveland, OH.

Somatic mutations in protein coding genes are well defined in many forms of cancer, but far less is known about mutations in noncoding regulatory elements. Active enhancer elements co-localize with acetylated lysine 27 on histone H3 (H3K27ac). Through direct interrogation of H3K27ac ChIP-seq reads, we searched for somatic indel mutations across the enhancer epigenomes of a cohort of clinically and genetically diverse human colorectal cancer (CRC) specimens. We identified potential "enhancer activating" indels that acquire H3K27ac in CRC compared to healthy normal colon cells. Strikingly, CRC samples with deficiencies in mismatch repair (MMR) proteins show significant enrichment of potential enhancer activating indels, and acquire these indels at a 2 to 100-fold higher rate than MMR-proficient samples ( $P < 9.2e-5$ ). The enhancer indels show evidence of positive selection and are significantly associated with overexpressed cancer-related genes in CRC ( $P < 0.05$ ). A subset of the indels are recurrent in primary CRC tumors. The indels arise mostly in short (5-10 bp) stretches of poly (A/T) tracts and generate sequences that closely resemble consensus motifs for the FOX family of pioneer transcription factors. Through ChIP-seq studies, we verified enrichment of FOX factors predicted to bind at the indels ( $P < 0.05$ ). Moreover, at loci harboring the canonical FOX motif-like sequence (TGTTT\*), MMR-deficient CRC samples contain 1,500 to 2,300 more active enhancers than CRC samples with intact MMR machinery. MMR-deficient endometrial cancers also show evidence of enhancer-activating indel mutations, suggesting that the effects are not limited to CRC and may be a general feature of cancers with MMR-deficiencies. Our results suggest that indel mutations in noncoding poly (A/T) sequences, previously presumed benign, frequently activate multiple enhancers in the epigenomes of MMR-deficient cancers and provide a selective advantage for tumor growth.

**827T****The genetic diversity affects the cell-fate in genotoxicity test.**

*C.C. Lin<sup>1</sup>, S.M. Chuang<sup>2</sup>, Z.C. Hung<sup>3</sup>, Y.C. Li<sup>3</sup>.* 1) Lab Chromosome Res, China Medical University & Hospital, Taichung, Taiwan; 2) Institute of Biomedical Sciences, National Chung Hsing University, Taichung, Taiwan; 3) Department of Biomedical Sciences, Chung Shan Medical University, Taichung, Taiwan.

The genetic diversity is a concerned issue in population, disease susceptibility, and drug response. However, it is less noticed about the genetic diversity among cell types in cell-based study. Generally, the preclinical study used one kind of cell line for *in vitro* genotoxicity test. CHO (Chinese hamster ovary) cell lines are commonly used for *in vitro* chromosomal aberration test suggested by FDA for the guideline of *in vitro* genotoxicity testing of chemicals. In addition to the result of chromosome aberrations, the used dosage, and the cytotoxicity responses are the reference indicators for a new drug development in pharmaceutical industry. In our study, we used two different mammalian cell lines, CHO-K1 (Chinese hamster ovary cell line) and SG (Human gingival epithelioid cell line) to test the genotoxicity and cytotoxicity of arecoline. Both cell lines were considered as non-tumorigenic cell lines but both have aberrant karyotypes. We found that the numbers of chromosome aberrations induced by arecoline in CHO-K1 cells is lower than that in SG cells at the same dosage used. CHO-K1 was more resistant to arecoline induced cytotoxicity than SG. Surprisingly, ROS (reactive oxygen species) was dose dependently induced by arecoline in CHO-K1, but not in SG. Moreover, ROS caused the cell cycle arrest at G2/M phase and then the cell death (pyknotic necrosis) of CHO-K1, while chromosome aberrations caused the cell death (apoptosis) of SG. Arecoline induced chromosome aberrations (a kind of DNA damage) in both cell lines. However, arecoline-induced DNA damage resulted in different cell fate between CHO-K1 and SG. It had been known that CHO-K1 is a p53 mutant cell line and SG has a functional p53. The mutant p53 lacks of G1 checkpoint. This could be one of reasons to cause cell cycle arrest at G2/M phase in CHO-K1, and the functional p53 of SG once detected the damaged DNA and then induced apoptosis. Our findings suggested that the genetic diversity affects the response of genotoxicity (quantitatively or qualitatively) and the mechanism of genotoxic agent induced cytotoxic response. More attention should be paid for the genetic diversity than cell phenotype (such as normal, non-tumorigenic, and carcinogenic) in studying genotoxic and cytotoxic responses in future.

**Genome-wide map of APA in lung cancer: A pilot study.** A. Zingone<sup>1</sup>, M. Ante<sup>2</sup>, KA. Mitchell<sup>1</sup>, BM. Ryan<sup>1</sup>. 1) Laboratory of Human Carcinogenesis, National Cancer Institute, Bethesda, MD; 2) Lexogen GmbH, Vienna, Austria.

Alternative polyadenylation (APA) is emerging as an alternative mechanism for proto-oncogene activation. The process generates shorter mRNA transcripts, which results in the loss of miRNA repression and mRNA stability. The 3'UTR is globally shortened in many types of cancer. In addition, environmental exposures can also mediate usage of a proximal polyadenylation site (PAS) over a distal one. However, the role of 3'UTR shortening in cancer and the contribution of environmental exposure to this process remains understudied. We hypothesized that smoking could induce APA in lung epithelial cells and contribute to their transformation. Previously we found a shorter isoform of the KRAS 3'UTR over-represented in primary lung tumors, expression of which correlated with increased pack-years of smoking. Thus, we sought to systematically map the APA landscape in lung cancer using a novel RNA-seq method termed QuantSeq-Rev 3'UTR. This method allows the identification of distinct APA within a single transcript, as well as quantification of gene expression. A pilot study comparing 8 matched primary lung tumors/non-involved samples was designed to validate the method. To measure the 3'UTR length of transcripts we developed a PAS index. Lung cancer samples had a lower PA index value compared with controls, indicating a significant switch in the use of proximal PAS ( $P < 0.0001$ ). We found over 4000 genes that were significantly more likely to use the proximal PAS in lung cancer tissues (FDR < 0.01). Interestingly, these genes were associated with pathways regulating translation initiation and protein synthesis. Conversely, genes more likely to use distal sites associated with pathways present in cells that undergo differentiation or low proliferative status. DeSeq2 analysis identified over 2000 genes differentially expressed in tumor versus normal. Interestingly, the Cleavage Stimulating Factor 2 (CSTF2) expression was 2-fold higher in tumor tissues. Overexpression of CSTF2 has been associated with poor prognosis of patients with non-small cell lung cancer. In parallel, we studied the effect of nicotine on APA *in vitro* and found that nicotine exposure induces preferential usage of the proximal PAS. Currently, we are studying APA in 100 primary tumors and 100 matched normal tissues. We have hypothesized that we will identify distinct APA signatures that can predict clinical outcome and exposure related changes.

## 829W

**A genome-wide association study (GWAS) implicates NR2F2 in lymphangiomeiomatosis pathogenesis.** K. Giannikou<sup>\*</sup>, S. Won<sup>2,3,4</sup>, W. Kim<sup>2</sup>, J.R. Dreier<sup>1</sup>, X. Qiu<sup>5</sup>, M. Tyburczy<sup>1</sup>, E.K. Silverman<sup>1,6</sup>, E. Radzikowska<sup>7</sup>, P. Rao<sup>8</sup>, H. Long<sup>9</sup>, E.P. Henske<sup>1</sup>, G. Hunninghake<sup>1</sup>, J. Moss<sup>8</sup>, M. Pujana<sup>9</sup>, D.J. Kwiatkowski<sup>1</sup>, \*equal contribution. 1) Division of Pulmonary and Critical Care Medicine and of Genetics, Brigham and Women's Hospital and Harvard Medical School, Boston, 02115, MA, USA; 2) Department of Public Health Science, Seoul National University, Seoul 151742, Korea; 3) Interdisciplinary Program of Bioinformatics, Seoul National University, Seoul 151742, Korea; 4) Institute of Health and Environment, Seoul National University, Seoul 151742, Korea; 5) Center for Functional Cancer Epigenetics, Dana-Farber Cancer Institute, Harvard Medical School, 450 Brookline Avenue, Boston 02215, MA, USA; 6) Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, 02115, USA; 7) National Tuberculosis and Lung Diseases Research Institute, Warsaw, Poland; 8) Cardiovascular and Pulmonary Branch, NHLBI, NIH, Bethesda, 20824-0105 MD, USA; 9) Catalan Institute of Oncology, Barcelona 08908, Spain.

**Background:** Lymphangiomeiomatosis (LAM) is a rare aggressive low-grade neoplasm which affects almost exclusively women and causes cystic lung destruction. LAM can either be associated with Tuberous Sclerosis Complex (TSC) or be sporadic and it is known to be due to TSC2/TSC1 genetic alterations. Risk factors for development of sporadic LAM (S-LAM) are unknown, and understanding of disease origins remains limited. We hypothesized that DNA sequence variants outside of TSC2/TSC1 are associated with susceptibility/risk for LAM disease development, and performed a Genome-Wide Association Study (GWAS) on sporadic adult female S-LAM patients, the largest LAM cohort ever assembled. **Methods:** Over 600 S-LAM subjects were collected from 14 countries, and saliva DNA from 479 S-LAM and blood DNA from 1261 matched healthy female control subjects from the COPDGene cohort were genotyped on the Infinium *OmniExpress-24 v1.2* BeadChip (discovery phase). Standard quality controls were employed, and 550,923 SNPs were analyzed in 1690 subjects. Principal components analysis was performed to adjust for genetic ancestry and exclude outliers. Conditional logistic regression for matched cases and controls was done. **Results:** Two non-coding SNPs met genome-wide significance, rs4544201 (minor allele frequency(MAF) 0.143 in cases vs. 0.255 in controls,  $P = 2.8 \times 10^{-9}$ ) and rs2006950 (MAF 0.164 in cases vs. 0.274 in controls,  $P = 2.9 \times 10^{-8}$ ), which are in the same 34kb LD block on chr15q. These findings were replicated with an independent set of 220 S-LAM cases and 1214 controls, with  $P = 2.1 \times 10^{-6}$  and  $1.5 \times 10^{-6}$ , respectively. Another intergenic SNP mapped within this LD block, rs4561414, has a tissue-specific eQTL relationship with *NR2F2* (located 700kb away) expression in thyroid,  $P = 3.7 \times 10^{-6}$ ; a member of the steroid thyroid hormone superfamily of nuclear receptors and a key developmental transcription factor in neural crest, candidate cell of origin for LAM. *NR2F2* expression was found remarkably high in RNA-seq data for kidney angiomyolipoma, a LAM-related tumor after comparison with all other cancer types (TCGA consortium) and identified as a super-enhancer gene in H3K27ac ChIP-seq data. **Conclusions:** This S-LAM GWAS has identified replicable SNPs on chr15q whose alleles are associated with LAM in patients of European ancestry. The biological mechanism related to this genetic association requires further investigation and functional assessment of *NR2F2* is in progress.

**In silico reanalysis reveals novel prognostic miRNAs in pancreatic neuroendocrine tumors.** V.K. Grolmusz<sup>1,2</sup>, K. Borka<sup>3</sup>, A. Szentpéteri<sup>1</sup>, Zs. Vásárhelyi<sup>1</sup>, P. Igaz<sup>1</sup>, K. Rácz<sup>1,4</sup>, A. Patócs<sup>2,4,5</sup>. 1) 2nd Department of Medicine, Semmelweis University, Budapest, Hungary; 2) MTA-SE "Lendület" Hereditary Endocrine Tumours Research Group, Hungarian Academy of Sciences – Semmelweis University, Budapest, Hungary; 3) 2nd Department of Pathology, Semmelweis University, Budapest, Hungary; 4) MTA-SE Molecular Medicine Research Group, Hungarian Academy of Sciences – Semmelweis University, Budapest, Hungary; 5) Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary.

Pancreatic neuroendocrine tumors (PNETs) are rare tumors arising from the endocrine islets of the pancreas. The prognosis and the therapeutical strategy of these tumors are determined by Ki-67 proliferation index and mitotic rate. Upon the proliferative phenotype, WHO classifies PNETs as G1 (least proliferative), G2 and G3 (most aggressive) tumors. MiRNAs are small, noncoding RNAs posttranscriptionally regulating gene expression. The expression of hsa-miR-21 has been shown to be associated with aggressive PNETs. Our aim was to detect novel miRNAs which expression can be used as prognostic biomarkers. Reanalysis of miRNA expression profiles of 40 PNETs were performed in datasets downloaded from Gene Expression Omnibus and differently expressed miRNAs upon tumor grade (discovery cohort) were identified. Of these the expression of 5 chosen miRNAs was evaluated in 67 histopathologically diagnosed PNET tissues by quantitative real-time PCR (validation cohort). Kaplan-Meier analysis was performed to analyze the role of tissue miRNA expression upon survival. Expression of 19 miRNAs were significantly different among tumors with different grade. Among 5 chosen miRNAs hsa-miR-21, hsa-miR-106b and hsa-miR-10a were upregulated in G3 PNETs compared to G1 and G2 PNETs. Survival analysis demonstrated a significant association between the expression of these three miRNAs and prognosis. The expression of hsa-miR-21, hsa-miR-106b and hsa-miR-10a may be useful prognostic biomarkers in PNETs.

**Colorectal cancer-upregulated long non-coding RNA lincDUSP regulates DNA damage response genes and promotes resistance to apoptosis.**

M.E. Forrest<sup>1</sup>, A. Saiakhova<sup>1</sup>, L. Beard<sup>3</sup>, V. Varadan<sup>2</sup>, D. Buchner<sup>2</sup>, P. Scacheri<sup>1</sup>, S. Markowitz<sup>1,3</sup>, A.M. Khalil<sup>1,2,3</sup>. 1) Department of Genetics and Genome Sciences, Case Western Reserve University, Cleveland, OH; 2) Department of Biochemistry, Case Western Reserve University, Cleveland, OH; 3) Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH; 4) Department of Pathology, Case Western Reserve University, Cleveland, OH.

Long non-coding RNAs (lncRNAs) are powerful regulatory molecules involved in critical cellular processes that can control gene expression at multiple levels. LncRNAs are frequently dysregulated in many cancer types and may serve as useful therapeutic targets. Given the high tumor complexity and heterogeneity observed in colorectal cancer (CRC), we hypothesized that specific lncRNAs act as "oncogenic" RNAs to drive the colon tumor phenotype and disease progression. To identify candidate oncogenic lncRNAs in CRC, we leveraged RNA sequencing data from 22 colon tumor and matched normal colon samples from The Cancer Genome Atlas (TCGA), yielding ~200 differentially expressed lncRNAs. lincDUSP emerged as a notable candidate oncogenic lncRNA due to its consistently low expression in normal colon and high expression in a subset of colon tumors. Knockdown of lincDUSP in patient-derived colon tumor cell lines by LNA GapmeRs resulted in significantly decreased cell proliferation and clonogenic potential as well as significantly increased induction of apoptosis. Studies are currently underway to characterize the effects of lincDUSP overexpression in early-stage colon tumor cell lines using a dCas9-VP64 CRISPR activation system. In an effort to elucidate the mechanism of action of lincDUSP, we chose a three-part approach: 1) query transcriptome changes associated with altered lincDUSP expression, 2) map genomic occupancy, and 3) identify protein interactions. RNA-Seq was performed in patient-derived colon tumor cell lines with or without lincDUSP knockdown, yielding ~800 differentially expressed genes. NCI pathway enrichment analysis of this gene list showed enrichment of cell cycle control, DNA replication, and DNA repair pathways. Further, identification of genome-wide lincDUSP chromatin occupancy sites by ChIRP-Seq demonstrated association with genes involved in the replication-associated DNA damage response (including *PCNA*, *EXO1*, and *XRCC2*) and cell cycle control (including *MYC* and *CCND2*). Consistent with these findings, preliminary cell cycle phase analysis in colon tumor cell lines showed early S-phase arrest upon lincDUSP knockdown; further, lincDUSP knockdown showed increased  $\gamma$ H2AX foci, indicating DNA damage response induction. Future studies to elucidate the mechanism of action of lincDUSP will involve identification of interacting protein effectors by ChIRP-MS and functional analysis of the effect of lincDUSP knockdown on DNA damage response pathways.

**832W****Antisense long non-coding RNAs in breast cancer: A transcriptome-wide disruption.**

S. Wenric<sup>1,2</sup>, S. El Guendi<sup>1</sup>, J.H. Caberg<sup>3</sup>, W. Bezzaou<sup>1</sup>, C. Fasquelle<sup>1</sup>, B. Charloteaux<sup>4</sup>, L. Karim<sup>4</sup>, B. Hennuy<sup>4</sup>, P. Frères<sup>2</sup>, J. Collignon<sup>2</sup>, M. Boukerroucha<sup>2</sup>, H. Schroeder<sup>2</sup>, F. Olivier<sup>2</sup>, V. Jossa<sup>2</sup>, G. Jerusalem<sup>2</sup>, C. Josse<sup>1,2</sup>, V. Bours<sup>1,3</sup>. 1) GIGA-Research, Unit of Human genetics, University of Liège, Liege, Belgium; 2) University Hospital (CHU), Department of Medical Oncology, Liège, Belgium; 3) University Hospital (CHU), Center of Genetics, Liège, Belgium; 4) University of Liège, GIGA-Genomics Platform, Liège, Belgium; 5) Clinique Saint-Vincent (CHC), Department of Pathology, Liège, Belgium.

**Introduction:** Non-coding RNAs (ncRNA) represent at least 1/5 of the mammalian transcript amount, and about 90% of the genome length is actively transcribed. Many ncRNAs have been demonstrated to play a role in cancer. Among them, antisense long non-coding RNAs (lncRNAs), also called natural antisense transcripts (NAT) are RNA sequences which are complementary and overlapping to those of protein-coding transcripts (PCT). NATs were punctually described as regulating gene expression, and are expected to act more frequently in cis than other ncRNAs that commonly function in trans.

**Materials and Methods:** In this work, 22 breast cancers expressing estrogen receptors and their paired healthy tissues were analyzed by strand-specific RNA sequencing. Differential expression analysis of all expressed antisense transcripts, differential correlation analysis between each antisense transcript and their paired protein coding genes, and read counts ratios variation analysis between the antisense transcripts and their paired protein coding genes have been performed. Besides providing information regarding the disruption happening both at the transcriptome-wide scale and at the scale of gene pairs, these three methods yielded candidate antisenses lists for which the association with survival of the corresponding protein coding gene has been tested on an independent cohort of 1060 breast cancer patients from the TCGA. **Results:** We observed a significant global over-expression of antisenses in breast cancer tumors. We also reported a disruption of mainly positive correlations between antisenses and protein-coding genes. Finally, all three lists of antisenses obtained with the different methods are enriched in genes significantly associated with survival.

**833T****Single cell RNA sequencing identifies novel gene expression signatures in a mouse model of multiple myeloma treated with the cIAP antagonist LCL161.**

N.E. Banovich<sup>1</sup>, M. Boateng<sup>1</sup>, L. Bergsage<sup>2</sup>, M. Ches<sup>2</sup>, J.J. Keats<sup>1</sup>. 1) TGen, Phoenix, AZ; 2) Mayo Clinic Arizona, Scottsdale, AZ.

Multiple myeloma (MM) is the second most common hematological cancer, accounting for roughly 2% of all cancer deaths. Unfortunately, MM remains incurable and nearly all patients experience relapse. Recently, we have identified a novel cIAP1 antagonist, LCL161, with remarkable anti-MM effects. Interestingly, unlike in other tumor types, our prior work found LCL161 does not directly induce apoptosis of MM cells, but rather drives activation and infiltration of macrophages to the tumor bed and phagocytosis of tumor cells. Furthermore, it appears the anti-MM activity of the agent relies on complex interactions between the tumor and the immune microenvironment. While LCL161 has been advanced to phase 2 clinical trials, the molecular mechanisms underlying the immune response remain poorly understood. We believe identifying cell-type specific gene expression changes after LCL161 treatment will aid in elucidating these mechanisms, potentially leading to additional and more targeted therapies. To this end, we collected whole spleens from three control and ten VK\*MYC tumor bearing mice – three untreated, two treated with LCL161, two treated with cyclophosphamide, and three treated with bortezomib – for single cell RNA-sequencing (scRNA-seq). All samples were collected and processed in tandem 48 hours after treatment using the 10X genomics chromium platform. Ultimately, we measured mRNA levels in over 52,000 individual cells. We identified groups of cells with shared expression profiles, corresponding to known cell-types, using graph based clustering. Consistent with our previous work we observed a marked reduction in tumor cells and activation of the non-canonical NFκB pathway in mice treated with LCL161. Moreover, we identified immune cell-types with enrichments and depletions of cells treated with LCL161, compared to other tumor bearing mice. Focusing on cells annotated as macrophages, we found a clear separation between those treated with LCL161 and other conditions. Using a binomial model we identified over 500 upregulated genes in LCL161 treated macrophages. Of note, we identified two genes, *Saa3* and *Spp1*, which are expressed exclusively in LCL161 treated macrophages (~0.4% of total cells). Due to this small number cells, the signal is unobservable using traditional bulk RNA-seq; yet we believe it may play a critical role in the efficacy of LCL161. We are currently performing experiments to reveal the role of these genes in LCL161 mediated tumor phagocytosis.

**Investigation of a transcription factor network involved in exocrine pancreatic development and homeostasis reveals a putative tumor suppressor role and a novel genetic interaction.** *J. Hoskins, E.M. Mobaraki, M. Zhang, I. Collins, A. Jermusyk, L. Amundadottir.* LTG, National Cancer Institute, Gaithersburg, MD.

In contrast to many cancers, early detection and treatment for pancreatic cancer has shown little improvement. Understanding the functional consequences of germline risk altering variants is one approach that may aid both of these aspects of cancer management. However, despite successful linkage and genome wide association (GWA) studies, much of the estimated heritability for pancreatic cancer remains unaccounted for. One suggested source of this missing heritability is interaction effects, either gene by gene or gene by environment, but the false positive rate of genome wide scans for such interaction effects is prohibitive due to the number of tests performed. Reducing the number of analyzed variants can greatly relax this constraint, but requires prior knowledge of candidates likely to interact. GWA studies to date have identified 16 loci with 20 independent signals associated with risk of pancreatic cancer among the European population, and four of these loci lie in or near genes encoding transcription factors (TFs) thought to be important for exocrine pancreas development and homeostasis. These TFs (HNF1A, HNF1B, PDX1 and NR5A2) form a putative network of positive feedback expression regulatory relationships based on previous studies with other tissues (e.g. liver and islet cells). Such functional interactions imply possible genetic interactions between these loci. Indeed, our preliminary pairwise interaction analyses revealed a significant interaction effect between the *HNF1A* and *HNF1B* risk loci ( $P_{\text{interaction}} = 0.017$  in 5113 cases and 8846 controls). Functional studies with inducible expression cell lines indicated reduced cell proliferation upon over expression of each of the four TFs, though the effects were most striking for HNF1A and HNF1B. ChIP-seq analysis of binding sites and time-course RNA-seq of downstream expression effects are underway for all four TFs, which should yield a more complete model of the gene regulatory effects of this pancreatic homeostasis TF network.

**835W**

**Disruption of Mi2b and MBD2/3 corepressor functions mediates LINE-1 reactivation and tumorigenicity in human bronchial epithelial cells challenged with benzo(a)pyrene.** *P. Bojang<sup>1</sup>, K.S. Ramos<sup>1,2,3</sup>* 1) Pulmonary, Allergy and Critical Care, University of Arizona, Tucson, KY; 2) Division of Medical Toxicology and Precision Medicine, Department of Medicine, University of Arizona College of Medicine, Phoenix, Arizona; 3) Center for Applied Genetics and Genomic Medicine, University of Arizona Health Sciences, Tucson and Phoenix, Arizona.

Long Interspersed Nuclear Element-1 (LINE-1 or *L1*), the only autonomous retroelement that remains active in the human genome, is silenced early during embryonic development and reactivated by tobacco carcinogens such as benzo(a)pyrene (BaP). The genetic and molecular mechanisms of *L1* reactivation are of interest because retroelement expression is associated with poor prognosis in Non-Small Cell Lung Carcinoma (NSCLC). In this report, we show that challenge of human bronchial epithelial cells (HBECs) with BaP shifts the *L1* promoter from a heterochromatic to euchromatic state through the disassembly of the Nucleosomal and Remodeling Deacetylase (NuRD) complex followed by shifting of constituent proteins from the nucleus to the cytoplasm. Under these conditions, the loss of NuRD corepression is associated with transcriptional activation and accumulation of *L1* proteins and loss of Mi2 $\beta$  (Chromodomain helicase DNA-binding protein 4) interaction with the *L1* promoter. The repressor functions of Mi2 $\beta$  on *L1* required the DNA and ATPase binding domains, but not the chromo domain, and were confirmed in genetic ablation experiments where either Mi2 $\beta$  and Methyl-CpG Binding Domain proteins 2/3 (MBD2/3) downregulation increased retroelement activity. Inoculation of HBECs expressing constitutively active *L1* in SCID mice induced tumours that failed to grow, suggesting that epigenetic silencing of ectopic *L1* may contain the tumorigenic response. Together, these results identify Mi2 $\beta$  and MBD2/3 as key effectors of *L1* silencing in HBECs and raise important questions about the tumorigenicity of *L1* *in vivo*.

**836T**

**Genetic variations in alcohol-metabolizing genes (*GSTM1*, *GSTT1*, *CYP2E1*, *ADH2* and *ADH3*) and pancreatitis risk in alcoholics.** V. Aaren<sup>1</sup>, L.R.S. Girinadh<sup>2</sup>, G. Sudhakar<sup>1</sup>. 1) Department of Human Genetics, Andhra University, Visakhapatnam, Andhra Pradesh, India; 2) Department of Gastroenterology and Hepatology, Andhra Medical College, King George Hospital, Maharanipeta Visakhapatnam- 530002, India.

The pancreas produces hormones such as trypsin, which is important for digestion, and insulin, which controls blood sugar levels. Long-term alcohol use can cause pancreatitis, an inflammation of the pancreas. The mortality rate of patients with alcoholic pancreatitis is about 36 percent higher than that of the general population. Approximately 50 percent of patients with alcoholic pancreatitis die within 20 years of onset of the disease. To determine the genetic susceptibility to alcoholic pancreatitis (AP) in South Indian populations, we investigated the genetic variations of exon 3, Arg47His G/A of *ADH2/ADH1B*; exon 8, Ile349Val G/A of *ADH3/ADH1C*; intron 6, T7678A of *CYP2E1*; *GSTM1*; and *GSTT1* genes in 100 cases and an equal number of age, ethnic and sex-matched controls. A detailed history of each case including the age, alcohol consumption (quantity and type of beverage), smoking, tobacco intake and other lifestyle factors were recorded. PCR-restriction fragment length polymorphism (RFLP)-based analysis of blood DNA samples were analyzed using gene and locus specific oligos. Gene polymorphisms were compared between alcoholic pancreatitis subjects (AP) vs alcoholic controls (AC) and alcoholic pancreatitis (AP) vs healthy controls (HC). Genotypic frequencies were calculated and odds ratios (OR) were determined using 2 × 2 contingency tables with 95% confidence intervals. Statistical significance for Odds Ratio (OR) was calculated by chi-square test using SPSS Version 16 software. Fisher's exact test was used when expected cell frequency was less than five. The association of the gene polymorphisms in patients and controls was examined using OR and Chi-square tests with CI 65%.  $P < 0.05$  was considered as significant. A significant association between *ADH3 Ile349Val* polymorphism and AP was observed, when compared to the AC controls ( $P = 0.0072$ ) and HC controls ( $P = 0.024749$ ). Markers *CYP2E1* T7678A failed to show any significant association with AP compared to controls ( $P = 0.42736$ ). *GSTM1* ( $P = 0.87417$  and  $P = 0.32052$ ), and *GSTT1* ( $P = 0.39718$  and  $P = 0.305749$ ) genotypes were not significantly associated with AP when compared to AC controls and HC controls. Similarly, *ADH2/ADH1B* Arg47His showed a lack of association with AP. Our research on the causes of alcoholic pancreatitis may support more effective disease management, provide hope for a potential cure and aid in developing strategies for the prevention or treatment of alcoholic pancreatitis.

**Determinants and consequences of ribosomal poverty and subsistence in *C. elegans*.** E. Cenik, N. Jain, AZ. Fire. Pathology, Stanford University, Stanford, CA.

Mutations in ribosomal protein (RP) genes can lead to diverse pathologies that include heritable ribosomopathy syndromes and several cancers. For 16 such genes, heterozygous loss-of-function leads to a syndrome, Diamond Blackfan Anemia (DBA), with variable anemia, bone marrow failure, cancer predisposition, and organ malformation. We have applied the power of *C. elegans* genetics to characterize mechanisms responding to RP heterozygosity and to understand the substantial phenotypic variation in human ribosomopathies. With Cas9, we generated heterozygous knockouts for six *C. elegans* DBA homologs. Paralleling the phenotypic variability in human syndromes, these mutant heterozygotes exhibited a variety of phenotypes with different severity, including slow growth, dominant-lethality, and sterility. RNAseq of heterozygote populations showed a global feedback process regulating ribosomal gene expression. Imbalances in large and small subunits of the ribosome exhibited different consequences. In addition, shared changes in gene expression highlight disturbances in various signaling pathways and metabolic processes. Ongoing work on RP heterozygosity is directed toward identifying specific genes/pathways where intervention will mitigate pathogenic consequences. Our RP heterozygote strains combined with this animal's intensively characterized (and transparent) embryogenesis provide an additional window on an extreme (and likely biologically relevant) regulatory situation. To date, few studies have addressed consequences of a complete loss of ability to produce new ribosomal components. Although organisms clearly require new ribosomes for growth and proliferation, certain cell populations (such as platelets) can persist and provide biological contributions without new ribosome synthesis. Ribosomes are a developmentally diverse and dynamic population. Surprisingly, we find for *C. elegans* that RP null homozygotes can produce fully functional first stage larvae. These animals, relying on maternal but not zygotic contribution of specific ribosomal components, are capable of completing embryogenesis and of fully differentiating every tissue type in the complex organism. These observations suggest that all diversity required of the translational machinery during functional tissue diversification can derive from the pool of RP transcripts and protein components present in the oocyte.

**838W****Genetic variations in ERCC2 gene and the risk of developing head and neck cancer in an Indian population.** K. Chukka<sup>1,2</sup>, Z. Vishnuvardhan<sup>3</sup>, U. Radhakrishna<sup>4</sup>.

1) Department of Biotechnology, Acharya Nagarjuna University, Guntur, Andhra Pradesh, India; 2) Department of Biochemistry, University College of Sciences, Osmania University, Hyderabad- 500007, India; 3) Department of Botany and Microbiology, Department of Environmental Sciences, Acharya Nagarjuna University, Nagarjuna Nagar, Guntur, India; 4) Department of Obstetrics & Gynecology, Oakland University William Beaumont School of medicine. MI, USA.

Head and Neck Cancers (HNCs) constitute a difficult challenge for oncologists across the globe, with one person dying every hour of every day. HNCs can disfigure the face, strip away the voice and rob one of the basic ability to eat, drink and swallow. The psychosocial impact is severe. HNCs are a significant problem in India, and constitute approximately one-third of cancer cases in contrast to 4-5% in the developed world. *XRCC1* (X-ray cross-complementing group 1) and *ERCC2* (excision repair cross-complementing group 2) are two major DNA repair proteins. Polymorphisms of these two genes have been associated with altered DNA repair capacity and increased cancer risk. In this study, 60 HNC patients and 60 matched controls were selected from the Department of Radiotherapy, Government General Hospital, Guntur, India. The mean age of participants was 54.23 years of age, and most were 40 to 60 years of age. Most participants were illiterate daily wageworkers and accustomed to hard work. Smoking, alcoholism and high consumption of spices and very hot beverages are predisposing factors in this region. We explored the gene-environment interaction between *ERCC2* (Lys751Gln) polymorphism and smoking exposure, alcohol consumption and dietary factors in the development of HNC by PCR-RFLP. Data showed no significant allelic associations for *ERCC2* (Lys751Gln). 86.66% (N=52) of the HNC cases were heterozygous and only 13.32% (N=8) of the cases were homozygous. All the controls (N=60) were heterozygous. The  $\chi^2$  value calculated for heterozygotes frequency in controls and cases did not differ significantly showing that there is no direct association between SNPs of *ERCC2* gene and outcome of HNC. The analysis of other genetic factors along with this parameter may provide the answer for personal risk assessment and an opportunity for individualized therapy.

**839T****MiR-450a and miR-450b-5p negatively impact the tumorigenic potential of ovarian epithelial cancer cells.** B.R. Muys<sup>1,2</sup>, J.F. Sousa<sup>2</sup>, L.F. Araújo<sup>1,2</sup>, F. Turaça<sup>1</sup>, I.S. Rodrigues<sup>3</sup>, D.O. Vidal<sup>4</sup>, W.A. Silva Júnior<sup>1,2</sup>. 1) Ribeirã Preto Medical School, Ribeirã Preto, São Paulo, Brazil; 2) Center for Cell-Based Therapy (CEPID/FAPESP); National Institute of Science, and Technology in Stem Cell and Cell Therapy (INCTC/CNPq), Regional Blood Center of Ribeirã Preto, Ribeirã Preto, Brazil; 3) Faculty of Philosophy, Sciences and Literature of Ribeirã Preto, University of Soã Paulo, Ribeirã Preto, Brazil; 4) Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, Brazil.

**Ovary cancer is the fifth largest cause of cancer-related deaths for women worldwide, with patients presenting extremely low 5-year survival rates. Differently from most types of solid tumors, which disseminate through the bloodstream, ovarian tumor cells frequently metastasize via transcoelomic dissemination, spreading to the peritoneum and many peritoneal organs. MicroRNAs (miRNAs), non-coding RNAs around 22 ribonucleotides long, play a critical role in gene expression regulation in virtually all biological processes. miRNAs induce gene silencing of their targets through translation repression or mRNA cleavage. In a previous work we showed that miR-450a and miR-450b-5p, two functionally underexplored miRNAs in gynecologic tumors, were downregulated in ovarian tumor cell lines in comparison to normal tissue. The aim of this work was to verify the hypothesis that both miR-450a and miR-450b-5p display tumor suppressor functions in ovarian cancer. For this purpose, we utilized in vitro assays and an in vivo xenographic model. Using a lentiviral expression vector, miR-450a and miR-450b-5p were stably overexpressed in SKOV-3 and A2780 ovarian tumor cell lines. First, apoptosis was analyzed in transduced cells submitted to low adherence conditions for 24 hours. We observed that miR-450a overexpression resulted in lower viability in A2780 and SKOV-3 cells in comparison to the control ( $p < 0.001$  and  $p < 0.05$ , respectively). We also measured cell migration and invasion rates using transwell assays. Overexpression of miR-450a or miR-450b resulted in lower migration for both cell lines ( $p < 0.001$  and  $p < 0.01$ , respectively). The same result was verified for invasion after up-regulation of miR-450a ( $p < 0.001$ ) or miR-450b in A2780 and SKOV-3 cell lines ( $p < 0.05$  and  $p < 0.01$ , respectively). Transduced A2780 cells were also injected intraperitoneally in 9-11 weeks immunodeficient mice and the weight of dissected tumors compared after 29 days. In this in vivo xenographic model of ovarian cancer, we verified that both miRNAs impaired tumor growth ( $p < 0.001$  for miR-450a and  $p < 0.01$  for miR-450b) and therefore their ability to metastasize, which corroborates our in vitro assays. To date, our analysis points to the scenario of miR-450a and miR-450b-5p playing functions proven to be relevant to the tumorigenic process of ovarian epithelial tumors. Financial Support: CAPES and FAPESP.**

**Integrative genome analysis of somatic p53 mutant osteosarcomas identifies *Ets2* dependent regulation of small nucleolar RNAs by mutant p53 protein.** R. Pourebrahimbadi<sup>1</sup>, Y. Zhang<sup>1</sup>, B. Liu<sup>1</sup>, R. Gao<sup>1</sup>, PP. Lin<sup>2</sup>, M.J. McArthur<sup>3</sup>, M.C. Ostrowski<sup>4</sup>, G. Lozano<sup>1</sup>. 1) Department of Genetics, University of Texas MD Anderson Cancer Center, Houston, TX; 2) Department of Orthopedic Oncology, University of Texas MD Anderson Cancer Center, Houston, TX; 3) Department of Veterinary Medicine and Surgery, University of Texas MD Anderson Cancer Center, Houston, TX; 4) Department of Cancer Biology & Genetics, The Ohio State University, Columbus, OH.

*TP53* is the most frequently mutated gene in cancer. Many mutant p53 proteins exert oncogenic Gain-of-Function (GOF) properties that contribute to metastasis, but the mechanisms mediating these functions remain poorly defined *in vivo*. To elucidate how mutant p53 GOF drives metastasis, we developed a traceable somatic osteosarcoma model that starts with either a single p53 mutation (p53R172H), or p53 loss specifically in osteoblasts. p53 mutant mice developed osteosarcomas with higher metastasis rate as compared to p53-null mice. Comprehensive transcriptome analysis of sixteen tumors identified a cluster of small nucleolar RNAs (snoRNAs) being highly upregulated in p53 mutant tumors. Regulatory element analysis of snoRNA genes identified an *Ets2* binding site to be the most common transcription factor binding site enriched in those genes. Homozygous deletion of *Ets2* in p53 mutant mice resulted in strong downregulation of snoRNAs and reversed the pro-metastatic phenotype of mutant p53, but had no effect on the rate of tumor formation, and mice continued to produce osteosarcoma with 100% penetrance. These studies identify *Ets2* inhibition as a potential therapeutic vulnerability in p53 mutant cancers.

**NF1 mutation structure-function analyses using a full-length mouse cDNA.** D. Wallis, K. Li, M-J. Chen, A. Challa, J. Li, H. Liu, J. Kang, B. Korf, R. Kesterson. Genetics, University of Alabama at Birmingham, Birmingham, AL.

To determine the functional consequences of NF1 patient mutations and variants of unknown significance, we have established a heterologous cell culture expression system using a full-length mouse *Nf1* cDNA and human cell lines. We demonstrate a full-length mouse *Nf1* cDNA (longest known coding *Nf1* mRNA of 2841 amino acids) placed downstream of the CMV promoter will produce a >250 kDa neurofibromin protein capable of modulating Ras signaling when expressed in wild type or *NF1*-deficient cells. Knockout HEK293 and human iPS cell lines have been established wherein *NF1*-deficiency was induced with CRISPR/Cas9. When the m*Nf1* cDNA is transiently transfected into HEK293 cells (or expressed in stable cell lines), western blot shows over-expression of neurofibromin in both *NF1* replete (*NF1*<sup>+/+</sup>) and deficient (*NF1*<sup>-/-</sup>) cells. Moreover, the re-expression of mouse neurofibromin from the cDNA is able to suppress the elevated p-ERK seen in the *NF1*<sup>-/-</sup> HEK293 cells, thereby demonstrating that the mouse neurofibromin protein is functional in the human cell line. This system provides the ability to assess the functional effect of *NF1* genetic variants found in patients with neurofibromatosis. We have thus far found that a relatively frequent cryptic splicing mutation (c.1466A>G, p.Tyr489Cys reported 34 cases that leads to a 62bp deletion in exon 13) will however produce functional neurofibromin if a full length mRNA is made (i.e. mouse p.Tyr489Cys *Nf1* cDNA is functional). The ability to express mouse *Nf1* cDNAs in human cell lines has also led to the validation of antibodies that recognize mature and truncated versions of neurofibromin proteins with different specificity to either C-terminus (SC-67, rabbit polyclonal) or N-terminus (H-12, mouse monoclonal) regions. Additional studies are underway with other NF1 mutations, including out-of-frame deletions (c.2393\_2408del16), nonsense point mutants (c.2041C>T, p.R681\*), and missense mutations (c.5425C>T, p.Arg1809Cys and c.3827G>A, p.R1276Q) that are associated with different phenotypes clinically.

**842T**

**Whole exome sequencing of patient cell lines with hypersensitivity to radiation exposure identifies ATIC as a novel target for chemoradiosensitization.** X. Liu<sup>1</sup>, D.U. Paila<sup>2</sup>, N.S. Teraoka<sup>1</sup>, J. Wright<sup>1</sup>, X. Huang<sup>1</sup>, A. Quinlan<sup>3</sup>, R. Gatti<sup>4</sup>, P. Concannon<sup>1</sup>. 1) University of Florida Genetics Institute, Gainesville, FL; 2) University of Virginia, Department of Public Health Sciences, Charlottesville, VA; 3) University of Utah, Department of Human Genetics and Department of Biomedical Informatics Salt Lake City, UT; 4) UCLA Department of Pathology and Laboratory Medicine, and Department of Human Genetics, Los Angeles, CA.

**Purpose:** A frameshift mutation in the gene encoding 5-aminimidazole-4-carboxamide ribonucleotide formyltransferase/IMP cyclohydrolase (ATIC), a bifunctional enzyme that catalyzes the final two steps of the purine *de novo* biosynthetic pathway, was identified during a screen of cell lines displaying unexplained hypersensitivity to ionizing radiation. Functional studies were carried out to determine if ATIC inhibition was radiosensitizing, and if so, to elucidate the mechanism of this effect and to determine if small molecule inhibitors of ATIC could act as effective radiosensitizing agents. **Methods and Materials:** Both siRNA knockdown and small molecule inhibitors were used to inactivate ATIC in cell culture. Clonogenic survival assays, the neutral comet assay, and  $\gamma$ H2AX staining were used to assess the effects of ATIC inhibition on cellular DNA damage responses. **Results:** Depletion of ATIC or inhibition of its enzymatic activity significantly reduced the surviving fraction of cells in clonogenic survival assays in multiple cancer cell lines. In the absence of ionizing radiation exposure, ATIC knockdown or chemical inhibition activated cell cycle checkpoints, shifting cells to the more radiosensitive G2/M phase of the cell cycle, and significantly depleted cellular ATP, but did not result in detectable DNA damage. Cells in which ATIC was knocked down or inhibited and then treated with ionizing radiation displayed increased numbers of DNA double-strand breaks, and a delay in the repair of those breaks relative to irradiated, but otherwise untreated, controls. Supplementation of culture media with exogenous ATP reversed these phenotypes, indicating that the ATP depletion resulting from ATIC inhibition is critical to its radiosensitizing effects. **Conclusions:** These findings implicate ATIC as an effective, and previously unrecognized, target for chemoradiosensitization and more broadly suggest that the energy balance in cells may have an underappreciated role in modulating the efficiency of DNA damage responses that could be exploited in radiosensitizing strategies. .

**Transcriptomic changes in NF1 deficient cells.** C. Skefos, M-J. Chen, A. Challa, K. He, H. Liu, BR. Korf, R. Kesterson, D. Wallis. University of Alabama at Birmingham, Birmingham, AL.

In efforts to define pathways responsible for the initial development of neurofibromas, we have been evaluating transcriptomic changes in a non-malignant *NF1* null cell line. We created *NF1* null HEK293 cells using CRISPR/Cas9 technology and performed transcriptomic analysis in comparison to HEK293 wild type (*NF1* +/+) cells. We have found that there are 352 genes that are up-regulated and 445 genes down-regulated by 2 fold or more ( $q < 0.05$ ) in the null cells. Ingenuity Pathway analysis has revealed that the top canonical pathways include: GABA Receptor Signaling ( $p=9.73E-06$ ), Regulation of the Epithelial-Mesenchymal Transition Pathways ( $p=1.55E-04$ ), and Axon Guidance Signaling ( $p=1.8E-04$ ). In addition, the top three Diseases and Biological functions associated with these expression changes are "Dermatological Diseases and Conditions" ( $p < 5.43E-06$ ), "Organismal injury and abnormalities" ( $p < 2.64E-05$ ), and "Cancer" ( $p < 2.64E-05$ ). Next, we compared our data set to nine other published studies that involve analysis of cells or tumors that are deficient for *NF1* and a *KRAS*-mutant cross-tumor screen. We found that 125 genes reoccur in our sample and others. Panther Gene List Analysis indicates that over a third are involved in binding (GO: 0005488). Based on our interest, we chose to validate a few genes via q-RT-PCR and see statistically significant differences between genotypes for *CACNG2*, *ETV4*, *LAMB3*, and *SLITRK5*. Though still in the validation stages, our differential expression data support continued evaluation for known disease targets and therapeutic inhibitors (e.g., FOSL1 and alisertib or BET inhibitors, HNMT and ketotifen or other mast cell stabilizers, RUNX and Ro5-3335, and inhibition of the GABA-ergic system). Some genes we've identified could be used as biomarkers or prognostic indicators (*ANXA1*, *LAMB3*, *ETV4*). Finally, we have implicated new genes and potentially druggable targets in the *NF1* phenotype. Our identification of *SLITRK5* and *SLIT2* is a novel association for this gene family involved in both neurite outgrowth and the development of neoplasia with *NF1*. *LAMB3* also offers a potential therapeutic target as its over-expression has been associated with *KRAS*-driven cancers and poorer survival while its knock-down was able to selectively initiate cell death. We are working to further investigate some of our hits and complement our RNA-Seq data with proteomics data with the goal of defining new pathways and functions of neurofibromin.

**Consequences of miR-122 loss in the development of hepatocellular carcinoma.** P.N. Valdmanis<sup>1,2</sup>, K. Chu<sup>2</sup>, F. Zhang<sup>2</sup>, M.A. Kay<sup>2</sup>. 1) Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 2) Pediatrics and Genetics, Stanford University, Stanford, CA.

MicroRNAs play important roles in fine-tuning gene expression and directing cell fate in various tissues. miR-122 is a highly-expressed liver microRNA that accounts for up to 70% of hepatic microRNAs. miR-122 expression is activated perinatally and aids in regulating cholesterol metabolism, promoting terminal differentiation of hepatocytes and suppressing genes that are active in liver embryonic development. Disrupting the expression of miR-122 can re-activate these embryo-expressed adult-silenced genes and this ultimately leads to the development of hepatocellular carcinoma (HCC) in mice. We performed small RNA sequencing and RNA-seq at various time points after genomic excision of miR-122 to determine the pathways and transcriptional progression to oncogenesis. The loss of miR-122 led to specific and progressive increases in imprinted clusters of microRNAs and mRNA transcripts at the *Igf2* locus and the *Dlk1-Dio3* locus on mouse chromosome *12qF1* that are typically restricted to embryo development. This progression can be curbed by re-introduction of exogenous miR-122. Interestingly, the chromosome *12qF1* locus is also enriched for adeno-associated virus (AAV) genomic integrations in liver tumors after gene therapy approaches using AAV. From a quantitative standpoint, we have utilized this system to elucidate the degradation pathway of miR-122 isoforms. We also demonstrate that mRNA targets of other abundant hepatic microRNAs such as miR-21 and let-7 are functionally repressed leading to global hepatic transcriptional de-regulation though this is alleviated through administration of a various microRNA-like small hairpin RNAs. Together, this reveals a transcriptomic framework for the hepatic response to loss of miR-122 and the outcome on other microRNAs and their cognate gene targets. Recognizing the progression and reversibility from miR-122 loss to HCC can provide insight into disease pathogenesis.

## 845T

**Modeling human cancer syndromes using TALEN and CRISPR/Cas9 mediated genome editing in *Xenopus tropicalis*.** K. Vleminckx<sup>1,2,3</sup>, T. Naert<sup>1,3</sup>, R. Noelanders<sup>1,3</sup>, D. Dimitrakopoulou<sup>1,3</sup>, T. Van Nieuwenhuysen<sup>1</sup>. 1) Department of Biomedical Molecular Biology, Ghent University, Ghent, Belgium; 2) Centre for Medical Genetics, Ghent University, Ghent, Belgium; 3) Cancer Research Institute Ghent, Ghent, Belgium.

CRISPR/Cas9 and TALEN mediated genome editing is creating unique and unmatched opportunities in several research fields. For the first time it is now possible to create functional gene knockouts in a number of model organisms. The tetrapod species *Xenopus tropicalis* is extremely well positioned for modeling human disease. It shares with zebrafish the aquatic habitat and easy manipulations associated with its external development. However, it manifests unique features making it a more favorable and powerful organism for modeling human genetic disease. (1) Unlike zebrafish (and *Xenopus laevis*), *Xenopus tropicalis* has a true diploid genome. Hence, gene disruption studies are not suffering from redundancy. (2) The *Xenopus tropicalis* genome shows high synteny with humans, which greatly facilitates the identification of orthologs of human disease genes. (3) Gene manipulations can be restricted to specific tissues and organs via targeted injection of individual blastomeres. More than 60 genes have meanwhile been analyzed in our experimental CRISPR/Cas9 pipeline, including genes associated with retinal disease and limb malformations. Furthermore, we have recently generated the first genetic tumor models in *Xenopus tropicalis*. Via mosaic targeting of the tumor suppressor gene *apc* we generated tadpoles that rapidly (< 1.5 months) and efficiently (>90%) developed a range of neoplasia characteristic for Familial Adenomatous Polyposis, including intestinal neoplasia, desmoid tumors and medulloblastomas (Van Nieuwenhuysen *et al.*, *Oncoscience* 2015). Similarly, using CRISPR/Cas9 techniques we found that *rb1/rb1* double mosaic mutant tadpoles rapidly develop retinoblastoma (Naert *et al.* *Sci. Rep.* 2016). More recent work also indicates the possibility of modeling T-cell acute lymphoblastic leukemia (T-ALL) and bladder cancer. The rapid kinetics of tumor development in the tadpoles and froglets pave the way for use as pre-clinical models. Additionally, these tumor models provide unique possibilities for fast identification of modifier genes and novel drug targets by multiplexed CRISPR/Cas9 gRNA injections (*tumor suppressor gene + candidate therapeutic target gene*). We present our first promising results with multiplexed gene targeting in desmoid tumors. We believe that genetic *Xenopus tropicalis* models offer a unique experimental platform that can be easily plugged into the research lines of several groups active in the field of human cancer and medical genetics.

**Five cases report with maple syrup disease over a period of 16 years: Metabolic screening, detection of inborn errors of metabolism at the Hospital para el Niño Poblano, Mexico.** *P. Sánchez Meza<sup>1</sup>, J.M. Aparicio-Rodríguez<sup>2,4</sup>, M.L. Hurtado-Hernández<sup>3</sup>.* 1) Hematology; 2) Genetics; 3) Cytogenetics, Hospital para el Niño Poblano, Puebla; 4) Estomatology Benemerita Universidad Autonoma de Puebla, Mexico.

The congenital inborn errors of metabolism (IEM) are detectABLE diseases since 1908. Some of the most frequent IEM reported are fenilketonuria, galactosemia as albinism, cystinuria and porfira and more rarely maple syrup urine disease reported in this study. It is caused by a deficiency of the branched-chain alpha-keto acid dehydrogenase complex (BCKDC), leading to a buildup of the branched-chain amino acids (leucine, isoleucine, and valine) and their toxic by-products are detected in the blood and urine. Case reported. 102 clinical cases with polymalformed muscle esqueletal and skull and dental dismorfies from this Hospital were already published Ma. De Lourdes Hurtado-Hernández et al, 2009, Figure 1. Only 5 patients with maple syrup urine disease have been reported in a 16 years period of time Table 1, where the clinical evolution of one of the patients is reported in this study. Conclusions. Actually, the IEM are defined as monogenic inherited diseases or mendelian, due to a metabolic error for a protein or enzyme absence. It might be incompatible with the patient life and sometimes if the patient lives it will modify its quality of life, especially in a severe metabolic disease as it is maple syrup urine disease. Key Words: Inborn errors of metabolism, protein, enzyme and maple syrup.

**847W**

**The use of livers with metabolic disease for domino transplantation: Can a patient with an inherited metabolic disorder act as a liver transplant donor?** *P.A. Levy<sup>1</sup>, K. Gallagher<sup>1</sup>, N. Ovichinsky<sup>2</sup>, R.M. Cunningham<sup>2</sup>, D. Kogan-Liberman<sup>2</sup>, S. Bellemar<sup>3</sup>, M. Kinkhabwala<sup>3</sup>, D. Jan<sup>3</sup>.* 1) Pediatrics, Genetics, Children's Hospital at Montefiore, Bronx, NY; 2) Pediatrics, GI & Nutrition, Children's Hospital at Montefiore, Bronx, NY; 3) Surgery, Montefiore Medical Center, Bronx, NY.

Domino transplantation involves the transplantation of the native liver from a transplant recipient into another patient. It is generally assumed that patients with inherited metabolic disease that primarily affect the liver are not good candidates to be donors due to fear that the disease would be expressed in the recipient. We recently had a 4 year old patient with propionic aciduria who was receiving a liver transplant from a deceased donor. Another patient, a 14-year-old male with acute liver failure of unknown etiology, had no suitable liver for transplant. It was decided that the 4-year old's explanted liver would be used for the 14 year old as a temporizing measure. Post-op results showed improvement in organic acids for the propionic aciduria patient: 3-OH propionic 1996±699 pre, 172±53 post; propionylglycine 1606±1262 pre, 94±123 post; methylcitric 307±33 pre, 295±247 post). Normal values for 3-OH propionic 2-42 mmol/mol Cr, propionylglycine ≤ 2 mmol/mol Cr, and methylcitric ≤ 6 mmol/mol Cr. The recipient of the liver with propionic aciduria, showed only a slight rise in metabolites (3-OH propionic 13.3±11 post; propionylglycine 0±0 post; methylcitric 15±11 post). We had anticipated that medical and nutritional therapy for propionic aciduria would be required post operatively, but this proved not to be necessary. There are reports of inadvertent liver transplants where the donor was found to have an inherited metabolic disorder when the recipient became ill. Ornithine transcarbamylase was fatal in the recipient. There are also reports of domino liver transplants with maple syrup urine disease, and methylmalonic aciduria with good results in the recipient. Our report is the first with propionic aciduria that has been reported. Our patients are now almost 2 years out from transplant and are doing well. With an increasing need for liver grafts to donate, this experience suggests that metabolic patients who receive a liver can have their liver used in another patient with some known disorders. We have shown that with Propionic aciduria, domino transplantation is successful. This could open a pool of donors that in the past might have been summarily rejected.

**CPT1A p.P479L and long QT syndrome in Northern BC: Evidence for an increased risk for symptomatic hypoglycemia and implications for management.** S.A. Collins<sup>1</sup>, S. McIntosh<sup>1</sup>, C. Ens<sup>2</sup>, G. Sinclair<sup>2</sup>, H. Vallance<sup>3</sup>, S. Stockler<sup>4</sup>, C. Greenberg<sup>5</sup>, S. Sanatani<sup>5</sup>, L. Arbour<sup>1</sup>. 1) Dept of Medical Genetics, University of British Columbia, Victoria BC, Canada; 2) Division of Cardiology, Dept of Pediatrics, BC Children's Hospital, Vancouver BC, Canada; 3) Dept of Pathology & Laboratory Medicine, University of British Columbia, Vancouver BC, Canada; 4) Dept of Pediatrics, University of British Columbia, Vancouver BC, Canada; 5) Dept of Pediatrics and Child Health, University of Manitoba, Winnipeg MB, Canada.

Usually rare, autosomal dominant Long QT syndrome (LQTS) is common in First Nations people of Northern BC (1/125) due to 2 different pathogenic variants in *KCNQ1* (p.V205M and p.R591H) originating in 2 different communities. LQTS is a potentially fatal condition characterized by a prolonged QT interval, corrected for heart rate (QTc) on electrocardiogram. Reflective of prolonged repolarization in the cardiac cycle, there is risk of serious arrhythmia that can deteriorate to ventricular fibrillation and cardiac arrest. Loss-of-function mutations in *KCNQ1* (LQTS1) and *KCNH2* (LQTS2) have recently been shown to also predispose to symptomatic postprandial hyperinsulinemia due to the role of potassium channels in insulin secretion. Beta-blockers are commonly prescribed for children with LQTS; however, hypoglycemia is a potential side-effect of treatment. Recently, it has been shown (Poterucha et al 2015) that children with LQTS on beta-blocker therapy may be at risk for hypoglycemia (3% N=9/322); however, it remains unclear under what circumstances and whether secondary genetic factors can influence the risk. Of note, one case in the above study was subsequently diagnosed with a metabolic disorder. Alarming, hypoglycemia is known to prolong the QTc possibly increasing risk for cardiac events. This potential risk for hypoglycemia is a concern in the BC First Nations LQTS population since ~50% of the Northern BC First Nations population, in general, are carriers for the *CPT1A* p.P479L variant (25% homozygous). This variant, common in Northern Indigenous populations, is important in fatty acid oxidation during fasting and may predispose to hypoglycemia. Currently, it is not known how many mutation positive LQTS patients in this population are also carriers of the *CPT1A* p.P479L variant. We present a case report of four First Nations children between the ages of 2.5 and 4 years who presented with documented hypoglycemic seizures. All of the children were carriers of a pathogenic *KCNQ1* variant, were heterozygous or homozygous for the *CPT1A* p.P479L variant, and were taking beta-blockers. All four children presented with seizures in the morning, presumably after fasting through the night. We propose that the *CPT1A* p.P479L variant in combination with a LQTS causing variant in *KCNQ1* increases risk for hypoglycemia in this population. We will describe the multiple mechanisms of hypoglycemia involved and considerations for optimum management strategies to lower risk.

**Chart review is insensitive to ascertain pathogenicity of MODY gene variants of unknown significance.** J. Goehringer<sup>1</sup>, B. Federman<sup>2</sup>, K. Nori<sup>3</sup>, U. Mirshahi<sup>4</sup>, T. Govina<sup>1</sup>, Y. Hu<sup>1</sup>, J. Williams<sup>1</sup>, T. Pollin<sup>3</sup>, A. Shuldiner<sup>2</sup>, D. Carey<sup>1</sup>, Geisinger-Regeneron DiscovEHR Collaboration. 1) Geisinger Medical Center, 100 North Academy Ave, Danville PA 17822; 2) Regeneron Genetics Center, 777 Old Saw Mill Road, Tarrytown, NY 10591; 3) University of Maryland, 800 West Baltimore Street, Baltimore MD 21201; 4) Sarah Lawrence College, 1 Mead Way, Bronxville NY 10708.

Maturity onset diabetes of the young (MODY) is an autosomal dominant form of monogenic diabetes that accounts for 1-2% of diabetes. While usually characterized as onset before age 25 in lean individuals, and not requiring insulin, many patients do not fit these criteria. Diagnosis is complicated by phenotypic heterogeneity, overlap with more common forms of diabetes mellitus (DM), and uncertain pathogenicity of MODY variants, leading to mis- and under-diagnosis. In this study we determined the value of systematic chart review of MODY gene variant carriers for variant interpretation. Within the DiscovEHR Cohort exome sequence database of 60,873 exomes, we identified carriers of rare (MAF cutoff 0.002) coding variants in *HNF4A*, *GCK*, and *HNF1A*, the genes that account for ~90% of known MODY cases. The variant data is linkable to longitudinal electronic health records, which contain diagnosis, medication, and laboratory data. We focused on 48 carriers of MODY gene variants of unknown clinical significance, and 48 non-carriers matched for age, sex, and BMI. This clinical population has a high prevalence of obesity (mean and median BMI = 30 kg/m<sup>2</sup>), which is a confounding factor in diagnosing MODY. Chart review was blinded and included 48 carriers of variants in *HNF4A* (14), *GCK* (7), *HNF1A* (26) and one patient with *HNF1A* and *HNF4A* variants. Charts were reviewed for DM-associated factors (fasting blood glucose [FBG] > 125 mg/dL or hemoglobin A1c [HbA1c] ≥6.5%) or pre-DM (FBG 100-125 mg/dL or HbA1c 5.7 - 6.4%), family history of DM, medication, age of diagnosis, and diabetic complications. Chart review yielded no documentation of MODY diagnoses for carriers. Overall, chart review did not show a difference in diabetes prevalence between gene variant carriers and non-carriers. Of the carriers, 24% had documented DM, and 39% were suspected to have pre-DM or DM based on FBG or HbA1c values. Of the non-carriers, 33% had documented DM and 48% were suspected to have pre-DM or DM. There was no difference in the age at diagnosis between carriers and non-carriers. We conclude that chart review of existing medical data does not facilitate classification of MODY variants due to phenotypic overlap of MODY with other forms of DM, inconsistencies in clinical documentation, and missing data. Future studies to determine pathogenicity of MODY variants of unknown significance will require information not systematically captured in the EHR or part of standard medical care.

Kadowaki<sup>1</sup>. 1) Department of Diabetes and Metabolic Diseases, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan; 2) Department of Pediatrics, Sanno Hospital, Tokyo, Japan; 3) Department of Medical Science Mathematics, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan; 4) Laboratory for Medical Science Mathematics, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; 5) Division of Endocrinology and Metabolism, Saitama Children's Medical Center, Saitama, Japan; 6) Department of Pediatrics, The Jikei University School of Medicine, Tokyo, Japan; 7) Department of Pediatrics, Osaka City University Graduate School of Medicine, Osaka, Japan; 8) Department of Pediatric Nephrology and Metabolism, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan; 9) Department of Pediatrics, Atsugi City Hospital, Kanagawa, Japan; 10) Department of Endocrinology and Metabolism, Saitama Medical Center, Jichi Medical University, Saitama, Japan; 11) Department of Neurology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan.

Mutations in the insulin receptor (*INSR*) gene cause a clinical spectrum of severe insulin resistance syndromes that range from Donohue syndrome (DS, the most severe) to Rabson-Mendenhall syndrome (RMS, intermediate severity) and type A insulin resistance (type A-IR, the least severe). Here, *INSR* was analyzed and five previously unreported mutations and a deletion that removed exon 2 were identified in four patients with extreme insulin resistance (one patient with DS, two with RMS, and one with type A-IR). The patient with DS had a previously unknown mutation, c.1969G>T (p.V657F), in the second fibronectin type III domain (FnIII-2), which contains a part of the insulin binding site and an  $\alpha$ - $\beta$  cleavage site. Furthermore, one of the two patients with RMS was a compound heterozygote for two novel mutations, c.2504G>T (p.S835I) and c.2525C>T (p.A842V), both of which were also within FnIII-2. A patient with type A-IR had a c.3160G>A (p.V1054M) mutation in the tyrosine kinase domain (TK) of *INSR*. Insulin proreceptor processing and the activation of signaling cascades were impaired by the mutation in FnIII when expressed in Chinese hamster ovary cells. Using mutation data from the NCBI ClinVar database, Human Gene Mutation Database (HGMD), and UniProt database, we analyzed the distribution of 82 *INSR* missense mutations for a correlation between the localization of these mutations and the severity of insulin resistance. We found that missense mutations in the FnIII domains of *INSR* resulting in DS were significantly more frequent than those resulting in type A-IR. In addition, mutations in the TK domain were found at a significantly higher frequency in patients with type A-IR than in patients with DS or RMS. Next, we analyzed missense mutations in the FnIII and TK domains by a structural bioinformatics approach to determine the correlation with phenotypic expression. This analysis revealed that missense mutations predicted to severely affect formation of the hydrophobic core of FnIII and domain stability caused DS, while mutations predicted to result in localized destabilization of FnIII and not affect domain folding led to RMS. Additionally, we showed that a number of mutations situated in structurally important/functional sites in the TK domain caused extreme insulin resistance. These results suggest the importance of the FnIII and TK domains, and thus could facilitate early diagnosis, and may also provide new therapeutic approaches.

## 851T

**Blue genes or red genes: Using large scale sequencing cohorts to reassess the pathogenicity of monogenic diabetes genes.** T.W. Laver, M. Wakeling, O. Knox, K.A. Patel, R.C. Caswell, E. De Franco, S.E. Flanagan, S. Ellard, A.T. Hattersley, M.N. Weedon. University of Exeter Medical School, University of Exeter, Exeter, Devon, United Kingdom.

Genetic testing relies on accurate information on the pathogenicity of genes. Projects such as the Transforming Genetic Medicine Initiative (TGMI) are attempting to definitively map genes to diseases (red genes) and just as importantly re-classify those without robust evidence for association with the disease (blue genes). There is considerable controversy about whether some genes proposed to cause Maturity Onset Diabetes of the Young (MODY) actually cause young-onset diabetes when mutated. MODY is an autosomal dominant, Mendelian form of diabetes which typically presents before 25 years of age. MODY is an example of where genetics enables precision medicine: a genetic diagnosis can dictate the correct treatment for a patient. Large sequencing cohorts like ExAC (n=60,706) along with extensive sequencing efforts of potential MODY cases offer new opportunities to investigate the pathogenicity of the proposed MODY genes - most were proposed before the availability of large sequencing cohorts, which may have led to incorrect association with the disease. We used a cohort of patients referred for MODY genetic testing and the ExAC cohort to assess the likelihood that variants in these genes are highly penetrant MODY mutations. We performed targeted next generation sequencing of 13 proposed MODY genes on a cohort of 596 MODY patients. For genes reported to cause MODY by haploinsufficiency we would expect to see enrichment of rare loss of function (LoF) and missense variants in a MODY cohort compared to ExAC. We see enrichment for the most common cause of MODY, *HNF1A* (LoF  $P=4 \times 10^{-6}$ , missense  $P=5 \times 10^{-8}$ ), but not for *BLK* (LoF  $P=0.4$ , missense  $P=0.5$ ) or *PDX1* (LoF  $P=1$ , missense  $P=1$ ). Additionally, reported variants in *BLK*, *KLF11*, *PAX4*, *PDX1*, and *NEUROD1* are present in ExAC at a frequency not consistent with the frequency of MODY. MODY has an estimated prevalence of 1 in 10,000. Variants in all of these genes, reported in HGMD (Human Gene Mutation Database) as pathogenic, are present at greater than 1 in 2,000 in ExAC. For example, the sole non-synonymous variant reported in the original *BLK* study occurs at a frequency of 1 in 85 in ExAC. Large scale sequencing cohorts are an important tool for assessing pathogenicity in rare Mendelian diseases. Our results suggest *BLK* and *PDX1* should be classified as TGMI blue genes and not screened on diagnostic MODY panels.

**Personalized medicine in diabetes mellitus: Lessons from the US Monogenic Diabetes Registry.** M. Sanyoura<sup>1</sup>, D. del Gaudio<sup>2</sup>, L. Letourneau<sup>1</sup>, A. Knight Johnson<sup>2</sup>, S. Greeley<sup>1</sup>, L. Philipson<sup>1</sup>. 1) Section of Adult and Pediatric Endocrinology, Diabetes, and Metabolism, The University of Chicago, Chicago, USA; 2) Department of Human Genetics, The University of Chicago, Chicago, IL, USA.

Monogenic forms of are often difficult to distinguish from type 1 and type 2 diabetes. As a result, a majority of patients remain misdiagnosed and often inappropriately treated. An accurate diagnosis is important, as the molecular subtype can direct appropriate treatment and define prognosis. The U.S Monogenic Diabetes Registry, created in 2008 at the University of Chicago, facilitates recruitment of appropriate patients and collects genetic, medical and clinical information. As of May 2017, 1430 families have been enrolled in the registry. Due to the vast number of genes implicated and the phenotypic overlap within these disorders, a gene panel-based approach to genetic testing is preferred, as it offers the ability to analyze multiple genes simultaneously. We developed and validated a next-generation sequencing (NGS) assay to evaluate all genes known to cause monogenic diabetes. To date, a pathogenic cause was identified in 429 families (774 individuals). Mutations in *KCNJ11* were found to be the most common cause of neonatal diabetes diagnosed under 1 year of age (43.2%), followed by *INS* (16.5%), 6q24 (12.2%) and *ABCC8* (10.6%). 11% of cases has pathogenic variants in syndromic genes, namely, *WFS1*, *FOXP3*, *GATA4*, and *GATA6* that would not have been correctly diagnosed otherwise. Mutations in *GCK* were found to be the most common cause of Maturity Onset Diabetes of the Young (MODY) (62%) followed by *HNF1A* (30%), *HNF4A* (7%), *HNF1B* (1%). Of all GCK-, HNF1A-, and HNF4A-MODY positive probands, 23% were misdiagnosed as type 1 diabetes, 42% were misdiagnosed as type 2 diabetes, and more than 55% of them were inappropriately treated with either insulin or other glucose-lowering agents. Similarly, 45% of probands positive for mutations in *INS*, *KCNJ11*, and *ABCC8* were misdiagnosed as type 1 diabetes. Those with diabetes due to mutations in *KCNJ11*, *ABCC8*, *HNF1A* and *HNF4A* may be more effectively managed with sulfonylurea therapy instead of insulin injections, while individuals with GCK-related diabetes generally do not require any treatment. Monogenic diabetes should be considered in any diabetic patient who has features inconsistent with their current diagnosis or presents with additional features characteristic to a specific syndromic subtype of monogenic diabetes. Rapid and cost-effective molecular genetic tests are now readily available to help define the diagnosis, alter prognosis and optimize treatment of children, young adults, and their families.

**853W**

***MAT1A* variants in methionine adenosyltransferase deficiency (MAT I/III) suggesting dominant inheritance.** J. Higgs, D. Wang, R. Salomon Kent, S. Suchy. GeneDx Inc., Gaithersburg, MD.

Elevated methionine (Met) on newborn screening can detect abnormal Met-homocysteine metabolism that may be associated with cystathionine  $\beta$ -synthase deficiency, tyrosinemia type I, glycine N-methyltransferase deficiency, adenosylhomocysteine hydrolase deficiency, adenosine kinase deficiency or MAT I/III. MAT I/III is inherited as an autosomal recessive (AR) or AD disorder. Most individuals, particularly those with the AD R264H variant, have a benign clinical course, however, patients with AR MAT I/III may have more severe findings including cognitive deficits, abnormal brain MRIs and other neurologic abnormalities. In addition to R264H, other AD variants (R249Q, G280R) have been described in association with a benign phenotype. These AD variants are located at the dimer interface of the MAT protein. We report here the results of *MAT1A* analysis in 84 cases suspected of MAT I/III. A definitive diagnosis was made in 43%: 10 homozygous/compound heterozygous for pathogenic (PATH)/likely pathogenic (LPATH) variants, 11 heterozygous for R264H and 15 with no reportable variants. Of the remaining patients, 5 were heterozygous for 2 variants of uncertain significance (VUS) or for a VUS and a PATH/LPATH variant and 43 had a single heterozygous variant not known to be associated with AD inheritance. Further review of these 43 cases revealed that 33 were heterozygous for a PATH/LPATH variant and 10 were heterozygous for a VUS. In 41 of these 43 cases, exon-level deletion/duplication testing of *MAT1A* was also performed and was negative. The 33 cases heterozygous for a single PATH/LPATH variant included 11 different variants with 7 (64%) reported as located in either the dimer interface or the substrate binding pocket or involved in Met binding/positioning (A55D, I322F, I322T, R249W, G253R, P255S, A259V) where other AD variants have been proposed. Of the 11 variants 4 were observed as single het variants in multiple individuals referred for elevated Met (A55D, P255S, A259V, I322F) comprising 17 of the 33 cases (52%). If other causes of hyper-Met have been excluded, the clinical outcome for the 33 patients is expected to be favorable as they are either heterozygous carriers of AR MAT I/III or have AD MAT I/III. Whether any of the 4 recurrent single het variants have a dominant negative effect requires further study. Such information would confirm the cause of the abnormal biochemical results, aid in the prediction of phenotype and enable accurate genetic counseling.

**854T**

**Case report of congenital disorder of glycosylation caused by novel variant on COG6 gene diagnosed in early infancy.** Z. Wei<sup>1</sup>, B. Wu<sup>2</sup>, K. Meirelles<sup>1</sup>, W. Li<sup>1</sup>, L. Yang<sup>2</sup>, H. Wang<sup>2</sup>, W. Zhou<sup>2</sup>. 1) WuXi NextCode Genomics (Shanghai) Co., Ltd., Shanghai, China; 2) The Molecular Genetic Diagnosis Center, Shanghai Key Lab of Birth Defect, Children's Hospital of Fudan University, Shanghai, China.

**Background:** Congenital disorders of glycosylation (CDG) comprise a group of autosomal recessive inherited metabolic diseases caused by synthesis defect of glycans and glycoprotein. CDG type III is caused by mutations of the conserved oligomeric Golgi (COG) complex, which is important for the proper transport and positioning of Golgi proteins. Only 10 COG6-deficient patients have been reported in the literature so far, showing a broad spectrum of clinical features. **Cases report:** Here we report a 1.5 month old Chinese male with COG6 deficiency. The patient is the first child of non-consanguineous parents with noncontributory family history. He was conceived *via in vitro* fertilization and he was born prematurely at 34 weeks of gestation *via* c-section due to fetal distress. The major clinical findings include recurrent hyperpyrexia, hypohidrotic ectodermal dysplasia, elevated liver enzymes, bronchopulmonary dysplasia, congenital heart disease (ASD, PFO, pulmonary hypertension, left superior vena cava, bradycardia), prolonged APTT, multiple small crystals in left kidney, micrognathia, no calcification of second molar and eosinophil deficiency. Whole-exome sequencing of the proband identified two compound heterozygous variants in the COG6 gene (c.511C>T, c.540G>A). The nonsense variant c.511C>T (p.Arg171\*), maternally inherited, was previously reported as pathogenic, while the novel synonymous variant c.540G>A (p.Glu180Glu) paternally inherited was predicted to affect mRNA splicing. c.540G>A is not reported in any known exome and whole genome database including the 1000 genomes and ExAC database. Sanger sequencing revealed that c.540G>A resulted in a 26bp deletion (c.515\_c.540del) of cDNA, leading to the premature truncation of the protein (p.Thr173Phefs\*13). **Conclusion:** This is the first case of COG6-CDG reported from China, which suggests hypohidrotic ectodermal dysplasia and abnormal liver enzymes could represent main clinical features for this neonatal presentation. Gene sequencing can help diagnose COG-CDG in the neonatal period and provide the basis for accurate diagnosis, clinical decision-making and outcome prediction of COG-CDGs.

**The incidence and mutational spectra of hyperphenylalaninemia in the Xinjiang Uygur population.** Y. Su<sup>1</sup>, H. Wang<sup>2</sup>, N. Rejjafu<sup>1</sup>, B. Wu<sup>2,3</sup>, H. Jiang<sup>1</sup>, H. Chen<sup>2</sup>, X. A<sup>1</sup>, Y. Qian<sup>2</sup>, M. Li<sup>1</sup>, Y. Lu<sup>2</sup>, Y. Ren<sup>1</sup>, W. Zhou<sup>2,3</sup>, L. Li<sup>1</sup>. 1) Department of Neonatology, People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi, China; 2) Children's Hospital of Fudan University, Shanghai Key Laboratory of Birth Defects, The Translational Medicine Center of Children Development and Disease of Fudan University, Shanghai; 3) Key Laboratory of Neonatal Diseases, Ministry of Health, Shanghai.

**Objective:** Hyperphenylalaninemia (HPA) is an autosomal recessive disease caused by deficiencies in phenylalanine hydroxylase (PAH) activity. Blood phenylalanine (Phe) levels greater than 360µmol/L often cause mental retardation. This is the first study to interrogate the HPA incidence rate within a large Xinjiang Uygur population sample. A further aim was to characterize the mutation spectrum of the PAH gene within the Uygur population. **Methods :** Cross-sectional data from the 2010 to 2016 National Direct Reporting System database was used to calculate the incidence rate. All HPA patients were diagnosed at birth using tandem mass-spectrometry (TMS) following exclusion of a defect in tetrahydrobiopterin metabolism, and further confirmed by direct Sanger sequencing. A low Phe diet was immediately implemented following Phenylketonuria (PKU) diagnosis. Intelligence tests were performed at the age of 18 months to assess the level of mental development. Eligible patients were followed-up from the date of diagnosis until the present day. **Results** A total of 580,607 Uygur neonates were screened and 110 were diagnosed with HPA; resulting in an incidence of 1:5278. Among these 110 Uygur patients, 105 were followed up in subsequent evaluations, 61.97% of them had normal intelligence scores (DQ > 85); 14.08% had marginal normal intelligence (DQ 75-85) and 23.94% have mental retardation. All 105 Uygur patients were genetically sequenced for PAH, as well as 3 children of their relatives and 3 children diagnosed as outpatients. We detected 55 different mutations, c.1238G>C (p. R413P) was the most frequent mutation. Furthermore, we identified 6 novel variants: c.32T>A, c.590T>A, c.1102G>A, c.1109A>G, c.1200-2A>C and c.1304A>T, which predicted to be pathogenic. Finally, the hotspot mutation of R413P was found in 4 patients from a village in Aksu in the Southern Xinjiang with a carrier rate of approximately 1:2.1. **Conclusions and Relevance:** The HPA incidence rate within the Uygur population is significantly high. Our data further highlights regional differences in PAH genotypes and mutation rates, suggesting not only a consanguineous relationship but also distinct differences between Asian and Caucasian populations.

**Mucopolysaccharidosis type VI (MPS VI) and molecular analysis: A review of published classified variants in the ARSB gene.** *M. Bailey<sup>1</sup>, R. Tomanin<sup>2</sup>, L. Karageorgos<sup>3</sup>, M. AlSayed<sup>4</sup>, E. Izzo<sup>5</sup>, N. Miller<sup>1</sup>, H. Sakuraba<sup>5</sup>, A. Zanetti<sup>2</sup>, J.J. Hopwood<sup>3</sup>.* 1) Medical Affairs, BioMarin Pharmaceutical Inc., Novato, CA; 2) Laboratory of Diagnosis and Therapy of Lysosomal Disorders, Department of Women's and Children's Health, University of Padova, Padova, Italy; 3) Lysosomal Diseases Research Unit, South Australian Health and Medical Research Institute, Adelaide, South Australia, Australia; 4) King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; 5) Department of Clinical Genetics, Meiji Pharmaceutical University, Tokyo, Japan.

MPS VI (Maroteaux-Lamy syndrome) is an autosomal recessive lysosomal storage disorder caused by mutations in the *ARSB* gene that result in deficient activity of the lysosomal catabolic enzyme N-acetylgalactosamine-4-sulfatase (arylsulfatase B, ASB). Deficient ASB activity causes lysosomal storage and elevated urinary excretion of the glycosaminoglycan enzyme substrates dermatan sulfate and chondroitin-4-sulfate. MPS VI is diagnosed through clinical findings and deficient ASB enzyme activity with normal activity of control enzymes; detection of pathogenic variants in each *ARSB* allele can independently confirm the diagnosis and facilitate genetic counseling. A previous report (Karageorgos et al. 2007) on a cohort of 105 individuals diagnosed with MPS VI documented that most *ARSB* variants are rare or private. Since 2007, with the increasing use of molecular testing, many new *ARSB* variants have been published. To uniformly summarize all *ARSB* variants, we collected and analyzed from the literature and public databases 822 reports of 193 distinct variants in the *ARSB* gene from individuals diagnosed with MPS VI. In agreement with previous reports (Karageorgos et al. 2007), most variants are missense (60%; 115 of 193); next most common are deletions (18%; 34 of 193), followed by nonsense (12%; 23 of 193), and splice site/intronic variants (6%; 11 of 193). Many reported *ARSB* variants are rare, with 33% (64 of 193) reported only once. Zygosity of individuals with MPS VI (n=411) distributed as: 51% homozygous (209 of 411) and 42% heterozygous (173 of 411); in 7% of cases only one allele was identified (29 of 411). Of the 193 unique *ARSB* variants summarized here, only 18% (34 of 193) are recorded in public databases (Clinvar, EmvClass, Invitae, ARUP) in association with supporting evidence/clinical significance. This analysis illustrates the heterogeneity of alleles linked to MPS VI and lack of representation of otherwise characterized pathogenic *ARSB* alleles in publicly available variant databases. We emphasize the importance of maintaining high clinical suspicion during MPS VI diagnosis and confirming diagnosis via ASB enzyme testing as many *ARSB* alleles may have yet to be formally classified as MPS VI-associated. Timely submission and classification of *ARSB* variants in public databases in association with biochemical and clinical data will help improve a timely diagnosis of MPS VI.

**857T**

**Teeth loss and ungueal dysplasia as atypical features in Hunter syndrome.** *P. Garavito<sup>1</sup>, J. Estrada<sup>2</sup>, B. Orozco<sup>1</sup>, A. Cortés<sup>1</sup>, C. Silvera<sup>1</sup>, C. Gallón<sup>2</sup>.* 1) Universidad del Norte, Barranquilla, Colombia; 2) Clínica San Martín, Barranquilla, Colombia.

**Background:** Hunter syndrome (OMIM 309900) or mucopolysaccharidosis type II (MPS II) is a rare disorder caused by deficiency of iduronate-2-sulfatase (I2S) enzyme, which is inherited as an X-linked recessive disorder. **Case report:** The patient is the younger of three boys of nonconsanguineous parents. At 30-month-old he presented with weight loss, short stature, and hepato-splenomegaly. He has a past medical history of fever, spontaneous teeth loss, otitis media, gastroenteritis, and intermittent abdominal pain. On clinical examination, as positive findings: brachycephaly, posterior rotation of the ears, mild icteric skin, loose teeth (upper incisors), prominent abdomen with hepato-splenomegaly, bilateral ear secretion. No coarse face, joint contractures, or hernias were observed. Dermatologic assessment described the typical cutaneous lesions of ivory-white papules on the pectoral region, pebbling of the skin, and ungueal dystrophy in hands. In the diagnostic workup, abdominal US showed hepatosplenomegaly and enlarged bile ducts. Laboratory work-up evidenced increased liver proteins (ALT, AST, GGT), hypercholesterolemia, anemia, and hypothyroidism (TSH 15.96). Serologic I2S was 4.2 umol/L/h (normal values >5.6 umol/L/h), and molecular confirmation revealed a pathogenic hemizygous mutation c.854A>G. This mutation leads to a substitution of a Tyrosine for Cysteine, p.(Tyr285Cys) and has not been described in the literature. Among the differential diagnosis that were considered in this patient were Langerhans cell histiocytosis, hypophosphatasia, and others lysosomal storage diseases. **Discussion:** The dermatologic and oral cavity findings in our patient could be secondary to glycosaminoglycans accumulation in skin and gums, and could correlate with this newly described mutation.

**858F**

**Type 2 Gaucher disease in an infant despite a non-mutated maternal *GBA1* gene.** R. Grey, E. Hagege, G. Lopez, T. Roshan Lal, B. Stubblefield, E. Sidransky, N. Tayebi. Medical genetics, NHGRI, NIH, Bethesda, MD.

Gaucher disease (GD), a recessively inherited autosomal lysosomal storage disease, results from a deficiency of the enzyme glucocerebrosidase. Over 400 mutations have been identified in *GBA1*. This gene is located in a gene-rich region on chromosome 1q21 and has a highly homologous pseudogene located 16kb downstream, which leads to a large number of recombinant alleles. The disease most frequently results from the inheritance of one *GBA1* mutation from each parent. Here we report an infant with type 2 GD who inherited one mutant allele, Arg257Gln (c.887G>A; p.Arg296Gln) from his father, while his second mutation, Gly202Arg (c.721G>A; p.Gly241Arg) was not identified in three different DNA sources (skin, fibroblasts and buccal swab) from the mother. Quantitative real-time PCR, performed on genomic DNA, failed to demonstrate any deletions, duplications or recombinations in the proband not detected by sequencing. The proband and mother's results were confirmed by sequencing cDNA made from fibroblast RNA. RNA expression and glucocerebrosidase enzyme activity and protein levels in the mother's samples were in the control range, while both were almost undetectable in the proband. These results suggest that the maternal mutation arose from germline mosaicism in the mother's ova or a single *de novo* mutation in one ovum. While there have been other cases implicating *de novo* mutations in patients with type 2 GD previously, this is the first time mutation Gly202Arg has been reported to be inherited non-traditionally. This case is part of a growing literature suggesting that Gaucher disease can be inherited via germline or *de novo* mutations, and emphasizes that it is critical for clinicians to consider such inheritance when making diagnostic decisions or providing genetic counseling. Furthermore, it will be important to evaluate the factors underlying this disease mechanism, and to explore why it seems to occur more frequently in type 2 Gaucher disease. .

**Comparative plasma proteomic analysis in Korean patients with Fabry disease pre and post enzyme replacement therapy.** S. Heo<sup>1</sup>, M. Kang<sup>1</sup>, G. Kim<sup>2</sup>, J. Choi<sup>3</sup>, S. Jung<sup>4</sup>, R. Desnick<sup>5</sup>, H. Yoo<sup>2</sup>, B. Lee<sup>2</sup>. 1) Genome Res Ctr/Asan Inst, Asan Medical Ctr, Seoul, South Korea; 2) Department of Pediatrics, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Korea; 3) Medical Genetics Center, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Korea; 4) Department of Biochemistry, School of Medicine, Ewha Womans University, Seoul, Korea; 5) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY, USA.

Fabry disease is a rare X-linked lysosomal storage disease caused by a deficiency in  $\alpha$ -galactosidase A (GLA). It is characterized by the progressive accumulation of globotriaosylceramide (Gb3) and related glycosphingolipids in the vascular endothelial, perithelial, and smooth muscle cells. Enzyme replacement therapy clears this accumulation. Herein, we analyzed plasma proteome profiles before and after enzyme replacement therapy in eight patients with Fabry disease to characterize its molecular pathology. After short-term enzyme replacement therapy (4–12 months), the abundances of 15 plasma proteins involved in inflammation, oxidative and ischemic injury, or complement activation were reduced significantly. Among them, ACTB, inactivated C3b (iC3b), and C4b were elevated significantly in pre-enzyme replacement therapy Fabry disease plasma compared with control plasma. After longer-term enzyme replacement therapy (46-96 months), iC3b levels gradually decreased, whereas the levels of other proteins varied. The gradual reduction of iC3b was comparable to that of Gb3 levels. In addition, iC3b increased significantly in pre-enzyme replacement therapy Fabry disease mouse plasma, and C3 deposits were notable in renal tissues of pre-enzyme replacement therapy patients. These results indicated that C3-mediated complement activation might be altered in Fabry disease and enzyme replacement therapy might promote its stabilization.

**Evaluation of intracerebroventricular enzyme replacement therapy treatment with rhNAGLU-IGF2 from birth onwards in MPS IIIB mice.** S.-h. Kan<sup>1</sup>, S.Q. Le<sup>1</sup>, J.D. Cooper<sup>1</sup>, M.S. Sands<sup>2</sup>, P.I. Dickson<sup>1</sup>. 1) Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA, 90502; 2) Washington University School of Medicine in St. Louis, St. Louis, MO 63110.

Mucopolysaccharidosis IIIB (MPS IIIB, Sanfilippo B syndrome) is an inherited lysosomal storage disease caused by the deficiency of the enzyme, alpha-N-acetylglucosaminidase (NAGLU) associated with the degradation pathway of heparan sulfate. Patients with MPS IIIB have a progressive neurological disorder and a lifespan of about two decades. Current studies have shown that intracerebroventricular (ICV) enzyme replacement therapy (ERT) with a fusion protein (rhNAGLU-IGF2) of recombinant human NAGLU and an IGF-2 motif is a feasible treatment in MPS IIIB mice. To further evaluate the biochemical efficacy of single dose of rhNAGLU-IGF2 *in vivo*, neonatal MPS IIIB mice (postnatal day 1 or 2) were given rhNAGLU-IGF2 (100 µg) into the left lateral ventricle. Mice were harvested at 2, 4, 8 and 12 weeks old and their brains were homogenized for enzyme activity assays. Heterozygous littermates and untreated MPS IIIB mice were used as controls. The average NAGLU enzyme activity from the whole brain homogenate ranged from 26x (2 weeks, ranged from 0.93-43 fold, n = 3), 12x (4 weeks, ranged from 3.6-21 fold, n = 3), 1.7x (8 weeks, ranged from 0.18-2.90 fold, n = 4), and 0.74x (12 weeks, ranged from 0.29-1.38 fold, n = 7) in rhNAGLU-IGF2 treated mice vs. heterozygous littermates. The estimated half-life of the enzyme *in vivo* is approximately 13.2 days. The secondary elevation of hexosaminidase activity was reduced to the heterozygous levels up to 8 weeks post-treatment with ICV rhNAGLU-IGF2 ( $p < 0.001$ ), and 81% reduced at 12 weeks post-treatment vs untreated MPS IIIB mice ( $p < 0.001$ ). The overall therapeutic effect of single dose ICV ERT with rhNAGLU-IGF2 in newborn MPS IIIB mice was stable in brain up to 12 weeks. These results, together with ongoing behavioral and pathological analyses will inform the further development of treatment protocols in MPS IIIB.

**Genetic modifiers of NGLY1 deficiency, a rare deglycosylation disorder, identified by exploiting natural variation in *Drosophila*.** C.Y. Chow, K. Owings, N. Russell, J. Lowry, R. Palu. Department of Human Genetics, University of Utah, Salt Lake City, UT.

Autosomal recessive loss-of-function mutations in *N-Glycanase 1 (NGLY1)* cause *NGLY1* deficiency, the only known human disease of deglycosylation. *NGLY1* deficiency is a devastating, rare, neglected disease. Patients with *NGLY1* deficiency present with developmental delay, movement disorder, seizures, liver dysfunction, and alacrima. *NGLY1* is a conserved component of the endoplasmic reticulum associated degradation (ERAD) pathway. ERAD degrades misfolded proteins that accumulate in the lumen of the ER. *NGLY1* deglycosylates misfolded proteins as they are translocated from the ER lumen to the cytoplasm for degradation. Patients with *NGLY1* deficiency show a wide spectrum of severity. This is especially striking since all identified patients carry two null mutations. This phenotypic heterogeneity poses a great challenge to treating this disorder. To understand what may be underlying inter-individual differences in severity of *NGLY1* deficiency, we undertook a natural genetic variation screen. We developed a *Drosophila* model of *NGLY1* deficiency and crossed it into 200 strains from the *Drosophila* Genetic Reference Panel (DGRP), a collection of wild-derived *Drosophila* strains that harbor polymorphisms present in a natural population. We assessed the effect of natural genetic variation in modulating the impact of loss of *NGLY1* activity by quantifying the number of mutant flies that survived to adulthood. Across the 200 strains, we found a very large phenotypic spectrum in survival in the absence of *NGLY1*. We found that some strains showed nearly 100% survival without *NGLY1* function, while, as expected, a number of other strains were completely lethal without *NGLY1*. We performed an association analysis to identify natural polymorphisms that modify survival in flies lacking *NGLY1*. Modifier genes fell into diverse categories not predicted to be involved in *NGLY1* function, including ER Ca<sup>2+</sup> homeostasis (*TMTC1/2*), ER proteostasis (*ERMP1*), ubiquitination (*MYCBP2*), and vesicle trafficking (*RAB26*). Over half of the candidate genes that we tested strongly suppressed or enhanced the original *NGLY1* survival phenotype. The genes identified from this study have excellent biological support and may serve as candidate modifiers of *NGLY1* deficiency. This study represents an important step to understanding the pathogenesis underlying *NGLY1* deficiency and provides a general framework for incorporating phenotypic variability, when developing personalized therapies for rare diseases.

**862W**

**Clinical and molecular variability in Niemann-Pick disease type B.** *I. Focsa<sup>1</sup>, S. Macovei<sup>2</sup>, I. Dobrescu<sup>2</sup>, L. Bohiltea<sup>1</sup>, M. Budisteanu<sup>2,3,4</sup>.* 1) Carol Davila University of Medicine and Pharmacy Bucharest, Romania; 2) Prof. Dr. Alexandru Obregia Clinical Hospital of Psychiatry, Bucharest, Romania; 3) Victor Babes National Institute of Pathology, Bucharest, Romania; 4) Titu Maiorescu University, Bucharest, Romania.

Niemann-Pick disease (NPD) is a lysosomal storage disorder, transmitted in autosomal recessive manner with a wide spectrum of phenotype. Based on clinical and molecular findings, several types have been described to date: while types A and B represents allelic variations in a single gene (*SMPD1*), type C1 is caused by mutation in the gene *NPC1* and in the *NPC2* gene (*HE1*) - type C2. Although type B is known as a "visceral non-neurologic form" with adult-onset disorder, an increased number of patients with highly variable phenotypes have been described, making it difficult to delineate the types in the absence of molecular diagnosis. We report on three pediatric patients with Niemann-Pick type B disease and variable phenotypes. The first patient is a girl with hepatosplenomegaly (HSM) from the age of 1 year, with psychomotor regression starting at the age of 3 years followed by a slow gradual decline resulting in quadriplegia, absent speech, severe intellectual disability, and sleep disorders (insomnia) at the age of 12 years. At 10 years epileptic seizure occurs. She died at the age of 15 years. The second case is an 8 years girl who was first admitted to the hospital at the age of 1 year because of HSM. At 6 years growth retardation, kyphosis, neurodevelopment regression (mild intellectual disability, poor speech with dyslalia) were noted. The third patient: a 17-year-old boy exhibited HSM from the age of 1,3 year, recurrent respiratory infection, delayed developmental milestones (first steps at 2,3 years, first syllables at 9 months), moderate intellectual disability (QI 47), behavior problems. In 1 and 3 cases lysosphingomyelin-509 marker was elevated. *NPC1*, *NPC2*, *SMPD1* genes sequencing was performed in all patients. Two heterozygous mutations *c.573delT* (p.Ser192Alafs\*65) and *c.1177T>G* (p.Trp393Gly) was found in the first case. In the second case we also identified two heterozygous mutations: *c.560\_606del* in exon 2 leading to a premature stop at codon 208 and *c.177T>G* (p.Trp393Gly), while a homozygous mutation *c.1177T>G* (p.Trp393Gly) was revealed in our third case. All the mutations was detected in *SMPD1* gene and was previously described as pathogenic. Since the *c.1177T>G* mutation is common in all patients and seems to be associated with mild phenotype, the other two mutations could play a role in phenotype severity. The *c.573delT* mutation is related with the most severe phenotype. Our study brings new evidence in a better genotype-phenotype correlation.

**Monoallelic mutations in *OXCT1* in clinically and biochemically proven SCOT deficiency: Evidence of deep intronic mutations?** *C. Murali, M. Yudkoff, C. Ficicioglu, R. Ganetzky.* Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA.

Ketone body utilization defects are metabolic disorders with impaired ketolysis. Patients typically present in the newborn period or in childhood. Many manifest continual ketosis; others become ketotic in response to metabolic stress. A deficiency of succinyl-CoA 3-oxoacid CoA transferase (SCOT) is a common cause. Inheritance is thought to be autosomal recessive, but here we present 2 cases with severe ketosis and only a single mutation in *OXCT1*. Subject 1 is a full term exclusively breastfed girl who presented with lethargy and tachypnea on day of life 4. She had severe anion gap acidosis (pH 7.01, bicarbonate 3.8 mmol/L) with large ketones and euglycemia. Ammonia was mildly elevated at 141  $\mu$ mol/L. Ketosis resolved in response to treatment with intravenous dextrose. Urine organic acids showed massive ketonuria (beta-hydroxybutyrate: 4156 mg/g creatinine; acetoacetate: 690 mg/g creatinine). Exome sequencing revealed a maternally-inherited heterozygous variant of uncertain significance in *OXCT1* (*c.1376C>G*). At 4 months, she has had no further episodes of decompensation, but does have intermittent, unprovoked, trace ketonuria (41 mg/g creatinine). She is managed with frequent feedings and strict fasting precautions. Subject 2 is a boy who presented with ketotic hypoglycemia at age 2 years. He has had recurrent episodes of ketotic hypo- and euglycemia over the subsequent 11 years. He requires chronic bicarbonate supplementation and a high-carbohydrate diet; he previously required a gastrostomy tube to maintain euglycemia. Enzymology showed low SCOT activity in fibroblasts (2.3 nmol/min/mg; normal > 2.6). Exome sequencing revealed a maternally-inherited heterozygous likely pathogenic variant in *OXCT1*, as well as a heterozygous mutation in *SLC22A5*. His medical problems include executive function problems, depression, hand tremor, and migraines. Targeted del/dup analysis of *OXCT1* was negative in both subjects. These cases show the classic, severe ketosis of SCOT deficiency, despite having only monoallelic mutations in *OXCT1*. We speculate that these subjects either have a second deep intronic mutation missed by exome sequencing; or, in the setting of additional metabolic stressors (exclusive breast feeding, *SLC22A5* carrier status), there may be haploinsufficiency. We propose that manifestation of disease in apparent *OXCT1* heterozygotes is an important consideration in the differential diagnosis of severe ketosis.

**864F**

**Newborn screening for Hunter Disease: Is the c.103+56\_34 dup allele a pathogenic variant or a pseudodeficiency variant?** *Y.H. Huang<sup>1</sup>, S.P. Lin<sup>1,2,3</sup>, C.C. Chiang<sup>4</sup>, M.J. Chan<sup>4</sup>.* 1) Rare Disease Center, MacKay Memorial Hospital, Taipei, Taiwan; 2) Department of Pediatrics, MacKay Memorial Hospital, Taipei, Taiwan; 3) Department of Medical Research, MacKay Memorial Hospital, Taipei, Taiwan; 4) Newborn Screening Center, Chinese Foundation of Health, Taipei, Taiwan.

Mucopolysaccharidosis type II (MPS II, Hunter Disease) is an X-linked lysosomal storage disease caused by a deficiency of iduronate-2-sulfatase (IDS). Since August 2014, we started large-scale newborn screening for Hunter disease by using dried blood spots (DBS) of LC-MS/MS method for measuring IDS activity. In the past 20 months, a total of 103,025 newborns were screened, 66 newborns were referred to the confirmatory center for further evaluation. Leucocyte enzymatic assay was done and IDS gene analysis was performed for those with leukocyte enzyme deficiency. 50 newborns were confirmed with reduction of IDS enzyme activity and a variant was found in IDS gene. According to the current database, only one case has been categorized as Hunter disease patient with a R273W mutant and others were variants of unknown significance (VOUS): c.103+34\_56dup (43 cases), R297H (1 case), R493H (3 cases), P197S (1 case), and H342R (1 case). The c.103+34\_56dup variant was identified in 86% of the VOUS groups and average IDS activity was  $3.67 \pm 1.38$  (NR: 30-53 nmol/4h/mg. protein). A total of 21 adjunctive maternal family members undertook the genetic testing for this variant, and 5 cases were found to have this variant. None of the cases with c.103+34\_56dup variant have any feature and characteristic of Hunter disease, including heart and abdomen sonography, X-ray of T-L spine and bilateral hand, even disaccharide units (KS, DS and HS) of urine GAG detected by LC-MS/MS were no specific findings, except only one newborn has mild hepatomegaly (liver span: 8.08 cm at mid-clavicular line). This information collected over 20 months of newborn screening for Hunter disease highlights the importance of genetic counseling and testing among newborns and high-risk family members. The high prevalence of the c.103+34\_56dup variant in Taiwan raises an issue that whether this variant is truly a pathogenic mutation or just a pseudodeficiency variant. Further studies are demanded to analyze functional data and to evaluate the frequency of this variant in general population, furthermore, newborns and family members who have this variant also need to long term follow up.

**Pharmacokinetics of glycerol phenylbutyrate in pediatric patients 2 months to 2 years of age with urea cycle disorders.** *S.A. Berry<sup>1</sup>, J. Vockley<sup>2</sup>, A.A. Vinks<sup>3</sup>, M. Dong<sup>4</sup>, R. Perdok<sup>4</sup>, B. Robinson<sup>4</sup>, R.J. Holt<sup>4</sup>, N. Longo<sup>5</sup>.* 1) University of Minnesota, Minneapolis, MN; 2) University of Pittsburgh, Pittsburgh, PA; 3) Cincinnati Children's Hospital Medical Center and University of Cincinnati, Cincinnati, OH; 4) Horizon Pharma USA, Lake Forest, IL; 5) University of Utah, Salt Lake City, UT.

**Introduction.** Glycerol phenylbutyrate (GPB) is approved in the US and EU for the management of patients  $\geq 2$  months of age with urea cycle defects (UCDs) who cannot be managed by dietary protein restriction and/or amino acid supplementation alone. It is hydrolyzed by pancreatic lipases to yield phenylbutyric acid (PBA), converted in the liver to phenylacetic acid (PAA) that binds with glutamine to form phenylacetylglutamine (PAGN) which is excreted in urine (UPAGN). Here we examine the short- and long-term PK of GPB in very young UCD patients whose pancreatic and liver function might be immature. **Methods.** PK was analyzed using WinNonlin@NONMEM® in UCD patients aged 2 mos to <2 yrs from two open label clinical studies. **Study 1** (NCT02246218) analyzed PK for 1-2 days and UPAGN for 1 week in 10 patients with blood/urine sampling completed pre-dose and periodically thereafter. Only 3 patients were dosed with GPB for  $\geq 6$  mos. **Study 2** (NCT01347073) compared the 24 hour PK in 4 patients switched from sodium PBA to GPB. These patients plus 3 additional patients were analyzed for up to 1 yr on GPB. **Results. Short Term:** Mean PBA/PAA/PAGN  $C_{max}$  were 42.4/36.5/62.5 mcg/mL on the first day of GPB-only dosing; UPAGN averaged 7,561 mcg/mL at 12-24 hr on day 1 and 8,859 mcg/mL on Day 7 (Study 1). Body surface area (BSA) correlated with PAA  $C_{max}$  and  $AUC_{0-24}$ , PAGN  $C_{max}$  and to a lesser extent  $AUC_{0-24}$  (Study 1). Population modeling found BSA to be the most significant covariate for PK analytes. PAA exposure ( $AUC_{0-24}$ ) with GBP and Sodium PBA was 3,322 & 4,138 mcg\*hr/mL (Study 2). **Long Term:** Plasma PBA/PAA/PAGN values did not significantly change over time. Overall median plasma PAA was ~1 mcg/ml and median plasma PAA:PAGN ratio <1 (Study 2). One PAA value exceeded 500 mcg/ml but was lower 9 months later at similar GPB doses. Mean targeted ammonia values were maintained at scheduled visits throughout the studies. **Conclusions.** GPB dosing was followed by prompt appearance (first day) of metabolites in blood and PAGN in urine. Elevated PAA levels were infrequent, transient and the median PAA:PAGN ratio of <1 indicate that PAA to PAGN conversion was not saturated. The findings collectively indicate that pediatric UCD patients aged 2 mos–2 yrs effectively hydrolyze GPB to release PBA and convert PAA to UPAGN so as to maintain blood ammonia within normal limits.

**Increased expression of *SLC26A9* delays age at onset of diabetes in cystic fibrosis.** A. Lam, M. Atalar, B. Vecchio-Pagan, S. Blackman, G. Cutting. Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD.

Diabetes is a common complication of cystic fibrosis (CF) with a number of clinical and histological similarities to type 2 diabetes. Genome-wide studies have identified significant association with CF-related diabetes for variants near and within *SLC26A9*, which encodes a chloride/bicarbonate transporter that interacts with CFTR, the protein defective in CF. The *SLC26A9* locus is of particular interest as it has also been identified as a modifier of intestinal obstruction and drug response in CF. A biologic role for *SLC26A9* in exocrine pancreatic function is supported by single cell RNA sequencing indicating that *SLC26A9* is predominantly expressed in pancreatic ductal cells, along with *CFTR*. To assess the genetic architecture of *SLC26A9*, the entire locus was sequenced in 762 individuals with CF (all F508del homozygotes). Two linkage disequilibrium (LD) blocks were identified and defined by a single recombination in intron 8. Two common haplotypes (24.2% and 28.4% frequency) exist within the 5' LD block corresponding to the variants associated with higher-risk (HR) and lower-risk (LR) of diabetes, respectively. No coding variants were in LD with either haplotype, and no individual variant showed greater association with diabetes than the two common haplotypes. To determine if the region containing the diabetes-associated variants encompasses regulatory sequences, 2.3 kb corresponding to the HR and LR haplotypes were cloned into a dual luciferase/renilla reporter system (DLRS). Combined analysis of the normalized data from 3 independent transfections into PANC-1, a surrogate for pancreatic ductal cells, with 4 biological clones per haplotype (technical replicates: transfection well N=78 for HR and N=77 for LR; DLRS N=234 for HR and N=230 for LR) showed that HR had a 13% lower promoter activity compared to LR ( $p=5.9E-11$ ). Luciferase expression was negligible when the DNA sequences were cloned in the reverse orientation indicating that the 2.3kb region 5' of *SLC26A9* drives expression in an orientation-specific manner. These results are consistent with eQTL predictions from RNA sequencing data suggesting that LR variants in the 2.3 kb region correlate with higher levels of expression than HR variants (rs61814953;  $p=6.24E-03$ ;  $\beta=0.238$ ). Taken together, these results indicate that increased expression of *SLC26A9* delays onset of diabetes in individuals with CF, possibly by modification of pancreatic ductal function. *Supported by CFF, Gilead Sciences.*

**Genetic causes of hypercholesterolemia in the Emirati population.** H. Daggag<sup>1</sup>, A. Rimbart<sup>2</sup>, A. Buckley<sup>1</sup>, R.J. Sinke<sup>3</sup>, M.T. Barakat<sup>1</sup>, J.A. Kuivenhoven<sup>2</sup>. 1) Imperial College London Diabetes Centre, Abu Dhabi, Abu Dhabi, United Arab Emirates; 2) Department of Pediatrics, University of Groningen, University Medical Center Groningen, The Netherlands; 3) Department of Genetics, University of Groningen, University Medical Center Groningen, The Netherlands.

Cardiovascular disease is the leading cause of morbidity and mortality in the UAE. Of the 5434 registered deaths in the UAE in 2000, 1381 were due to cardiovascular disease. Worldwide the two most important risk factors for ischaemic heart disease and myocardial infarction are smoking and dyslipidaemia. Familial hypercholesterolemia (FH) is an autosomal dominant genetic disorder that leads to premature arterial disease and cardiac death if left untreated. FH is widely under diagnosed and the prevalence in the Emirati population has not been established. The molecular diagnosis includes screening for monogenic as well as polygenic causes of this disorder. Of 39 patients screened as potential index cases by our clinical service, only five were found to have mutations in known FH genes (13.1%). Further five patients were carriers of a variant of unknown significance (VUS), further supporting the need to perform a research study and identify FH genetic causes specific to the Emirati population. In this study, we will apply a two-stepped approach using Next-Generation Sequencing (NGS) tools to investigate genetic bases of FH in our population. We will first screen known and candidate FH related genes using a novel dedicated kit which combines: targeted capture of genes and loci related to FH, NGS and an up to date bio-informatics pipeline. We recently showed for the first time that this kit can assess all possible causes of FH known to date. Secondly, for patients without established genetic diagnostics, we will investigate novel genetic causes using whole-exome sequencing. To date, 330 patients have been recruited from clinical areas at Imperial College London Diabetes Centre (ICLDC), an outpatient diabetes and general endocrine clinic based in the United Arab Emirates. 68 patients with LDL-c value higher than 6mmol/L (after correction for lipid reducing agents) will be selected for a molecular diagnosis of FH. This approach will contribute to our understanding of the epidemiology of FH in Emirati people and could potentially identify novel FH-causing genes susceptible to be of therapeutic interest. Proactive genetic screening of individuals who meet clinical criteria for FH and subsequent cascade screening of families may well provide a comprehensive tool for accurate diagnosis, facilitate early preventative clinical intervention and reduce overall healthcare costs.

**868W**

**CEBPA mutation as a potential clinically novel cause of congenital generalized lipodystrophy.** *R.M. Mostafavi<sup>1</sup>, A. Lahoti<sup>2,3</sup>, S.F. Miller<sup>2,3</sup>, E.K. Pivnick<sup>2,3</sup>.* 1) Le Bonheur Children's Hospital, Memphis, TN; 2) University of Tennessee Health Science Center, Memphis, TN; 3) UT Le Bonheur Pediatric Specialists, Memphis, TN.

Congenital generalized lipodystrophy (CGL) is a rare autosomal recessive disorder characterized by absent adipose tissue at birth, bone cysts and insulin resistance. Mutations in *AGPAT2* and *BSCL2* account for the two most common types of CGL. We present a patient with CGL in whom whole exome sequencing (WES) identified a mutation in *CEBPA*, a gene involved in adipocyte differentiation and a potential candidate for unexplained cases of CGL. An AA female born at 35 weeks gestation had hepatomegaly, lack of subcutaneous fat, muscular hypertrophy, hyperpigmentation and hypertrichosis. Parents were non-consanguineous and healthy with negative family history. Laboratory findings showed elevated direct bilirubin, mildly high triglycerides and transaminitis. At 8 months, she developed growth failure. Skeletal survey demonstrated profound changes of vitamin D deficiency rickets with secondary hyperparathyroidism and hypophosphatemia. Treatment with Vitamin D and calcium supplementation led to improvement but not complete resolution of rachitic changes, improvement of biochemical abnormalities and improved growth. Skeletal survey at 18 months demonstrated mild persistent rickets along with mild osteosclerosis. Subtle intramedullary lucent foci were seen within the femoral and tibial diaphyses, as well as within multiple metatarsals and phalanges. Ultrasound demonstrated moderate hepatomegaly with hypoechoic hepatic parenchyma but no focal lesions. At 2 years age, she has developmental delay, wasted appearance, hepatomegaly, severe generalized acanthosis nigricans and hirsutism. Lab testing showed normal glucose levels and HbA1c with low HDL and mild hypercholesterolemia. Leptin was <0.6 ng/mL. CGL was suspected. Molecular analysis of *AGPAT2* and *BSCL2* were negative. WES revealed a de novo heterozygous missense mutation of *CEBPA* gene (c.874A > C; p.N292H). The CCAAT enhancer binding proteins (CEBPs), which include CEBPB, CEBPD, and CEBPA, are a family of basic-leucine zipper proteins that function as transcription factors in terminal adipocyte differentiation. In the process of adipocyte differentiation, *CEBPB* and *CEBPD* are upregulated in committed preadipocytes and induce expression of *PPARG* and *CEBPA*, which promote terminal differentiation of adipocytes. We propose that *CEBPA* mutations may account for unexplained cases of CGL given the findings in our patient and the role of *CEBPA* in adipocyte differentiation.

**Biallelic mutations in *GPD1* gene in a Chinese boy mainly presented with obesity, insulin resistance, fatty liver, and short stature.** *N. Li<sup>1</sup>, G.Y. Chang<sup>2</sup>, Y.F. Xu<sup>1</sup>, Y. Ding<sup>2</sup>, G.Q. Li<sup>1</sup>, T.T. Yu<sup>1</sup>, R.E. Yao<sup>1</sup>, Y.P. Shen<sup>1,3</sup>, X.M. Wang<sup>2</sup>, J. Wang<sup>1</sup>.* 1) Department of Medical Genetics and Molecular Diagnostic Laboratory, Shanghai Children's Medical Center, Shanghai Jiaotong University School of Medicine, Shanghai, China; 2) Department of Endocrinology and Metabolism, Shanghai Children's Medical Center, Shanghai Jiaotong University School of Medicine, Shanghai, China; 3) Division of Genetics and Genomics, Boston Children's Hospital, Harvard Medical School, Boston, MA.

Biallelic mutations in the *GPD1* gene cause a rare autosomal recessive inherited disease known as transient infantile hypertriglyceridemia (OMIM #614480). To date, only five pathogenic variants have been reported in 15 patients from 3 studies. The clinical symptoms of the affected individuals present a certain degree of heterogeneity. Here, we describe a 13 years and 8 months old Chinese male patient who mainly presented with obesity, insulin resistance, fatty liver, and short stature. Targeted next-generation sequencing revealed a novel compound heterozygous variant in *GPD1* gene (c.220-2A>G and c.820G>A; p.Ala274Thr). *In vitro* studies demonstrated that the Ala274Thr variant induced a decrease in *GPD1* protein expression. Further *in vitro* investigation of the splicing pattern in a minigene construct in HEK293 cells showed that the c.220-2A>G variant generated an altered transcript with one cryptic splice site in exon 3, resulting in the loss of 69 bases in exon 3 (c.220\_288del, p.74\_96del). This is the first report involving an Asian who harbored *GPD1* mutations. Our work not only expands the mutant spectrum of the *GPD1* gene but also provides new insights on its resulting phenotype. Moreover, we suggest that the term *GPD1* deficiency is more appropriate in describing this phenotype in OMIM than the phrase transient infantile hypertriglyceridemia.

**Systematic characterization of mutations in familial hypercholesterolemia linked genes in Estonia.** M. Alver<sup>1,2</sup>, A. Reigo<sup>1</sup>, L. Leitsalu<sup>1</sup>, M. Palover<sup>1,2</sup>, T. Nikopensius<sup>1</sup>, P. Natarajan<sup>7,8</sup>, S.M. Zekavat<sup>7,8</sup>, A. Irs<sup>3,5</sup>, T. Ainla<sup>4</sup>, A. Saar<sup>3,4</sup>, R. Mägi<sup>1</sup>, M. Kals<sup>1</sup>, T. Marandi<sup>3,4</sup>, N. Tõnisson<sup>1,6</sup>, A. Metspalu<sup>1,2</sup>, S. Kathiresan<sup>7,8</sup>, T. Esko<sup>1,7</sup>. 1) Estonian Genome Center, Tartu, Estonia; 2) Department of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia; 3) Department of Cardiology, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia; 4) Cardiology Clinic, North Estonia Regional Hospital, Tallinn, Estonia; 5) Chair of Clinical Pharmacology, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia; 6) Department of Genetics, Tartu University Hospital, Tartu, Estonia; 7) Broad Institute, Cambridge, MA, USA; 8) Massachusetts General Hospital, Boston, MA, USA.

While familial hypercholesterolemia (FH) is one of the most common single-gene disorders, it remains significantly under-diagnosed and inadequately treated, underscoring the paramount need to identify individuals affected by FH for timely diagnosis and treatment. Estonian Biobank's population-based collection in combination with comprehensive health data and genomic profiles offers a state-of-the-art platform to reliably determine carriers of FH mutations. Via implementation of a genotype-first approach we determined index cases by screening for rare pathogenic/likely pathogenic variants in 3 FH linked genes (*LDLR*, *APOB*, *PCSK9*) in 30X whole genome (n=2420) and 60X whole exome sequence (n=2384) datasets associated with untreated baseline LDL cholesterol (LDL-C) level  $\geq 4.0$  mmol/L ( $\geq 130$  mg/dl). All research participants and their 1<sup>st</sup> and 2<sup>nd</sup> degree relatives undergo clinical investigation to determine the presence of overt or subclinical cardiovascular pathology and genetic counselling. We have identified 9 *LDLR*, 3 *APOB* and 2 *PCSK9* gene variants, of which 5 are novel (1 novel substitution) and 8 have previously not been associated with FH, in 30 index cases. So far, 21 individuals with LDL-C values between 2.72 to 9.21 mmol/L (mean=4.91, SD=1.96; not adjusted for statin treatment) and their 26 family members have attended a multi-module phenotyping appointment with special cardiovascular refocus highlighting generally low pre-established treatment adherence (38% were on lipid-lowering therapy) and unawareness of the familial background of the disease (FH suspected in 3 index cases (11%)). Compared to 970 non-FH-mutation carriers, individuals who harbour a disease-causing variant, display on average higher LDL-C level as well as larger variability of LDL-C concentration. Based on genetic feedback survey, all participants have expressed interest of disclosure of genetic finding. Preliminary results indicate that the established genotype-first framework provides a powerful platform to determine the Estonian population specific genetic landscape of FH and that the implementation of cascade screening and deep-phenotyping proves highly valuable for estimating the pathogenicity of discovered variants. Further attempts are being made to infer discovered mutation carriers in the whole cohort of Estonian Biobank (n=52,000; array genotyped only).

**Androgens and antioxidants management improve clinical & hematologic response of Fanconi Anemia Egyptian patients to bypass hematopoietic stem cell transplantation unavailability.** A. Attia, G. El-Kamah, M. Eid. Medical Molecular Genetics, Human Genetics and Genome Research, National Research Centre of Egypt, Giza, MI., Egypt.

Fanconi anemia (FA) is the most common inherited bone marrow failure syndrome characterized by hypersensitivity to clastogenic agents particularly diepoxybutane (DEB) and cancer predisposition. Oxidative stress plays a major role in the pathogenesis of leukemia-prone diseases such as FA. Recently there is controversy concerning hematopoietic stem cell transplantation (HSCT) as they don't always abolish the threat of malignancies, which with progressive bone marrow failure are the cause mortality in FA. Aim: Evaluating clinical & hematological response to androgens and antioxidant therapy as an alternative when HSCT is not available. Subjects and Methods: 45 cases descending from unrelated consanguineous pedigrees were included in the study and confirmed through DEB hypersensitivity. DNA micronuclear damage, among other parameters, was measured as an indicator to FA patients' stress condition. Patients were kept on androgens, prednisone and Vitamins A, E, and C according to the recommended daily allowance. Clinical and hematological follow-up were conducted for all patients over a period of two years with 3 monthly reevaluation schemes. Results: The median age at onset was 7 years (4m–10.5 years). Average Hb (7.6 g/dl), RBC ( $2.6 \times 10^{12}/L$ ), WBC ( $3.7 \times 10^9/L$ ) and platelet count ( $53 \times 10^3/uL$ ). 20% had low birth weight, 90% café au lait spots, 38% radial reduction, renal disease in 4 cases & other skeletal affection in 78%. DEB showed wide range of break/cell (3.4–12.5), with mean 6.0. Elevated levels of oxidative stress and DNA damage were detected. Hematological parameters improved in response to androgen therapy, mostly WBCs by 40%, followed by hemoglobin (9%) and lastly platelets by only 5%. Oxidative stress parameters and DNA damage improved after antioxidant administration. Conclusion: Androgen therapy improved the hematological condition of patients. Early administration of antioxidants in FA slows disease course, ameliorate symptoms and improve general health.

Very early-onset inflammatory bowel disease (VEOIBD) refers to IBD presented in children before the 6<sup>th</sup> year of life, few cases have been reported occurring before the first year of life. VEOIBD share the clinical picture of multifactorial Crohn's and ulcerative colitis clinical and endoscopic characteristics, such as deep intestinal mucosal ulcerations, perianal inflammation with abscess and fistula formation. Linkage studies and candidate gene approach found recently, that monogenic autosomal recessive mutations in *IL10* receptor chains, alpha or beta, leads to a severe pancolitis with perianal inflammation syndrome. Since today few patients with alpha or beta (*IL10RA* and *IL10RB*) mutations had been reported. We present a case of a VEOIBD in a Mexican patient with a novel homozygous novel mutation in *IL10RB* gene. The index patient was from Tabasco, Mexico, he is the second child of a young consanguineous parents. The sib present at 3 months with VEOIBD and recurrent pneumonias, at 3 years the patient died secondary to intestinal perforation. The proband presented at the age of 1 month with perianal bleeding secondary to multiple perianal abscesses. Colonoscopy revealed multiple ulcerations through the entire colon. Colon biopsy revealed cryptitis and crypt abscesses. At 2 months intestinal present coinfection with CMV that was treated with valganciclovir. Peripheral plasma flow cytometry revealed a low concentration of NKs cells 0.63 (1-6%). The patient was treated initially with mesalazine and then with azathioprine and ciclosporine, with poor response, and nowadays, at 11 months, is in bone marrow HSCT protocol. Clinical picture suggests a monogenic VEOIBD, molecular analysis was performed using DNA peripheral blood, that was extracted using Maxwell 16 DNA purification kit® and perform a NGS approach using Nextera Rapid Illumina inc®. The NGS revealed an homozygous variant c.49C>T (p.Ala17Pro), the carrier status was confirmed in the parents. Mutation Taster and Polyphen 2 predicts pathogenicity, the variant also is absent in ClinVar, HGMD, ExAC and 1000 genomes databases. Literature review revealed 18 cases of *IL10RB* mutations reported in series of VEOIBD mainly in caucasian and asian ancestry with severe clinical picture like our patient phenotype. Monogenic etiology has to be ruled out in patients with VEOIBD patients.

**PIDDGEN: A multi-disciplinary team providing molecular diagnoses of primary immunodeficiency diseases in South Africa.** C. Kinnear<sup>1</sup>, M. Moller<sup>1</sup>, B. Glanzmann<sup>1</sup>, N. Schlechter<sup>1</sup>, E. Banda<sup>1</sup>, E. Hoal<sup>1</sup>, M. Schoemann<sup>1</sup>, R. Nortje<sup>2</sup>, M. Urban<sup>1</sup>, M. Esser<sup>1</sup>. 1) SAMRC Centre for Tuberculosis Research, Biomedical Sciences, Stellenbosch University, Cape Town, Western Cape, South Africa; 2) Immunological Unit, National Health Laboratory Service, Cape Town, South Africa.

The diagnosis of Primary Immunodeficiency disorders (PIDs) remains challenging. In South Africa, based on global estimates, the projected number of individuals with PIDs should range from 2850 to 45723, however, to date, less than 500 cases have been reported and approximately 300 have been enrolled in the South African national PID registry. To raise awareness for PID in our country and to facilitate the molecular diagnosis of these patients, the Primary Immunodeficiency Diseases Genetics group (PIDDGEN), a multi-disciplinary group of specialists interested in the immunological and genetic diagnosis of PID, was founded in 2013 at Tygerberg Hospital, Stellenbosch University in Cape Town. PIDDGEN pursues the genetic diagnosis of PID diagnoses from across South Africa. Thus far, PIDDGEN has sequenced exomes of 17 South African PID patients and, where available, unaffected family members. Exome sequencing allowed for the definitive molecular diagnosis for three of these patients. Furthermore, using targeted sequencing of known PID-causing genes, we have been able to provide molecular diagnosis for five patients with X-linked Chronic Granulomatous Disease (CGD) (three novel *CYBB* mutations), two patients with an interferonopathy (novel *SAMHD1* mutation), and one patient with Mendelian Susceptibility to Mycobacterial Disease (MSMD) (*INFRG1* mutation). These mutations and patients only represent a fraction of the PID cases reported on the South African PID registry. Hence, we believe that PIDDGEN has an important role to play in the improved awareness, definitive diagnosis and targeted management of PID patients in South Africa.

**Exome sequencing of extreme phenotypes identifies potential novel genes as modifiers of leg ulcer in sickle cell anemia.** G.Q. Carvalho-Siqueira<sup>1</sup>, B.B. Souza<sup>2</sup>, M.G. Borges<sup>3</sup>, M.T. Ito<sup>1</sup>, G. Ananina<sup>1</sup>, A.S.C. Strega<sup>3</sup>, M.S. Gonçalves<sup>4</sup>, I.T.L. Cendes<sup>5</sup>, F.F. Costa<sup>5</sup>, M.B. Melo<sup>1</sup>. 1) CBMEG, University of Campinas-UNICAMP, Campinas, Brazil; 2) FCM, University of Campinas-UNICAMP, Campinas, Brazil; 3) Foundation of Hematology and Hemotherapy-HEMOBA, Salvador, Brazil; 4) Institute Gonçalo Moniz-Fiocruz, Salvador, Brazil; 5) Hematology and Hemotherapy Center-UNICAMP, Campinas, Brazil.

**Background:** Although sickle cell anemia (SCA) [603903] results from homozygosity of a single mutation at position 6 of the  $\beta$ -globin locus, the clinical aspect of this disease is very heterogeneous. Leg ulcer is one of the worst complications, exerting a highly negative impact in the quality of life of patients with SCA, and is related to the severity of the clinical aspect of the disease. **Objective:** Seeking for novel candidate genes associated with leg ulcer in sickle cell anemia, we proposed this search through exome sequencing of extreme phenotypes in a sample of the Brazilian population. **Methods:** The project was approved by the Research Ethics Committee of the Faculty of Medical Sciences of the State University of Campinas. Our sample consisted of 40 patients with sickle cell anemia from the Hematology and Hemotherapy Center, out of which 20 didn't have leg ulcer, with ages varying from 40 to 61 years (it is unusual the appearance of this disorder at such age) and 20 had chronic leg ulcer. DNA was extracted from peripheral blood leukocytes and submitted to exome sequencing. Capture and enrichment were performed with the Nextera Rapid Capture Exome kit (Illumina) and samples were loaded in the Illumina HiSeq 2500. The quality of the reads was verified through FastQC, the files were then submitted to the GATK Pipeline generating a vcf file for each individual. In the bioinformatics processing, several filters were applied using vcftools. Non-synonymous variants were prioritized according to various conditions, such as score quality, depth and Hardy-Weinberg equilibrium. The Fisher association test was performed with the remaining variants, through PLINK, resulting in 734 variants, selected with a  $p < 0.05$ . The annotation was made through Annovar. In the annotated file, the synonyms, the non-deleterious variants, as well as the barely conserved variants were removed, generating 54 variants. **Results:** Six genes were selected, according to the literature, involved in angiogenesis, inflammation, coagulation and thrombosis: *AHNK2* [608570], *CEACAM8* [615747], *FLG2* [616284], *LAMA1* [150320], *RNF213* [613768], and *ZNF540* [613903]. **Conclusion:** Therefore, we suggest that these genes could potentially be related to the development of leg ulcer in SCA. However, they should all be validated in other populations for confirmation.

## 875T

**Genomic characterization of F8 and F9 copy number variants in the My Life, Our Future TOPMed hemophilia cohort.** M.M. Wheeler<sup>1</sup>, D.J. Aschman<sup>2</sup>, G.F. Pierce<sup>3</sup>, B. Konkle<sup>4,5</sup>, J. Morales<sup>6</sup>, J.M. Johnsen<sup>4,5</sup>, D.A. Nickerson<sup>1</sup>, NHLBI Trans-Omics for Precision Medicine. 1) Department of Genome Sciences, University of Washington, Seattle, WA; 2) American Thrombosis and Hemostasis Network, Chicago, IL; 3) National Hemophilia Foundation, New York, NY; 4) Bloodworks NW, Seattle, WA; 5) Division of Hematology, University of Washington, Seattle, WA, USA; 6) Bioverativ, Waltham, MA.

Hemophilia A and B are X-linked bleeding disorders commonly resulting from genetic alterations of the genes, *F8* and *F9*. These genes encode Factor VIII and Factor IX of the coagulation cascade; deficiencies in one of these two factors define hemophilia A and hemophilia B, respectively. Numerous genetic variants in *F8* and *F9* have been identified. The majority include single nucleotide variants (SNVs), copy number variants (CNVs), and in the case of *F8*, large intra-chromosomal inversions. Most CNVs have been found through analyses of targeted regions or techniques that detect differences in gene dosage. However, these methods cannot fully characterize the extent of each CNV as they are unable to detect breakpoints precisely. In this study, our goal was to characterize *F8* and *F9* CNVs in the My Life, Our Future hemophilia cohort that was recently whole genome sequenced (WGS) by the NHLBI TOPMed program. This cohort mainly comprised samples from males diagnosed with hemophilia A (N=1,959) or hemophilia B (N=227). Comprehensive analysis of WGS data, revealed 64 CNVs in hemophilia A (57 deletions and 7 duplications) and 24 deletions in hemophilia B subjects. In hemophilia A, CNV size ranged from <100bp to > 100Kb and comprised single exon *F8* deletions to multi-genic CNVs. Several *F8* CNVs (N=14) included the first or last exon and exhibited heterogeneous breakpoints that differentially affected neighboring genes. In hemophilia B, CNV size ranged from approximately 1Kb to 6.5Mb and most included deletions of multiple exons or multi-genic deletions with substantial breakpoint heterogeneity. Most CNVs detected are causal for severe hemophilia (Factor VIII and Factor IX levels < 1%) and a subset of CNVs (N=16) are likely novel causal variants as they have not been previously reported. CNVs in two samples co-occurred with likely deleterious variants and a subset of CNVs co-occurred with likely benign missense variants. Together, these analyses demonstrate substantial heterogeneity in CNV size and breakpoint location. The identification of CNVs which impact a hemophilia gene and neighboring gene(s) may have clinical implications and raises the possibility of previously undetected hemophilia-associated syndromes. Moreover, combined analysis of SNVs and fully characterized CNVs will enable increased understanding of hemophilia presentation and complications.

**Exome sequencing reveals novel compound heterozygous mutations in FOXP1 in patients with severe immunodeficiency and no alopecia.** S. Khan<sup>1</sup>, G. Pardon<sup>2</sup>, Q. Du<sup>1</sup>, B. Wakeland<sup>1</sup>, K. Viswanathan<sup>1</sup>, M. Louise Markert<sup>2,3</sup>, M. Teresa de la Morena<sup>4,5,6</sup>, N. van Oers<sup>1,4,7</sup>, E. Wakeland<sup>1</sup>. 1) Department of Immunology, University of Texas Southwestern Medical Center, Dallas, TX; 2) Department of Pediatrics, Duke University, Durham, NC; 3) Department of Immunology, Duke University, Durham, NC; 4) Department of Pediatrics, University of Texas Southwestern Medical Center, Dallas, TX; 5) Department of Internal Medicine, University of Texas Southwestern Medical Center, Dallas, TX; 6) Children's Health, Dallas, TX; 7) Department of Microbiology, University of Texas Southwestern Medical Center, Dallas, TX.

Primary immune deficiency diseases (PIDs) are a diverse group of genetic disorders in humans of varied clinical and genetic heterogeneity that result in altered immune function. More than 220 PIDs have been identified thus far, however, many patients with a PID phenotype remain with an unknown genetic etiology. Recent approaches to identify novel mutations in genes resulting in PIDs have included both whole genome and exome sequencing. Here we utilized Exome sequencing in a child that presented with unique clinical presentation: T cell lymphopenia and no alopecia. In order to identify underlying causative genetic mutations, we sequenced proband, parents and all the unaffected siblings. Detailed genetic and phenotypic characterization identified novel compound heterozygous mutations in Forkhead Box N1 (*FOXP1*) gene in the proband. In addition we independently identified compound heterozygous mutations in *FOXP1* gene in two other patients with similar clinical presentation. *FOXP1* is an epithelial-specific transcription factor essential for the development of the thymus. Patients with mutations in *FOXP1* (OMIM # 600838) are born with a severe T-cell lymphopenia that presents in combination with alopecia and nail dystrophy. However all three patients in this study had normal hair and skin development. In order to better understand the functional impact of mutations, we used CRISPR/Cas techniques and generated the corresponding mutations in the mouse *FOXP1* sequence. We are in the process of phenotypically characterizing these mice. We hope that our findings will provide novel insight into distinct functional role of *FOXP1* in thymus and skin. .

**877W**

**An update on the diagnostics, phenotype and treatment of deficiency of ADA2 (DADA2).** I. Aksentijevich<sup>1</sup>, N. Deutch<sup>1</sup>, W. Pei<sup>2</sup>, K. Bishop<sup>2</sup>, J. McElderry<sup>2</sup>, S. Burgess<sup>2</sup>, R. Sood<sup>2</sup>, D. Stone<sup>1</sup>, A.K. Ombrello<sup>1</sup>, D.L. Kastner<sup>1</sup>, Q. Zhou<sup>1</sup>. 1) Inflammatory Disease Section, National Human Genome Research Institute, Bethesda, MD; 2) Translational and Functional Genomics Branch, National Human Genome Research Institute, Bethesda, MD.

**Background:** DADA2 is a recessively inherited disease caused by loss-of-function mutations in the *CECR1* gene, which encodes adenosine deaminase 2 (ADA2). Patients typically present with fevers, livedoid rashes, polyarteritis nodosa (PAN) and recurrent ischemic strokes leading to neurological impairment. Recently, DADA2-associated phenotypes have expanded to include pure red cells aplasia, Diamond-Blackfan anemia (DBA), Sneddon's syndrome, and patients with common variable immunodeficiency (CVID). The precise molecular mechanism of this disease is not clear and it appears that ADA2 plays an important role in the development of myeloid cells. **Meth-ods:** We Sanger sequenced all 9 exons of *CECR1* in 84 new patients with suspected DADA2. Serum ADA2 enzyme activity was tested using a modified kit from Diazyme. Patient samples were analyzed by Nanostring, RT-PCR, and cytokine profiling. CRISPR/Cas-9 KO zebrafish were made to study the mechanism of vascular phenotype. **Results:** We identified 39 patients with pathogenic mutations in *CECR1*. Thirty-three patients carry bi-allelic homozygous or compound heterozygous mutations, while 6 patients carry only a single detectable pathogenic mutation suggesting the presence of cryptic mutations. We report 16 *CECR1* mutations that had not previously been associated with DADA2. The 20 patients tested for ADA2 activity had significantly decreased protein activity compared to healthy controls and unaffected family members. Interferon-mediated gene expression signature correlate with the disease severity. Intracellular cytokine staining in primary mononuclear cells demonstrated increased production of IL-1b, TNF and IL-6 in patients. Zebrafish KO embryos presented with hemorrhagic strokes. This extended cohort of patients has helped identify other previously unappreciated clinical features associated with DADA2. Many of the patients have been misdiagnosed until the adult age and subjected to unnecessary and non-effective therapies. Treatment with TNF inhibitors proved to efficiently reduce inflammation and prevent recurrence of strokes. **Conclusion:** Since the initial description of the disease in 2014, there have been 99 reported cases in the literature. The phenotype variability is significant among family members and even in individuals with the same genotype emphasizing a role for other modifying gene alleles. Therapies with TNF inhibitors have been life changing. .

There has been a reinvigorated interest in Mendelian diseases. Hemophilia A (HA), an X-linked bleeding disorder and classical Mendelian disease, is caused by Factor VIII (FVIII) gene (F8) mutations and plasma deficient in FVIII clotting activity. While FVIII replacement is the standard treatment for HA, the development of neutralizing antibodies (“inhibitors”) to FVIII therapeutics is the most serious obstacle to effective patient care. Because there are many important variables that influence the development of inhibitors and because the number of patients that may be enrolled in investigative studies tend to be small, compared to numbers available for complex disease studies, it is important to develop powerful approaches that can simultaneously and yet robustly account for multiple variables given limited data on small sample sizes. Toward this end, we have applied the mixed linear model of statistical genetics to data on inhibitor development in the PATH Study. To control for confounding due to genetic relatedness, we used a genetic relationship kernel estimated from the study participants’ own genomic data measured with the ImmunoChip. We analyzed three dichotomous inhibitor variables: historical inhibitor status (H-Inh); enrollment inhibitor status (E-Inh); and lifetime inhibitor status (L-Inh). We used backward-selection, Bayesian model averaging and selection methods to evaluate the importance of age, race, baseline HA severity, therapeutic exposure days, FVIII haplotype, a mutation-type ranking score (Mu), and a dichotomous variable contrasting plasma derived (pd) vs. recombinant (r)FVIII (scored 1 if rFVIII and 0 if pdFVIII) denoted by PvR. Mu was constructed by assigning ordered ranks to a patient’s mutation-type, where the ranks were determined in accordance with current knowledge about the severity-level associated with each mutation-type. We found that both Mu and PvR were significantly associated with increased risk for H-Inh (Mu:  $p = 0.003$ ; Posterior Probability (PP) = 0.66; PvR:  $p = 0.001$ ; PP = 0.78), for E-Inh (Mu:  $p = 0.005$ ; PP = 0.82; PvR:  $p = 0.003$ ; PP = 0.72), and for L-Inh (Mu:  $p = 0.0009$ ; PP = 1; PvR:  $p = 0.002$ ; PP = 0.88). Our statistical genetic approach to studying HA is both novel and powerful, and the results lead us to conclude that both the type of HA-causing F8 mutation and type of FVIII therapeutic (with rFVIII having greater risk than pdFVIII) have a significant influence on the development of inhibitors.

Hemophilia A (HA) is the X-linked recessive bleeding disorder caused by loss-of-function factor (F)VIII gene (F8) mutations leading to deficiencies in plasma FVIII coagulant activity. While FVIII replacement is currently the standard treatment for HA, the development of neutralizing anti-FVIII antibodies (“inhibitors”) is the most serious and common obstacle to effective patient care. In this report, we present results from the PATH Study subjects for the identification of population specific immune-response gene variants associated with the development of FVIII inhibitors. We analyzed the relationship between causative F8 mutations, patient race and disease severity to the development of these neutralizing anti-drug antibodies (ADAs). PATH participants were genotyped using the ImmunoChip array, which enabled empirical estimates of genetic relatedness between all pairs of individuals. This information was used in a linear mixed model to test the association of each single-nucleotide polymorphisms (SNP) with a dichotomous lifetime inhibitor status variable. We stratified our overall sample by race into Black and White subsets of patients. We located two SNPs with significant regulatory potential—one each on chromosome (Chr)1 and Chr9—in the White patients only, which remained significant after combining their likelihood ratio test statistics with those from the analysis of the Black patients. The most significant result was for rs2276404 ( $p$ -value <  $4.27e-08$ ) in IFI16, which encodes  $\gamma$ -interferon-inducible (IFI) protein 16. The only other array-wide significant result was for a variant located at position 4,291,392 on Chr9 which, while not present in dbSNP, is in a highly-conserved region of GLIS3 intron-1. As neither IFI16 nor GLIS3 has ever been associated with the development of inhibitors, our results further support the involvement of immune-response gene variation in FVIII immunogenicity risk and provide the first evidence that their influence may be race-specific. Furthermore, they indicate the need for patient-specific immune- cell-based platforms to elucidate the mechanisms by which these variants influence ADA development and to identify potential therapeutic immune system targets.

**880W**

**A new patient with common variable immunodeficiency (CVID) and autoinflammation due to biallelic mutations in HOIP.** H. Oda<sup>1,2</sup>, H. Kuehn<sup>1</sup>, P. Hoffmann<sup>1</sup>, N. Deutch<sup>1</sup>, J. Stoddard<sup>1</sup>, M. Gadina<sup>1</sup>, S. Rosenzweig<sup>1</sup>, I. Aksentjevich<sup>1</sup>, D. Kastner<sup>1</sup>. 1) NIH, Bethesda, MD; 2) Kitano Hospital, Japan.

**[Background]** HOIP is the catalytic subunit of the linear ubiquitination chain assembly complex (LUBAC), which is important for the activation of the innate and adaptive immune responses. LUBAC depletion leads to attenuation of NF- $\kappa$ B signaling, and LUBAC-deficient patients present with recurrent invasive bacterial infections. In contrast to immunodeficient fibroblasts, monocytes of LUBAC-deficient patients are highly responsive to IL-1 stimulation and produce high levels of proinflammatory cytokines IL-6 and MIP-1 $\alpha$ . To date only one patient with the HOIP deficiency has been reported; her symptoms include, multiorgan autoinflammation, immunodeficiency, amylopectinosis, and systemic lymphangiectasia (Boisson, 2015). **[Case]** We investigated a 7 year-old girl with CVID and systemic autoinflammation. She has a clinical history of severe viral and bacterial infections, and while her immunoglobulin levels were normal, impaired antibody response to pneumococcal polysaccharide vaccines was observed. She also experiences episodes of autoinflammation including recurrent fevers, arthritis, rash, and persistent ESR elevation.

**[Method and Results]** We performed NGS-based targeted sequencing of 353 immunologically related genes, followed by Sanger sequencing. In the *RNF31* gene, which encodes HOIP, we identified a rare missense variant (NM\_017999;c.1336C>T;p.R446W) in exon 8 and a novel intronic variant (c.1737+3A>G) in intron 9, which were confirmed to be biallelic by subcloning. RT-PCR amplification of exons 6 through 10 of the patient's cDNA followed by subcloning demonstrated that both of the variants create alternatively spliced *RFN31* transcripts. siRNA-mediated knockdown of HOIP in THP1, a human monocytic cell line, resulted in higher responsiveness to cytokine stimulations, which phenocopied the cellular phenotype of the previously reported patient with HOIP deficiency. **[Discussion]** We report a second patient with suspected HOIP-deficiency. The phenotypic similarity and the preliminary results suggest that these two HOIP mutations could explain the patient's phenotype. Further molecular analyses are required to elucidate mechanisms of the apparently contradictory observation of immunodeficiency and autoinflammation associated with the HOIP deficiency.

**881T**

**Novel truncating variant in single immunoglobulin Interleukin-1 receptor related (SIGIRR) gene in a dominant family with early-onset inflammatory bowel disease.** J.E. Horowitz<sup>1</sup>, J. Staples<sup>1</sup>, A. Klauer King<sup>1</sup>, E. Coonrod<sup>2</sup>, A. Rutherford<sup>2</sup>, J.G. Reid<sup>1</sup>, J.D. Overton<sup>1</sup>, J. Singer<sup>1</sup>, B. Moore<sup>2</sup>, M. Yandell<sup>2</sup>, A.R. Shuldiner<sup>1</sup>, F.E. Dewey<sup>1</sup>, O. Gottesman<sup>1</sup>, S. Guthery<sup>2</sup>, C. Gonzaga-Jauregui<sup>1</sup>. 1) Regeneron Genetics Center, Regeneron Pharmaceuticals, Tarrytown, NY; 2) Department of Pediatrics, University of Utah, Salt Lake City, UT.

Inflammatory bowel disease (IBD) is a genetically heterogeneous, chronic inflammatory response to commensal microbiota in the GI tract with average age of onset at 30y. Severe, monogenic forms of IBD can present with pediatric onset (<18y) and have been attributed to rare, highly-penetrant variants in ~50 'Mendelian' genes. However, the genetic architecture of early onset IBD (EO-IBD) is poorly understood, and the majority of patients remain genetically undiagnosed. To identify novel candidate EO-IBD genes, we performed whole-exome sequencing and trio-based variant analysis on a 13-year-old EO-IBD patient, his IBD-affected mother, and his unaffected father. Through this, we identified a novel, predicted-deleterious truncating indel variant in the Single Immunoglobulin Interleukin-1 Receptor Related (*SIGIRR*: c.557delA; p.K186fs\*31) in the EO-IBD proband inherited from his affected mother. *SIGIRR* encodes a negative regulator of interleukin (IL)-1 and toll-like receptor (TLR) signaling expressed in gut epithelial and hematopoietic cells. In mice, *Sigirr* is a critical regulator of gut homeostasis, and humans with variants in the extracellular domain of *SIGIRR* develop necrotizing enterocolitis in infancy. However, a role for *SIGIRR* in EO-IBD has not been established. To functionally validate *SIGIRR* as a mediator of EO-IBD, we generated a lymphoblastoid cell line (LCL) from the EO-IBD patient and analyzed it using a pro-inflammatory cytokine screen complemented with RNA-sequencing. In unstimulated cells, we observed upregulation of key immune modulators IL-1 $\beta$ , IL-8, and IL-6 in the *SIGIRR* EO-IBD patient LCLs relative to both LCLs generated from healthy controls and from EO-IBD patients not harboring truncating *SIGIRR* variants, suggesting a unique inflammatory signature in IBD patients carrying truncating *SIGIRR* variants. Further, we observed that *SIGIRR* EO-IBD patient-derived LCLs are refractory to either IL-1 $\beta$  or TLR stimulation, suggesting constitutive activation of these inflammatory pathways in the truncation of *SIGIRR*. Our analysis has identified a cytoplasmic truncation in *SIGIRR* in an EO-IBD patient with a unique, constitutively active pro-inflammatory cytokine profile. Future studies will seek to determine how this truncation affects downstream IL-1 $\beta$  and TLR signaling, to elucidate how *SIGIRR* maintains commensal tolerance, and to identify potential therapeutic pathways to ameliorate inflammation in EO-IBD patients.

**882F**

**Utility of whole genome sequencing for population newborn screening for immunodeficiencies.** *D.L. Bodian<sup>1</sup>, A.R. Pavey<sup>1,2,3</sup>, T. Vilboux<sup>1</sup>, A. Khromykh<sup>1</sup>, N.S. Hauser<sup>1</sup>, K. Huddleston<sup>1</sup>, E. Klein<sup>1</sup>, A. Black<sup>1</sup>, M.S. Kane<sup>1</sup>, R.K. Iyer<sup>1</sup>, J.E. Niederhuber<sup>1</sup>, B.D. Solomon<sup>1,4,5</sup>.* 1) Inova Translational Medicine Institute, Falls Church, VA; 2) Department of Pediatrics, Walter Reed National Military Medical Center, Bethesda, MD; 3) Department of Pediatrics, Uniformed Services University of Health Sciences, Bethesda, MD; 4) Inova Children's Hospital, Falls Church, VA; 5) GeneDx, Gaithersburg, MD.

Immunodeficiency screening has been added to many state-directed newborn screening programs but is currently limited to screening for severe T-cell lymphopenia disorders. To evaluate the potential of genomic sequencing to augment current immunodeficiency screening, we analyzed whole genome sequences (WGS) and clinical data from a cohort of 1,349 newborn-parent trios by genotype-first and phenotype-first approaches. For the genotype-first approach, we analyzed the WGS data for predicted protein-impacting variants in 329 immunodeficiency-related genes. As a phenotype-first approach, electronic health records were used to identify children with clinical features suggestive of immunodeficiency. Genomes of these children and their parents were analyzed using a separate pipeline for identification of candidate pathogenic variants for rare Mendelian disorders. The results show that WGS provides adequate coverage for most known immunodeficiency-related genes. Within these genes, 8,502 distinct predicted protein-impacting variants were identified in the cohort, and 5 individuals carried potentially pathogenic variants requiring expert evaluation. One clinically asymptomatic individual was found genomically to have C9 deficiency. Of the symptomatic children, one was molecularly identified as having an immunodeficiency condition and two were found to have other molecular diagnoses. These results suggest that neonatal genomic sequencing can potentially augment newborn screening for immunodeficiency by broadening the range of immunodeficiencies that can be screened, and by identifying likely causative mutations.

**883W**

**Severe EDS III with cell activation syndrome (MCAS) in infancy and young children.** *C. Tsai.* pediatrics/genetics, childrens Hospital colorado, Aurora, CO.

Mast cell activation syndrome (MCAS), is a condition in which mast cells inappropriately and excessively release chemical mediators, resulting in a range of chronic symptoms. Recently, it has been noticed that there is a higher-than-normal representation of MCAS among the EDS population and often complicated with flushing, pruritus, dysautonomia, functional gastrointestinal symptoms, chronic pain, and connective tissue abnormalities, POTS, migraines and psychiatric symptoms. I herein present 5 young children with EDS type III with MCAS: two presented as infants with severe feeding difficulty, inconsolable crying and irritability, hypermobile joints and multiple fractures in ribs, without other finding consistent with NAT. One of them has bleeding from a torn frenulum during bottle feeding. Both received molecular work up for 9 plus gene OI/ brittle bone disease panels and were negative. MOC of both infants have history of depression required antidepressant during pregnancy. Both infant required G tube and one required GJ tube and eventually both improved dramatically with H1 and H2 antihistamine. Family three have two siblings sets, both presented with severe feeding difficulty, flushing, vomiting and hypermobile joints, thin transparent skin, and required G tube; exome sequencing was not revealing and both respond well to antihistamine treatment. The 4<sup>th</sup> patient presented with low tone, poor feeding requiring G tube, rashes, food allergy, periodic fever, severe sensory defensiveness, but respond well with Periactin and fluid therapy. Elevated tryptase levels were not found in any of these patients. Mast cells are found in tissues throughout the body, particularly in association with structures such as blood vessels and nerves. Activation through various receptors leads to distinct signaling pathways and synthesis of chemokines and cytokines. There is no universal recognized explanation to why MCAS is disproportionately found in EDS. I hypothesize that the mast cells in some patients with EDS are more fragile, and subject to mechanical changes such as over stretching of the cell membrane/receptors and subsequently trigger histamine, cholinergic, inflammatory and serotonergic pathways. Proper blockage by antihistamine can avoid further complications and improve feeding. I also emphasize the recognition of clinical features of young infants to avoid wrongful accusation of NAT. This should be considered as a differential diagnosis of brittle bone diseases. .

**Case report of a patient with uncharacterized IFN- $\gamma$  mediated autoinflammatory disorder.** O. Schnappauf, A. Ombrello, P. Hoffmann, D. Kastner, I. Aksentjevich. NHGRI (National Human Genome Research Institute), Inflammatory Disease Section, Bethesda, USA.

**Background:** We report a 3.5y old female patient from a non-consanguineous marriage who was seen at the NIH in September of 2015. She was born full-term with a normal weight, but soon after birth developed fevers accompanied by an erythema annulare rash on her cheeks that spread to her entire body. She also presented with conjunctivitis and abdominal bloating. During her disease, she had multiple episodes of infection, septicemia and two episodes of aseptic meningitis. Multiple lumbar punctures revealed increased lymphocyte counts while brain CT showed increased CSF and micro calcifications. Her skin biopsy revealed lobular panniculitis with inflammatory infiltration composed mostly of myeloid cells. Previous treatments included; immunosuppressives, steroids, IVIG, and anti TNF and anti IL-1 therapies. She did not respond to either cytokine inhibitor. **Results:** During her visit to the NIH the patient had extremely high serum cytokine levels of APRIL and BAFF, consistent with low or absent B-cells. Additionally, the levels of proinflammatory cytokines IFN- $\alpha$ , IFN- $\gamma$ , IP-10, IL-12, TNF-R1 and TNF-R2 were significantly increased. In particular, CXCL9/MIG (monokine induced by gamma interferon) was too high to be determined. Functional assays showed increased levels of pSTAT1 and pSTAT3 at baseline and in IFN- $\alpha$  stimulated CD4<sup>+</sup>, CD8<sup>+</sup> T-cells and monocytes. Gene expression analysis of whole blood samples showed a strong interferon signature, which was comparable to that seen in CANDLE-patients. Together, these results suggest that she has an IFN- $\gamma$  mediated disease. Genetic testing of known primary immunodeficiency genes, autoinflammatory genes and four hemophagocytic lymphohistiocytosis (HLH) -associated genes (*PRF1*, *UNC13D*, *STX11*, *STXBP2*) was inconclusive. No obvious candidate gene was identified via the patient's, unaffected parents and an unaffected sibling by WES. Patient had excellent response to anti-IFN- $\gamma$  therapy, however she later died from the complications of allogeneic bone marrow transplantation. **Conclusion:** We describe a patient with an uncharacterized type II (IFN- $\gamma$ )-mediated disease. Most patients with interferonopathies have type I (IFN- $\alpha$ , IFN- $\beta$ )-mediated inflammatory diseases. Analysis of the family whole genome sequencing data is in progress.

**A novel *GF11B* mutation at the first zinc finger domain causes congenital macrothrombocytopenia.** Y. Uchiyama<sup>1,2</sup>, Y. Ogawa<sup>2</sup>, S. Kunishima<sup>3</sup>, M. Shiina<sup>4</sup>, M. Nakashima<sup>5</sup>, K. Yanagisawa<sup>2</sup>, A. Yokohama<sup>6</sup>, E. Imagawa<sup>1</sup>, S. Miyatake<sup>1</sup>, T. Mizuguchi<sup>1</sup>, A. Takata<sup>1</sup>, N. Miyake<sup>1</sup>, K. Ogata<sup>1</sup>, H. Handa<sup>2</sup>, N. Matsumoto<sup>1</sup>. 1) Human Genetics, Yokohama City University, Yokohama, Kanagawa, Japan; 2) Department of Hematology, Gunma University Graduate School of Medicine, Gunma, Japan; 3) Department of Advanced Diagnosis, Clinical Research Center, National Hospital Organization Nagoya Medical Center, Nagoya, Japan; 4) Department of Biochemistry, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 5) Department of Biochemistry, Hamamatsu University School of Medicine, Hamamatsu, Japan; 6) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Congenital macrothrombocytopenia (CMTP) is characterized by thrombocytopenia and giant platelets with variable bleeding tendency. *GF11B* encoding growth factor independent 1B transcriptional repressor is one of the mutant genes causing autosomal dominant CMTP. Thrombocytopenia, giant platelets, and reduction in platelet  $\alpha$ -granule content were common features in previous seven CMTP cases with *GF11B* mutations. The residual CD34 expression on the giant platelets and the abnormally shapes of red blood cells were reminiscent of the three reported cases. *CD34*, an optical marker for haematopoietic stem cells, is expressed on the surface of platelets in patients with *GF11B* macrothrombocytopenia, and abnormal differentiation of megakaryocyte-erythroid progenitor cells is implicated. Functional analysis based on cell lines and null mice showed that mutant *GF11B* led to aberrant development and differentiation of megakaryocytes and erythroid cells. Previous studies also showed that mutations depleting the fifth to sixth zinc finger domains lose their binding ability to the target genes and *GF11B*-macrothrombocytopenia was occurred to the dominant negative fashion. Here, we identified a novel missense *GF11B* mutation c.494G>T:p.(Cys165Phe) located at the first zinc finger domain in five cases of a CMTP family by whole exome sequencing. Current cases also showed that thrombocytopenia and giant platelets. However, number of  $\alpha$ -granules in the platelets and red blood cell morphology were normal in our patients. Persistent CD34 expression was recognized in the surface of platelets in our cases. These findings imply that the first and second zinc finger domains of *GF11B*, which do not directly bind to the target genes are also important for the development and the differentiation of megakaryocytes. Furthermore, the detection of CD34 on platelets might be a useful diagnostic biomarker for *GF11B* macrothrombocytopenia.

## 886W

**Identification and characterization of adenosine deaminase 2 variants in pediatric vasculitis.** K. Gibson<sup>1,2</sup>, D.A. Cabral<sup>3,4</sup>, B. Drogemoller<sup>5,6</sup>, X. Xhan<sup>2,5</sup>, F. Miao<sup>2,5</sup>, K. Morishita<sup>3,4</sup>, E. Gill<sup>6</sup>, R.E.W. Hancock<sup>6</sup>, C. Ross<sup>5,2</sup>, K. Brown<sup>3,2</sup> *On behalf of the PedVas Initiative Investigator Network.* 1) Dept of Medical Genetics, The University of British Columbia, Vancouver, British Columbia, Canada; 2) BC Children's Hospital Research Institute, Vancouver, BC; 3) Dept of Pediatrics, The University of British Columbia, Vancouver, British Columbia; 4) BC Children's Hospital, Vancouver, British Columbia; 5) Faculty of Pharmaceutical Sciences, The University of British Columbia, Vancouver, British Columbia; 6) Dept of Microbiology and Immunology, The University of British Columbia, Vancouver, British Columbia.

Deficiency of adenosine deaminase 2 (DADA2) is a recently recognized, autosomal recessive genetic disease with various systemic vascular and inflammatory manifestations; patients present with early-age onset and often recurrent strokes. The clinical features and histological findings of DADA2 overlap with those of early childhood onset polyarteritis nodosa (PAN), a primary "idiopathic" systemic vasculitis, characterized by necrotizing inflammatory lesions of small and medium-sized vessels. Despite similar clinical presentation, individuals with PAN and DADA2 may benefit from different therapy. While treatment of primary chronic vasculitis is usually with toxic immunosuppressive drugs, there has been clinical indication that DADA2 patients respond better to less toxic IL-6 receptor antagonists and anti-TNF $\alpha$  therapy. We aimed to screen patients with PAN, cutaneous PAN, unclassifiable phenotype, or chronic vasculitis of any type with onset-age less than 5 years for variants in adenosine deaminase 2 (ADA2). Of the 493 pediatric patients included in our international, multi-ethnic cohort, ARChive (A Registry of Childhood Vasculitis), there were 99 patients who provided DNA samples, and 41 of these fulfilled screening criteria. We have sequenced the coding exons of ADA2 in these 41 patients and identified variants in ADA2 with known and novel association with DADA2; four patients were found to be homozygous or compound heterozygous for rare (MAF < 0.01) predicted pathogenic variants. The impact of the identified variants on ADA2 expression, secretion, and enzymatic activity were quantified by qPCR, standard ELISA, and colorimetric assays. Whole blood RNA sequencing enabled transcriptomic profiling of patients with DADA2 versus PAN and other types of chronic vasculitis that could inform treatment. At present, the gold standard for direct diagnosis of vasculitis is histopathological examination of biopsy specimens from involved organs. Screening for pathogenic variants in ADA2 among patients with possible early onset chronic vasculitis or PAN phenotype may identify and diagnose patients, perhaps without requirement for biopsy. Early diagnosis of DADA2 patients may spare them treatment with toxic systemic immunosuppressive drugs, and allow more effective intervention with targeted biologic and/or gene therapy. This work was supported by a Canadian Institutes of Health Research grant for the PedVas Initiative [TR2-119188 to DAC].

**Variants in FOXP1 cause syndromic genitourinary tract defects.** N. Bekheirnia<sup>1</sup>, J.A. Rosenfeld<sup>1</sup>, M.A. Manning<sup>2</sup>, M.F. Wangler<sup>1</sup>, J.S. Pluciniczak<sup>3</sup>, M. Pietryga<sup>3</sup>, N.L. Rider<sup>1</sup>, Y. Yang<sup>1</sup>, C. Eng<sup>1</sup>, M.C. Braun<sup>1</sup>, D.J. Lamb<sup>1</sup>, M.R. Bekheirnia<sup>1</sup>. 1) Baylor College of Medicine, One Baylor Plaza, Houston, TX.77030; 2) Stanford University School of Medicine, 291 Campus Drive, Stanford, CA 94305; 3) Nationwide Children's Hospital, 700 Children's Drive, Columbus, OH 43205.

**Background:** Forkhead box P1 (FOXP1) is a key transcription factor in the development of major organs including heart, lung and brain. FOXP1 helps regulate cell-type- and tissue-specific gene transcription both during development and in the adult stage. *De novo* variants in FOXP1 (OMIM # 613670) have been associated with a syndrome consisting of intellectual disability (ID), hydrocephalus, cognitive impairment, cardiac defect, kidney and genitourinary (GU) tract abnormalities by our group in 8 individuals. **Methods:** Whole exome sequencing (WES) was performed in a clinical diagnostic setting in ~8,000 individuals with variable indications including ID and other neurological presentations. Patient information was collected as part of clinical laboratory intake form and families were consented accordingly. **Result:** *De novo* variants in FOXP1 were identified in 5 additional individuals. These variants include p.E463A, p.V445fs, p.R544X, p.N516S, and p.R525X. None of these variants expect for p.R525X have been previously reported in patients or controls. The patients' phenotypes are consistent with the FOXP1-associated syndrome, with the additional finding of GU/kidney abnormalities in 4 out of 5 patients, including hydronephrosis, undescended testes, micropenis, duplicated collecting system, and retractile testes. Information about one patient's GU/ kidney phenotype is not available at this time. **Conclusion:** In this study, we now report five additional cases (total of 13) with *de novo* variants in FOXP1. Ten out of thirteen individuals have kidney and GU abnormalities. We conclude that kidney and GU defects can be part of the FOXP1 syndrome, and therefore these patients require clinical evaluations for such abnormalities. These findings also implicate FOXP1 in kidney and GU development. This study was supported in part by K12 DK083014 Multidisciplinary K12 Urologic Research Career Development Program.

**Comprehensive analysis using targeted sequencing panel for congenital anomalies of the kidney and urinary tract and nephronophthisis in Japan.** N. Morisada<sup>1,2</sup>, A. Shono<sup>1</sup>, K. Nozu<sup>1</sup>, R. Tanaka<sup>2</sup>, K. Iijima<sup>1</sup>. 1) Pediatrics, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan; 2) Clinical Genetics, Hyogo Prefectural Kobe Children's Hospital, Kobe, Hyogo, Japan; 3) Nephrology, Hyogo Prefectural Kobe Children's Hospital, Kobe, Hyogo, Japan.

**Background** Chronic kidney disease (CKD) in children has very important problems for childhood growth and neurocognitive development. Genetic renal disorders such as congenital anomalies of the kidney and urinary tract (CAKUT), chronic hereditary glomerulonephritis (GN), steroid resistant nephrotic syndrome (SRNS) and nephronophthisis (NPHP) are major leading diseases to a pediatric CKD. Urinalysis can indicate chronic GN and SRNS with CKD, CAKUT and NPHP however show only slight abnormalities in urinalysis. In addition, both CAKUT and NPHP are highly genetically heterogeneous disorders, therefore the exact molecular diagnosis for CAKUT and NPHP is much difficult. **Methods** Next-generation sequencing (NGS) analysis was performed on 157 Japanese individuals who were clinically diagnosed as CAKUT, NPHP or renal insufficiency of unknown cause in childhood using three custom designed panels containing 91, 128 and 172 genes associated with CAKUT or NPH. All procedures were reviewed and approved by the Institutional Review Board of Kobe University School of Medicine. **Results** Seventeen responsible genes in 30 individuals were identified (diagnostic rate 19.1%). The detected responsible genes were as follows; *BBS10*, *GATA3*, *HNF1B*, *INF2*, *NPHP1*, *NPHP3*, *OFD1*, *PAX2*, *PKD1*, *PKHD1*, *REN*, *RET*, *SALL1*, *SDCCAG8*, *TMEM67*, *TTC21b* and *WDR19*. It is noted that renal cystic phenotypes including NPHP were most frequently found in cases, of which causative genes were identified (50.0%). Furthermore, we found that five individuals of which clinical diagnosis and genetic diagnosis were considerably different. Two individuals with serum electrolyte abnormalities, who were clinically diagnosed as Bartter syndrome but no associated responsible genes were identified, were both resulted in harboring *PAX2* pathogenic variants and thereby diagnosed as papillorenal syndrome. Another two individuals with multiple renal cysts, who were diagnosed as NPHP or autosomal recessive polycystic kidney disease, were resulted in carrying *HNF1B* pathogenic variants and followed by diagnosis of an autosomal dominant CAKUT; renal cysts and diabetes (RCAD). **Conclusion** It is suggested that NGS analysis using targeted sequencing panels is useful for the definitive diagnosis and genetic counselling for CAKUT and NPHP.

**HES1 gene screening in a cohort of patients with hypopituitarism reveal an allelic variant c.578G→A (p.G193D).** R. Kertesz, A.P Otto, J.L.O Madeira, L.R.S Carvalho. Unit of Developmental Endocrinology, University of Sao Paulo Medical School, Sao Paulo, Sao Paulo, Brazil.

Hypopituitarism is defined as deficiency of one or more hormones produced and secreted by the pituitary gland. *HES1* is a gene that encodes a transcription factor that plays a role in the pituitary development and differentiation, which makes it a possible candidate gene for hypopituitarism in humans. In order to look for allelic variants in *HES1*, 193 Brazilian patients (124 male) with congenital hypopituitarism were analyzed with mean age of 11.9 years ( $\pm$  6.9), -4.4 Z score for height, -0.8 ( $\pm$  1.5) Z score for BMI, 60 were isolated growth hormone deficiency (GHD) and 132 combined GHD. The code region was amplified by polymerase chain reaction, followed by the Sanger sequencing method. The allelic variant c.578G→A (p.G193D) was found in heterozygous state in a male patient with growth deficit since childhood, diagnosed with GH and TSH deficiencies at 11 years that evolved with LH/FSH and ACTH deficiencies. The pituitary resonance image reveals an ectopic neurohypophysis, non visualized stalk and hypoplastic adeno-hypophysis. Familial segregation revealed that mother and 3 out of 5 siblings did not harbor the variant. Father's DNA was unavailable. The two siblings harboring the allelic variant did not present growth deficit. *In silico* analysis using 4 different tools showed a contradictory result. Polyphen, Sift and SNAP tools suggested being benign and Mutation Taster, disease-causing by altering the chemical physical amino-acid characteristic leading to a possible splicing site modification. It is under rs771445679 in the GenomAD data base with 7.083e-5 allele frequency (AF). Two other allelic variant were found in our cohort c.741C→T (p.Val247Val) in 7 patients (1 homozygous) that it was described in the genomAD data base under rs7629144 with 0,01361 AF. Another allelic variant in a splicing region c. 293-5 C→T was described under rs148500265 in the genomAD presenting 0,003399 AF. This residue is not conserved among different species. The 88 final residues of *HES1* (193-280) interacts with the 60 final residues of *CBFA1* leading to transactivation, what prompted us to test the functional impact of *HES1* c.G578A (p.G193D) in vitro. *Hes1* cDNA WT plasmid was obtained and the mutant generated through mutagenesis. The assay for the in vitro analysis is under development. We conclude that *HES1* in the pedigree presents an incomplete penetrance and in vitro study will collaborate to establish a relationship between phenotype and genotype.

**Rapid paediatric sequencing (RaPS) from patient to variant: A step-by-step workflow and case report.** L. Boukhibar<sup>1</sup>, H. Williams<sup>1</sup>, A. Gagunashvili<sup>1</sup>, L. Ocaka<sup>1</sup>, P. Le Quesne Stabej<sup>1</sup>, E. Clement<sup>1</sup>, W. Jones<sup>2</sup>, L. Jenkins<sup>3</sup>, S. Marks<sup>4</sup>, C. Bacchelli<sup>5</sup>, M. Bitner-Glindzicz<sup>6</sup>, P. Beales<sup>1</sup>. 1) GOSgene, Genetics and Genomic Medicine, Great Ormond Street Institute of Child Health, UCL., London, United Kingdom; 2) Clinical Genetics and Genomic Medicine, Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; 3) NE Thames Regional Genetics Laboratory, Great Ormond Street Hospital, London, United Kingdom; 4) Department of Paediatric nephrology, Great Ormond Street Hospital for Children NHS Foundation Trust, London, UK; 5) Experimental and Personalised Medicine, UCL Great Ormond Street Institute of Child Health, London, United Kingdom; 6) Genetics and Genomic Medicine, UCL Great Ormond Street Institute of Child Health, London, United Kingdom.

Disease in severely ill children is often undifferentiated at birth, clinically heterogeneous and progression is extremely rapid. To address the unmet need to quickly identify a genetic cause, we started the **RaPS** (Rapid Paediatric Sequencing) project in collaboration with Great Ormond Street Hospital and NE Thames Regional Genetics Lab. We developed a workflow template to rapidly sequence, analyse and report likely causative variants from patient/parent trios. We describe our workflow and illustrate its clinical impact with a case report. The RaPS workflow comprises 3 stages: 1) patient referral, evaluation and consent 2) whole genome sequencing and data analysis, and 3) variant selection. **Stage 1** involves the referring clinicians and clinical geneticists to rapidly assess suitability based on RaPS Inclusion Criteria. In **stage 2**, library preps and rapid sequencing (Illumina NextSeq/Hiseq Rapid mode **29 hrs**) are followed by rapid data analysis from fastq to vcf (*Genalice*, **1.5 hrs/trio**). **Stage 3** variant analysis and selection is performed using *Ingenuity Variant Analysis* and consists of filtering steps based on population allele frequencies, predicted deleterious effect and mode of inheritance. Importantly, Stage 3 is a phased variant selection: each phase is powered by panel-specific filters. Phase I analysis comprises phenotype-specific gene panels and is performed as first line of investigation. If no likely-causative variant is identified in Phase I; Phase II and/or III analyses are performed. Phase II panels consist of broader disease-associated genes (OMIM, DDG2P databases). Phase III analysis is research-oriented and consists of variant sharing with the scientific community through GeneMatcher. Likely-causative variants are discussed with at least two clinical geneticists for a consensus and a diagnostic report is issued. We present the RaPS workflow and a case report side-to-side to depict each stage of the process. We report a three week old neonate admitted to PICU with metabolic acidosis, hyperkalaemia and oligoanuric kidney injury. We identified a pathogenic *WT1* variant thus providing a diagnosis of Denys-Drash syndrome. RaPS allowed an early diagnosis and re-shaped clinical management to minimize future tumour development before kidney transplant. The strength of the RaPS workflow lies in its rapidity (5 days) and phased analysis. Our workflow is adaptable for other clinical settings where rapid and accurate genetic diagnosis is a necessity.

**891F**

**A novel deletion in ABCC9 gene identified through whole-exome sequencing of patient with clinical spectrum of Cantú syndrome.** O. Migita<sup>1,2</sup>, M. Mizuno<sup>1</sup>, K. Aso<sup>1</sup>, H. Yamamoto<sup>1</sup>, K. Hata<sup>2</sup>. 1) Department of Pediatrics, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan; 2) Department of Maternal-Fetal biology, National Center Institute for Child Health and Development.

Cantú syndrome is a clinically characterized by hypertrichosis, osteochondrodysplasia and cardiomegaly. Most of the patients have their unique DNA sequences in the *ABCC9* gene that codes for an sulfonyleurea receptor 2 (SUR2) protein, which is a member of the superfamily of ATP-binding cassette (ABC) transporters. We conducted a next generation sequencing analysis of whole exon from a 4 month female with phenotypes of a hypertrichosis and cardiomegaly, which were compatible to Cantú syndrome. We detected a novel heterozygous deletion in *ABCC9* that may impact to *ABCC9* proteins. This is the first report to detect *ABCC9* deletion mutation in a patient with Cantú syndrome.

**Population-scale linkage mapping in a healthcare system uncovers novel signal for primary biliary cirrhosis.** G.M. Belbin<sup>1,2</sup>, S. Kohli<sup>1</sup>, M.C. Yee<sup>3</sup>, G.L. Wojcik<sup>4</sup>, E. Sorokin<sup>4</sup>, C.R. Gignoux<sup>5</sup>, J.H. Cho<sup>1,2,6</sup>, R.J.F. Loos<sup>1,2,7</sup>, G. Nadkarni<sup>1</sup>, E.E. Kenny<sup>1,2</sup>. 1) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, NY, USA; 2) Department of Genetics and Genomics, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 3) Carnegie Institution for Science, Department of Plant Biology, Stanford, CA, USA; 4) Department of Genetics, Stanford University School of Medicine, Stanford, CA, USA; 5) Colorado Center for Personalized Medicine, University of Colorado, Aurora, CO, USA 5. Division of Gastroenterology, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 6) Division of Gastroenterology, Icahn School of Medicine at Mount Sinai, New York, NY, USA; 7) The Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA.

Linkage mapping is a classical method for the genetic identification of monogenic disease in the absence of a known molecular mechanism. This approach has been used to uncover loci underlying suspected genetic disorders segregating in pedigrees or probands. Broad-scale adoption of genomic data in health systems offers opportunities for population-scale disease mapping. Here we introduce a method that combines genome-wide association with linkage mapping to discover genomic disorders in the BioMe Biobank in New York City. First we detected tracts of genetic homology shared between pairs of patients in the Puerto Rican founder population in BioMe (N=5213) to infer distant pedigree relationships in the absence of known genealogy. Next, we performed statistical association of regions of shared genetic homology with ICD9 billing codes derived from the Electronic Health Record (billing codes; n=8386). One ICD9 code was significantly associated (FDR<0.05) between a recessive locus and a rare ICD9 code (occurrence 27/5213) encoding for "Primary Biliary Cirrhosis" (PBC,  $p < 2.9 \times 10^{-9}$ , frequency=0.73%). The significant locus was homozygous in three distantly related individuals (greater than 5<sup>th</sup> cousins), each of whom had a diagnosis of PBC (11% of total PBC diagnoses in Puerto Ricans in BioMe). The mapping interval spanned 2.8cM at 7q21.12 and included the *ABCB4* gene, which has been extensively implicated in monogenic forms of hepatobiliary disease. Whole genome sequencing ruled out any of the 15 known variants underlying dominant or recessive forms of hepatobiliary disease, but revealed sharing of multiple rare variants in the mapping interval, suggesting that the detected signal may be driven by previously unreported variation at the *ABCB4* locus. Finally, analysis of ICD9 codes in heterozygous carriers (n=70) uncovered significant associations to "biliary calculus with cholecystitis" ( $p < 4.5 \times 10^{-5}$ , O.R=5, (95% CI=3-9)) and "hydrops of the gallbladder" ( $p < 0.00016$ , O.R=151 (95% CI=16-1690)), which were both ranked within the top three hits. This analysis provides a methodological framework for bridging statistical genetics and clinical genomics, and demonstrates that EHR-embedded, population-level research can elucidate the pathology of rare genetic disorders.

**893T**

**A case of vitamin D-dependent rickets type 1a with a novel pathogenic variant in a Mexican patient.** M. Abreu-González<sup>1</sup>, C. Candia-Tenopala<sup>2</sup>, Y. Mena<sup>1</sup>, S. Martínez-Gutiérrez<sup>1</sup>, B.A. Rodríguez-Espino<sup>1</sup>, V. Flores<sup>1</sup>, O.C. Azotla-Vilchis<sup>1</sup>. 1) Genos Medica, Centro Especializado en Genética, Mexico City, Mexico; 2) Centro Endocrino, Mexico City, Mexico.

Vitamin D-dependent rickets type 1A (VDDR-1A) (MIM #264700), also called pseudovitamin D deficiency, is an inborn error of vitamin D metabolism involving defective or diminished conversion of 25-hydroxyvitamin D3 (25(OH)D3) to the active form 1,25-dihydroxyvitamin D3 (1,25(OH)2D3) in the kidney by the enzyme 25(OH) D-1-hydroxylase. This type of rickets presents early in infancy with hypotonia, weakness, severe skeletal disease, failure to thrive, and growth retardation. The treatment consists of supplementation with calcium and active forms of vitamin D. VDDR-1A is an autosomal recessive disorder due to pathogenic variants in the *CYP27B1* gene (MIM \*609506). In this study we present a male Mexican patient born to the first pregnancy of a non-consanguineous, young, healthy couple. He started at 7 months with bilateral tibial bowing and at 1 year old he had two long bone fractures. He was referred to our clinic with the clinical suspicion of osteogenesis imperfecta. The physical examination at 2 years old revealed that his weight and height were below the 3rd centile, mid facial hypoplasia, rachitic rosary, thickness of the wrists with shortening and bowing of the limbs. Biochemically, he had hypocalcaemia, hypophosphatemia with elevated parathormone levels, leading the diagnosis to hypophosphatemic rickets. A next generation sequencing targeted panel was performed (TruSight One Sequencing Panel). The bioinformatics pipeline analysis of the 26 genes associated with rickets identified two genetic variants located in *CYP27B1*. The first one is an insertion of 7 bases (NM\_000785.3: c.1325\_1326insCCCACCC) that have been previously reported as pathogenic and a novel transition (NM\_000785.3:c.227G>A) that generates a premature stop codon (NP\_000776.1:p.Trp76\*). This novel variant has not been described, but *in silico* analyses indicated a loss of function for the coded protein due to either a truncated protein or a nonsense mediated decay of the *CYP27B1* mRNA. No additional changes of clinical significance were found in the rest of the analyzed genes, suggesting that the cause for the observed phenotype was indeed due to variants in *CYP27B1*. This case shows a patient who presented with severe skeletal signs of VDDR-1A at a young age probably due to the type of the variants detected. Using a next generation sequencing strategy we could identify the genetic basis of the disease and start an early appropriate pharmacological treatment.

Protein-losing enteropathy (PLE) is caused by disruption of lymphatic or intestinal integrity, manifesting as hypoalbuminemia, edema, hypogammaglobulinemia, lymphopenia, and malabsorption. One primary disorder manifesting as PLE is primary intestinal lymphangiectasia (PIL), a rare life-threatening disorder of unknown etiology. We studied an extended consanguineous Muslim-Arab family comprising of six patients diagnosed with PLE; one of the patients had pathological and endoscopic evidence of PIL. Hypercoagulability was observed in three of the patients. Whole exome sequencing was performed on three affected individuals and a healthy mother, revealing a candidate frameshift homozygous variant in the *CD55* gene. The finding was supported by Two-Point LOD score for the variant of 4.43, based on genotype information from 32 tested family members. *CD55* encodes the decay-accelerating factor (DAF), a membrane-bound complement-regulatory protein that inhibits the C3 and C5 convertases, thus preventing C3 and C5 cleavage and activation, and protecting cells against complement-induced self-injury. Previous studies in a mouse model of dextran sulfate sodium (DSS)-induced colitis demonstrated that DAF loss leads to a more severe phenotype compared to wild-type animals, reinforcing the protein's role in intestinal tissue protection. We demonstrate by hemagglutination tests and flow cytometry the absence of DAF, confirming the variant's predicted loss-of-function effect. Furthermore, membrane attack complex (MAC) and iC3b depositions on white blood cells (WBC), tested by flow cytometry, were significantly increased in patients compared to age-matched controls. Evidence of abnormal complement activation in the patients corroborated the genetic findings, and prompted off-label approved compassionate therapy with eculizumab (Soliris), a humanized anti-C5 monoclonal antibody, that serves as a terminal complement inhibitor. We report on 100 days of successful treatment in three PLE patients, with significant clinical improvement, normalization of serum albumin, and 60% reduction in MAC deposition on WBCs. The path from genetic analysis to tailored therapy with anti-C5 has provided hope for amelioration of symptoms in *CD55*-related PLE patients. This proof of principle demonstration of eculizumab treatment benefits in *CD55*-related PLE patients should prompt further study regarding the role of complement and *CD55* in other intestinal disorders that may benefit from similar treatment.

**895W**

**High prevalence of PKD2 R803\* mutation in Taiwan.** D. Hwang, C. Yu. Division of Nephrology, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Kaohsiung, Taiwan.

**Purpose** To study the disease-causing mutations of *PKD1* and *PKD2* of autosomal dominant polycystic kidney disease (ADPKD) in Taiwan, we enrolled 109 families with the diagnosis of ADPKD which were established by clinical and image studies from nephrology investigators in Taiwan. Most of the families were from southern Taiwan. The study was approved by the institutional review board of the Kaohsiung Medical University Hospital, and all procedures were performed in accordance with the declaration of Helsinki. All subjects provided written informed consent before participating in this study. **Methods** Long-range PCR primers were designed for *PKD1* and *PKD2* genes to avoid the amplification of *PKD1* pseudogenes. Second PCR primers were designed to cover the coding and intron-exon boundaries. Products from long-ranged PCR were 2500-fold diluted to prevent genomic DNA carryover. Multiplex microfluidic PCR system (Fluidigm Access-Array) was used for the second PCR, followed by barcoding PCR with next-generation re-sequencing on Illumina MiSeq. Fastq files from MiSeq were loaded into CLCbio Genomic Workbench for bioinformatics analysis. Data was compared with dbSNP database, Mayo Clinic ADPKD Mutation Database, and functionally prediction with polyphen2. Five microsatellites markers (D4S1534, D4S1542, D4S1563, D4S1544, D4S414) were used to analyze 17 families of *PKD2* R803\* mutation. **Results** We potentially can identify mutations in 75% (82/109) of the ADPKD families in Taiwan by our high-throughput method. Forty percent of our cohort (34/82) was due to mutation in the *PKD2* gene, and half of them (17/34) had *PKD2* R803\* mutation. Microsatellite analysis showed only marker D4S1563 differentiated those 17 *PKD2* R803\* families into two groups, indicating two different but closely related founders leading to the high prevalence of *PKD2* R803\* mutation in Taiwan.

**Novel genotype-phenotype correlations in X-linked Alport syndrome: Serum albumin level, age at onset of hematuria and hypertension.** *L.I. Shag- am<sup>1</sup>, A.N. Gerasimov<sup>2</sup>, T.A. Kuznetsova<sup>1</sup>, M.E. Aksenova<sup>1</sup>, V.S. Sukhorukov<sup>1,2</sup>, T.V. Akopova<sup>1</sup>, V.V. Dlin<sup>1</sup>.* 1) Research Institute of Pediatrics, Pirogov Russian Medical University, Moscow, Russian Federation; 2) Sechenov Moscow State Medical University, Moscow, Russian Federation.

Alport syndrome (AS) is a hereditary nephritis with an estimated population frequency of 1:5000 – 1:53000 that varies from region to region. It is characterized by hematuria, proteinuria, progressive loss of kidney function and usually accompanied by hearing loss and/or ocular abnormalities. X-linked AS caused by *COL4A5* gene defects comprises ~85% of all Alport syndrome cases. Males with the X-linked AS harboring missense mutations are known to demonstrate milder phenotype than those with frameshift, splice site, nonsense mutations or deletions covering at least 1 exon including later age at end stage renal failure, hearing loss and eye lesions' manifestation. However, little is known about genotype correlations with other phenotypic characteristics such as hematuria and hypertension manifestation age, biochemical characteristics of blood and urine. We have performed a longitudinal clinical and comprehensive genetic research on patients with AS. A gene panel covering coding exons and adjacent 5bp intronic regions of *COL4A3*, *COL4A4* and *COL4A5* genes has been used with Ion Torrent sequencer for confirmation of the diagnosis. A sample of 43 patients from Russia aged 1 to 17 years old (average 11) at last examination, 26 males and 17 females with X-linked AS and *COL4A5* pathogenic or likely pathogenic variants has been subjected to study of genotype-phenotype correlations. Here we show that patients with missense mutations resulting in glycine substitutions in the *COL4A5* collagenous domain (n=26) are characterized by later age at onset of hematuria and hypertension (p<0,05 according to Mann-Whitney U test) than those with frameshift, splice site, start codon, nonsense mutations or deletions covering at least 1 exon (n=16). The abovementioned associations have been shown for males and for both sexes taken together, whereas they do not reach statistical significance threshold in the female sample. Moreover, among patients of both sexes harboring the glycine substitutions (n=21) we demonstrate a negative correlation of the mutation position with age-adjusted serum albumin level (i.e., C-terminal mutations tend to lead to lower albumin level than N-terminal) with Pearson correlation coefficient of -0,46 and Spearman correlation coefficient of -0,45 (p<0,05). The results herein reported expand the knowledge on phenotypic characteristics of patients with X-linked Alport syndrome caused by different mutation types.

**Exome sequencing reveals novel candidate genes and potential oligogenic inheritance in patients with hypergonadotropic hypogonadism.**

*A. Jolly<sup>1</sup>, Y. Bayram<sup>1</sup>, S. Turan<sup>2</sup>, Z. Aycan<sup>3</sup>, T. Tos<sup>4</sup>, B. Hacıhamdioglu<sup>5</sup>, Z.C. Akdemir<sup>6</sup>, S. Bas<sup>7</sup>, Z. Atay<sup>8</sup>, T. Guran<sup>2</sup>, S. Abali<sup>2</sup>, J.J. White<sup>1</sup>, G. Yesil<sup>6</sup>, E. Karaca<sup>1</sup>, S.N. Jhangiani<sup>7</sup>, D.M. Muzny<sup>7</sup>, A. Bereket<sup>2</sup>, R.A. Gibbs<sup>7</sup>, J.E. Posey<sup>1</sup>, J.R. Lupski<sup>1,7,8,9</sup>.* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Pediatric Endocrinology and Diabetes, Mamara University Hospital, Istanbul, Turkey; 3) Department of Pediatric Endocrinology, Sami Ulus Children's Hospital, Ankara, Turkey; 4) Department of Medical Genetics, Sami Ulus Children's Hospital, Ankara, Turkey; 5) Department of Pediatric Endocrinology, Suleymaniye Training and Research Hospital, Istanbul, Turkey; 6) Department of Medical Genetics, Bezmialem University, Istanbul, Turkey; 7) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 8) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 9) Texas Children's Hospital, Houston, TX.

Hypergonadotropic hypogonadism (HH) is characterized by hypogonadism due to an impaired response of the gonads to the gonadotropins (FSH and LH) and in turn a lack of sex steroid production and elevated gonadotropin levels. HH can be caused by environmental factors such as acquired damage to the ovaries, and congenital disorders that affect normal ovarian development and function, as well as syndromic and non-syndromic single gene disorders. However, in most cases of gonadal dysfunction the molecular etiology and molecular diagnosis remain an enigma. To identify novel molecular etiologies in HH we applied whole exome sequencing (WES) to 32 affected female individuals from 29 unrelated families including 21 with reported parental consanguinity. WES revealed likely pathogenic variants in known HH-associated genes in 7/29 (24%) including *AR*, *NOBOX*, *MCM8*, *PADI6*, *PSMC3IP*, and *TG*. In six families, we found likely pathogenic variants in candidate disease genes including *SOHLH1*, *C3*, *IGSF10*, *MRPSS22*, and *MAST4*. GeneMatcher facilitated the identification of 1 family of 3 affected individuals with homozygous variation in *MRPSS22* and 1 family of 4 affected individuals with homozygous variation in *IGSF10*. Interestingly, in three families we found evidence for a potential mutational burden or oligogenic inheritance model. In one patient with HH and obesity we identified homozygous variants in two known genes associated with hypogonadism (*CHD7* and *MCM9*) and another homozygous variant in *PRKD1* that was reported as a candidate gene for obesity. In a second subject, we identified homozygous variation in *GALT*, associated with Galactosemia, a known cause of HH. In the same subject, we identified a homozygous variant in *DNAH6* that had been previously reported in a patient with ovarian failure. Variation at both *ITGA11* and *TMPRSS9* were found in a third family with potential multilocus inheritance. In this study, we identified both potential novel genes associated with HH, as well as variants in known HH genes in a cohort of 32 affected female individuals. A genome-wide approach enabled both identification of seven potential novel disease genes as well as an oligogenic mutational burden model in three families. We suggest that increased application of WES and WGS in clinical genomics of genetically heterogeneous phenotypes such as HH will provide further molecular etiological insights including the potential contributions of multilocus variation.

**Enzyme replacement therapy during dialysis in a patient with Fabry disease in a community hospital in New York.** *E. Astiazaran-Symonds, S. Lee, P.D. Lopez, M. Maik, M. Banikazemi.* Internal Medicine, Metropolitan Hospital Center, New York, NY.

A 31 year old Mexican male was admitted to the hospital due to acute presentation of end stage renal disease. He reported experiencing acroparesthesia since early childhood. He also complains of anhidrosis, poor heat tolerance and fatigue. Enzyme and molecular testing for Fabry disease were performed. Patient was found to have low  $\alpha$ -galactosidase A activity. DNA sequencing confirmed a *GLA* nonsense mutation (c.748C>T). Patient was placed on hemodialysis three times per week, as well as enzyme replacement therapy (ERT) with r-h $\alpha$ GalA every other week. It has been reported that administration of r-h $\alpha$ GalA during hemodialysis is not associated with a reduced efficacy of r-h $\alpha$ GalA therapy or loss of enzyme into the dialysate. Therefore, we have arranged that his ERT be continued during hemodialysis. Since the start of ERT, patient reports decreased acroparesthesia, better performance at work and increased heat and exercise tolerance. Fabry disease is an X-linked lysosomal storage disorder, caused by reduced activity of the lysosomal enzyme  $\alpha$ -galactosidase A. Globotriaosylceramide (GL3) accumulates, leading to renal, cardiac, and cerebrovascular manifestations, and risk of early death from end-stage renal disease, coronary artery disease or stroke. Characteristic features of FD begin early in life and include acroparesthesia, angiokeratomas, anhidrosis, corneal opacities, gastrointestinal symptoms, tinnitus and hearing loss. Specific treatment for Fabry is available by means of ERT with recombinant agalsidase alpha and beta. ERT slows disease progression by reducing levels of GL3. This in turn protects organs from irreversible damage and improves patient's symptoms and quality of life. To the best of our knowledge, this is the first case of a patient with Fabry receiving ERT during dialysis in the United States. This arrangement has increased patient's satisfaction and quality of life.

**899T**

***CFTR* gene mutations in the São Miguel island (Azores, Portugal): 20 years follow-up study.** *L. Mota-Vieira<sup>1,2</sup>, P. Gaspar-da-Silva<sup>3</sup>, P. Pacheco<sup>4</sup>, C. Silva<sup>4</sup>, C.C. Branco<sup>1,2</sup>, A. Carreiro<sup>5</sup>, M.D. Amara<sup>1,6</sup>, J. Gonçalves<sup>3</sup>, J. Rosa<sup>3</sup>.* 1) Molecular Genetics and Pathology Unit, Hospital of Divino Espírito of Santo Ponta Delgada, Azores Islands, Portugal; 2) BiolSI - Biosystems & Integrative Sciences Institute, Lisboa, Portugal; 3) Pediatrics Dept, Hospital of Divino Espírito of Santo Ponta Delgada, Azores Islands, Portugal; 4) Human Genetics Dept, INSA, Lisboa, Portugal; 5) Pneumology Dept, Hospital of Divino Espírito of Santo Ponta Delgada, Azores Islands, Portugal; 6) Faculty of Sciences, University of Lisbon, Portugal.

The advent of new drugs targeting specific *CFTR* gene mutations is highlighting the importance to characterize, clinically and molecularly, each patient with cystic fibrosis and their populations (CF, MIM#219700; *CFTR*, MIM\*602421). Here, we performed a cross-sectional study on CF patients admitted to the Hospital of Divino Espírito Santo of Ponta Delgada, over the last 20 years (1997–2016). This hospital is the only one in the Azorean island of São Miguel (137,699 inhabitants; 55.9% of the total Azores population; Portugal Census, 2011). The diagnosis of the CF was based on clinical symptoms and elevated sweat chloride concentrations ( $\geq 60$  mmol/L). Two disease-causing *CFTR* mutations were identified in each patient, using a two-step mutation screening that covers the most frequent (98%) mutations found in Portuguese CF population. This strategy allowed us to confirm the disease in 14 CF patients, being 7 male and 7 female, 11 unrelated and 3 related. There was 1 dead patient (18 years-old), and 13 patients are alive with a mean age of 14.8 years in 2016 (range 6.4–22.2). Clinically, all patients have, or had for the deceased patient, exocrine pancreatic insufficiency (fecal elastase-1 activity:  $< 200$   $\mu$ g/g) and respiratory infections. We identified 4 different *CFTR* mutations in 28 CF chromosomes, namely (NM\_000492.3): c.1521\_1523delCTT (p.Phe508del) [allele frequency: 85.7%], c.-12\_10del23 [7.1%], c.11C>A (p.Ser4Ter) [3.6%], and c.3299A>C (p.Gln1100Pro) [3.6%]. In genotypic terms, only 1 patient (a compound-heterozygous for p.Gln1100Pro and p.Ser4Ter) does not carry the p.Phe508del. In other words, the p.Phe508del, which is the most common among Caucasian population, was found more frequently in homozygosity (78.6%: 11 patients of which 3 were born from consanguineous parents); only 2 patients were compound-heterozygous with the c.-12\_10del23. Indeed, until now, the c.-12\_10del23 is considered a private mutation, since it was reported in few CF patients, but it could be found in patients of Azorean origin living abroad. In terms of population genetics, we calculated the prevalence of the p.Phe508del in 469 individuals from São Miguel Island. We found 7 heterozygous individuals for this mutation, corresponding to an allele frequency of 0.7% and predicting 1 in 17.956 individuals could be homozygous and 1 in 68 should be heterozygous. Now, we are studying the specific genotype-phenotype correlation in three non-classical CF patients carrying other *CFTR* mutations.

**900F****TRPV4 alternative splicing transcripts in metatropic dysplasia.** *S.M.*

*Kirwin<sup>1</sup>, KM. Robbins<sup>1</sup>, MB. Bober<sup>2</sup>, VL. Funanage<sup>1</sup>.* 1) Molecular Diagnostics Laboratory, Nemours/duPont Hospital for Children, Wilmington, DE; 2) Orthopedics Department, Nemours/duPont Hospital for Children Wilmington, DE.

The transient receptor potential vanilloid 4 (TRPV4) cation channel mediates calcium influx in tissues in response to chemical, physical, and hormonal stimuli, and is a member of the Transient Receptor Potential (TRP) super family of cation channels. Deleterious mutations cause a group of skeletal dysplasias including Metatropic dysplasia (MD). Although phenotypes may differ widely, they all share defects in bone ossification. Metatropic dysplasia is a rare skeletal dysplasia (OMIM 156530) characterized by a narrow chest, reduced spinal integrity with platyspondyly and progressive kyphoscoliosis, shortened long bones with metaphyseal widening and often a delay of endochondral ossification. Pathologic *TRPV4* variants are also associated with several neurological disorders, including hereditary motor and sensory neuropathy type IIC ; and scapuloperoneal spinal muscular atrophy. *TRPV4* mutations associated with disease are located throughout the gene, resulting in a gain of function in this heterogeneous group of disorders ranging from mild to lethal. *TRPV4* mRNA is reported with variable expressivity in a wide range of tissues and cell types: cardiac, immune system, CNS, respiratory system, skin, and musculoskeletal system. There are six reported isoforms: full length (TRPV-A), isoform 2 (TRPV-B,  $\Delta 7$ ), isoform 3 (partial exon16 deletion), isoform 4 (TRPV-C,  $\Delta 5$ ), isoform 5 (TRPV-D,  $\Delta 2$ ), isoform 6 (TRPV-E,  $\Delta 5\Delta 7$ ). This study sought to determine which alternative splice variants exist in samples collected from skin fibroblasts, bone or chondrocyte cells, in patients with metatropic dysplasia. Furthermore, we sought to characterize why the same mutation (p.P799L) in patients may present with widely differing phenotypes, and determine whether mutations of the *TRPV4* gene affected RNA splicing in the affected tissues. It is unknown whether differential expression of splice variants based on cell type play a role in pathology of the *TRPV4* channelopathies. Preliminary results show the full-length transcript and the minor splice variant isoforms with skipped exons 5 and 7 as the primary transcripts detected in bone and fibroblasts. Of interest, both the wild-type and p.P799L mutation were detected in an RNA delta 7 transcript isolated from cultured bone cells. Thus, the expression of the *TRPV4* mutation in various RNA transcripts may explain the phenotypic variability in this autosomal dominant disease.

**901W****Nora's Lesion or something less "bizarre": Case report of family with benign bone tumors and review of the literature.** *E. Carter, J. Davis.* Ctr Skeletal Dysplasias, Hosp Special Surgery, New York City, NY.

Siblings with a history of benign bone tumors were referred to our service for genetic evaluation. Family history was unremarkable. The brother, now 5 yrs old, presented at birth with painless masses between the base of his 2nd/3rd toes on his left foot (surgically excised at 3yrs) and along the radial aspect of his right index finger. Nora's lesion, also known as bizarre parosteal osteochondromatous proliferation (BPOP), was suspected given the localization in hands and feet. His 3-yr-old sister subsequently developed a painless lump on the outside of her right knee. She had been diagnosed prenatally with bilateral clubfeet; amniocentesis revealed a normal female karyotype. Radiographically, no lesion was contiguous with cortical and cancellous bone, as seen in osteochondromas, and none appeared to represent an osteochondroma emanating from the physis. Small foci of mineralization were noted in the boy's left foot 1st MTP joint and right hand 2nd PIP and 1st MCP joints. MRI of the right index finger described an osteochondromatous lesion originating from the distal proximal phalanx with no prominent overlying cartilaginous cap, and a mass along the dorsal aspect of the distal metacarpal physis. His sister's X-ray showed an anterolateral soft tissue mass at the proximal fibula with calcifications suggestive of a chondral lesion; there was no clear abnormality of the underlying bone to indicate osteochondroma. Post-operatively the inter-toe tumor was described as being attached in a stalk-like manner to the metaphysis of the 2<sup>nd</sup> proximal phalanx. It had sparsely cellular cartilaginous nodules, overlying fibrous periosteal tissue, and extensive endochondral ossification. *EXT1* and *EXT2* analysis is pending. Benign bone tumors can be categorized into 8 types. Although incidence varies by tumor type, overall they most commonly arise in people <30 yrs old and can be triggered by the hormones that stimulate normal growth. BPOP lesions are rare; recently an association with t(1:17)(q32;q21) was reported. Osteochondromas are the most common benign bone tumor. ~85% of individuals with hereditary multiple osteochondromas have dominant mutations of the *EXT1* or *EXT2* genes in the growth plate cartilage. Clinical manifestations vary; individuals may be asymptomatic, may experience pain, or restricted motion. Surgery may be indicated with pain and/or functional limitations. Risk of malignant degeneration is reported in 0.5-20% of cases. .

**902T**

**A novel mutation in the C-Terminal Associated Peptide (TCAP) region of Teneurin 3 found to co-segregate in all affecteds in a multi-generation family with developmental dysplasia of the hip.** G.J. Feldman<sup>1</sup>, T. Freeman<sup>1</sup>, A. Fertala<sup>1</sup>, J. Parvizi<sup>1,2</sup>. 1) Division of Orthopaedic Research, Thomas Jefferson University, Philadelphia, PA; 2) Rothman Institute, Philadelphia, PA.

DDH is a debilitating condition characterized by incomplete formation of the acetabulum leading to dislocation of the hip, suboptimal joint function and accelerated wear of the articular cartilage resulting in early onset crippling arthritis of the hip in 20-40 year olds. Undetected DDH in this age group accounts for 40-60% of hip osteoarthritis. Current diagnostic tests in newborns using physical manipulation of the femur or ultrasound either under or over-diagnose this condition. DDH is a complex disorder having environmental and genetic causes. Evidence for the genetic cause is well established and includes concordance between identical twins and high rates of transmission among first degree relatives. To better understand the biologic pathways involved in acetabular development, DNA from severely affected individuals in a 4 generation family that showed inter-generational transmission of the disorder was isolated and whole exome sequenced. Shared variants were filtered using various parameters including biological impact and relevance to chondrogenesis and osteogenesis. A novel A to C transversion at position 183721398 on human chromosome 4 was found to co-segregate with the affected phenotype in this family. This mutation encodes a glutamine to proline change at position 2665 in the Teneurin 3 (Tenm3) gene and was judged damaging by 4 prediction programs and by computer modeling of the scFv structure. Teneurin 3 is located on human chromosome 4q35, a region previously strongly linked to DDH in an unrelated 4 generation family. This transmembrane protein is thought to function in signal transduction, and is most strongly expressed in the perichondrium and proliferating chondrocytes in the femoral cartilage of 1 day old mice. This mutation resides near the amino terminal, cleavable end of TCAP domain of Teneurin 3. Within the TCAP domain is a motif bearing strong homology to calcitonin- a hormone strongly associated with endochondral bone formation in early life. This variant and others that remain to be found in other families and sporadic individuals may begin to elucidate the pathways responsible for normal hip development. .

**903F**

**Dual genetic diagnoses identified in a large family with brachydactyly type A1 and insulin resistance using whole-exome sequencing.** R. Ho<sup>1,2</sup>, A.D. McIntyre<sup>1</sup>, B.A. Kennedy<sup>1</sup>, R.A. Hegele<sup>1,2,3</sup>. 1) Robarts Research Institute, Western University, London, Ontario, Canada; 2) Department of Biochemistry, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada; 3) Department of Medicine, Schulich School of Medicine and Dentistry, Western University, London, Ontario, Canada.

Brachydactyly is an umbrella term describing shortened fingers and toes, often part of an autosomal dominant complex malformation syndrome. Although various forms of brachydactyly have been characterized and several causative genes have been found, many forms remain genetically undefined. Here, we describe a 15-year-old unsolved medical case of a Canadian family with a history of brachydactyly and insulin resistance that remained genetically undiagnosed. To characterize the genetic basis of the brachydactyly and insulin resistance in this family, DNA was extracted from 18 family members (14 definitely affected) who were previously Sanger sequenced but not found to have mutations in known genes underlying the disorder. One patient was recently whole-exome sequenced at the London Regional Genomics Centre, and a rare variant prioritization approach was used to identify variants of interest. In this patient, a novel candidate variant for brachydactyly (exon 1, c.285\_287dupGAA, p.Glu95\_Asn96insLys) was identified in the Indian hedgehog (*IHH*) gene, and confirmed through Sanger sequencing to co-segregate with affected status in the pedigree. Mutations in this gene are known to cause autosomal dominant brachydactyly type A1, which correlates with the clinical phenotype of the family. Using statistical analyses, we found that in comparison to an unaffected control population, the *IHH* variant is associated with shortened middle phalange length by 21.1% ( $P<0.001$ ), palm length by 13.8% ( $P<0.01$ ), digit-palm ratio by 6.8% ( $P<0.03$ ) and stature by 9.5% ( $P<0.001$ ), strengthening the association. Current studies are focusing on *ex vivo* and *in vitro* assessment of the *IHH* variant, and identifying the genetic basis of the insulin resistance segregating in this family. These data highlight the power of next-generation sequencing to solve or clarify the genetic basis of "cold cases". They also indicate the need to consider independently segregating etiologies for dual diagnoses when studying complex disorders. Determining the molecular basis of these disorders will allow for further understanding of disease mechanisms, and will help other health care providers caring for families with the same condition caused by the same genes.

## 904W

**Mutated *DMRT2* causes a distinct type of spondylocostal dysostosis (SCD).** Q. Waisfisz<sup>1</sup>, A. Bouman<sup>2</sup>, J. Admiraal<sup>3</sup>, M. van de Loo<sup>3</sup>, R.R. van Rijn<sup>4</sup>, R.J. Oostra<sup>5</sup>, I.B. Mathijssen<sup>2</sup>. 1) Department of Clinical Genetics, VU University Medical Center, Amsterdam, Netherlands; 2) Department of Clinical Genetics, Academic Medical Center, Amsterdam, Netherlands; 3) Department of Neonatology, Emma Children's Hospital, Amsterdam, The Netherlands; 4) Department of Radiology, Academic Medical Center, Amsterdam, The Netherlands; 5) Department of Anatomy, Embryology & Physiology, Academic Medical Center, Amsterdam, The Netherlands.

Spondylocostal dysostosis (SCD) is a rare disorder characterized by vertebral segmentation defects and malformations of the ribs. In addition, SCD-patients have some degree of (kypho)scoliosis, short stature and suffer from respiratory impairment due to the reduced size of their thoracic cage. Mutations in *DLL3*, *MESP2*, *LFNG*, *HES7*, *TBX6* and *RIPPLY2* are known to cause different subtypes of SCD. Here, we present a male neonate with an apparent severe type of SCD only partly overlapping the previously described SCD-subtypes. Diagnostic radiological imaging demonstrated multiple costovertebral abnormalities. The proband presented with severe costal malformations (missing, fused, bifid, and hypoplastic ribs), vertebral malformations (including intervertebral fusions of the laminae and irregular ossification of the vertebral bodies) and a mild scoliosis. Other dysmorphic features included: cleft palate (soft palate), posteriorly rotated ears, short neck, asymmetry of the thorax, extra nipple, transverse palmar creases, sandal gap (bilateral), and sacrum acutum. Severe respiratory insufficiency was present from birth. Whole exome sequencing (WES) identified a homozygous start-loss variant in *DMRT2* (NM\_006557.6: c.1A>T p.(Met1?)). Mutations in *DMRT2* (OMIM#604935) have not been described in relation to SCD before. It has been demonstrated that *DMRT2* knock-out mice exhibit severe rib and vertebral defects overlapping with the radiological phenotype of our patient. Therefore, it seems plausible that mutations in *DMRT2* can cause a severe type of SCD characterized by a striking skeletal phenotype in combination with extra-skeletal features. This is the first report of a human proband with a severe SCD-like phenotype most probably caused by a homozygous mutation in *DMRT2*.

## 905T

**Potential pathogenic variants identified in a Turkish tooth agenesis cohort via whole exome sequencing.** R. Du<sup>1</sup>, N. Dinckan<sup>2,10</sup>, L.E. Petty<sup>6</sup>, Z. Coban-Akdemir<sup>1</sup>, S.N. Jhangjani<sup>1</sup>, I. Paine<sup>1</sup>, E.H. Baugh<sup>5</sup>, A.P. Erdem<sup>6</sup>, H. Kayserili<sup>7</sup>, H. Doddapaneni<sup>8</sup>, J. Letra<sup>10,11</sup>. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030, USA; 2) Department of Medical Genetics, Istanbul Medical Faculty, Istanbul University, Istanbul, 34093, Turkey; 3) Human Genetics Center, University of Texas Health Science Center at Houston School of Public Health, Houston, TX 77030, USA; 4) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX 77030, USA; 5) Department of Biology, New York University, New York, NY 10012, USA; 6) Department of Pedodontics, Faculty of Dentistry, Istanbul University, Capa, Istanbul, 34390, Turkey; 7) Department of Medical Genetics, Koc University, School of Medicine (KUSOM), Istanbul, 34010, Turkey; 8) Department of Pediatrics, Baylor College of Medicine, Houston, TX 77030, USA; 9) Texas Children's Hospital, Houston, TX 77030, USA; 10) Department of Diagnostic and Biomedical Sciences, University of Texas Health Science Center at Houston School of Dentistry, Houston, TX 77054, USA; 11) Center for Craniofacial Research, University of Texas Health Science Center at Houston School of Dentistry, Houston, TX 77054, USA.

Tooth agenesis (TA) is a common craniofacial abnormality in humans and represents the failure to develop one or more permanent teeth. Isolated TA has complex underlying genetic etiology and variations in at least ten genes have been reported as contributing to TA. Although comprehensive efforts were conducted to elucidate genetic susceptibility, novel causative variants remain to be identified. We recruited a Turkish TA cohort consisting of 11 multiplex families affected with TA, and applied whole exome sequencing (WES) using HGSC VCRome capture reagent to identify candidate causative variants for TA. Array-based genotyping and linkage analysis were also employed to facilitate the identification of candidate variants. Sanger sequencing confirmation and segregation analysis were also conducted for all variants of interest. Homozygous and heterozygous rare variants in *WNT10A*, *LRP6*, *LAMA3*, *KREMEN1*, *DKK1*, *COL17A1*, and *ANTXR1* were identified as known or potentially pathogenic in the studied families. Notably, *WNT10A* variants (c.697G>T, c.682T>A, and c.433G>A) were found in six families with isolated TA, one of which had a dual molecular diagnosis and presented also with a variant in *LAMA3* (c.1097G>A), segregating with tooth agenesis. Different variants in *KREMEN1* (c.146C>G, and c.773\_778del) were found in two families with additional ectodermal dysplasia findings. An indel variant in *LRP6* (c.3607+3\_6delAAGT) was found to segregate in one family, and functional assay suggested that the variant mRNA was subject to nonsense-mediated decay as predicted. A homozygous rare variant was found in *ANTXR1* (c.1312C>T) in one family. *ANTXR1* has been reported to be associated with GAPO syndrome. However, in our case, the patient was not affected with GAPO syndrome but oligodontia. To the best of our knowledge, this is the first report of association between homozygous *ANTXR1* gene mutation and TA. We also identified one family in which novel heterozygous variants in *DKK1*(c.548-4G>T), *COL17A1*(c.3277+3G>C), and *LAMA3*(c.2798G>T) were segregating with TA, suggesting potential oligogenic inheritance. In conclusion, our results support a major role for genes (*WNT10A*, *LRP6*, *KREMEN1*) encoding proteins that function in the WNT signaling pathway in the etiology of TA while revealing new candidate genes. In addition, mutational burden and oligogenic co-segregation was suggestive for complex inheritance contributing to improved understanding of the genetic etiology of familial TA.

**Clinical and molecular heterogeneity in VCP autosomal dominant inclusion body myopathy.** S. Al-Tahan<sup>1</sup>, E. Al-Obeidi<sup>1</sup>, M. Omizo<sup>2</sup>, J. Palmio<sup>3</sup>, M. Grafe<sup>4</sup>, Y. Harati<sup>5</sup>, B. Udd<sup>6,7</sup>. 1) Division of Genetics and Genomic Medicine, Depart, UC Irvine, Irvine, CA; 2) Oregon Osteoporosis Center, Bend, OR; 3) Neuromuscular Research Center, Tampere University and University Hospital, Neurology, Tampere, Finland; 4) Department of Pathology, Oregon Health and Science University, Portland; 5) Department of Neurology, Baylor College of Medicine, Houston, TX, USA; 6) Folkhälsan Institute of Genetics and the Department of Medical Genetics, Haartman Institute, University of Helsinki, Helsinki, Finland; 7) Vaasa Central Hospital, Department of Neurology, Vaasa, Finland.

**Introduction:** Our lab has focused on Autosomal Dominant Inclusion Body Myopathy (IBM) for almost two decades. Over forty missense mutations in the gene coding for valosin-containing protein (VCP) are associated with a unique autosomal dominant adult onset progressive disease associated with combinations of proximo-distal inclusion-body myopathy (IBM), Paget's disease of bone (PDB), frontotemporal dementia (FTD), and amyotrophic lateral sclerosis (ALS). We report the clinical, and molecular findings in four new patients/families carrying novel VCP mutations. Interestingly in two families, individuals also had Parkinson's disease (PD). We have recently identified **Results:** The novel VCP mutations included: c.473 G>A, p.M158I associated with IBM and PDB in addition to ALS; c.478 G>C, p.A160P associated with IBM, ALS and PD; c.383G>C, p.G128A IBM and PD. Interestingly patient with c.382G>T, p.G128C only had had non familial IBM. There was wide inter and intra-familial variation making genotype-phenotype correlations difficult in these families.

**Conclusions:** We report four novel mutations to the >50 previously reported in VCP disease associated with inclusion body myopathy, PDB, FTD and ALS. Furthermore with the addition of these families we have further established VCP in the etiology of PD. Previous cases associated with PD included p.R159C, p.R191Q, p.T262A, and p.P137L VCP mutations. Because of wide spectrum of mutations and heterogeneity establishing genotype-phenotype correlations is challenging. We however recommend routine testing of VCP in familial PD. By understanding the variability of clinical presentations clinicians will be better able to identify and diagnose VCP-related diseases and thus proactively manage associated treatable features more effectively.

**907W**

**Survey of patients with Ollier disease and Maffucci syndrome over Facebook compared to review of clinical literature.** C. Smith<sup>1</sup>, S.M. Robbins<sup>1,2,3</sup>, N.L.M. Sobreira<sup>1,3</sup>. 1) Johns Hopkins University School of Medicine, Baltimore, MD; 2) Predoctoral Training Program in Human Genetics, Baltimore, MD; 3) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD.

Ollier disease (OD) and Maffucci syndrome (MS) are rare disorders characterized by multiple enchondromas. OD is characterized by multiple enchondromas, with onset in early childhood, that are typically asymmetrical in distribution with a predilection for the appendicular skeleton. MS is characterized by multiple enchondromas distributed symmetrically in combination with vascular anomalies; about 25% of cases are noticeable at birth. Both disorders can cause multiple swellings on the extremities, deformity around the joints with limitations in joint mobility, scoliosis, bone shortening, leg-length discrepancy, gait disturbances, pain, and loss of function. The risk of developing a chondrosarcoma in OD and MS is up to 57%, and other malignancies have also been associated with these disorders. This clinical information about the natural history of OD and MS is based on a few cases described in the literature and most likely represent the extreme presentation of these disorders. The prevalence of other malignancies outside of chondrosarcomas is unknown. To address this gap in the natural history, we created a survey that was recently distributed directly to patients through Facebook. The survey has 84 questions and collects self-reported clinical and family history, molecular test results, and demographic information. Here we discuss the results of the survey's responses and compare to a review of the cases described in the literature. To date, 54 patients have answered the survey. Forty-eight patients have OD, and 2 have MS. Twenty-four have more than 10 enchondromas. Twelve have enchondromas affecting their ribs, 1 has the spine affected, 1 has the skull affected, and 2 have their scapula affected. Three patients also have exostoses. Nine had chondrosarcomas. Ten have hemangiomas, and 1 had a spindle cell hemangioma. Two had other kind of malignancies: a brain tumor not specified and a grade II astrocytoma. Seven had developmental delays, and 2 have intellectual disabilities. Two have a family history of enchondromatosis. This information will be compared to the data collected in a literature review of 197 publications found in Pubmed. We expect that the analysis of the survey will give us a better understanding of the natural history, severity and prognosis of these diseases, as well as the prevalence of chondrosarcomas and other malignancies in these patients. This survey may also uncover unexpected diagnoses in these patients.

**908T**

**Dyggve-Melchior-Clausen syndrome, a case report with typical family tree.** *L. Mora, F. Suarez, A. Paredes.* Medical Genetics, Pontificia Universidad Javeriana, Bogota, Colombia.

**Introduction:** Dyggve-Melchior-Clausen (DMC) syndrome belongs to the group of spondyloepimetaphyseal dysplasias. Is caused by mutation of the DYM gene, encodes for Dymeclin, a protein that is involved in skeletal development and brain function, the inheritance pattern could be autosomal recessive or X-linked recessive. Patients presents short trunk, microcephaly, pectus carinatum and intellectual disability, characteristically known as a progressive dwarfism, very similar to the clinical presentation of mucopolysaccharidosis (MPS), therefore genetic testing is necessary to confirm a diagnosis. **Case presentation:** We present a Colombian family of consanguineous parents and five children, four of them referred for study of disproportionate short stature, intellectual disability and facial dysmorphism (coarse facies), with the suspicion of MPS were requested, extension studies: echocardiogram was normal, dorso-lumbar vertebrae radiography which evidences kyphosis, cuneiform vertebral bodies some members with platyspondyly, dysplastic iliac crests, long-bone radiographic with metaphyseal abnormalities and enzymatic tests without alterations. Thinking in differential diagnosis of MPS molecular study was performed confirming homozygous mutation on DYM gene, associated with Dyggve-Melchior-Clausen disease. **Discussion:** Dyggve-Melchior-Clausen syndrome is a progressive spondyloepimetaphyseal dysplasia, result of mutations in DYM gene, located in 18q12-12.1 chromosomal region, codify for dymeclin protein that participated in bone development, necessary for correct organization of Golgi apparatus, perhaps its role within the cell is unknown. Lack of this protein is associated with two pathologies Smith-Mccort Dysplasia and Dyggve Melchior Claussen. The first one differs from our exposed case because it does not have intellectual disability. Other differential diagnosis is morquio disease, but has specific radiological and enzymatic findings, like in this family. Due to the clinical and the low prevalence of DMC syndrome it could be confused with MPS and subdiagnosed, been necessary the molecular study. **Conclusion:** Over time the correlation phenotype-genotype of patients with DMC syndrome will allow functional studies to understand differences between this disorders or a possible spectrum disease and future treatments.

**909F**

**Case series of individuals with novel syndromic phenotypes characterized by enchondromas and/or exostoses with or without vascular anomalies.** *S.M. Robbins<sup>1,2,3</sup>, C. Smith<sup>1</sup>, B. Cohen<sup>1</sup>, E. Lie<sup>1</sup>, C. Haldeman-Englert<sup>4</sup>, E. Boyd<sup>4</sup>, J. Hoover-Fong<sup>1</sup>, M. Cernach<sup>5</sup>, N.L.M. Sobreira<sup>1,3</sup>.* 1) Johns Hopkins University School of Medicine, Baltimore, MD, USA; 2) Predoctoral Training Program in Human Genetics, Johns Hopkins University, Baltimore, MD, USA; 3) Institute of Genetic Medicine, Johns Hopkins Hospital, Baltimore, MD, USA; 4) Fullerton Genetics Center Mission Health, Asheville, NC, USA; 5) Escola Paulista de Medicina, Sao Paulo, Brazil.

Enchondromatoses are a group of 9 rare diseases characterized by multiple enchondromas. Here we describe 4 individuals with novel syndromic phenotypes characterized by enchondromas and/or exostoses with or without vascular anomalies. Case 1 is a 23 yo male with a history of a region of epidermal and dermal atrophy on the left chest, lymphoepithelioma of the nasopharynx with parapharyngeal involvement, multiple enchondromas, an exostosis, and a vascular anomaly affecting his chest, back and left arm. He also had developmental delay and has intellectual disability. Case 2 is a 14 yo with history of developmental delay, hypotonia, swallowing difficulties, vocal cord dysfunction, mild cerebral palsy, immunodeficiency, short stature, low weight, a vascular anomaly in the right arm noticed at 1 year of age, and enchondromas in his hands and feet first diagnosed at 3 years of age. DNA extracted from one of his enchondromas was negative for variants in *IDH1* and *IDH2*. Case 3 is a family where the proband (8 yo), his mother, maternal uncle, and maternal grandfather are affected with short stature, acromesomelia, and rhizomelia. The proband also has attention deficit, epicanthal folds, a broad nasal bridge, pectus excavatum, asymmetric sternum, kyphosis, brachydactyly, increased upper to lower segment, decreased arm span to height ratio, and exostoses. Case 4 is a 4 yo female with disproportionate short stature (short trunk), frontal bossing, strabismus, conical teeth, microdontia, tooth agenesis, short neck, asymmetric chest, fused ribs, pectus carinatum, scoliosis, platyspondyly, irregular ilium, clinodactyly of 5th fingers, dysplastic nails, enchondromas and asymmetric legs size. For each of these cases, we performed whole exome sequencing in the affected proband and family members or in the proband's germline and tumor DNA. Analysis in these cases did not reveal pathogenic variant in a known disease gene associated with similar or overlapping phenotypes, but candidates have been submitted to GeneMatcher, and further functional studies are being performed to investigate their pathogenicity. In summary, here we expand the clinical variability of the phenotypes associated with enchondromatoses. We anticipate that the identification of the molecular basis of these cases will uncover pathways involved in the mechanism by which enchondromas, exostoses and vascular anomalies arise in patients with multiple enchondromas with unknown molecular basis.

## 910W

**Biallelic mutations in FLNB cause a skeletal dysplasia with 46,XY gonadal dysgenesis by increasing  $\beta$ -catenin expression.** K. Upadhyay<sup>1</sup>, J. Loke<sup>1</sup>, V. Wu<sup>1</sup>, B. Taragin<sup>2</sup>, H. Ostrer<sup>1</sup>. 1) Albert Einstein College of Medicine, Bronx, NY; 2) Montefiore Medical Center, Bronx, NY.

Filamin B (FLNB) functions as a switch that can affect chondrocyte development and endochondral bone formation through a series of signaling molecules and transcription factors that also affect Sertoli cell development. Here, we report a subject with a novel skeletal dysplasia and co-existing 46,XY gonadal dysgenesis and biallelic mutations in *FLNB*. The presence of these mutations *FLNB* (NM\_001457.3) c.2890T>C p.F964L and c.4730C>T p.A1577) increase binding of FLNB protein to a signal transduction complex that includes the MAP3K1 and RAC1 proteins and activation of  $\beta$ -catenin relative to wildtype. These mutations have different effects on the phosphorylation of intermediates in the MAP kinase pathway and the expression of SOX9; thus, their mechanism of action varies from those reported previously for loss-of-function mutations in *SOX9* and gain-of-function mutations in *MAP3K1*. These findings highlight that subjects with skeletal dysplasias or 46,XY gonadal dysgenesis should be assessed for dual phenotypes. Variants in newly identified candidate chondrogenesis or sex determining genes can be annotated for pathogenic functional effects on the activities of  $\beta$ -catenin, SOX9 and their intermediate regulators.

**Introduction:** Congenital scoliosis (CS) is a common type of vertebral malformation. The genetic basis of a significant portion of sporadic CS has been elucidated and explained by a model of compound inheritance. The observation of CS in selected patients with either deletion of the 16p11.2 region or point mutations in *TBX6*, a critical gene mapped to the same chromosomal locus, led to the investigation of the molecular pathogenesis of CS among these individuals (Wu 2015 *NEJM*, 372: 341-350). **Methods:** Although it has been clearly demonstrated that *TBX6*-associated CS (TACS) has unique molecular genetic underpinnings, the clinical characterization remains less well established. We enrolled two cohorts (PUMCH and JSCRG) of CS patients. All patients were divided into two groups according to the genetic characteristics of variant alleles at the *TBX6* locus, and we compared the clinical data based on specific genetic types. Furthermore, the animal model of TACS harboring compound *TBX6* heterozygous mutations was generated by using CRISPR/Cas9. A systemic detailed phenotypic evaluation of the patients and the mice was also conducted. **Results:** Of the 332 Chinese cases, we identified 34 patients with *TBX6* loss-of-function mutations *in trans* with the risk haplotype at the second allele and classified them as TACS. The remaining patients were classified into the non-TACS (NTACS) group. The patients with TACS were significantly younger at onset (Avg age 7.76 $\pm$ 4.70y;  $p=1\times 10^{-4}$ ). For the vertebral defects, failure of formation was more commonly seen in the TACS group. Vertebral anomalies were significantly more extensive in the NTACS group. Remarkably, all 34 TACS patients uniformly exhibited a phenotype with one or more hemivertebrae or butterfly vertebrae. Involvement of the lower part of the spine was more prevalent in TACS. These phenotypic features were confirmed by the replication study in the Japanese cohort of 96 CS cases. Similarly, vertebral hypoplasia was the most common malformation observed in the *Tbx6*<sup>tm</sup> mice, and most vertebral defects (92.31%) involved the lower part of the spine (T10-S4). **Conclusions:** TACS share the same genetic etiology and have a unique and relatively uniform clinically recognizable presentation. TACS represents a distinct clinical entity, with specific etiologic genetic and molecular underpinnings, that separate it from the other CS for which the mechanisms remain elusive.

**Multicentric carpotarsal osteolysis syndrome in mother and daughter misdiagnosed as juvenile rheumatoid arthritis.** K. Chen<sup>1</sup>, M.Z. Souza<sup>1</sup>, M.F.F. Soares<sup>2</sup>, M.I. Melaragno<sup>1</sup>, V.A. Meloni<sup>1</sup>. 1) Genetics Division, Department of Morphology and Genetics, Universidade de Sao Paulo, SP, Brazil; 2) Department of Imaging Diagnosis, Universidade de Sao Paulo, SP, Brazil.

We report on two cases of Multicentric Carpotarsal Osteolysis syndrome (MCTO) previously misdiagnosed as Juvenile Rheumatoid Arthritis (JRA). MCTO (MIM #166300) is a rare skeletal disorder that in early childhood mimicks JRA, and is characterized by articular pain, progressive osteolysis, predominantly of the carpal and tarsal bones, minor facial anomalies, and oftentimes nephropathy and chronic renal failure, with autosomal dominant inheritance. The disease is caused by heterozygous mutation in the *MAFB* gene (608968), mapped on chromosome 20q12, reported on at least 35 patients. We report on a 13-year-old female patient with skeletal deformities, whose mother presented similar deformities but had been misdiagnosed as JRA. The patient is the first offspring of unrelated parents and has a nine-year-old brother and a seven-year-old maternal half-sister, both without similar symptoms. She presented unremarkable antenatal and postnatal histories, and normal growth and psychomotor development. At the age of 12, she developed pain in the upper limbs and feet, progressive joint restriction, and finger swelling. The first genetic evaluation at the age of 13, she presented mild facial dysmorphic features, flexion contracture of the right elbow, radial deviation of hands, swollen fingers and *pes cavus*. The proband's skeleton X-rays showed osteopenia, carpal and tarsal bones dissolution, proximal and distal metacarpal and metatarsal erosions. The mother's radiological findings indicated progressive bone resorption as the carpal and tarsal bones were completely destroyed. The clinical history and findings and the radiological abnormalities are consistent with MCTO. Similar to other cases of MCTO, this one was misdiagnosed and was followed up as JRA. For a precise assessment, complementary tests for renal function monitoring were requested. In this family, the siblings must be evaluated and monitored since they present 50% risk for the disease. The correct and early diagnosis allows the appropriate follow-up and specific therapeutics for changing the natural history of the disease. Studies indicate that drugs targeting *Mapk* signaling such as anti-RANKL may perform better than bisphosphonates in the treatment of the bone disease of MCTO, thus presenting as an alternative therapeutics. (Financial support of FAPESP).

**Recurrence of perinatal lethal osteogenesis imperfecta due to parental mosaicism for a novel dominant mutation in COL1A1.** A. Ruiz-Herrera<sup>1,2</sup>, M. Abreu-González<sup>3</sup>, Y. Mena<sup>2</sup>, V. Flores<sup>2</sup>. 1) Medical Genetics, Hospital de Especialidades Pediátrico de León. León, Guanajuato, Mexico; 2) Medical Genetics, Hospital Médica Campestre. León, Guanajuato, Mexico; 3) Genos Médica, Centro Especializado en Genética. Mexico City, Mexico.

**Introduction.** Perinatal lethal Osteogenesis Imperfecta (PL-OI, MIM #166210) is a skeletal dysplasia that is frequently attributable to heterozygous *de novo* variants in genes encoding type 1 collagens (*COL1A1* and *COL1A2*). However, recurrence can take place in siblings with normal parents. In these cases, the two possibilities are germline mosaicism and autosomal recessive inheritance. **Objective.** We present detailed clinical, radiographic, and molecular findings of a newborn with PL-OI due to parental mosaicism for a novel heterozygous variant in *COL1A1*. **Case Presentation.** The index case is a male newborn patient, born to a healthy young non-consanguineous Mexican couple with medical history of spontaneous abortion and a previous male son with PL-OI. In the proband, PL-OI was suspected prenatally until the third trimester. The patient was born at 35 weeks gestation with dark blue sclerae, absence of cranial ossification, multiple fractures, and bilateral clubfeet; and died shortly after birth. **Materials and Methods.** DNA was isolated from a buccal swab of the proband, and a next-generation sequencing panel for the 18 genes involved in Osteogenesis Imperfecta was performed. Both parents were screened for the *COL1A1* variant in DNA extracted from blood and oral samples in order to detect a possible mosaicism. **Results.** A novel heterozygous variant (NM\_000088.3:c.59C>A, NP\_000079.2:p.Thr20Lys) in *COL1A1* was detected in the proband and was confirmed by Sanger sequencing; however it was not found in none of the samples from the parents. **Conclusions.** We report a novel variant in PL-OI, with recurrence in a family due to suspected germline mosaicism in one of the parents.

**914T**

**Case report of a mild skeletal phenotype secondary to mutations in *LBR* gene.** *M.D.F. Carvalho*<sup>1,2,3,4</sup>, *K.M. Carvalho*<sup>1,4</sup>, *I.F. Carvalho*<sup>2,4</sup>, *D.P. Cavalcanti*<sup>5,6</sup>, *E.D.F. Carvalho*<sup>1,2,3,4</sup>. 1) Ceara State University, Fortaleza, CE 04013-000, Brazil; 2) Christus University Center, Fortaleza, CE, 04013-000, Fortaleza, Ceara, Brazil; 3) APAE, Fortaleza, Ceara, Brazil; 4) Genpharma Consultoria Farmaceutica e Genetica, Ltda, Fortaleza, CE 60160-230, Brazil; 5) Skeletal Dysplasia Group, Department of Medical Genetics, Faculty of Medical Sciences, State University of Campinas, Campinas, SP, Brazil; 6) Perinatal Genetics Program, Department of Medical Genetics, Faculty of Medical Sciences, State University of Campinas, Campinas, SP, Brazil.

Mutations in the The Lamin B receptor (*LBR*) gene were described capables to affect neutrophil and sterol reductase activity. Compound heterozygosity or homozygosity mutations in *LBR* gene can result in different clinical phenotypes: the perinatal lethal autosomal recessive skeletal dysplasia called Greenberg skeletal dysplasia (GSD) and milder skeletal phenotypes whose association with this gene was recently discovered. Heterozygous carriers do not present clinical manifestations but usually have Pelger–Huet anomaly (PHA) that result in a bilobed neutrophil nucleus. We report a child who has mild skeletal dysplasia associated with PH. The proband is an 8-month-old female infant that is the second child of a nonconsanguineous and healthy couple. There was no family history of congenital abnormalities. The prenatal ultrasound exams showed micromelia. The patient was born at term by elective cesarean section, at 36 weeks of gestation, the birth weight was 2880 g, birth height 42 cm and occipitofrontal circumference (OFC) 35,5 cm. Apgar scores were 9 and 9 at 1 and 5 min, respectively. At birth, short limbs were noted and with 1 month and fifteen days old of age the physical examination disclosed: 49 cm of height, normal OFC, eumorphic face and normal hands and feet. At 8-months-old the clinical exam showed discrete decreasing of severity of the rhizomelic shortening of the limbs and a normal neuropsychomotor development. Radiographs( at 15 days of age) showed: shortening of long bones with possible metaphyseal involvement and mild generalized platyspondyly. G-banded karyotype and echocardiography were normal. Whole exome sequencing revealed two novel mutations in the *LBR* gene: c.1756C>A (p.Arg586Ser) and c.43C>T (p.Arg15Ter). This and previously reported cases suggest that mutations in *LBR* gene can result in a spectrum of phenotypes, especially associated with skeletal manifestations.

**Loss of inhibition of mTOR signaling in a new form of a metaphyseal chondrodysplasia due to a recessively inherited mutation in salt inducible kinase 3 (*SIK3*).** *F. Csukasi*<sup>1</sup>, *I. Duran*<sup>1</sup>, *M. Barad*<sup>1</sup>, *J. Martin*<sup>1</sup>, *D.H. Cohn*<sup>1,4,5</sup>, *D. Krakow*<sup>1,2,3,5</sup>. 1) Department of Orthopaedic Surgery, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA; 2) Department of Human Genetics, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA; 3) Department of Obstetrics and Gynecology, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA; 4) Department of Molecular, Cell, and Developmental Biology, University of California, Los Angeles, Los Angeles, CA; 5) International Skeletal Dysplasia Registry, University of California, Los Angeles, Los Angeles, CA.

Newer genetic technologies have allowed for the identification of causative genes in uncharacterized disorders. Here we describe a recessively inherited unclassified metaphyseal chondrodysplasia characterized by extremely widened/flared metaphysis with irregular ossifications, moth-eaten long bones, fragmentation of proximal metacarpals, coronal clefts in the cervical spine region, absence of pubic bone ossification and widened spheno-occipital synchondrosis. Both patients (siblings) also manifested immunodeficiency, muscle weakness and developmental delay. Exome analysis identified a homozygous missense mutation in the kinase domain of the gene encoding salt-inducible kinase 3 (*SIK3*). Modeling of the protein showed that the amino acid change (p.Arg129Cys) is likely to compromise the ability of the mutated kinase to phosphorylate its substrate. Patient derived fibroblasts showed diminished amount of *SIK3* protein, but not cDNA levels, indicating that the *SIK3* mutation affects the stability of the protein. We found that *SIK3* regulates the mechanistic target of rapamycin (mTOR). *SIK3* acts as a negative regulator of mTOR complex 1 (mTORC1) and 2 (mTORC2) as evidenced by reduced phosphorylation of their targets S6K1, S6 and AKT when WT *SIK3* is overexpressed in chondrocytes. Contrarily, mutated *SIK3* is not fully active and cannot negatively regulate. *SIK3* is expressed in the cartilage growth plate, particularly in proliferating and hypertrophic chondrocytes where it is co-expressed with mTORC1 and mTORC2 components. Our results reveal a role for *SIK3* in producing a previously uncharacterized skeletal disorder and demonstrate that in part, the phenotype results from misregulation of mTOR activity.

**Enzyme replacement therapy in perinatal hypophosphatasia: Case report and recommendations for clinical practice.** L. Dupuis<sup>1</sup>, G. Costain<sup>1</sup>, G. Nimmo<sup>2</sup>, A.M. Moore<sup>2</sup>, L. Munroe<sup>2</sup>, J. Harrington<sup>3</sup>, A. Williams<sup>4</sup>, R. Zlotnik Shaul<sup>4</sup>, C. Rockman-Greenberg<sup>5</sup>, M. Offringa<sup>5</sup>, P. Kannu<sup>5</sup>. 1) Division of Clinical Genetics, Hospital for Sick Children, Toronto, Ontario, Canada; 2) Division of Neonatology, Hospital for Sick Children, Toronto, Ontario, Canada; 3) Division of Endocrinology, Hospital for Sick Children, Toronto, Ontario, Canada; 4) Department of Bioethics, Hospital for Sick Children, Toronto, Ontario, Canada; 5) Department of Paediatrics and Child Health, University of Manitoba, Winnipeg, Manitoba, Canada.

We present the case of a newborn with respiratory distress transferred to the Hospital for Sick Children. She required CPAP in the immediate neonatal period, then was intubated for respiratory failure beginning on day 3. On examination, she was found to have depressible skull bones, large anterior fontanelle, bell-shaped chest, and rhizomelia. Based on X-rays findings, undetectable serum ALP activity and markedly elevated urine phosphoethanolamine, a diagnosis was made of perinatal hypophosphatasia (HPP), a rare metabolic bone disorder. This was later confirmed by the identification of known pathogenic variants (compound heterozygote) in the *ALPL* gene. Enzyme replacement therapy (ERT) is a newly approved and costly disease-modifying treatment for HPP. Given that ERT is an orphan drug and that HPP is a rare metabolic bone disorder, it is important to share information concerning individuals' response to ERT, as any one centre's familiarity with its use will be limited. Two recently completed clinical trials have reported generally positive outcomes in infants and young children with life-threatening HPP. Here, we describe our patient with perinatal HPP in whom treatment with ERT was not successful. Lessons learned from this case are of importance in making decisions for treatment in patients with new diagnoses of perinatal HPP. We propose a basic protocol for initiating and monitoring treatment of neonates with HPP. We also discuss practical and ethical challenges related to treatment of a rare disease with a costly new drug within the context of a publicly-funded healthcare system.

**917T**

**Spinal manifestations of patients with musculocontractural Ehlers-Danlos syndrome caused by CHST14/D4ST1 deficiency (mcEDS-CHST14).** T. Kosho<sup>1,2</sup>, M. Uehara<sup>3</sup>, H. Kato<sup>3</sup>, J. Takahashi<sup>3</sup>. 1) Center for Medical Genetics, Shinshu University Hospital, Matsumoto, Japan; 2) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 3) Department of Orthopedics, Shinshu University School of Medicine, Matsumoto, Japan.

**Background:** Musculocontractural Ehlers-Danlos syndrome caused by CHST14/D4ST1 deficiency (mcEDS-CHST14) is a recently delineated form of EDS and also the first disorder affecting dermatan sulfate (DS) biosynthesis. Clinical characteristics include craniofacial, skeletal, visceral, and ocular malformations; and progressive cutaneous, skeletal, vascular, and visceral fragility-related manifestations. Though spinal deformities are one of the most important complications having a serious impact on the patients' quality of lives and activities of daily living, they have not been systematically investigated to date. **Materials and Methods:** Shinshu University Hospital has the largest cohort of patients with mcEDS-CHST14. The cohort includes 10 Japanese patients: five male and five female subjects of an age of  $11.8 \pm 7.1$  (mean  $\pm$  SD) years at the first visit. We comprehensively reviewed the prevalence of spinal lesions, vertebral malformations, changes in severity according to the ages, and atlantoaxial subluxation (AAS), through whole spine radiographs in a standing position and dynamic radiographs focused on the cervical spine.

**Results:** Six patients (60%) had a scoliosis with a Cobb angle  $\geq 10^\circ$ , and one had a severe scoliosis with a Cobb angle  $\geq 45^\circ$ . Six patients (60%) had a kyphosis at the thoracolumbar junction with a kyphotic angle  $\geq 10^\circ$ , and three (30%) had a severe thoracolumbar kyphosis with a kyphotic angle  $\geq 50^\circ$ . All patients with a severe thoracolumbar kyphosis had thoracic lordosis. The transitional level of kyphosis occurred in the thoracolumbar junctional level. Five patients (50%) had a cervical kyphosis, all of whom had more than  $20^\circ$  kyphosis at the thoracolumbar level. Two patients (20%) had AAS. Eight patients (80%) had vertebral malformations. **Conclusion:** This is the first series describing spinal deformities of patients with mcEDS-CHST14, demonstrating scoliosis, kyphosis, cervical kyphosis, and vertebral body malformations as frequent manifestations; also implicating potential importance of dermatan sulfate in the development and maintenance of human vertebral system.

## 918F

**Longitudinal growth curves for OI caused by structural mutations in type I collagen.**

*J. Marini<sup>1</sup>, V. Nakhate<sup>1</sup>, C. Abbott<sup>1</sup>, L. Barber<sup>1</sup>, A. Blissett<sup>1</sup>.* 1) Section on Heritable Disorders of Bone and Extracellular Matrix, NICHD/NIH, Bethesda, MD; 2) Office of the Clinical Director, NICHD/NIH, Bethesda, MD.

**Objective:** Growth deficiency is a cardinal feature of OI caused by collagen structural mutations, which in practice refers to Types III and IV OI. Growth deficiency is generally marked by the first year of life and progresses thereafter. OI-specific longitudinal growth charts are need to guide caregivers and families. **Methods:** From 100 participants in the NICHD/NIH longitudinal research program on OI, we compiled length, weight and head circumference from ages 2-17. Of the total, 55 are females, 56 have type IV OI and 56 have mutations in *COL1A1*. Data was binned into half year intervals and was analyzed by gender, type and mutated gene using non-linear multilevel modeling (SPSS) with percentile curves constructed using the GAMLSS package from R. **Results:** Sex and OI type had significant effects on stature and weight while the specific collagen gene causing the OI did not. The effect of OI type was greater than that of gender. Interestingly, head circumference was not significantly different by gender, type or mutated gene. OI-specific standard curves for height and weight were generated by gender and type. When OI height curves are superimposed on USA CDC growth curves, types III and IV curves overlap in both girls and boys, with the type III 50<sup>th</sup> centile curve similar to the type IV 5<sup>th</sup> centile in both genders. In girls, the type III 95<sup>th</sup> centile curve exceeded the type IV 50<sup>th</sup> centile curve, while the reverse occurs in boys. In both genders, the type IV 95<sup>th</sup> centile curve overlaps the lower general population curves. A pubertal growth spurt is generally not seen in type III OI, and is blunted in type IV. **Conclusions:** OI type is a stronger discriminating factor than gender for OI growth, while curves do not differ for *COL1A1* vs *COL1A2* mutations. OI-specific growth curves will facilitate care.

## 919W

**Gain of function germline mutations in *ABL1* are associated with congenital heart defects, skeletal malformations, and failure to thrive.**

Eng<sup>1,2</sup>, M. Walkiewicz<sup>1,2</sup>, F. Xia<sup>1,2</sup>, S.E. Plon<sup>1,8,9</sup>, J.R. Lupski<sup>1,3,8</sup>, C.P. Schaaf<sup>9</sup>.* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Genetics, Houston, TX; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 4) Department of Pediatrics, Tawam Hospital, Al-Ain, Abu Dhabi, United Arab Emirates; 5) Department of Pediatrics, College of Medicine & Health Sciences, United Arab Emirates University, Al-Ain, Abu Dhabi, United Arab Emirates; 6) Rare Diseases Institute, Children's National Health System, Washington DC; 7) Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; 8) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 9) Texas Children's Hospital, Houston, TX; 10) Department of Pediatrics, The University of Texas Medical School at Houston, Houston, TX.

Abelson murine leukemia viral oncogene homolog 1 gene, *ABL1*, is a proto-oncogene which encodes a non-receptor tyrosine kinase. Although the gene is well known as part of the fusion gene BCR-ABL on Philadelphia chromosome in leukemia cancer cells, inherited germline changes in *ABL1* had not been reported in patients until recently. We first reported that *ABL1* germline variants are associated with an AD disorder characterized by congenital heart disease, skeletal abnormalities, and failure to thrive [PMID: 28288113]. Here we provide characterization of eight affected individuals in five unrelated families identified from the clinical exome cohort in our laboratory. The eight individuals shared similar syndromic features including dysmorphic facial features (8/8), skeletal abnormalities (8/8), congenital heart disease (6/7), failure to thrive (6/7), joint laxity or arthritis (5/8), skin anomalies (4/8), GI issues (4/8) and male genital/sexual abnormalities (3/4). The recurrent variant, c.734A>G (p.Tyr245Cys), was seen in seven affected individuals from families 1-4 as either *de novo* or disease co-segregating. A *de novo* c.1066G>A (p.Ala356Thr) variant was identified in the eighth patient (family 5). Of note, the p.Tyr245 residue is one of the two key tyrosine residues required for autophosphorylation-induced activation of ABL1 intrinsic kinase activity, while p.Ala356 plays an important role in myristoylation induced autoinhibition function. We transfected the human embryonic kidney 293T cells with wild-type or mutant constructs and compared the endogenous tyrosine phosphorylation levels of whole cell lysates and of the specific ABL1 substrates. We observed increased phosphorylation suggesting increased ABL1 kinase activity associated with both substitutions. Intriguingly, severe congenital malformations have been reported in fetuses exposed to imatinib, a selective tyrosine kinase inhibitor drug, which inhibits BCR-ABL and is used in the treatment of Philadelphia-chromosome positive CML, raising concern for potential teratogenic effects of the drug. Our findings, together with previously reported teratogenic effects of selective BCR-ABL inhibitors in humans and developmental defects in *Abi1* knock-out mice, suggest *ABL1* plays an important role and needs to be tightly regulated during organismal development. The phenotypic features in our patients suggest *ABL1*-related disorder as a differential diagnosis for patients suspected of connective tissue disorders.

**920T****Investigation of the molecular basis of familial and isolated Tarlov cysts.**

M. Muriello<sup>1</sup>, C. Boehm<sup>1</sup>, K. Murphy<sup>2</sup>, D. Valle<sup>1</sup>, H. Dietz<sup>1</sup>, N. Sobreira<sup>1</sup>: 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 2) Department of Radiology, University of Toronto, Toronto, Canada.

Tarlov cysts (TCs) are extrathecal cerebrospinal fluid-filled cavities that develop at the junction of the dorsal ganglion and posterior nerve root between the endoneurium and perineurium. The cause of the formation of TCs is unclear and hypotheses include microcommunication with the subarachnoid space and a ball-valve mechanism allowing CSF influx and restricting efflux, secondary to inflammation or trauma and/or a developmental predisposition. Symptoms are caused by involvement of nerve roots and include pain and neurologic deficits. TC disease is a frequently underdiagnosed condition with a prevalence ranging from 2 to 15%. Cases associating TCs with Marfan and Ehlers-Danlos syndromes have been reported. Familial cases suggest the possibility of autosomal dominant inheritance. Here we report the results of whole exome sequencing (WES) of a cohort of 20 affected individuals with TCs from 14 families. Initial analysis of WES data focused on identifying pathogenic or likely pathogenic variants related to connective tissue disease. Both autosomal dominant and recessive inheritance models were investigated using the PhenoDB Variant Analysis tool to select rare coding or UTR variants with mean allele frequency (MAF) < 1% and < 5% in the 1000 genomes and Exome Variant Server databases. Next, we also selected the genes that were mutated in 3 or more of the 14 probands. Our analysis identified 33 genes, including *PKHD1*, *LAMB3*, and *FAT4*. Pathogenic variants in *PKHD1* are known to cause autosomal recessive (AR) polycystic kidney and liver disease. Pathogenic variants in *LAMB3*, which encodes a widely-expressed laminin protein, cause both AR epidermolysis bullosa and AR amelogenesis imperfecta. *FAT4*, aka protocadherin, is known to play a key role in vertebrate planar cell polarity as well as several other signaling pathways. *FAT4* knockout leads to cystic kidney disease in *Drosophila*. *FAT4* pathogenic variants cause AR Van Maldergem and Hennekam syndromes. In our cohort, the patients with variants in these genes were heterozygous. However, because of the association of these phenotypes with cyst formation, we prioritized the investigation of the variants in these genes in our patients. It is unknown if the individuals with any of the conditions caused by these genes or their heterozygous relatives have TCs but the investigation of TCs in these patients may lead to the discovery of the molecular basis of the non-syndromic presentations of disease.

**921F*****TMEPAI* mutation causes MFS/LDS-like phenotypes in 2 Japanese families.**

H. Morisaki<sup>1,2,3</sup>, I. Yamanaka<sup>3</sup>, T. Ohata<sup>4</sup>, T. Kosho<sup>5</sup>, K. Waku<sup>6</sup>, Y. Fukushima<sup>6</sup>, M. Masuno<sup>6</sup>, K. Takahashi<sup>7</sup>, T. Watabe<sup>7</sup>, T. Morisaki<sup>2,3</sup>: 1) Saka-kibara Heart Institute, Tokyo, Japan; 2) Tokyo University of Technology School of Health Sciences, Tokyo, Japan; 3) National Cerebral and Cardiovascular Center, Osaka, Japan; 4) Okinawa Prefectural Hospitals, Okinawa, Japan; 5) Shinshu University Graduate School of Medicine, Nagano, Japan; 6) Kawasaki Medical School, Okayama, Japan; 7) Tokyo Medical and Dental University, Tokyo, Japan.

To date, several genes have been identified to be responsible for hereditary aortopathies including systemic connective tissue disorders such as Marfan syndrome (MFS) and Loey-Dietz syndrome (LDS). Some of these genetic mutations were found to cause high transforming growth factor (TGF)- $\beta$  signaling. To identify new genes responsible for these diseases, 304 patients with MFS/LDS-like features and young aortopathy negative in *FBN1*, *TGFBR1*, *TGFBR2*, *TGFB2*, *TGFB3* or *SMAD3* mutation were subjected to exome sequencing. Three patients with family history of skeletal and/or aortic features resembling MFS/LDS were identified to have a novel mutation in *TMEPAI*. Case 1 was a 43y tall male with funnel chest, arachnodactyly and a history of osteosarcoma with leg amputation in childhood. His mother was also tall and had abdominal aortic aneurysm. His 13y daughter (Case 2) and 11y son (Case 3) were both tall and showed funnel chest, dural ectasia and arachnodactyly without lens dislocation. Case 2 had scoliosis and mitral valve prolapse. Case 3 showed mild aortic root dilatation. Genetic analysis revealed no pathogenic gene variation in known MFS/LDS disorders in these patients. Exome sequencing revealed candidate variants in 12 genes and only 3 of them (*TMEPAI*: c.624\_625insC, p.S209Qfs; *AP5M1*: c.A262T, p.I88L; *ESRRB*: c.C156G, p.H52Q) were segregated with similar stature and deformities in this family members. In addition, Case 4, 33y female in unrelated family, showing arachnodactyly with aortic and axillar arterial dissection, revealed to have the same mutation of *TMEPAI*. Since all individuals with *TMEPAI* mutation showed MFS/LDS habitus and some had aortic diseases, *TMEPAI* mutation were segregated with these phenotypes. Then, we studied the expression of fibronectin after TGF- $\beta$ 2 stimulation and the patient's fibroblasts with the *TMEPAI* mutation showed significant upregulation of fibronectin than control fibroblasts, suggesting upregulation of TGF- $\beta$  signals. It was reported that *TMEPAI* suppresses TGF- $\beta$  signals and its overexpression promotes progression of prostate cancer. Since *TMEPAI* gene plays an important role in regulation of TGF- $\beta$  signals, it is thought that *TMEPAI* mutation can cause MFS/LDS-like features. This is the first report of *TMEPAI* mutation found in familial cases with MFS/LDS-like features. Based on these results, we conclude that *TMEPAI* is essential not only for cancer progression but also for systemic connective tissue disorders similar to MFS/LDS.

**A distinct cutaneous blistering phenotype with multi-system manifestations caused by a mutation in CD151, the 20th causative gene in epidermolysis bullosa.** H. Vahidnezhad<sup>1,2</sup>, L. Youssefian<sup>1,3</sup>, A. Saeidian<sup>1</sup>, H. Mahmoudi<sup>1</sup>, A. Touati<sup>1</sup>, A. Kajbafzadeh<sup>5</sup>, J. McGrath<sup>6</sup>, S. Zeinali<sup>1,7</sup>, P. Fortina<sup>8</sup>, J. Uitto<sup>1</sup>. 1) Department of Dermatology and Cutaneous Biology, Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, Pennsylvania, USA;; 2) Molecular Medicine Department, Biotechnology Research Center, Pasteur Institute of Iran, Tehran, Iran; 3) Department of Medical Genetics, Tehran University of Medical Sciences, Tehran, Iran; 4) Department of Dermatology, Razi Hospital, Tehran University of Medical Sciences, Tehran, Iran; 5) Paediatric Urology Research Center, Department of Urology, Children's Hospital Medical Center, Tehran University of Medical Sciences, Tehran, Iran; 6) St. John's Institute of Dermatology, King's College London (Guy's Campus), UK; 7) Kawsar Human Genetics Research Center, Tehran, Iran; 8) Department of Cancer Biology, Sidney Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, Pennsylvania, USA.

Epidermolysis bullosa (EB) is caused by mutations in as many as 19 distinct genes. We have developed a next generation sequencing (NGS) panel targeting genes known to be mutated in EB. This panel includes *CD151*, encoding a transmembrane tetraspanin CD151 expressed in keratinocytes. The NGS panel was applied to a cohort of 92 consanguineous families, consisting of 134 individuals of unknown subtype of EB. To direct the bioinformatics analysis to appropriate candidate genes, we applied a genome-wide homozygosity mapping with a SNP-based array consisting of 550,000 markers. In one family, a homozygous *CD151* mutation (NM\_139029; c.351+2T>C) at the canonical splice junction at intron 4/exon 5 border was identified, predicting aberrant splicing. RT-PCR confirmed deletion of the entire exon 5 consisting of 75 bp and encoding 25 amino acids. The in-frame deletion resides within the third transmembrane domain of CD151, suggesting aberrant membrane targeting of the protein. Immunofluorescence of skin and Western analysis with a monoclonal antibody revealed the absence of the CD151 epitope. Transmission electron microscopy showed intracellular disruption and cell-cell dysadhesion of keratinocytes in the lower epidermis. Clinical examination of the 35-year old proband revealed widespread blistering, particularly on pretibial areas, nail dystrophy and early onset alopecia, as well as esophageal webbing and strictures. The patient also had history of nephropathy with proteinuria. Collectively, the results provide evidence of a distinct form of EB with systemic involvement. The results suggest that *CD151* should be considered as the 20th causative, EB-associated gene.

**Early oro-dental manifestations as a clue for the clinical diagnosis of infantile systemic hyalinosis.** I.S.M. Sayed<sup>1</sup>, M.I. Mehrez<sup>1</sup>, G.Y. El-Kamah<sup>2</sup>, M.S. Abdel-Hamid<sup>3</sup>, G.M.H. Abdel-Salam<sup>2</sup>. 1) Oro-Dental Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 2) Clinical Human Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 3) Medical Molecular Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt.

Biallelic mutations of *ANTXR2* gene cause hyaline fibromatosis syndrome (OMIM #228600) which is a very rare autosomal recessive disorder. It has two forms; the juvenile and the infantile types. Infantile systemic hyalinosis has an earlier onset and displays a more severe presentation when compared with the juvenile type. Interestingly, infantile systemic hyalinosis shows considerable clinical overlap with Farber syndrome. Both show severe, progressive and painful contractures, papular skin rashes, hyperpigmented plaques over the joints, nodular eruptions, gingival enlargement and early morbidity. We describe five patients from four unrelated families with pathogenic mutations of the *ANTXR2* gene. All patients presented with severe irritability and generalized joint contractures while two of them displayed hyperpigmented skin plaques over the knuckles and papular skin. The segmented alveolar ridges and fibrous nodules at the corners of the mouth were consistent features that manifested as early as the age of 2 months. Gingival enlargement obscuring the erupting teeth and stiff long philtrum were additional distinctive findings observed in this series. Thus, suggesting the specificity of these oral features of infantile systemic hyalinosis, they could be taken to differentiate it from Farber syndrome. Three different novel homozygous mutations in exons 9 and 13 were identified, c.1069\_1069delG (p.A357Pfs\*52), c.1052A>C (p.D351A) and c.700\_700delG (p.E234Nfs\*6). The c.700\_700delG (p.E234Nfs\*6) mutation was recurrent in two families who shared similar haplotype suggesting a founder effect. This study highlights the need for thorough oro-dental examination as part of the initial evaluation. Further, we report the distinctive appearance of segmented alveolar ridge and gingiva as new additional features that could be taken as a clue in the clinical diagnosis of patients with infantile systemic hyalinosis.

## 924F

**Novel compound heterozygous variants in the gene *CHUK* associated with AEC syndrome-like phenotype and immune system involvement.**

M. Cadieux-Dion<sup>1,2</sup>, N. Safina<sup>3,4,5</sup>, K. Engleman<sup>3,4</sup>, L. Zellmer<sup>1,2</sup>, E. Repnikova<sup>1,2</sup>, C. Saunders<sup>1,2</sup>, I. Thiffault<sup>1,2</sup>. 1) Pathology and Laboratory Medicine, Children's Mercy Hospital, Kansas City, MO; 2) Center for Pediatric Genomic Medicine, Children's Mercy Hospital, Kansas City, MO; 3) Division of Clinical Genetics, Children's Mercy Hospital, Kansas City, MO; 4) Department of Pediatrics, Children's Mercy Hospitals, Kansas City, MO; 5) University of Missouri, Kansas City School of Medicine, Kansas City, MO.

Ectodermal dysplasias (ED) are a group of disease that affects the development or function of the teeth, hair, nails and exocrine and sebaceous glands. Among ED, ankyloblepharon-ectodermal defects-cleft lip/palate syndrome (AEC or Hay-Wells syndrome), is caused by heterozygous pathogenic variants in the *TP63* gene. A classical feature of AEC syndrome is the presence of skin erosions affecting the palms, soles and scalp. Other clinical manifestations include ankyloblepharon filiforme adnatum, cleft lip, cleft palate, craniofacial abnormalities and ectodermal defects such as sparse wiry hair, nail changes, dental changes, and subjective hypohydrosis. Here, we present a patient with clinical features reminiscent of AEC syndrome with recurrent infections suggestive of immune deficiency. Genetic testing for *TP63*, *IRF6* and *RIPK4* were negative. Using clinical exome sequencing, we uncovered two novel heterozygous variants *in trans* in the *CHUK* gene: a maternally-inherited frameshift (c.1365del, p.Arg457AspfsTer6) and a *de novo* missense (c.1388C>A, p.Thr463Lys). These variants are absent from population databases and paternity was confirmed. To our knowledge, pathogenic variants in the *CHUK* gene have been reported in 3 families. In 2010, a homozygous loss of function variant was found in a Finnish family with Cocoon syndrome, a lethal condition characterized by severe fetal malformations. In 2015, a homozygous splice acceptor site variant was identified in a family with Bartsocas-Papas syndrome (BPS). Recently, a *de novo* missense variant was reported in one patient with ED, orofacial clefting, limb anomalies and hypogammaglobulinemia. This patient had more severe skeletal and immune defect compared to our patient. In summary, we have identified the first case with compound heterozygous variants in the *CHUK* gene with a milder AEC syndrome-like phenotype along with immune system involvement. This shows that pathogenic variants in *CHUK* can cause a range of severity along the AEC-BPS spectrum, and expand the phenotypic spectrum of disorders caused by *CHUK* deficiency. Therefore, it is unclear if *de novo* heterozygous *CHUK* variant are sufficient to cause the phenotype in the patient presented here. Even if the majority of pathogenic *de novo* variants are involved in dominant genetic disorders, there are growing examples of recessive disorders that can be caused by the combination of an inherited variant on one allele and a *de novo* variant on the other.

## 925W

**Understanding the impact of a novel homozygous nonsense *CAST* gene mutation in a PLACK family.**

S.G. Temel<sup>1</sup>, B. Karakas<sup>2</sup>, B. Turkgenç<sup>3</sup>, O. Zorlu<sup>4</sup>, O. Ozturk<sup>5</sup>, U. Kiran<sup>6</sup>, B. Erguner<sup>6</sup>, M. Sagioglu<sup>6</sup>, C. Yakicier<sup>7</sup>, H. Saricaoglu<sup>4</sup>. 1) Dept Histol & Embryol, Fac Medicine, Univ Uludag, Bursa, Turkey; 2) Sabancı University, Molecular Biology, Genetics and Bioengineering Program, Istanbul, Turkey; 3) University of Acibadem, Acibadem Genetic Diagnostic Center, Istanbul, Turkey; 4) University of Uludag, Faculty of Medicine, Department of Dermatology, Bursa, Turkey; 5) Baskent University, Faculty of Medicine, Department of Medical Genetics, Adana, Turkey; 6) Advanced Genomics and Bioinformatics Research Group TÜBİTAK BİLGEM UEKAE, Gebze/Kocaeli, Turkey; 7) University of Acibadem, Faculty of Arts and Sciences, Department of Molecular Biology and Genetics, Istanbul, Turkey.

Peeling skin syndrome is an autosomal recessive disease characterized by continuous shedding of the stratum corneum of the epidermis with onset from birth or infancy and lasting throughout life. It can be accompanied by erythema, vesicular lesions, or other ectodermal features like fragile hair and nail abnormalities. We report a 5.5 year old boy who initially presented with skin fragility. He was the first-born of IVF twins from a consanguineous marriage at 33+5 week gestational age with hypotonia at birth. The main clinical findings included fragile skin, woolly hair, sparse eyelashes and brows, palmoplantar punctate keratoderma, follicular hyperkeratosis, knuckle pads and cheilitis. Exome sequencing revealed a homozygous c.544G>T (p.Glu182\*) nonsense mutation in the *CAST* gene. Segregation analysis was confirmed by Sanger sequencing. This novel stop-gain E182X variant produces a truncated protein lacking inhibitory domains II-IV. Notably, the variant is absent in all public databases, also the region is highly conserved among species. H&E stainings of the proband's skin biopsy showed hyperkeratosis, mild spongiotic changes, Toluidine Blue stainings of semithin sections showed elongated epidermal rete pegs, dermal papilla, thick stratum corneum, extensive karyolysis and loss of chromatin pattern in all epithelial cells. Electronmicrographs of the lesioned skin showed widened intercellular space, proapoptotic membrane invaginations, nuclear chromatin accumulations. Immunohistochemistry results showed absent calpastatin staining in the proband compared to normal staining throughout the epidermis in the control. Calpastatin activity assay revealed reduced calpain proteolysis in affected ones. Immunoblot results showed tissue-specific expression of calpastatin, similar to RT-qPCR results. Confocal microscopy results confirmed the expression pattern shown in immunoblot results. *CAST* is an endogenous specific inhibitor of calpain, a calcium-dependent cysteine protease. Recently, autosomal recessive loss of function mutations in *CAST* were described in PLACK syndrome characterized by peeling skin, leukonychia, acral punctate keratoses, cheilitis, and knuckle pads. This case is the fifth case of PLACK syndrome without leukonychia but with some additional previously unreported features. Treatment with calpain inhibitors could be used to reduce the unwanted symptoms. Our findings might pave the way to explore new routes in proteolytic pathways in skin. .

**926T**

**Delineation of musculocontractural Ehlers-Danlos syndrome caused by dermatan sulfate epimerase deficiency (mcEDS-DSE): Report of additional patients and comprehensive review of reported cases.** A. Unzaki<sup>1,2,3</sup>, CK. Lautrup<sup>4</sup>, K. Wee Teik<sup>5</sup>, S. Mizumoto<sup>6</sup>, H. Hock Sin<sup>7</sup>, IK. Nielsen<sup>8</sup>, S. Markholt<sup>9</sup>, S. Yamada<sup>6</sup>, N. Matsumoto<sup>9</sup>, N. Miyake<sup>9</sup>, T. Kosho<sup>1,2</sup>. 1) Center for Medical Genetics, Shinshu University Hospital, Matsumoto, Japan; 2) Department of Medical Genetics, Shinshu University School of Medicine, Matsumoto, Japan; 3) Problem-Solving Oriented Training Program for Advanced Medical Personnel: NGSD (Next Generation Super Doctor) Project, Matsumoto, Japan; 4) Department of Clinical Genetics, Aalborg University Hospital, Aalborg, Denmark; 5) Department of Genetics, Hospital Kuala Lumpur, Kuala Lumpur, Malaysia; 6) Department of Pathobiochemistry, Faculty of Pharmacy, Meijo University, Nagoya, Japan; 7) Department of Pediatrics, Sabah Women and Children's Hospital, Kota Kinabalu Sabah, Malaysia; 8) Department of Clinical Genetics, Aarhus University Hospital, Aarhus, Denmark; 9) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

Musculocontractural Ehlers-Danlos Syndrome (mcEDS) is a recently identified connective tissue disorder, classified into a subtype of EDS in the 2017 International Classification of the EDS (Malfait et al., *Am J Med Genet Semin Med Genet* 175C: 8–26, 2017). It is caused by loss-of-function mutations in *CHST14* encoding dermatan 4-O-sulfotransferase-1 (D4ST1) (mcEDS-*CHST14*) or in *DSE* encoding dermatan sulfate epimerase (mcEDS-*DSE*), both resulting in defective biosynthesis of dermatan sulfate (DS). Whereas 40 patients with mcEDS-*CHST14* from 27 families have been published to date, only three patients from two families with mcEDS-*DSE* have been published (Müller et al., *Hum Mol Genet* 22: 3761–3772, 2013; Syx et al., *Hum Mutat* 36: 535–547, 2015). In this report, we present three additional patients from two consanguineous families. Patient 1, a boy, had developmental delay, hypertelorism, a large anterior fontanel, bilateral adducted thumbs, bilateral hydronephrosis, cryptorchidism, and constipation in infancy. Later, he showed skin hyperextensibility, delayed wound healing, myopia, strabismus, mild hearing loss, joint hypermobility, scoliosis, recurrent shoulder dislocations, large subcutaneous hematomas, and hemoptysis. At age 18 years, he had a normal stature with mild pectus excavatum and bilateral pes cavus, and no intellectual disability. Patient 2, a boy, had normal developmental milestones, myopia, large subcutaneous hematomas, fractures, talipes equinovarus, and severe scoliosis. At age 21 years, he had a short stature with an asymmetric chest, hallux valgus, and multiple contractures. He had mild hypertelorism, blue sclerae, and atrophic scars. Patient 3, a younger sister of Patient 2, had normal developmental milestones, joint pain and swelling, and astigmatism. At age 14 years, she had a short stature with pectus carinatum and kyphoscoliosis. She had hypertelorism and blue sclerae. She had no joint hypermobility, skin hyperextensibility, or fragility. Pathogenic *DSE* mutations were found in all the three patients and no DS was detected in urine sample of Patient 1, indicating generalized depletion of DS. Review of previously published patients and the current series would delineate the disorder as milder phenotypes with less characteristic facial features and less severe skin/joint/vascular manifestations than mcEDS-*CHST14*.

**ANKRD26 loss of function somatic mutation in a female case with Tree Man Syndrome.** K.M.F. Uddin<sup>1,4</sup>, M.R. Amin<sup>2</sup>, S.N. Majumder<sup>2</sup>, M.A. Aleem<sup>3</sup>, N.J. Dity<sup>4</sup>, A. Rahman<sup>4</sup>, H. Akter<sup>4</sup>, M.A. Baqui<sup>1,4</sup>, M. Woodbury-Smith<sup>5</sup>, S.W. Scherer<sup>6,7,8</sup>, M. Uddin<sup>9</sup>. 1) Biochemistry Dept, Holy Family Red Crescent Medical College, Dhaka, Bangladesh; 2) Medicine Dept, Dhaka Medical College & Hospital, Department of Medicine, Dhaka, Bangladesh; 3) Infectious Disease Division, International Centre for Diarrhoeal Disease Research, Bangladesh (icddr'b), Dhaka, Bangladesh; 4) Genetics and Genome Biology Dept, NeuroGen Technologies Ltd, Dhaka, Bangladesh; 5) Institute of Neuroscience, Newcastle University, Newcastle upon Tyne, UK; 6) The Centre for Applied Genomics, Program in Genetics and Genome Biology, The Hospital for Sick Children, Toronto, Ontario, Canada; 7) Department of Molecular Genetics, University of Toronto, Toronto, Ontario, Canada; 8) McLaughlin Centre, University of Toronto, Toronto, Ontario, Canada; 9) College of Medicine, Mohammed Bin Rashid University of Medicine and Health Sciences, Dubai, UAE.

Epidermodysplasia verruciformis (EV), referred to colloquially as 'tree man syndrome' is a lifelong exceedingly rare hereditary skin disease. It is characterized by abnormal susceptibility to the human papilloma virus (HPV) infection causing defect in cell-mediated immunity. Its dermatological manifestations vary from flat wart like lesion, flat-topped papule, plaques to verrucous or seborrheic keratosis like lesions and even cutaneous horn like lesion mainly seen in UV- exposed regions. Affected individuals have a lifelong increased risk for the development of cutaneous malignancy, especially squamous cell carcinoma. Both non-surgical and surgical options are implicated for the treatment of this condition. Loss of function mutation within *EVER1* and *EVER2* genes has been reported for 25% of the male cases. Up until now the severe form of this syndrome was described exclusively among males. Here we report the first female case, a 10-year-old girl who presented to Dhaka Medical College & Hospital in Bangladesh with a severe dermatological condition, histopathologically confirmed in resected tissue as EV. Local examination revealed multiple tree bark like lesions 2-3 cm in size and conical in shape projecting from various tissues, including the cheek, chin, nose, and ear lobules. Although surgical intervention initially removed all bark like lesions, aggressive regrowth of lesions was observed after one week. From whole genome sequencing data we have identified a rare stop gain somatic mutation in *ANKRD26* and subsequently confirmed the mutation in the tree bark like lesion. *ANKRD26* is strongly associated with thrombocytopenia and myeloid neoplasm. Our findings identify a new pleiotropic gene for EV.

**928W****Mutations in *SULT2B1* cause autosomal recessive congenital ichthyosis**

**in humans.** L. Heinz<sup>1,2</sup>, G.-J. Kim<sup>1,3</sup>, S. Marrakchi<sup>4</sup>, J. Christiansen<sup>5</sup>, H. Turki<sup>6</sup>, M.-A. Rauschendorf<sup>7</sup>, M. Lathrop<sup>6</sup>, I. Ichthyoses are a clinically and genetically heterogeneous group of genodermatoses associated with abnormal scaling of the skin over the whole body. Mutations in nine genes are known to cause non-syndromic forms of autosomal recessive congenital ichthyosis (ARCI). However, not all genetic causes for ARCI have been discovered to date. Using whole exome sequencing (WES) and multigene panel screening we identified 6 ARCI individuals from three unrelated families with mutations in Sulfotransferase family 2B member 1 (*SULT2B1*), showing their causative association with ARCI. Cytosolic sulfotransferases form a large family of enzymes that are involved in the synthesis and metabolism of several steroids in humans. We identified four distinct mutations including missense, nonsense and splice site mutations. We demonstrated the loss of *SULT2B1* expression at RNA and protein levels in keratinocytes from individuals with ARCI by functional analyses. Furthermore, we succeeded in reconstructing the morphologic skin alterations in a 3D organotypic tissue culture model with *SULT2B1*-deficient keratinocytes and fibroblasts. By thin layer chromatography (TLC) of extracts from these organotypic cultures we could show the absence of cholesterol sulfate, the metabolite of *SULT2B1*, and an increased level of cholesterol indicating a disturbed cholesterol metabolism of the skin upon loss of function mutation in *SULT2B1*. In conclusion, our study reveals an essential role for *SULT2B1* in the proper development of healthy human skin. Mutation in *SULT2B1* leads to an ARCI phenotype via increased proliferation of human keratinocytes, thickening of epithelial layers, and altered epidermal cholesterol metabolism.

**929T****Cutaneous neurofibromas in neurofibromatosis type 1: A quantitative**

**natural history study.** A. Cannon<sup>1</sup>, M.-J. Chen<sup>1</sup>, P. Li<sup>2</sup>, KP. Boyd<sup>2</sup>, A. Theos<sup>2</sup>, DT. Redden<sup>3</sup>, B. Korfi<sup>3</sup>. 1) Genetics, University of Alabama at Birmingham, Birmingham, AL; 2) Dermatology, University of Alabama at Birmingham, AL; 3) Biostatistics, University of Alabama at Birmingham, AL.

**Background:** Neurofibromatosis type 1 (NF1) is a disorder characterized by a predisposition to develop multiple benign tumors, including localized cutaneous neurofibromas (cNFs) that affects >99% of adults with NF1. Previous reports have correlated increased burden of cNFs with age and pregnancy, but longitudinal data are not available to establish a quantitative natural history. The purpose of this study was to quantify cNF number and size to establish a quantitative natural history of these lesions. **Methods:** A prospective cohort analysis of 22 adults with NF1 was conducted over an 8-year period. The primary outcome measures were number and volume of cutaneous neurofibromas in three body sites: back, abdomen, and upper arm or thigh. **Results:** The average monthly increase in volume for cutaneous neurofibromas was 0.37 mm<sup>3</sup> in the back region (95% CI (0.23, 0.51), p<0.0001), 0.28 mm<sup>3</sup> in the abdominal region (95% CI (0.16, 0.41), p<0.0001), and 0.21 mm<sup>3</sup> in the arm/leg region (95% CI (0.08, 0.34), p=0.0022). The number of cutaneous neurofibromas significantly increased in the back (slope=0.032, p=0.011) and abdominal (slope=0.018, p=0.026) regions, while the leg/arm regions retained a positive trend (slope=0.004, p=0.055). **Conclusion:** The number and volume of cNFs significantly increase over an 8-year timespan; however, the rate of increase is variable by body region. These findings may provide insight into cNF development and benefit researchers considering clinical trials targeting cNFs.

**930F**

**Abnormal splicing in a case of epidermolysis bullosa with a novel synonymous mutation in the *ITGB4* gene.** E. Tan, H.W. Lim, E.C.P. Lim, D. Lian, M. Koh. KK Women s & Children s Hospital, Singapore.

**Introduction:** Integrins are protein heterodimers involved in the maintenance of cell-cell adhesion, signal transduction, and regulation of cell growth. We report the findings from a female infant who presented with feed intolerance, vomiting and scattered skin blisters and erosions shortly after birth. Immunofluorescence mapping showed fraying of the integrin alpha-6 / beta-4 complex, consistent with a clinical diagnosis of epidermolysis bullosa with pyloric atresia (EB-PA). There was no family history and parents were non-consanguineous. **Methodology:** Genomic DNA from the child was extracted from venous blood and sequenced using a targeted panel on the MiSeq System. Identified variants were confirmed by Sanger sequencing followed by targeted testing of parental samples. **Results and discussion:** For the *ITGB4* (integrin beta-4 protein) gene, there was a heterozygous frameshift variant (p.S265fs) which has been reported as disease-causing in HGMD and a heterozygous synonymous variant (p.Cys536Cys) which has not been reported previously. Testing of parental samples showed that the frameshift variant is from the mother while the synonymous variant is from the father. In silico analysis predicted that the synonymous variant might cause abnormal splicing. RNA work was thus carried out on the patient's blood sample and intestinal biopsy tissue, PCR products from cDNA of both tissues were of a smaller product size compared to those obtained using cDNA from HeLa cells and a normal stoma tissue sample as templates. Sanger sequencing indicated that the last 51 bp from exon 13 was missing from the shorter PCR product. The absence of a normal RNA species from the patient's tissues is consistent with the immunostaining result. **Conclusion:** We describe a novel synonymous variant and show that the encoded RNA in the patient's tissues is smaller due to abnormal splicing. This variant is inherited from a healthy parent. Together with a known pathogenic frameshift variant inherited from the other healthy parent, the patient presented with EB-PA due to compound heterozygous mutations in *ITGB4*. **Acknowledgment:** Supported by NMRC/CG/006/2013. .

**A disease-associated *REEP1* variant affects splicing of the gene's 3'UTR.** C. Beetz<sup>1</sup>, S.L. Rydning<sup>2</sup>, A. Jahic<sup>1</sup>, L. Goldberg<sup>1</sup>, C. Tallaksen<sup>2</sup>. 1) Department of Clinical Chemistry, Jena University Hospital, Jena, Germany; 2) Department of Neurology, Oslo University Hospital, Oslo, Norway.

Heterozygous loss-of-function mutations in *REEP1* cause autosomal dominant hereditary spastic paraplegia (HSP). We identified the previously reported c.\*43G>T substitution in the gene's 3'UTR in an apparently sporadic patient. Age at onset was comparatively late, and the patient's father and daughter are unaffected carriers. The variant is found in control populations, but shows a much higher frequency amongst HSP patient. The mode of action of this apparently only mildly pathogenic variant is unclear. We applied MiniGene assays to test for a potential effect on splicing. We found the GT dinucleotide at c.\*58\_59 to constitute a functional splice donor, the activity of which is decreased in the presence of the c.\*43G>T variant. Screening candidate downstream motifs identified a corresponding splice acceptor with the core AG-motif at c.\*1645\_1646. *In silico* analysis of the spliced out ~1,6 kb sequence revealed a cluster of high scoring AU-rich elements, i.e. regions that mediate RNA degradation. The decrease in 3'UTR splicing as observed for c.\*43G>T is predicted to result in an increase of the fraction of molecules carrying degradation motifs and, thereby, in reduced *REEP1* mRNA levels. Our findings are consistent with a novel mechanism for how 3'UTR variants may confer a partial loss of gene function.

**Synonymous variant in *KCTD7* causes alternative splicing in siblings with progressive epilepsy.** D.B. Zastrow<sup>1,2</sup>, C. Prybol<sup>1,2</sup>, J.M. Davidson<sup>1,2</sup>, A.M. Dries<sup>1,2</sup>, L. Fernandez<sup>1,2</sup>, J.N. Kohler<sup>1,2</sup>, Z. Zappala<sup>3</sup>, L. Fresard<sup>4</sup>, K.S. Smith<sup>4</sup>, D. Bonner<sup>1,2</sup>, C. McCormack<sup>1,2</sup>, M. Majcherska<sup>1,2</sup>, D. Waggott<sup>1,2</sup>, S. Marwaha<sup>1,2</sup>, N. Friedman<sup>1,2</sup>, P. Ward<sup>5</sup>, Y. Yang<sup>6</sup>, C. Eng<sup>6</sup>, U.D.N. Members<sup>6</sup>, S.B. Montgomery<sup>6,4</sup>, P.G. Fisher<sup>7,8</sup>, E.A. Ashley<sup>2,3</sup>, J.A. Bernstein<sup>1,7,9</sup>, M. Wheeler<sup>1,2</sup>. 1) Stanford Center for Undiagnosed Diseases, Stanford University, Stanford, CA; 2) Division of Cardiovascular Medicine, Stanford University, Stanford, CA; 3) Department of Genetics, Stanford School of Medicine, Stanford, CA; 4) Department of Pathology, Stanford School of Medicine, Stanford, CA; 5) Baylor Miraca Genetics Laboratories, Houston, TX; 6) NIH Undiagnosed Diseases Network, Common Fund, Office of the Director and the National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 7) Department of Pediatrics, Stanford School of Medicine, Stanford, CA; 8) Department of Neurology, Stanford School of Medicine, Stanford, CA; 9) Lucille Packard Children's Hospital Stanford, Palo Alto, CA.

A 13-year-old Hispanic female presented at 18 months with regression, loss of milestones, head control, and speech. Tremors began at 21 months, and seizures at 22 months (occasional myoclonus). She also has scoliosis, dysphagia, encephalopathy, and corticovisual impairment. A diagnostic odyssey began which encompassed 32 laboratory studies (including 17 genetic tests and 9 imaging studies) over 11 years. A genetic etiology could not be uncovered. Her 5-year-old brother had a different onset noted at 13 months of ataxia, autism, developmental delay and recurrent febrile seizures. *KCTD7* sequencing was done in 2014 for the proband which found 2 variants: c.280C>T (R94W) and c.456G>A (V152V). The R94W variant is classified as pathogenic in ClinVar (VarID 37010). The c.456G>A variant was interpreted as likely benign (VarID 206004). Her brother had *KCTD7* deletion/duplication analysis via high-density array CGH, which was normal. As part of her evaluation in the Undiagnosed Diseases Network (UDN) at Stanford, quad whole exome sequencing was performed. The *KCTD7* variants in the proband and her brother were appreciated and further investigated. The R94W variant is paternally inherited, and the c.456G>A variant is maternally inherited consistent with autosomal recessive inheritance. *KCTD7* mutations are associated with Epilepsy, progressive myoclonic 3 (EPM3 [MIM 611726]). Features of EPM3 (myoclonic seizures, neurologic regression, truncal ataxia, limited expressive language, and visual loss) are seen in the proband and her younger brother. During curation of the c.456G>A variant, MutationTaster predicted it to be disease causing based on potential splicing effect (donor increased). We then set out to confirm this prediction. We performed Sanger sequencing of the major *KCTD7* isoform on the siblings' cDNA and confirmed a splicing gain. RNAseq performed on patient blood samples and induced pluripotent stem cells also detected a splicing gain. Therefore, this synonymous variant appears to create a splice donor site that truncates *KCTD7* exon 3. Additional validation is in progress including family segregation and model organism studies. This adds to the small number of reported EPM3 cases (~19) and informs the interpretation of this potential pathogenic synonymous variant. The UDN clinical research network provides a means for the efficient and effective assessment of variants leading to improved care.

## 933F

**NeuroChip genotyping of the Johns Hopkins brain bank reveals common and rare genetic associations.** C. Blauwendraat<sup>1</sup>, J.T. Geiger<sup>1</sup>, O. Pletnikova<sup>2</sup>, F. Faghri<sup>2</sup>, L.S. Rosenthal<sup>2</sup>, N.A. Murphy<sup>2</sup>, B. Crain<sup>2</sup>, Y. Abramzon<sup>2</sup>, G. Rudow<sup>2</sup>, C. Ruth<sup>2</sup>, J. Ding<sup>2</sup>, T.M. Dawson<sup>2</sup>, A. Pantelyat<sup>2</sup>, M.S. Albert<sup>2</sup>, A.E. Hillis<sup>2</sup>, J.C. Troncoso<sup>2</sup>, S.W. Scholz<sup>1,3,4</sup>. 1) Neurodegenerative Diseases Research Unit, National Institute of Neurological Disorders and Stroke, National Institutes of Health, Bethesda, MD, USA; 2) Department of Pathology (Neuropathology), Johns Hopkins University School of Medicine, Baltimore, MD, USA; 3) Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health, Bethesda, MD, USA; 4) Department of Neurology, Johns Hopkins University Medical Center, Baltimore, MD, USA.

Genetics has proven to be a powerful tool in research and diagnostics, resulting in the identification of causal and risk variants in numerous diseases including neurodegenerative diseases like Alzheimer's disease (AD) and Parkinson's disease (PD). Array based genotyping and sequencing are the primary techniques used to identify these variants. The downsides of these techniques are typically the lack of rare/pathogenic variants included (genotyping) and the high costs (sequencing). To overcome this, we previously developed the NeuroX genotyping array and we report here its updated successor, NeuroChip. The NeuroChip is a low cost (~\$40 per sample) custom-designed array containing 179,467 custom content variants alongside a genome-wide tagging backbone of 306,670 variants (Infinium HumanCore-24 v1.0). These custom content variants have been identified in large sequencing and genotyping studies in several diseases including AD, PD, Lewy body dementia (LBD), amyotrophic lateral sclerosis (ALS), frontotemporal dementia (FTD) and progressive supranuclear palsy (PSP). Additionally, there are over 1,000 known pathogenic variants included e.g. *PSEN1*-AD (n=175), *LRRK2*-PD (n=80), *SOD1*-ALS (n=70) and *MAPT*-FTD (n=39). As a proof of principle, we genotyped the Johns Hopkins brain bank consisting of 1,405 brain tissues. The most common pathological diagnosis was AD (n=621), followed by complex dementia, which constitutes as having two or more distinct pathologies (n=302), control or no significant pathology present (n=118), Lewy body, including both PD and LBD (n=99), ALS-FTD (n=94), atypical PD (n=55) and other or unclassified pathologies (n=116). In this cohort, we identified multiple *PSEN1* variants and *APP* variants (both missense and duplications), but also *LRRK2* variants in brains that were classified as complex dementia. Additionally, mini GWAS and genetic risk score (GRS) calculations were performed showing specific trends for disease groups including *APOE* association in AD, *MAPT* association in PSP and overall GRS association with PD. In summary, we report here the usage of the NeuroChip array, and show its capability of detecting both common and rare (pathogenic) variants in a large cohort. The NeuroChip has a comprehensive and improved custom content which makes it a high-throughput and cost-effective screening genotyping array for future research in neurodegenerative diseases.

**934W****A *PSEN2* frameshift variant associated with early onset AD in two families.**

1) Neurology, University of Washington, Seattle, WA; 2) Pathology, University of Washington, Seattle, WA; 3) UW Medicine Center for Precision Diagnostics, University of Washington, Seattle, WA; 4) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 5) Psychiatry & Behavioral Sciences, University of Washington, Seattle, WA.

Heterozygous mutations in Amyloid Precursor Protein, Presenilin 1 and Presenilin 2 (*PSEN2*) cause autosomal dominant Alzheimer Disease (AD). The mechanism by which Presenilin mutations lead to AD has been debated; there is evidence to support both toxic gain of function as well as loss of normal function mechanisms. We previously reported a 56 year-old woman with early onset AD found to have a novel heterozygous *PSEN2* 2-base pair deletion leading to a frame shift and premature termination codon in exon 5 (*PSEN2* p.K115Efs\*11). The *PSEN2* K115Efs variant is predicted to lead to nonsense mediated decay or result in a stable transcript translated into an early truncated PS2 peptide. The variant, if truly causing familial AD, significantly informs our understanding of *PSEN* gene mutation function because heretofore only missense *PSEN2* mutations have been considered associated with AD. Here we describe a second early onset AD case heterozygous for the *PSEN2* K115Efs variant discovered during a targeted exome screen of early-onset dementia cases. The subject had a maternal history of AD and was diagnosed with dementia at age 51. Her autopsy confirmed neuropathological AD diagnosis with neurofibrillary tangles (Braak Stage VI), and neuritic plaques. To investigate pathogenicity *in vitro*, we measured the expression and function of *PSEN2* K115Efs. Sanger sequencing of cDNA confirmed the presence of mutant transcript in fibroblasts and cortical tissue isolated from two unrelated variant carriers. Western blot analysis of primary cells isolated from control subjects and *PSEN2* variant carriers showed decreased PS2 c-terminal fragment in *PSEN2* K115Efs suggesting insufficient compensation for PS2 levels by the wildtype allele. Furthermore, similar to what has been previously shown with *PSEN2* N141I (familial AD Volga German mutation), we found decreased Ab<sub>40</sub> released into conditioned medium from *PSEN2* K115Efs and *PSEN2* N141I primary fibroblasts compared to controls, suggesting that like the *PSEN2* N141I mutation, *PSEN2* K115Efs leads to impaired APP processing, a biochemical loss of function. In summary, we report evidence demonstrating loss of normal PS2 levels and function associated with the *PSEN2* K115Efs\*11 variant which has now been identified in two individuals with familial early onset AD. Further, the biological and genetic features associated with this variant type underscore the complexity of *PSEN2* mutation mechanisms of action leading to AD.

**935T****Comparison of the mutations that cause Alzheimer's disease on secondary protein misfolding on transgenic mouse models.**

G. Xu, M. Pace, S. Fromholt, J. Triplett, Y. Levites, P. Chakrabarty, T. Golde, J. Lewis, D.R. Borchelt. Neuroscience, University of Florida, Gainesville, FL.

Mutations in amyloid precursor protein (APP), presenilins (PS1, PS2) or microtubule-associated protein tau (MAPT or tau) can cause familial Alzheimer's disease (AD). Multiple transgenic mouse models developed by expressing these mutations reproduce amyloidosis or tau pathology of human disease. In our prior studies, we used proteomic analyses to determine that mice overexpressing mutant human APP and PS1 genes that develop severe amyloidosis show secondary protein misfolding in the brain. In the current study, using the same strategy of bottom-up LC-MS/MS, we identified the proteins in the detergent-insoluble fraction of the brain homogenates of many different mouse AD models, we found the similar secondary misfolding in both amyloidosis mice and tauopathy mice. Additionally, we sought to comparatively analyze the effects that different initiating proteinopathies have upon secondary protein misfolding. We compared the mice expressing mutant human APP with or without co-expressing of PS1, transgenic mice expressing mouse APP with or without PS1, mice expressing Abeta42 fragment, and transgenic mice overexpressing mutant human tau. Although some of the misfolding proteins are the same across all the models, some proteins are unique to each model. We found the amount of secondary misfolding is not simply corresponded to amyloid deposition level. The mice that develop cored amyloid plaques seem to have higher levels of secondary misfolding than the mice develop diffuse plaques. In both Abeta mice and tau mice, as soon as the disease-driving transgene's expression is switched off in the tetracycline-inducing system, the level of secondary misfolding declines even though the primary pathology persisted. Our data demonstrate that secondarily misfolded proteins are not simply co-aggregated with the main protein deposition. Overall, our findings fit with a model in which an independent dysfunction of protein homeostasis mechanism causes widespread protein misfolding in neurodegenerative disease.

Naga<sup>1</sup>. 1) Center for Personalized Medicine for Healthy Aging, Tokyo Med & Dental Univ, Tokyo, Tokyo, Japan; 2) Dept of Neurology and Neurological Science, Graduate School, and The Center for Brain Integration Research (CBIR), Tokyo Med & Dental Univ, Tokyo, Tokyo, Japan; 3) Dept of Neurotherapeutics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan; 4) Dept of Degenerative Neurological Diseases, Natl Inst of Neurosci, National Center for Neurology and Psychiatry, Kodaira, Tokyo, Japan; 5) Dept of Translational medicine and neurogenetics, IGBMC, CNRS UMR7104, INSERM U964, Université de Strasbourg, Illkirch, France; 6) Dept of Chemistry, Faculty of Science and Technology, Keio University, Yokohama, Kanagawa, Japan; 7) Dept of Genetics & Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada; 8) Dept of Cell and Molecular Biology, St. Jude Children's Research Hospital, Memphis, TN.

Microsatellite expansion disorders are pathologically characterized by RNA foci formation and repeat-associated non-AUG (RAN) translation. However, their underlying pathomechanisms and regulation of RAN translation remain unknown. We report that expression of expanded UGGAA (UGGAA<sub>exp</sub>) repeats, responsible for spinocerebellar ataxia type 31 (SCA31) in *Drosophila*, causes neurodegeneration accompanied by accumulation of UGGAA<sub>exp</sub> RNA foci and translation of repeat-associated pentapeptide repeat (PPR) proteins, consistent with observations in SCA31 patient brains. We revealed that motor-neuron disease (MND)-linked RNA-binding proteins (RBPs), TDP-43, FUS and hnRNPA2B1, bind to and induce structural alteration of UGGAA<sub>exp</sub>. These RBPs suppress UGGAA<sub>exp</sub>-mediated toxicity in *Drosophila* by functioning as RNA chaperones for proper UGGAA<sub>exp</sub> folding and regulation of PPR translation. Furthermore, nontoxic short UGGAA repeat RNA suppressed mutated RBP aggregation and toxicity in MND *Drosophila* models. Thus, functional crosstalk of the RNA/RBP network regulates their own quality and balance, suggesting convergence of pathomechanisms in microsatellite expansion disorders and RBP proteinopathies.

## 937W

**Genetic analysis in pediatric patients with ataxia.** J. Lee<sup>1</sup>, B. Lim<sup>2</sup>, K. Kim<sup>2</sup>, M. Seong<sup>3</sup>, J. Chae<sup>2</sup>. 1) Gachon University Gil Medical Center, Incheon, South Korea; 2) Pediatric Clinical Neuroscience Center, Seoul National University Children's Hospital, Seoul National University College of Medicine, Seoul Korea; 3) Seoul National University College of Medicine, Seoul Korea.

**Objectives** Childhood-onset cerebellar ataxia is usually genetic conditions rather than disorders with acquired etiologies. However, there are few studies about genetic analysis for ataxia. The aim of this study is to investigate the genetic profiles of pediatric patients with ataxia in Korea. **Methods** Fifteen patients with cerebellar ataxia of suspicious genetic origin at the Seoul National University Children's Hospital were included. Some trinucleotide repeat disorders were excluded. Whole-exome sequencing was performed and candidate variants were validated with Sanger sequencing. Their medical records, including neuroimaging studies, were reviewed. **Results** The mean age at onset was 6.2 years (range, 1.5 to 16 years). All cases except one were sporadic. Most patients had cerebellar atrophy, although some had normal or nonspecific findings in cerebellum. Pathogenic variants in genes previously shown to cause ataxia were identified in 5 patients (5/15=33.3%). The results showed the genetic complexity: *SLC2A1*, *SYNE1*, *ITPR1*, *CYP7B1*, and *GFAP*. All the pathogenic variants identified in this study have never been reported. **Conclusion** To our knowledge, this is the first study to identify the genetic causes in pediatric patients with ataxia in Korea, which shows the genetic heterogeneity of child-onset cerebellar ataxia. To establish a molecular diagnosis of ataxia is very important due to genetic counseling and potential therapeutic interventions.

## 938T

**A novel *PRRT2* pathogenic variant in a family with paroxysmal kinesigenic dyskinesia and benign familial infantile seizures.** J.G. Lu<sup>1</sup>, J. Bishop<sup>1</sup>, S. Cheyette<sup>2</sup>, S. Guo<sup>1</sup>, N. Sobreira<sup>2</sup>, S.E. Brenner<sup>1,2</sup>. 1) University of California, San Francisco, CA; 2) University of California, Berkeley, CA; 3) Palo Alto Medical Foundation, Palo Alto, CA; 4) Johns Hopkins University, Baltimore, MD.

Paroxysmal Kinesigenic Dyskinesia (PKD) is a rare neurological disorder characterized by recurrent and brief attacks of dystonic movements without alteration of consciousness, which are often triggered by the initiation of voluntary movements. The molecular basis of PKD has recently been identified. Whole exome sequencing has revealed a cluster of pathogenic variants in *PRRT2*, a gene with a function in synaptic regulation that remains poorly understood. Further studies have confirmed its role in the disease. Here, we report the discovery of a novel *PRRT2* pathogenic variant inherited in an autosomal dominant pattern in a family with PKD and Benign Familial Infantile Seizures (BFIS). After targeted Sanger sequencing failed to uncover the existence of previously described *PRRT2* pathogenic variants, we carried out whole exome sequencing in the proband and her affected paternal grandfather. This led to the discovery of a novel *PRRT2* variant, p.A320V, altering an evolutionarily conserved Alanine at the amino acid position 320, located in the M2 trans-membrane domain. Sanger sequencing further confirmed the presence of this variant in four affected family members (paternal grandfather, father, brother, and proband) and its absence in two unaffected ones (paternal grandmother and mother). This newly found variant further reinforces the importance of *PRRT2* in PKD, BFIS, and possibly other movement disorders. Future functional studies using animal models and human pluripotent stem cell models will provide new insights into the role of *PRRT2* and the significance of this variant in regulating neural development and/or function.

## 939F

**Expanded-(TGGAA)<sub>n</sub>-associated unconventional translation in spinocerebellar ataxia type 31.** N. Sato<sup>1,2</sup>, T. Ishiguro<sup>2</sup>, Y. Niimi<sup>2</sup>, M. Higashi<sup>2</sup>, T. Yokota<sup>2</sup>, H. Mizusawa<sup>2,3</sup>, K. Ishikawa<sup>1,2</sup>. 1) Center for Personalized Medicine for Healthy Aging, Tokyo Medical & Dental University, Tokyo, Japan; 2) Department of Neurology and Neurological Science, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan; 3) National Center of Neurology and Psychiatry, Tokyo, Japan.

**Background:** Spinocerebellar ataxia type 31 (SCA31) is a dominantly inherited neurodegenerative disorder that manifests late-onset, slowly progressive cerebellar ataxia. The causative mutation for SCA31 is complex penta-nucleotide repeats including (TGGAA)<sub>n</sub> in an intronic region shared by two genes, *BEAN1* and *TK2*, which are transcribed in opposite directions. Like SCA31, some neurodegenerative disorders are caused by intronic expanded variable numbers of tandem repeats (VNTRs), such as myotonic dystrophy type 1 and 2, and amyotrophic lateral sclerosis caused by C9orf72 mutation. Recently, evidence has been accumulating that these disease-related expanded VNTRs are unconventionally translated into polypeptides, and this repeat-associated non-ATG (RAN) translation has been suspected to be part of the pathogenesis leading to neurodegeneration. The SCA31 mutation in the *BEAN1* direction is somewhat unique in this context as it has numerous ATG start codons, and followed by (TAGAA)<sub>n</sub> and (TAAAA)<sub>n</sub>, both of which could serve as stop codons. **Purpose:** To elucidate if unconventional, expanded-VNTR-associated translation takes place in SCA31. **Materials and Methods:** Polyclonal antibodies against (MEWNG)<sub>3</sub> were developed by immunizing rabbits with the oligopeptide, part of polypeptides potentially translated from (AUGGA)<sub>n</sub> in the direction of *BEAN1*. These antibodies were first tested by western blot with recombinant GST-(MEWNG)<sub>3</sub>. Then, immunohistochemistry was carried out on cerebellar specimens of two SCA31 patients and two control subjects. **Results:** The obtained in-house antibodies were proved to recognize (MEWNG)<sub>3</sub>. Immunohistochemistry on the cerebellar sections showed aggregation-like staining in the cytoplasm and in the primary shafts of the dendrites of Purkinje cells in SCA31, but not in controls. The observed staining manifested various morphological appearances, from granular to rod-like shapes. **Conclusions:** Our immunohistochemistry analysis suggests that unconventional translation originating from seemingly "intronic" expanded (TGGAA)<sub>n</sub> may take place in SCA31. Further investigations are needed to clarify how and to what extent these polypeptides contribute to the pathogenesis of SCA31, and on potential translation from (TTCCA)<sub>n</sub> in the direction of *TK2*, which lacks the ATG codon.

**940W****A novel mutation in eukaryotic elongation factor 2 kinase (eEF2K) decreases phosphorylation of eEF2 in a patient with degenerative ataxia.**

*K.L. Sund<sup>1</sup>, J.E. Jones<sup>2</sup>, J. Briggs<sup>3</sup>, C.A. Prows<sup>1</sup>, J. Glass<sup>1</sup>, M. Sweeney<sup>4</sup>, D. Gilbert<sup>5</sup>, M. Sun<sup>1</sup>, C. Prada<sup>1</sup>, T.A. Burrow<sup>5</sup>, J.D. Dinman<sup>3</sup>.* 1) Department of Pediatrics, Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) Department of Pediatrics, Division of Neurology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 3) Department of Cell Biology and Molecular Genetics, University of Maryland, College Park, MD; 4) Division of Neurology, University of Louisville, Louisville, KY; 5) Department of Pediatrics, Section of Genetics and Metabolism, University of Arkansas for Medical Sciences, Little Rock, AR.

Eukaryotic elongation factor 2 kinase (eEF2K) has been extensively studied as a potential therapeutic target for treatment of tumors and epilepsy. It is expressed in cerebral cortex ventricular zone during mouse brain development, transiently upregulated during synaptogenesis, and maintained in the adult brain. We performed whole exome sequencing (WES) on a 27 year old female with adult-onset ataxia, tremor, spasticity, declining cognition, and balance problems. Within 2 years, she was nonambulatory, incontinent, and unable to feed herself. MRI showed innumerable white matter loss lesions consistent with progressive multiple sclerosis. Trio WES revealed a de novo missense mutation in a highly conserved nucleotide of *eEF2K*. The mutation fell within a kinase domain, was uniformly called deleterious by computational algorithms, and was not found in control populations. In addition to autophosphorylation, the only known substrate for eEF2K phosphorylation is eEF2, which is mutated in Spinocerebellar Ataxia, type 26 (SCA 26). Functional studies of the equivalent *eEF2* mutation demonstrated an increased rate of -1 frameshifting indicating dysregulation of protein translation as a mechanism of disease in SCA 26. To determine the impact of the identified mutation in *eEF2K*, we transiently transfected HA-tagged WT eEF2K and eEF2K-Asp<sup>244</sup> into HEK293 cells. Despite persistent levels of eEF2 protein in both cultures, western blot analysis revealed decreased phosphorylation of eEF2 in the presence of eEF2K-Asp<sup>244</sup> compared to WT eEF2K, indicating a dominant negative inhibition of kinase function. Typically, eEF2K is believed to confer cell survival under acute nutrient depletion by blocking translation elongation. Tumor cells can exploit this pathway by inhibiting eEF2 and decreasing the demand for protein synthesis, thereby decreasing cell death. Inhibition of eEF2K in cancer cells leads to increased cell death. A common endpoint for SCAs is increased cell death in the Purkinje cells. Further research will determine whether loss of eEF2K function similarly results in increased cell death in Purkinje cells. Ongoing in vitro studies, more patients and animal models are needed to further implicate eEF2K in causation of this neurodegenerative ataxia that may be misdiagnosed as multiple sclerosis. Conclusive studies may also aid treatment for these patients, especially since eEF2K is inhibited by mTOR and mTOR inhibitors such as Sirolimus are currently used in clinic.

**941T****Japan Consortium of Ataxias (J-CAT): A cloud-based national registry for degenerative ataxias providing comprehensive genetic diagnosis and prospective natural history researches.**

Mizusawa<sup>16</sup>.* 1) Dept Neurology, National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan; 2) Department of Neurology and Neurological Science, and Predictive and Preventive Medicine, Tokyo Medical and Dental University; 3) Department of Neurology, School of Medicine, Fukushima Medical University; 4) Department of Neurology, Brain Research Institute, Niigata University; 5) Department of Neurology, Neurological Institute, Graduate School of Medical Sciences, Kyushu University; 6) Department of Neurology, Graduate School of Medicine, Chiba University; 7) Department of Neurology, Hokkaido University Graduate School of Medicine; 8) Department of Neurology, Nagoya University Graduate School of Medicine; 9) Department of Neurology and Geriatrics, Kagoshima University, Graduate School of Medical and Dental Sciences; 10) Department of Neurology, University of Yamanashi; 11) Department of Neurology, Sendai Nishitaga National Hospital; 12) Department of Neurology, Graduate School of Medicine, The University of Tokyo; 13) Division of Neurology, Department of Brain and Neurosciences, Faculty of Medicine, Tottori University; 14) Neurorehabilitation Research Institute, Morinomiya Hospital; 15) Division of Neurogenetics, Department of Brain Disease Research, Shinshu University School of Medicine; 16) National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan.

[Background] Spinocerebellar degeneration (SCD) is a group of heterogeneous disorders composed of hereditary and sporadic ataxias: the majority of hereditary ataxias are autosomal-dominant SCD and the remaining are autosomal-recessive SCD or X-linked SCD. Clinical manifestations including natural history vary greatly among SCDs with different molecular backgrounds, necessitating the accurate genetic diagnosis to establish disease-specific natural history and then disease modifying therapy. [Objective] We aim to develop a national registry for SCDs providing framework for comprehensive genetic diagnosis and prospective study of natural history. [Subjects and Methods] We developed a cloud-based registry system for ataxias, Japan Consortium of ATaxias (J-CAT), supported by Ministry of Health, Labor and Welfare, Japan and Japan Agency for Medical Research and Development (AMED). The system implemented a searchable encryption technology to ensure the security. We also established a multi-institutional network for comprehensive genetic diagnosis including PCR fragment analysis, direct nucleotide sequence analysis and whole exome sequencing analysis. The system allows us to conduct disease-specific prospective natural history researches according to established genetic causes. [Results] J-CAT allows patients themselves to register with informed consent and input clinical data with the assistance of physicians online, providing a platform for prospective natural history research. The registered patients are routinely subjected to mutational analysis including PCR-fragment analysis for triplet repeat diseases and SCA31, followed by systematic diagnostic procedure including whole exome analysis. The concept, registration procedure and contact information of J-CAT are readily available on the website (<http://jcat.umin.ne.jp/>). Eighty-two patients have been registered until June 6<sup>th</sup>. Genetic analysis has been conducted in 50 patients in whom the molecular diagnosis was established in 26 patients (52%) including 9 patients with MJD/SCA3, 8 with SCA31, 5 with SCA6, 2 with DRPLA, 1 with SCA2 and 1 with SCAR8. [Conclusion] J-CAT has been launched to facilitate genetic diagnosis, establish disease-specific natural history and identify genetic causes of SCD.

**Two patients with *PNKP* mutations presenting microcephaly, seizure, and oculomotor apraxia.** M. Taniguchi-Ikeda<sup>1</sup>, N. Morisada<sup>2</sup>, H. Inagaki<sup>3</sup>, N. Okamoto<sup>4</sup>, T. Toda<sup>5</sup>, I. Morioka<sup>1</sup>, H. Kurahashi<sup>3</sup>, K. Iijima<sup>1</sup>: 1) Pediatrics, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan; 2) Clinical Genetics, Hyogo prefectural Childrens Hospital, Kobe, Hyogo, Japan; 3) Molecular Genetics, Fujita health University, Toyoake, Aichi, Japan; 4) Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Osaka, Japan; 5) Neurology/Molecular Brain Science, Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan.

Microcephaly with early-onset, intractable seizures and developmental delay (MCSZ, OMIM #613402) is an autosomal recessive group of heterogeneous disorders, which can also be associated with other severe neurological defects. Mutations in polynucleotide kinase 3'-phosphatase (*PNKP*) have been suggested to cause MCSZ. Additionally, *PNKP* mutations also cause ataxia-oculomotor apraxia type 4 (AOA4) without symptoms of epilepsy or microcephaly. The reported AOA4 cases carried mutations in the kinase domain of *PNKP*. Here we identified three new mutations in two Japanese MCSZ patients who also exhibited AOA4 symptoms. All mutations resided within the kinase domain and both patients showed severe epilepsy and microcephaly with congenital anomalies. A 38-year old MCSZ patient showed apparent AOA symptoms with spinocerebellar degeneration. Another patient with MCSZ showed lissencephaly and frequent horizontal headshaking from age 1, suggestive of oculomotor apraxia. Kinase domain mutations in *PNKP* may manifest as a wide spectrum of overlapping phenotypes of MCSZ and AOA4. Therefore, we suggest that each MCSZ and AOA is not a distinct phenotype, but sequential phenotypes of *PNKP* mutations in kinase domain.

**943W**

**Identification of novel *de novo* *CHD8* variants associated with autism, language disability and overgrowth.** Y. An<sup>1,2</sup>, L.N. Zhang<sup>3</sup>, W.W. Liu<sup>3</sup>, J. Wang<sup>3</sup>, J.F. Gusella<sup>2</sup>, Y.S. Du<sup>3</sup>, Y.P. Shen<sup>2,4,5</sup>: 1) Institute of Biomedical Sciences and MOE Key Laboratory of Contemporary Anthropology, Fudan University, Shanghai, China; 2) Molecular Neurogenetics Unit, Center for Genomic Medicine, Massachusetts General Hospital, Harvard Medical School, Boston, MA., USA; 3) Shanghai Mental Health Center, Shanghai Jiaotong University School of Medicine, Shanghai, China; 4) Boston Children's Hospital, Harvard Medical School, Boston, MA., USA; 5) Shanghai Children's Medical Center, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Autism spectrum disorders (ASD) are childhood neurodevelopmental disorders that have a strong genetic basis. *CHD8*, a gene encoding a chromo-domain helicase DNA-binding protein that plays an important role on chromatin remodeling has been implicated as a strong effect cause of ASD inactivated by translocation, deletion or point mutation. *Chd8* deficient mice display increased brain weight, craniofacial abnormalities and autistic-like behaviors, as well as defects in synaptic function, resembling the human phenotype. Recently several functional studies of reduced *CHD8* expression by RNAi suppression or CRISPR/Case9 mediated mutation in iPSC-derived neural progenitor cells (NPCs) have showed that *CHD8* regulates, directly or indirectly, a number of other ASD risk genes. To explore the role of *CHD8* in the Chinese population, we used target capture and next generation sequencing of *CHD8* in a total of 96 ASD subjects. We identified three patients with novel *de novo* variants: a nonsense change (p.Arg1188\*), a splice site mutation (c.4818-1G>A) and a missense mutation (p.Tyr1168Asn). We also identified a second missense change (p.Lys2286Arg) in a fourth subject where inheritance could not be tested. Retrospective follow-up of the phenotypic manifestations of these ASD patients revealed macrocephaly detectable from the prenatal ultrasound test, dysmorphic features, overgrowth, gastrointestinal complaints and intellectual delay. More specific examination of published *CHD8*-associated phenotypes revealed repetitive behaviors involving the fingers, evident interest in communicating hindered by a significant expressive language defect, large testes and a tendency to overgrow during puberty. To assess potential genotype-phenotype correlations, we compiled all ASD-associated *CHD8* variants from literature and databases. Among 30 variants from patients, 20 are clear loss-of-function variants; the majority of these (15 of 20) are located in highly conserved functional domains of *CHD8*. In particular, individuals who carried *CHD8* mutations located in the helicase domain tended to have a more prominent and consistent overgrowth phenotype suggesting that disruption of this functional domain in *CHD8* might lead to a specific phenotype different from other *CHD8* mutations. Our study has expanded the phenotype spectrum of subjects with ASD due to *CHD8* mutation and added to the list of ASD-associated loss-of-function mutations in this gene.

**944T**

***Tmlhe* and *Bbox1* null mouse models of carnitine deficiency.** A. Ye<sup>1</sup>, F. Jimenez-Rondan<sup>1</sup>, Q. Sun<sup>1</sup>, J. Ge<sup>1</sup>, J. Heaney<sup>1</sup>, D. Lanza<sup>1</sup>, C. Burger<sup>2</sup>, D. Jjiang<sup>2</sup>, J. Seavitt<sup>1</sup>, M. Samuel<sup>2</sup>, A. Beaudet<sup>1</sup>. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Huffington Center on Aging and Department of Molecular Physiology & Biophysics, Baylor College of Medicine, Houston, TX.

**Background:** *TMLHE* deficiency is an X-linked, very common inborn error of carnitine biosynthesis affecting about 1 in 350 healthy males. It is reported to be a risk factor for autism with a penetrance of approximately 3%. We have hypothesized that brain carnitine deficiency can cause up to 10-20% of all autism apart from *TMLHE* deficiency in infants with a normal physical exam and absence of high penetrance Mendelian mutations (*BioEssays* in press). We wish to test whether brain carnitine deficiency in mice can cause any phenotypic features that might have parallels with autism. **Methods:** In both humans and mice, *TMLHE* encodes the first enzyme for carnitine biosynthesis, and *BBOX1* encodes the last enzyme in the pathway. *Tmlhe* null mice were generated using CRISPR methods to delete 10 bp of a coding exon while *Bbox1* null mice were generated through the Knockout Mouse Project (KOMP) with ES cell methods to delete an essential exon. *Bbox1* null mice were phenotyped as part of the KOMP project, and more limited phenotyping was performed on *Tmlhe* null mice. Metabolomic analysis was performed by Metabolon, Inc. **Results:** *Tmlhe* null mice are viable and fertile. *Bbox1* null mice born to  $-/+ \times -/+$  matings show 50% survival to weaning. In contrast, *Bbox1* null mice born to  $-/- \times -/-$  matings all die shortly after birth with the difference likely related to placental transfer of carnitine and the carnitine content of breast milk in  $-/+$  compared to  $-/-$  mothers. Plasma carnitine levels are reduced to 2% and 8% of wild-type levels in adult *Bbox1* and *Tmlhe* null mice respectively. Breast milk for null mothers showed 15% and 10.6% of wild-type levels of carnitine for *Bbox1* and *Tmlhe* respectively. Metabolomic analysis of *Bbox1* null mice revealed severely reduced levels of carnitine and many acyl-carnitines in plasma, liver, and brain and marked elevation of  $\gamma$ -butyrobetaine. We first evaluated the well-ordered retinal system. Immunohistochemical staining for microglia revealed increased distances between microglia cell somata and decreased total microglia numbers in *Bbox1* null mice. Remaining microglia were larger in size and exhibited increased process length. Other studies are in progress. **Conclusion:** These *Tmlhe* and *Bbox1* mouse models demonstrate severe carnitine deficiency in brain, liver, and plasma and should be helpful in testing whether brain carnitine deficiency can cause developmental or functional abnormalities that might parallel human autism.

**945F**

**Severity of *GABBR2* mutations determines neurological phenotypes ranging from Rett-like syndrome to epileptic encephalopathy.** Y. Yoo<sup>1</sup>, J. Jung<sup>2</sup>, Y. Lee<sup>3</sup>, K. Miller<sup>4</sup>, N. Shur<sup>4</sup>, C. Clow<sup>4</sup>, R. Ebel<sup>5</sup>, S. DeBrosse<sup>5</sup>, J. Y. Seong<sup>6</sup>, H. Jung<sup>2</sup>, J.-H. Chae<sup>2</sup>, M. Choi<sup>1,6</sup>. 1) Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, 03080, Republic of Korea; 2) Department of Anatomy, Brain Research Institute, and Brain Korea 21 PLUS Project for Medical Science, Yonsei University College of Medicine, Seoul, 03722, Republic of Korea; 3) Graduate School of Medicine, Korea University, Seoul, 02841, Republic of Korea; 4) Albany Medical Center, Albany, NY 12208, USA; 5) UH Cleveland Medical Center, Center for Human Genetics, Cleveland, OH 44106, USA; 6) Department of Pediatrics, Seoul National University College of Medicine, Seoul National University Children's Hospital, Seoul, 03080, Republic of Korea.

Rett syndrome (RTT) and epileptic encephalopathy (EE) are devastating neurodevelopmental disorders with distinct diagnostic criteria. However, highly heterogeneous and overlapping clinical features often allocate patients into the boundary of the two conditions, complicating accurate diagnosis and proper medical interventions. Although previous studies revealed genetic causes that lead to the two diseases, the specific molecular mechanism that allows an understanding of the pathogenesis and relationship of the two conditions remains to be uncovered. Here we show GABAB receptor R2 (*GABBR2*) as a genetic factor that determines RTT- or EE-like phenotype expression depending on the variant positions. By screening genetic factors from RTT-like patients without *MECP2* mutations, which account for ~90% of RTT patients, we identified a recurring *de novo* variant in *GABBR2* that reduces the receptor function from four patients (two Korean and two European origins), while different *GABBR2* variants from EE patients possess a more profound effect in reducing receptor activity when tested on a cell culture system and is more responsive to agonist rescue in an animal model. Finally, transcriptome-wide analysis of developing human brain tissues demonstrated *GABBR2* as a bridging factor that provides a link between RTT- and EE-associated genes, further supporting the notion that *GABBR2*-mediated GABA signaling is a crucial factor in determining the severity and nature of neurodevelopmental phenotypes.

**946W**

**Characterization of a complex translocation causing 3q28ter duplication and 10q26.2ter deletion in a child with self-injurious behavior.** *I.M. Adeshina<sup>1,2</sup>, A.T. Joynt<sup>1</sup>, A.L. Norris<sup>2</sup>, J. Thorpe<sup>2</sup>, J. Schmidt<sup>2</sup>, A. Fatemi<sup>2</sup>, L. Hagopian<sup>2</sup>, J. Pevsner<sup>1,2</sup>.* 1) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Neurology, Kennedy Krieger Institute, Baltimore, MD.

The identification of genetic factors that drive self-injurious behavior (SIB) is complicated by the heterogeneity of patient phenotypes. Here we report a nonverbal female adolescent with severe stereotypic movement disorder with SIB, and complex cytogenetics. The proband's full phenotype included global developmental delay, congenital scoliosis, dysthymia, and anhedonia. Previous cytogenetics revealed a complex translocation that was also present in the mother: 46,XX,t(3;14;10)(q27;q22;q26.1).ish t(3;14;10)(D3S4560-,D10S2490+;D14S308-,D3S4560+;D10S2490-,D14S308+). To clarify the nature of the abnormality and to identify genes disrupted by the translocations, we subjected DNA from the proband and her parents to whole genome sequencing (WGS, Illumina HiSeq X), and whole genome optical mapping with *de novo* assembly (Bionano Saphyr). Translocations were mapped and identified from structural variant (SV) and copy number variant (CNV) analyses of WGS and Bionano data, and confirmed by Sanger sequencing. Finally, to correlate phenotype and genotype in the proband, we systematically reviewed related case reports in the literature. Genomic analysis revealed that the complex translocations were balanced in the mother, but unbalanced in the proband. While the proband did harbor t(10;14) and t(14;3), instead of inheriting a maternal t(3;10), she inherited the normal maternal copy of chromosome 3, resulting in a 10q26.2ter deletion and 3q28ter duplication. Genes in one or both of these regions likely underlie the proband's phenotype, spanning neurodevelopmental, musculoskeletal, and psychiatric domains. Several dozen cases of 10q26 deletion syndrome (MIM #609625) have been reported. However, there are only sporadic reports of duplications involving 3q28ter. Phenotypes reported in 10q26.2 syndrome patients closely mirrored those in the proband, notably aggressive behavior with limited attention span and violent mood swings, alternating between being provocative or destructive and affectionate. Using complementary methods of WGS and Bionano, we characterized complex germline translocations present in an apparently normal female, and the incomplete transmission of these translocations to her child. Consequently, the child harbored 10q28ter deletion and 3q26.2ter duplication. Review of the literature implicates 10q26.2 genes, while there is insufficient evidence to suggest or refute contribution from 3q28 genes.

**947T**

**The novel aldehyde trap ADX-102 reduces accumulations of GHB and GABA in brain tissue from succinic semialdehyde dehydrogenase-deficient mice.** *S.G. Macdonald<sup>1</sup>, V. Cullen<sup>1</sup>, A. Halilovic<sup>1</sup>, L. Case<sup>2</sup>, T. Brady<sup>1</sup>, S.L. Young<sup>1</sup>.* 1) Aldeyra Therapeutics, Inc., Lexington, MA; 2) Jackson Laboratory, Bar Harbor, ME.

ADX-102 is a novel aldehyde-sequestering agent that forms irreversible adducts with aldehydes, including succinic semialdehyde (SSA). Succinic semialdehyde dehydrogenase deficiency (SSADHD; MIM 271980) is an inherited disorder associated with intellectual disability, seizures, ataxia, sleep disorders and anxiety. A loss-of-function mutation in succinic semialdehyde dehydrogenase (SSADH; ALDH5A1), which metabolizes SSA to succinate, results in accumulation of gamma-hydroxybutyrate (GHB) and 4-amino-butyrate (GABA). ADX-102, which covalently sequesters aldehydes on a 1:1 stoichiometric basis, may deplete SSA and result in reduced levels of GHB and GABA in SSADHD. Thus, we tested ADX-102 in a mouse model of SSADHD. Wild type (wt) and B6.129-Aldh5a1<sup>tm1Kmg</sup>/J (null) mice were given 50 mg/kg ADX-102 or vehicle intraperitoneally once or twice daily from birth. After 3.5, 7, or 15 days, plasma and brain were analyzed for GHB and GABA. At birth, brain and plasma GHB levels (~400 μM) were 173- and 81-fold higher, respectively, in null mice than wt mice; brain and plasma GABA levels were 2.8- and 3.8-fold higher, respectively, in null mice than wt mice. Brain GHB and GABA accumulated through day 15 of life, with a sharp increase in GHB seen between days 7 and 15. The phenotype was severe, with some null mice dying by Day 11. ADX-102 had little effect on accumulations of GHB and GABA in plasma or brain. The results are consistent with a parallel pharmacokinetic study in wt mice indicating that there was ~10-fold more GHB in plasma and 12-fold more GHB in brain of null mice at birth, relative to ADX-102 levels after one day of dosing; GABA in plasma and brain of null mice at birth was 1.2- and 122-fold higher, respectively, than ADX-102 levels. The data suggest that ADX-102:SSA adduct formation in plasma may result in too little ADX-102 reaching the brain to affect GHB and GABA levels in null mice. To maximize drug exposure, brain slices from null and wt mice treated for 3.5 days *in vivo*, were incubated *ex vivo* for 24 hours, in the presence or absence of 422 μM ADX-102. ADX-102 statistically reduced GHB and GABA levels in brain tissue from null mice and in the incubation medium. Reductions ranged from 32% to 40% for GHB and 24% to 63% for GABA ( $p < 0.0001$  to  $p < 0.05$ ). The data show that ADX-102 can significantly reduce the formation of GHB and GABA in null mouse brain. ADX-102, and aldehyde-trapping in general, represent a novel approach to the treatment of SSADHD.

**Identification of mutations in patients from southern Italy with amyotrophic lateral sclerosis using multigene panel testing.** G. Annesi<sup>1</sup>, M. Gagliardi<sup>1</sup>, G. Iannello<sup>1</sup>, R. Procopio<sup>1</sup>, A. Quattrone<sup>1,2</sup>. 1) National Research Council, Catanzaro, catanzaro, Italy; 2) Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia, Catanzaro, Italy.

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease that primarily affects motor neurons, resulting in progressive paralysis and death. The majority of ALS cases are sporadic, meaning that they occur with no family history of the disease (sALS). The remaining 5–10% of cases are familial (fALS), where the disease is inherited in a Mendelian, generally dominant, fashion within a family. In recent years several genes have been linked to both fALS and sALS. In this study, we performed multigene panel testing to identify mutations in ALS-related genes. We tested 25 consecutive patients with sporadic ALS. Exome sequencing was performed using the Ion AmpliSeq Exome kit on Ion Torrent Proton Sequencer. In total, 21 genes were ultimately selected for the targeted sequencing panel. Several bioinformatics analyses were performed to identify the functional and structural significance of missense mutations or splice-site variants observed in patients. Based on a comparison with the dbSNP and HGMD databases, we identified known pathogenic variants of the ALS-related genes in 25 ALS patients. We searched dbSNP and HGMD to identify known pathogenic variants that had been previously reported to cause ALS. We also identified novel nonsynonymous variants that were classified as “Probably Damaging” by PolyPhen2 and Mutation Taster which yielded a list of novel potentially pathogenic variants. All variants screened were validated by Sanger sequencing. Among the potentially pathogenic variants, we focused on nonsynonymous variants that did not appear in genome databases and were predicted to be pathogenic by an *in silico* analysis.

**949W**

**Evaluation of pathogenic non-coding variants within whole genome data using encephalopathies as a model.** D. Misceo<sup>1</sup>, D. Sanjeevani<sup>1</sup>, A. Holmgren<sup>1</sup>, M.D. Vigeland<sup>1</sup>, P. Strømme<sup>2,3</sup>, M. van de Vorst<sup>4</sup>, C. Gilissen<sup>4</sup>, S. Rayner<sup>1</sup>, E. Frengen<sup>1</sup>. 1) Oslo University Hospital and University of Oslo, Oslo, Norway; 2) Faculty of Medicine, University of Oslo, Oslo, Norway; 3) Division of Pediatric and Adolescent Medicine, Oslo University Hospital, Oslo, Norway; 4) Department of Human Genetics Radboud University Medical Center, Nijmegen, The Netherlands.

The roles of protein coding DNA variants in human diseases have been extensively studied, while variants in non-coding (nc) DNA have received less attention. In this work we report our progress on the development of a pipeline to investigate nc genomic regions and identifying their association with disease. The project focuses on a patient cohort with progressive encephalopathies (PE). PE encompasses a broad group of diseases with childhood onset that are mostly metabolic or neurodegenerative in nature. The cohort comprises 71 families selected by a single child neurologist among patients that he has seen in the past 25 years. The patients in these families were negative for common lysosomal, mitochondrial, peroxisomal, and relevant metabolic and degenerative diseases, with no history of infectious diseases or perinatal hypoxia. Trio WES and subsequently WGS were performed (average 10X depth 97% and 20X depth 92% in WGS data). Analysis of protein coding DNA revealed a pathogenic variant for 38 families, but not in the remaining 33. We are therefore initiating the investigation of the nc regions of the genome in these 33 families. Because of the magnitude of the nc regions, we focus on regions related to regulation of gene expression (for examples promoters and enhancers) and miRNA. Our primary aim is to develop a pipeline to systematically and comprehensively annotate and prioritize putative pathogenic nc DNA variants in Mendelian diseases using WGS data. A key component of this work is our effort to standardize and integrate annotation to generate a comprehensive reference source for nc features. This can be used to interpret WGS data, to identify signature variants, which can then be used as input to (for example) statistical learning packages to predict associations with phenotype. The nc DNA variants prioritized as putatively pathogenic can then be studied functionally. In this step we use fibroblasts from patients and/or commercial cell lines. Variants with documented *in vitro* effect will be studied *in vivo*, providing novel knowledge on the function of nc DNA in human biology and pathology. We present our initial efforts on this work, related to both the pipeline (methodology, annotation) and some preliminary findings based on investigation of these regions.

**Novel mutations in *CLN6* cause late-infantile neuronal ceroid lipofuscinosis in two unrelated patients.** B. Behnam<sup>1</sup>, J. Chin<sup>1</sup>, M. Davids<sup>1</sup>, P. Sharma<sup>1</sup>, C. Wang<sup>1</sup>, W. Zein<sup>2</sup>, G.A. Gretchen<sup>1,2</sup>, C. Toro<sup>1,2</sup>, X. Chepa Lotrea<sup>1</sup>, D.R. Adams<sup>1,2</sup>, C.J. Tiff<sup>1,2</sup>, W.A. Gahl<sup>1,2</sup>, M.C. Malicdan<sup>1,2</sup>. 1) UDP Translational Lab, NHGRI, National Institute of Health (NIH), Bethesda, MD; 2) 1. Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 3) National Eye Institute (NEI), National Institute of Health (NIH), Bethesda, MD.

Ceroid-lipofuscinosis neuronal 6 (*CLN6*) is a transmembrane protein located in the endoplasmic reticulum and involved in lysosomal lumen acidification. Mutations in *CLN6* are implicated in late-infantile neuronal ceroid lipofuscinosis (LINCL), or Batten disease, and in adult-onset Kufs disease type A. Here, we report two patients from unrelated families evaluated by the NIH Undiagnosed Diseases Program at age 9 (Patient 1) and 11 (Patient 2), and diagnosed with LINCL. Both patients demonstrated some of the typical phenotypic features, namely motor impairment, seizures and developmental regression, though ophthalmologic examination did not reveal any visual impairment. Whole-exome and Sanger sequencing identified novel compound heterozygous mutations in *CLN6*. Patient 1 has compound heterozygous c.218-220dupG-GT; p.Trp73dup and c.296A>G; p.Lys99Arg mutations, while Patient 2 has a homozygous c.723G>T; p. Met241Ile mutation. Skin biopsy electron micrographs show large numbers of small membrane-bound vesicles, in addition to lipofuscin deposits. Expression analysis in dermal fibroblasts showed no change in *CLN6* mRNA levels from both patients when compared to control. Immunofluorescence studies of patients' cells showed enlarged lysosomes and increase in LysoTracker Red staining suggesting that the acidification of the lysosomes is increased. Western blot analysis showed increased amounts of lipidated autophagosome-specific protein (LC3-II), indicating impaired basal levels of autophagy. To date, among >200 reported cases of *CLN6*-related Batten disease, nine patients, including those in this report, do not manifest or developed delayed onset of visual impairment. Although the precise function of *CLN6* is not well understood, its role in regulation of lysosomal acidity may be important in enzymatic degradation of post-translationally modified proteins. Lysosomal accumulation and aggregation of undegraded proteins is cytotoxic, particularly to neurons. The absence of visual impairment in our patients may indicate some residual expression of functional protein. This study supports the role of *CLN6* in lysosomal function, and highlights the importance of considering a *CLN6* diagnosis even in patients with seemingly normal vision.

**951F**

**17p13.3 microdeletions between *YWHAE* and *LIS1* (*PAFAH1B1*) cause a unique leukoencephalopathy.** L.T. Emrick<sup>1</sup>, J.A. Rosenfeld<sup>1</sup>, L.C. Burrage<sup>1</sup>, M. Jain<sup>1</sup>, J.W. Belmont<sup>1</sup>, C.A. Bacino<sup>1</sup>, L. Immken<sup>2</sup>, B. Lee<sup>1</sup>, S.R. Lalani<sup>1</sup>, Members of the UDN. 1) Baylor College of Medicine, Houston, TX; 2) Dell Childrens Hospital, Austin, TX.

17p13.3 deletions cause Miller-Dieker syndrome, when the deletion includes the *YWHAE* and *LIS1* (*PAFAH1B1*) genes. Smaller 17p13.3 deletions may cause isolated lissencephaly sequence when only involving *LIS1*. In larger deletions, it is thought that haploinsufficiency of *YWHAE* and *CRK* contributes to the more severe Miller-Dieker phenotypes, and smaller deletions including *YWHAE* and *CRK* but sparing *LIS1* have been described in individuals with growth restriction, cognitive impairment, dysmorphic features, and various brain abnormalities. We have identified four individuals from three families with 17p13.3 deletions between and not including *LIS1* and *YWHAE/CRK*, who all have multi-focal white matter lesions and hypermobile joints. Cognition is normal, although some behavioral concerns are present. A fifth individual with a deletion of the distal portion of this region was identified with a normal MRI, suggesting that the proximal genes in the region may be critical for the brain findings in these individuals, although reduced penetrance cannot be ruled out. A combination of our patients and those in the literature with white matter changes with deletions in this chromosomal region narrows the overlapping region for this phenotype to ~300kb, including 10 RefSeq genes. Previous literature has hypothesized some dysmorphic features and white matter changes related to *YWHAE*, however our patients do not have this gene deleted. Our cohort contributes evidence to the presence of multiple genes within 17p13.3 required for proper brain formation.

**Large-scale systematic analysis of recessive neurodevelopmental disorders in consanguineous families.** A. Gregor<sup>1</sup>, R.D. George<sup>2</sup>, B. Saunders<sup>2</sup>, J.G. Gleeson<sup>1,2</sup>. 1) Laboratory of Pediatric Brain Disease, The Rockefeller University, New York, NY; 2) Howard Hughes Medical Institute, Rady Children's Institute of Genomic Medicine, University of California, San Diego, CA.

Consanguineous marriages are common in about one-fifth of the world's population. In children from consanguineous marriages, homozygous mutations are common and lead to a doubling of birth defects. To analyze the contribution of recessive mutations to developmental brain diseases, we assembled a cohort of more than 2,200 consanguineous families from the Greater Middle East with various neurodevelopmental brain disorders with suspected autosomal recessive inheritance. Each case was phenotyped in detail, which included brain MRI, metabolic testing, electrophysiology and detailed history/physical examination. We performed whole-exome sequencing across these families to systematically discover putatively causal variants in both known and novel disease genes. All samples were processed jointly to identify rare, potentially damaging variants that followed expected recessive inheritance patterns. We identified likely deleterious variants in previously published disease genes in about half of the families. These mutations affected more than 400 genes, highlighting the extreme genetic heterogeneity of neurodevelopmental disorders. Roughly 60 of these genes have previously been implicated in only single cases. These previously published cases had overlapping phenotypes with our patients, but our patients extended the phenotype in specific ways. About half of the identified mutations were predicted protein truncations, and half were predicted missense variants affecting highly conserved amino acids. In line with a recessive mode of inheritance, mutated genes were enriched for genes affecting metabolic processes ( $P = 9.8 \times 10^{-6}$ ). Newborn metabolic screening is not routinely offered at our sites of recruitment, and thus our genetic diagnosis led to changes in diet or treatment for many of these patients. Work is ongoing to identify recurrently mutated novel genes within our cohort and to identify further factors that may contribute to the likelihood of solving cases from this cohort. .

**Genetic, clinical, and imaging study of Pelizaeus-Merzbacher disease using the Integrative Brain Imaging Support System (IBISS).** K. Inoue<sup>1</sup>, K. Sumida<sup>2</sup>, J. Takanashi<sup>3</sup>, H. Matsuda<sup>4</sup>, M. Sasaki<sup>5</sup>, N. Sato<sup>2</sup>. 1) Dept MR & BD Res, Natl Inst Neurosci, NCNP, Kodaira, Tokyo, Japan; 2) Department of Radiology, National Center Hospital of Neurology and Psychiatry, Kodaira, Tokyo, Japan; 3) Pediatrics, Tokyo Women's Medical University, Yachiyo Medical Center, Yachiyo, Chiba, Japan; 4) Integrative Brain Imaging Center, NCNP, Kodaira, Tokyo, Japan; 5) Pediatrics, National Center Hospital of Neurology and Psychiatry, Kodaira, Tokyo, Japan.

Background: Pelizaeus-Merzbacher disease (PMD) represents the most common disorder of hypomyelinating leukodystrophies. PMD is caused by mutations in *PLP1*, which encodes a major myelin membrane protein in the CNS. Amino acid substitutions, genomic duplications, and null mutations of *PLP1* cause different severity of the disease through distinct molecular mechanisms. Magnetic resonance image (MRI) findings are the most critical diagnostic tool for hypomyelinating leukodystrophies including PMD. However, correlation among genotype, clinical severity and MRI findings has not been thoroughly studied in a large cohort of PMD. Methods: We established an MR imaging database for hypomyelinating leukodystrophies, termed Integrative Brain Imaging Support System (IBISS). We selected 19 PMD patients from IBISS and analyzed their genetic, clinical, and imaging data. Results: We identified 10 patients with *PLP1* duplication and 9 patients with point mutations (including 1 with in-frame deletion and 1 with splicing mutation). The clinical stage tended to be more severe when the whole brainstem, or corticospinal tract in the internal capsule showed abnormally high intensity on T2WI. Diffuse T2-high signal of brainstem was observed only in the patients with *PLP1* point mutation. Myelination age "before birth" on T1WI was correlated with the clinically severe phenotypes. On the other hand, eight patients whose myelination ages were > 4 months on T1WI were associated with mild clinical phenotypes. Advanced myelination was observed in 3 of the 7 followed-up patients. Four patients had atrophy of the cerebellum, and 17 patients had atrophy of the corpus callosum. Discussion: We have demonstrated a wide variety of imaging findings of PMD using a imaging DB, IBISS. Signal intensity of brainstem and corticospinal tract of internal capsule would be the points to presume clinical severity in PMD patients. The spectrum of MRI findings should be kept in mind to diagnose PMD and to differentiate from other demyelinating leukodystrophies.

**Rare SOX30 variants in juvenile myoclonic epilepsy.** S. Jaishankar<sup>1</sup>, R. Ratnapriya<sup>1</sup>, S. Nayak<sup>1</sup>, R. Reddy<sup>1</sup>, M. Sharma<sup>1</sup>, R. Ghugari<sup>1</sup>, A. Kapoor<sup>1</sup>, S. Shankar<sup>2</sup>, S. Sinha<sup>3</sup>, P. Satishchandra<sup>4</sup>, A. Anand<sup>1,2</sup>. 1) Molecular Biology and Genetics Unit, Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR), Bangalore 560 064, India; 2) Neuroscience Unit, Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR), Bangalore 560 064, India; 3) Department of Neuropathology, National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore 560029, India; 4) Department of Neurology, National Institute of Mental Health and Neurosciences (NIMHANS), Bangalore 560029, India.

Juvenile myoclonic epilepsy (JME) is the most common subtype of genetic generalized epilepsy syndrome characterized by frequent early morning seizures beginning during early adolescence. The genetics of JME is complex and not completely understood. To date, 29 genetic loci are known for the disorder. Here, we present our work aimed at identifying the causative gene in a family segregating JME in an autosomal dominant manner. Genome wide linkage analysis helped us to identify a critical region of about 15 megabases between markers D5S2012 and D5S2075 (two-point lod score 3.66 at  $\theta = 0$  for D5S415 at chromosome 5q34). We carried out whole genome sequencing of two members (unaffected father and affected daughter) of the family and examined genomic sequences in the critical interval. The 5q34 JME locus consists of a cluster of GABA genes (*GABRG2*, *GABRA1*, *GABRA6* and *GABRB2*) which are strong candidates for JME. We analyzed exonic, intronic and promoter sequences of these four genes by Sanger sequencing and found no potentially functional variant. In the analysis of whole genome sequence data for the region, 5673 sequence variants were obtained. These variants were scrutinized based on their zygosity, allele frequencies among controls and segregation with the clinical phenotype in the family. We detected four variants: c.-57 G>A in the 5' UTR of *SOX30*; and c.\*1437 T>C, c.\*1058 C>T and c.\*322 G>A in the 3' UTRs of *EBF1*, *CNOT8* and *ZBED8*, respectively. We carried out mammalian cell based luciferase reporter assays for the 5' UTR and 3' UTR variants. The c.-57 G>A *SOX30* variant exhibited significantly altered reporter activity while the other three variants did not produce a significant difference. Further, we examined complete transcript structure of *SOX30* in 480 JME patients and 480 control samples. In this search, 15 additional rare coding variants present almost exclusively in the patients were obtained. Functional correlates of these variants were studied in cultured mammalian cells. Immunocytochemistry indicated no changes in the localization of the proteins carrying the variants, while reporter luciferase assay indicated that a sub-set of these variants had substantially altered their ability to regulate the reporter gene. Our observations provide prima facie evidence of the role of *SOX30* for JME.

## 955W

**AOH-mediated recessive mutation burden can result in blended phenotypes.** E. Karaca<sup>1</sup>, J. Punetha<sup>1</sup>, J.E. Posey<sup>1</sup>, Z. Coban Akdemir<sup>1</sup>, X. Song<sup>1</sup>, M.M. Khayat<sup>1</sup>, T. Harel<sup>1,2</sup>, S.N. Jhangiani<sup>3</sup>, O. Ozalp Yuregir<sup>4</sup>, S. Bozdogan<sup>5</sup>, G. Yesil<sup>6</sup>, S. Isikay<sup>7</sup>, Y. Bayram<sup>1</sup>, D. Pehlivan<sup>1</sup>, J.M. Fatih<sup>1</sup>, D.M. Muzny<sup>8</sup>, R.A. Gibbs<sup>2</sup>, J.R. Lupski<sup>1,8,9</sup>. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Genetic and Metabolic Diseases, Hadassah-Hebrew University Medical Center, Jerusalem 91120, Israel; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, USA; 4) Genetic Diagnosis Center, University of Health Sciences, Numune Training and Research Hospital, Adana 01370, Turkey; 5) Department of Medical Genetics, Cukurova University Faculty of Medicine, Adana 01330, Turkey; 6) Department of Medical Genetics, Bezmialem University, Istanbul 34093, Turkey; 7) Department of Physiotherapy and Rehabilitation, Hasan Kalyoncu University, School of Health Sciences, Gaziantep 27410, Turkey; 8) Department of Pediatrics, Baylor College of Medicine, Houston, TX, USA; 9) Texas Children's Hospital, Houston, TX, USA.

Phenotypic expression can be impacted by variation at more than one locus, complicating the molecular diagnosis. In some cases, phenotypic expansion observed in association with a known Mendelian disease gene may also be a hallmark of a blended phenotype resulting from multilocus variation. We hypothesized that such multi-locus disorders would be enhanced in situations that favored a high burden of 'absence of heterozygosity' (AOH), as observed in families with high levels of consanguinity. Whole exome sequencing (WES) was applied in 197 families with neurodevelopmental phenotypes, of which the results of initial exome variant analyses have been reported for 128. Approximately 80% of families reported consanguinity, suggesting AOH may contribute to molecular diagnoses. We calculated B-allele frequency from exome variant data to detect regions of AOH for each case. Analysis of the first 128 families resulted in identification of molecular diagnoses for 85.2% (109/128) cases, of which multilocus variation contributing to the observed clinical phenotype was identified in 11% (12/109) of cases. AOH contributed to the multilocus variation in 7 of these 12 families, including one family for which 3 distinct loci contributing to the phenotype were located within the same 44.8 Mb region of AOH on chromosome 1. Analyses of the additional 69 cases are ongoing and have yielded at least 4 more families for which multilocus variation within regions of AOH potentially contributes to a blended phenotype. Our preliminary data suggest that the portion of these diagnosed cases that have apparent multilocus effects is both enriched for AOH, and is potentially greater than the approximately 5% observed in mixed, unascertained populations with no suspectedly high levels of consanguinity (Posey et al., 2017). The observation of AOH may lead to a prediction of more likely involvement of additional loci, and variability of the size and location of AOH regions between affected siblings can lead to differences in recessive disease burden, offering a rich opportunity to dissect genotype-phenotype relationships. Comprehensive implementation of WES has thus enabled genomic medicine to move from individual study of single gene Mendelian disorders to a more comprehensive understanding of the interplay of genetic variation at more than one locus and resulting phenotypic expression; i.e. from Mendelian genetics to Mendelian genomics.

**Characterizing genetic causes of neurodevelopmental disorders with brain malformations in a predominantly Turkish cohort.** J. Punetha<sup>1</sup>, E. Karaca<sup>1</sup>, J.E. Posey<sup>1</sup>, Z. Coban Akdemir<sup>1</sup>, X. Song<sup>1</sup>, M.M. Khayat<sup>1</sup>, T. Harel<sup>1,2</sup>, S.N. Jhangiani<sup>3</sup>, Y. Bayram<sup>1</sup>, D. Pehlivan<sup>1</sup>, J.M. Fatih<sup>1</sup>, D. Muzny<sup>3</sup>, R.A. Gibbs<sup>3</sup>, J.R. Lupski<sup>1,3,4,5</sup>, *Baylor-Hopkins Center for Mendelian Genomics*. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Genetic and Metabolic Diseases, Hadassah-Hebrew University Medical Center, Jerusalem 91120, Israel; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, USA; 4) Department of Pediatrics, Baylor College of Medicine, Houston, TX, USA; 5) Texas Children's Hospital, Houston, TX, USA.

Neurodevelopmental disorders (NDDs) show a wide range of genetic and clinical heterogeneity making their genetic diagnoses challenging and highlighting the complexity of the human nervous system developmental processes. Clinical heterogeneity observed in NDDs is generally categorized into either structural or functional brain deficits, requiring a thorough analysis of phenotype, brain imaging, and molecular data. In this study, we have performed whole exome sequencing (WES) for molecular diagnoses of approximately 197 families with NDDs (mostly consanguineous) associated with structural brain malformations. Out of these, 128 families have been previously reported (Karaca *et al.*, *Neuron* 2015) with a molecular diagnosis rate of ~85% which included known single nucleotide variants (SNVs) and copy number variants (CNVs) in known disease genes, novel disease genes, and potential candidate genes. Potential disease-causing variants were identified in 41 candidate disease genes in 46 families. Here, we discuss the fate of candidate genes that have since been confirmed as pathogenic through ascertainment of additional families with similar phenotypes, supporting functional data, and/or reports in the literature: *PRUNE*, *VARs*, *SMARCA1*, *SLC18A2*, *OGDHL*, *CPLX1*, and *ASTN1*. We include follow-up studies of these potential candidate genes and an update on their pathogenicity status. In addition, we present new findings from WES analyses of an additional 69 families with brain malformations that have revealed novel candidate genes as well as novel variants in known disease genes. Further studies including segregation and functional studies are being carried out in order to determine pathogenicity for these candidates. As we delve deeper into the molecular basis of neurodevelopmental disorders in a large cohort with structural brain malformations, we aim to maximize our understanding of different genetic mechanisms that underlie the complexity of development in the human central nervous system.

**c.105C>A [p.(Tyr35Ter)] variant in *AIMP2* causes microcephaly, intellectual disability, seizures and spastic quadripareisis.** A. Shukla<sup>1</sup>, A.D. Bhowmik<sup>2</sup>, M. Hebbar<sup>3</sup>, K.V. Rajagopal<sup>3</sup>, K.M. Girisha<sup>4</sup>, N. Gupta<sup>4</sup>, A. Dalal<sup>4</sup>. 1) Medical Genetics, Kasturba Medical College, Manipal, Udipi, Karnataka, India; 2) Diagnostics Division, Centre for DNA Fingerprinting and Diagnostics, Hyderabad, India; 3) Department of Radiodiagnosis and Imaging, Kasturba Medical College, Manipal University, India; 4) Division of Genetics, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India.

We ascertained two consanguineous families with two affected children each with microcephaly, refractory seizures, intellectual disability and spastic quadripareisis. Brain MR imaging showed atrophy of cerebrum, cerebellum and spinal cord, prominent cisterna magna, symmetric T2 hypointensities in the bilateral basal ganglia and thinning of corpus callosum. Whole exome sequencing of three affected individuals revealed c.105C>A [p.(Tyr35Ter)] variant in *AIMP2* as the likely cause of their condition. In human and other mammalian cells, a unique large tRNA multi-synthetase complex organizes 9 cytoplasmic aminoacyl-tRNA synthetases consisting of bifunctional, as well as the monospecific tRNA synthetases and 3 non-enzyme factors, namely p43 (*AIMP1*), p38 (*AIMP2*) and p18 (*AIMP3*). The p38 protein is a key component of the multi-ARS complex and is crucial for the assembly of the complex. *In vitro* and animal studies have shown that *AIMP2* may be a tumor suppressor, however in human cancers the expression status at the tissue level is not well understood. Various components of the ARS complex are now known to cause encephalopathies, peripheral neuropathies and other sensorineural disorders. Among them, mutations in 10 cytosolic ARSs are associated with Charcot-Marie-Tooth and related neuropathies and 14 mitochondrial ARSs are associated with severe leukoencephalopathies. *AIMP1* has been associated with hypomyelinating leukodystrophy-3 characterized by progressive neurodegeneration, microcephaly, spasticity, coarse facies, progressive contractures, generalized brain atrophy and early death. The phenotype of our patients shares marked similarity with that of mutations in closely related gene, *AIMP1*. We hereby report the first human disease associated with deleterious mutations in *AIMP2*.

**Expanding the genetic spectrum in myoclonic astatic epilepsy.** S. Tang<sup>1,2</sup>, L. Addis<sup>1</sup>, A. Smith<sup>1</sup>, S. Topp<sup>1</sup>, D. Meß<sup>1</sup>, A. Parker<sup>1</sup>, S. Agrawal<sup>1,6</sup>, E. Hughes<sup>2</sup>, K. Lascelles<sup>2</sup>, R. Williams<sup>2</sup>, P. Fallon<sup>2</sup>, R. Robinson<sup>2</sup>, J.H. Cross<sup>2</sup>, T. Hedderly<sup>2</sup>, C. Eltze<sup>2</sup>, C. Ferrie<sup>2</sup>, T. Kerr<sup>2</sup>, A. Desurkar<sup>2</sup>, N. Hussain<sup>10</sup>, M. Kinali<sup>11</sup>, G. Vassallo<sup>12</sup>, W. Whitehouse<sup>13</sup>, S. Goyal<sup>1</sup>, M. Absoud<sup>2</sup>, C. Marin<sup>1,3</sup>, R. Guerrini<sup>4</sup>, M.A. Simpson<sup>1</sup>, D.K. Pal<sup>1,2</sup>, Euroepinomics RES consortium. 1) King's College London, London, United Kingdom; 2) Kings Health Partners, London, United Kingdom; 3) Anna Meyer Children's Hospital, Florence, Italy; 4) Adenbrookes Hospital, Cambridge, United Kingdom; 5) Birmingham Childrens Hospital, United Kingdom; 6) St Georges Hospital, London, United Kingdom; 7) Great Ormond Street Hospital, London, United Kingdom; 8) Leeds University Hospital, United Kingdom; 9) Sheffield University Hospital, United Kingdom; 10) Leicester University Hospital, United Kingdom; 11) Chelsea and Westminster Hospital, United Kingdom; 12) Manchester Children's Hospital, United Kingdom; 13) Nottingham University Hospital, United Kingdom.

Myoclonic astatic epilepsy (MAE) is a rare childhood onset epilepsy in which the spectrum of neurodevelopmental impairment and genetic aetiology are largely unknown. We therefore deeply phenotyped MAE patients and performed exome analysis filtered on curated epilepsy, intellectual disability, autism and developmental disorder gene sets to identify genetic aetiologies. Variants were considered pathogenic if they were novel in Gnomad, *de novo*, correlated with gene function and correlated with previously associated phenotypes. We assembled the largest MAE cohort (n=109, 67% male) to date. A family history of epilepsy was reported in 38% and febrile seizures in 9%. The epilepsy phenotype is similar to previously published cohorts. We identified likely pathogenic or candidate variants in 18 (16.5%) of 109 cases. This compromised known genes associated with MAE: *CHD2* n=2, *KCNA2* n=1, *KIAA2022* n=2, *SCN1A* n=1, *SCN2A* n=1, *SLC6A1* n=1, *STX1B* n=1, *SYNGAP1* n=3; epilepsy associated genes novel for MAE: *KCNB1* n=1, *MECP2* n=1, *KCNH5* n=1, and three new candidate genes: *ASH1L* n=1, *CHD4* n=1 and *SMARCA2* n=1. The major genetic pathways involved are ion channels, synaptic transmission, transcription regulation and chromatin modification. We describe phenotype-genotype correlations and recognised that patients with identified monogenic aetiology tended to have a severe neurodevelopmental phenotype with intellectual disability present in 17/18, autism in 8/18 and attention deficit hyperactive disorder in 6/18. These findings reveal the shared genetic aetiology and pathways of epilepsy and neurodevelopmental disorders and the extent of genetic heterogeneity of MAE and highlight the promise of precision medicine for these patients. .

## 959T

**Exome sequencing identifies a novel *FBXO38* variant inherited from a mosaic mother to cause distal hereditary motor neuropathy Type IID with distinct features.** S.A. Ugur Iseri<sup>1</sup>, N.H. Akcakaya<sup>1,2</sup>, B. Salman<sup>1</sup>, Z. Yapiçlı<sup>3</sup>. 1) Istanbul University, Aziz Sancar Institute of Experimental Medicine, Department of Genetics, Istanbul, Turkey; 2) Turkey Spastic Children Foundation, Istanbul, Turkey; 3) Istanbul University, Istanbul Medical Faculty, Department of Neurology, Division of Child Neurology, Istanbul, Turkey.

**Introduction:** The *FBXO38* gene encodes a large protein that contains an F-box domain, which acts as a transcriptional co-activator of the Kruppel-like factor 7. *FBXO38* may also be participated in protein ubiquitination. Heterozygous *FBXO38* variations have been implicated in distal hereditary motor neuropathy type IID (HMN2D) with autosomal dominant inheritance only in two unrelated families. The disease starts with the onset of walking difficulty in the second to fourth decade of life. **Methods and Results:** Two siblings; a 20-year-old male and an 11-year-old female have been referred to our clinic due to walking difficulty. The major neurological symptoms at the age of evaluation were severe atrophy and spasticity predominantly in the lower extremities. EMG studies showed sensory motor polyneuropathy with axonal involvement. Sural nerve biopsy was indicative of hypo/demyelination and axonal loss. Cortical-subcortical atrophy was detected at late-term brain MRI. The parents mentioned breath-holding spells in infancy for the affected sibling pair. There was fatigue and tachycardia with effort starting from the age of 4 years in both children. After the age of 6, the siblings developed progressive weakness, scoliosis and loss of vision. Painful muscle spasms and rapid aggravation were observed only in the male patient. DNA samples of both patients were subjected to whole exome sequencing (WES) to reveal the genetic defect underlying these complex neurologic findings. The data was filtered for both recessive and dominant inheritance patterns, which revealed a shared and novel heterozygous *FBXO38* variation (NM\_030793.4: c.173G>A; p.Arg58Gln) inherited from the asymptomatic mosaic mother. Various *in silico* tools modeled a damaging effect for the amino acid substitution. **Discussion:** WES in two affected sib-pairs followed by data analysis with various inheritance models and segregation studies have led us to diagnose the condition as HMN2D in two affected siblings. We have thus accordingly expanded the clinical spectrum associated with *FBXO38* variations and presented a family in which there is juvenile onset unlike the previously reported families in which the age of onset varies between 13 to 48 years of age. We have also managed to detect the mosaic pattern in the unaffected mother, which in turn demonstrates that the etiology of many unresolved neurological disorders might be explained by pathogenic mosaic mutations.

**960F**

**Aspartate supplementation for aspartate-glutamate carrier isoform 1 deficiency.** S. Yano<sup>1</sup>, A. Partikian<sup>2</sup>, S. Blum<sup>3</sup>, K. Moseley<sup>4</sup>, Y. Watanabe<sup>4</sup>, H. Saitsu<sup>5</sup>, N. Matsumoto<sup>5</sup>. 1) Pediatrics/Gen Div, 1G24, LAC+USC Med Ctr, USC, Los Angeles, CA; 2) Pediatrics/Neurology, LAC+USC Med Ctr, USC, Los Angeles, CA; 3) Radiology, Children's Hospital Los Angeles, USC, Los Angeles, CA; 4) Pediatrics, Kurume University, Kurume, Japan; 5) Human Genetics, Yokohama City University, Yokohama, Japan.

**Introduction:** The mitochondrial aspartate-glutamate carrier isoform 1 (AGC1) is a component of the malate-aspartate shuttle which transfers reducing equivalents from NADH from the cytosol to the mitochondria. AGC1 deficiency is a rare autosomal recessive condition causing seizures, intellectual disability, and the characteristic brain MRI finding with hypomyelination as well as the MR spectroscopy (MRS) finding with a low N-acetylaspartic acid (NAA) signal. NAA is synthesized from aspartic acid and acetyl-CoA by aspartate N-acetyltransferase which is localized in the mitochondrion and the cytosol. Aspartic acid supplementation may improve NAA synthesis through the cytosolic pathway in patients with AGC1 deficiency. **Case Study:** Two Hispanic male siblings (9 y and 13 y) with AGC1 deficiency due to a homozygous p.Gly398Val mutation in *SLC25A12* presenting with intellectual disability, seizures, and the characteristic abnormal brain MRI/MRS findings were treated with aspartic acid at 100 mg/kg/d for 5 months and subsequently at an increased dose of 200 mg/kg/d for 7 months. No specific clinical improvement was observed including in their reported high protein diet preference. Brain MRI/MRS studies at base line and the follow up at 12 months after aspartic acid supplementation did not show significant changes: mild generalized cerebral volume loss and increased lactate and decreased NAA signals were noted. Plasma aspartic acid concentrations as well as urine organic acid analyses did not show significant changes after aspartic acid supplementation. **Discussion:** AGC1 deficiency results in decreasing the cytosolic NAD/NADH ratio leading to inhibition of glycolytic activity. In neuronal cells, NAA is synthesized from aspartic acid and acetyl-CoA primarily in the mitochondria and to some extent in the endoplasmic reticulum. Aspartate supplementation did not improve clinical symptoms nor MRI/MRS study findings in these two cases. Our results indicate that aspartate supplementation (1) did not improve the NAD/NADH ratio and glycolytic activity in the neuronal cells and/or (2) did not result in increased aspartic acid concentrations at least in the dose given to increase NAA synthesis in the neuronal cytosol. Based on these negative results, aspartic acid monotherapy appears to have no therapeutic utility in AGC1 deficiency.

**De novo missense variants in *GNAI1* gene are associated with epileptic encephalopathy.** M. Liao<sup>1</sup>, L. Rhodes<sup>1</sup>, H. Dubbs<sup>2</sup>, E. Goldberg<sup>2</sup>, L. Zitano<sup>3</sup>, C. Bupp<sup>3</sup>, J. Chen<sup>4</sup>, K.J. Wierenga<sup>4</sup>, G. Purcarin<sup>5</sup>, G.N. Wilson<sup>6</sup>, J. Martinez<sup>7</sup>, A. Crunk<sup>1</sup>, I.M. Wentzensen<sup>1</sup>, R.E. Schnur<sup>1</sup>, K.G. Monaghan<sup>1</sup>, J. Juusola<sup>1</sup>. 1) GeneDx, Gaithersburg, MD; 2) Department of Pediatrics, Division of Neurology, Children's Hospital of Philadelphia, Philadelphia, PA; 3) Spectrum Health Medical Genetics, Grand Rapids, MI; 4) Department of Pediatrics, Section of Genetics, University of Oklahoma Health Sciences Center, Oklahoma City, OK; 5) Department of Neurology, Section of Child Neurology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; 6) Texas Tech Health Science Center, Lubbock and KinderGenome Medical Genetics, Dallas, TX; 7) Department of Pediatrics and Adolescent Medicine, Division of Genetics, University of South Alabama, Mobile, AL.

The Gi protein belongs to the family of inhibitory heterotrimeric G proteins which, upon activation, inhibit the adenylyl cyclase activity and reduce cAMP levels. Gi activation is promoted by receptor-induced exchange of GDP for GTP on its  $\alpha$  subunit, which has an intrinsic GTPase to deactivate Gi through hydrolysis of bound GTP to GDP. The widely expressed *GNAI1* gene, located at 7q21.11, encodes the  $\alpha$ -subunit of subtype 1 Gi (Gi $\alpha$ 1). Disruption of *GNAI1* was reported to cause long term memory defects in mice, suggesting that it may play a role in neurologic function. Here we show that germline variants in *GNAI1* may associate with a neurodevelopmental disorder characterized by developmental delay, seizure, and hypotonia. Exome sequencing (ES) was performed on 9,659 patients with developmental delay or intellectual disability (ID). Four *de novo* heterozygous missense variants in *GNAI1* were identified in five individuals from unrelated proband-parent trios. The five probands were males between 3-11 years of age with developmental delay and ID. Among them, absent or minimal speech, significant gross motor delay, hypotonia, and seizures were common. Two of the four individuals with brain imaging studies had cerebral atrophy. Of all five patients, two had microcephaly and two had macrocephaly. Short stature was also seen in two of those patients. All detected *GNAI1* variants were absent from the ExAC database as well as our internal ES database of unaffected individuals, and occurred at highly conserved codons 40 or 48. Each alteration was predicted to damage protein function by *in silico* algorithms. Two of the variants (p.Thr48Lys and p.Thr48Ile) are located within the GTP binding domain, while the other two (p.Gly40Cys and p.Gly40Arg) lie adjacent to this domain, indicating that changes of those amino acids might disrupt binding of Gi $\alpha$ 1 to GTP. In addition, the variants p.Gly40Cys (c.118G>T) and p.Gly40Arg (c.118G>C) are both located in the last nucleotide of exon 1 and were found to have potential impact on splicing. We propose that *de novo* heterozygous missense *GNAI1* variants impacting the GTP binding domain may lead to a novel neurodevelopmental disorder. The findings presented in this case series may facilitate the identification of additional affected individuals and increase understanding of the phenotype associated with pathogenic variants in *GNAI1*.

**962T**

***BICD2*-related arthrogryposis with unexplained cardiomyopathy.** R.D. Kastury<sup>1</sup>, M. MacNeal<sup>2</sup>, H. Seiden<sup>3</sup>, H. McLaughlin<sup>4</sup>, L. Mehta<sup>5</sup>. 1) Medical Genetics and Genomics, Icahn School of Medicine at Mount Sinai Medical Center, New York, NY; 2) Medical Genetics and Genomics Cardiovascular Genetics Program Icahn School of Medicine at Mount Sinai Medical Center, New York, NY; 3) Associate Professor Pediatric Cardiology Icahn School of Medicine at Mount Sinai Medical Center, New York, NY; 4) GeneDx, 207 Perry Parkway, Gaithersburg, MD 20877; 5) Professor Director, Clinical Genetics Department of Medical Genetics and Genomics, Dept. of Pediatrics Icahn School of Medicine at Mount Sinai Medical Center, New York, NY.

Mutations in *BICD2* are a cause of autosomal dominant spinal muscular atrophy (SMALED2) (OMIM#615290), characterized by congenital or early onset lower limb-predominant weakness with slow progression, muscle wasting and contractures. In-utero onset has been associated with arthrogryposis, though most cases present in the first decade. We evaluated a 12 year old girl with history of decreased fetal movement, bilateral femur fractures and contractures of the ankles, digits and wrists at birth. She required gastrostomy feeding and a tracheostomy, which was removed at age 8 yrs. She had severe kyphoscoliosis and underwent multiple orthopedic procedures and spinal fusion surgery. She was non-verbal and non-ambulatory with history of possible seizures. Brain MRI showed volume loss with thinning of the cortex. At age 11, a heart murmur was heard and an echocardiogram showed concentric left ventricular hypertrophy with moderate LVOT obstruction and moderate to severe mitral valve regurgitation. Parents had normal echocardiograms. SNP microarray, chromosome analysis, carbohydrate deficient transferrin and plasma amino acids were normal. Whole exome sequencing (WES) revealed a *de novo*, previously unreported, heterozygous, likely pathogenic variant, c.1636\_1638delAAT in exon 5 in the *BICD2* gene. The in-frame 3 bp deletion is predicted to cause loss of an evolutionarily conserved Asparagine residue as position 546 in the protein (p.Asn546del). A heterozygous *de novo*, VUS (p.P957L), was present in the *SBF1* gene which is a cause of autosomal recessive CMT4B3; no other *SBF1* variants were identified. Mitochondrial genome sequencing with deletion testing was normal. The *BICD2* gene encodes a dynein adaptor protein that appears to be critical in axonal transport and neuron development and maintenance. The phenotype has been expanded to include cortical malformations, intellectual disability, seizures and spastic paraplegia, but no cardiac muscle involvement or non-neurological phenotype is described. No pathogenic mutations related to cardiomyopathy were identified in our patient. Therefore, it is more likely that her recent onset cardiomyopathy is a secondary phenotype due to other factors, and not directly related to *BICD2* mutations. Cardiac work up of patients diagnosed with *BICD2* mutations and further follow up of our patient's cardiac findings will be helpful in determining the natural history and progression of cardiac muscle involvement in *BICD2*-related disorders.

**A tuberous sclerosis positive case without cortical tubers and subsequent diagnosis of "unaffected" family members.** R. Caylor<sup>1</sup>, L. Grote<sup>3,7</sup>, I. Thiffault<sup>1,2,8</sup>, E. Farrow<sup>2,7,8</sup>, L. Willig<sup>2,4,7,8</sup>, S. Amudhavall<sup>3,7,8</sup>, A. Nopper<sup>6,7</sup>, A. Abdelmoitey<sup>5,7,8</sup>, C. Saunders<sup>1,2,8</sup>. 1) Department of Pathology and Laboratory Medicine; 2) Center for Pediatric Genomic Medicine; 3) Division of Clinical Genetics; 4) Division of Nephrology; 5) Division of Neurology; 6) Division of Dermatology; 7) Department of Pediatrics, Children's Mercy Hospitals; 8) University of Missouri-Kansas City School of Medicine, Kansas City, MO, USA.

Tuberous sclerosis complex (TSC) is an autosomal dominant neurocutaneous disorder that results from variants in *TSC1* or *TSC2*. TSC is characterized by neurocutaneous lesions and benign tumors in multiple organ systems. Common neurological findings include intellectual disability, seizures and cortical tubers. Common cutaneous findings include hypomelanotic macules and angiofibromas. Renal, cardiovascular, ophthalmologic and pulmonary abnormalities are also frequently observed in TSC. Diagnosis is based on well-established clinical criteria or molecular genetic testing; penetrance is thought to be 100%. We describe a family exhibiting extreme variability in clinical presentation and disease severity, including the incidental diagnosis of individuals thought to be unaffected. The proband is a 20-year-old Pakistani woman with intractable epilepsy, autism, absent speech, and normal MRI. Family history was positive for a brother with well-controlled epilepsy, normal intelligence and MRI. Whole exome sequencing of the proband revealed a likely pathogenic variant, c.196G>T (p.Glu66\*), in *TSC1*, a surprising diagnosis given a previous negative MRI and no reported skin findings. The patient's mother and all three of her siblings, two of whom had no medical complaints, also tested positive for the variant. Assessment of the family history revealed a diagnosis of renal cell carcinoma in the mother. Follow-up examinations of her siblings revealed renal cysts, seizures and hypomelanotic macules for two siblings. The third sibling's brain MRI showed lesions that likely represent subcortical tubers, and an abdominal MRI revealed a solitary renal mass, which will require further surveillance. The family represented a difficult genetic counseling situation for several reasons. Initially, the variable presentation was challenging for the family to accept and led to distrust and withholding phenotypic information. Cultural practices inhibited full participation from the mother and children. This led to additional limitations in phenotypic characterization and inability to explore the guilt the mother was experiencing due to these results. This case illustrates how an unbiased molecular approach may help reveal underlying defects in patients harboring pathogenic variants in genes not entirely expected due to the observed clinical manifestations, which can lead to diagnoses that otherwise would not be made or not made until more harmful symptoms of disease have manifested.

Fisher*<sup>4,5</sup>, *E.A. Ashley*<sup>1,2,7</sup>, *J.A. Bernstein*<sup>1,2,6</sup>, *M. Wheeler*<sup>1,2,7</sup>. 1) Stanford Center for Undiagnosed Diseases, Stanford University, Stanford, CA; 2) Division of Cardiovascular Medicine, Stanford University, Stanford, CA; 3) NIH Undiagnosed Diseases Network, Common Fund, Office of the Director and the National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 4) Department of Pediatrics, Stanford School of Medicine, Stanford, CA; 5) Department of Neurology, Stanford School of Medicine, Stanford, CA; 6) Lucille Packard Children's Hospital Stanford, Palo Alto, CA; 7) Department of Genetics, Stanford School of Medicine, Stanford, CA.

**Introduction:** *ALG13* encodes a subunit of the UDP-GlcNAc glycosyltransferase involved in N-linked glycosylation. *ALG13* was first reported in a male patient with congenital disorder of glycosylation type 1 (CDG1) who was hemizygous for a pathogenic variant inherited from his unaffected mother. In recent years, a different recurrent *de novo* variant (*ALG13* c.320A>G) has been identified in at least 9 unrelated females with early infantile epileptic encephalopathy, type 36 (EIEE36; OMIM:300884). All of these cases have been female. Despite the role of *ALG13* in N-linked glycosylation, glycosylation studies performed on a subset of these cases have so far been normal. **Case report:** A 2yo female was evaluated at the Stanford Center for Undiagnosed Diseases (CUD) for refractory infantile spasms of unknown etiology. She first presented to neurology clinic at 9 months with global developmental delay (GDD), severe hypotonia, and choreoathetoid movements. At 12 months she developed infantile spasms demonstrated by hypsarrhythmia on EEG. Brain MRI showed generalized white matter volume loss. Poor visual tracking and food intolerance were noted. Metabolic work up showed elevated pyridoxal 5'-phosphate and low alkaline phosphatase compatible with hypophosphatasia. During evaluation at the CUD, whole exome sequencing (WES) was sent on the patient, her parents, and her unaffected twin brother. Sequence analysis identified the recurrent *de novo* *ALG13* c.320A>G variant. Utilizing the resources of the Undiagnosed Diseases Network, CDG studies, metabolomics, RNA sequencing, and fibroblast studies were performed to better understand the effect of the c.320A>G variant at a molecular level. **Discussion:** This patient's phenotype overlaps with aspects of reported *ALG13* c.320A>G cases in the literature. Similarities include GDD, infantile spasms, hypotonia, movement disorder, visual impairment, abnormal MRI, and poor feeding. Our patient, however, lacks reported characteristics including dysmorphic features, joint contractures, and sleep disturbance. Hypophosphatasia has not been reported and therefore its association with the c.320A>G variant remains unclear. **Conclusions:** This case contributes to the emerging phenotype associated with the *ALG13* c.320A>G variant. Functional studies will clarify the disease mechanism of the c.320A>G variant.

## 965T

**Clinical presentation and genotype-phenotype correlation of a complex neurodevelopmental disorder caused by mutations in *ADNP*.**

Vandeweyer*<sup>1</sup>, *ADNP consortium*. 1) Department of Medical Genetics, University of Antwerp, Antwerp, Antwerp, Select a Country; 2) Department of Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands; 3) Department of Psychiatry of the University of Washington, USA; 4) Lily and Avraham Gildor Chair for the Investigation of Growth Factors, Elton Laboratory for Molecular Neuroendocrinology, Department of Human Molecular Genetics and Biochemistry, Sackler Faculty of Medicine, Sagol School of Neuroscience and Adams Super Center for Brain Studies, Tel Aviv University;; 5) Department of Genome Sciences, University of Washington, Seattle, Washington, USA; 6) Unit of Pediatrics and Medical Genetics, I.R.C.C.S. Associazione Oasi Maria Santissima, Troina, Italy.

**Background:** In genome-wide screening studies for *de novo* mutations as a cause of autism, intellectual disability and related developmental disorders, mutations in the *ADNP* gene are consistently reported amongst the most frequent causes. Mutations in this gene have been identified in children with autism spectrum disorder co-morbid with intellectual disability, facial features and deficits in multiple organ systems. However, a comprehensive description of the clinical features of the Helsmoortel - Van der Aa syndrome is lacking. **Methods:** We identified a cohort of 78 individuals with likely disruptive mutations in *ADNP* dispersed across the globe from January 2014 to October 2016 through a systematic literature search, by contacting collaborators, and through direct interaction with parents on social media. Clinicians were asked to fill in a structured questionnaire on the genetic and clinical findings to enable genotype-phenotype correlations. Clinical photographs and medical specialist reports were gathered and parents of several individuals were interviewed to complement the written questionnaires. **Findings:** We report on the detailed clinical characterization of a large cohort of patients and demonstrate a distinctive combination of clinical features, including mild to severe intellectual disability, autistic features, severe speech and motor delay and common facial characteristics. Hypotonia, short stature, gastrointestinal and visual problems, congenital heart defects, brain abnormalities, hormonal deficiencies, behavioral problems, sleep disturbance and epilepsy are common co-morbidities. Strikingly, individuals with the recurrent p.Tyr719\* mutation were more severely affected for a restricted set of clinical features. **Interpretation:** This overview defines the full clinical spectrum of individuals with *ADNP* mutations, a specific subtype of autism. We show that individuals with mutations in *ADNP* have many overlapping clinical features, distinctive from other known autism/ID syndromes. In addition, our data show evidence for a genotype-phenotype correlation. .

**966F**

**A novel homozygous mutation in two sisters diagnosed with Joubert syndrome.** A. Sen<sup>1</sup>, H.M. Serin<sup>2</sup>, S. Gungor<sup>3</sup>, D. Sen<sup>1</sup>, S. Ceylaner<sup>4</sup>. 1) Medical Genetics Department, Firat University Hospital, Elazig, Turkey; 2) Pediatric Neurology Department, Firat University Hospital, Elazig, Turkey; 3) Obstetrics and Gynecology Department, Elazig Medical Park Hospital, Elazig, Turkey; 4) InterGen Genetic Centre, Ankara, Turkey.

Two sisters admitted to our medical genetics polyclinic. They were diagnosed with Joubert Syndrome clinically when they were 3 months old and 2,5 years old. Follow-up procedure has done by pediatric neurologist. Their mom had an abort and gynecologist referred her to us to evaluate the complete family for an exact diagnose approved by molecular genetic techniques. Because, fetus was also suspected to have Joubert Syndrome. After evaluating them at clinical genetics department, we also suggested the same syndrome. As known, Joubert Syndrome has phenotypic series and many genes are responsible for different types of this syndrome. Both of them has been underwent to DNA sequencing panel. The genes responsible for Joubert Syndrome sequenced in this panel. Sequencing analysis revealed a novel mutation in *TMEM237* gene. The mutation detected was homozygous c.394C>T (p.Q132\*). Therefore, both of these patients are diagnosed as Joubert Syndrome 14. Genetic counseling is provided. Parental carrier analysis planned.

**967W**

**Parent-of-origin effects in 15q11.2 BP1-BP2 deletion syndrome.** K. Davis, C. Robinson, M. Serrano. Lineagen, Inc., Salt Lake City, UT.

The 15q11.2 deletion from breakpoints 1 to 2 cause a neurodevelopmental syndrome that is highly variable with low penetrance and includes four core genes: *CYFIP1*, *NIPA1*, *NIPA2*, and *TUBGCP5*. The *TUBGCP5* gene is involved in cell division, is ubiquitously expressed, and is associated with obsessive-compulsive disorder and attention-deficit hyperactivity disorder. A recent study has reported that the promoter of *TUBGCP5* is maternally methylated. Deletions of 15q11.2 may therefore show a parent-of-origin effect (POE) like other conditions in this region. We hypothesized that paternal deletions would be more deleterious, as probands would theoretically lack a functional copy of *TUBGCP5*. To test for a POE, we collected 56 total reports with known inheritance from our internal database (N=7), online databases (N=14), and primary literature (N=35). Sibling pairs were omitted from analysis, as were cases with known genetic conditions or *de novo* inheritance from an unknown parental allele. Cases were analyzed by parental inheritance and the proband's clinical features with chi-squared and Mann-Whitney U tests. Maternally inherited deletions (N=30; 53.6%) outnumbered paternally inherited deletions (N=26; 46.4%). Probands with maternal deletions showed a higher, but non-significant average number of total features (3.3 vs. 3.1; standard deviation: 2.3 for both). Mann-Whitney U tests did not find significant differences between parental inheritance and: total number of clinical features, non-dysmorphic features, physical and dysmorphic features, or behavioral features (all  $p>0.1$ ). Chi-squared analyses showed probands with maternal deletions associated with more diagnoses of epilepsy ( $p=0.02$ ) and autism spectrum disorder (ASD;  $p=0.005$ ), while paternal deletions were associated with developmental delays ( $p=0.03$ ). A sex-based difference was also observed, with more females than males having epilepsy ( $p=0.01$ ). Unexpectedly, paternal deletions were not associated with more specific clinical features or more total features than maternal deletions. This evidence indicates a possible POE, although the mechanism causing parental differences in clinical features may not be due to maternal imprinting at *TUBGCP5*. Limitations included: possible ascertainment bias, variable quality in phenotypic information, and that this population was not evaluated by us or the same observer(s). Further studies analyzing POEs in this condition are warranted.

**Case report of a patient with a *TANGO2* deletion that provides additional phenotype information.** *R. Godshalk, D. Adams.* Jacobs Levy Genomic Medicine and Research Program, Atlantic Health System, Morristown, NJ.

We report the case of a 17 year old male that had history of delayed walking but no other issues at the time of an illness that hospitalized him in a coma for 2 days at the age of 18 months. In his early childhood he was evaluated for a possible mitochondrial disorder. TV communicates with an iPad and his own sign language. Testing of the mitochondrial DNA was performed at the age of 15 and was found to be most likely negative. Chromosome microarray performed at the age of 17 identified a 17kb deletion of chromosome 22q11.21 that includes the *TANGO2* gene. This deletion includes exons 4-9 of the *TANGO2* gene. There have been other individuals with homozygous and compound heterozygous mutations that have episodic muscle weakness with recurrent rhabdomyolysis, hypoglycemia, hyperammonia, hyperlactacidemia, intellectual disability, seizures, gait disturbances, dysarthria, myopathic facies, cerebral atrophy, and susceptibility to cardiac tachyarrhythmias. Our patient's clinical picture may be an additional case. Sequencing of the other copy of *TANGO2* is being pursued. One patient began to develop developmental regression following a febrile seizure at a year of age. Physical exam showed microcephaly and myopathic facies. The second patient had similar physical features after initial cardiac presentation of a long QT. Both patients were also thought to have a mitochondrial disorder when they first presented. Both patients were found to have abnormalities in the *TANGO2* gene. Lelani et al identified various homozygous and compound heterozygous alterations in the area of the *TANGO2* gene including copy number variants that range from 9 to 34 KB. The families may be an etiology for a progressive neurologic disorder characterized by intellectual disability. There are cases of patient dying during an acute crisis therefore this underscores the importance of testing of a chromosome microarray analysis in patients with a clinical diagnosis of "mitochondrial" disorders. Lelani et al also stated that their study showed that deletion of exons 3-9 are common in the European population. Kremer et al also stated that deficiency of *TANGO2* should be considered in cases of episodic encephalopathy and/or myopathy in infancy and childhood of unknown cause, especially in individuals with laboratory findings suggestive of impaired mitochondrial fatty acid oxidation.

**Periventricular nodular heterotopia as hallmark of a new ciliopathy related to *CRB2* mutation.** *G.M.S. Mancini, R. Schot, M. Wilke, M. van Slegtenhorst, F.W. Verheijen.* Clinical Genetics, Erasmus Medical Center, Rotterdam, The Netherlands.

Biallelic mutations in this Crumbs homolog-2 gene, *CRB2* (MIM 609720) have been described in 2015 as cause of isolated steroid-resistant nephrotic syndrome and histopathological findings of Finnish type congenital nephrosis, but also as cause of nephrosis with severe congenital ventriculomegaly and periventricular nodular heterotopia, already detected at prenatal ultrasound. Although periventricular nodular heterotopia (PNH) has been documented in 20% of the cases (Slavotinek et al 2016), this abnormality has not been considered a hallmark of the disorder. Two brothers, aged 36 and 20 years, were referred because of detection of bilateral diffuse PNH and mega cisterna magna at MRI, with overall normal CSF spaces. One presented with ID, autism, motor delay, anxiety. The other had autism, psychosis and unexplained persistent proteinuria from childhood. The head circumference was normal. DNA and RNA sequences of *FLNA* were normal. Whole genome sequencing showed in both brothers the same novel compound heterozygote mutation in *CRB2*, a missense change leading to an amino acid substitution and a 16-bp deletion leading to a premature stop. An unrelated infant was referred with dextrocardia, hydrocephalus, diffuse bilateral PNH. A renal biopsy because of persistent proteinuria showed at the age of 23 months prominent glomerular podocytes and accentuated mesangial layer. A ciliopathy was suspected; skin fibroblasts were immunostained for cilia after serum starvation and repeatedly showed strongly reduced number of ciliated cells (av. 25%, normal range 50-80%, n=100). Targeted analysis of 43 genes involved in ciliopathies, including *CRB2*, showed in this gene a novel compound heterozygote amino acid substitution and a base-pair deletion leading to a premature frame shift and, in addition, a heterozygote missense in *WDPCP*. These cases illustrate that PNH is an important hallmark of *CRB2* mutations, which underlie a novel group of ciliopathies with heterogeneous manifestations, possibly modified by additional variants.

**970W**

**Clinical management of patients with GLUT1 deficiency syndrome (De Vivo disease).** T. Kozhanova<sup>1,2</sup>, S. Zhilina<sup>1,2</sup>, T. Mescheryakova<sup>1</sup>, S. Aivazyan<sup>1</sup>, K. Osipova<sup>1</sup>, L. Suchko<sup>1</sup>, E. Luk'yanova<sup>1</sup>, A. Prityko<sup>1</sup>. 1) St.Luka Scientific and Practical Center of Specialized Medical Care for Children, Moscow, Russia, Aviatorov Street, 38; 2) Pirogov Russian National Research Medical University, Moscow, Russia. Ostriviyanova street, 1.

GLUT1 (glucose transporter type 1) deficiency syndrome (GLUT1DS, De Vivo disease) is characterized by the infantile-onset encephalopathy (resistant to traditional seizure medications), acquired microcephaly, developmental delay with spasticity, dysarthria and a complex movement disorder consisting of ataxia, dystonia, alternating hemiplegia. In most patients, the level of glucose in the cerebrospinal fluid (CSF) is low to normal. We observed six clinical cases of GLUT1DS in children admitted to the neuropsychiatric department of Scientific and Practical Center of children medical care. The drug-resistant epilepsy, different movement disorders, psychomotor and intellectual disabilities, low cerebrospinal fluid glucose were diagnosed in all children. One patient had microcephaly. The different types of mutations in the *SLC2A1* gene (c.1305-1306insTGAAGA, c.115-2A>G, c.101A>G, c.400G>A) that are responsible for the development of GLUT1DS were detected by targeted sequencing in only 4 patients. The diagnosis in two patients was established according to clinical criteria, as there was no informed consent for genetic testing from parents. At present all patients are taking ketogenic diet (KD). A ketogenic diet is highly effective method of pathogenesis therapy, which can reduce the clinical manifestations: controlling the seizures, improving the movement disorder and speech. Thus, lumbar puncture should be considered the first diagnostic step for diagnosis of GLUT1DS. Mutational analysis of *SLC2A1* gene should be performed in patients with highly suggestive clinical findings and low cerebrospinal fluid glucose. Early diagnosis is critical because it allows prompt initiation of treatment with KD. Childhood is the critical period for treatment of GLUT1DS and for an effective etiological therapy.

**CAD mutations and uridine-responsive epileptic encephalopathy.** I. Badner<sup>1</sup>, J. Mayr<sup>1</sup>, B. Alhaddad<sup>2</sup>, C. Rauscher<sup>1</sup>, R. Kovacs-Nagy<sup>2</sup>, M. Holzhaecker<sup>1</sup>, H. Prokisch<sup>2,3</sup>, F. Distelmaier<sup>4</sup>, T. Polster<sup>5</sup>, S. Leiz<sup>6</sup>, C. Betzler<sup>7</sup>, T. Strom<sup>2,3</sup>, W. Sperl<sup>1</sup>, T. Meitinger<sup>2,3,8</sup>, S. Wortmann<sup>1,2,3</sup>, T. Haack<sup>2,3</sup>. 1) Department of Pediatrics, Salzburger Landeskliniken (SALK) and Paracelsus Medical University (PMU), Salzburg, Austria; 2) Institute of Human Genetics, Technische Universität München, Munich, Germany; 3) Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Munich, Germany; 4) Department of General Pediatrics, Neonatology and Pediatric Cardiology, University Children's Hospital, Heinrich-Heine University Dusseldorf, Dusseldorf, Germany; 5) Department of Child Neurology, Bethel Epilepsy Center, Bielefeld, Germany; 6) Department of Pediatric Neurology, Childrens Hospital Dritter Orden, Munich, Germany; 7) Clinic for Neuropediatrics and Neurorehabilitation, Epilepsy Center for Children and Adolescents, Vogtareuth, Germany; 8) Munich Cluster for Systems Neurology (SyNergy), Munich, Germany.

We report biallelic mutations in *CAD*, encoding an enzyme of *de novo* pyrimidine biosynthesis, in four patients with developmental disability, epileptic encephalopathy, anaemia, and anisopoikilocytosis. Two children died after a neurodegenerative disease course. Treatment of two surviving children with oral uridine led to immediate cessation of seizures in both. A four-year-old girl, who was previously in minimal conscious state, started to communicate and walk with assistance after nine weeks of treatment. A three-year-old girl likewise showed developmental progress. Blood smears normalised and anaemia resolved. Our findings support the efficacy of uridine supplementation rendering *CAD* deficiency a treatable neurometabolic disorder.

## 972F

**Impact of a targeted next generation sequencing (TNGS) strategy for the genetic diagnosis of early onset epileptic encephalopathies.** S. Gobin<sup>1</sup>, E. Azouguene<sup>1</sup>, S. Hanein<sup>2</sup>, N. Chemaly<sup>3</sup>, M. Hully<sup>4</sup>, L. Routier<sup>5</sup>, C. Barnerias<sup>6</sup>, N. Bahi Buisson<sup>6</sup>, M. Rio<sup>5,2</sup>, I. Desguerre<sup>4</sup>, A. Kaminska<sup>6</sup>, JP. Bonnefont<sup>1</sup>, J. Steffann<sup>1</sup>, R. Nabbout<sup>4</sup>, G. Barcia<sup>1,2</sup>. 1) Laboratory of Molecular Biology, Department of Medical Genetics, Necker Enfants, Paris, France; 2) INSERM U1663, Imagine Institute for Rare Diseases, Paris Descartes University, Paris, France; 3) Department of Pediatric Neurology, Amiens-Picardie University Hospital, Amiens, France; 4) Reference Centre for Rare Epilepsies, Department of Pediatric Neurology, Necker Enfants-Malades Hospital, Paris Descartes University, Paris, France; 5) Department of Medical Genetics, Necker Enfants-Malades Hospital, APHP, Paris Descartes University, Paris, France; 6) Department of Clinical Neurophysiology, Necker Enfants-Malades Hospital, APHP, Paris, France.

**Objective:** The identification of the genetic bases of epileptic encephalopathies (EE) has rapidly increased in the last years. Genetic diagnosis of EE can orient patient management and clinical outcome. We developed a custom targeted next generation sequencing (TNGS) strategy for the molecular diagnosis of EE. We evaluated the efficacy of this approach. **Methods:** A custom next generation sequencing panel targeting 151 epilepsy genes was applied to a cohort of 92 consecutive patients (51 boys and 41 girls) affected by early onset EE, classified as known syndromes in 58% and unclassified conditions in 41%. Acquired pathologies, metabolic diseases, brain malformations were excluded for all patients. **Results:** A disease-causing genetic variant was identified in XX of patients. Variants lied on XX different genes including *KCNT1*, *WWOX*, *SCN2A*, *SCN1A*, *SCN8A*, and *CDKL5*. Patients with epilepsy of infancy with migrating focal seizures (EIMFS) and Dravet syndrome (DS) had the highest rate of positive findings, respectively 75% and 60%. TNGS allowed the detection of a *KCNT1* mutation previously undetected by Sanger sequencing in one patient, of a *SCN1A* variant at a low rate mosaicism and of two deletions of the exons 6-7 of *WWOX*. **Conclusions:** With a diagnostic yield of 38%, TNGS is an efficient strategy for the first-step genetic screening of EE, avoiding incidental findings, and at a lower cost compared to WES. Even if targeted approaches are restricted to a selected group of genes, interpreting variants generated by TNGS is challenging. A dynamic interaction between physicians and molecular biologists is necessary to interpret TNGS results and to draw genotype-phenotype correlations. TNGS, enabling a comprehensive screening of all known genes involved in EE, offers a rapid, cost effective and relevant selection of patients available for the identification of novel genes by WES and WGS in the research setting.

**[Background]** Benign adult familial myoclonic epilepsy (BAFME) is an autosomal dominant disorder characterized by myoclonic tremor and infrequent epilepsy with a benign clinical course. Several previous studies demonstrated a linkage to 8q24 in Japanese families, whereas families of Italian, French, and Thai origins with similar clinical presentations have been shown linkages to 2p, 5q, and 3q, respectively, indicating locus heterogeneity. To refine the candidate region of BAFME in Japanese, we performed linkage and detailed haplotype analyses. **[Methods]** Nineteen patients and three unaffected individuals from six families with a clinical diagnosis of BAFME were included in the study after written informed consent was obtained. Parametric linkage analysis was performed using high-density SNP data (Genome-Wide Human SNP array 6.0, Affymetrix) assuming autosomal dominant inheritance with complete penetrance. Haplotype was reconstructed inferred by manual inspection to minimize recombination events. In one family in which genotypes of parents or offspring were unavailable, droplet digital PCR and 10X GemCode technology were used for haplotype reconstruction. **[Results]** Linkage analysis revealed a single peak of cumulative multipoint parametric LOD scores at 8q22.1-8q24.13 (a maximal LOD score of 3.1) with the candidate region spanning 30 Mb, overlapping with a critical region of Japanese BAFME families that have been determined by previous studies. Detailed haplotype analysis revealed a core haplotype shared among the families, further narrowing the candidate region to a 134 kb region. **[Discussion]** The result strongly suggest that Japanese BAFME families share a common founder chromosome. We narrowed down the candidate region of BAFME by linkage and haplotype analyses. Further sequence analysis will be needed to identify the causative gene for BAFME.

**974T****New epilepsy genes and variants discovered utilizing patients referred for clinical genetic testing.** *K. McCarty<sup>1</sup>, O.A. Moody<sup>2</sup>, C. da Silva<sup>3</sup>, J.J. Alexander<sup>1,3</sup>, M. Hegde<sup>1</sup>, A. Jenkins<sup>2</sup>, A. Escayg<sup>1</sup>.*

1) Department of Human Genetics, Emory University, Atlanta, GA; 2) Department of Pharmacology, Emory University, Atlanta, GA; 3) EGL Genetics, Tucker, GA.

Epilepsy is a neurological disorder characterized by recurrent, unprovoked seizures caused by neuronal synchrony and hyperexcitability. To date, mutations in over one hundred genes have been identified in different types of epilepsy. Despite this progress, mutations in these genes only explain a fraction of the estimated genetic contribution to epilepsy. The goal of our research is to elucidate the mechanisms of seizure generation through a better understanding of the genetic causes of epilepsy. We are collaborating with EGL Genetics, a CLIA-certified and CAP-accredited laboratory, to examine available sequence data from clinically-referred epilepsy patients. Upon referral, patient DNA samples are screened using the Epilepsy and Seizure Disorders (ESD) panel, a sequencing panel of 110 known epilepsy genes. The ESD panel is derived from a larger Mendeliome library of approximately 5000 evidence-based disease genes, making this a valuable resource for research-based identification of putative disease-causing alleles and novel disease genes. Approximately 25% of referred patients have a positive finding from the ESD panel. We are currently examining variants from the Mendeliome library for the patients that are negative for mutations from the ESD panel. To date, we have identified at least 65 potentially causal variants in 40 genes. Several variants occur in genes not currently associated with epilepsy, including a novel variant in *GABRA2* that was identified in an individual with epileptic encephalopathy. Functional studies of the single point mutation in the TM2 segment of the receptor subunit encoded by *GABRA2* revealed a constitutively open ion channel that was unresponsive to GABA but was blocked by picrotoxin.

**An integrated whole-genome, whole-transcriptome approach to genetic diagnosis in developmental and epileptic encephalopathies.** *A.M. Muir<sup>1</sup>, K. Boysen<sup>2</sup>, G. Hollingsworth<sup>2</sup>, C. King<sup>3</sup>, A.L. Schneider<sup>2</sup>, U.W. Center for Mendelian Genomics<sup>4</sup>, L.G. Sadleir<sup>5</sup>, I.E. Scheffer<sup>2,5,6</sup>, H.C. Mefford<sup>1</sup>.* 1) Department of Pediatrics, Division of Genetic Medicine, University of Washington, Seattle, Washington 98195, USA; 2) Epilepsy Research Centre, Department of Medicine, Austin Health, The University of Melbourne, Heidelberg, Victoria, 3084, Australia; 3) Department of Paediatrics and Child Health, University of Otago, Wellington, New Zealand; 4) University of Washington, Seattle, Washington 98195, USA; 5) Florey Institute of Neuroscience and Mental Health, The University of Melbourne, VIC 3010, Australia; 6) Department of Paediatrics, Royal Children's Hospital, The University of Melbourne, Parkville, Victoria, 3050, Australia.

**Objective:** Developmental and epileptic encephalopathies (DEE) are a large heterogeneous group of severe, early onset epilepsies characterized by refractory seizures, developmental delay and/or regression, and often a poor prognosis. Next generation sequencing approaches have revealed *de novo* variants in coding regions of genes as the most common cause of DEE, with clinical diagnostic labs reporting a molecular diagnosis in 24-40% of cases. Despite this significant progress, the majority of DEE cases remain unexplained, even after whole exome sequencing. We sought to investigate potential disease-causing variants in noncoding regions of the genome. **Methods:** We are performing whole genome sequencing (WGS) of 20 exome-negative proband-parent trios. However, a major hurdle for genome-based diagnostics is our ability to interpret the functional and clinical impact of variants in non-coding sequence. In order to determine whether noncoding variants of interest impact gene expression, we will use RNA-seq to detect changes in transcript abundance, evidence of allele specific expression, and the presence of aberrant splicing. Recent large-scale gene expression studies have highlighted the importance of using disease-relevant tissue in transcriptome sequencing; analysis of available data confirms that the majority of established DEE genes are poorly expressed in skin and whole blood, limiting the use of these easily accessible tissues. To overcome this limitation, we are approximating brain tissue by reprogramming primary skin fibroblasts into neurons. We will use genome-wide expression data from the reprogrammed neurons to interpret the clinical relevance of noncoding *de novo* mutations identified by WGS in patients with exome-negative DEE. **Results:** To date, we have performed whole genome sequencing on 5 of 20 exome-negative cases and identified 37-68 *de novo* variants per trio. We have collected fibroblasts from three cases and established a protocol to directly reprogram primary skin fibroblasts to neuronal cells that will be used to aid in the functional interpretation of these sequence variants. **Conclusions:** This work establishes a framework for the investigation of non-coding variants in DEE and will facilitate improved diagnostic testing for DEE.

**The genetic landscape of the epilepsy-aphasia spectrum disorders.** C. Myers<sup>1</sup>, M. Mehaffey<sup>1</sup>, A. Schneider<sup>2</sup>, G. Hollingsworth<sup>2</sup>, A. Rosen<sup>1</sup>, A. LaCroix<sup>1</sup>, U.W. Center of Mendelian Genomics<sup>3</sup>, L. Sadleir<sup>4</sup>, I. Scheffer<sup>2,5,6</sup>, H. Mefford<sup>1</sup>.

1) Department of Pediatrics, University of Washington, Seattle, WA, USA; 2) Epilepsy Research Centre, Department of Medicine, Austin Health, The University of Melbourne, Heidelberg, Victoria, 3084, Australia; 3) University of Washington, Seattle, WA, USA; 4) Department of Paediatrics and Child Health, University of Otago, Wellington, New Zealand; 5) Florey Institute of Neuroscience and Mental Health, The University of Melbourne, VIC 3010, Australia; 6) Department of Paediatrics, Royal Children's Hospital, The University of Melbourne, Parkville, Victoria, 3050, Australia.

**Objective:** The epilepsy-aphasia spectrum (EAS) refers to a complex group of epilepsy syndromes associated with language impairment and variable outcome. On the severe end of the spectrum is Landau-Kleffner syndrome (LKS) and epileptic encephalopathy with continuous spike-and-wave during sleep syndrome (ECSWS) which often carry a poor prognosis including impaired cognitive function with speech and language difficulties. Related to the EAS from an electroencephalographic perspective but without major cognitive problems is the mild epilepsy syndrome of childhood epilepsy with centrotemporal spikes (CECTS). CECTS is the most common focal epilepsy in children and carries an excellent prognosis. It is unknown whether there is a common underlying mechanism to syndromes lying along the EAS. A genetic basis was not suspected until recently with the discovery that copy number variations (CNVs) and mutations in *GRIN2A* cause 5-20% of cases of dominant familial and sporadic EAS. We sought to identify novel genetic causes of sporadic EAS through whole-exome sequencing. **Methods:** Whole exome sequencing was performed in 16 proband-parent trios and a single proband-mother duo. We prioritized the following genotypes for review of their relevance to EAS: *de novo* mutations and/or parental mosaic variants, compound heterozygous, newly homozygous, and X-linked hemizygous genotypes. **Results:** We identified pathogenic or likely pathogenic *de novo* variants in 3/17 probands providing a potential molecular diagnosis for 18% of the cohort. The *de novo* variants in these three individuals were in *FOXP1*, *KCNMA1*, and *SETD1B*. No single gene was responsible for multiple cases, nor did the genes converge on a single molecular pathway. We also identified potentially pathogenic variants in 5 candidate genes (*CSNK1D*, *ATP1A2*, *PPFIA3*, *DEPTOR*, *NCAPG2*). Targeted sequencing of these 8 genes in a cohort of 525 probands with diverse developmental and epileptic encephalopathies did not yield any additional pathogenic variants. **Conclusion:** We expand our understanding of the genes associated with EAS and highlight the genetic heterogeneity of these severe disorders. We provide important phenotype expansion of the recently discovered neurodevelopmental genes *FOXP1*, *KCNMA1*, and *SETD1B*.

## 977T

***STXBP1* encephalopathy with epilepsy: 6-year-old girl with de novo missense variant in *STXBP1* expands the phenotype.** J. Pappas<sup>1</sup>, J. Borsuk<sup>1</sup>, S.S. Nadkarni<sup>2</sup>, D.A. McKnight<sup>2</sup>. 1) Dept Pediatrics, Clin Genetic Scvs, New York Univ, Sch Med, New York, NY; 2) GeneDx, Neurogenetics, Gaithersburg, MD; 3) Dept Neurology, Dept Psychiatry, Epilepsy program, New York Univ, Sch Med, New York, NY.

The association of epilepsy and encephalopathy with variants in *STXBP1* has been established and reviewed by Stamberger H et al, 2016 and, Khaikin Y and Mercimek-Mahmutoglu S, 2016. Publications in the medical literature report that about 1/3 of the patients with variants in *STXBP1* and seizures in infancy become seizure-free between the ages of 1 and 4 (Stamberger H et al, 2016; Di Meglio C et al, 2015 and Milh et al, 2011). Stamberger H et al, 2016 suggests that the encephalopathy in children with variants in *STXBP1* is unrelated to epilepsy. We present a 6-year-old girl with a novel missense variant in *STXBP1*. She was born full-term after uncomplicated pregnancy and delivery. She had two episodes of generalized tonic-clonic seizures at 4 months. The EEG was abnormal and the brain MRI normal. She was treated with Keppra that was discontinued because she had no more seizures and her EEG normalized. She was hypotonic and started walking and talking at the end of her second year with the help of therapies. Attention deficit, hand flapping, eye rolling without associated epileptiform activity and constant nail biting were her behavioral characteristics. Her development was progressing during her third year of life with attention deficit, hyperactivity (ADHD) and many sleep interruptions being her main problems. She started having seizures again at age 4 controlled with three medications. She developed aggressive behaviors and her ADHD necessitated management with medications. Chromosome analysis and SNP microarray analysis using the Affymetrix Cytoscan HD platform were reported normal. Blood testing of a panel of genes associated with epilepsy revealed the c.1643 A>T p.N548I variant in *STXBP1*. This variant has not been reported before in the medical literature, ClinVar and ExAC. Parental testing revealed that the variant is *de novo*. The variant is a non-conservative amino acid substitution and it is conserved in mammals. Missense mutations in nearby residues (including R551H, R551L) have been reported in the Human Gene Mutation Database in association with *STXBP1*-related disorders (Stenson et al, 2014). The variant was classified as likely pathogenic. Our case shares onset of epilepsy in infancy and prolonged seizure free interval with many cases in the medical literature. This seizure-free interval may be characteristic of the *STXBP1*-related infantile epilepsy. The regression of the neurodevelopment seen in our patient at age 4 is unique to our case.

**978F**

**High-depth multi-gene panel analysis with integrated sequence and copy number detection is a useful first-tier test with a high diagnostic yield and broad mutation spectrum detection in childhood epilepsy.** *N. Patil, R. Truty, D. Riethmaier, L. Elias, A. Entezam, A. Fuller, T. Hambuch, M. Hogue, A. Khouzam, Y. Kobayashi, R. Lewis, K. Nykamp, M. Rabideau, P. Taylor, J. Westbrook, M. Zeman, S. Aradhya.* Invitae Corporation, 1400 16th Avenue, San Francisco, CA 94103.

Epilepsy is a common disorder that is increasingly known to result from genetic causes, particularly when it occurs in early childhood. Understanding the genetic etiology can inform treatment strategies, prognosis, and recurrence risk. The objective of this study was to use a multi-gene panel with simultaneous sequence and exonic copy number variant detection to evaluate the clinical yield and assess its utility relative to exome sequencing. Using high depth next-generation sequencing, we investigated subsets of 186 genes in 1131 unrelated individuals diagnosed with epilepsy. We observed a total of 1840 clinically reportable variants in 885 individuals. 14% of patients received a definitive molecular diagnosis by panel testing, and another 29% had results that in some cases would likely reach clinical significance with additional evidence. 14% of positive results were chromosomal or exonic copy number changes or large indels. Most pathogenic variants were in genes for early-onset epilepsy and 22% of molecular diagnoses had treatment implications. Mosaic variants were seen in three genes and one individual had diagnostic results in two genes. Half of the variants of unknown significance identified were likely not clinically significant since they were found alone in an autosomal recessive gene or in the presence of a diagnostic result in another gene. A meta-analysis of published exome data showed that >70% of positive results for individuals with seizures were in genes present in available gene panels. We also evaluated sequence data for epilepsy genes in exome data derived from three different exome kits and bioinformatics pipelines and found a risk of up to 1.6% for false negative results, and that does not consider novel deleterious variants. These observations emphasize that a multi-gene panel for epilepsy is a useful first test prior to exome sequencing because of a high diagnostic yield and reliable detection of a broad range of mutations, including both sequence and copy number variants.

**979W**

**Novel biallelic *SZT2* mutations in three cases of early-onset epileptic encephalopathy.** *N. Tsuchida<sup>1,2</sup>, M. Nakashima<sup>3</sup>, A. Miyauchi<sup>4</sup>, S. Yoshitomi<sup>5</sup>, T. Kimizu<sup>6</sup>, G. Vigneswari<sup>6</sup>, WT. Keng<sup>7</sup>, C. Gaik-Siew<sup>7</sup>, M. Kato<sup>8,9</sup>, T. Mizuguchi<sup>1</sup>, A. Takata<sup>1</sup>, S. Matsumoto<sup>1</sup>.* 1) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 2) Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan; 3) Department of Biochemistry, Hamamatsu University School of Medicine, Hamamatsu, Japan; 4) Department of Pediatrics, Jichi Medical University, Tochigi, Japan; 5) Department of Pediatrics, Shizuoka Institute of Epilepsy and Neurological Disorders, Shizuoka, Japan; 6) Department of Pediatrics, Penang Hospital, Pulau Pinang, Malaysia; 7) Genetic Department, Hospital Kuala Lumpur, Kuala Lumpur, Malaysia; 8) Department of Pediatrics, Yamagata University Faculty of Medicine, Yamagata, Japan; 9) Department of Pediatrics, Showa University School of Medicine, Tokyo, Japan; 10) Clinical Genetics Department, Yokohama City University Hospital, Yokohama, Japan.

The seizure threshold 2 (*SZT2*) gene encodes a large, highly-conserved protein related to mTORC1 signaling. In mice, *Szt2* is abundantly expressed in the central nervous system and associated with epileptogenesis. Recently, biallelic *SZT2* mutations were found in seven patients from five families presenting with epileptic encephalopathy with dysmorphic features and/or non-syndromic intellectual disabilities. By whole-exome sequencing, we found compound heterozygous *SZT2* mutations in three unrelated patients with early-onset epileptic encephalopathies. Six novel *SZT2* mutations were found, including three truncating, one splice site and two missense mutations. The splice site mutation resulted in skipping of exon 20 and was associated with a premature stop codon. All individuals presented with seizures, severe developmental delay and intellectual disabilities with high variability. Brain MRIs revealing a characteristic thick and short corpus callosum or a persistent cavum septum pellucidum in each of two cases. Interestingly, in the third case, born to consanguineous parents, had unexpected compound heterozygous missense mutations. She showed microcephaly despite the other case and previous ones presenting with macrocephaly, suggesting that *SZT2* mutations might affect head size. These observations indicate that *SZT2* abnormalities are phenotypically heterogeneous.

Jhangiani<sup>11</sup>, D.M. Muzny<sup>11</sup>, R.A. Gibbs<sup>11</sup>, B. Tuysuz<sup>2</sup>, N. Elcioglu<sup>12</sup>, J.R. Lupski<sup>11,13,14</sup>, Baylor-Hopkins Center for Mendelian Genomics. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas; 2) Section of Neurology, Department of Pediatrics, Baylor College of Medicine, Houston, Texas; 3) Department of Pediatric Genetics, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey; 4) Department of Medical Genetics, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey; 5) Department of Pediatrics, Division of Pediatric Genetics, Faculty of Medicine, Ondokuz Mayıs University, Samsun, Turkey; 6) Department of Medical Genetics, Necip Fazıl City Hospital, Kahramanmaraş, Turkey; 7) Medical Genetics Unit, University of Health Sciences, Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey; 8) Department of Medical Genetics, Afyon Kocatepe University, Afyon, Turkey; 9) Medical Genetics Clinic, Mersin Women and Children Hospital, Mersin, Turkey; 10) Department of Medical Genetics, Faculty of Medicine, Onsekiz Mart University, Canakkale, Turkey; 11) Human Genome Sequencing Center, Baylor College of Medicine, Houston, Texas; 12) Department of Pediatric Genetics, Marmara University School of Medicine, Istanbul, Turkey; 13) Department of Pediatrics, Baylor College of Medicine, Houston, Texas; 14) Texas Children's Hospital, Houston, Texas.

Arthrogryposis is defined as congenital joint contractures in two or more body areas. It is a clinical sign rather than a specific disease diagnosis and is present in more than 400 different disorders with a majority involving the neuromuscular system, skeletal system and connective tissue. Although variants of more than 220 genes have been associated with arthrogryposis, the underlying molecular etiology remains unknown in a majority of cases. We applied whole exome sequencing (WES) to 117 affected individuals from 105 families with the clinical sign of arthrogryposis to identify potential molecular etiologies. We have previously published the results of 48 families with a molecular diagnostic rate of 58.3% by identifying variants in known genes in 17 families (then most variants were identified in *CHRNA1* in 5 families and *ECEL1* in 4 families), variants in candidate novel disease genes (*FBN3*, *MYO9A*, and *PSD3*) in 3 families, and potential oligogenic inheritance in 8 families. The family-based and cohort analysis of the WES results in subsequently collected samples from 57 families with arthrogryposis revealed variants in known genes in 20 families with the most common known genes being *CHRNA1* (4 families) and *ECEL1* (2 families) which is consistent with our previous findings. Likely pathogenic variants in candidate novel genes including *DRG1*, *HS6ST2*, *GBP5*, and *NUGGC* were found in 4 families. Additionally, as we found in first batch analysis, there was evidence of mutational burden or multi-locus pathogenic variation contributing to the phenotype, i.e. either rare homozygous variants in two known genes (i.e. *FBN2+COL6A3*, *KLHL7+HOXA11*, and *NEB+SCN9A*) or a homozygous and likely pathogenic variant in a novel gene in addition to a homozygous variant in a known gene (*MID1IP1+NEB*) in 4 families. In total, the arthrogryposis manifestation could be explained by a molecular diagnosis in 53.3% of families (known genes in 37 families [35.2%], novel genes in 7 families [6.7%], and oligogenic inheritance in 12 families [11.4%]) using WES. Our approach using genome-wide analysis allowed the identification of novel candidate disease genes as well as the exploration of potential oligogenic and mutational burden models in the arthrogryposis trait. We suggest that increased implementation of genomic sequencing methods in genetically heterogeneous phenotypes such as arthrogryposis provides a comprehensive understanding of the potential contributions of multilocus variation.

**981F**

**A novel *MTMR2* gene mutation (c.1168 G>T, p.E390\*) in a patient with Charcot-Marie-Tooth Disease Type 4B1.** M. Erdogan<sup>1</sup>, B. Balta<sup>1</sup>, A. Kiraz<sup>1</sup>, H. Gumus<sup>2</sup>. 1) Medical Genetics, Kayseri Research And Educational Hospital, Kayseri, Turkey; 2) Erciyes University Medical Faculty, Department Of Paediatric Neurology, Kayseri, Turkey.

Charcot-Marie-Tooth Disease (CMT) is a heterogeneous group of inherited disorder associated with over 80 disease causing genes. CMT hereditary neuropathy syndrome can be inherited in an autosomal dominant, autosomal recessive, or X-linked manner. *MTMR2* encodes a protein possesses phosphatase activity towards phosphatidylinositol-3-phosphate and phosphatidylinositol-3,5-bisphosphate. Mutations in this gene are a cause of Charcot-Marie-Tooth disease type 4B1 (OMIM:#601382), an autosomal recessive demyelinating neuropathy. By whole exome sequencing we detected a *MTMR2* homozygous nonsense mutation (c.1168 G>T, p.E390\*) in a 6 years old patient with gait disturbance, muscle weakness, mild ptosis, claw hand, bilaterally pes planus and demyelinating polyneuropathy. The aforementioned mutation has not been previously reported.

## 982W

**Exome sequencing in Italian FTD patients reveals probable novel mutations in neurodegeneration associated genes.** M. Hammer<sup>1</sup>, R. Capozzo<sup>2</sup>, C. Sassi<sup>1</sup>, C. Zecca<sup>2</sup>, M. Federoff<sup>1</sup>, C. Blauwendraat<sup>1</sup>, N. Bernstein<sup>1</sup>, J. Ding<sup>1</sup>, J.R. Gibbs<sup>1</sup>, T. Price<sup>1</sup>, A. Singleton<sup>1</sup>, G. Logroscino<sup>2,3</sup>. 1) Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health, Bethesda, MD, USA; 2) Department of Clinical Neurology and Research, University of Bari, "Pia Fondazione Cardinale G. Panico", Tricase (LE), Italy; 3) Neurodegenerative Diseases Unit, Department of Basic Medical Science, Neuroscience and Sense Organs, University of Bari, Italy.

**Background** Frontotemporal dementia (FTD) is a group of familial and sporadic neurodegenerative disorders affecting the frontal and temporal lobes. It is the second most common cause of dementia following Alzheimer's disease. **Objective** We aim at identifying known causative mutations and novel variants in genes associated with FTD and other related neurodegenerative disorders. **Methods** Ninety-two unrelated clinically diagnosed FTD patients (9.8% familial, 90.2% sporadic) were selected from the Apulia-FTD Registry in Italy. Whole exome sequencing was performed to identify the genetic origin of the disease. All subjects were screened for a pathological hexanucleotide repeat expansion in *C9ORF72* based on a repeat primed PCR. **Results** By focusing on pathogenic/likely pathogenic variants in established FTD genes, we identified three variants in *GRN*; two missense variants that have been previously published (c.G314A:p.C105Y and c.T415C:p.C139R) and one truncating frameshift deletion (c.1165delT:p.C389fs). Pathogenic repeat expansions in the *C9ORF72* gene were identified in two sporadic patients. In contrast to previous reports on genetic FTD, we did not find any variants in *MAPT*. Despite being rare causes of dementia, we detected variants that are likely pathogenic in *CHMP2B* (c.C49A:p.Q17K), *CSF1R* (c.G1646A:p.R549H and c.G1717A:p.E573K), *FUS* (c.G151A:p.G51S), *TBK1* (c.G1214T:p.R405L) and *CCNF* (c.A1240G:p.K414E and c.C326G:p.A109G). Furthermore, pathogenic and likely pathogenic variants in genes not commonly associated with clinical FTD were found (Alzheimer's disease genes: *PSEN2*, *SORL1*; ALS genes: *FIG4*, *MATR3*; other dementia/ neurodegeneration genes: *VPS13C*, *NPC1*, *ITM2B*). **Conclusion** Our study is of relevance for FTD genetics as it shows that a wide panel of neurodegenerative disorders causing genes should be considered when testing FTD patients.

## 983T

**Clinical and molecular insights into developmental abnormalities of corpus callosum.** M. Hebbar<sup>1</sup>, C. Galada<sup>1</sup>, A. Kanthi<sup>1</sup>, R. Kadavigere<sup>1</sup>, A. Shrikiran<sup>1</sup>, L. Lewis<sup>1</sup>, S. Nampoothiri<sup>2</sup>, V. Bhat<sup>3</sup>, M. Muranjan<sup>4</sup>, S. Bajaj<sup>5</sup>, S.L. Bielas<sup>5</sup>, K.M. Girisha<sup>1</sup>, A. Shukla<sup>1</sup>. 1) Kasturba Medical College, Manipal - 576104, Karnataka, India; 2) Amrita Institute of Medical Sciences and Research Centre, Ponekkara, Cochin, Kerala, India; 3) Department of Neonatology, JIPMER, Pondicherry, India; 4) Seth GSMC and KEM Hospital, Mumbai, India; 5) Department of Human Genetics, University of Michigan, Ann Arbor, Michigan, USA.

The development of corpus callosum is a composite process likely involving interplay of various genes and regulatory developmental mechanisms. The developmental abnormalities of corpus callosum is the most common brain malformation and genetically heterogeneous. We carried out an observational study in all patients with brain imaging studies consistent with agenesis or dysgenesis of corpus callosum and their families. We recruited 55 affected individuals from 51 families. Parental consanguinity was reported in 55% (28/51) of families. The syndromic form of corpus callosum abnormality was observed in 42% (23/55) of the cases. Non-syndromic form of corpus callosum abnormalities was seen in 58% (32/55) of the subjects, out of which majority were of complex type (90%, 29/32). Hypoplasia of corpus callosum observed in 51% (28/55) of the cases was the most common malformation, followed by partial agenesis of corpus callosum (15%, 8/55), complete agenesis of corpus callosum (27%, 15/55), hyperplasia of corpus callosum (2%, 1/55) and malformed (others) corpus callosum (5%, 3/55). The associated malformations noted in complex non-syndromic type were white matter disorders (52%) and posterior fossa anomalies (15%). Eight of them (23%) patients had neuronal migration defects. Enlarged subarachnoid spaces, hippocampus flattening, hyperintensity in the basal ganglia were other brain anomalies noted in five individuals. Genetic testing was completed in 43 families. Chromosomal microarray was performed in 16 patients, and mosaicism of chromosome 8, neurofibromatosis microdeletion syndrome, *6q21-q22.31* microdeletion syndrome, *13q13.3-21.1* microdeletion and *17q25.1* microduplication syndrome were detected. Whole-exome sequencing analysis in thirty-three families led to a definitive molecular diagnosis in 60% families. They were mostly autosomal recessive disorders constituting a spectrum of monogenic neurodevelopmental disorders including neurometabolic conditions, leukoencephalopathies and complex brain malformations. In addition, we also identified two novel candidate genes associated with these disorders, *ISCA1* (mitochondrial dysfunctions syndrome) in two unrelated families and *AIMP2* (neurodegenerative disease) in one family.

**984F**

**Heterozygous missense variant in *TDRKH* encoding tudor and KH domain-containing protein associated with autosomal dominant motor neuropathy.** K. Kosaka<sup>1</sup>, S. Miura<sup>2</sup>, T. Shimojo<sup>1</sup>, S. Nagata<sup>3</sup>, T. Morikawa<sup>1</sup>, R. Fujioka<sup>4</sup>, T. Nomura<sup>5</sup>, T. Taniwaki<sup>5</sup>, H. Shibata<sup>1</sup>. 1) Genomics, Medical Institute of Bioregulation Kyushu University, Fukuoka, Fukuoka, Japan; 2) Division of Respiriology, Neurology and Rheumatology, Department of Medicine, Kurume University School of Medicine, Kurume 830-0011, Japan; 3) Department of Radiology, Kurume University School of Medicine, Kurume 830-0011, Japan; 4) Department of Food and Nutrition, Beppu University Junior College, Beppu 874-8501, Japan; 5) Dr. Nomura's Clinic of Internal Medicine and Neurology, Fukuoka 812-0012, Japan.

Hereditary motor neuropathies (HMN) comprise a group of clinically and genetically heterozygous inherited disorders mainly characterized by slowly progressive motor neuropathies. We ascertained a four-generation pedigree of a Japanese family with a hereditary motor neuropathy with the autosomal dominant mode of inheritance, consisting of six family members including two patients. The cardinal clinical features were as follows: i) slow progression; ii) adult onset (37 and 51 years old, respectively); iii) drop foot; iv) facial muscle impairment; v) sternocleidomastoid muscle impairment; vi) areflexia; vii) no sensory impairment. Nerve conduction studies demonstrated axonal change in peroneal nerve. To elucidate the genetic basis of HMN in the pedigree, we performed exome sequencing of the two patients with the average depth of 11.1x. From the total of 16,427 single nucleotide variants (SNVs) shared with the patients, we remained eight functional heterozygous variants to be extremely rare (< 0.2 %) in our unrelated in-house exome data (n = 9) and in public databases such as 1000G, ExAC, ToMMo and HGVD. By Sanger validation of the all six of family members, we confirmed cosegregation with the disease in only two SNVs. One is a single nucleotide substitution, c.851G>A (p.(R284H)) in *TDRKH* (NM\_001083964) encoding tudor and KH domain containing protein. The other is a 10-bp deletion, c.749-758delATGACATATT (p.(Y250fs\*33)) in *LILRB5* (NM\_001081442) encoding leukocyte immunoglobulin-like receptor, subfamily B protein. By additional Sanger sequencing of 500 unrelated Japanese control samples, we excluded the deletion variant, Y250fs\*33 in *LILRB5* to be relatively common (0.29 %) and unlikely to be pathogenic. On the other hand, we confirmed ;R284H in *TDRKH* is absent in the 500 controls. The SNV is located in a highly conserved region in the tudor domain in *TDRKH*. The tudor domain is also located in survival of motor neuron protein 1, encoded by *SMN1* and most of the responsible variants for another motor neuron disease, spinal muscular atrophy is known to be located in the tudor domain of *SMN1*. Therefore, it is reasonable that the SNV in the tudor domain may critically affect the *TDRKH* protein function. In conclusion, R284H in *TDRKH* is responsible for the hereditary motor neuropathy in our pedigree through functional alteration in the tudor domain. This is the first report of a human disease associated with *TDRKH*.

**Familial choreoathetosis: A novel heterozygous mutation in *PDE10A*.**

D. Narayanan<sup>1</sup>, D. Deshpande<sup>2,3</sup>, A. Bhowmik<sup>2</sup>, D. Ravi Varma<sup>4</sup>, A. Dalal<sup>1</sup>. 1) Medical Genetics, Nizam's Institute of Medical Sciences, Hyderabad, India; 2) Diagnostics Division, Centre for DNA Fingerprinting and Diagnostics, Hyderabad, India; 3) Graduate Studies, Manipal University, Manipal, India; 4) Citi Neurocentre, Hyderabad, India.

Chorea is a hyperkinetic movement disorder characterized by brief involuntary repetitive movements and is a symptom of many inherited neurological disorders. Recently Mencacci et al described three unrelated European descent individuals with childhood onset chorea and bilateral striatal abnormalities on cerebral MRI with de novo mutations in *PDE10A*. Diggle et al described eight individuals from two unrelated families with biallelic mutations in *PDE10A* and striatal abnormalities and hyperkinetic movement disorder with onset in infancy. We describe a family of Indian origin with multiple affected individuals harboring a novel heterozygous probable pathogenic variant in *PDE10A* identified by exome sequencing. A 24 year old female had progressively increasing involuntary movements of hands, face and head since 5 years of age. She had increasing difficulty in articulation of speech and difficulty in writing. She never had any seizures or worsening of intellect. On examination, she had choreiform movements involving upper limbs, facial grimace and head nodding. Higher mental status, cranial nerves, bulk, tone, power and reflexes, sensory system and cerebellar examination were normal. Her father was 60 years old and had a similar history with onset of symptoms at three years of age. Multiple members in father's family had similar symptoms. The husband of the proband was 35 years male born to consanguineous parents and had biallelic pathogenic variants in *SERPINF1* gene, causing autosomal recessive osteogenesis imperfecta type VI. MRI head of the patient showed volume loss in putamina and caudate nucleus and hypointense signals on T1 weighted images and hyperintense signals on T2 weighted and FLAIR sequences. A novel nonsynonymous pathogenic variant was identified (NM\_001130690.2:c.1001T>G,p.F334C) in *PDE10A* by exome sequencing. Sanger sequencing confirmed the presence of variant in the patient and her father. In silico protein modeling showed that the mutation affected the binding affinity of cAMP to the GAF-B domain due to plausible change in the structure of binding pocket. Genetic counseling was offered to the family. Childhood onset of chorea with normal cognition and striatal hyperintensities should prompt further evaluation beyond benign hereditary chorea and heterozygous or homozygous mutations in *PDE10A* can cause such a phenotype. Making an exact molecular diagnosis is important in providing prenatal diagnosis and genetic counseling to families.

**986T**

**A novel *de novo* alteration in *SLC12A6* in a patient with early-onset severe progressive sensorimotor polyneuropathy and abnormal EEG.** M. Rossi<sup>1</sup>, K. Scherer<sup>2</sup>, M. Galindo<sup>2</sup>, K. Radtke<sup>1</sup>, Z. Powis<sup>1</sup>, D. Shinde<sup>1</sup>. 1) Clinical Genomics, Ambry Genetics, Aliso Viejo, CA; 2) Children's Clinics, Tucson, AZ.

The *SLC12A6* gene encodes a potassium-chloride cotransporter (KCC3) belonging to a family of transmembrane proteins that regulate cell volume and control neuronal activity by transporting K<sup>+</sup> and Cl<sup>-</sup> ions across the plasma membrane. Biallelic truncating and missense mutations in *SLC12A6* cause autosomal recessive agenesis of the corpus callosum with peripheral neuropathy associated with hydrocephalus, developmental delay, intellectual disability and seizures. However, only one patient with a *de novo* heterozygous missense alteration, c.2971A>G (p.T991A), in the *SLC12A6* gene has been reported till date. This patient presented with progressive, and early-onset axonal motor neuropathy with normal corpus callosum, cognition, and no epilepsy (Kahle *et al.* 2016). Functional studies demonstrated that this alteration results in constitutive KCC3 activity. We report an additional patient with a previously unpublished *de novo* missense alteration c.620G>A (p.R207H) in *SLC12A6* and severe sensorimotor polyneuropathy with distal and proximal weakness and abnormal EEG. The alteration was identified through diagnostic exome sequencing (DES) and reported as a candidate genetic etiology due to limited clinical validity of the association of monoallelic *SLC12A6* alterations with human genetic disease. A different alteration at the same codon, p.R207C, has been previously reported in a patient with developmental delay and mild intellectual disability, significant hypotonia with areflexia, pyramidal signs, complete agenesis of the corpus callosum, and an axonal and demyelinating neuropathy of the motor and sensory nerves with reduced motor nerve conduction velocity. The patient was found to be homozygous for the alteration and the carrier parents were asymptomatic. *In vitro* functional studies of the p.R207C alteration demonstrated decreased transport activity of the mutant KCC3 when expressed in *Xenopus* oocytes (Salin-Cantegrel *et al.* 2011). Functional studies of the effect of the p.R207H alteration need to be performed in order to determine whether this alteration has a loss- or gain-of-function effect and hence has been classified as a variant of uncertain clinical significance. There is also the possibility of another alteration on the second allele that could be intronic or located in the regulatory region, and therefore not detected by exome sequencing. RNA-sequencing studies could be pursued to confirm the state of the second allele in this patient.

**987F**

**N98S mutation in *NEFL* gene causing a mild form of Charcot-Marie Tooth disease.** A. Sanchez<sup>1</sup>, J.C. Prieto<sup>1,2</sup>. 1) Instituto de Genética Humana, Pontificia Universidad Javeriana Bogotá, Bogota, Colombia; 2) Hospital la Victoria, Bogotá Colombia.

**Introduction:** Charcot-Marie Tooth disease (CMT) is an heterogeneous group of inherited peripheral neuropathies affecting motor and sensory nerves of peripheral nervous system. Prevalence is 1 in 2500 individuals. CMT is classified into demyelinating or axonal forms depending on nerve conduction velocities (CMT1 - CMT2 respectively), however there is a dominant CMT intermediate form with clinical and electrophysiological characteristics that do not fit into either CMT1 or CMT2. Approx 1000 mutations in 80 genes have been identified as a cause. Neurofilament lightchain polypeptide (*NEFL*) gene codes for a protein of neurofilaments involved in axonal transport processes of mature neurons. Mutations distributed throughout *NEFL* may cause either dominant axonal CMT2E or dominant demyelinating CMT1F. **Case Report:** 23 y/o male patient with bilateral pes-cavus since age 13y. He was born from non-consanguineous parents. Family history was negative for neuromuscular or CNS diseases. At age 20, he developed ataxia. EMG showed demyelinating pattern in lower extremities. Brain MRI was normal. On examination, he was able to stand with support and walk few steps with bilateral steppage and marked postural instability. Bilateral forefoot pes-cavus was evident and had scar sequelae from orthopedic surgical procedure. Muscle power of lower extremities was diminished. Upper extremities were normal. Whole exome sequence showed a heterozygous missense pathogenic mutation N98S and a heterozygous likely benign A195V mutation in *NEFL* gene, which is associated with CMT2E and CMT1F. **Discussion:** *NEFL* related-CMT is clinically and genetically heterogeneous, and accounts only for <1% of all CMT cases. Additional features besides neuropathy are seen. Patients with N98S have hearing loss, ataxia and cerebellar atrophy. Here we report a patient with two variants on *NEFL*, a benign mutation inherited from father (A195V) and a *de novo* mutation (N98S). The N98S mutation has been reported as a cause of severe and very early onset disease, however this patient manifests a unique mild phenotype. Patient has a mild late onset demyelinating form of CMT with ataxia, without cerebellar atrophy. **Conclusion:** this report highlights the phenotypic variability in CMT patients with *NEFL* mutations and expands the clinical phenotype of dominant mutation N98S. There is an increased necessity of more genotype-phenotype correlations to clearly elucidate the pathogenesis of this wide clinical spectrum disease.

**988W**

**Missense mutations and duplications of alpha-synuclein in familial Parkinson's disease: Genotype-phenotype correlation.** K. Nishioka<sup>1</sup>, H. Yoshino<sup>1</sup>, Y. Li<sup>1</sup>, M. Funayama<sup>1</sup>, T. Candido<sup>2</sup>, M. Farrer<sup>2</sup>, N. Hattori<sup>1</sup>. 1) Department of Neurology, Juntendo University School of Medicine, 2-1-1 Hongo, Bunkyo-ku, Tokyo 113-8421, Japan; 2) Department of Medical Genetics, Brain Research Centre, University of British Columbia, Vancouver, British Columbia V6T 2B5, Canada.

Alpha-synuclein is a major component of Lewy bodies and neuritis which are pathological hallmark of Parkinson's disease (PD). We have assessed the frequency of alpha-synuclein (*SNCA*) mutations in Japanese patients with familial or sporadic Parkinson's disease (PD), and surveyed their associated clinical manifestations. We screened *SNCA* exon 3 in 988 patients without *SNCA* duplications (430 with autosomal dominant PD and 558 with sporadic PD), and duplications in 1620 with familial PD, sequenced by Sanger method using BigDye Terminators v1.1 Cycle Sequencing Kit and 3130 Genetic Analyzer (Life Technologies, Foster City, CA, USA) and MLPA methods (Multiplex ligation-dependent probe amplification, MRC\_Holland, Netherlands). We detected one patient harboring a homozygous *SNCA* p.A53V substitution (frequency 2/860 = 0.2%), 13 probands with duplication, and one patient with triplication in the regions of *SNCA* (14/1620). According to inheritance pattern, there were autosomal dominant in 13 families, autosomal recessive-like in one family, and sporadic in one family. The average age at onset was 43.1 ± 13.7 (±SD) years of duplication, 28 years of triplication, and 55 years of homozygous p.A53V. Triplication presented most severe prognosis of rapid and progressive parkinsonism and cognitive decline with high concentration of psychosis in the pedigree. Following, duplication showed various types of clinical course such as slow or rapid progression of parkinsonism and cognitive decline. The prevalence of cognitive decline was 5/13 in *SNCA* duplication. However, most of them had segregation of cognitive decline, presented rigidity, akinesia, and gait disturbance, of which manifestations resembled with rigid-akinesia parkinsonism. Levodopa response mostly seems to be good at early stage. A patient with homozygous p.A53V, she manifested slow and progressive parkinsonism at 55 years. Cognitive decline was prominent at 74 years. MIBG myocardial scintigraphy indicated decreasing of heart/mediastinum ration in all patients. In Japan, the frequency of duplications were higher than missense mutation in *SNCA*. Clinical phenotype reflected on gene dosage effect, related to over-expression mechanisms of alpha-synuclein. High dosage of alpha-synuclein likely induces severe form of familial parkinsonism.

**989T**

**Expanding the clinical spectrum of ARL6IP1-associated hereditary spastic paraplegia.** S. Majid<sup>1</sup>, A. Alazami<sup>1</sup>, H. Al Dossari<sup>1</sup>, S. Al-Hissi<sup>1</sup>, A. Al Qahtani<sup>1</sup>, R. Al Humaidy<sup>1</sup>, B. Meyer<sup>2</sup>, S. Bohlega<sup>2</sup>, A. Al Hashem<sup>3</sup>. 1) KFSHRC, RIYADH, India; 2) Department of Neurosciences, King Faisal Specialist Hospital & Research Center, Riyadh; 3) Prince Sultan Riyadh Military Medical City, Riyadh, KSA.

Mutations in ARL6IP1 (ADP ribosylation factor like GTPase 6 interacting protein 1) encoding a tetra-span membrane protein localized to the Endoplasmic Reticulum, have been recently described in an extended family with a complicated form of Hereditary Spastic Paraplegia (HSP). ARL6IP1 was first identified as an interacting molecule of ARL6, a member of the ARL subfamily of small GTPases which mainly regulates intracellular trafficking pathways in the ER membrane. In our quest to study HSP in the Saudi population, we uncovered a family with a severe and distinct phenotype that resulted in the spontaneous neonatal death of both affected. Clinical features encompassed not only complicated HSP but also developmental delay, microcephaly, periventricular leukomalacia and respiratory distress. Molecular Karyotyping was found to be normal. Homozygosity mapping localized the phenotype to a region on chromosome 12, and whole exome sequencing of the index case identified a homoallelic truncating mutation in ARL6IP1 that was predicted to result in complete loss of the protein. The mutation was confirmed by Sanger sequencing and segregated with the disease state with an autosomal recessive pattern of inheritance and complete penetrance. Our findings expand the phenotypic and mutational spectrum of ARL6IP1-associated neurodegenerative disorders.

## 990F

**Genomic analysis identifies new loci associated with motor complications in Parkinson's disease.** S. Chung<sup>1</sup>, J. Kim<sup>2</sup>, M.J. Kim<sup>1</sup>, M. Kim<sup>3</sup>, Y.J. Kim<sup>1</sup>, K.J. Kim<sup>1</sup>, H.S. Ryu<sup>1</sup>. 1) Asan Medical Center, Seoul, South Korea; 2) Metro hospital, Anyang; 3) Korean University Medical Center Guro.

**Background:** Over the past 20 years, genetic causes and risk factors for Parkinson's disease (PD) have been identified by high-throughput genotyping technologies. However, previous genetic studies have typically focused on disease risk rather than disease-specific symptomatology. **Objectives:** We aimed to identify the genomic variants that are associated with the occurrence of motor complications in patients with PD. **Methods:** Genomic data was produced using the Korean Chip (K-CHIP), Affymetrix Axiom™ KORV1.1, which contains imputation genome-wide association study (GWAS) grid and other GWAS loci, functional variants of nonsynonymous exome, pharmacogenetics variants, variants in genes involved in absorption, distribution, metabolism and excretion (ADME) of drugs, and expression quantitative trait loci (eQTL), in 1,070 PD patients. The association between genomic data and clinical features of motor complications of PD patients was analyzed using Jonckheere-Terpstra test with codominant coding scheme as a primary analysis. **Results:** The intergenic variant (to be presented) in chromosome 2 had the most significant association with the occurrence of levodopa-induced dyskinesia within 5 years after PD onset ( $P = 3.57 \times 10^{-6}$ ). This association was also significant after Bonferroni correction. There are several other genomic variants that showed nominally significant association with the occurrence of levodopa-induced dyskinesia within 5 years after PD onset, which warrant further evaluation. There was no significant association between genomic variants and the occurrence of wearing-off within 5 years after PD onset, although several genomic variants showed a nominal significance. **Conclusions:** This genomic study identified a new locus associated with the occurrence of levodopa-induced dyskinesia within 5 years after PD onset. These findings need to be validated by replication studies and functional studies.

## 991W

**Genome-wide association study identifies potential genetic modifiers in Charcot-Marie-Tooth disease type 1A.** F. Tao<sup>1</sup>, G. Beecham<sup>1</sup>, S. Blanton<sup>1</sup>, L. Abreu<sup>1</sup>, F. Baas<sup>2</sup>, B. Choi<sup>3</sup>, D. Pareyson<sup>4</sup>, M. Reilly<sup>5</sup>, M. Shy<sup>6</sup>, S. Zuchner<sup>1</sup>, *Inherited Neuropathy Consortium*. 1) Dr. J.T. MacDonald Department for Human Genetics, Hussman Institute for Human Genomics, University of Miami, Miami, FL; 2) Department of Genome Analysis, Academic Medical Centre, Amsterdam, The Netherlands; 3) Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea; 4) Department of Clinical Neurosciences, C. Besta Neurological Institute, Milan, Italy; 5) MRC Centre for Neuromuscular Diseases, UCL Institute of Neurology, London, UK; 6) Department of Neurology, University of Iowa, Iowa City, IA.

Charcot-Marie-Tooth disease type 1A (CMT1A), caused by a canonical *PMP22* duplication on chromosome 17p11.2, is the most common subtype of inherited peripheral neuropathies and affects 1 in 10,000 individuals worldwide. While sharing the same genetic cause, CMT1A patients often present great variability in their phenotypic presentation and disease severity. The cause of the phenotypic variability is largely unclear. In this study, we performed a case only genome-wide association study (GWAS) to identify novel genetic modifiers of various phenotypes in CMT1A. DNA samples from 971 CMT1A patients were genotyped on Illumina OmniExpress platform. After standard quality control, the dataset includes 600k markers in 857 individuals (644 individuals from European ancestry, and 213 individuals from Asian ancestry). We focused our analyses on the European population. Logistic regression in PLINK was used to analyze the association between clinical outcomes and patient genotypes in an additive model. For CMT neuropathy score (CMTNS), the analysis was performed using linear regression in PLINK, adjusting for age of patients. The analyses yielded several suggestive association signals. An association peak on chromosome 6 was identified in difficulty with eating utensils (lead SNP rs12192704, chr6:30792270,  $P=1.15E-06$ , odds ratio=3.25). The peak is located within a non-coding gene *LINC00243*. Hearing loss showed an association peak on chromosome 5 (lead SNP rs7720606, chr5:126551732,  $P=2.22E-07$ , odds ratio=3.457), located in an intergenic region near the *MEGF10* gene. In foot plantar flexion, an association signal was identified in the *DSCAM* gene on chromosome 21 (lead SNP rs2249498, chr21:41431874,  $P=5.13E-07$ , odds ratio=2.437). CMTNS showed an association signal on chromosome 1 (lead SNP rs12137595, chr1:4094068,  $P=1.14E-07$ , beta=3.014), located within an intergenic region close to *DFFB*, *C1orf174*, and *LINC01134*. While these suggestive signals require further validation, our study provides novel insights into the genetic architecture of CMT1A. Novel genetic modifiers may serve as potential targets for therapeutic interventions in the future.

## 992T

**Integrative omics analysis of a cohort of 198 singletons with cerebral palsy.** J. Gecz<sup>1,2,3</sup>, CL. vanEyck<sup>1,2</sup>, JL. Broadbent<sup>1</sup>, K. Harper<sup>1</sup>, A. Gardner<sup>1,2</sup>, BW. Van Bon<sup>1</sup>, MA. Corbett<sup>1,2</sup>, A. MacLennan<sup>1,2</sup>. 1) Australian Collaborative Cerebral Palsy Research Group, Robinson Research Institute, Adelaide, SA 5006; 2) Adelaide Medical School, The University of Adelaide, Adelaide, SA 5005, Australia; 3) South Australian Health and Medical Research Institute, Adelaide SA 5000, Australia; 4) Department of Human Genetics, Radboud University Medical Center, Nijmegen, the Netherlands.

Cerebral palsies (CP) describe a heterogeneous group of permanent, non-progressive disorders of movement and posture diagnosed between birth and age 3-5 years. Our pioneering research into genetics of CP shows that, similar to other neurodevelopmental disorders, CP is likely to be genetically heterogeneous, with 100s of genes involved. Many of the CP genes & mutations will be 'shared' with intellectual disabilities, epilepsies or autisms. Our conservative diagnostic rate from the first 198 CP whole exome (WES) cohort, 98 of which were trios, was 14%. This has now been replicated by WES on our new collaborative cohort of 95 CP trios (M Krueer, Phoenix, USA; unpublished), reaching 35% or more genetic contribution to CP. Subsequent analysis of our CP cohort (n=198) for copy number variants (CNVs) resolved additional 7% of cases (7 dels; 6 dups), with some well-known neurodevelopmental loci involved, i.e. 16p11.2-12.2 or 2p25.3 deletions or 1q21.1 microduplication. Currently we are whole genome sequencing part of this CP cohort (25 trios) as well as investigating genome-wide methylation. RNA sequencing of patient cell lines of 182 cases and 120 controls revealed significant upregulation (n=132) of genes involved in the immune response and downregulation (n=320) of genes involved in cell communication and signalling. Application of Weighted Gene Co-expression Network Analysis identified a coordinated downregulation of expression of a module of 376 genes. This module is enriched for genes from the brain-derived neurotrophic factor (BDNF) signalling pathway and microglial expression. Overall the RNA sequencing data suggests a possible interplay between genetic and environmental factors in CP aetiology. Our ultimate goal is to integrate the 'omics' and clinical data to comprehensively address the aetiology of CP as a multifactorial neurodevelopmental disorder. The long term clinical applications include clinical and medico-legal assertion of causation, better genetic counselling before subsequent pregnancies, early pregnancy diagnosis and precision medicine delivery informed by the expanding knowledge of CP neurobiology. This research was supported by grants from the Australian National Health and Medical Research Council, Cerebral Palsy Alliance and Channel 7 Children's Research Foundation.

## 993F

**Novel TSC1/TSC2 pathogenic variants in Hungarian cohort with tuberous sclerosis complex: Clinical and molecular genetic aspects.** E. Kovcsd<sup>1,2</sup>, K. Hadzsiev<sup>1,2</sup>, K. Komlosi<sup>3</sup>, E. Horvath<sup>4</sup>, A. Horvath<sup>5</sup>, M. Farkas<sup>6</sup>, V. Farkas<sup>6</sup>, L. Timar<sup>7</sup>, A. Csaba<sup>8</sup>, K. Sumegi<sup>1,2</sup>, B. Meleg<sup>1,2</sup>. 1) Medical Genetics, University of Pecs, Pecs, Hungary; 2) Human Genetic And Pharmacogenomic Research Group, Szentagothai Research Centre, Pecs, Hungary; 3) Department of Human Genetics, University Medical Center of the Johannes Gutenberg University Mainz, Germany; 4) Department of Medical Genetics, Faculty of Medicine, University of Szeged, Hungary; 5) EEG Diagnostic and Epilepsy Center, Markusovosky University Hospital, Szombathely, Hungary; 6) Children's Neurology, 1st Department of Pediatrics, Semmelweis University, Budapest, Hungary; 7) National Institute of Child Health, Budapest, Hungary; 8) 1st Department of Obstetrics and Gynecology, Semmelweis University, Budapest, Hungary.

**Background:** Tuberous sclerosis complex (TSC) is an autosomal dominant disorder, affecting approximately 1,600 individuals in Hungary. It is characterized by the appearance of non-malignant brain tumors, skin, eye, heart and kidney abnormalities. The most common and disabling neurological manifestation of TSC are epilepsy, developmental delay, mental retardation, behavioral disorders, and autism. **Purpose:** This study describes the broad spectrum of clinical phenotype -including disease causing mutations- of 14 Hungarian TSC patients, who showed pathogenic *de novo* genetic variants of *TSC1/TSC2* genes. **Methods:** Blood samples of patients with clinically definite or suspected TSC have been collected since 2011 at the Department of Medical Genetics, University of Pecs (Hungary). Before molecular genetic testing, all patients underwent detailed clinical examinations, including dermatology, internal medicine and neurological assessments. *TSC1/TSC2* genes of 83 Hungarian patients with clinical signs of TSC were analyzed by Sanger-sequencing. **Results:** We identified 14 cases (5 male and 9 female) with previously unpublished *de novo* pathogenic mutations in *TSC1/TSC2* genes. Most of the affected organs were the central nervous system (n=13) and the skin (n=8), while only 1 patient had renal abnormalities. From the 14 cases, epilepsy (n=10), hypopigmented spots (n=8) and cortical tubers (n=7) were the most frequented clinical manifestation of the disease. Regarding the genetic testing we found 3 cases with mutations in the *TSC1* and 11 in the *TSC2*. In the case of *TSC1*, 3 different exons were affected in 3 cases. One patient had splicing, the other a nonsense mutation, and 1 was subject to an intronic deletion affecting 8 bases. In *TSC2* gene we found 1 patient with splicing, 1 with missense and 1 with nonsense mutations. Three had small, three had gross deletion, and 2 subjects with small insertion. In *TSC2* gene, exon 16 was the mostly effected region (n=3), however with completely different numbers and severity of clinical signs. **Conclusion:** Based on the severity and the number of the clinical signs of TSC, it is not possible to predict which gene and type of the mutation is involved in the clinical manifestation of the disease. However, through molecular genetic analysis, followed by detailed genotype-phenotype comparison of patients showing symptoms of TSC, one can gain significant new information about the disease, and patients can receive the right diagnosis and care.

**994W**

**Structural and sequence characterization of SMN1 and SMN2 genes in SMA patient collection.** C. Sun, M. Liu, J. Hurt, J. Staropoli, J. Carulli, M. Penny. Biogen Inc. 115 Broadway, Cambridge, MA 02142.

Spinal muscular atrophy (SMA) is a neuromuscular degenerate disease caused by deletion of or mutations in SMN1 gene (Survival of motor neuron 1) on chromosome 5. SMN2, a partially functional centromeric copy of SMN1 gene in the SMA locus, is the major known modifier of this disease, due to the fact each copy of SMN2 can generate 10-20% of functional SMN transcript, and copy number of SMN2 varies in human population. A greater SMN2 copy number is usually correlated with a milder presentation of SMA. However, SMN2 copy number and SMA subtype are not perfectly correlated, thus SMN2 copy number is not a diagnostic marker. To investigate whether structural or nucleotide sequence variation in SMN2 contribute to this imperfect correlation, we characterized SMN1 and SMN2 genes in 39 SMA patients with known disease type from I to III, and 66 of their first degree relatives, by ddPCR and NGS approach covering all coding exons and flanking intronic sequences. Our results lend support to a recently reported modifier in intron 6 of SMN2 (A-44G). A patient with this allele has a milder disease type than SMN2 copy number alone would suggest. More importantly, our data suggests a previously unreported SNP in SMN2 may be another disease modifier, and with higher frequency than that of A-44 G allele.

**995T**

**Heterozygous COG4 variant causes a non-lethal type of COG4-CDG**

**(formerly CDG-IIj).** R. Hamid<sup>1</sup>, A. Clement<sup>2</sup>, B. Blanco-Sánchez<sup>2</sup>, A. Robertson<sup>1</sup>, L. Wolfe<sup>3</sup>, M. Davids<sup>3</sup>, M. Malicdan<sup>2</sup>, J. Phillips<sup>1</sup>, J. Newman<sup>1</sup>, J. Cogan<sup>1</sup>, J. Phillips<sup>2</sup>, J. Wegner<sup>2</sup>, M. Westerfield<sup>2</sup>. UDN collaborators. 1) Dept Pediatrics, Div Med Gen, Vanderbilt Univ Sch Med, Nashville, TN; 2) Institute of Neuroscience, University of Oregon; 3) NIH/NHGRI, Bethesda, MD.

Congenital disorder of glycosylation COG4-CDG is a rare autosomal recessive (AR) disorder caused by mutations in the *component of oligomeric golgi complex 4 (COG4)* gene. This disorder has been reported previously in only two individuals and is associated with a severe phenotype with dysmorphism, delays, hypotonia, liver dysfunction, CNS abnormalities including cerebral atrophy, and early death. Here we report a 22-month-old male who presented to the Undiagnosed Diseases Network (UDN) with mild developmental delay, prominent forehead, triangular face, ptosis, nystagmus, blue sclera, bilateral clubfoot, and history of IUGR with proportionate slow growth and growth hormone deficiency. He also had mild-moderate (2000-4000Hz) bilateral SNHL. MRI showed abnormally dilated semicircular canals, chiari malformation and hydrocephalus. A trio exome did not identify an obvious AR or AD candidate that could explain the patient's phenotype. A de novo novel c.1546G>A (p.Gly516Arg) missense variant was identified and Sanger validated in one allele of the *COG4* gene (NM\_015386.2). This variant was rare and absent from 1KGP, EVS, ExAC and GnomAD databases. Deletion duplication and cDNA analyses were negative. Given that the only two patients reported previously had homozygous mutations and this patient had a rare novel variant in only one allele, we generated homozygous and heterozygous zebrafish models of the *COG4* deficiency by targeting CRISPRs to the region encoding the variant amino acid and also in an early exon. These two alleles shift the open reading frame, truncate the protein, and fail to complement. By day 5 post fertilization, homozygous mutants present with a shorter body axis and smaller inner ears. Morphogenesis of the semicircular canals is severely disrupted, and they have a hearing and balance defects. Craniofacial cartilage and fin malformations are also observed. Alcian blue staining shows that chondrocytes fail to stack and that extracellular matrix is affected, consistent with a defect in secretion and possibly glycosylation. Heterozygous mutants showed less severe but significant defects, consistent with haploinsufficiency. In support of this, Golgi morphology changes were observed in the patient's fibroblasts. These data suggest that this rare heterozygous *COG4* variant was likely pathogenic and expands the phenotype associated with COG4-CDG and suggests that COG4 heterozygous mutations can also cause a phenotype, albeit milder and non-lethal.

**996F**

**Spectrum of *TTN* variants in a patient cohort of neuromuscular disorders.** P.S. Lai, Z. Yong, S. Tomar, R. Sethi, P.S. Low, S.K.H. Tay. Paediatrics, National University of Singapore, Singapore, Singapore, Singapore.

Titin is the largest known human protein encoded by the *TTN* gene spanning 364 exons and has been known to generate numerous isoforms through alternative splicing. Mutations in *TTN* have been associated with a wide range of disorders from cardiomyopathy to muscular dystrophy. Next gene sequencing approaches (NGS) have uncovered large numbers of missense and truncating variants in *TTN*, many of which are novel. However, there is still a lack of complete understanding in the distribution of these variants across the gene and their association with disease phenotypes. Identification of a titin causing muscle disease or cardiac phenotype is important for clinical management and/or early interventions. In this study, we analyzed the spectrum of *TTN* variations in a cohort of 130 neuromuscular disorder cases that have been sequenced using standard NGS pipelines. Identified variants from whole genomes were analyzed using known population databases such as 1000 Genomes Project, Exome Sequencing Project (ESP) and Exome Aggregation Consortium (ExAC), all known *TTN* mutation databases, ClinVar repository and *in silico* prediction tools. A total of 25,663 non-synonymous variants were identified with an average of 197.41 variants found per individual with 6.79 variants being rare (MAF<1%) and 7.62 variants being novel (MAF=0%). Missense mutations accounted for more than 59.39% of the variants. More than half of the 1373 unique variants (57.17%) identified in our cohort were either novel or rare in the general population. Most of the variants (90.60%) were non-synonymous occurring at a hotspot in the Z-disk/I-band junction, further up the I-band (exon 77-93), A-band and the A-band/M-band junction. Heterozygous potentially pathogenic *TTN* truncating variants (TTNtv) were found in 14 cases (10.77%) with 11 being novel and not predicted to generate a recessive neuromuscular condition. The high incidence of novel *TTN* variants points to the challenges in interpreting their significance in a clinical setting with many ending up being classified as VUS, and thus leading to an inconclusive diagnosis. Reporting of such variants in databases and future functional studies can facilitate further understanding on the classification of these mutations for pathogenicity effect. .

**997W**

**Whole exome sequencing data analysis in hereditary spastic paraplegia patients from Turkey.** B. Ozes<sup>1</sup>, O. Ari<sup>1</sup>, Y. Parman<sup>2</sup>, E. Battaloglu<sup>1</sup>. 1) Molecular Biology and Genetics, Bogazici University, Istanbul, Turkey; 2) Istanbul University, Istanbul Medical School, Department of Neurology, Istanbul, Turkey.

Hereditary Spastic Paraplegia (HSP) is defined as a rare group of clinically and genetically heterogeneous neurodegenerative disorders. Main symptoms are lower limb spasticity and progressive weakness manifested in pure type of the disease. In complicated HSP cases, neurological and non-neurological symptoms can be observed, additionally. Disease might be inherited in autosomal dominant, autosomal recessive, or X-linked manner. Fifty-one loci and forty-three genes are associated with the autosomal recessive form of HSP (ARHSP). In this study, we have investigated twenty families with autosomal recessive HSP inheritance. With the aim of identifying causative genes and variants in these families, whole exome sequencing (WES) was performed for one affected individual from each family. Known HSP genes and genes related to other neurological diseases (app. 1800 genes) were analyzed initially in the WES data. Missense, non-synonymous and splice site variants, predicted as 'effective' by *in silico* tools and with MAF value less than 1% were chosen as candidate variants. Sanger sequencing was performed for the family members to understand inheritance pattern of the variants in the family. The causative variants were identified in seven of the families. These were c.1235C>G, c.6215\_6219dupAGAT and c.3036C>A in *SPG11* gene, c.825T>A in *CYP7B1* gene, c.2104-2A>G in *SPG7* gene, c.437A>T in *CCT5* gene, and c.637G>A in *SACS* gene. The segregation analyses for the identified candidate variants are currently being performed for other thirteen families. At this stage of the study, genetic diagnosis rate is 35%. This study shows that WES is an effective technique for genetic diagnosis of HSP since causative variants in both HSP and other neurological disease-associated genes can be identified. Besides, it helps identification of overlapping genes in neurological diseases that is an important contribution to fulfill the overall picture of mechanism underlying neurodegeneration.

**998T****Mutations of the *ZNF292* gene are a novel cause of neurodevelopmental disability, behavioral problems, and autism spectrum disorders (ASD).**

Bamshad<sup>8</sup>, *University of Washington Center for Mendelian Genomics*. 1) Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA; 2) Department of Pediatrics, University of Washington, Seattle, Washington; 3) Laboratoire de diagnostic génétique, Institut de Génétique Médicale d'Alsace, Hôpitaux Universitaires de Strasbourg, 67000 Strasbourg, France; 4) Department of Pediatrics, Al duPont Hospital, Wilmington, Delaware, USA; 5) Riley Hospital for Children, Indianapolis, Indiana, USA; 6) Department of Genetics and Genomics Sciences, Icahn School of Medicine, Mount Sinai, New York, NY, USA; 7) Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany; 8) GeneDx, Gaithersburg, Maryland, USA.

Intellectual disability (ID) and Autism Spectrum Disorders (ASD) are highly genetically heterogeneous neurodevelopmental phenotypes, and the genetic landscape of these disorders continues to rapidly expand with the wide use of Next Generation Sequencing (NGS) methods. By far, most of the mutations underlying ID and ASD are *de novo*. However, dominant, recessive and maternally-inherited X-linked etiologies have been identified as well. Using whole exome sequencing, we identified *de novo* and dominant mutations in Zinc Finger Protein 292 (*ZNF292*), in 16 unrelated families ascertained on ID in both clinical and research settings. Affected individuals also had behavioral issues including attention-deficit-hyperactivity disorder (ADHD), and ASD, among others. Fourteen mutation-positive families were sporadic (i.e. no sibling recurrence), whereas sibling recurrence was seen in two families suggesting either parental germline mosaicism or autosomal dominant inheritance. All identified *ZNF292* mutations in this series were truncating (frameshift, nonsense) suggesting loss of gene function (LoF). Mutations were distributed among several critical domains of the gene, with several occurring within critical DNA binding domains. *ZNF292* encodes a transcription factor that has possible roles in tumor development as a tumor suppressor. Somatic frameshift mutations in *ZNF292* have been identified in tumors of the liver, colon and bone marrow. *ZNF292* is highly expressed in the human brain, with the highest expression identified during the prenatal period. In summary, we report discovery of a novel gene underlying ID, ASD and neurobehavioral issues. We anticipate that mutations of *ZNF292* will be identified in additional children and may in fact be a relatively common single-gene cause of ID.

**999F****Correction of *NAGLU* mutation p.R297X using CRISPR/Cas9 gene editing in mucopolysaccharidosis IIIB patient-derived iPSCs.** C.L. Christensen<sup>1,2</sup>, S.S. Chu<sup>1,2</sup>, F.Y.M. Choy<sup>1,2</sup>. 1) Department of Biology, University of Victoria, Victoria, B.C., Canada; 2) Centre for Biomedical Research, University of Victoria, Victoria, B.C., Canada.

Mucopolysaccharidosis IIIB (MPS IIIB) is a rare autosomal recessive lysosomal storage disease (LSD), wherein affected individuals experience progressive neurodegeneration and succumb to the disease within the first three decades of life. Mutations in *NAGLU* result in the production of non-functional N-acetyl glucosaminidase (Naglu), an enzyme that is responsible for breaking down heparan sulfate. In MPS IIIB, heparan sulfate accumulates within lysosomes, leading to disease manifestation. There are currently no treatment options for MPS IIIB due to the inability of recombinant *NAGLU* to cross the blood-brain barrier, in order to reach the central nervous system and alleviate the aforementioned neurodegeneration. CRISPR/Cas9, a recent tool in biotechnology with myriad applications, allows for precise genome editing driven by homology directed repair following double stranded cleavage. This technique has been used for targeting and correction of patient-specific mutations in a number of cell types. CRISPR/Cas9 genome editing, in conjunction with reprogrammed patient-derived somatic cells to induced pluripotent stem cells (iPSCs) has been explored as a regenerative medicine for genetic disease. Edited iPSCs can be differentiated to neural progenitor cells and intracerebrally transplanted into the patient. This process circumvents the blood-brain barrier to deliver continuous functional Naglu via mannose-6-phosphate receptors to neighbouring neurons. As proof-of-concept, we have generated iPSCs from MPS IIIB patient skin fibroblasts using transcription factors c-Myc, Sox2, Klf4, and Oct3/4 and identified candidate guide RNAs (gRNA) for targeting and correction of a common *NAGLU* mutation, p.R297X, using CRISPR/Cas9. Preliminary Cas9:gRNA lipofection of iPSCs, along with a single-stranded oligonucleotide (ssODN) correction template, resulted in a correction efficiency of 0.3%, as confirmed by restriction enzyme digest and Sanger sequencing. By using second generation CRISPR-Cas9 (Alt-R™ two-part system, IDT) in combination with an asymmetrical ssODN (*Nature Biotechnology* **34**, 339–344 (2016)), we are aiming to improve the correction efficiency of p.R297X, characterize corrected iPSCs, and target three other *NAGLU* mutations in similar fashion. This work will allow for a better understanding of the applications and limitations of this technique as a potential tool in regenerative medicine for MPS IIIB. .

**Progressive abnormal myelination and cerebrospinal fluid volume in canine mucopolysaccharidosis type I: A neuroimaging and neuropathological study.** P. Dickson<sup>1</sup>, S. Chen<sup>2</sup>, I. Nestrasi<sup>3</sup>, S.Q. Le<sup>1</sup>, S.-h. Kan<sup>1</sup>, J. Jens<sup>4</sup>, E. Snella<sup>5</sup>, N.M. Ellinwood<sup>6</sup>, M. Guzman<sup>7</sup>, L.E. White<sup>8</sup>, J.D. Cooper<sup>1</sup>, M. Egeland<sup>1</sup>, C. Vite<sup>1</sup>, J. Provenzale<sup>2,8</sup>. 1) Dept Pediatrics, LA BioMed Harbor-UCLA Med Ctr, Torrance, CA; 2) Department of Radiology, Duke University, Durham, NC; 3) Department of Pediatrics, University of Minnesota, Minneapolis, MN; 4) Department of Animal Science, Iowa State University, Ames, IA, USA; 5) Department of Pathology, Saint Louis University School of Medicine, Saint Louis, MO; 6) Department of Orthopedic Surgery, Duke University, Durham, NC; 7) Department of Clinical Studies, University of Pennsylvania School of Veterinary Medicine, Philadelphia, PA; 8) Department of Radiology, Oncology & Biomedical Engineering, Emory University, Atlanta, GA.

We performed neuroimaging studies in a canine model of the lysosomal storage disease, mucopolysaccharidosis type I (MPS I). Brain imaging findings in MPS I patients and dogs include hydrocephalus, white matter hyperintense lesions, enlarged Virchow-Robin spaces, and cortical atrophy. Previously, we found abnormal myelination in the corpus callosum of adult MPS I dogs compared to controls, with reduced fractional anisotropy measured by diffusion tensor imaging and abnormal myelin composition (Provenzale et al, 2015). In the present study, we performed serial neuroimaging of a cohort of 5 MPS I and 6 heterozygous (normal) control dogs using magnetic resonance imaging and DTI prospectively. Imaging was performed on a 3Tesla Siemens Prisma scanner with a 16-channel knee coil at age 3, 6, 12, 18, and 24 months. T1-weighted, T2-weighted, and diffusion weighted images were acquired. For T1 weighting we applied Three Dimensional Magnetization Prepared Rapid Acquisition Gradient-Echo sequence with parameters TR/TE/TI 2530/3.48/1100 ms, flip angle 7 degrees, 1 average, isotropic voxel with slice thickness 0.7mm, 144 slices, FoV phase 100%; scan duration was 10 min. 48 sec. For T2 weighting we applied spin-echo sequence with following parameters TR/TE 3200/563 ms, 1 average, isotropic voxel with slice thickness 0.7mm, 144 slices, FoV phase 100%, acceleration factor GRAPPA of 2; scan duration was 6 min. 22 sec. For diffusion weighting we acquired echo-planar imaging sequence with TR/TE 4900/78 ms, GRAPPA acceleration factor of 2, 1.4 mm in plane resolution, FoV phase 100%, 62 diffusion directions, 40 1.5mm-thick slices. Five dogs died during the study, one under anesthesia (due to dislodged endotracheal tube) and four from progressive MPS I disease. We found that fractional anisotropy in the genu and splenium of the corpus callosum increased in control dogs over time as expected, but decreased over time in MPS I dogs. We performed compartment segmentation to measure volume of cerebrospinal fluid. MPS I dogs show larger volumes of cerebrospinal fluid versus controls at all ages, and these also increased over time. The expression of myelin-related genes was reduced in MPS I dogs versus controls at 6 weeks, 4 months, 12 months, and 18-24 months of age. We conclude that myelination abnormalities in the corpus callosum of MPS I dogs may be progressive, and that cerebrospinal fluid volume may be increased from an early age.

**1001T**

**Magnetic resonance spectroscopy and lipid profiling of myelin composition in corpus callosum of mucopolysaccharidosis I mice.** S. Le<sup>1</sup>, S.-H. Kan<sup>1</sup>, J. Yee<sup>1</sup>, J. Tolar<sup>2</sup>, I. Tkac<sup>3</sup>, I. Nestrasi<sup>2</sup>, P. Dickson<sup>1</sup>. 1) Dept Pediatrics, LA Biomed Harbor-UCLA, Torrance, CA; 2) Dept Pediatrics, University of Minnesota, Minneapolis, MN; 3) Dept Radiology, University of Minnesota, Minneapolis, MN.

Brain MRI frequently shows hyperintense lesions of white matter in patients with the lysosomal disease, mucopolysaccharidosis (MPS) type I that are thought to be due to demyelination. Previously, we reported abnormal myelin composition and reduced expression of myelin-related genes in a canine model of MPS I. Here, we studied myelin composition in the corpus callosum of MPS I mice. We performed a cross-sectional study of male MPS I mice and controls at 52 weeks of age. In vivo <sup>1</sup>H MR spectroscopy data were acquired from a 3.6 μL volume centered in the corpus callosum using ultra-short echo-time STEAM (TE = 2 ms) at 9.4T. Seventeen brain metabolites were reliably quantified in vivo using LCModel analysis. Mice were sacrificed after scanning and corpus callosum tissue was dissected from whole brains harvested after imaging. Comparison of neurochemical profiles revealed significantly decreased concentrations of N-acetylaspartate (marker of neuronal and axonal integrity, -0.5 μmol/g, p = 0.004) and of phosphoethanolamine (precursor of myelin, -0.6 μmol/g, p = 0.018) in MPS I mice relative to controls (heterozygote littermates). In addition, a trend for increased level of ascorbate (antioxidant, +0.5 μmol/g, p = 0.086) was observed. Total polar lipid content and ceramide/hexosylceramide content was analyzed by LC-MS/MS. Twenty-two compounds showed significant differences between MPS I and control mice at p and q < 0.05. The groups separated by principal components analysis. Phosphoethanolamine levels measured by <sup>1</sup>H MRS showed a linear relationship to tissue phosphatidylethanolamine levels (r<sup>2</sup> = 0.17, p = 0.04). There were no intergroup differences in corpus callosum myelin gene expression, MBP, cholesterol, or protein. While intergroup differences in MPS I mice compared to controls were subtle, noninvasive, quantitative measurements of the corpus callosum integrity represent a tempting target for monitoring therapeutic efficacy in MPS I patients. .

**Evaluation of sibling pairs with Gaucher disease discordant for Parkinsonism.** G. Lopez<sup>1</sup>, A. Steward<sup>1</sup>, G. Monestime<sup>2</sup>, C. Groden<sup>1</sup>, E. Wiggs<sup>1</sup>, N. Tayebi<sup>1</sup>, T. Roshan Lal<sup>1</sup>, E. Sidransky<sup>1</sup>. 1) NHGRI/NIH, Bethesda, MD; 2) University of Massachusetts Medical School, Worcester, MA.

The association between mutations in the gene encoding glucocerebrosidase (*GBA1*) and the development of parkinsonism has been well established. However, most *GBA1* mutation carriers never develop parkinsonism, implicating contribution of other genetic modifiers in *GBA1*-associated Parkinson disease (GBA-PD). Studies of sibling pairs where both have Gaucher disease (GD) but are discordant for PD (DSP) could help to elucidate some of these modulating factors. In this prospective longitudinal study, nine DSP were evaluated through the Genetics Clinic at the National Institutes of Health. Participants provided relevant medical history, including family history and pedigrees, in addition to undergoing clinical and research evaluations. Clinical assessments included neurological, neuropsychological, olfactory, motor, and non-motor testing, including validated questionnaires to determine the presence and/or severity of PD motor or prodromal symptoms. Several of the DSP were followed longitudinally for over a decade. Multiple genotypes were detected among the DSP. There was no relationship between treatment with enzyme replacement therapy, substrate reduction therapy, genotype, or splenectomy and development of PD symptoms. General severity of Gaucher disease, determined by the degree of skeletal involvement, hematological abnormalities, and organomegaly, varied widely across the sample. However, in the majority of pairs, the younger sibling had PD and milder Gaucher symptoms. No parkinsonian features were observed in any of the non-PD siblings. Continued longitudinal evaluation, next generation sequencing, and ongoing recruitment of additional DSP will be useful in identifying genetic, environmental, and epigenetic factors contributing to phenotypic expression that may diminish or augment risk for PD.

**Phenotypic profiles of *GBA1* mutation carriers with and without Parkinson disease: A data-driven approach.** A.M. Steward<sup>1</sup>, L.M. Koehly<sup>1</sup>, N.S. Trivedi<sup>1</sup>, T.M. Lindstrom<sup>1</sup>, G. Monestime<sup>2</sup>, N. Tayebi<sup>1</sup>, E. Sidransky<sup>1</sup>, G.J. Lopez<sup>1</sup>. 1) National Institutes of Health, Bethesda, MD; 2) University of Massachusetts Medical School, Worcester, MA.

Mutations in the glucocerebrosidase gene, *GBA1*, represent the number one genetic risk factor for the development of Parkinson disease (PD). However, not every individual who carries a *GBA1* mutation goes on to develop PD. Careful phenotyping has revealed that there are specific prodromal symptoms of PD, including a decreased sense of smell, depression, and rapid eye movement (REM) sleep behavior disorder (RBD). Among *GBA1* carriers, a population with a higher-risk for PD, we aimed to classify individuals by symptom profiles using a data-driven approach. Latent class cluster analysis is a computational method which uses Bayesian probabilities to determine the likelihood that an individual within a larger sample belongs to a certain underlying distribution. Clustering was performed on a sample of individuals carrying at least one *GBA1* mutation with and without PD, and individuals without a *GBA1* mutation with PD. The Fatigue Severity Scale (FSS), Geriatric Depression Scale (GDS), University of Pennsylvania Smell Identification Test (UPSIT), State Trait Anxiety Inventory (STAI), and demographic variables were used as predictors for the model. Number of clusters and goodness-of-fit were determined and assessed using the BIC score. Cluster profiles were compared with *GBA1* mutation and PD status to determine whether cluster assignment aligned with clinical and molecular diagnoses. Discriminant analyses were also performed to determine whether the predictors used in the cluster model could independently predict *GBA1* mutation and PD status. This study represents the first use of latent class cluster analysis to analyze phenotypic profiles of *GBA1* mutation carriers in an objective and unbiased manner.

**The Lysosomal Disease Network.** C.B. Whitley, B. Diethelm-Okita, J.R. Jarnes, J. Cloyd, *the Lysosomal Disease Network*. University of Minnesota, Minneapolis, MN.

The combined, integrated efforts of researchers involved in the Lysosomal Disease Network (LDN) continue to focus on using limited resources to create a network of clinical research centers focused on solving the major challenges in diagnosis, disease management, and therapy for these complex, rare disorders. Finding solutions to both the clinical and social problems associated with lysosomal disease will have direct impact on patients and inform medical practice. Toward that goal, the LDN facilitates clinical research in rare diseases through a program that supports (1) collaborative research via nine longitudinal and five pilot project studies that each strive to find answers to the fundamental issues of a given disease, (2) supportive cores providing integral services to investigators across the network, (3) train clinical investigators in lysosomal disease research, (4) provide access to information related to lysosomal conditions by submission of data to the Data Management and Coordinating Center (DMCC), (5) involvement of patient advocacy groups (PAG) in the recruitment, scientific advisement, and transmission of research results to the community at large. Because central nervous system (CNS) involvement is prevalent in lysosomal conditions—while being difficult to measure and treat—we include a major emphasis on qualitative analysis of CNS structure, function, and the discovery of biomarkers for relevant conditions including: mucopolysaccharidosis (MPS), mucopolipidosis IV, Batten disease, and the gangliosidoses (including Tay-Sachs disease). Systematically-collected data on brain effects will help us develop outcome measures that are specific and sensitive to change in disease status. To drive cutting-edge research in what are multi-system diseases, we also have projects focused on immune modulation in Pompe disease, kidney structure and function in Fabry disease, the search for undiagnosed Fabry patients in high-risk populations, and the role of oxidative stress in Gaucher disease. We also continue to emphasize the collection of natural history data for those lysosomal conditions for which there are no current therapies: Krabbe disease, mucopolipidosis type IV, and Sanfilippo syndromes type C and D. The Lysosomal Disease Network (U54NS065768) is part of Rare Diseases Clinical Research Network funded through collaboration between NCATS, the National Institute of Neurological Disorders and Stroke (NINDS), and the National Institute of Diabetes.

**A novel pathogenic variant of *PURA* in a patient with severe developmental delay, delayed myelination and empty sella.** K. Hosoki<sup>1</sup>, T. Kimura<sup>2</sup>, K. Yanagi<sup>2</sup>, M. Iso<sup>1</sup>, Y. Kuroki<sup>2</sup>, H. Ogata<sup>3</sup>, K. Nakabayashi<sup>3</sup>, K. Okamura<sup>4</sup>, K. Hata<sup>5</sup>, T. Shinozaki<sup>2</sup>, Y. Matsubara<sup>2</sup>, T. Kaname<sup>1</sup>. 1) Genome Medicine, National Center for Child Health and Development (NCCHD), Tokyo, Japan; 2) Nihonkai General Hospital, Yamagata, Japan; 3) Department of Maternal-Fetal Biology, NCCHD, Tokyo, Japan; 4) Department of Systems Biomedicine, NCCHD, Tokyo, Japan; 5) National Center for Child Health and Development, Tokyo, Japan.

**Introduction:** Whole exome sequencing (WES) of case-parent trios is a powerful method to identify genetic causes in undiagnosed patients. Several reports employing such method revealed that patients with severe neurodevelopmental delay, learning disability, neonatal hypotonia, feeding difficulties, abnormal movements and epilepsy were caused by pathogenic variants in *PURA*. Here we report a patient with severe developmental delay, neurological and endocrinological abnormalities associated with a novel pathogenic variant in *PURA* identified by WES analysis. **Case Presentation:** The patient was a 9-year-old boy. The boy was born at 39 weeks of gestation as the first child of healthy parents. His birthweight and Apgar score was 2210 g and 8/9, respectively. The boy showed nystagmus from infancy with delayed myelination in the brain. He was suspected to Pelizaeus-Merzbacger syndrome at 7 months of age, but it was excluded. He presented with severe developmental delay, intellectual impairment with no meaningful words, short stature, empty sella and pseudobulbar palsy. **Methods:** Written informed consent was obtained from his parents. Whole exome sequencing analysis was performed using Human All Exon V6 kit (Agilent) and HiSeq 2500 (Illumina). The detected variants were confirmed by Sanger sequences. **Results:** A novel heterozygous 8-bp insertion in the *PURA* gene was found in the patient. The variant was *de novo* and it causes frameshift and premature stop codon. **Discussion:** We found the novel frameshift variant at 5'-side of the PUR repeat region I related to severe developmental delay. *PURA* is one of the primary responsible genes for 5q31.3 microdeletion syndrome. Twenty-one patients with neurodevelopmental disorder and brain abnormality caused by *de novo* variants in *PURA* have been reported. Our finding and those reports suggest that loss-of-function of *PURA* causes the disease.

**1006W**

**Novel *NTRK1* gene mutation and clinical report of HSAN-IV phenotype in a Mexican patient.** L. Patron<sup>1</sup>, BL. Camacho<sup>1</sup>, VG. Patron<sup>2</sup>, HE. Almanza<sup>1</sup>. 1) Universidad Autónoma de Baja California, Calzada University 14418, UABC, Parque Internacional Industrial Tijuana, 22390 Tijuana, B.C.; 2) Rush University Medical Center, Psychiatry Department, 1645 W Jackson Blvd Suite 600, Chicago, IL 60612, EE. UU.

The hereditary sensory and autonomic neuropathy Type IV (HSAN-IV; MIM #256800), also known as congenital insensitivity to pain and anhidrosis (CIPA) is a rare condition; its frequency is estimated to be 1 in 125 millions, with an autosomal recessive pattern. It is caused by mutations in the neurotrophic tyrosinase kinase type 1 *NTRK1* gene (MIM\*191315). The clinical diagnosis criteria include: (1) Lack of perception of painful stimulus from birth onward, with unimpaired touch and pressure sensitivity, (2) anhidrosis, and (3) moderate to severe mental retardation. We present the case of a six year-old Mexican male. The patient is the only child of first degree cousins. He was born by C-section of full term pregnancy. Neonatal screening was reported normal. His mother noticed symptom within 48 hours after birth, when he developed fever every time he covered with clothes, but no sweating. Also, the patient did not cry when vaccinated. The patient was referred to our center because of chronic arthritis, episodes of fever, self-mutilating behavior and mental retardation. Because of the symptoms and the suspicion of Lesh-Nyhan Syndrome, uric acid levels were measured, but levels were within normal values. Physical findings included absence of pain response, warm and dry skin. Facial asymmetry secondary to a previous jaw fracture. He showed normal tactile sensation, lacrimation, corneal reflex and anisocoria. There was absence of teeth due self-extraction, absence of left nasal alae due amputation, severe tropic changes in the skin of distal limbs, hyperkeratosis, fissuring and absence of distal phalange in first and second digit of the right hand. He was able to walk but running was limited because of a right tibial fracture and edema secondary to chronic arthropathy. Basic laboratory evaluations were normal. Skin biopsy demonstrated atrophic changes and absence of sweat glands. The molecular genetic analysis detected a homozygous pathogenic variant in the *NTRK1* gene. DNA Sequencing results showed a novel transversion of a guanine to a thymine (NM\_001007792.1:c.334G>T), this substitution resulted in a nonsense mutation due substitution a glutamine for a stop codon (NP\_001007793.1:p.Glu112\*). This pathogenic variant has not yet been described in the international database. The treatment of HSAN-IV is focused on the prevention of injuries and arthropathy, making early recognition is important. Currently there are no guidelines available to treat this disease.

Retterer<sup>6</sup>, C. Forster<sup>7</sup>, D. McKnight<sup>8</sup>, L. Vincent<sup>9</sup>, G. Douglas<sup>1</sup>, R. Person<sup>1</sup>, L. Henderson<sup>1</sup>, M.J. Guillen Sacoto<sup>1</sup>, H. McLaughlin<sup>1</sup>, J. Juusola<sup>1</sup>. 1) GeneDx, Gaithersburg, MD, United States; 2) Département de Génétique (Pr Soubrier), Hôpital Pitié-Salpêtrière, Paris, France; 3) Service de Neuropédiatrie, Hôpital Armand-Trousseau, Paris, France; 4) Boston Children's Hospital, Boston, MA, United States; 5) Cleveland Clinic, Cleveland, OH, United States; 6) Children's Hospital of Eastern Ontario, Ottawa, ON, Canada; 7) Hospital for Sick Children, Toronto, ON, Canada; 8) North York General Hospital, Toronto, ON, Canada; 9) University of Louisville, Louisville, KY, United States.

The *ATP8A2* gene (MIM# 605870) is highly expressed in the retina, spinal cord, and cerebellum with knockout mice showing central and peripheral nervous system abnormalities such as progressive ataxia and neurodegeneration. Previously reported cases with *ATP8A2* variants include compound heterozygous and homozygous variants in patients with intellectual disability, movement disorders, optic atrophy, and hypotonia. Here we describe six unrelated patients ranging in age from one to nine years with clinical features consistent with those previously described. We looked at 11,749 exomes with a neurodevelopmental phenotype, and identified five unrelated affected individuals to be either compound heterozygous or homozygous for variants in the *ATP8A2* gene. A sixth patient was identified through GeneMatcher. Movement disorders in our patients included: chorea in two patients, dystonia in two patients, ataxia in two patients, and tremor in one patient. Additional features reported in our patients include brain abnormalities in two patients, one of whom had macrocephaly, and dysmorphic features, hypermobility, sleep abnormalities, seizures, reported in a single patient each. The variants identified ranged from missense, splicing, intragenic deletions, and frameshift, including: p.W702R, p.K429M, p.D49Y, p.D765Y, p.D428A, c.2211+1G>A, c.1185+5G>A, intragenic deletion of exons 28-33, c.1787delA, c.321+3\_321+8delAATGGT. All variants were seen with insignificant frequency in the Exome Aggregation Consortium (ExAC) public database and the GeneDx exome database of unaffected individuals. All variants occurred within highly conserved domains, and were predicted to be damaging or possibly damaging from multiple in silico models. The findings presented in this case series add to the already described *ATP8A2*-related disorder by further characterizing this autosomal recessive neurodegenerative disorder molecularly and phenotypically.

**1008F**

**Evaluating clinical and biochemical endpoints for therapy in Pex7 deficient mouse models.** W. Fallatah<sup>1,2</sup>, W. Cui<sup>1</sup>, E. DiPietro<sup>1</sup>, N. Braverman<sup>1</sup>. 1) Human Genetics, McGill University - Research Institute of the MUHC, Montreal, Quebec, Canada; 2) Department of Medical Genetics, King AbdulAziz University, Jeddah, Saudi Arabia.

**Background:** Rhizomelic chondrodysplasia punctata type 1 (RCDP1) is a peroxisome biogenesis disorder clinically distinguished by skeletal dysplasia with significant growth deficiency, severe neurological impairment and congenital cataracts. RCDP1 is caused by mutations in *PEX7*, which encodes the cytosolic receptor for peroxisomal matrix proteins carrying the Peroxisomal Targeting Signal 2 (PTS2), resulting in reduced biosynthesis of ether phospholipid compounds, plasmalogens (PL). PL deficiency is the primary cause of RCDP pathology and the severity of the disease directly correlates to residual PL levels. Currently, there is no definitive treatment. Our lab generated and reported a hypomorphic Pex7 mouse model that resembles mild RCDP. To fully understand the RCDP spectrum, we have now generated two additional substrains that represent the intermediate and severe forms of the disease due to a differential decrease in Pex7 transcript and protein levels. **Aim:** To characterize the behavioral, biochemical and neurological phenotypes of our Pex7 mouse models to get ready for future therapies. **Results:** We analyzed PL species in erythrocytes, cerebral cortex and cerebellum of Pex7 mice using LC/MSMS technology and found a significant decrease in total PL levels that correlated to the clinical severity of the Pex7 substrain. In contrast to what is known in human RCDP, very long chain fatty acids (VLCFA) were mildly elevated in some tissues and correlated inversely with the severity of PL deficiency. We evaluated the general locomotor activity of Pex7 mice in the open field environment and found that our Pex7 mouse models - in comparison to their littermate controls - exhibit a hyperactive behavior measured by their increased total distance traveled ( $P < 0.001$ ) and mobility time ( $P < 0.0001$ ), again correlating with the levels of Pex7. Lastly, through a histological evaluation of the brain, we found a reduction in Purkinje cell number in Pex7 mice compared to littermate controls. **In conclusion,** we have established biochemical and neurobehavioral characterizations of our Pex7 mouse models that are useful as valuable preclinical endpoints to determine efficacy in future clinical trials. The Pex7 mouse models also allow us to determine the minimal amount of Pex7 transcript needed to improve the disease.

**1009W**

**Mitochondrial accumulation and increased lipid metabolism in a *Dhtkd1*<sup>Tyr486</sup> knock-in mouse model of the CMT2Q neuropathy.** M. Gu<sup>1</sup>, C. Luan<sup>1</sup>, W. Guo<sup>1,4</sup>, L. Chen<sup>1</sup>, X. Wei<sup>1</sup>, Y. Kuang<sup>2</sup>, S. Dang<sup>3</sup>, L. Van Den Bosch<sup>4</sup>, Z. Wang<sup>1,2,3</sup>. 1) Department of Medical Genetics, Shanghai Jiao Tong University School of Medicine, Shanghai, China; 2) Shanghai Research Centre for Model Organisms, Shanghai, China; 3) Research Center for Experimental Medicine, Rui-Jin Hospital at SJTUSM, Shanghai, China; 4) KU Leuven, Laboratory of Neurobiology, Experimental Neurology, Department of Neurosciences and VIB Center for Brain and Disease Research, 3000 Leuven, Belgium.

Charcot-Marie-Tooth disease (CMT) is also known as 'hereditary motor and sensory neuropathy' and is one of the most common inherited disorders of the peripheral nervous system with a prevalence of at least 1 in 2500. Clinically, CMT is characterized by progressive muscular and sensory defects starting at the distal extremities with chronic atrophy and weakness. CMT is divided into two main types: a demyelinating form called CMT1 and CMT2, which is the axonal form. Genetically, CMT is a highly heterogeneous disease with more than 80 disease-associated genes identified to date. Nearly 30 genes have been identified as a cause of CMT2. One of these is the 'dehydrogenase E1 and transketolase domain containing 1' (*DHTKD1*) gene. We previously demonstrated that a nonsense mutation [c.1455T>G (p.Tyr485\*)] in exon 8 of *DHTKD1* is one of the disease-causing mutations in CMT2Q (MIM 615025). The aim of this study was to recapitulate the CMT2Q phenotype and to investigate the physiological function and pathogenic mechanism of the *Dhtkd1* gene *in vivo*. Therefore, we generated a knock-in mouse model with the *Dhtkd1*<sup>Tyr486</sup> mutation. We observed that the *Dhtkd1* expression level in liver and sciatic nerve of homozygous (*mt/mt*) mice was significantly lower than in the wild-type (*wt*) mice. Moreover, the ATP production in liver of *mt/mt* mice was significantly lower than in *wt* mice. We also observed abnormal peripheral nerve phenotypes, including reduced axon diameter and excessive myelination. The *mt/mt* mice also displayed clear sensory defects, while no abnormalities in the motor performance were observed. Apparently, the lack of energy production is compensated by an accumulation of mitochondria, an enhanced lipid metabolism in the muscle of knock-in mice. Taken together, we show that the *Dhtkd1*<sup>Tyr486</sup> knock-in mouse model partially recapitulated phenotypes of CMT2Q, especially related to the sensory abnormalities. We hypothesize that the lack of a more pronounced CMT phenotype might be due to a mechanism that compensates for the defects in energy metabolism. This work is partially supported by National Natural Science Foundation of China (Proj. No. 30470951, 31071107).

**Myotonia congenita with a novel missense mutation in *CLCN1* gene (c.680T>A, p.Ile227Asn).** A. Kiraz<sup>1</sup>, M. Erdogan<sup>1</sup>, B. Balta<sup>1</sup>, M. Tuna<sup>2</sup>, G. Akinci Gönen<sup>1</sup>. 1) Department of Medical Genetics, Health Sciences University, Education and Research Hospital, Kayseri, Turkey; 2) Department of Neurology, Health Sciences University, Education and Research Hospital, Kayseri, Turkey.

Myotonia congenita (MC) is a group of genetically and clinically heterogeneous congenital neuromuscular disease characterized by muscle stiffness and an inability of the muscle to relax after voluntary contraction, hypertrophy, transient weakness and cramping. It is caused by a mutation in the gene encoding skeletal muscle chloride channel-1 (*CLCN1*). More than 120 mutations have been found in this gene. Here, we report a case of 19-year-old female who exhibited myotonia with periodic paralysis. She has complained of congenital myotonia since she was a child. We analyzed *CLCN1* sequence in this patient and we found a new homozygous missense mutation in *CLCN1* gene (c.680T>A, p.Ile227Asn). *In silico* analyses (Mutation Taster, PolyPhen-2, SIFT) this nucleotide change is reporting as a mutation that highly likely affecting the disease. We plan to analyse *CLCN1* sequence on the other members of her family. This new mutation may help identify genetic determinants of the disease as well as clarify genotype-phenotype relationships. Also this variation can be used for prenatal diagnosis in this family.

**1011F**

**Is the association of heterozygous variations in *MORC2*, *MFN2* and *AARS* genes responsible for a severe axonal form of Charcot-Marie-Tooth disease?** A. Lia<sup>1,2</sup>, F. Miressi<sup>1</sup>, H. Dzugan<sup>1,2</sup>, P. Cintas<sup>3</sup>, C. Magdelaine<sup>1,2</sup>, F. Sturtz<sup>1,2</sup>. 1) Limoges University, Limoges, France; 2) Limoges Hospital, Limoges, France; 3) Toulouse Hospital, Toulouse, France.

Charcot-Marie-Tooth (CMT) disease is one of the most frequent inherited peripheral neuropathies (1/2500). So far, mutations in more than 50 genes have been identified causing either the demyelinating form (CMT1) or the axonal form (CMT2). While causative mutation is found in 70% of CMT1 patients, only 30% of the CMT2 patients obtain a positive diagnosis. We present here the complex genetic analysis of a family presenting two CMT2 cases. Patient A (mother), a 56-years-old woman of European origin, presents axonal impairment and patient B (daughter), a 23-years-old woman, is more severely affected. Patients C, D and E (respectively the maternal grandmother and the maternal aunts of Patient B) are unaffected. Targeted NGS sequencing screening 89 genes involved in CMT and associated neuropathies was first performed on Patient B to detect pathogenic SNVs. Using Cov'Cop, CNVs were then looked for and confirmed by real time PCR. Last step consisted in a trio exome sequencing (Patients A, B and D). In Patient B, targeted sequencing allowed to detect the heterozygous c.1403G>A (p.Arg468His) mutation in *MFN2* gene. This mutation already described is usually associated to discreet or mild CMT phenotype. Considering the severe symptomatology of Patient B, and the absence of p.Arg468His in her affected mother, we enriched our study with CNVs research in Patient B and found complete duplication of *AARS* gene, whose mutations had been previously associated to CMT2. This duplication is present in the affected mother, absent in the unaffected grandmother, but present in the unaffected aunts. Whole exome sequencing showed then the heterozygous missense mutation c.568C>T (p.Arg190Trp) in *MORC2* gene, which was present in the affected individuals (A and B) and absent in the healthy ones (D, but also C and E). This mutation, already described, is responsible for classical CMT2. In conclusion, the complete *AARS* duplication, which has never been described so far, seems not to be involved in the pathological mechanisms of the disease, since it is also present in two unaffected individuals. According to our findings and previous results, we can assume that the heterozygous *MORC2* mutation is the main cause for the axonal neuropathy in Patient A. The newly described association of *MORC2* and *MFN2* heterozygous missense mutations seems to be responsible for the more complex and severe phenotype observed in Patient B.

**Development of new strategies for the treatment of hereditary cystatin C amyloid angiopathy (HCCAA).** A. Gutierrez-Uzquiza, M. March, L. Matsuoka, K. Nguyen, H. Hakonarson. The Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA.

Hereditary cystatin C amyloid angiopathy (HCCAA) is a dominantly inherited disease caused by a leucine 68 to glutamine variant of cystatin C (L68Q-cystatin C). This cystatin C variant forms amyloid deposits in brain arteries and arterioles that are associated with changes in the arterial wall structure and deposition of extracellular matrix proteins. Most carriers of the mutation suffer micro-infarcts and brain haemorrhages, ultimately leading to paralysis, dementia and death in young adults. Post-mortem studies of patients have shown that mutant cystatin C is deposited in all brain areas. Although the mechanism of action of this disease is known, no treatment to avoid early death by brain hemorrhage is available. The cystatin C amyloid fibrils are generated by propagated domain swapping between cystatin C monomers in which N- and C-terminal parts of the monomers are exchanged, forming long protein chains. The purpose of this study is to develop a cellular model that allows testing the ability of drugs to reduce the formation of cystatin C dimers/oligomers and to identify substances potentially useful for the treatment of patients with HCCAA. Much of the previous work describing aggregation of the L68Q-cystatin C and identification of compounds to reduce it have been performed using non-physiological systems. We aimed at developing a system that would allow evaluation of the ability of a molecule to interfere with aggregation of mutant cystatin C while also given some information about toxicity to cells or organisms. To this end, we have generated genetically engineered 293T cells with expression of human wild type (wt) and L68Q cystatin C. These cells produce and secrete detectable levels of cystatin C (wt or L68Q) capable of oligomerizing under non-reducing conditions. They constitute a perfect model to test the ability of different compounds to decrease the level of oligomers and fibrils of L68Q Cystatin C. Interestingly, we have found that short incubation with reducing agents breaks oligomers into monomers of both intracellular and secreted cystatin C L68Q. In summary, this study establishes proof-of-principle that mutant cystatin C is a pharmacological target for reducing redox agent, and most importantly, provide evidence that redox agents could potentially useful to treat this devastating disease and related conditions.

**Search for target genes of transcriptional regulation by dentatorubral-pallidoluysian atrophy protein (DRPLA) that acts as transcriptional co-regulator.** K. Hatano<sup>1</sup>, H. Ishiura<sup>1</sup>, H. Date<sup>1</sup>, J. Goto<sup>2</sup>, M. Tanaka<sup>1</sup>, J. Mitsui<sup>1</sup>, J. Yoshimura<sup>2</sup>, K. Doi<sup>2</sup>, S. Morishita<sup>2</sup>, S. Tsuji<sup>1</sup>. 1) Department of Neurology, University of Tokyo, Graduate School of Medicine, Tokyo, Japan; 2) Department of Neurology, International University of Health and Welfare Mita Hospital; 3) Department of Computational Biology, Graduate School of Frontier Sciences, The University of Tokyo, Chiba.

**Backgrounds:** Dentatorubral-pallidoluysian atrophy (DRPLA [MIM 125370]) is an autosomal dominant ataxia caused by unstable expansion of CAG repeats in the coding sequence of *DRPLA* gene (*ATN1*). Previous studies have shown that DRPLA protein (DRPLAp) functions as a transcriptional co-regulator. Its target genes, however, remain unknown. **Purposes:** To determine the target genes regulated by wild type and mutant DRPLAp based on expression profiling in cultured cells expressing full-length wild-type or mutant DRPLAp. **Materials:** Flp-In T-REx 293 cells stably expressing *GFP*-fused full-length human *DRPLA* cDNA (Q19 or Q88) under the control by Dox (doxycycline) -On system were used. **Methods:** Total RNA was extracted from the cells (Q19 or Q88) 24 hours after incubation with Dox. Expression profiling analyses were performed in four independent experiments. Strand-specific cDNA libraries were generated from ribosomal RNA-depleted RNA using random primers. Paired-end RNA-seq was performed using HiSeq2500 and analyzed by Cufflinks2 and edgeR. Differentially expressed genes (DEGs) by expressing wild-type, full-length DRPLAp (Q19) and those by expressing mutant, full-length DRPLAp (Q88) were extracted from each experiment. Transcriptional target genes were defined as DEGs obtained by both softwares with reproducibility confirmed by all independent experiments. All the transcriptional target genes were validated by qRT-PCR. **Results:** As transcriptional target genes validated by qRT-PCR, 8 up-regulated genes and 7 down-regulated genes were revealed by expressing full-length DRPLAp (Q19), and 8 up-regulated genes and 11 down-regulated genes were revealed by expressing full-length DRPLAp (Q88). Four up-regulated genes and another 4 down-regulated genes were common when Q19 or Q88 was expressed. A causative gene of epilepsy which is implied to cause epilepsy by loss-of-function mutation was demonstrated to be down-regulated when DRPLAp (Q88) was expressed. **Conclusions:** We found 15 target genes whose expression levels were controlled by full-length wild type DRPLAp and 19 target genes whose expression levels were controlled by full-length mutant DRPLAp. Four up-regulated genes and another 4 down-regulated genes were common when full-length wild type DRPLAp or full-length mutant DRPLAp was expressed. The finding that a causative gene of epilepsy was down-regulated in cells expressing full-length mutant DRPLAp might be related to epilepsy presented in patients with DRPLA.

**New *DNAJC5* mutation initially missed by Sanger sequencing and whole-exome sequencing identified in a familial case of adult-onset neuronal ceroid lipofuscinosis (ANCL).** I. Jedlickova<sup>1</sup>, M. Cadieux-Dion<sup>2</sup>, A. Pristoupilova<sup>1</sup>, V. Stranecky<sup>1</sup>, H. Hartmannova<sup>1</sup>, K. Hodanova<sup>1</sup>, H. Hulko-va<sup>1</sup>, J. Sikora<sup>1</sup>, V. Baresova<sup>1</sup>, L. Noskova<sup>1</sup>, P. Vyletal<sup>1</sup>, M. Zivna<sup>1</sup>, P. Cossette<sup>2</sup>, E. Andermann<sup>3</sup>, F. Andermann<sup>3</sup>, S. Knoch<sup>1</sup>, *The Adult NCL Gene Discovery Consortium*. 1) Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University, Prague, Czech Republic; 2) Centre Hospitalier de L'Université de Montréal, Montréal, Canada; 3) Montreal Neurological Hospital & Institute, McGill University, Montreal, Québec, Canada.

Adult-onset neuronal ceroid lipofuscinosis (ANCL) are a group of rare genetic diseases characterised clinically by the progressive deterioration of mental and motor functions and histopathologically by the intracellular and ultrastructurally distinctive accumulation of autofluorescent lipopigment – ceroid – in the brain and other tissues. Clinical heterogeneity of ANCLs is in line with diverse inheritance patterns, increasing number of identified causal genes *DNAJC5*, *CLN6*, *CTSF*, *GRN*, *CLN1*, *CLN5*, *ATP13A2* and various types of disease causing mutations. Diagnosis of ANCLs is challenging from clinical, histopathological as well as laboratory perspectives. Even with advancements in technology, many ANCL families and cases still remain without established genetic diagnosis. Aware of this, we recently established **The Adult NCL Gene Discovery Consortium** involving research groups from Australia, UK, Europe, USA and Canada. Within the Consortium we review clinical and histopathological data and classify recruited cases into categories as definite, probable, possible and not ANCL. ANCL cases are then subjected to candidate gene and whole-exome sequencing (WES). In one family with autosomal dominant ANCL we identified a **30 bp in-frame insertion in *DNAJC5* encoding the cysteine-string protein alpha (CSP $\alpha$ )**. The insertion leads to a duplication of a central core motif of the cysteine-string domain (CSD) of CSP $\alpha$  p.Y120YCCCLCCCFN. The mutation affects palmitoylation-dependent sorting of CSP $\alpha$  in neuronal cell model as do the previously described mutations p.Leu115Arg and p.Leu116del. The mutation is remarkable diagnostically. It was initially missed by Sanger sequencing of *DNAJC5* and by WES, to be identified later by re-analysis of original WES data that are shared within the Consortium. Modified protocol for Sanger sequencing of *DNAJC5* confirmed segregation of the mutation within the family and excluded its presence in other 17 cases studied within the Consortium. Our work identifies novel *DNAJC5* mutation in ANCL and provides cautionary tale about the challenges in identification of even relatively short insertions by current genetic methods.

**Clinical features and the pathomechanism of early childhood-onset neurodegenerative encephalopathy arising from biallelic *TBCD* mutations.**

N. Miyake<sup>1</sup>, T. Chihara<sup>2</sup>, M. Miura<sup>2</sup>, H. Shimizu<sup>2</sup>, A. Kakita<sup>2</sup>, M. Matsumoto<sup>1</sup>.

1) Department of Human Genetics, Yokohama City University, Yokohama, Kanagawa, Japan; 2) Department of Biological Science, Graduate School of Science, Hiroshima University, Hiroshima, Japan; 3) Department of Genetics, Graduate School of Pharmaceutical Sciences, The University of Tokyo, Tokyo, Japan; 4) Department of Pathology, Brain Research Institute, University of Niigata, Niigata, Japan.

Tubulin folding cofactor D (TBCD) is a member of tubulin specific chaperone and plays an important role for microtubule formation together with other tubulin specific chaperones, TBCA, TBCB, TBCC, and TBCE. We analyzed four families (two Japanese families, a Chinese family, and an Israeli family) with affected siblings showing early onset (before 1 year of age), progressive diffuse brain atrophy with regression, postnatal microcephaly, postnatal growth retardation, muscle weakness/atrophy, and respiratory failure. One family is consanguineous. Based on autosomal recessive model, we identified biallelic *TBCD* mutations in eight affected individuals from the four families by whole exome sequencing. A total of seven mutations were found: five missense mutations, one nonsense, and one splice site mutation resulting in a frameshift. These variants were unreported or extremely rare in control databases, and all missense variants were thought to be pathogenic *in silico* predictions. *TBCD* was ubiquitously expressed in all tissues, but highly expressed in brain, heart, and skeletal muscle in the fetus and adult. This expression pattern was consistent with the affected organs in the patients, including the central nervous system and skeletal muscles. To see the mutational effects of the identified variants, protein-protein interactions between TBCD (wild type and mutant) and other complex components ( $\alpha/\beta$ -tubulin, TBCE, TBCC, and ARL2) were examined by co-immunoprecipitation, and revealed the impaired binding between most mutant TBCD proteins and ARL2, TBCE, and  $\beta$ -tubulin. The *in vivo* experiments using olfactory projection neurons in *Drosophila melanogaster* indicated that the *TBCD* mutations caused loss-of-function effects. Furthermore, the autopsied brain from one deceased individual showed characteristic neurodegenerative findings: cactus and somatic sprouts formation in the residual Purkinje cells in the cerebellum which are also seen in some diseases associated with mitochondrial impairment. These findings might reflect structural and metabolic abnormalities resulting from disrupted mitochondrial transport in neuronal cells caused by TBCD depletion.

**Mutant human proteins linked to familial neurodegeneration cause secondary protein misfolding in the spinal cord.** *M.C. Pace, G. Xu, S. Fromholt, J. Howard, B.I. Giasson, J. Lewis, D.R. Borchelt.* Neuroscience, University of Florida, Gainesville, FL.

The relationship between protein homeostasis (proteostasis) and the pathology in neuromuscular disorders characterized by neurodegeneration, such as amyotrophic lateral sclerosis (ALS) and Parkinson's disease (PD), has become an area of intense interest. Prior studies in *C. elegans* demonstrated that the expression of aggregation-prone proteins compromised the folding of other proteins, causing "bystander" or "secondary" misfolding. In prior studies of mice that develop Alzheimer-amyloidosis, we found evidence of secondary misfolding in brains of mice with high amyloid burden using detergent-extraction coupled to bottom-up proteomics analysis. Here, our goal was to translate this methodology to identify secondarily misfolded proteins in transgenic mouse models of spinal proteinopathies. Additionally, we sought to comparatively analyze the effects that different initiating proteinopathies have upon secondary protein misfolding. Our model system used transgenic mice that express mutant superoxide dismutase 1 (SOD1, associated with familial ALS), tau (associated with tauopathies such as frontotemporal dementia with Parkinsonism linked to chromosome 17), and  $\alpha$ -synuclein ( $\alpha$ Syn, linked to familial variants of PD); mice expressing these genes (including P301L tau, A53T  $\alpha$ Syn, and G93A SOD1) develop spinal motor neuron degeneration. In spinal cords of paralyzed mice from these strains of mice, we identified hundreds of proteins that aberrantly fractionate to detergent-insoluble fractions in tissues with abundant pathologic inclusions. Although many of the identified proteins were common to all the models, there were also proteins unique to each model. These findings indicate that multiple types of proteinopathy can induce "secondary" misfolding, and that the vulnerability of a subset of proteins to secondary misfolding is dependent upon the nature of the initial proteinopathy (whether this be mutant forms of tau,  $\alpha$ Syn, or SOD1). Future studies will be necessary to determine the degree to which mutations in other pathological proteins associated with neurodegeneration, such as *TARDBP*, *FUS*, and *UBQLN2*, result in the secondary misfolding of proteins.

**1017F**

**Unbalanced translocation causing unbalanced brain: A case of hemimegalencephaly.** *A.R. Barone<sup>1</sup>, G.M. Mirzaa<sup>2</sup>, D. McDonald-McGinn<sup>1</sup>, L. Conlin<sup>1</sup>, E.H. Zackai<sup>1</sup>.* 1) Children's Hospital of Philadelphia, Philadelphia, PA; 2) Seattle Children's Hospital, Seattle, WA.

**Background:** Whole exome sequencing in patients with focal cortical dysplasia (FCD), hemimegalencephaly (HME) and megalencephaly has revealed constitutional and mosaic changes in genes in the PI3K-AKT-mTOR pathway and its regulators, such as *PIK3CA*, *PTEN*, *AKT3*, and *DEPDC5*. It has been found that up-regulation of the mechanistic target of rapamycin (mTOR) pathway can result in cortical malformations and epilepsy. Here we report a patient with HME whose mTOR pathway gene studies on brain tissue were normal. However, a constitutional unbalanced translocation with a derivative chromosome 16 with a terminal deletion of 695kb in 16p13.3 and a terminal duplication of 1.91Mb in chromosome 1q44 was found. The terminal deletion in 16p13.3 includes 45 genes, most importantly *NPRL3* (nitrogen permease regulator-like-3). **Case Report:** A non-dysmorphic male infant was born by C-section at 36 6/7 weeks gestation to a 35 yo G2P1->2 mother. Growth parameters included weight and length less than 10%ile with head circumference at 20%ile. Seizures began on DOL#1. MRI had abnormalities in the right hemisphere of the brain consistent with HME. He was transferred to our hospital DOL#6 and found to have subclinical status epilepticus. As the only intervention remaining was hemispherectomy, parents elected to withdraw care and the patient expired. Autopsy results of right-sided brain biopsy included: 1) widened cortical ribbon with hypercellularity, 2) parenchymal calcifications, 3) a "chicken wire"-like vascular pattern, and 4) nodules of gray matter heterotopia within the white matter. Biopsy results from the left side of the brain were normal. Genetic testing included microarray and sequencing of targeted PI3K-AKT-mTOR genes from brain samples, blood, and skin. Gene sequencing was unrevealing, but the infant had a constitutional unbalanced translocation resulting in heterozygous deletion of *NPRL3* as detailed above. **Conclusion:** There have been heterozygous *NPRL3* missense, frameshift, and nonsense mutations in patients with focal epilepsy and FCD. *NPRL3* is a subunit of GAP activity toward RAGs complex 1 (GATOR1), a negative regulator of mTOR. Functional studies of these *NPRL3* mutations have indicated loss of the protein product of the mutated allele, indicating haploinsufficiency. Interestingly, there have been no prior reports of HME with the 16p13.3 deletion. We propose this case as a first example of *NPRL3* haploinsufficiency via unbalanced translocation as causative of the HME.

**1018W****Expanding the natural history of *KIF1A* associated disorders (KAND).**

L. Boyle<sup>1</sup>, W.K. Chung<sup>1,2</sup>. 1) Columbia University College of Physicians and Surgeons, New York, NY; 2) Department of Pediatrics, Columbia University Medical Center, New York, NY.

The gene *KIF1A* encodes for a kinesin responsible for anterograde axonal transport of synaptic-vesicle precursors and neurotransmitters. *KIF1A* has been associated with distinct disorders including the peripheral nervous system disorder hereditary sensory neuropathy IIC (HSN2C), the central nervous system upper motor neuron disorder hereditary spastic paraplegia-30 (SPG30), as well as a complex syndrome with a constellation of symptoms including axial hypotonia, peripheral spasticity, intellectual disability, and variable cerebellar and cerebral atrophy (MRD9). Though pathogenic variants in *KIF1A* with each of these distinct diagnostic categories based on phenotype and mode of inheritance, as we expand our understanding of the natural history of these disorders, these discrete disorders are really a spectrum of clinical severity across KAND currently associated with 30 genetic variants. To gather phenotypic data on mutations carriers, we collected caregiver reported medical history and Vineland Adaptive Behavior Scales (VABS-II) on 20 individuals, age 5 months to 21 years (mean=8 years, median=5 years), 18 of whom have *de novo* mutations in the motor domain of *KIF1A* and two of whom are compound heterozygotes with one mutation in the motor domain and one outside the motor domain. New features not previously observed in KAND include a high prevalence of gastrointestinal reflux (50%) and multiple males with genital abnormalities including micropenis, microorchidism, and cryptorchidism. The majority of individuals have ophthalmologic findings (90%), including optic nerve hypertrophy and atrophy (40%), strabismus (20%), cataracts (10%), and cortical visual impairment (15%). Half of the individuals have seizures, most commonly absence and generalized tonic clonic seizures (25% each). Developmentally, the majority of individuals have adaptive behavior composite scores in the low range on the VAB II (mean=52.9, SD=15.5). The phenotype associated with the recurrent p.E253K variant is particularly severe and includes severe neonatal hypotonia, with 3 of the 5 known individuals dying before 4 years of age. Our findings expand the phenotypic spectrum of KAND.

**1019T****An autopsy case of familial amyloid polyneuropathy (FAP) with novel transthyretin (TTR) mutation (TTR, Lys80Arg).**

H. Furuya<sup>1</sup>, Y. Miyamoto<sup>1</sup>, T. Yamamoto<sup>2</sup>, Y. Morita<sup>1</sup>, Y. Osaki<sup>1</sup>, K. Furuta<sup>1</sup>, M. Ueda<sup>3</sup>, N. Maeda<sup>4</sup>, H. Kitoaka<sup>2</sup>, T. Iwaki<sup>1</sup>, Y. Ando<sup>3</sup>. 1) Neurology, Kochi Medical School, Kochi University, Kochi, Kochi, Japan; 2) Cardiology, Kochi Medical School, Kochi University, Kochi, Kochi, Japan; 3) Neurology, Kumamoto University, Kumamoto, Japan; 4) Neuropathology, Kyushu University, Fukuoka, Japan.

Hereditary transthyretin (TTR) amyloidosis is caused by inheritance of an abnormal TTR gene in an autosomal dominant fashion. Here, we report a Japanese late onset case with familial amyloid polyneuropathy (FAP), caused by a novel TTR mutation of TTR compound heterozygous amyloidogenic TTR (ATTR) with wild type TTR (TTR 30Val / ATTR 80Arg), who shows orthostatic hypotension, electric shock like pain and allodynia in the trunk and severe pre / post micturitional pain with mild neuropathy and cardiopathy without vitreous opacity. Post-mortem examination showed severe amyloid deposition in peripheral nerve, dorsal root ganglion and vascular wall of the choroid plexus, which is compatible with that of severe case of type 1 FAP with mutation TTR (ATTR 30Val / TTR 80Lys). Though, his younger brother possessed compound heterozygous pathological mutation in each allele (ATTR 30Met / ATTR 80Arg), he only showed mild neuropathy. These results indicate that the novel TTR mutation (ATTR Lys80Arg) is the cause of amyloidosis with symptoms of micturitional abdominal pain and without or mild cardiopathy and vitreous opacity, if it exists compound heterozygous with wild type TTR (TTR 30Val / ATTR 80Arg).

**1020F****Identification of novel *SNORD118* mutations in seven patients with**

Leukoencephalopathy with brain calcifications and cysts (LCC) is neuroradiologically characterized by leukoencephalopathy, intracranial calcification, and cysts. Coats plus syndrome is also characterized by the same neuroradiological findings together with defects in retinal vascular development. LCC and Coats plus were originally considered the same clinical entity that was termed cerebroretinal microangiopathy with calcifications and cysts, but evidence now suggests that they are genetically distinct. Mutations in CTS telomere maintenance complex component 1 (*CTC1*) and small nucleolar RNA, C/D box 118 (*SNORD118*) genes have been found to cause Coats plus and LCC, respectively. We recruited eight unrelated families with LCC. These patients typically showed major neuroradiological findings of LCC with no other signs of extra-neurological manifestations. *SNORD118* was examined by Sanger sequencing in these families. Seven out of eight (87.5%) probands carry compound heterozygous mutations, suggesting that *SNORD118* mutations are the major cause of LCC. We identified a total of eight mutations, including four novel. Although some of the variants identified in this study are heterozygously present in public databases with an extremely rare frequency (<0.1%), biallelic mutations were exclusively found in most unrelated LCC families. Importantly these mutations were overlooked in our initial whole exome sequencing (WES) study focusing on only protein-coding genes. *SNORD118* is located in the 3'-untranslated region of the protein-coding gene transmembrane protein 107 (*TMEM107*), which was targeted by our exome capture. Indeed, we could confirm these variants retrospectively by utilizing the annotation database of Ensemble human genes. In summary, point mutations in the non-protein-coding RNA *SNORD118* were causal for a specific neurological phenotype, LCC. Our results indicate that functionally important region such as non-coding RNAs also warrant investigation by whole exome or genome sequencing.

**1021W****New homozygous missense mutation in *NT5C2* underlying hereditary spastic paraplegia SPG45.** A. Onoufriadis<sup>1,7</sup>, R. Straussberg<sup>2,3,7</sup>, O. Koner<sup>2,4</sup>, Y. Zouabi<sup>2,3</sup>, L. Cohen<sup>2,5</sup>, J.W.C. Lee<sup>1</sup>, C. Hsu<sup>1</sup>, M.A. Simpson<sup>6</sup>, J.A. McGrath<sup>1</sup>.

1) St John's Institute of Dermatology, Division of Genetics and Molecular Medicine, King's College London, London SE1 9RT, United Kingdom; 2) Neurogenetic Clinic, Neurology Institute, Schneider Children's Medical Center, Petah Tikva 49202, Israel; 3) Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv 69978, Israel; 4) Radiology Institute, Schneider Children's Medical Center, Petah Tikva 49202, Israel; 5) Genetic Institute, Schneider Children's Medical Center, Petah Tikva 49202, Israel; 6) Department of Genetics, Division of Genetics and Molecular Medicine, King's College London, Guy's Hospital, London SE1 9RT, United Kingdom; 7) These authors have contributed equally to the work.

SPG45 is a rare form of autosomal recessive spastic paraplegia associated with mental retardation. This condition results from biallelic loss-of-function mutations in *NT5C2* (5'-Nucleotidase, Cytosolic II) although only a small number of cases with mutations have been described and the spectrum of phenotypic abnormalities is not well defined. Detailed phenotyping and mutation analysis was undertaken in three individuals with SPG45 from a consanguineous family of Arab Muslim origin. All three subjects had moderate intellectual disability, attention deficit disorder and magnetic resonance imaging findings suggestive of significant corpus callosum and white matter pathology. Using whole-exome sequencing, we identified a novel homozygous missense mutation in *NT5C2* (c.1379T>C; p.Leu460Pro). Our data expand the molecular basis of SPG45, adding the first missense mutation to the current database of nonsense, frameshift and splice site mutations. *NT5C2* plays a key role in purine metabolism in the brain and contributes to the normal development of central white matter structures. *NT5C2* mutations seem to have a broad clinical spectrum and should be sought in patients manifesting either as uncomplicated or complicated HSP.

**Spastic paraplegia type 4: A novel *SPAST* splice site donor mutation and expansion of the phenotype variability.** A. Orlacchio<sup>1,2</sup>, C. Montecchiani<sup>1</sup>, R. Miyamoto<sup>3</sup>, L. D'Onofrio<sup>1</sup>, R. Rumore<sup>1</sup>, M. Miele<sup>1</sup>, F. Gaudiello<sup>1</sup>, Y. Izumi<sup>4</sup>, C. Caltagirone<sup>4</sup>, R. Kaji<sup>4</sup>, T. Kawara<sup>4</sup>. 1) Laboratorio di Neurogenetica, CERC - IRCCS Santa Lucia, Rome, Italy; 2) Dipartimento di Scienze Chirurgiche e Biomediche, Università di Perugia, Perugia, Italy; 3) Department of Clinical Neuroscience, University of Tokushima, Tokushima, Japan; 4) Dipartimento di Medicina dei Sistemi, Università di Roma "Tor Vergata", Rome, Italy.

**Background:** Mutations in *SPG4/SPAST* represent the most frequent molecular etiology in an autosomal dominant form of Hereditary Spastic Paraplegia (HSP). Previous studies demonstrated various molecular pathogenesis in *SPG4*, including loss-of-function, haploinsufficiency, dominant-negative effect, and dysregulation of microtubule-severing activity. The aim of this study is to reveal molecular pathogenicity and genotype-phenotype correlations in *SPG4*. **Methods:** A cohort of patients with spastic paraplegia recruited in Italy and Japan was investigated clinically and genetically. Initial diagnostic approach included targeted resequencing of currently-known HSP genes or resequencing of whole exomes. Biological effects by nucleotide variation were predicted using bioinformatic tools and confirmed by reverse transcription polymerase chain reaction (RT-PCR) experiment. Measurement of *SPG4* transcripts were conducted in cultured T cells treated with nonsense pre-mRNA mediated decay (NMD) inhibitor. **Results:** A novel *SPAST* intronic variation was found in two families, one from Italy and the other from Japan. The variant is located at the third position at 5'-splice-site of intron 6, c.1004+3A>C. RNA secondary structure seems to remain unchanged by the variant; however, skipping of exon 6 was shown by RT-PCR experiment, presumably leading to generation of frame shifts and premature stop codons (p.Gly290Trpfs\*5). Measurement of *SPAST* transcripts in lymphocytes demonstrated a reduction through NMD. Intra- and inter-familial phenotypic variations were observed, including age-at-onset, severity of spasticity, as well as scoliosis. **Conclusions:** Our study demonstrated further evidence of allelic heterogeneity in *SPG4*, dosage effects through NMD, and broad clinical features of *SPAST* mutation.

**1023F**

**A de novo *HNRNPU* gene mutation identified in a patient with symptomatic infection-associated acute encephalopathy and developmental delay.** S. Shimada<sup>1,2</sup>, H. Oguni<sup>2</sup>, Y. Otani<sup>2</sup>, A. Nishikawa<sup>2</sup>, S. Ito<sup>2</sup>, K. Eto<sup>2</sup>, T. Nakazawa<sup>1,4</sup>, S. Nagata<sup>2</sup>, T. Yamamoto<sup>3</sup>. 1) Department of Pediatrics, Juntendo University Urayasu Hospital, Chiba, MD; 2) Department of Pediatrics, Tokyo Women's Medical University, Tokyo, MD; 3) Institute of Medical Genetics, Tokyo Women's Medical University, Tokyo, MD; 4) Department of Pediatrics, Toshima Hospital, Tokyo, MD.

[;Introduction];Heterogenous nuclear ribonucleoprotein U (*HNRNPU*) codes for a highly conserved protein that binds RNAs and mediates different aspects of their metabolism and transport. Recent studies have revealed that *HNRNPU* is a causative gene of epileptic encephalopathy, severe intellectual disability, and hemiconvulsion-hemiplegia-epilepsy (HHE) syndrome. A de novo *HNRNPU* mutation was identified in this study. [;Patient];A 5 year-old boy had had global developmental delay since early infancy. At 13 months of age, he developed febrile status epilepticus triggered by parainfluenzae infection, leaving a residual high intensity diffusion in the right hemisphere. Four months later, he started to have frequent focal seizures, characterized by cyanosis and brief tonic contraction of his body. Since then, he had had various types of seizures refractory to all available to our hospital at 5 years of age, he showed stereotypic hand movements, autistic features, episode apnea, and hyperpnea followed by falling. [;Results];Next-generation sequencing detected one nucleotide deletion in the coding region of *HNRNPU*, which was negative in both parents, indicating a de novo origin. [;Conclusion];We identified a rare mutation of *HNRNPU* in a patient with symptomatic infection-associated acute encephalopathy followed by intractable epilepsy. The characteristics of patients with *HNRNPU* abnormalities should be further evaluated for better understanding.

**1024W**

**Naturally occurring human genetic variation suggests *LRRK2* inhibition is a safe therapeutic strategy for Parkinson's disease.** *I.M. Armean<sup>1,2</sup>, J.L. Marshall<sup>1,2</sup>, E.V. Minikel<sup>1,2</sup>, D.A. O'Connell<sup>1,2</sup>, S. Ashrafzadeh<sup>1,2</sup>, M. Chiumiento<sup>1,2</sup>, J. Alfoldi<sup>1,2</sup>, D.G. MacArthur<sup>1,2</sup>.* 1) Analytic and Translational Genetics Unit, Massachusetts General Hospital Research Institute, Boston, MA; 2) Broad Institute of MIT and Harvard, Cambridge, MA, USA.

The recent availability of very large collections of sequenced individuals provides an unprecedented opportunity to identify humans who carry naturally occurring loss-of-function (LoF) variation, representing unique "experiments of nature" that serve as *in vivo* models of the effects of the partial or complete inactivation of human genes. Human LoF variants can aid in the identification and validation of genes that would be effective and well-tolerated targets for therapeutic inhibition in both rare and common diseases. Human LoF variants have already been used to validate candidate drug targets, most visibly in the case of *PCSK9* in LDL-lowering therapy and more recently with *APOC3* and *NPC1L1* reducing the risk of coronary heart disease. Parkinson's disease (PD) is a common neurodegenerative disease affecting about 2% of people aged 60 years and older. Genetic causes account for about 10% of PD cases, of which mutations in *LRRK2* are the most prevalent. All known disease mutations in *LRRK2* are missense and occur in critical functional domains of the protein, suggesting that the mechanism of disease is gain-of-function. This observation is supported by evidence that pathogenic mutations increase *LRRK2*'s kinase activity and therefore lead to the hypothesis of *LRRK2* inhibition as a therapeutic strategy for PD. Here we present the results of the functional and phenotypic review of *LRRK2* LoF variants identified in over 123,136 exomes and 15,496 genomes assembled by the Genome Aggregation Database (gnomAD). Firstly, we performed deep manual review to confirm genotype calls and functional predictions of the 144 *LRRK2* LoF variants, resulting in 114 heterozygous high-confidence LoF variants. For a subset of individuals we have confirmed that heterozygous LoFs result in a clear reduction in protein levels. Through collaborations we have been able to obtain electronic health records for 75 samples carrying heterozygous *LRRK2* LoF variants, and to date find no evidence of consistent or severe disease. Our data validate the use of the gnomAD resource for genotype-guided target validation, and suggest that partial therapeutic reduction of *LRRK2* levels will be well-tolerated in humans.

**Phenotypical features and genetic findings in Lithuanian patients with CMTX1.** *B. Burnyte, I. Kavaliauskiene, L. Ambrozaityte, A. Morkuniene, A. Matuleviciene, B. Tumiene, V. Kucinskas, A. Utkus.* Dept. of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania.

**BACKGROUND:** X-linked Charcot-Marie Tooth disease (CMTX1) is caused by mutations in the *GJB1* gene that encodes a polypeptide which is arranged in hexameric array and form gap junctions. To date over 300 different *GJB1* variants are described in the HGMD® database. **OBJECTIVE:** To evaluate the phenotypical features and genetic findings in the CMTX1 patients. **METHODS:** Retrospective analysis of phenotypical and genetic data in CMT1X patients. **RESULTS:** In our cohort of 14 confirmed CMTX1 probands out of 336 CMT patients we identified a total of ten *GJB1* pathogenic mutations, three of which are novel. Three unrelated individuals carried a novel missense mutation c.290A>G, p.His97Arg. One patient had a novel nonsense mutation c.195T>A, p.Tyr65\*, while another one carried a novel missense mutation c.596G>A, p.Gly199Asp. In 50% of patients the age at disease presentation was in second decade whereas 28.57% of patients reported an onset before 10 years of age. Most common symptoms at onset were distal weakness of upper or lower limbs, unsteadiness and high stepping gait. Episodic transient fluctuating stroke-like episodes were diagnosed in one patient with described mutation. NCV showed a sensory and motor axonal neuropathy in two patients harboring novel mutations. Ten patients presented a mixed NCV pattern and one – demyelinating. **CONCLUSIONS:** Three novel out of ten different mutations identified in this study expands the up to date heterogeneity of the CMTX1. Analysis of phenotypes in patients with novel and known mutations of *GJB1* gene showed no phenotypic heterogeneity. The frequency of *GJB1* mutations is 4.16% in Lithuanian patients with CMT.

**Lack of CHCHD2 mutations in Parkinson's disease in a Southern Italy population.** G. Iannello<sup>1,2</sup>, R. Procopio<sup>1</sup>, M. Gagliardi<sup>1</sup>, A. Quattrone<sup>1,2</sup>, G. Annesi<sup>1</sup>. 1) Institute of Molecular Bioimaging and Physiology. National Research Council Magna Graecia University of Catanzaro.; 2) Institute of Neurology, Department of Medical and Surgical Sciences University Magna Graecia, Catanzaro, Italy.

Parkinson's disease (PD) is one of the most frequent neurodegenerative disorders, and although most PD cases appear to be sporadic, specific genetic defects have been linked to familial PD. Previously, mutations in *SNCA*, *LRRK2*, *VPS35*, *EIF4G1* and *DNAJC13* were considered responsible for the typical examples of autosomal dominant parkinsonism. However, potential genetic causes remain unidentified. Coiled-coil-helix-coiled-coil-helix domain containing 2 (*CHCHD2*) is a previously uncharacterized small mitochondrial protein thought to localize in the mitochondrial intermembrane space. *CHCHD2* mutations have recently been identified in families with autosomal dominant Parkinson's disease (ADPD); these patients present with dopa-responsive parkinsonism. Three mutations 182C>T (Thr611Ile), 434G>A (Arg145Gln), and 300+5G>A was identified in 4 Japanese. However, there are no reports of PD patients with *CHCHD2* mutations in Italian populations. In this study, we performed comprehensive *CHCHD2* mutation screenings in familial and sporadic PD cases to assess the frequencies of known and novel rare nonsynonymous mutations. The study assessed 165 ADPD pedigrees and 160 controls. The relevant ethical authorities approved the study, and written informed consent to participate in genetic research was obtained from all subjects. All patients submitted to a standardized neurological examination by 2 movement disorder specialists, and the criteria for diagnosing PD adopted by the participating neurologists was based on the United Kingdom Parkinson's Disease Society Brain Bank Eighteen known PD gene mutations were previously excluded in the familial cases by targeted high-throughput sequencing. The 4 exons and intron-exon boundaries of *CHCHD2* were amplified by PCR and sequenced with the ABI 3730 analyzer (Applied Biosystems). Primer sequences and PCR conditions were described previously. We did not identify any PD patients carrying *CHCHD2* mutations, but we found c.\*125G>A genetic variant in heterozygous and homozygous state in our study population already reported in dbSNP. Our results suggest that *CHCHD2* gene may not play a major role in familial and sporadic PD patients in our population.

**1027W**

**DNAJC13 familial Parkinson's disease from South Italy.** R. Procopio<sup>1</sup>, M. Gagliardi<sup>1</sup>, G. Annesi<sup>1</sup>, G. Iannello<sup>1,2</sup>, A. Quattrone<sup>1,2</sup>. 1) Institute of Molecular Bioimaging and Physiology, National Research Council, Germaneto, Catanzaro, Italy; 2) Institute of Neurology, Department of Medical and Surgical Sciences, University Magna Graecia, Catanzaro, Italy.

Parkinson's disease (PD) is the second most common neurodegenerative disorder, and the most common neurodegenerative form of parkinsonism. A pathogenic mutation (p.N855S) in *DNAJC13*(DnaJ [Hsp40] Homolog, Subfamily C, Member 13) was linked to autosomal dominant Lewy body PD in a Dutch–German–Russian Mennonite multi-incident kindred, and was found in four additional patients. 5 *DNAJC13* (RME-8) is a DnaJ-domain-containing protein that regulates endosomal trafficking and protein recycling. The p.N855S mutation causes an accumulation of receptors in endosomal compartments. In this study, we performed a comprehensive screening of *DNAJC13* in familial parkinsonism and in familial parkinsonism to assess the frequency of known and novel rare nonsynonymous mutations. All patients were examined and observed longitudinally by movement disorder neurologists and diagnosed with PD according to published criteria. To estimate the frequency of the Asn855Ser (in familial PD), we screened this variant in a southern Italy PD cohort and control subjects. Our population included 165 patients with familial PD, having at least 1 relative among their first degree, second degree, in third degree family members with a formal diagnosis of PD, major PD genes had been analyzed and they were excluded. Genomic DNA was extracted from peripheral blood by standard method. The purified polymerase chain reaction products were sequenced on an ABI 3500 sequencer. Our sequencing analysis of 165 patients with PD identified one carrier of p.Arg903Lys novel mutation in exon 24 of the *DNAJC13* gene, The carrier of p.Arg903Lys has late-onset PD (AAO 65), and his mother have parkinsonism.

**1028T**

**A rare male patient with classic Rett Syndrome caused by MeCP2\_e1 mutation.** A. Goji<sup>1</sup>, H. Ito<sup>1</sup>, N. Tokaji<sup>1</sup>, T. Kohmoto<sup>2</sup>, T. Naruto<sup>2</sup>, R. Takahashi<sup>1</sup>, T. Mori<sup>1</sup>, Y. Toda<sup>1</sup>, M. Saito<sup>2</sup>, S. Tange<sup>2</sup>, K. Masuda<sup>2</sup>, S. Kagami<sup>1</sup>, I. Imoto<sup>2</sup>. 1) Department of Paediatrics, Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan; 2) Department of Human Genetics, Graduate School of Biomedical Sciences, Tokushima University, Tokushima, Japan.

Rett syndrome (RTT) is a severe neurodevelopmental disorder typically affecting females. It is mainly caused by loss-of-function mutations affecting the coding sequence of exon 3 or 4 of the *methyl-CpG-binding protein 2* (*MECP2*) gene. Phenotype characterized by idiopathic intellectual disability, psychomotor regression involving loss of speech and hand use, development of gait problems, and characteristic repetitive hand stereotypies. A pathogenic *MECP2* variant in a male is most often presumed to be lethal. However, several groups of male patients with an *MECP2* mutation have been distinguished, which includes boys with RTT with a *MECP2* mutation diluted by an additional X chromosome (XXY) or somatic mosaicism. We report on 3-year-old male carrying a small duplication mutation in the open reading frame of *MECP2* exon 1. All symptoms of the main criteria of RTT started to appear after 6 months of age, although fewer milestones in psychomotor development, especially language skills, could be evaluated due to an earlier start of regression. The patient also met exclusion criteria. In addition, his phenotype met 7 of 11 supportive criteria, including breathing disturbances when awake, bruxism when awake, impaired sleep patterns, abnormal muscle tone, growth retardation, small cold hands and feet, and inappropriate laughing/screaming spells, although supportive criteria were entirely eliminated from the revised diagnostic criteria for classic RTT. Our molecular diagnostic analyses using targeted exome sequencing followed by Sanger sequencing detected a *de novo* 5-bp duplication within the open-reading frame of *MECP2* exon 1. This mutation, NM\_001110792.1:c.23\_27dup, caused a frameshift and introduced a stop codon downstream after 35 missense amino acids [p.(Ser10Argfs\*36)]. This mutation has been reported to cause classic RTT in the sporadic case of one female patient, but has not been reported to cause *MECP2*-related diseases in males. His karyotype was consistent with a normal male. No signs of somatic mosaicism were detected. Mutations in *MECP2* exon 1 affecting the MeCP2\_e1 isoform are relatively rare causes of RTT in females, and only one case of a male patient with *MECP2*-related severe neonatal encephalopathy has been reported. This is the first case of a male with classic RTT caused by a rare mutation in the MeCP2\_e1 isoform. Therefore, both males and females displaying at least some type of MeCP2\_e1 mutation may exhibit the classic RTT phenotype.

**1029F**

**Epidemiology and genetics of Chiari 1 malformation.** B. Sadler<sup>1</sup>, T. Kuenstling<sup>1</sup>, G. Haller<sup>2</sup>, M. Smyth<sup>3</sup>, D. Limbrick<sup>3</sup>, C. Gurnett<sup>1</sup>. 1) Neurology, Washington University, St Louis, MO; 2) Orthopedic Surgery, Washington University, St Louis, MO; 3) Neurosurgery, Washington University, St Louis, MO.

Background: Chiari 1 Malformation (CM1) is a common neurological disorder in which the cerebellar tonsils herniate through the foramen magnum, symptomatically affecting up to 1/1,000 people. Patients present with a wide array of symptoms stemming from compression of neural tissue that can lead to syringomyelia and/or hydrocephalus. In many cases CM1 is idiopathic but it can occur in the context of known genetic syndromes or genomic abnormalities (syndromic), including Ehlers-Danlos Syndrome, Klippel-Feil Syndrome and Neurofibromatosis Type I. We hypothesize that idiopathic CM1 represents a mild form of syndromic CM1, and that many of the same genes causing syndromic CM1 will be involved in idiopathic CM1. Sample/Methods: We performed a chart review of 500 individuals affected with CM1 who were seen at St Louis Children's Hospital by two neurosurgeons between 2003-2015. DNA is being prospectively collected and has been collected from ~150 of these CM1 cases and collection is ongoing. When possible, affected and unaffected family members, were also recruited. Exome sequencing was performed on 98 CM1 cases, including 8 trios consisting of early-onset CM1 cases with unaffected parents. Alignment and calling pipeline includes Burroughs-Wheeler Aligner (BWA) and Genome Analysis Tool Kit (GATK). Results: In the cohort of 500 patients with CM1, 69% had idiopathic CM1. These included individuals with scoliosis and/or syringomyelia. Genetic or genomic causes were identified in 8% of cases, including Marfan Syndrome, Crouzon Syndrome and Alagille Syndrome. 32 (6%) of patients had a known family history of CM1. Idiopathic CM1 cases had the oldest average age at diagnosis, although had a mean tonsillar ectopia reflective of the mean of the entire sample. Examination of sequence data resulted in the identification of rare nonsense and *de novo* mutations in several genes known to cause skeletal abnormalities. Discussion: The vast majority of CM1 cases are idiopathic. No genes have yet been conclusively identified for CM1. Mutations in skeletal disease genes indicate that pathways involving these genes may be critical for CM1 development.

**1030W**

**Report of phenotypic variability of periventricular nodular heterotopia in a four-generation Caucasian family with a novel *FLNA* mutation.** *D. Khat-tar, R.J. Hopkin.* Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

**Background:** X-linked periventricular nodular heterotopia (PVNH1 [MIM30049]) is characterized by delay in migration of neurons from the periventricular region resulting in nodular clumps lining the lateral ventricles. This is frequently associated with seizures, borderline to normal intelligence, and cardiac or vascular anomalies including coagulopathy. Most cases are the result of a new mutation, but familial cases have occurred. We report a four generation family with PVNH1. **Patients:** The proband was a 9 month female with gross motor delays, hip dysplasia, and failure to thrive. Significant cardiac findings included large PDA necessitating closure, mildly hypoplastic aortic annulus with dilated ascending aorta, and small patent foramen ovale. Brain MRI showed diffuse bilateral subependymal nodular heterotopia with enlarged cisterna magna. The mother of the proband was a 20 year old healthy female with normal cognition without cardiac or epileptic history. She had significant joint laxity. A novel heterozygous mutation, c.6923C>A, in exon 43 of *FLNA* gene [MIM 300019] resulting in p.S2308X was identified. The grandmother, great grandmother, and a maternal aunt of the proband have seizures and periventricular heterotopias, but have not yet had molecular testing. Other family members are also being evaluated. **Summary:** The inter-familial variability is remarkable ranging from near normal to perinatal disability. The mother adds particular emphasis of association with connective tissue findings as part of an extended spectrum of PVNH rather than a separate entity of Ehlers-Danlos Syndrome. Furthermore, the importance of multigenerational family history and screening for cardiac and aortic complications is evident. The cause of the variability is incompletely understood but not directly predicted by the mutation alone.

**Sensory, behavioral, and social phenotypes observed in individuals with Williams syndrome in Japan.** *T. Awaya<sup>1,2</sup>, R. Kimura<sup>1</sup>, M. Nakata<sup>1,2</sup>, T. Kato<sup>2</sup>, K. Matsushima<sup>2</sup>, T. Kato<sup>2</sup>, S. Okazaki<sup>3</sup>, K. Tomiwa<sup>4,5</sup>, T. Heike<sup>2</sup>, M. Hagiwara<sup>1</sup>.*

1) Department of Anatomy and Developmental Biology, Kyoto University Graduate School of Medicine, Kyoto, Japan; 2) Department of Pediatrics, Kyoto University Graduate School of Medicine, Kyoto, Japan; 3) Department of Human Health Science, , Kyoto University Graduate School of Medicine, Kyoto, Japan; 4) Department of Child Neurology, Osaka City General Hospital, Osaka, Japan; 5) Todajji Ryoiku Hospital for Children, Nara, Japan.

[Introduction] Williams syndrome (WS) is a genetic disorder caused by a microdeletion in 7q11.23. Although WS was originally reported as a neurodevelopmental disorder with distinctive facial features, cardiovascular problems, such as supravalvular aortic stenosis (SVAS) and transient hypercalciuria, it is now gathering significant attention because of its characteristic cognitive features. Several groups reported sensory modulation among people with WS, and its significance in their behavioral problems. Here, we investigated such properties along with social problems in Japanese cohort. [Methods] We included 54 participants with WS, divided into three groups (Ages 1.5-5, 6-18, 18-59, according to the questionnaire used for the Achenbach System of Empirically Based Assessment (ASEBA), n=13, 22, 19), who answered all the questionnaires below; the Hyperacusis questionnaire (HQ), the Fear Survey Schedule for Children-Revised (FSSC-R), the Short Sensory Profile (SSP), the Childhood or Adult Behavior Checklist (CBCL or ABCL) of ASEBA, and the Social Responsiveness Scale-2 (SRS-2). [Results] Individuals with WS showed high scores of HQ and FSSCR, as previously reported. We observed >90% individuals with high SSP scores, and 54.7% showed clinical to borderline T-score of total problems (37.7%, 39.6% for the internalizing/externalizing problems, respectively) in CBCL/ABCL. We observed significant correlation between the scores of SSP, CBCL/ABCL, SRS-2. Correlation analysis of SSP, CBCL/ABCL, and SRS-2 subscales indicated that there are several strong correlations among them. Of note, Under-responsive/Seeks sensation features of SSP was strongly correlated to several subscales of SRS-2, and Avoidance dimension of SSP was correlated to Externalizing problems assessed with CBCL/ABCL. [Discussion] The sensory modulation observed in WS significantly correlated with several aspects of behavioral and social problems. Visiospatial deficit among individuals with WS is well-known; however, other sensory problems also associated with their behavioral and social difficulties. We also noticed differences from previous reports for several features, probably due to sociocultural environment. Detailed data collection is needed for further clarification.

**1032F****Combining Bionano and exome sequencing identifies a homozygous structural variation in the novel *AGBL3* gene underlying microcephaly.**

*D. Belandres<sup>1</sup>, M. Breuss<sup>1</sup>, D. Musaev<sup>1</sup>, C. Bautista<sup>1</sup>, V. Stanley<sup>1</sup>, H. Kayserili<sup>2</sup>, J.G. Gleeson<sup>1</sup>.* 1) Howard Hughes Medical Institute, Rady Genomics Institute, UCSD, La Jolla, CA 92093 USA; 2) Department of Medical Genetics, Koç Üniversitesi Hospital, Istanbul 34010 Turkey.

Chromosomal structural variations (SVs) remain a challenge to molecularly characterize, especially when under 10 kbp in size. Here we present a combined approach in a family in which the proband presented with microcephaly with simplified gyral pattern (MSGP) in the setting of parental consanguinity. Whole exome sequence analysis from the proband failed to identify a likely cause, so we combined linkage analysis, XHMM, and Bionano's Saphyr™ Optical Mapping based System. The pedigree consisted of a single affected and two healthy siblings, which was studied first with linkage analysis, allowing exclusion of 90% of the genome, and identifying the major peak on chr. 7q33. Bionano Next-Generation Mapping (NGM) was applied to cell lines derived from affected and parent, and identified a deletion of 5-12 kbp encompassing part of the coding region of the *AGBL3* gene. This was found from both Nt.BspQI and Nb.BssSI restriction enzymes used for optical mapping, and was homozygous in the affected and heterozygous in the parent. The deletion was confirmed by review of the exome sequence pile-up, which showed absence of coverage from exons 9-11 in the affected, statistically flagged using the SV detection software XHMM. *AGBL3* encodes a cytosolic carboxypeptidase that removes acidic amino acid side chains from tubulins and other proteins, specifically cleaving polyglutamylation post-translational modifications. Integrating Bionano's NGM technique revealed that the deletion extended into flanking introns, which contained a high-density of repeated dinucleotide elements, suggesting ancestral homologous recombination. Synthesizing data from linkage, exome, and Bionano allowed for the discovery, confirmation, and refinement of a homozygous deletion in a novel gene. We expect that this integrative approach will be a powerful strategy in human genetics, especially for 'exome-negative' cases and we are currently applying it to additional cases.

**1033W**

**Genetics of childhood-onset psychosis.** *M. Ameri, A.C Need.* Centre for Psychiatry, Division of Brain Sciences, Department of Medicine, Imperial College London, Hammersmith Campus, Du Cane Road, London, W12 0NN, UK.

Childhood-Onset Psychosis (COP) is a very rare and debilitating disorder characterised by the onset of psychotic symptoms before age 14. Evidence suggests that it may be more frequently caused by rare (MAF<1%), highly penetrant genetic variants, in comparison to adult-onset schizophrenia. Here we report early findings from a study exploring the potential of exome sequencing as a diagnostic tool in child psychiatry clinics. We hypothesise that some occurrences of COP are the result of known Mendelian disorders manifesting primarily with psychiatric symptoms. In this study, we will extract saliva DNA from 100 trios, perform pedigree analysis, examine rare schizophrenia-associated copy number variants (CNVs) and perform exome sequencing to identify rare inherited or *de novo* SNVs or INDELS. To date we have recruited 19 families, with 9 male and 10 female probands, and generated 3-generation pedigrees for each family. Data on race, ethnicity, age of diagnosis and cognitive function will be presented. All probands have a primary diagnosis of a psychotic illness with 10/19 having a comorbid neurodevelopmental disorder. According to family report, 9/19 probands have a family history of a psychiatric diagnosis. Cognitive assessment (WASI-II) on the first 12 probands shows a variation in their full-scale intelligence quotient (FSIQ) whereby 3/12 scored extremely low (FSIQ<70), 2/12 scored borderline (FSIQ 70-80), 3/12 scored low average (FSIQ 80-90) and 4/12 scored average (FSIQ 90-110). In addition, 5/19 probands are on Clozapine, highlighting their disease severity. Genetic analysis of the first 8 probands indicates that none have common schizophrenia-associated chromosomal deletions or duplications. Exome sequence analysis based on ACMG guidelines suggests that 4/7 sequenced probands may have a mutation causing a Mendelian disease that is known to manifest with psychiatric symptoms. These will be investigated further with clinical assessments. The candidate disease genes are *SCN1A*, *L1CAM*, *RET* and *SIX3*. In addition, 2 probands have missense variants in *CLCN2* and *GRIN2A*, which may be contributing to their behavioural difficulties (including aggression), as well as speech delay. The identification of highly penetrant variants that predispose these probands to psychotic and severe neurocognitive phenotypes can have positive implications in the clinic as a diagnostic tool, as well as providing a platform for understanding of the underlying neurobiology of COP.

**Expansion of the molecular and phenotypic spectrum of *CAMTA1*-related neurological disorders.** L.B. Henderson<sup>1</sup>, H. Sroka<sup>1</sup>, B. O'Connor<sup>2</sup>, J.W. Innis<sup>3</sup>, M. Byler<sup>3</sup>, R.R. Lebel<sup>3</sup>, J. Humberson<sup>4</sup>, R. McClellan<sup>5</sup>, H. Vernon<sup>5</sup>, G. Mirzaa<sup>6</sup>, D. Castro<sup>7</sup>, B. Grysko<sup>8</sup>, L. Seaver<sup>8</sup>, F. Almesaifir<sup>8</sup>, T. Ben-Omran<sup>8</sup>, R. Willaert<sup>1</sup>, M.T. Cho<sup>1</sup>, J. Juusola<sup>1</sup>. 1) GeneDx, Gaithersburg, MD; 2) Division of Pediatric Genetics, Metabolism and Genomic Medicine, University of Michigan, Ann Arbor, MI; 3) SUNY Upstate University Hospital, Syracuse, NY; 4) Pediatric Genetics, University of Virginia, Charlottesville, VA; 5) Kennedy Krieger Institute, Baltimore, MD; 6) Division of Genetic Medicine, Department of Pediatrics, University of Washington, Seattle, WA; 7) Children's Medical Center of Dallas, Dallas, TX; 8) Spectrum Health Medical Genetics, Grand Rapids, MI; 9) Hamad Medical Corporation, Doha, Qatar.

The *CAMTA1* gene encodes calmodulin-binding transcription activator 1, a conserved calcium-sensitive transcription factor that is highly expressed in brain with enrichment in the cerebellum. Mice lacking *Camta1* display severe ataxia and cerebellar atrophy, indicating a role for this gene in neuronal maturation and survival. In humans, studies using chromosomal microarray have demonstrated that heterozygous intragenic rearrangements in *CAMTA1* are associated with intellectual disability (ID), congenital cerebellar ataxia, and behavioral problems. Point mutations in *CAMTA1* have not been reported to date, though some of the previously reported intragenic rearrangements were predicted to result in a frameshift leading to premature translational termination. Using clinical exome sequencing, we have identified pathogenic loss-of-function sequence variants in *CAMTA1* in nine unrelated patients. All individuals, ranging in age from 2 to 22 years, presented with developmental delays and/or ID. Other common features included abnormal behaviors (8/9), hypotonia (6/9), muscle weakness/myopathy (5/9), and ataxia (4/9). Three individuals were diagnosed with autism. Inheritance could be determined for eight variants: four occurred *de novo* in the affected proband and four were inherited from a parent, three of whom were noted to have some features consistent with a *CAMTA1* disorder (history of hypotonia, speech difficulties, cerebral palsy, poor coordination, autistic features and/or epilepsy). One carrier parent was apparently asymptomatic, thereby suggesting not only variable expressivity but also reduced penetrance of pathogenic variants in *CAMTA1*. In summary, our results expand the clinical knowledge of *CAMTA1*-related disorders and broaden the mutational spectrum to include loss-of-function sequence variants.

Whole exome sequencing in an index case of a 16-year-old male with autism, mild intellectual disability and behavioral concerns revealed a *de novo* mutation in *RFX3*, a gene without established medical significance. Through GeneMatcher we have now identified a total of 8 cases of *RFX3* mutations in association with autism spectrum disorder, behavioral difficulties, and variable cognitive outcomes including mild or moderate intellectual disability. *RFX3* is a member of the regulatory factor X gene family which encodes transcription factors that contain a highly-conserved DNA binding domain. Prior studies in mice prove that *RFX3* regulates the transcription of genes involved in cilia formation and is expressed in a wide array of tissues, including adult and developing brain. Biallelic knockout of *RFX3* in mice causes situs inversus, hydrocephalus, and agenesis of the corpus callosum, although the phenotypic consequences of heterozygous mutation have not been described. Our series includes 7 males and 1 female patient, all with autism, 5 patients with intellectual disability, 4 with diagnosed attention deficit hyperactivity disorder, and 4 with nonspecific behavioral functioning difficulties. Other common features include hypotonia and joint laxity. This case series suggests that *RFX3* mutation is responsible for a novel human neurobehavioral syndrome overlapping with autism spectrum disorder.

*TBR1* encodes a brain-specific T-box transcription factor highly expressed in the cerebral cortex. It plays an essential role in the differentiation of neocortical neurons, neuronal migration and axonal projection during embryonic development. *TBR1* regulates several candidate genes for autism spectrum disorders (ASD), such as *GRIN2B*, through interactions with *CASK*, *AUTS2* and *RELN*. Whole-exome sequencing and the molecular inversion probe method in a large series of 3700 probands with ASD identified 7 pathogenic *TBR1* variants in 7 unrelated patients. Besides, one patient with a 2q24.2 deletion encompassing only *TBR1* and presenting intellectual disability (ID), growth retardation, mild facial dysmorphism, pectus excavatum and long hands was fully described. *TBR1* has thus been reported as a high-confidence risk gene for ASD. Nevertheless, fine phenotype descriptions are lacking and *TBR1* is still not reported as a human disease-causing gene in the OMIM database. Here, we report on a full clinical description of 15 unrelated patients, 9 males and 6 females, all carrying *de novo* *TBR1* variants. The patients were recruited thanks to national and international datasharing, through databases such as PhenomeCentral and GeneMatcher. Clinical and molecular results were confronted to a review of the literature. In total, 28 patients presented with *TBR1* causal variants including 13 truncating and 7 missense variants located in functional domains, as well as 8 CNV (deletion) ranging from 122kb to 12.3Mb. All patients, aged from 1 to 29 years, presented with moderate to severe ID and ASD. Six patients had a history of seizures. Non-specific dysmorphic features were observed in all patients and growth retardation was frequently reported. Heterogeneous limb anomalies were present in half of the patients with almost constant joint laxity. About one third of the patients exhibited hypotonia, gastroesophageal reflux disease, constipation, and small cerebral imaging anomalies, but further analysis of the MRI pictures may highlight characteristic cerebral anomalies. Associated non-recurrent malformations included deafness, coloboma, hypothyroidism and acrocyanosis. This report, based on a review of the literature and reverse phenotyping, provides an accurate description of the phenotype associated with *TBR1* variants and confirms their implication in syndromic ASD. *TBR1* should thus be considered a human disease-causing gene and described as such in the OMIM database.

Neurodevelopmental disorders are genetically and phenotypically heterogeneous encompassing intellectual disability (ID), autism spectrum disorders (ASDs), structural brain abnormalities and neurological manifestations with a significant number of genes associated. Next generation sequencing can resolve locus heterogeneity underlying clinical phenotypes, that may otherwise be co-assigned as a specific syndrome based on shared clinical features and can link phenotypically diverse diseases to a single locus. By whole-exome sequencing (WES) and chromosomal microarray analysis (CMA), we identified five inactivating single nucleotide variants (one missense, three frameshifts and one non-sense) and two whole-gene deletions of *TCF20* gene in seven patients from unrelated families presenting with a phenotype characterized by intellectual disability with specific language deficits, hypotonia, variable dysmorphic features and other neurological deficits including ataxia and movement disorder. The missense change c.5129A>G (p.Lys1710Arg) occurs in a highly evolutionary conserved position of the functional F-Box/GATA-1 like finger motif of the protein. The variants were all found to be *de novo* in the six cases with available parental samples. To date, a few *de novo* mutations potentially disrupting *TCF20* function in patients with ID, ASD and hypotonia have been reported. *TCF20* encodes a transcriptional co-regulator related to *RAI1*, the dosage-sensitive gene responsible for Smith-Magenis and Potocki-Lupski syndromes. *TCF20* shares similar domains with *RAI1* that are involved in histone modification and co-transcriptional regulation of a plethora of genes involved in biological pathways likely disrupted in these two syndromes. Therefore, we propose that deleterious mutations in *TCF20* are associated with a novel syndrome that shares characteristics with Smith-Magenis syndrome. Together with previously described cases, our findings produce a more detailed picture of the phenotype of *TCF20*-associated neurodevelopmental disorder.

**Intellectual disability with severe self-injury behavior caused by *THOC2* splice site variant.** *N. Ishihara<sup>1</sup>, H. Inagaki<sup>2</sup>, M. Kawai<sup>2</sup>, C. Inuo<sup>1</sup>, H. Kura-hashiz<sup>2</sup>.* 1) Dept Pediatrics, Fujita Health University, Toyoake, Aichi, Japan; 2) Div Mol Genet. Inst Comprehensive Medical Science, Fujita Health University, Toyoake, Aichi, Japan.

[Introduction] *THOC2* encodes a subunit of the highly conserved TREX mRNA-export complex, and known to cause syndromic intellectual disability (ID). Here we present a boy with *THOC2* splice site mutation presented as ID with severe self-injury behavior. [Subject] Subject was a 3-year-old boy born to healthy non-consanguineous parents. His 7-year-old sister was healthy with normal development. He was pointed out nuchal translucency by fetal ultrasound scan at gestational age of 19 weeks, and received amniocentesis to reveal normal male karyotype. After birth, he showed developmental delay with axial hypotonia, speech delay, and failure to thrive caused by disturbance of oral ingestion and frequent aspiration pneumonia. After performing gastrostomy, he began to gain weight, and behavior problem of punching his own head and/or chin became obvious. [Results] Whole exome sequences were performed with trio DNA samples extracted from white blood cells of subject and his parents. Variants with less than one percent allele frequency were classified into de novo, autosomal recessive, and X-linked forms. Among these, we identified an X-linked, splice site mutation of *THOC2* exon 28 (c.3503+4A>C) of maternal origin. This mutation was neither reported in the public databases such as dbSNP build 147 nor ExAC. RT-PCR analysis of mRNA from subject's white blood cells revealed that this mutation led to intron retention resulted in introducing premature termination codon. Since we could not detect any intron retention product from his mother, we carried out HUMARA assay using DNAs from her white blood cells. The result revealed skewed inactivation (98:2), and that the inactivated X chromosome was inherited to subject. [Discussion] X-linked ID caused by *THOC2* mutations was first reported by Kumar et al. in four different multigenerational families. All four variants led to missense substitutions, a class of mutations for which it is difficult to assign functional effect. Our case is a first report of *THOC2* splice site mutation in which lead to intron retention resulted in introducing premature termination codon. The fact that his mother with whom carrying heterozygous variant had skewed X-inactivation indicate strongly the pathogenesis of the variant. Since our case appeared unique phenotype, decrease of normal mRNA expression may concern an important role of neuronal development, and it would be a key of unraveling the function of *THOC2* in the central nervous system.

**Guidelines for phenylbutyrate drug levels in the management of urea cycle disorders.** *Y. Jiang<sup>1</sup>, M. Almannai<sup>2</sup>, R. Sutton<sup>1,2</sup>, Q. Sun<sup>1,2</sup>, S. Elsea<sup>1,2</sup>.* 1) Biochemistry Department, Baylor Genetics, Houston, TX; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas.

Urea cycle disorders (UCDs) are heritable conditions that share a common biochemical perturbation of the accumulation of nitrogenous waste in the form of ammonia. UCDs result from a deficiency of one of six enzymes and include a spectrum of phenotypic presentations. Currently, sodium phenylbutyrate and glycerol phenylbutyrate are the primary medications used to treat patients with UCDs, and while a specific therapeutic range has not been determined, it has been demonstrated that phenylbutyrate overdose may result in toxicity. To monitor these drug metabolite levels, a fast and simple ultra-performance liquid chromatography (UPLC-MS/MS) method was developed and validated for quantification of phenylbutyrate (PB), phenylacetate (PA), and phenylacetylglutamine (PAG) in plasma and urine. The separation of all three analytes was achieved in 2 min, and the limits of detection were less than 0.04 µg/ml. Intra-precision and inter-precision were less than 8.5% and 4% at two quality control concentrations, respectively. Average recoveries for all compounds ranged from 100% to 106%. With the developed assay, we evaluated data from 35 patients with confirmed UCDs, including ornithine transcarbamylase deficiency, citrullinemia, argininemia deficiency, argininosuccinate lyase deficiency, carbamoyl phosphate synthetase deficiency, and N-acetylglutamate synthase deficiency, undergoing treatment with phenylbutyrate nitrogen scavengers. A strong correlation between the absolute PA level and the PA/PAG ratio and an inverse correlation between the PA/PAG ratio and glutamine level in plasma were observed. These findings confirm prior studies that the PA/PAG ratio is a good predictor of toxicity. Moreover, all individuals with a PA/PAG ratio  $\geq 0.6$  had plasma glutamine levels  $< 1000$  µmol/L in our study, suggesting that PA/PAG ratios in the range of 0.6 - 1.5 resulted in good control of glutamine levels in all subjects and PA and PA/PAG ratio were well below toxic levels of 500 µg/mL and 2.5. Thus, these data demonstrate that the PA/PAG ratio not only guide therapy to ensure toxic levels are not reached, but may also be considered in optimal dosing for therapeutic effect.

**1040T**

**Novel *de novo* *TAOK1* variants associated with a neurodevelopmental phenotype, macrocephaly, and joint hypermobility.** H.M. McLaughlin<sup>1</sup>, K. Langley<sup>1</sup>, A. Noyes<sup>1</sup>, K. Miller<sup>2</sup>, N. Shur<sup>2</sup>, S. Desai<sup>3</sup>, K. Baranano<sup>3</sup>, A. Schreiber<sup>4</sup>, A. Erwin<sup>4</sup>, A. Blesson<sup>5</sup>, K.W. Gripp<sup>6</sup>, M. Pearson<sup>6</sup>, T. Kleefstra<sup>7</sup>, A. Telegrafii<sup>8</sup>, L. Henderson<sup>1</sup>, K.G. Monaghan<sup>1</sup>, L. Kalsner<sup>8</sup>, J. Juusola<sup>1</sup>. 1) GeneDx, Inc., Gaithersburg, MD; 2) Albany Medical Center, Albany, NY; 3) Kennedy Krieger Institute, Baltimore, MD; 4) Cleveland Clinic Genomic Medicine Institute, Cleveland, OH; 5) Nemours/A.I. DuPont Hospital for Children, Wilmington, DE; 6) District Medical Group, Phoenix, AZ; 7) Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; 8) Connecticut Children's Hospital, Hartford, CT.

The *TAOK1* gene encodes the ubiquitously expressed thousand and one amino acid kinase 1, a Ste20-related mitogen-activated protein kinase kinase (MAP3Ks) (MIM 610266), which maintains mitotic microtubule dynamics, establishes proper chromosome-microtubule attachment, and ensures the accurate segregation of the chromosomes in both mitosis and interphase human cells. Expression of *TAOK1* has been shown to be concentrated in human brain tissue. Reduction of *TAOK1* expression in cells results in the inability to engage the DNA damage-induced G2/M checkpoint in the final attempt to catch cells that have escaped earlier checkpoints. In an attempt to find *de novo* causes for neurodevelopmental disorders, we looked at a total of 9,302 exome cases with a neurodevelopmental phenotype, and identified *TAOK1* as a strong candidate in six individuals with novel *de novo* heterozygous *TAOK1* variants; an additional affected individual was then identified through GeneMatcher. Multiple variant types, including missense, nonsense, frameshift, and splice site variants were identified among the seven unrelated patients. The *de novo* heterozygous presence of these variants suggests an autosomal dominant inheritance pattern. The range of neurodevelopmental concerns reported include severe intellectual disability, autism spectrum disorder, learning disabilities with attention issues, behavior problems, language and motor delays, and slow processing. Additional features reported included neonatal feeding difficulties, hypotonia, macrocephaly, and joint hypermobility. No patient was reported to have a seizure disorder. Two of the seven individuals were heterozygous for an additional *de novo* variant. One individual had a *de novo* variant in *KANK1*, and was the only patient to have multiple facial dysmorphisms, strabismus, and severe intellectual disability with regression. The second *de novo* variant reported was in *NLGN2*, a candidate gene which may also play a role in neurodevelopment. It is unclear if or how these additional variants are impacting the clinical picture. To our knowledge, this is the first report of novel *de novo* variants in *TAOK1* resulting in human disease. While the mechanism by which these variants affect *TAOK1* function has not been fully elucidated, we believe they may be related to the neurodevelopmental concerns, neonatal feeding difficulties, hypotonia, macrocephaly, and joint hypermobility observed in these seven individuals.

**Neurodevelopmental profile for boy with unique 6p deletion.** A. Saba<sup>1</sup>, C. Cappello<sup>1</sup>, A. Ganges<sup>1</sup>, C. Samango-Sprouse<sup>1,2,3</sup>. 1) The Focus Foundation, 820 W Central Ave. #190 Davidsonville, MD 21035; 2) Department of Pediatrics, George Washington University, 2121 I St. NW Washington, DC 20052; 3) Department of Human and Molecular Genetics, Florida International University 11200 SW 8th St. Miami, FL 33199.

**Introduction:** Interstitial 6p deletion syndrome is a very rare neurogenetic disorder that is typically caused by a *de novo* mutation, although in some cases it may be inherited. Phenotypic abnormalities commonly present in multiple areas, including neurodevelopment, ocular, auditory, cardiac, and musculoskeletal. We present a 9-year-old male with 6p21.33-6p22.3 deletion who has Childhood Apraxia of Speech (CAS), language-based learning disorder (LLD), ADHD, and global dyspraxia (GD), with intact nonverbal abilities. **Statement of Purpose:** We describe the neurodevelopmental profile (NDP) of a child with 6p21.33-6p22.3 deletion through serial evaluations to expand the genotypic and phenotypic profile of interstitial 6p deletion syndrome. **Methods:** NDP was assessed annually using Wechsler Scales (WISC), Leiter International Performance Scale-III (LIPS), Expressive (EOW) and Receptive One Word Vocabulary Test-4 (ROW), Bruininks-Oseretsky Test of Motor Proficiency (BOT-2), The Beery-Buktenica Developmental Test of Visual-Motor Integration (Beery), Child Behavioral Checklist (CBCL), and Sensory Profile for Children (SP). **Results:** WISC revealed composite scores of 64 and 82 in verbal comprehension and perceptual reasoning, respectively. On LIPS, mean nonverbal IQ was 83. Discrepancies between verbal and nonverbal abilities, along with his severe speech delays and distortions, support the presence of CAS. Standard scores on EOW and ROW were 79 and 80, respectively, which further support the presence of a receptive and expressive language disorder. Neuromotor assessments revealed GD with deficits in motor planning and coordination. On BOT-2, fine motor control was below the 1st percentile (SS= 22). Visual motor integration (SS = 46) and motor coordination (SS = 52) on the Beery were also below the 1<sup>st</sup> percentile. Total competencies on CBCL were below the 10<sup>th</sup> percentile and in the clinical range (t-score = 26). Sensory disturbances in the visual and auditory systems were indicated on the caregiver SP. **Discussion:** To our knowledge, this is the first reported case of 6p deletion in this chromosomal range associated with NDP findings of CAS, LLD, ADHD, and GD. Further studies on 6p21.33-6p22.3 deletion must be conducted to understand the complexity of the genotypic-phenotypic interaction. Our research further supports the importance of chromosomal microarray when complex learning disorders are present in young children. .

**ARID4A de novo variants identified by exome sequencing among individuals with neurodevelopmental disorders.** K.G. Monaghan<sup>1</sup>, N. Alexander<sup>1</sup>, A. Wilson<sup>2</sup>, A. Iglesias<sup>3</sup>, M. Azage<sup>4</sup>, D.M. Niyazov<sup>5</sup>, E. Moran<sup>6</sup>, J. Pappas<sup>6</sup>, J. Litwin<sup>6</sup>, J.M. Graham, Jr.<sup>7</sup>, K. Klinard<sup>8</sup>, M. Guzsavas-Calikoglu<sup>8</sup>, J. Hoffman<sup>1</sup>, M. Guillen<sup>1</sup>, R. Person<sup>1</sup>, R.E. Schnur<sup>1</sup>, G. Douglas<sup>1</sup>, S. Bale<sup>1</sup>, J. Juusola<sup>1</sup>. 1) GeneDx, Gaithersburg, MD, USA; 2) Children's Hospital of New York-Presbyterian, New York, NY, USA; 3) Division of Clinical Genetics, Department of Pediatrics, Columbia University Medical Center, New York, NY, USA; 4) Ochsner Hospital for Children, New Orleans, LA, USA; 5) NYU Hospital for Joint Diseases, New York, NY, USA; 6) University of California, San Francisco, San Francisco, CA, USA; 7) Department of Pediatrics, Cedars-Sinai Medical Center, Los Angeles, CA, USA; 8) University of North Carolina, Division of Genetics and Metabolism, Department of Pediatrics, Chapel Hill, NC USA.

Clinical exome sequencing (ES) is an effective tool to identify the genetic basis of neurodevelopmental disorders (NDD). Clinical ES was performed on 11,649 probands referred to our laboratory for NDD. Using trio-based ES, we identified de novo *ARID4A* variants in five unrelated individuals. In addition, we identified one individual with a missense variant, but were unable to confirm that it was de novo because the variant nucleotide was present in a small number of next generation sequencing reads in the unaffected father, indicating possible paternal mosaicism. One frame-shift and five missense variants were identified. The missense variants had damaging in-silico predictors and occurred in evolutionarily conserved amino acids. The 6 individuals in this cohort ranged in age from 6-28 years. They all had developmental delays and behavior abnormalities. Other common features included developmental regression (3/6), autism (4/6), and tone abnormalities (4/6). Intellectual disability was assessed and reported in 3 individuals. Two out of 4 individuals tested by brain MRI had brain anomalies (thin corpus callosum, absent septum pellucidum, and holoprocencephaly in one, pontocerebellar atrophy in another). Two patients had facial dysmorphism. *ARID4A*, located at 14q23.1, is ubiquitously expressed and participates with other proteins in epigenetic complexes to regulate genomic imprinting within the Prader-Willi/Angelman syndrome domain. In addition, through binding to the retinoblastoma protein (RB1), *ARID4A* represses transcription activity by serving as an adaptor to recruit histone deacetylases (HDAC) to its N-terminus repression domain-1 and provides a second HDAC-independent repression function at its C-terminus. To date, no sequence variants have been published in the *ARID4A* gene. However, a de novo 14q23.1q23.3 deletion including *ARID4A* was reported in an individual with developmental delay, hypoplasia of the corpus callosum, epilepsy, and neuroblastoma, suggesting a haploinsufficiency mechanism of disease. Our data suggest that de novo variants in *ARID4A* may be associated with a spectrum of clinical features including developmental delay, intellectual disability, autism, behavioral abnormalities, tone abnormalities, and brain anomalies. The findings presented in this case series may facilitate the identification of additional affected patients to further the knowledge regarding the phenotype associated with de novo variants in *ARID4A*.

**1043T**

**De novo missense variant in *CSNK2A1* can cause intellectual disability, behavioral problem, and dysmorphic features: The first male child with Okur-Chung neurodevelopmental syndrome.** M. Akahira-Azuma, Y. Tsurusaki, Y. Enomoto, M. Minatogawa, T. Yokoi, K. Kurosawa. Division of Medical Genetic, Kanagawa Children's Medical Center, Yokohama, Kanagawa, Japan.

Whole exome sequencing lead to elucidate the various kinds of novel genes with intellectual disability (ID). In 2016, Okur and Chung identified de novo heterozygous mutations in the *CSNK2A1* gene in 5 unrelated females with delayed psychomotor development, intellectual disability with poor speech, behavioral abnormalities, cortical malformations in some patients, and variable dysmorphic facial features. This was named Okur-Chung neurodevelopmental syndrome (OCNDS). To our knowledge, additional case was not reported, especially in males. We report on a 7-year and 4-month old Japanese male in severe developmental delay, speech impairment, past hypotonia, short stature, and dysmorphic features including synophrys, hypertrichosis, down-slanting palpebral fissures, and bulbous nose. Chromosome analysis was 46,XY and microarray did not show any abnormal CNVs. Brain MRI revealed delayed myelination in cortex and the decreased volume of pituitary gland. He walked alone at 3 years and started to speak meaningful words and two-phrase words at 6-year and 1-month. His clinical features resembled Coffin-Siris syndrome (histone remodeling complex) and Klefstra syndrome (*EHMT1* variant). At 7-year and 4-month of age, he was socialized at school, behaved hyperactive, spoke two phrases and counted one to 20, walked alone with wide gait, but toilet training was not completed. He had a recurrent, de novo c.A593G, p.K198R variant, which has been described previously by Okur et al. Functional studies of the variant and studies of patient cells were not performed. The mutation was found by whole exome sequencing (WES) and confirmed by trio Sanger sequencing. This is the first male case in OCNDS with a recurrent missense variant. Since Okur described 4 missense mutations and 1 splice site mutation, the mechanism of *CSNK2A1* variant could be the gain of function. In addition, somatic mutations in *CSNK2A1* have been implicated in various cancers. However, it may play a different role in germ line. Since phenotype of OCNDS overlaps with Coffin-Siris syndrome and Klefstra syndrome, we assume that *CSNK2A1* may have similar function as those two syndromes. The functional studies of the variant should be performed to confirm. .

**1044F**

**Exome sequencing links cerebellar malformations to known neurodevelopmental disorders.** K.A. Aldinger<sup>1</sup>, A.E. Timms<sup>2</sup>, V. Chung<sup>1</sup>, D. Doherty<sup>2</sup>, W.B. Dobyns<sup>1,3</sup>. 1) Center for Integrative Brain Research, Seattle Children's Research Institute, Seattle, WA; 2) Center for Developmental Biology and Regenerative Medicine, Seattle Children's Research Institute, Seattle, WA; 3) Department of Pediatrics, University of Washington, Seattle, WA.

Cerebellar malformations are common, heterogeneous birth defects that are associated with significant developmental disabilities, including coordination, intellectual and behavioral deficits, and epilepsy. Both non-genetic prenatal and genetic factors have been implicated in the cause of cerebellar malformations. However, few patients receive a genetic diagnosis and, for many patients, no underlying cause is sought or identified. To address the genetic basis of cerebellar malformations, we performed exome sequencing in 101 families with one or more children diagnosed with Dandy-Walker malformation (DWM) or cerebellar hypoplasia (CBLH). We identified an underlying genetic cause in 41 of 101 families. Among the 49 variants identified, 57% (28/49) were *de novo* and 80% (39/49) were missense; 24% (12/49) of these were already known to be pathogenic mutations. Our results include 28 genes previously associated with neurodevelopmental disorders, including 8 genes with mutations found in more than one patient, and 5 novel genes. Intellectual disability was significantly more frequent in CBLH (80%) than in DWM (59%;  $p=0.035$ ) and significantly more children with CBLH (55%) received a genetic diagnosis than individuals with DWM (26%;  $p=0.0024$ ). Our data show that exome sequencing is a powerful tool for establishing molecular diagnoses for children diagnosed with common cerebellar malformations. We also implicate several new genes in cerebellar development, and show that cerebellar malformations often occur as one component of a broader developmental brain disorder.

**De novo variants at residue 480 in *FAR1* are associated with an autosomal dominant early-onset neurological disorder.** J. Juusola<sup>1</sup>, M.T. Cho<sup>1</sup>, N. Alexander<sup>1</sup>, L. Brady<sup>2</sup>, M. Tamopolsky<sup>2</sup>, S. Sell<sup>3</sup>, R. Ladda<sup>3</sup>, J. Douglas<sup>4</sup>, C. Nowak<sup>5</sup>, E. Ulm<sup>6</sup>, C. Tian<sup>6</sup>, S. Perlman<sup>6</sup>, S. Matsumoto<sup>6</sup>, A. Calhoun<sup>6</sup>, A.V. Drack<sup>6</sup>, R. Person<sup>1</sup>, B. Baskin<sup>1</sup>, M.J. Guillen Sacoto<sup>1</sup>, A. Begtrup<sup>1</sup>. 1) GeneDx, Gaithersburg, MD; 2) Department of Pediatrics, McMaster Children's Hospital, Hamilton, ON; 3) Hershey Medical Center, Hershey, PA; 4) Division of Genetics, Boston Children's Hospital, Boston, MA; 5) Neuromuscular Clinic, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 6) University of Iowa, Iowa City, IA.

Exome sequencing (ES) is an established testing methodology for discovery of new associations between genes and human disorders. Novel inheritance patterns and/or phenotypes can emerge after initial characterization of disease-associated genes. Biallelic loss-of-function variants in *FAR1* have recently been implicated in peroxisomal fatty acyl-CoA reductase-1 disorder, which is an autosomal recessive condition characterized by severe intellectual disability (ID), microcephaly, cataracts, epilepsy, and growth retardation. The *FAR1* gene encodes fatty acyl-CoA reductase-1, which plays a role in plasmalogen biosynthesis by catalyzing the conversion of fatty acyl-CoA into a fatty alcohol. Analysis of 19,679 ES trios identified five probands with heterozygous *de novo* variants in the well-conserved amino acid residue 480 in *FAR1*. The *de novo* variants observed in our cases are p.Arg480His (c.1439G>A) (2 cases), p.Arg480Cys (c.1438C>T) (2 cases), and p.Arg480Leu (c.1439G>T) (1 case), none of which were observed in ExAC. The probands range in ages from 3.5 years to 6 years and have many features in common with those of the newly described recessive *FAR1* syndrome, such as spasticity (5/5), cataracts (4/5), and seizures (3/5). However, they have normal brain MRIs, no growth restriction, ID in only 2/5, and 2/4 actually have macrocephaly. All five probands display significant neurological symptoms including spastic di/paraplegia, ankle clonus, and hypo/hypertonia. As a result, they have gait abnormalities and are unable to walk independently (4/5) or are unable to walk at all (1/5). It is possible that heterozygous missense variants at the 480 residue variants confer a gain of function mechanism, rather than the loss of function resulting from biallelic variants. The features of this newly proposed autosomal dominant condition overlap with the recessive condition but appear to potentially differ in some aspects as well. Additional research on the effects of variants in *FAR1* is needed to further elucidate the clinical features and mechanism(s) of pathogenic variants.

## 1046T

**Alpha-thalassemia X-linked intellectual disability (ATRX) syndrome in a Colombian patient.** A. Paredes, J. Rojas. Instituto de Genética Humana, Pontificia Universidad Javeriana, Bogota D.C, Colombia.

**Introduction:** Alpha-thalassemia X-linked intellectual disability syndrome is rare genetic disorder caused by mutations on ATRX gene, mapped on Xq21 chromosome, encodes a protein that participates in the pattern of DNA methylation, but is still unclear its association with pathological phenotypes. Characteristically, patients have small head circumference, telecanthus, short nose, tented upper lip, genital anomalies, severe developmental delays, hypotonia, intellectual disability, and alpha-thalassemia. Detection of alpha thalassemia, molecular and functional studies confirm diagnosis, allows monitoring of thalassemia and gastroesophageal reflux, major comorbidities that can cause death. **Case Report:** We present a male patient of 3 years old, referred for study of perineoscrotal hypospadias, microtia, marked global neurodevelopmental delay, behavioral disorder within autistic spectrum and pulmonary hypertension. He has CGHarray, G-banded karyotype 46,XY, brain MRI and echocardiogram normal, abdominal ultrasound reports left renal pyelectasis. Familiar history, two maternal cousins in second grade, one with autism and the other one with hypospadias. We performed the whole exome sequence analysis which reports a variant hemizygous c.2519G>T (pR840I) in ATRX gen. **Discussion:** Prevalence of Alpha-thalassemia X-linked intellectual disability syndrome is not known, results from mutation in ATRX gene, which encodes a protein that belong to the SWI/SNF family of chromatin remodeling proteins, causing abnormalities in the pattern of ADN methylation. The variant c.2519G>T (pR840I) in ATRX gen was identified in this patient; is already recognized in different populations. It is located in the helicase domain, theoretically can lead to delayed psychomotor development together with mild urogenital abnormalities. Mutations in this domain are associated with milder phenotypes than mutations in the PHD-like domain. But due to its unknown prevalence and low knowledge we bring this case report. **Conclusion:** This patient has a variant classified as Variant of Uncertain Significance (VUS) by in silico analysis, however the clinical record of the patient agrees with the phenotype described according to literature reviews, whereby we consider the patient have Mental retardation-syndrome, X-linked caused by mutation in the ATRX gene. The knowledge and early diagnosis of this syndrome could prevent deaths caused by symptoms that can be monitored and management.

## 1047F

**Mutations in *DDX3X* are a common cause of syndromic intellectual disability.** X. Wang<sup>1,2</sup>, J. Rosenfeld<sup>1</sup>, C. Bacino<sup>1,3</sup>, B. Graham<sup>1,3</sup>, P. Moretti<sup>1,4</sup>, F. Scaglia<sup>1,3</sup>, L. Immken<sup>5</sup>, J. Harris<sup>5</sup>, S. Hickey<sup>6,7</sup>, T. Mosher<sup>7</sup>, A. Slavotinek<sup>8</sup>, J. Zhang<sup>2</sup>, J. Beuten<sup>2</sup>, M. Leduc<sup>1,2</sup>, W. He<sup>2</sup>, V. Vetrini<sup>2</sup>, M. Walkiewicz<sup>1,2</sup>, W. Bi<sup>1,2</sup>, R. Xiao<sup>1,2</sup>, Y. Shao<sup>1,2</sup>, D. Muzny<sup>1,9</sup>, R. Gibbs<sup>1,9</sup>, M. Eldomery<sup>1</sup>, Z. Akdemir<sup>1</sup>, T. Harel<sup>1</sup>, J. Posey<sup>1</sup>, J. Lupski<sup>1,9</sup>, C. Eng<sup>1,2</sup>, F. Xia<sup>1,2</sup>, Y. Yang<sup>1,2</sup>, members of the UDN. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Genetics, Houston, TX; 3) Texas Children's Hospital, Houston, TX; 4) Neurology, Baylor College of Medicine, Houston, TX; 5) Specially for Children, Austin, TX; 6) Clinical Pediatrics, the Ohio State University, Columbus, OH; 7) Division of Molecular & Human Genetics, Nationwide Children's Hospital, Columbus, OH; 8) Clinical Pediatrics, University of California, San Francisco, CA; 9) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX.

Pathogenic variants in the *DDX3X* (Xp11.4) gene have been recently reported to cause syndromic intellectual disability (ID) patients predominantly affecting females (38 patients, PMID: 26235985). Here we report 26 individuals with *DDX3X*-related disorders in a cohort of 4839 patients with developmental disorders. Among the 4839 (2152 females, 2687 males) patients referred to our laboratory for clinical whole exome sequencing and had developmental delay (DD) and/or ID, 26 (24 female and 2 male) have pathogenic or likely pathogenic variants in *DDX3X*. A total of 25 unique variants were identified (23 novel and 2 reported previously in patients with ID). The 25 variants include 10 missense, 6 frameshift, 3 splice site, 4 nonsense, and 2 in-frame deletion/duplication changes. In 24 patients, the *DDX3X* variants were confirmed as *de novo*, supporting the variant pathogenicity. Two of the *de novo* variants are mosaic with allele frequencies of 14% and 21% (mutant reads/total reads, 19/137 and 69/327). Altogether, *DDX3X* ranks the third among approximately 450 genes with *de novo* variants in our laboratory (*ARID1B* the first, 43 patients; *ANKRD11* the second, 29 patients). The most frequent clinical presentations for the 24 female patients include DD and/or ID (24/24), hypotonia (17/24), dysmorphic features (17/24), structural brain abnormalities (15/24), movement disorder (15/24), visual impairments (8/24), microcephaly (6/24), and autism spectrum disorder (5/24). Some of these patients had respiratory problems (5/24) and congenital heart disease (4/24), which were not previously reported. Mitochondrial DNA depletion was found in two patients undergoing muscle biopsies, which is another feature that has not been described. On the other hand, skin abnormalities (3/24) are underrepresented in our cohort, in comparison to previous publications (14/38). In addition, we report for the first time a male patient carrying a *de novo* variant. He had phenotypes more severe than that of the reported male patients with inherited variants in *DDX3X*. In summary we identified 26 unrelated patients with causal variants in *DDX3X* and expanded the genotypic and phenotypic spectrum of *DDX3X* related disorders. The collective data suggest that *DDX3X* defects are a frequent cause of syndromic ID in female patients and the causal variants are likely to be loss-of-function.

**1048W**

**It does not have to be the whole exome: Mendeliome sequencing increases the diagnostic yield in patients with unexplained intellectual disability by 30%.** A. Rump<sup>1</sup>, L. Gieldon<sup>1</sup>, L. Mackenroth<sup>1</sup>, A. Kahlert<sup>1</sup>, J. Lemke<sup>2</sup>, K. Hackmann<sup>1</sup>, A. Krueger<sup>1</sup>, F. Kuhlee<sup>1</sup>, F. Stuebner<sup>1</sup>, A. Tzschach<sup>1</sup>, A. Schrock<sup>1</sup>, N. Di Donato<sup>1</sup>. 1) University of Technology Dresden, Institute for Clinical Genetics, Germany; 2) Institute of Human Genetics, University Clinic Leipzig, Germany.

**Introduction** Advances in deciphering the genetic causes for impaired development have always been accompanied by advances in technology. In the past, array-CGH technology has boosted the detection rate significantly; but up to 50% of children with developmental delay still remain undiagnosed. Since the latest technological advance, next generation sequencing (NGS), has the power to improve the diagnostic yield tremendously, we applied this method to 108 index patients with developmental delay or intellectual disability (ID) and pre-excluded genomic imbalances. **Method** Genomic DNA samples of 80 parent-patient trios plus 28 individual patients were analyzed for mutations in 4813 genes, using the TruSight-One gene panel on the MiSeq platform (Illumina, San Diego, CA). After sequencing with median target coverage of 80-fold and mapping to hg19, sequence variants were called with the CLC Biomedical Genomics Workbench (Qiagen, Hilden, Germany). All *de novo* variants, homozygous variants with heterozygosity in both parents and compound heterozygous variants were analyzed as well as hemizygous variants in male patients. These variants were screened for clinical and molecular concordance (i.e. disease-association of the gene, published mutation). In addition, all splice-relevant variants, all frameshift and nonsense-mutations were screened for clinical concordance. The results were discussed in a team of clinicians and molecular geneticists, relevant variants were validated by Sanger-sequencing. **Results** Using the mendeliome in a diagnostic setting, we established a diagnosis in 33 of the 108 index patients (30%). For 12 further patients, we found one or two possibly causative candidates (11%). Five patients (4.6%) showed incidental findings which either made treatment or surveillance necessary. (e.g. homozygous *MUTYH*-mutations, *SDHA*-mutation). Nine patients (8%) have been identified to be carriers for a recessive disease (*PAH*- or *CFTR*-mutations). **Conclusion** Mendeliome next generation sequencing significantly increases the diagnostic yield in patients with ID unsolved by previous routine testing (array-CGH, conventional karyotyping) by at least 30%. However, variant interpretation remains challenging and calls for national and international data exchange and establishment of in vitro pipelines for variant evaluation.

**1049T**

**Exploring the therapeutic potential of CRISPR/Cas9 technology for the treatment of MeCP2 duplication syndrome.** E. Maino<sup>1,2</sup>, E.A. Ivakine<sup>1</sup>, R.D. Cohn<sup>1,2,3</sup>. 1) Program in Genetics and Genome Biology, The Hospital for Sick Children Research Institute, Toronto, Canada; 2) Department of Molecular Genetics, University of Toronto, Canada; 3) Department of Paediatrics, University of Toronto and The Hospital for Sick Children, Toronto, Canada.

Methyl-CpG-binding protein 2 (MeCP2) is a multifunctional chromatin protein required for the maintenance of neuronal functions. Duplications of the chromosomal region containing *MeCP2* gene drive the onset of MeCP2 Duplication Syndrome, an ultra rare X-linked condition, characterized by severe intellectual disability, motor dysfunction, recurrent respiratory tract infections and limited life expectancy. As of today, no suitable animal models of the disease are available, hampering the understanding of the disease pathogenesis and limiting the development of novel therapeutical strategies. To study MeCP2 Duplication Syndrome, I am generating the very first mouse model that recapitulates a patient duplication mutation, employing the new CRISVar technology. Based on this mouse model, I will then design a CRISPR/Cas9-one guide approach, recently proven effective in patients' cells by our group, aiming to remove the duplication and to improve disease outcomes. The ultimate long-term goal of the project is to develop gene editing strategies for treatment of MeCP2 Duplication patients, which can be translated to other genetic disorders caused by gene duplications. .

**1050F**

**A 10q23.31 microduplication is associated to autosomal dominant primary microcephaly.** *D. Oliveira<sup>1</sup>, G.F. Leal<sup>2</sup>, L.C. Caires<sup>3</sup>, E. Goulart<sup>1</sup>, C.M. Musso<sup>4</sup>, K. Silva<sup>1</sup>, A.L. Sertié<sup>1</sup>, J.R. Oliveira<sup>1</sup>, A.V. Krepischir<sup>1</sup>, A.M Vianna-Morgante<sup>1</sup>, M. Zatz<sup>1</sup>.* 1) Instituto de Biociências, Universidade de Sao Paulo, São Paulo, Brasil; 2) Instituto de Medicina Integral Professor Fernando Figueira, Recife, Pernambuco, Brasil; 3) Hospital Israelita Albert Einstein, São Paulo, Brasil; 4) Departamento de Neuropsiquiatria, Universidade Federal de Pernambuco, Recife, Pernambuco, Brasil.

A family with an autosomal dominant pattern of inheritance of primary microcephaly has been studied clinically and molecularly. The proband was born to a nonconsanguineous couple, from an uneventful pregnancy. He attended to school, but dropped out of it by the middle of primary course. Nevertheless, he was able to read and presented normal social skills. His OFC circumference was below the second percentile (SD < 2). Apart from him, his family consists of two other individuals with similar clinical profiles (his mother and sister) and a brother and father with normal head circumferences. Aiming to better understand the biological basis of microcephaly in these individuals, G banding karyotype was performed, but showed no abnormalities. DNA samples of the three affected and two normal patients were evaluated through array comparative genome hybridization (*SurePrint G3 Human CGH Microarray, Agilent Technologies*). This analysis identified a 382 kb duplication in 10q23.31, segregating with microcephaly and absent in the two normal individuals. This chromosomal alteration, which has not been associated to autosomal dominant primary microcephaly yet, was observed as very rare, due to its absence in public databases of general population (Database of Genomic Variants- DGV; <http://projects.tcag.ca/variation/>). Additionally, according to DECIPHER (<http://decipher.sanger.ac.uk/>), there have been described only patients with microdeletions in this region, with a variable overlapping with the copy number variation here presented. The 10q23.31 duplication involves entirely two genes, *PTEN* and *KLLN1*, and partially two others, *PAPSS2* and *ADA1A*. After informed consent, skin biopsies of two affected individuals were taken and employed for establishing a primary cell culture of fibroblasts. Functional studies are underway in order to better understand the molecular implications of this novel chromosomal microduplication.

**1051W**

**A missense mutation in the CRBN gene that segregates with intellectual disability and self-mutilating behaviour in a consanguineous Saudi family.** *A. Sheereen<sup>1</sup>, M. Alaamery<sup>1</sup>, S. Bawazeer<sup>1</sup>, Y. AlYafee<sup>1</sup>, S. Massadeh<sup>1</sup>, W. Eyaïd<sup>2</sup>.* 1) Developmental Medicine Department, King Abdullah International Medical Research Centre, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia; 2) Department of Pediatrics, King Abdulaziz Medical City (KAMC); Ministry of National Guard-Health Affairs (MNGHA), Riyadh, Saudi Arabia.

**Background** Autosomal recessive non-syndromic intellectual disability (ARNS-ID) is an etiologically heterogeneous disorder. Although little is known about the function of human cereblon (CRBN), its relationship to mild cognitive deficits suggests that it is involved in the fundamental processes of human memory and learning. **Objectives** We aim to identify the genetic cause of intellectual disability and self-mutilation in a consanguineous Saudi family with five affected members. **Methods** Clinical whole-exome sequencing was performed on the proband patient, and Sanger sequencing was done to validate and confirm segregation in other family members. **Results** A missense variant (c.1171T>C) in the CRBN gene was identified in five individuals with a severe intellectual disability (ID) in a consanguineous Saudi family. The homozygous variant was co-segregating in the family with the phenotype of severe ID, seizures and self-mutilating behaviour. The missense mutation (p.C391R) reported here results in the replacement of a conserved cysteine residue by an arginine in the CULT (cereblon domain of unknown activity, binding cellular ligands and thalidomide) domain of CRBN, which contains a zinc-binding site. **Conclusions** These findings thus contribute to a growing list of ID disorders caused by CRBN mutations, broaden the spectrum of phenotypes attributable to ARNS-ID and provide new insight into genotype–phenotype correlations between CRBN mutations and the aetiology of ARNS-ID.

**1052T**

**Novel *AHDC1* mutations cause intellectual disability and developmental delay.** Y. Tsurusaki<sup>1</sup>, Y. Enomoto<sup>1</sup>, K. Ida<sup>2</sup>, K. Kurosawa<sup>2</sup>. 1) Clinical Research Institute, Kanagawa Children's Medical Center, Yokohama, Japan; 2) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Japan.

Intellectual disability (ID) is a neurodevelopmental disorder that is characterized by significant limitations in intellectual functioning and adaptive behavior that are apparent before 18 years of age. An IQ score of less than 70 is characteristic. The prevalence of ID has been estimated at 1% of the worldwide population. To date, more than 700 causative genes have been reported for all forms of ID. To elucidate genetic causes in ID and developmental delay, we performed targeted resequencing using a TruSight One Sequencing Panel or whole exome sequencing in two unrelated Japanese pedigrees including a total of three patients. Genomic DNA libraries were sequenced using MiSeq with 151-bp paired-end reads or HiSeq2500 with 101 bp paired-end reads. Mapping to human genome hg19 was performed using Burrows-Wheeler Alignment. Aligned reads were processed by Picard to remove PCR duplicates. Variants were called using the Genome Analysis Toolkit, and annotated by ANNOVAR. Copy number variation analysis was performed using the log<sub>2</sub> ratio of read depth derived from next generation sequencing data. We found that *AHDC1* were mutated in a patient from a family. The novel heterozygous mutation c.1167\_1168insATAG (p.Pro390Ilefs\*128) confirmed in both the patient and his affected brother by Sanger sequencing, but this mutation was not identified in either of the parents. To investigate the mosaicism, we further performed deep resequencing for this mutation using Nextera DNA Library Preparation Kit. Somatic mosaicism was confirmed in the mother in her saliva and blood, respectively. Furthermore, we found 1.86Mb deletions at 1p36.11–p35.3 involving *AHDC1* in a patient from another family. Our study demonstrated that *AHDC1* mutations can cause intellectual disability and developmental delay and the diagnostic utility of next generation sequencing technologies is obvious.

**1053F**

**Mutation in *OASL* gene causing speech delay and intellectual disability.** M. Alfadhel<sup>1</sup>, A. Alasser<sup>2</sup>, W. Alharbi<sup>2</sup>, S. Al Ghamdi<sup>2</sup>. 1) Genetic Division, Department of Pediatrics, King Abdullah Specialized Children's Hospital, King Abdul Aziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia; 2) Medical Genomics Research Department, King Abdullah International Medical Research Centre, King Abdul Aziz Medical City, Ministry of National Guard Health Affairs, Riyadh, Saudi Arabia.

**Background:** *OASL* (oligoadenylate synthase-like) encodes an interferon-induced protein that is a member of the 2-5A synthetase family. 2-prime,5-prime oligoadenylates (2-5As) bind to and activate RNase L (180435), resulting in general RNA degradation and consequent inhibition of protein synthesis. 2-5As are produced by a well-conserved family of interferon-induced enzymes, the 2-5A synthetases or OASs. **Methods:** Whole exome sequencing followed by RNA sequencing. **Results:** The phenotype is a neuropsychiatric disorder characterized by speech delay, intellectual disability and autistic behavior. MRI scan of the brain showed no abnormalities. Whole exome sequencing revealed a homozygous non-sense mutation in *OASL* gene as follows: c.1054C>T/p.Arg352X **Conclusion:** We report the first human case of a biallelic truncation of the *OASL* gene, and alert clinicians to consider this novel gene variant in any patient with speech delay.

## 1054W

**Only genotype-first approach permits *BRWD3* mutations' diagnosis.** J. Delanne<sup>1,2,3,4</sup>, M. Lecat<sup>1</sup>, P. Blackburn<sup>5,6</sup>, E. Klee<sup>7</sup>, C. Stumpel<sup>8</sup>, S. Philippe<sup>3,4</sup>, L. Faivre<sup>2,3,4</sup>, C. Thauvin-Robinet<sup>1,2,3,4</sup>. 1) Centre de Génétique et Centre de référence « Anomalies du Développement et Syndromes Malformatifs », Hôpital d'Enfants, Centre hospitalier universitaire de Dijon, Dijon, France; 2) Laboratoire de Génétique chromosomique et moléculaire, UF Innovation en diagnostic génomique des maladies rares, Centre Hospitalier Universitaire de Dijon, Dijon, France; 3) Fédération Hospitalo-Universitaire Médecine Translationnelle et Anomalies du Développement (FHU TRANSLAD), Centre Hospitalier Universitaire de Dijon et Université de Bourgogne-Franche Comté, Dijon, France; 4) UMR-Inserm 1231 GAD team, Génétique des Anomalies du développement, Université de Bourgogne Franche-Comté, F-21000 Dijon, France; 5) Center for Individualized Medicine, Mayo Clinic, Jacksonville, Florida 32224, USA; 6) Department of Health Sciences Research, Mayo Clinic, Jacksonville, Florida 32224, USA; 7) Department of Health Sciences Research, Mayo Clinic, Rochester, MN; 8) Department of Clinical Genetics and School for Oncology and Developmental Biology (GROW), Maastricht University Medical Center (MUMC), Maastricht, The Netherlands; 9) Institute for Genomic Medicine, Columbia University, New York, NY 10032, USA; 10) Assistance Publique-Hôpitaux de Paris, Département de Génétique, Hôpital Pitié-Salpêtrière, Paris, France; 11) Department of Neurogenetics, Kennedy Krieger Institute, Baltimore, Maryland, 21205.

Since first description of *BRWD3* related phenotype in 2007, only two additional families have been reported with intellectual Disability (ID). Because phenotype appeared nonspecific, only genotype first approach could allow identifying new *BRWD3* variants. Indeed, using whole exome sequencing (WES) and international datasharing, we identified six new unrelated cases with *BRWD3* variant (4 males and 2 females). X-inactivation study performed in 1/2 female cases showed skewed X inactivation (100%/0%). Reviewing the 9 previously cases published in the literature, we describe the phenotype of 13 males and 2 females with *BRWD3* variant, representing 10 different variants (6 truncating variants and 4 missenses). Most common features in males (excluding the one with the mosaic variant) included ID (11/12 cases), speech delay (11/12 cases), macrocephaly with high forehead (9/12 cases), long face due to pointed chin (8/12 cases), shyness (6/12 cases), large fingers or toes (6/12 cases), and large ears (5/12 cases). Both females presented with macrocephaly and speech delay, as well as epilepsy that was only reported in one other male. Among these 15 cases, 10 variants (all in males) were maternally inherited from unaffected mothers and 5 cases occurred *de novo* (including the 2 females and the male with a mosaic variant). In males, the 8 *BRWD3* variants included 3 frameshifts (including 1 in mosaic), 1 stop-gained, 1 partial deletion and 3 missenses. When one female had a frameshift, the other presented a missense in the WD40 containing repeat domain with complete X-skewed inactivation. Macrocephaly was absent in both patients with missense variants but was present in all patients with truncating variants. This study evidences that the *BRWD3* related phenotype with ID, behavioural disturbances and macrocephaly could affect males and females, remaining mainly unspecific and hardly recognizable for clinicians. Only genotype-first approach permits *BRWD3* mutations' diagnosis. This fine clinical description will be so helpful for reverse phenotyping after whole exome/genome sequencing.

## 1055T

**Attempts to elucidate role of *ZBTB11* gene as a novel candidate gene in intellectual disability.** Z. Fattahi<sup>1</sup>, T. Sheikh<sup>2</sup>, K. Kahrizi<sup>2</sup>, R. Harripaul<sup>3</sup>, F. Larti<sup>4</sup>, N. Bazazzadegan<sup>1</sup>, M. Haddadi<sup>3</sup>, M. Ansari<sup>4</sup>, H.H. Ropers<sup>5</sup>, J.B. Vincent<sup>6</sup>, H. Najmabadi<sup>1</sup>. 1) Genetics Research Centre, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran, Islamic Republic of; 2) Molecular Neuropsychiatry & Development (MiND) Lab, Campbell Family Mental Health Research Institute, Center for Addiction and Mental Health, Toronto, ON, Canada; 3) Department of Biology, Faculty of Science, University of Zabol, Zabol, Iran, Islamic Republic of; 4) Department of Biochemistry, Quaid-i-Azam University, Islamabad, Pakistan; 5) Department of Human Molecular Genetics, Max Planck Institute for Molecular Genetics, Berlin, Germany.

Exploring genes and pathways underlying Intellectual Disability (ID) can provide insights into brain development and function clarifying the complex puzzle of how cognition develops. Nowadays, gene discovery is not a rate-limiting step in ID but biological interpretation of the identified mutations seems indispensable. As part of ongoing systematic studies to identify candidate ID genes, linkage analysis and next generation sequencing revealed *ZBTB11*, as a novel candidate ID gene, in two consanguineous families. *ZBTB11* encodes an understudied transcription repressor and as predicted by three-dimensional modeling, the two identified variants (p.H729Y, p.H880Q) disrupt canonical Zn2+-binding residues of C2H2 zinc finger domains, leading to possible altered DNA binding. This prediction was proved by localization study performed in HEK293T cells transfected by wild-type/mutant *ZBTB11*-GFP constructs. We found abolished localization for mutants being excluded from the nucleolus where the wild-type recombinant protein is localized. Next, exploring target genes and pathways, ChIP-sequencing was performed. Although ChIP-sequencing results did not fulfill quality criteria, the enriched pathways and biological functions detected with the help of ENCODE data of HEK293 stably expressing eGFP-*ZBTB11* is in concordance with its nucleolus localization. The genes with "ribonucleoprotein complex binding" GO molecular function are enriched indicating fundamental role of this gene in cellular pathways. This provides another evidence for the role of mutated *ZBTB11* in ID, since abnormal nucleoli is considered as one of the hallmarks in some developmental disorders with ID. Recently, it is shown that this gene is widely expressed in Zebrafish early development that remains in nervous system afterwards. The zebrafish mutant has shown brain and spinal cord degeneration with prominent apoptosis of central nervous system. In order to provide another model, we started to investigate *ZBTB11*-ortholog in *Drosophila* brain by targeting RNAi using UAS/Gal4 system. The *drosophila* F1 offspring with lower expression of *ZBTB11*-ortholog in brain were generated. Immunofluorescence study of mushroom bodies in *drosophila*'s brain revealed no prominent structural changes, not excluding the presence of subtle changes but proposing the involvement of *ZBTB11* in more basic pathways that should be assessed by the upcoming behavior assays. In conclusion, this study elucidates involvement of *ZBTB11* in ID.

**Inositol monophosphatase 1 (IMPA1) deficiency and cognitive impairment.** T. Figueiredo<sup>1</sup>, C.P. Walker<sup>2</sup>, G.S. Kobayashi<sup>1</sup>, A. Pessoa<sup>3</sup>, P. Nóbrega<sup>4</sup>, U.S. Melo<sup>5</sup>, D.F. Oliveira<sup>1</sup>, N. Murphy<sup>2</sup>, M. Rafferty<sup>2</sup>, F. Kok<sup>1</sup>, R. Cho<sup>2</sup>, S. Santos<sup>2</sup>, M. Zatz<sup>1</sup>. 1) Human Genoma and Stem Cell Research Center, Biosciences Institute, University of São Paulo, São Paulo, Brazil; 2) Psychiatry, University of Texas Health Science Center at Houston, Houston, TX, USA; 3) Neurology Department, State University of Ceará, Fortaleza, Brazil; 4) Neurology Department, Federal University of Ceará, Fortaleza, Brazil; 5) Centre for Public Health Research, Paraíba State University, Campina Grande, Brazil.

Dysfunctions of the inositol cycle has been implicated in a wide variety of human diseases including developmental defects and neurological diseases. IMPA1 has attracted much interest in genetic studies of neuropsychiatric diseases because in therapeutic concentrations, lithium, the main pharmacological treatment for bipolar disorder it is an uncompetitive inhibitor of IMPA1. Although animal models and *in vitro* analysis have contributed to the understanding of the pathophysiology of IMPA1 deficiency, no human disease had been attributed to a malfunction of this protein. We identified a homozygous 5 bp duplication (c.489\_483dupGGGCT) in *IMPA1*, leading to a frameshift (p.Ser165Trpfs\*10), in a consanguineous family with severe intellectual disability and disruptive behaviors from geographically isolated and very poor region of Northeastern Brazil (Figueiredo *et al.*, 2015). The *IMPA1* mutation generates a restriction site for the *BseYI* enzyme (New England BioLabs), allowing to identify three different bands patterns according to the three different genotypes. We investigated the mutation in 69 family members and identified: 9 affected homozygotes (AH), 21 heterozygotes (HET) and 39 normal homozygotes (NH). Next, we investigated resting Electroencephalogram (EEG) data from 30 participants (17 NH, 9 HET, 4 AH). Brain Magnetic Resonance Imaging revealed no structural abnormalities in affected individual. In resting conditions we observed a parametric reduction in  $\alpha$ - and  $\beta$ -band power over right frontal and temporal scalp regions (i.e., WT > HET > HOM). Eyes-closed dominant gamma2 frequency and  $\gamma_1$  and  $\gamma_2$  variability demonstrated a parametric increase across groups in frontal electrodes (i.e., WT < HET < HOM). This pattern is consistent with *IMPA1* mRNA expression patterns which show higher expression in subcortical and prefrontal brain regions. This data suggests that the loss of function associated with *IMPA1* mutation may be related to impaired regulatory mechanisms (i.e.,  $\alpha/\beta$  activity) with subsequent dysregulation of high frequency synchrony. We have now generated induced pluripotent stem cells (iPSCs) from affected patients blood samples to further investigate the effects of mutation on disruption of signaling pathway networks and morphofunctional characteristics in neuronal cell derived from iPSCs. Funding: FAPESP, CNPq and FAPESQ. .

**A novel pathogenic variant of the *HECW2* gene in a Japanese boy with global developmental delay, hypotonia, and short stature.** M. Minatogawa<sup>1</sup>, M. Maeda<sup>2</sup>, K. Yanagi<sup>1</sup>, K. Hata<sup>3</sup>, Y. Matsubara<sup>4</sup>, T. Kaname<sup>1</sup>. 1) Genome Medicine, National Center for Child Health and Development, Tokyo, Japan; 2) Saga Handicapped Children's Hospital, Saga, Japan; 3) Maternal-Fetal Biology, National Center for Child Health and Development, Tokyo, Japan; 4) National Center for Child Health and Development, Tokyo, Japan.

**Background:** Exome sequencing is an effective strategy to identify genetic causes of developmental delay, intellectual disabilities (ID), and congenital anomalies. Recently, it has been reported that loss-of-function variants of *HECW2* gene are assumed to be responsible for neurodevelopmental disorder with hypotonia, seizures, and absent language [Berko *et al.*, 2017]. We report on a Japanese boy with global developmental delay, autism spectrum disorder, hypotonia, short stature, and mild dysmorphic facial features associated with a novel variant in the *HECW2* gene. **Case Report:** The proband was a 5-year-old male. He was born at 40 weeks of gestation by normal delivery after uneventful pregnancy. His birth weight was 2998 g, and his length was 48.2 cm. He presented with global developmental delay, hypotonia, and feeding difficulties in his infancy. On closer clinical examination at the age of 1 year old, nothing was to be found but brain MRI revealed arachnoid cysts in both of the middle cranial fossa. G-Banded karyotype showed a normal male karyotype 46,XY. At the age of 5 years, he was referred to our hospital to determine the existence of the underlying disease. At that time, he also showed short stature 99cm (-2.0 SD), mid-facial hypoplasia, autism spectrum disorder, and severe constipation. **Methods:** Written informed consent was obtained from his parents. Whole exome sequencing was performed using Human All Exon V6 kit (Agilent) and Hiseq 2500 (Illumina). The detected variants were confirmed by Sanger sequences. **Results:** A novel heterozygous missense variant was detected. The variant was *de novo* and was not found in the variant database, such as 1000Genome, dbSNP and ExAC. The variant lies within the HECT domain of the protein. **Conclusion:** We found the novel variant in the *HECW2* gene related to neurodevelopmental disorder. A few cases of neurodevelopmental disorder caused by the pathogenic variants of *HECW2* have been reported. It has not been known well about the pathogenic variants specific mechanisms. To reveal the phenotypes associated with *HECW2* variants required further analysis. Our report of phenotypes data on the case will be helpful to establish the *HECW2* related disorder.

**De novo LoF mutations in *MED12* cause a syndromic form of X-linked ID in females.** D.L. Polla<sup>1</sup>, R.B. Hufnagle<sup>2</sup>, A.T. Vulto-van Silfhout<sup>3</sup>, R. Pfundt<sup>3</sup>, E.M.H.F. Bongers<sup>3</sup>, D. Li<sup>3</sup>, E.J. Bhoj<sup>3</sup>, J.B.G.M. Verheij<sup>3</sup>, J.S. Klein Was-sink-Ruiter<sup>4</sup>, H. van Bokhoven<sup>1</sup>, C. Zweier<sup>5</sup>, A.P.M. de Brouwer<sup>1</sup>. 1) Department of Human Genetics, Donders Institute for Brain, Cognition and Behavior, Radboud University Medical Center, Nijmegen, The Netherlands; 2) Ophthalmic Genetics and Visual Function Branch, National Eye Institute, National Institutes of Health, Bethesda, Maryland, USA; 3) Department of Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands; 4) Department of Medical Genetics, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands; 5) Department of Pediatrics, Division of Human Genetics and Molecular Biology, Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 6) Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany.

Intellectual disability (ID) is a clinically and genetically heterogeneous disorder affecting 2-3% of the general population. There are many genetic and non-genetic causes of ID; the X-linked forms are most intensively studied. Mutations in the X-linked gene *MED12* are known to cause at least three different, but closely related, syndromic intellectual disability disorders in males: Opitz-Kaveggia syndrome, Lujan-Fryns syndrome and Ohdo syndrome. These hemizygous mutations are invariably missense changes suggesting that loss-of-function (LoF) mutations, i.e. nonsense, frame shift, and canonical splice site variants, are likely embryonically lethal. Carrier females in these families are usually not affected. *MED12* is a member of the Mediator complex, a multiprotein complex which has a central role in RNA polymerase II transcription. Mediator regulates signals involved in cell growth, development and differentiation, as well as in the Sonic hedgehog signaling and the extraneuronal gene silencing network. This could explain its role in the different X-linked intellectual disability syndromes. In our study, we found *de novo* LoF mutations in five females, seemingly resulting in an overlap in phenotypic features consisting of ID, speech delay, short stature, tall prominent forehead, low set ears, syndactyly, and severe feeding problems. These features are present in at least four out of the five patients. We hypothesize that even though LoF mutations in males are lethal, LoF mutations in females are not lethal due to X-inactivation and give rise to a clinically distinct intellectual disability phenotype.

**1059F**

**A novel missense variant in the *POMK* gene causes Walker-Warburg syndrome.** E. Preiksaitiene<sup>1</sup>, N. Voisin<sup>2</sup>, L. Gueneau<sup>2</sup>, E. Benušienė<sup>1</sup>, A. Raymond<sup>2</sup>, V. Kučinskas<sup>1</sup>. 1) Department of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 2) Center for Integrative Genomics, University of Lausanne, Lausanne, Switzerland.

Muscular dystrophy-dystroglycanopathy (congenital with brain and eye anomalies) type A, 12, also known as Walker-Warburg syndrome represents the most severe phenotype of dystroglycanopathies (OMIM 615249). We present a new family with three affected individuals manifesting clinical features of Walker-Warburg syndrome due to homozygous nonsense variant in the *POMK* gene. Whereas the first pregnancy of an unrelated Lithuanian couple was uneventful and gave birth to a healthy son, the second pregnancy fetal ultrasound examination at 22-23 weeks of gestation showed internal hydrocephalus of a female fetus. Both infections and molecular genetic tests for aneuploidies were negative. Delivery was induced at 32 weeks of gestation and resulted in a stillbirth with severe hydrocephalus. During the third and fourth pregnancies internal hydrocephalus of male fetuses has been noted at 12-15 weeks of gestation and the pregnancies have been terminated. Exome sequencing of fetal DNA from the third fetus revealed a homozygous nonsense variant c.136C>T (p.(Arg46Ter)) in the *POMK* gene. Sanger sequencing confirmed that this variant was homozygote in the proband and the two other affected siblings and heterozygote in the parents and their healthy son. Only three families with pathogenic variants in the *POMK* gene, causing congenital muscular dystrophy-dystroglycanopathy with brain and eye anomalies have been reported to date. Clinical and molecular findings of this fourth family provide additional details of the phenotypic manifestation of *POMK*-related congenital disorders.

## 1060W

**Clinical heterogeneity in Renpenning Syndrome patients due to c.459\_462del mutation in PQBP1 gene: A case report.** *J. Rojas, A.I Sánchez.* Cundinamarca, Pontificia Universidad Javeriana, Bogota, Cundinamarca, Colombia.

**Introduction:** Mutations in *PQBP1* have been identified in families with non-syndromic X-linked intellectual disability and syndromic cases like Sutherland-Haan, Cerebropalatocardiac, Golabi-Ito-Hall, and Renpenning syndromes (RS) among others. This gene encodes for the polyglutamine tract binding protein1, located in Xp11.2. The most frequently clinical features associated with mutation in *PQBP1* are microcephaly and short stature, however some other characteristics may be seen such as spasticity, small testes, anal atresia or stenosis, cardiac defects, ocular coloboma and cleft palate. RS is a very rare and well-recognized condition of unknown prevalence, characterized by severe cognitive impairment, microcephaly, small stature and hypogonadism. **Case report:** 22 y/o male patient who was the 1st pregnancy of a healthy non-consanguineous couple. Family history was unremarkable. He was born by uncomplicated spontaneous vaginal delivery after a full non-controlled preterm gestation. Birth weight at 36 weeks was 2350g and height was 47cm. Tetralogy of fallot was diagnosed at birth for which he required surgery. Patient was classified as having moderate cognitive impairment. Physical examination revealed microcephaly, prominent ears, long-shaped face, mild facial coarsening and thick lips. Short stature and pectus carinatum were seen with no hypogonadism/small testes. A friendly personality was evident. Karyotype, aCGH and molecular testing for Williams syndrome were negative. Whole exome sequence analysis was performed. A pathogenic hemizygous mutation in *PQBP1* gene was detected: c.459\_462del (p.(Arg153Serfs\*41). Mother was a carrier. **Discussion:** Approximately 80 X-linked genes have been reported associated with intellectual disability. Mutations in *PQBP1* gene have considerable inter and intrafamilial phenotypic variation. This variant has been previously reported as a cause of X-linked intellectual disability and has been reported as a gain-of-function pathogenic mutation that interacts with FMRP protein. This interaction may suggest an overlapping phenotype of our patient and X fragile syndrome patients. It is important to highlight that the typical features of small testes in RS were not seen in this patient, however he present with some dysmorphic features that to our knowledge, have never been reported with this mutation. **Conclusion:** more genotype-phenotype correlation studies are necessary to characterize the whole phenotype of this very rare syndrome. .

## 1061T

**Intellectual disability and macrocephaly in three sisters from a consanguineous marriage with a novel SZT2 homozygous mutation.** *C. Trujillo<sup>1</sup>, M.K. Alwasiyah<sup>2,3</sup>, M.I. Naseer<sup>2</sup>, M. Abu-Elmagd<sup>2</sup>, M.A. Jafri<sup>2</sup>, R.A. Bajamma<sup>2</sup>, A. Chaudhary<sup>2</sup>, H. Bouazziz<sup>4,5</sup>, M. Al-Qahtani<sup>2</sup>.* 1) Erfan and Bagedo Hospital, Jeddah, Saudi Arabia; 2) Center of Excellence in Genomic Medicine Research; Jeddah, Saudi Arabia; 3) Aziziah Maternity & Children Hospital, Jeddah, Saudi Arabia; 4) Research Unit: Epidemiology, Etiology of Congenital Malformations and Therapeutics, Monastir Faculty of Medicine, Tunisian Republic; 5) Hôpital Necker - Enfants Malades, Medical Genetics Laboratory, Paris Descartes University, France.

We have identified a large consanguineous Saudi family with 3 sister presenting a similar clinical picture of developmental delay, intellectual disability, high forehead and macrocephaly.

At 3 years of age we saw the third affected sister. She was the born to first cousins parents, by cesarean section due to macrosomia. Her birth weight was 3600 gr, height 52 cm and Head Circumference 36 cm. Apgar score 8 at one minute and 10 at five minutes. She was discharge with no complaints.

At 3 years of age she was not able to walk or stand or sit without support and she cannot crawl. Her language was practically absent and limited to guttural sounds without words. There was no history of seizures or abnormal movements, although one of the sisters had history of seizure.

Her HC was 51 cm in the 95th percentile, Height was 90 cm in the 10th percentile and her weight 11.5 kg below the 5th percentile.

She did not have dysmorphic features or skin stigmata. Cranial nerves were normal, cardiopulmonary normal, and no abdominal masses or organomegaly. Routine laboratory CBC, thyroid hormone, liver enzymes, creatinine, ammonia, lactic acid etc were normal. Tandem Mass Spectrophotometry was normal Brain MRI showed prominent extra axial CSF space with wide Sylvian fissure, no abnormal signal intensity, no ventriculomegaly, normal corpus callosum, normal posterior fossa and cerebellum.

Exome sequencing was performed in affected siblings of this family and their parents. Whole exome sequencing data analysis, confirmed by subsequent Sanger sequencing validation, identified a novel homozygous mutation c.9368G>A resulting in a substitution of a conserved glycine residue into a glutamic acid in the exon 67 of *SZT2* gene. The mutation was ruled out in 100 unrelated healthy controls. The missense variant detected in this study has not yet been reported as pathogenic in literature or variant databases. Seizure threshold 2 (*SZT2*) gene located on chromosome 1p34.2 encode protein mainly expressed in the parietal, frontal cortex and dorsal root ganglia in the brain. Previous studies in mice showed that mutation in this gene can confers low seizure threshold, enhance epileptogenesis and in human may leads to facial dysmorphism, intellectual disability, seizure and macrocephaly. This homozygous *SZT2* variant might be the causative gene that further explain the ID and developmental delay in this Saudi family.

**1062F**

**The phenotypic spectrum of Xia-Gibbs Syndrome.** Y. Jiang<sup>1,2</sup>, M.F. Wangler<sup>2,3</sup>, A.L. McGuire<sup>4</sup>, J.R. Lupski<sup>1,2,5,6</sup>, J.E. Posey<sup>6</sup>, F. Xia<sup>2</sup>, Q. Meng<sup>1,2</sup>, M. Murgan<sup>1,2</sup>, R.A. Gibbs<sup>1,2</sup>. 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, 77030; 3) Texas Children's Neurological Research Institute, Houston, TX, 77030; 4) Center for Medical Ethics and Health Policy, Houston, TX, 77030; 5) Department of Pediatrics, Baylor College of Medicine, Houston, TX, 77030; 6) Texas Children's Hospital, Houston, TX, 77030.

**Background:** *De novo* truncating mutations of AT-Hook DNA Binding Motif Containing 1 gene (*AHDC1*) lead to Xia-Gibbs Syndrome (XGS: OMIM # 615829). Phenotypes of this disorder were described in an initial report of four probands (Xia et al., 2014: PMID 24791903) and a subsequent report of seven patients (Yang et al., 2015: PMID 27148574), and include intellectual disability, developmental delay, hypotonia, speech delay and dysmorphic features. We have established a Xia-Gibbs Syndrome registry in order to more systematically evaluate the clinical spectrum of XGS through collecting detailed clinical information from patient families. Here we report the aggregate evaluation of the clinical spectrum of a cohort of 19 patients including five individuals previously reported. **Methods:** We obtained institutional review board (IRB) approval at BCM to recruit families to the Xia-Gibbs Syndrome registry. A total of 19 families in the registry submitted a comprehensive clinical survey to allow detailed assessment of phenotypic information. **Results:** This cohort includes 10 male and 9 female patients at a median age of 8 (3~21) years old. Common phenotypes include: intellectual disability (17/19), hypotonia (17/19), speech delay (19/19), ataxia (13/19), sleep apnea (8/19), abnormal MRI (8/19) and strabismus (8/19). We also assessed the age range of patients who achieve the following developmental milestones: the median age for independent walking (16 patients) is 2.5 (1.5~6) years. The median age for using first words (12 patients) is 2.75 (1~5) years and the median age for using two words together (8 patients) is 3.5 (2~7) years. In addition, seven of the 19 patients were reported to have no speech, and all these individuals were male ( $p < 0.01$ ). Seizures were reported in 6 out of 19 patients, with median age-of-onset = 4 years (range: 9months~12 years). Scoliosis was reported in 4 out of 19 patients, an increase rate relative to the general population ( $p < 0.001$ ). **Conclusion:** Data from this cohort have expanded our knowledge of the common phenotypes of XGS and provided further information for developmental milestones. In addition, we identified that XGS patients are at an elevated risk of developing seizures and scoliosis, and male patients are more likely to be non-verbal than females. The ability to aggregate data from the observation and care of individuals with XGS is a key step for clinical management, family counseling and molecular research into the condition.

**1063W**

**Updating penetrance estimates for deletion and duplication syndromes with variable phenotypic manifestation.** J.W. Ahn<sup>1</sup>, A. Corrigan<sup>2</sup>, S. Bint<sup>1</sup>, C. Mackie Ogilvie<sup>2</sup>. 1) Genetics Laboratories, Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom; 2) Genetics Laboratories, Viapath, London, United Kingdom.

Deletion and duplication syndromes that exhibit incomplete penetrance are frequently detected by chromosomal microarray-based testing for copy number variation in the genomes of patients referred for neurodevelopmental disorders. Examples include 1q21.1 (OMIM 612474) and 16p11.2 (OMIM 611913) deletion syndromes, and collectively, these syndromes are often referred to as susceptibility loci, as the expressivity of associated phenotypic traits is highly variable. These syndromes also make up a large proportion of the findings in these patients, e.g. 16p11.2 deletion syndrome represents ~10% of all syndromic findings in this cohort. Due to the clinical importance of this group of syndromes, attempts have been made to estimate penetrance for each of these susceptibility loci, most notably by Rosenfeld et al. (2013; doi:10.1038/gim.2012.164) and Kirov et al. (2014; dx.doi.org/10.1016/j.biopsych.2013.07.022). Respectively, these studies described a diagnostic cohort of ~30,000 cases compared to ~22,000 controls, and ~6800 cases against ~6300 controls. However, both these studies derive penetrance estimates from the incidence of each syndrome, and incidence (number of new cases detected in a given period of time) may vary between populations due to a variety of factors including testing methodology, access to genetic healthcare and population stratification-type effects. The Guy's & St Thomas' Regional Genetics Centre serves a population of ~7 million in South East England and patients referred for neurodevelopmental disorders are routinely tested by chromosomal microarray. We present data for 12 susceptibility loci from a diagnostic cohort of ~30,000 patients. Of these, 11 were found to have a lower incidence than in the diagnostic cohort presented by Rosenfeld et al, and penetrance estimates are accordingly affected. The largest difference was for 1q21.1 duplication syndrome (OMIM 612475) which had a >3-fold reduced incidence in our cohort. These findings have implications for variant interpretation and patient counselling for our diagnostic cohort. Furthermore, they indicate that incidence of these syndromes may also be different in other cohorts, which questions the applicability of previously published estimates across different populations.

**1064T**

**Exome Pool-Seq in neurodevelopmental disorders.** C. Zweier, A. Ekici, C. Thiel, J. Hoyer, A. Wiesener, C. Kraus, A. Reis, B. Popp. Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany.

High throughput sequencing has greatly advanced disease gene identification, especially in heterogeneous entities such as neurodevelopmental disorders (NDDs), comprising intellectual disability (ID) and autism spectrum disorders. Despite falling costs this is still an expensive and laborious technique, particularly when studying large cohorts. To address this problem we developed Exome Pool-Seq as an economic and fast screening technology. Sequencing of 96 individuals can be performed in eight pools of 12 equimolar concentrated samples on less than one Illumina sequencer lane. Calling variants using a ploidy of 24 and performing subsequent validation and segregation analysis by Sanger sequencing, we identified 27 (likely) pathogenic mutations in a pilot study of 96 cases. Twenty five loss-of function or likely pathogenic (previously reported, deleterious prediction) missense variants were identified in 923 established NDD genes (based on SysID database, status November 2016) (*ACTB*, *AHDC1*, *ANKRD11*, *ATP6V1B2*, *ATRX*, *CASK*, *CHD8*, *GNAS*, *IFIH1*, *KCNQ2*, *KMT2A*, *KRAS*, *MAOA*, *MED12*, *MED13L*, *RIT1*, *SETD5*, *SIN3A*, *TCF4*, *TRAPPC11*, *TUBA1A*, *WAC*, *ZBTB18*, *ZMYND11*), two in 543 (SysID) candidate genes (*ZNF292*, *BPTF*), and additionally a *de novo* loss-of-function variant in *LRRC7*, not previously implicated in NDDs. Identified mutations included mainly *de novo*, but also X-linked and autosomal-dominantly or autosomal-recessively inherited variants. With a detection rate of 28 %, Exome Pool-Seq achieves comparable results to individual exome analyses but reduces costs by more than 85 %. Compared to other large scale approaches using Molecular Inversion Probes (MIP) or panels of a predefined set of disease genes, it allows flexible re-analysis of data at any time. Exome Pool-Seq is thus well suited for large-scale, cost-efficient and flexible screening in characterized but heterogeneous entities like NDDs.

**1065F**

**Novel mutation in *ARHGEF9* associated with developmental delay and seizures.** E. Fattakhov<sup>1</sup>, M. Byler<sup>2</sup>, K. Werner<sup>2</sup>, R.R. Lebel<sup>1</sup>. 1) Genetics Section, Upstate Medical University, Syracuse, NY; 2) Neurology Department, Upstate Medical University, Syracuse, NY.

This boy was the product of term delivery after an uncomplicated pregnancy in a 22 year old primigravid woman and her 27 year old non-consanguineous partner, in their native Macedonia. The child presented to genetics clinic at age 3.5 years with global developmental delays. Brain MRI, metabolic panels, and SNP array all had normal/negative results before this evaluation. Our whole exome sequencing revealed an alteration, p.E115K (c.3343G>A), in the *ARHGEF9* gene on the X chromosome. Mother left when child was 2 months of age and is likely still in Macedonia. She was unavailable to determine whether the trait is inherited or *de novo*. Because it has not been reported to date, this alteration is considered to be a variant of uncertain clinical significance. However: the amino acid is highly conserved in vertebrates, the alteration is predicted theoretically to be significant, and it has not been found in a large cohort of persons with normal phenotypes. Further, Table 1 demonstrates a close correspondence of the phenotype to the eight cases reported thus far. The E115K mutation has the potential to modify secondary protein structure, given that glutamine contains a polar neutral side chain, while lysine is a basic electrically charged amino acid. The *ARHGEF9* gene typically encodes functional collybistin, a neuronal GDP-GTP exchange factor. Collybistin has been shown to interact with rapamycin complex 1 (mTORC1), which is vital for neural differentiation in the central nervous system. Furthermore, collybistin binds to the neuronal scaffolding protein gephyrin, which allows for the post-synaptic recruitment of GABA<sub>A</sub> receptors, thus modulating the robustness of inhibitory synapses. We propose that alteration of *ARHGEF9* is the cause of the seizures and the developmental delay in this patient.

**Is incontinentia pigmenti a genetic male disease?** *F. Fusco<sup>1</sup>, R. Sabbatella<sup>1</sup>, V. Valente<sup>1</sup>, D. Fergola<sup>1</sup>, M.B. Lio<sup>2</sup>, M.V. Ursini<sup>1</sup>.* 1) Institute of Genetics and Biophysics "ABT", IGB-CNR, Naples, Italy; 2) University of Basilicata, Potenza, Italy.

Post-zygotic Somatic mosaicism of *NEMO/IKBK*G mutation causes Incontinentia Pigmenti (IP; OMIM#308300) in IP male patients. Indeed, IP is an X-linked dominant disease and generally is lethal in males, and only the females survive. Therefore the transmission of the disease is always from the IP affected mother to the daughter. We report for the first time that IP males are able to transmit their *NEMO/IKBK*G somatic mutation to their IP children by a germline mosaicism for the same mutation. We found this *unusual transmission* of the disease from IP father-to-daughter in two families belonging to the Incontinentia Pigmenti Genetic Biobank, IPGB (<http://www.igb.cnr.it/ipgb>). We report the Family1 with the IP father and his IP-daughter with classical IP signs, both with novel p.Gln132X mutation of *NEMO/IKBK*G and the Family2 with the IP father had two IP-daughters all with the same *NEMO/IKBK*G recurrent exon4-10 deletion. Low level mosaicism for the *NEMO/IKBK*G mutation in the skin (20%; 1%) in the urine (8.3%; 35%) and in germline tissue (16.7%; 35%) was detected in both IP fathers, respectively. We concluded that the somatic mosaicism the IP males includes germline mosaicism that impacts not only on the transmission but also on the recurrence risk of the disease. We are evaluating 38 additional IP males, teenagers belonging to our IPGB biobank testing them for mosaicism which represent a helpful tool in the genetic counseling of these families.

**1067T**

**A new X-linked form of syndromic intellectual disability on Xp11.22.** *D.A. Scott<sup>1,2</sup>, C. Grau<sup>1</sup>, M. Starkovich<sup>2</sup>, M.S. Azamian<sup>1</sup>, F. Xia<sup>1,3</sup>, S.W. Cheung<sup>1,3</sup>, P. Evans<sup>4</sup>, A. Henderson<sup>5</sup>, S.R. Lalani<sup>1</sup>.* 1) Department of Molecular & Human Genetics, Baylor College Medicine, Houston, TX; 2) Department of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX; 3) Baylor Genetics, Houston, TX; 4) Departments of Pediatrics and Neurology, University of Texas Southwestern Medical School, Dallas, TX; 5) The Newcastle upon Tyne Hospitals, Newcastle upon Tyne, England.

By searching a clinical database of over 60,000 individuals referred for array-based copy number variant (CNV) analyses and online resources, we identified four males from three families with intellectual disability, developmental delay, hypotonia, severe joint hypermobility and relative macrocephaly who carried small, overlapping deletions of Xp11.22. The maximum region of overlap between their deletions spanned ~430 kb and included two protein coding genes, *GSPT2* and *MAGED1*. Deletions of this ~430 kb region have not been previously implicated in human disease. *GSPT2* is abundantly expressed in the brain and plays a critical role in preventing translational readthrough. Duplications of *GSPT2* have been documented in individuals with intellectual disability, but the phenotypic consequences of a loss of *GSPT2* function have not been elucidated in humans or mouse models. Changes in *MAGED1* have not been associated with intellectual disability in humans, but loss of *MAGED1* function is associated with neurocognitive and neurobehavioral phenotypes in mice. Although the molecular mechanisms by which *MAGED1* affects brain development and function have not been fully elucidated, *MAGED1* binds and positively regulates the transcriptional activity of a subset of transcription factors including *SIM1*, *NPAS4* and *ARNT2* whose deficiencies have been shown to affect brain development and function. All of the affected males in these families inherited their Xp11.22 deletions from their unaffected mothers. Studies performed on DNA from one of these mothers did not show evidence of skewed X-inactivation. These results suggest that Xp11.22 deletions that encompass *GSPT2* and *MAGED1* cause an X-linked form of syndromic intellectual disability and that loss of *GSPT2* and/or *MAGED1* function may contribute to the intellectual disability and developmental delay seen in affected males.

**1068F**

**Family-based whole exome sequencing for identifying novel variants in primary myopathies.** *J. Hwang<sup>1</sup>, H. Kim<sup>1</sup>, S. Park<sup>1</sup>, J. Chae<sup>2</sup>, Y. Ahn<sup>1</sup>.* 1) Division of Rare Diseases, Center for Biomedical Sciences, National Research Institute of Health, Chungcheongbuk-do, Republic of Korea; 2) Department of Pediatrics, Pediatric Clinical Neuroscience Center, Seoul National University Children's Hospital, Seoul National University College of Medicine, Seoul, Korea.

Primary myopathy is a clinical and genetic heterogeneous muscle disorder, sub-classified into dystrophies, myotonia, congenital myopathies, familial periodic paralysis, mitochondrial myopathies, and metabolic myopathies. Despite clinical and histological investigations, the genetic information about causes of primary myopathy is not fully established. Whole exome sequencing approaches have been used to uncover novel variants as a discovery and diagnostic tool on rare diseases. Here, we conducted family-based whole exome sequencing (130 trio). Integrative functional enrichment analyses allowed us to understand and interpret novel variants better, including analyzing the functional annotations of structural variation and genetic regulation. To study functional implications, follow-up experiments were conducted using the zebrafish model. Our results could provide additional insight into phenotypic convergence and divergence in the diagnosis of muscle disorders. .

**Engineering tissue specific delivery of enzymes for lysosomal disease treatment.** *K. Cygnaar, A. Baik, C. Schoenherr, A. Murphy, A. Economides.* Regeneron, Tarrytown, NY.

Many lysosomal diseases (LDs) are caused by deficient enzymatic processing of substrates in the lysosome and their resultant accumulation. Disease manifestation varies depending on the affected tissues and the residual enzyme activity, with consequences from mild impairment to neonatal lethality. The advent of enzyme replacement therapy (ERT), in which recombinant enzyme is delivered to clear the accumulated substrate from affected tissues, revolutionized the treatment of LDs. In ERT, tissue targeting and lysosomal trafficking of recombinant enzymes occurs primarily through the cation-independent mannose-6-phosphate receptor (CI-MPR) pathway. However, many clinically relevant tissues express this receptor (*e.g.* skeletal muscle in Pompe disease) weakly, hence rendering the delivery of enzyme to the affected tissues inefficient. Delivering therapeutic amounts of recombinant enzyme to the lysosomes of affected tissues remains a challenge for many LDs due to this unfavorable biodistribution. Here, we present an antibody-guided enzyme delivery technology to create tunable patterns of tissue biodistribution by using antibody targeting to a chosen internalizing cell-surface protein, thereby bypassing the limitations of CI-MPR-mediated delivery of native enzymes. The antibody acts as a guide for the enzyme to reach the lysosomes of the tissues of interest in ERT. As a proof of concept, an antibody against an internalizing surface protein enriched in muscle was fused to alpha glucosidase (GAA). Enzymatic activity, intracellular half-life, lysosomal processing of the enzyme, and antibody binding were unaffected in this format. We demonstrated antibody-dependent, CI-MPR-independent uptake of the antibody-GAA drug in several cell types, including skeletal myoblasts and HEK 293. In a mouse model of Pompe Disease, we also found that the antibody-GAA reduced accumulated lysosomal glycogen in skeletal and cardiac muscle. Importantly, glycogen was significantly reduced in skeletal muscles compared to GAA alone. This technology is generalizable to other LSDs and also amenable to depot-based cross-correctional gene therapy models.

**Mutational spectrum of Duchene Muscular Dystrophy in Colombian patients.** P. Ayala-Ramírez<sup>1</sup>, M. Garcia-Acero<sup>1,3</sup>, T. Pineda<sup>2</sup>, M. Guerra-Torres<sup>1</sup>, R. Garcia-Robles<sup>1</sup>, T. Buitrago<sup>1</sup>, A. Poveda<sup>1</sup>, F. Suarez-Obando<sup>1,3</sup>. 1) Instituto de Genética Humana, Pontificia Universidad Javeriana, Bogotá, Colombia; 2) Biotecnología y Genética - Biotecgen S.A.; 3) Servicio de Genética, Hospital Universitario San Ignacio.

**Introduction:** Duchenne muscular dystrophy (DMD) is the most common muscular dystrophy in children, characterized by rapidly progressive muscle weakness and wasting of skeletal, smooth and cardiac muscle. Is a X-linked recessive muscular dystrophy caused by absence of dystrophin, usually due to mutations in DMD gene, 70% of DMD cases are caused by deletions/duplications of one or more DMD exons and 30% of cases have alterations in sequence. The phenotype depends on the location of the mutation in the gene and does not necessarily depend on the size of the deletion or the duplication. The molecular characterization of the disease is necessary for the genetic counseling, the prognosis and for the possible pharmacological management of certain mutations. **Methodology:** descriptive analysis of mutational spectrum of 62 Colombian DMD individuals. For the identification of the exon deletion or duplication of dystrophin was first done multiple ligation-dependent probe amplification (MLPA) and then mutations were identified with direct sequencing. **Results:** A total of 62 patients with suspected DMD were confirmed by molecular analysis. The average age of the individuals was 9 years with age at onset of symptoms less than 4 years in 79% of patients. Most patients with DMD presented deletions (54.8%) or duplications (24.1%) in the dystrophin gene. The remaining 24.1% corresponds to the set of point mutations, highlighting nucleotide substitutions nonsense and frameshift type as the most common. The variants were distributed throughout the gene and 5 new mutations in *DMD* were identified. **Conclusions.** Mutational analysis of the patients studied confirms the great genetic heterogeneity of DMD, mutations in the *DMD* gene may lead to a broad spectrum of clinical phenotypes that are closely correlated with molecular alterations and with the severity of the altered protein function caused by the mutation, however the phenotype - genotype correlation is uncertain, although the location of the isoforms and in some cases their function is known, the mutation of certain regions does not behave similarly in all patients.

**A combination of capture-based high-coverage NGS and WES analysis uncovers potential deleterious variants in the *NARS2* gene expanding the phenotypical spectrum of combined oxidative phosphorylation deficiencies.** Y. Wang<sup>1,2</sup>, F. Vetrini<sup>1</sup>, A.V. Dharmadhikari<sup>1</sup>, J.A. Rosenfeld<sup>2</sup>, V.M. Knight<sup>3</sup>, R. Gavrilova<sup>4</sup>, R. Lutz<sup>5</sup>, S. Agadi<sup>6</sup>, Y. Yang<sup>1,2</sup>, F. Li<sup>2</sup>. 1) Baylor Genetics, Houston, TX,; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Department of Pediatric Neurology and Epilepsy, Yale University, New Haven, CT; 4) Department of Neurology, Mayo Clinic, Rochester, MN,; 5) Department of Pediatrics, University of Nebraska Medical Center, Omaha, NE; 6) Department of Pediatrics-Neurology, Baylor College of Medicine, Houston, TX.

Mitochondrial respiratory chain diseases represent a large and heterogeneous group of energy deficiency disorders that are caused by both nuclear and mitochondrial-encoded genetic variants. Nuclear genes responsible for combined oxidative phosphorylation (OXPHOS) include proteins involved in mtDNA replication, transcription, RNA maturation and translation. Mitochondrial asparaginyl-tRNA synthetase *NARS2* belongs to a large group of aminoacyl-tRNA synthetases genes necessary for the mitochondrial translation process. Defects in *NARS2* gene are associated with combined oxidative phosphorylation deficiency 24, MIM: 616239, with wide phenotypic variability ranging from a milder form affecting only skeletal muscle to a more severe infantile-onset neurodegenerative disorder. Very few cases have been reported thus far in the literature. Capture NGS reliably detects SNVs and small indels whereas CNVs require sophisticated analysis via an in house-designed algorithm. In combination with whole exome sequencing (WES), we have identified a deletion encompassing exons 8 and 9, eight SNVs (p.R51C, p.S83G, p.A123A, p.R243Q, p.N186S, p.R348W, p.P214L and c.689+1G>A) in a compound heterozygous state in five patients presenting with neurodevelopmental abnormalities of unknown etiology. These five patients presented with variable clinical phenotypes including early onset epileptic encephalopathy (n=3), structural brain abnormalities (n=4), intellectual disability (n=3), myopathy (n=2), hearing loss (n=1), hypoglycemia (n=1), lactic acidosis (n=1), and hepatomegaly (n=1). Among these changes, p.R51C, p.S83G, p.A123A, p.R243Q, p.N186S, p.R348W and c.689+1G>A have never been reported to be associated with disease. The synonymous change p.A123A was predicted to reduce the affinity for the SF2/ASF splicing enhancer factor; others were predicted to be damaging/deleterious to the structure of the NARS protein via *in silico* predictions. All the missense changes potentially affect conserved domains of the protein: two in the anti-codon binding domain (p.R51C, p.S83G) and four potentially affect the catalytic domain (p.R243Q, p.N186S, p.P214L and p.R348W). In conclusion, we report nine *NARS2* potentially deleterious changes in five new patients thus expanding the phenotype and the mutation spectrum of combined oxidative phosphorylation deficiency 24. .

**Adenosylcobalamin synthesis in cultured fibroblasts from patients with isolated methylmalonic aciduria.** D. Watkins, D. Rosenblatt. Child Health & Human Development, Research Institute, McGill University Health Centre, Montreal, Quebec, Canada.

Methylmalonic aciduria (MMA) occurs in patients with decreased activity of the mitochondrial enzyme methylmalonyl-CoA mutase, which catalyzes conversion of methylmalonyl-CoA to succinyl-CoA, either due to mutations affecting the mutase enzyme itself (the *mut* complementation class) or by mutations affecting synthesis of its adenosylcobalamin (AdoCbl) cofactor (*cbIA*, *cbIB* and *cbID* variant 2 classes). The *mut* class is subdivided into *mut*<sup>o</sup> and *mut*<sup>-</sup> groups, depending on whether or not there is residual enzyme activity. We have investigated the synthesis of cobalamin cofactors from exogenous [<sup>57</sup>Co] cyanocobalamin (CNCbl) in cultured fibroblasts from patients with isolated methylmalonic aciduria: 72 *cbIA*, 45 *cbIB*, 3 *cbID* variant 2, 194 *mut*<sup>o</sup> and 53 *mut*<sup>-</sup> patients. Fibroblasts were incubated for 96 hours in medium supplemented with labeled CNCbl bound to human transcobalamin, and cellular cobalamins were extracted in hot ethanol and separated by high performance liquid chromatography. No significant differences in incorporation of labeled CNCbl were detected between the different classes of isolated MMA patients. Synthesis of AdoCbl from exogenous CNCbl was decreased compared to control fibroblasts in all classes. AdoCbl as a percentage of total labeled cellular cobalamin was less in *cbIA* (3.3% ± 1.6, mean ± SD), *cbIB* (3.0% ± 2.1), and *cbID* variant 2 (3.5% ± 1.8) cells than in either *mut*<sup>o</sup> (8.1% ± 4.4) or *mut*<sup>-</sup> (8.3% ± 6.9) cells. AdoCbl was 15.3% ± 4.2 of labeled cellular cobalamin in control fibroblasts. There was no significant difference in AdoCbl levels between *mut*<sup>o</sup> and *mut*<sup>-</sup> cells. Thus, the level of AdoCbl synthesis in cultured fibroblasts can distinguish between disorders involving the synthesis of the cofactor from primary mutase disorders, but cannot distinguish between the two subtypes of mutase deficiency.

**A zebrafish *mut*<sup>o</sup> model recapitulates key aspects of severe methylmalonic acidemia.** K.T. Ellis<sup>1</sup>, M. Arnold<sup>1</sup>, R. Sood<sup>2</sup>, B. Carrington<sup>2</sup>, K. Bishop<sup>2</sup>, V. Hoffmann<sup>2</sup>, P. Zervas<sup>2</sup>, N. Achilly<sup>1</sup>, J. Sloan<sup>1</sup>, O.A. Shchelochkov<sup>1</sup>, C. Venditti<sup>1</sup>. 1) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Department of Health and Human Services, Bethesda, MD; 2) Zebrafish Core, Translational and Functional Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 3) Diagnostic and Research Services Branch, Office of the Director, NIH, Bethesda, MD; 4) Office of the Director, National Institutes of Health, Department of Health and Human Services, Bethesda, MD.

Methylmalonic acidemia (MMA) is an autosomal recessive inborn error of metabolism caused by mutations in methylmalonyl-CoA mutase (MUT), the enzyme responsible for metabolizing methylmalonyl-CoA into succinyl-CoA. Patients with *mut*<sup>o</sup> type MMA, characterized by a severe deficiency of the MUT enzyme, present neonatally with lethargy, acidosis, and encephalopathy resulting in high mortality. Despite dietary therapy, patients can experience failure to thrive, life-threatening episodes of acidosis, and poorly understood multisystemic complications including renal failure and basal ganglia injury. To create a tractable disease model and investigate disease mechanisms, we generated a zebrafish model of *mut*<sup>o</sup> MMA using zinc finger nucleases to target exon 2 of the zebrafish *mut* gene. This resulted in a 10 bp deletion (c.326\_335del, p.Tyr109\*). *mut*<sup>o</sup> fish presented with growth retardation at 7 days post fertilization (dpf) with growth ceasing at 4.5 mm standard length, the size of unaffected clutchmates at this time. The onset of growth retardation coincided with the depletion of maternally transferred *mut* mRNA present in the egg as identified by RT-PCR. By 19 dpf, *mut*<sup>o</sup> fish continued to display a significant reduction in size, at 59% of the wildtype standard length (p<0.0001). *mut*<sup>o</sup> fish showed 100% mortality by 26 dpf (p=0.0016). RT-PCR revealed a decrease in *mut* mRNA levels at 15 dpf, suggesting that the mutant mRNA is degraded by nonsense-mediated decay. Tissue metabolite analysis at 15 dpf displayed a 28-fold increase in methylmalonate and 2-methylcitrate levels compared to age-matched clutchmates (p<0.0001), a metabolic hallmark seen in the human disease. Further, at this age, *mut*<sup>o</sup> hepatocytes exhibited eosinophilic inclusions ranging from 1-3 microns in size that resemble megamitochondria seen in liver and kidney tissues from MMA patients and mouse models. To assess mitochondria in a zebrafish organ sharing function with mammalian kidneys, we performed transmission electron microscopy on the gills of *mut*<sup>o</sup> fish, an organ playing a key role in acid-base equilibrium. Here, clearing of cristae from the mitochondrial matrix in the gill epithelium of *mut*<sup>o</sup> fish is observed. These data demonstrate that this novel zebrafish model recapitulates key features of *mut*<sup>o</sup> type MMA. To characterize the contribution of individual organs to the pathology of MMA, we are generating transgenic lines expressing human *MUT* to restore enzyme function in the liver and muscle.

**Novel biallelic mutations in the *PNPT1* gene encoding a mitochondrial-RNA-import protein PNPase cause delayed myelination.** A. Kikuchi<sup>1</sup>, R. Sato<sup>1,2</sup>, N. Arai-Ichinoi<sup>1</sup>, T. Matsuhashi<sup>1</sup>, Y. Numata-Uematsu<sup>1</sup>, M. Uematsu<sup>1</sup>, Y. Fujii<sup>3</sup>, K. Murayama<sup>4</sup>, A. Ohtake<sup>5</sup>, T. Abe<sup>6</sup>, S. Kure<sup>1</sup>. 1) Department of Pediatrics, Tohoku University Hospital, Sendai, Japan; 2) Department of Pediatric Neurology, Miyagi Children's Hospital, Sendai, Japan; 3) Department of Pediatrics, Hiroshima University Hospital, Hiroshima, Japan; 4) Department of Metabolism, Chiba Children's Hospital, Chiba, Japan; 5) Department of Pediatrics, Saitama Medical University, Saitama, Japan; 6) Department of Nephrology, Endocrinology, and Vascular Medicine, Tohoku University School of Medicine, Sendai, Japan.

Recent studies suggest that impaired transcription or mitochondrial translation of small RNAs can cause abnormal myelination. A polynucleotide phosphorylase (PNPase) encoded by *PNPT1* facilitates the import of small RNAs into mitochondria. *PNPT1* mutations have been reported in patients with neurodevelopmental diseases with mitochondrial dysfunction. We report here two siblings with *PNPT1* mutations who presented delayed myelination as well as mitochondrial dysfunction. We identified compound heterozygous mutations (c.227G>A; p.Gly76Asp and c.574C>T; p.Arg192\*) in *PNPT1* by quartet whole-exome sequencing. Analyses of skin fibroblasts from the patient showed that PNPase expression was markedly decreased and that import of the small RNA *RNase P* into mitochondria was impaired. Exogenous expression of wild-type *PNPT1*, but not mutants, rescued ATP production in patient skin fibroblasts, suggesting the pathogenicity of the identified mutations. Our cases expand the phenotypic spectrum of *PNPT1* mutations that can cause delayed myelination.

***RMND1*-related mitochondrial disease: Phenotypic delineation of four patients including renal manifestations.** N.T. Le<sup>1</sup>, N. Bekheirnia<sup>1</sup>, J.A. Rosenfeld<sup>1</sup>, A.C. Goldstein<sup>2</sup>, D.W. Bartholomew<sup>3</sup>, M.T. Pastore<sup>3</sup>, C.C. Muraresku<sup>4</sup>, E.M. McCormick<sup>4</sup>, F. Xia<sup>1</sup>, C. Eng<sup>1</sup>, Y. Yang<sup>1</sup>, F. Scaglia<sup>1</sup>, M.R. Bekheirnia<sup>1</sup>. 1) Baylor College of Medicine, Houston, TX; 2) Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; 3) Nationwide Children's Hospital, Columbus, OH; 4) Children's Hospital of Philadelphia, Philadelphia, PA.

**Background:** *RMND1* (Required for Meiotic Nuclear Division 1 homolog) is a nuclear gene which codes for a protein believed to be involved in mitochondrial translation. Pathogenic variants in the *RMND1* gene have been shown to cause recessively inherited infantile-onset mitochondrial disease with neurological, developmental, intellectual, cardiac, gastrointestinal, metabolic, and renal manifestations. **Methods:** We report the clinical, phenotypic, and molecular genetic findings of four patients diagnosed with *RMND1*-related mitochondrial disease. Whole exome sequencing (WES) was used to identify the single nucleotide variants (SNVs) of each respective patient. All SNVs were validated by Sanger sequencing. Patient information was collected as part of the clinical laboratory intake form, and families were consented accordingly. **Results:** We present four patients with recessive mutations in *RMND1* involving the following SNVs: c.485delC, p.P162fs; c.713A>G, p.N238S; and c.533C>T, p.T178M. Developmental delay, sensorineural hearing loss, and renal deficiencies—which include chronic renal failure due to interstitial nephritis, renal tubular acidosis, and end-stage renal disease—were observed in all four patients. Motor delay and structural neurologic findings—such as cortical volume loss, basal ganglia calcification, and white matter abnormalities—were present in three patients. Short stature, intellectual disability, speech delay, absence of speech, seizures, hyperreflexia, and lactic acidosis were observed in half of the patients. **Discussion:** The clinical findings of the four patients demonstrate that mutations in *RMND1* result in a heterogeneous array of phenotypic manifestations. In addition to the recent work described by other research groups, the findings of our study depict the clinical spectrum of *RMND1* mutations by delineating the diverse phenotypic manifestations of *RMND1* variants. **Acknowledgment:** This study was supported in part by K12 DK083014 Multidisciplinary K12 Urologic Research Career Development Program.

**Identification of the genetic causes of mitochondrial oxidative phosphorylation (OXPHOS) disease.** S.C. Lim<sup>1</sup>, Y. Kishita<sup>1,2</sup>, M. Kohda<sup>2,3</sup>, Y. Mizuno<sup>1</sup>, T. Hirata<sup>3</sup>, Y. Yatsuka<sup>1</sup>, N.N. Borna<sup>1</sup>, H. Harashima<sup>4</sup>, K. Murayama<sup>5</sup>, A. Ohtake<sup>4</sup>, Y. Okazaki<sup>1,2,3</sup>. 1) Division of Functional Genomics & Systems Medicine, Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan; 2) Intractable Disease Research Center, Graduate School of Medicine, Juntendo University, Tokyo, Japan; 3) Division of Translational Research, Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan; 4) Department of Pediatrics, Saitama Medical University, Saitama, Japan; 5) Department of Metabolism, Chiba Children's Hospital, Chiba, Japan.

Oxidative phosphorylation (OXPHOS) is a biochemical pathway within mitochondria that generates energy for cellular activities. The proper function of OXPHOS requires many nuclear DNA and mitochondrial DNA (mtDNA)-encoded products, such as the structural components and biogenesis factors of the OXPHOS complexes, and the proteins required for mtDNA replication and expression. Disruption of OXPHOS can cause human metabolic disease, affecting ~1 in 5,000 live births (Skladal et al., 2003). OXPHOS disease can have any age of onset, a wide spectrum of clinical presentations, and generally have poor phenotype-genotype correlations. To-date, more than 250 OXPHOS disease genes have been identified. Nevertheless, these genes account for ~60% of OXPHOS patients, implying that additional causal genes remain undiscovered. DNA samples of 58 early-onset OXPHOS disease patients recruited from Saitama Medical University Hospital and Chiba Children's Hospital in Japan were analyzed with whole exome sequencing (WES) using the Illumina HiSeq platform. Variants that are common in 2,049 healthy Japanese individuals (2KJPN database) were excluded from subsequent bioinformatic and functional analyses. We identified candidate mutations in 6 known OXPHOS disease genes in 6 patients. Additionally, 3 candidate mutations were identified in 2 novel OXPHOS disease genes in 2 patients – one encodes a translocase in the mitochondrial inner membrane and the other encodes a WD repeat domain-containing protein with unknown function in the mitochondria. To confirm the pathogenicity of candidate mutations, functional studies are being performed and include SDS-PAGE and BN-PAGE western blotting, lentiviral-mediated expression of the wildtype gene in patient cultured fibroblasts and analysis of gene knock-out/knock-in cell models generated using the CRISPR/Cas9 system. This research will identify novel OXPHOS disease genes and contribute to the expansion of our knowledge for the genetic basis of OXPHOS disease and the biology of OXPHOS system.

**1077F**

**The clinical spectrum of BCS1L mutations: Case report of a novel mutation and review of the literature.** J. Priestley<sup>1</sup>, E. Fernandez-Vizarra<sup>2</sup>, P. Mark<sup>3</sup>. 1) College of Human Medicine, Michigan State University, Grand Rapids, MI; 2) MRC-Mitochondrial Biology Unit, University of Cambridge, Cambridge, UK; 3) Division of Medical Genetics, Spectrum Health Medical Group, Grand Rapids, MI.

BCS1L is a ubiquitously-expressed mitochondrial member of the AAA+ (AT-Pases associated with various cellular activities). It functions as a translocase in the integration of Rieske Fe/S protein during respiratory chain complex III assembly. Since 2001, 40 different *BCS1L* mutations have been identified in clinically affected patients, making them the most frequent cause of isolated mitochondrial complex III deficit. Phenotypes are varied and as mild as Björnstad syndrome (characterized by pili torti and sensorineural hearing loss) or as severe as GRACILE (growth restriction, aminoaciduria, cholestasis, iron overload, lactic acidosis, and early death) syndrome. *BCS1L* mutations are also linked to a third entity: an undefined complex III deficiency, which is a heterogenous-condition generally involving low birth weight, renal and hepatic pathologies, hypotonia, and developmental delay. However, some patients with phenotypes more severe than Björnstad and less severe than GRACILE have no demonstrable reduction in complex III activity or quantity, adding confusion to this intermediate phenotype. Here, we present a female patient initially seen in our clinic at six months of age with failure to thrive, growth restriction, developmental delay, microcephaly, hypotonia, hearing and vision loss, transient lactic acidosis, transient elevation in liver enzymes, and brittle hair – a phenotype both similar to and disparate from those previously described. Subsequent exome sequencing revealed compound heterozygosity in the *BCS1L* gene: p.Arg184Cys, previously identified in patients with *BCS1L*-associated complex III deficiency and in patients with Björnstad syndrome; and p.Leu280Phe, a previously unreported mutation at a highly conserved amino acid residue. Together with a review of the current literature, these data suggest a clinical spectrum of disease within *BCS1L* mutations that does not fit cleanly into the three aforementioned disease entities. We propose a nomenclature scheme in which Björnstad syndrome is defined as isolated pili torti with sensorineural hearing loss, GRACILE syndrome is defined by its eponymous components and by the homozygous p.Ser78Gly mutation, and all other *BCS1L* mutations and clinical phenotypes are termed “*BCS1L* mitopathies.” In doing so, we provide a potential work-up for patients with suspected or known *BCS1L* mutations, so that no key aspects of the *BCS1L* mitopathy are missed.

**1078W**

**Severe lactic acidosis, myopathy, and normal mental status in an infant with biallelic *GTPBP3* pathogenic variants.** H. Vernon<sup>1</sup>, C. Peroutka<sup>1</sup>, J. Albert<sup>2</sup>, K. Doheny<sup>3</sup>, K. Hetrick<sup>3</sup>, L. Kratz<sup>3</sup>, D. Murdock<sup>3</sup>, A. Murphy<sup>4</sup>, M. Parsons<sup>4</sup>, A. Robinson<sup>3</sup>, N. Sobreira<sup>1</sup>, T. Wang<sup>1</sup>, D. Witmer<sup>3</sup>. 1) Inst Gen Med, Johns Hopkins Hosp, Baltimore, MD; 2) Kennedy Krieger Inst, Johns Hopkins Med Inst, Baltimore, MD; 3) Genetics Ctr for Inhrtd Dis Res, Johns Hopkins Univ, Baltimore, MD; 4) Johns Hopkins Univ Dept of Cardiology, Baltimore, MD.

**Background:** More than 90 nuclear and 37 mitochondrial (mt) genes are involved in post-transcriptional modification of mitochondrial tRNAs (mt-tRNAs) or in OXPHOS polypeptide synthesis. Pathogenic variants in genes involved in translation of mt-transcripts, including *GTPBP3*, *MTO1* and *TRMU*, are a recently described cause of mt disease. **Case Study:** Our patient presented with perinatal myopathy and severe lactic acidosis (15 mmol/L) with lactate/pyruvate ratio of 36 (N 10-20) but normal mental status. Also present were persistently increased plasma alanine and 3-hydroxybutyrylcarnitine levels. Free carnitine was normal. Multiple urine organic acid analyses showed markedly increased lactate excretion with moderate increases of 2-hydroxyisovalerate, 2-hydroxybutyrate, 3-hydroxyisobutyrate and 3-hydroxybutyrate, but only trace amounts of acetoacetate, suggesting a mt redox abnormality. There were mild increases of 2-methyl-2,3-dihydroxybutyrate and other hydroxy- and keto-hexanoic acids, absence of significant dicarboxylic aciduria, and trace 3-hydroxyglutarate. By 3 weeks, the urine 2-ketoglutarate and fumarate increased to 3-4 times normal for age. Liver transaminases were unremarkable aside from the immediate perinatal period. There was no hypoglycemia. Cardiomyopathy was first detected at 5 weeks. Rapid whole exome sequencing (WES) from the NICU at 5 weeks revealed 2 heterozygous presumed pathogenic missense variants in *GTPBP3*: c.215C>T(p.Pro721Leu) and c.1175C>G(p.Pro392Arg). c.215C>T(p.Pro721Leu) has a frequency of ~0.8% in African populations (ExAC), though the impacted amino acid, Pro, is highly conserved across species. c.1175C>G(p.Pro392Arg) has not been previously described, and the impacted amino acid (also Pro) is highly conserved across species. At 2.5 years, the patient has non-compaction cardiomyopathy, is ventilator dependent, and has motor developmental delays, but normal cognitive function. **Discussion:** In the setting of significant perinatal instability, rapid WES resulted in a diagnosis for a rare Mendelian disorder in our patient. A cohort of 11 patients with variants in *GTPBP3* was reported in the month our patient was born. Our patient has a novel exon 2 variant and previously unreported biochemical findings. Given variable expressivity in other patients, this case adds to our understanding of *GTPBP3*-associated mt disease and of mt translation defects as an important cause of mt disease to be considered in infants with lactic acidemia.

Leventer<sup>2,4,15</sup>. 1) Bruce Lefroy Centre for Genetic Health Research, Murdoch Children's Research Institute, Victoria, Australia; 2) Department of Neurology, Royal Children's Hospital, Victoria, Australia; 3) Victorian Clinical Genetics Service, Murdoch Children's Research Institute, Victoria, Australia; 4) Department of Paediatrics, University of Melbourne, Victoria, Australia; 5) Mitochondrial Research Group, Murdoch Children's Research Institute, Victoria, Australia; 6) Department of Metabolic Medicine, Royal Children's Hospital, Victoria, Australia; 7) Metabolic Research Group, Murdoch Children's Research Institute, Melbourne, Victoria, Australia; 8) Institute for Molecular Bioscience, University of Queensland, St. Lucia, Queensland, Australia; 9) Illumina Inc, San Diego, California; 10) School of Medicine and Health Sciences, The George Washington University, Washington, DC; 11) Department of Child Neurology, VU University Medical Center, Amsterdam, The Netherlands; 12) Department of Neurology, Children's National Medical Center, Washington, DC; 13) Department of Integrated Systems Biology, George Washington University, Washington, DC; 14) Department of Pediatrics, George Washington University, Washington, DC; 15) Neuroscience Research Group, Murdoch Children's Research Institute, Melbourne, Victoria, Australia.

**Aim:** To identify the genetic aetiology of a distinct leukodystrophy causing acute neurological regression in infancy with complete clinical recovery. **Methods:** We performed trio genome sequencing to identify the causal variants. Analysis of mitochondrial function in cultured patient fibroblasts was undertaken to confirm the pathogenicity of candidate variants. **Results:** Our patient presented at 18 months with acute right hemiplegia and cognitive regression without obvious trigger. Over five years he had complete recovery of neurological function and continues to have age-appropriate motor and cognitive function at age eight. Cerebral MRI at disease onset revealed extensive, bilateral, heterogeneous T2 hyperintensity involving the periventricular and deep white matter with sparing of the subcortical white matter, basal ganglia, brainstem and cerebellum. There was restricted diffusion at the periphery of the white matter change and no contrast enhancement. MRS of the frontal white matter demonstrated a lactate doublet with decreased NAA. The most recent MRI at age four showed evolution in the diffuse leukodystrophy with decrease in the degree of restricted diffusion. The pattern of white matter abnormality was most consistent with a mitochondrial disorder. Serum and CSF lactate levels were normal, as were mitochondrial respiratory chain enzyme function in liver and muscle. Urine and plasma glycine were elevated. Trio genome sequencing identified compound heterozygous variants in *BOLA3*: one previously reported variant for multiple mitochondrial dysfunctions syndrome 2 (MMDS2), and a novel variant that disrupts a critical residue for Fe-sulfur cluster biogenesis. Analysis of cultured patient fibroblasts demonstrated deficient pyruvate dehydrogenase activity and reduced quantity of protein subunits of mitochondrial complexes I, II, and III, consistent with *BOLA3* dysfunction. Previously reported cases of MMDS2 caused by *BOLA3* mutation have leukodystrophy with severe, progressive, life-limiting neurological and multisystem disease. **Conclusions:** We report a novel phenotype for multiple mitochondrial dysfunctions syndrome (MMDS2), associated with complete clinical recovery. We have identified a novel disease-causing variant in *BOLA3* validated by functional cellular studies. Our patient's unique clinical course provides important information on the phenotypic spectrum of MMDS2.

Epping<sup>1</sup>, P. Zerfas<sup>2</sup>, I. Manoli<sup>1</sup>, J. Segre<sup>3</sup>, C.P. Venditti<sup>1</sup>. 1) Medical Genomics and Metabolic Genetics Branch, NHGRI, National Institutes of Health, Bethesda, MD; 2) Diagnostic & Research Services Branch, OD, National Institutes of Health, Bethesda, MD; 3) Microbial Genomics Section, NHGRI, National Institutes of Health, Bethesda, MD.

Isolated methylmalonic acidemia (MMA) is a group of inherited metabolic disorders characterized by the inability to generate succinyl-CoA from (*R*)-methylmalonyl-CoA as a result of mutations in the methylmalonyl-CoA mutase (MUT) gene or deficiencies in enzymes involved in the synthesis (MMAB or *cbIB*) or transfer (MMAA or *cbIA*) of its cofactor, 5'-deoxyadenosylcobalamin (AdoCbl). Studies on the bacterial homolog protein MeaB show that it functions as a G-protein chaperone, facilitating the loading of AdoCbl to MUT, as well as the catalytic turnover and rescue of the MUT enzyme. The function of the mammalian protein is not well understood. MMAA patients have an attenuated biochemical and clinical phenotype compared to the classic MUT deficiency, but remain at risk for metabolic decompensations and disease complications including basal ganglia strokes, chronic renal failure and optic nerve atrophy. The treatment for *cbIA* MMA includes strict adherence to a protein restricted diet, hydroxocobalamin injections, and in some cases, periodic use of antibiotics to reduce propionate production from the gut microbiome. We previously generated an *Mmaa* deletion mutant allele using homologous recombination and noted neonatal lethality on the C57Bl6;129 background that could be modified by the introduction of FVBN genes. [C57Bl6xFVBN] *Mmaa*<sup>-/-</sup> mice recapitulate the *cbIA* patient phenotypes, but uniformly survive until weaning, and experience severe growth failure and reduced survival when transitioned to regular chow. *Mmaa*<sup>-/-</sup> mice also display elevated plasma methylmalonic acid ( $p < 0.0001$ ), decreased 1-<sup>13</sup>C-propionate oxidation, and the hepatorenal mitochondriopathy seen in other forms of MUT deficiency. To explore vitamin responsiveness on the clinical and metabolic phenotype of the *Mmaa*<sup>-/-</sup> mice, the animals were treated with 2.5 mg/kg hydroxycobalamin twice a week for two weeks. An increase in weight ( $p < 0.05$ ) was seen in the treated *Mmaa*<sup>-/-</sup> males. A separate cohort of *Mmaa*<sup>-/-</sup> mice underwent antibiotic treatment for 7 days, which was associated with an increase in weight ( $p < 0.01$ ) and a decrease in plasma methylmalonic acid ( $p < 0.01$ ). The *Mmaa*<sup>-/-</sup> mice expand the ability to model MMA without the obligate requirement for a rescue transgene. This *cbIA* mouse model informs our understanding of the effects of genetic background, dietary interventions, cobalamin response, and microbiome manipulations and shapes our efforts to develop new therapies for propionate oxidation disorders.

**Identification and validation of new hepatic biomarkers in methylmalonic acidemia (MMA).** I. Manoli<sup>1</sup>, J.R. Sysol<sup>1</sup>, M.W. Epping<sup>1</sup>, C. Wang<sup>1</sup>, L. Li<sup>1</sup>, J.L. Sloan<sup>1</sup>, J. Gagne<sup>1</sup>, P.M. Zerfas<sup>2</sup>, V. Hoffmann<sup>2</sup>, J. Cheng<sup>3</sup>, R.J. Chandler<sup>1</sup>, C.P. Venditti<sup>1</sup>. 1) Organic Acid Research Section, MGMGB, NHGRI, NIH, Bethesda, MD; 2) Division of Veterinary Resources, NIH, Bethesda, MD; 3) Embryonic Stem Cell and Transgenic Mouse Core Facility, NHGRI, NIH, Bethesda, MD.

Methylmalonic acidemia (MMA) caused by methylmalonyl-CoA mutase (*MUT*) deficiency, is characterized by recurrent episodes of life-threatening metabolic ketoacidosis and multiorgan complications. Studies in knockout mice (*Mut*<sup>-/-</sup>) and transplanted MMA patients suggested that extrahepatic organs, mainly the skeletal muscle, are a major source of circulating methylmalonic acid. To study the effects of restoring *Mut* activity in skeletal muscle on the hepatorenal phenotype of MMA, we generated mice expressing the *Mut* gene under the control of the muscle creatine kinase promoter (*Mut*<sup>-/-</sup>;Tg<sup>INS-MCK</sup>-*Mut*). Although *Mut* expression in the muscle rescued *Mut*<sup>-/-</sup> mice from neonatal lethality, the *Mut*<sup>-/-</sup>;Tg<sup>INS-MCK</sup>-*Mut* mice exhibited severe growth failure, hepatic mitochondriopathy, renal dysfunction, and were resistant to obesity when fed a carbohydrate and lipid-enriched diet. We used a fasting challenge to model the metabolic decompensations seen in patients and probed the hepatic adaptations using transcriptomics to identify candidate genes and pathways mediating the stress response. Among the most upregulated genes in the *Mut*<sup>-/-</sup>;Tg<sup>INS-MCK</sup>-*Mut* mice was fibroblast growth factor - *Fgf21*, a key circulating metabolic regulator. After validation in mice, plasma FGF21 concentrations were measured in a large cohort of patients with different subtypes of isolated MMA (54 *mut*, 8 *cbIA* and 5 *cbIB*). FGF21 levels correlated with disease subtype severity ( $p = 0.0001$  between *mut* and *cbIA* patients or controls) and showed an inverse relation to height Z-scores ( $r = -0.455$ ,  $p = 0.03$ ). In contrast to serum methylmalonic acid concentrations, which are influenced by renal dysfunction, plasma FGF21 levels were not affected by renal function indices (creatinine, cystatin-C, eGFR), but did correlate with markers of secondary mitochondrial dysfunction, including plasma glycine, allanine and urinary isoprostanes (all  $p < 0.05$ ). In further support of the use of FGF21 as a biomarker of hepatic mitochondrial dysfunction in MMA, we studied 9 patients before and after liver transplantation, as well as *Mut*<sup>-/-</sup>;Tg<sup>INS-MCK</sup>-*Mut* mice treated with a liver-directed AAV8 *MUT* gene therapy vector. In both the patients and mice, a decrease in plasma FGF21 was accompanied by a restoration of 1-<sup>13</sup>C-propionate oxidation, reduced circulating metabolites and, in the mice, weight gain. Our studies demonstrate the utility of 1-<sup>13</sup>C-propionate oxidation and plasma FGF21 as treatment biomarkers for MMA.

**Identification of large effect variants underlying non-syndromic MA in families segregating the disease.** G.A. Arenas-Perez, A. Reyes-de la Rosa, P. Baeza-Capetillo, C. Garcia-Delgado, V.F. Moran-Barroso, J. Aguirre-Hernandez. Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico DF, Mexico.

**Introduction:** Microtia-atresia (MA) refers to the developmental anomalies of the ear (e.g., shape and size). These may be accompanied by hearing difficulties. It has a variable phenotypic expression and its genetic basis is mostly unknown. Most cases are isolated, with a higher prevalence in populations with Native American ancestry. This has led to suggest that it is a complex disease arising from genetic predisposing variants interacting with environmental factors. A small proportion of cases (~6%) show mendelian inheritance, mostly with incomplete penetrance. The identification of the genes involved in MA in these families may lead to the identification of the genes and variants implicated in the more common sporadic form. **Objective:** To find large-effect variants associated with MA showing mendelian inheritance. **Material and methods:** Records of patients with MA were examined (2007-2015), and cases showing familial segregation were identified. Subsequently, four additional familial cases were identified and in the largest of these families showing MA segregation, whole exome sequencing was performed. The study was approved by the institution's ethics committee, and informed consent was obtained from all participants. **Results:** 242 MA patients were assessed; 22 (9%) had isolated non syndromic MA; 16/22 were male (66%), and 20/22 (83%) were unilateral mostly on the right side. Of these 22 isolated non-syndromic cases, 6 (27%) belonged to families segregating MA, with either an autosomal dominant or an autosomal recessive pattern. In 2016 four additional familial cases were identified. The largest of these latter families segregating MA was chosen for whole exome sequencing. Segregation was consistent with an autosomal dominant model with incomplete penetrance and affected members showed variable expressivity, from prominent helix to grade II MA. After filtering by quality, variant consequence and variant frequency in public databases and in a local database, a single missense variant in *ASIC1* was left (c.475G>A\_p.Asp159Asn). **Discussion:** The gender, type and side of MA in this cohort were similar to the data reported in the literature, except for the higher proportion of isolated MA cases. A single candidate variant was observed associated with the disease. This variant was not present in public databases.

**DFNA5 and the infamous skipping of exon 8.** K.T. Booth<sup>1,2,4</sup>, H. Azaiez<sup>1,4</sup>, K. Kahrizi<sup>3</sup>, H. Najmabadi<sup>3</sup>, R.J. Smith<sup>1,2</sup>. 1) Otolaryngology-Head and Neck Surgery, University of Iowa, 200 Hawkins Drive, IA; 2) Department of Molecular and Cellular Biology, University of Iowa, Iowa City, Iowa; 3) Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran, Iran; 4) Authors Contributed Equally.

Like most cellular processes, RNA-splicing; the formation of mature messenger RNA (mRNA) from transcribed RNA, is a highly conserved and tightly regulated process. Dysregulation of splicing is a common factor underlying many inherited diseases, including deafness. For one deafness-associated gene, *DFNA5*, perturbation of exon 8 splicing results in a constitutively active truncated protein. To date only intronic mutations have been reported to cause exon 8 skipping in patients with *DFNA5*-related deafness. Here we present three families with post-lingual progressive autosomal dominant non-syndromic hearing loss, segregating novel *exonic* missense mutations in exon 8 of *DFNA5*. Computational analyses predicted these mutations decrease splicing efficiency of exon 8 or obliterate it. Mini-gene assays using wild-type and mutant exon 8 of *DFNA5* revealed all three mutations alter normal splicing in-vivo. This is the first report of exonic mutations in the *DFNA5* gene to cause deafness. Although at the DNA level the reported mutations here and the six previously reported mutations are unique, at the mRNA level they are indistinguishable; resulting in the skipping of exon 8, yielding the same truncated *DFNA5* protein. This study expands the mutational spectrum of *DFNA5* related deafness to include missense mutations and highlights the importance of assessing the effects of coding variants influence on splicing.

**Genetics mutation: A novel frameshift mutation in the *USH1G* gene in an Iranian patient with USHER syndrome.** F. Tabei<sup>1</sup>, H. Dastsooz<sup>2</sup>, S. Mohammedi<sup>2</sup>, A. Taghipour<sup>2</sup>, F. Kamgarpour<sup>2</sup>, M. Alipour<sup>2</sup>, S. Tabei<sup>3</sup>, M. Fardaei<sup>3</sup>. 1) International Branch of Medical School, Shiraz University of Medical Sciences, Motahari Hospital, Marvdasht, Iran; 2) Comprehensive Medical Genetic Center, Shiraz University of Medical Sciences, Shiraz, Iran; 3) Medical Genetic Department, Medical School, Shiraz University of Medical Sciences, Shiraz, Iran.

Introduction: Usher syndrome, type II is characterized by congenital, bilateral sensorineural deafness, intact vestibular responses, and retinitis pigmentosa. Diagnosis is usually established with the use of electrophysiologic and subjective tests of hearing and retinal function. However, genetic testing covering its related genes can be very helpful if clinical features are inconclusive.

The goal of this study was to identify mutation in a patient affected by Usher Syndrome type II. **Materials and Methods:** The Genetic test was performed using a custom designed Nimblegen chip capturing different genes, including *CDH23*, *USH1C*, *PCDH15*, *USH1G*, *USH2A*, *PDZD7*, *MYO7A*, *GPR98*, *DFNB31*, *CLRN1* followed by Next Generation Sequencing. **Results:** One novel homozygous frameshift mutation c.993\_994insACGGACTGGGCCGC (p.Arg331ArgfsX54) in *USH1G* gene was found and this frameshift mutation can lead to early termination of the amino acid coding, affecting the protein's function. Sanger sequencing was also performed to confirm this mutation in proband and his parents. It is worth noting that this novel mutation is inherited from two unrelated parents, predicting the same origin for this mutation. So, genetic screening for this mutation in their extended family members is necessary to reduce further affected individuals. **Conclusions:** This mutation is the first large insertion mutation in *USH1G* and since it is occurred exactly adjacent to the same 14 nucleotides in this gene, it can propose a new mechanism for occurrence of this particular mutation in *USH1G*. This work was supported by a grant from the International Branch, Shiraz University of Medical Sciences.

Genetic investigations in patient cohorts of consanguineous origin can help to unravel the underlying genetic defect in genetically heterogeneous diseases such as inherited retinal diseases (IRD). A combination of homozygosity mapping and whole exome (WES) or genome sequencing (WGS) already proved to be effective to identify novel IRD genes and causative variants underlying IRD. Here, it was our aim to leverage consanguinity in a cohort of 100 unrelated families of different ethnicities, segregating non-syndromic and syndromic IRD phenotypes. Using an integrative approach combining homozygosity mapping, targeted next-generation sequencing and WES, we identified 76 unique mutations in 44 IRD genes underlying IRD in 74% of the patients. Moreover, we uncovered homozygous mutations in six novel candidate IRD genes in six unrelated families: four of them, *CEP162*, *EML4*, *ERICH6*, and *FBN2*, as the primary genetic defect, and two of them, *EML2* and *PATJ*, in combination with other mutations in known IRD genes, in total contributing to 6% of the IRD cohort. Finally, we also demonstrated the importance of copy number variations (CNVs) in IRD, identifying CNVs in 7% of patients, including the first CNV ever described in the *PDE6G* gene. Overall, our study shows the utility of genetic studies in consanguineous pedigrees, further elucidating the hidden genetic variation of genetically heterogeneous diseases such as IRD. It reveals a high mutational load (78%) in 100 unrelated families, consisting of a myriad of novel mutations in previously well-described IRD genes (74%), including CNVs (7%), and a small number of novel IRD genes (4%). Using an exome-oriented approach focusing on different types of hidden genetic variation such as novel mutations in previously described disease genes, novel disease genes, and CNVs, a causal genetic defect remained unidentified in 22% of our IRD cohort, assuming that non-coding mutations will significantly contribute to the overall genetic architecture of IRD and demonstrating that they require genome-oriented approaches.

**1086F****In silico analysis and identification of TYR mutations in a Cypriot family.**

R. Kalkan<sup>1</sup>, P. Tulay<sup>1</sup>, M.C. Ergoren<sup>2</sup>, B. Turkgenç<sup>3</sup>, C. Oğur<sup>4</sup>, S.G. Temel<sup>5</sup>. 1) Medical Genetics, Faculty of medicine, Near East University, Nicosia, Cyprus; 2) Faculty of Medicine, Department of Medical Biology, University of Near East, Nicosia, Cyprus; 3) Genetic Diagnostic Center, University of Acibadem, Istanbul, Turkey; 4) Genetic Diagnostic Center, Memorial Health Group, Istanbul, Turkey; 5) Faculty of Medicine, Department of Histology and Embryology, University of Uludag, Bursa, Turkey.

Oculocutaneous albinism (OCA) is a rare heterogeneous group of genetic disorders characterized mainly by decreased or absent pigmentation in the skin, hair and eyes. A number of distinct ocular changes are important for the diagnosis of OCA including the reduced melanin amounts in the developing eye leading to abnormalities in the optic system. Mutations in different genes cause different types of OCA in which the prevalence of the different subtypes varies considerably among different ethnic groups. Four-year-old boy was referred our clinic with albinism related characteristics. He had a very light yellow hair and white skin. He was observed to have a pendular nystagmus and mild iris transillumination. Monocular flash responses were observed to be comparable for each eye at the midline, however the responses were asymmetrical. This kind of crossed asymmetry was in consistent with albinism. Sequencing was performed to investigate the possible TYR mutations present in the patient as well as in his relatives. Two variations of homozygous c.575C>A (p.Ser192Tyr) in exon 1 and homozygous c.1205G>A (p.Arg402Gln) in exon 4. were detected for the proband. Both of the parents were shown to be carriers of c.575C>A and c.1205G>A variations. The possible effects of both these variations on the structure and function of tyrosinase were investigated using HGMD, SIFT, MutationTester and PolyPhen. According to the HGMD, c.575C>A (p.Ser192Tyr) and c.1205G>A (p.Arg402Gln) are related with skin pigmentation and reported as a polymorphism. While SIFT and MutationTester has no prediction for these variations, PolyPhen reported them as probable damaging mutations. ClinVar database reported these as benign variants and dbVar reported an association between these variations and presence of freckles. In conclusion, we identified two previously-reported homozygous variations, c.575C>A and c.1205G>A, and family members of our proband are compound heterozygous of these variations. Our proband shows some of the clinical problems of OCA1 which includes hypopigmentation of the skin and hair, nystagmus, iris trans illumination, reduced stereoscopic vision, blonde fundi and crossed asymmetry of monocular flash responses that was in concordant with the variations we detected.

**1087W****Genetic therapeutic strategies for Bardet-Biedl syndrome type 1. M.**

Cring, A. Drack, V. Sheffield. University of Iowa, 4171 MERF, Iowa City, IA.

Bardet-Biedl syndrome (BBS) is a rare, autosomal recessive ciliopathy that results in retinal degeneration, male infertility, polydactyly, obesity, intellectual disability, renal anomalies, and several other phenotypes. Currently, there are no treatments for this genetically heterogeneous disease. The M390R mutation in BBS1 is the most common genetic lesion implicated in patients. Patients with this mutation typically go blind within the first two decades of life, and males are infertile. Each of these phenotypes are recapitulated in mouse models of *BBS1*<sup>M390R</sup>. The eye and testes are attractive targets for gene therapy and gene editing due to their accessibility for delivery of vectors. Previous work using gene therapy of *BBS1* via subretinal injection in mice has shown that overexpression of BBS1 causes toxicity and further degradation of the retina. One method of overcoming overexpression toxicity of BBS1 is to use CRISPR/Cas9 mediated homologous recombination to edit the native gene. Using ribonucleoprotein (RNP) transfection and an optimized ssODN donor template, we have achieved editing rates of approximately 23% *in vitro*. Continued work is aimed at using CRISPR/Cas9 RNPs delivered *in vivo* and *ex vivo* to rescue male fertility and preserve photoreceptors in a mouse model of BBS1. Additionally, we are preparing an AAV2/5 viral vector expressing N-terminal Flag tagged *BBS1* driven by the endogenous promoter. Previous work has shown that the Flag tag does not interfere with BBSome formation *in vitro*. We have shown that systemic delivery of AAV vectors via tail vein injections results in significant expression of an eGFP reporter gene in the retina. We will test for overexpression toxicity *in vitro* by transfecting or transducing HEK293 cells with our BBS1 constructs and assessing cellular proliferation and cell death. We will also test for overexpression toxicity *in vivo* by delivering the viral vector to *BBS1*<sup>M390R/M390R</sup> and wild-type mice via subretinal injections and comparing retinal thickness between treated and mock injected animals. We will test the effectiveness of rescue of retinal degeneration and visual preservation by immunohistology, electroretinograms, and swim tests. This study will show the feasibility of using genome editing and gene therapy to treat patients with male infertility and retinal degenerative diseases using a gene that requires well-regulated expression.

**Unique mutation spectrums in hearing-impaired Mongolian patients reveal possible migration events and founder effects of common deafness mutations.** *Y.H. Lin<sup>1,2,3</sup>, J. Erdenechuluun<sup>4</sup>, Z. Makhbal<sup>5</sup>, D. Bataakhuu<sup>6</sup>, Y.H. Lin<sup>1,7</sup>, C.J. Hsu<sup>1,3</sup>, C.C. Wu<sup>1,8</sup>, P.L. Chen<sup>2,7,8,9</sup>.* 1) Department of Otolaryngology, National Taiwan University Hospital, Taipei, Taiwan; 2) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan; 3) Department of Otolaryngology, Taichung Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Taichung, Taiwan; 4) Department of Otolaryngology, Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia; 5) Department of Otolaryngology, EMJJ hospital, Ulaanbaatar, Mongolia; 6) Department of Otolaryngology, National Center for Maternal and Child Health, Ulaanbaatar, Mongolia; 7) Graduate Institute of Molecular Medicine, National Taiwan University College of Medicine, Taipei, Taiwan; 8) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 9) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan.

More than 60% of patients with sensorineural hearing impairment have a genetic cause. From epidemiological perspectives, mutations of some deafness genes, including *GJB2*, *SLC26A4*, and *MTRNR1*, are much more prevalent than those of other genes worldwide. However, mutations spectrums of these common deafness genes differ significantly across different populations. To trace the origins of certain common deafness mutations in the Asian patients and to explore possible migration events, we performed genetic examination and haplotype analyses in 105 hearing-impaired families of Mongolian ethnicity, and compared their mutation spectrums and haplotypes to those of other East Asian cohorts, including Taiwanese, Japanese, Koreans, and Han Chinese. Dried blood spots samples were collected from Mongolian National University of Medical Sciences (Ulaanbaatar, Mongolia), and were transported to National Taiwan University Hospital (Taipei, Taiwan) for DNA extraction and mutation screening of three common deafness genes, i.e. *GJB2*, *SLC26A4*, and *MTRNR1*. In the Mongolian patients, the more prevalent *GJB2* mutations included c.23+1G>A (allele frequency of 3.33%) and c.235delC (2.86%), the more prevalent *SLC26A4* mutations included c.919-2A>G (3.81%), and the frequency of the m.1555A>G in *MTRNR1* was 1.90%. We also identified several special *GJB2* mutations which had never been reported in other East Asian populations, including c.35delG and c.269T>C (p.L90P). Further haplotype analyses revealed that some *GJB2* variants detected in the Mongolian and other East Asian patients might have the same origin. We also found some unique haplotypes only shared in the Mongolian patients, indicating migration events occurred through Central Asia to East Asia.

**1089F**

**Single base deletion in *ATOH7* gene causes abnormal eye development in a consanguineous family.** *M. Ansar, Z. Khan, E. Ullah, S. Sajid.* Department of Biochemistry, Faculty of Biological Sciences, Quaid I Azam University, 45320, Islamabad, Pakistan.

Atonal Homolog 7 (*ATOH7*) is an intronless gene that encodes a 152 amino acid protein. The encoded protein has a basic helix loop helix (bHLH) domain and works as a transcription factor to carry out spatial and temporal regulation of target genes expressed in the retinal ganglion cells (RGCs). *ATOH7* is a candidate gene in several ocular defects of optic nerve and retinal vasculature. Till to date nine mutations in *ATOH7* gene have been identified in patients presenting persistent hyperplastic primary vitreous (PHPV), optic nerve aplasia (ONA), non-syndromic congenital retinal nonattachment (NCRNA) and familial exudative vitreoretinopathy (FEVR). For this study a consanguineous family was recruited from a remote village which consisted of six individuals presenting autosomal recessive PHPV. After detailed clinical evaluations blood samples were collected from 12 individuals (including six PHPV patients) and their genomic DNA underwent genome-wide homozygosity mapping with 550K Illumina array. Homozygosity mapping led to the identification of a 9.5Mb homozygous region on chromosome 10:68180999-77687528 (GRCh37/hg19). This homozygous region included the candidate gene *ATOH7*, which was selected for Sanger sequencing in all available individuals of this family. DNA sequencing identified a novel homozygous mutation c.531delG in all affected individuals, while the mutation was in heterozygous form in the unaffected carrier parent. The variant c.531delG segregates in the family and is absent in the healthy controls and public databases. Mutation taster predicts that c.531delG deletion alters the open reading frame (ORF) and produces a premature stop codon p.Ala32Profs\*55, which probably result in the formation of a truncated protein. DNA binding and dimerization ability of the *ATOH7* encoded protein resides in the protein region spanning from 42 to 92 amino acids. It is therefore very likely that loss of this region due to c.531delG deletion (p.Ala32Profs\*55) in the affected individuals of this family compromise the role of *ATOH7* encoded protein as transcription factor. However additional functional characterization is required to explore the pathogenic mechanism of *ATOH7* mutation identified in this study.

**1090W**

**Molecular genetics of the Usher syndrome in Saudi Arabia: Identification of known and novel mutations by homozygosity mapping and next generation sequencing.** K. Ramzan<sup>1</sup>, M. Al Owain<sup>1</sup>, S. Al Hazzaa<sup>1</sup>, S. Afzal<sup>2</sup>, F. Imtiaz<sup>1</sup>. 1) King Faisal Specialist Hospital and Research Centre, Riyadh, Central, Saudi Arabia; 2) King Saud university, Saudi Arabia.

Usher syndrome (USH) is the most common cause of combined deafness and blindness inherited in an autosomal recessive mode. Molecular diagnosis is of great significance in revealing the molecular pathogenesis and aiding the clinical diagnosis of this disease. However, the molecular diagnosis remains a challenge due to the phenotypic and genetic heterogeneity in USH. Our study aims to comprehensively delineate the genetic basis of this disorder in Saudi Arabia. Consanguineous families are a powerful resource for genetic linkage studies/homozygosity mapping for recessively inherited hearing impairment. Prioritized linkage analysis and homozygosity mapping for was conducted. A next-generation sequencing-based multiplexing assay that encompasses the 120 known hearing loss genes was also used. For genes involved in Usher syndrome, we found mutation in MYO7A (42 families), CDH23 (5 families), PCDH15 (4 families), USH1G (1 family), USH1C (1 family) and USH2A (2 family). The overall results of this study are highly suggestive that the underlying molecular basis of hearing loss in Saudi Arabia is very genetically heterogeneous. The benefit of this study will hopefully provide foundation for knowledge and awareness through screening of carrier status and genetic counseling, thereby having a major impact upon early intervention for and prevention of Usher syndrome in our population.

**1091T**

**SLC6A6: Nutritional therapeutic potential of a novel autosomal recessive gene for progressive retinal degeneration and cardiomyopathy.** E. Ranza<sup>1</sup>, M. Ansar<sup>2</sup>, M.T. Sarwar<sup>2,3</sup>, M. Shetty<sup>4</sup>, S.A. Paracha<sup>3</sup>, J. Khan<sup>3</sup>, I. Kern<sup>5</sup>, C.J. Pournaras<sup>6</sup>, A. Malcles<sup>7</sup>, F.A. Santoni<sup>1,2</sup>, P. Makrythanasis<sup>1,2</sup>, K. Henry<sup>4</sup>, J. Ahmed<sup>3</sup>, S.E. Antonarakis<sup>1,2,8</sup>. 1) Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland; 2) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 3) Institute of Basic Medical Sciences, Khyber Medical University, Peshawar, Pakistan; 4) Dept. of Biomedical Sciences, School of Medicine and Health Sciences, University of North Dakota, N.Columbia, USA; 5) Pediatric Nephrology and Metabolism Unit, Pediatric Subspecialties Service, Children's Hospital, Geneva University Hospitals, Geneva, Switzerland; 6) Hirslanden Clinique La Colline, Geneva, Switzerland; 7) Department of Ophthalmology, University Hospitals of Geneva, Geneva, Switzerland; 8) iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

*SLC6A6* (OMIM#186854) encodes a taurine transporter, whose knockout in a reported mouse model causes progressive retinal degeneration, cardiomyopathy and very low taurine levels in blood and other tissues. Taurine deficiency in cats leads to retinal degeneration and cardiomyopathy. To date, *SLC6A6* pathogenic variants have not been linked to any pathology in humans. By a combination of exome sequencing and homozygosity mapping, we have studied a Pakistani consanguineous family (F315), with two children suffering from progressive visual impairment. We have identified a recessively segregating likely pathogenic homozygous missense variant Gly399Val in the 8<sup>th</sup> transmembrane domain of *SLC6A6*. Gly399 is very well conserved down to zebrafish. Molecular modeling of this variant has indicated that it likely cause displacement of the Tyr138 (TM3) side chain, which is important for recognition and transport of taurine. The two affected children (15-years old boy and 6-years old girl) have very low blood taurine levels (6 and 7  $\mu\text{mol/l}$ ), while their heterozygous parents have intermediate levels (24 and 34  $\mu\text{mol/l}$ ), and an unaffected non-carrier sibling has normal levels (71  $\mu\text{mol/l}$ ) (normal values: 37-127  $\mu\text{mol/l}$ ). In-vitro experiments showed that the taurine uptake of HEK-293 cells with mutant (Gly399Val) *SLC6A6* was between 11-18% compared to normal. Detailed clinical evaluation showed that the affected boy has complete visual loss, while the affected girl has severe but partial retinal degeneration. In addition, both affected siblings have mild hypokinetic cardiomyopathy with systolic dysfunction. After ethical approval, an oral taurine loading test of 100mg/kg was performed in the family as recommended by the literature and the pharmacological assessment. We observed that the patients receiving a taurine supplementation of 100mg/kg/day (divided in 3 doses) have nearly normal taurine levels in blood. We have initiated a taurine supplementation to both affected individuals with the objective to delay the progression of the visual impairment in the affected girl and to treat the cardiomyopathy in both siblings. We conclude that *SLC6A6* is a novel causative gene for progressive visual loss and cardiomyopathy in humans and provides a potential target for nutritional therapeutic intervention.
