CHARGE syndrome is an autosomal dominant, multiple congenital anomaly condition associated with combined vision and hearing loss and malformations in craniofacial structures. CHARGE syndrome affects 1 in 10,000 newborns worldwide and is the second leading cause of deafblindness. Individuals with CHARGE syndrome exhibit variable expressivity of major clinical features, including ocular coloboma, choanal atresia, clefting, and ear abnormalities including hearing loss and inner ear dysplasia. Minor clinical features include global developmental delay, hypogonadotropic hypogonadism, cardiac malformations, and skeletal/renal abnormalities. Pathogenic variants in the ATP-dependent chromatin-remodeling gene *CHD7* are present in the majority of individuals with CHARGE syndrome. However, a fraction (5-40%, depending on the study) of individuals with clinical features of CHARGE syndrome test negative for *CHD7* pathogenic variants, deletions, or duplications, raising the possibility of other genetic and non-genetic etiologies. We hypothesized that non-coding variants in *CHD7* and pathogenic variants in other genes may also cause CHARGE syndrome. To test this, we performed whole exome sequencing (WES) on 28 families with at least one individual who had clinical features of CHARGE syndrome. Pathogenic variants in *CHD7* were present in 15 affected individuals (53.6%), whereas 4 affected individuals (14.3%) exhibited pathogenic variants in genes other than *CHD7* (*EP300*, *KDM6A*, *RERE*, and *PUF60*). The remaining 9 affected individuals (32.1%) were not confirmed to have a pathogenic variant, and thus require further analysis. The individuals with pathogenic variants in *EP300*, *KDM6A*, and *PUF60* exhibit clinical features of Rubinstein-Taybi, Kabuki, and Verheij syndromes, respectively, prompting reassignment of clinical diagnoses. *RERE* encodes Arginine-Glutamic acid dipeptide repeats protein, a broadly expressed nuclear receptor and positive regulator of retinoic acid signaling. Pathogenic variants in *RERE* have been previously reported in two individuals with clinical diagnoses of CHARGE syndrome, one of whom tested negative for *CHD7* pathogenic variants. Taken together, our results show that comprehensive WES can clarify clinical diagnoses and establish new phenotype-genotype relationships. These observations highlight overlapping molecular and epigenetic mechanisms that contribute to the pathogenesis of CHARGE syndrome and related clinical disorders.

**Novel mutations underlying sensorineural hearing loss in Brazil.** K. Lezirovitz<sup>1</sup>, G. Vieira-Silva<sup>1</sup>, V. Pedroso-Campos<sup>1</sup>, E. Pardono<sup>2</sup>, J. Sampaio-Silva<sup>1</sup>, R. Jesus-Santos<sup>1</sup>, L. Reis-Nascimento<sup>1</sup>, R.K. Tsuji<sup>3</sup>, A.C. Batissoco<sup>1</sup>, R.F. Bento<sup>1</sup>, J. Oiticica<sup>1</sup>. 1) Otolaryngology Lab/LIM32, School of Medicine Clinics Hospital, University of São Paulo, São Paulo, São Paulo, Brazil; 2) Health Sciences School of São Paulo – FACIS, São Paulo, SP, Brazil; 3) Cochlear Implant Group, Otolaryngology Department, School of Medicine Clinics Hospital, University of São Paulo, São Paulo, SP, Brazil.

Hearing loss is a highly genetic heterogeneous disorder with many causative genes for syndromic and nonsyndromic forms. It has major impacts in language acquisition and communication leading to social, physical and psychological issues. We investigated the prevalence of *GJB2* gene mutations in 339 sensorineural hearing loss Brazilian patients, assisted by the Department of Otolaryngology, São Paulo Clinics Hospital, the largest hospital complex from Latin America. Besides, the prevalence of other known deafness genes were studied in selected cases (*PAX3*, *MITF*, *SLC26A4*, *OTOF*). Novel mutations were considered as probably pathogenic based on at least two bioinformatics tools and absence in databases (ExAC, 1000G). Among the 339 patients, 92% were nonsyndromic and 1,4% has clinical suspicion of Waardenburg syndrome (WS). Sanger sequencing of *GJB2* and screening of *GJB6* deletions revealed biallelic pathogenic mutations in 11% of our samples, the most frequent mutations being c.35delG and p.W24X. We identified a novel pathogenic mutation, c.79\_82delGTCCinsAGA (p.Val27fs\*8), in compound heterozygosity with c.35delG in one isolated case with prelingual profound deafness. WS has autosomal dominant inheritance and is characterized by pigmentary defects, facial dimorphisms and hearing loss, with a large inter- and intra-familial expressivity. From the five cases with clinical suspicion of WS, we identified novel probably pathogenic mutations in three of them: one in *PAX3* (c.281C>A, p.G94A) and two in *MITF* (c.1052C>A, p.S351Y; c.644\_645insA, p.H215Qfs\*11). Segregation analysis confirmed these mutations as probably causative: affected mother and two affected uncles also had p.G94A; p.S351Y was inherited from the father, who presented a blond wick above the right ear; c.644\_645insA was *de novo* and the parents has no clinical signs of WS. In eight selected patients with inner ear malformation we found biallelic *SLC26A4* mutations in two (25%): the previously undescribed c.481T>A (p.F161I) and three already described as pathogenic (c.G636T, p.V138F; c.554G>C, p.R185T and c.1615-2A>G). Among four patients with auditory neuropathy, biallelic mutations in *OTOF* were identified in one case and his brother (25%): the novel pathogenic mutation c.3048C>A (p.E1017\*) and c.3400C>T (p.R1134\*), previously described as pathogenic. Our data highlights the importance of these genes for molecular diagnosis, genetic counselling and better comprehension of genotype-phenotype correlations.

**Unexpected difficulties in discovery of genes involved in hearing loss.** S. Naz<sup>1</sup>, N. Sobreira<sup>2</sup>, D. Witmer<sup>3</sup>, M. Ramzan<sup>1</sup>, *Baylor-Hopkins Center for Mendelian Genomics*. 1) School of Biological Sciences, University of the Punjab, Lahore, Punjab, Pakistan; 2) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 3) Center for Inherited Disease Research (CIDR), Johns Hopkins University School of Medicine, Baltimore, MD.

The incidence of recessively inherited moderate to severe hearing loss is unknown, though it is believed to be more common as compared to profound deafness. We ascertained three consanguineous families, with three individuals each who manifested moderate to severe hearing loss. We excluded the known deafness genes by linkage analyses. We completed whole exome sequencing in order to identify the pathogenic variants responsible for the phenotype in the participants. Variants with an allele frequency of <0.01 were retained. Apart from all missense, frameshift, in-frame indels, stop-loss and nonsense variants, we examined compound heterozygous variants as well as synonymous and intronic variants located in regions of homozygosity shared by affected individuals in each family. The frequency of the variants was checked in gnomAD. Ambiguous results were obtained in all three cases. In the first family, a homozygous variant (p.P78Q) was identified in the paralogue of a known deafness gene. This co-segregating variant was predicted to be damaging by three of seven *in silico* prediction tools. However, the glutamine residue is fixed in the same corresponding position in one orthologous protein. Comparative genomics indicates the possibility of a cis-suppression effect (Jordan et al. 2015, Nature) since the immediate upstream amino acid is a proline, instead of the serine present in humans. In the second family with three affected cousins, we found a co-segregating, predicted pathogenic variant (p.G>R) in a gene on chromosome 2. The glycine residue is conserved in evolution, but the affected gene is located close to *OTOF*, a known deafness gene. Though, we excluded *OTOF* both by linkage and sequencing, the possibility remains that a disease causing variant is located in an unsequenced regulatory element which affects *OTOF*. In the third family, a predicted pathogenic missense variant (p.Q101P) was identified in the deafness gene *SLC26A4* which was homozygous in the three affected individuals. However, the variant was also homozygous in the unaffected father who manifested no hearing loss even in the fourth decade of his life. These findings highlight challenges for the identification of pathogenic variants in moderate to severe hearing loss. Functional testing is required as well as whole genome sequencing in order to unambiguously elucidate the genetic underpinnings of the disorders in these families. **Investigation of novel genetic bases for strabismus using linkage analysis and next-generation sequencing.** J. Jurgens<sup>1</sup>, M. Brucato<sup>2</sup>, D. Avramopoulos<sup>1</sup>, E. Pugh<sup>1</sup>, D. Witmer<sup>1</sup>, H. Ling<sup>1</sup>, K. Hetrick<sup>1</sup>, P. Zhang<sup>1</sup>, K. Doheny<sup>1</sup>, C. Ladd-Acosta<sup>2</sup>, D. Valle<sup>1</sup>, N. Sobreira<sup>1</sup>, J. Nathans<sup>3</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3) Department of Molecular Biology and Genetics, Johns Hopkins University School of Medicine, Baltimore, MD.

Strabismus is a common disorder affecting 1-4% of the population. Despite evidence for high heritability, the genetic basis of strabismus remains poorly understood. Parikh et al. (2003) described a pedigree (19 affected, 26 unaffected) in which strabismus appeared to be inherited as an autosomal dominant trait with affected members in 3 successive generations, but the phenotype was linked to chromosome 7p22.1 under a recessive inheritance model (LOD=4.51). To search for novel genetic causes of strabismus, we first repeated linkage analysis in this family using SNP array data and identified three linked regions with LOD scores>2.0. Two linked intervals on 7p21.1-7p21.3 (LOD=3.3; 11.5 Mb containing 38 genes) and 1p22.3-1p31.1 (LOD=2.5; 3.6 Mb containing 35 genes) were consistent with an autosomal recessive model, while one region on 7q11.21-7q22.1 fit an autosomal dominant model (LOD=2.4; 31.3 Mb containing 214 genes). We performed whole exome sequencing (WES) on 7 affected family members from this pedigree but failed to identify rare (MAF<0.01) functional variants (missense, nonsense, splice site, and indels) co-segregating with strabismus inside or outside of the linked regions. To investigate variants that were missed by WES, we next conducted whole genome sequencing (WGS) on 4 severely affected and genetically distant family members. We began by analyzing WGS in the same manner as WES, but found no variants that had not been identified by WES. Using five algorithms, we searched for CNVs and structural variants in the linkage regions that co-segregated with strabismus, but found none that perturbed coding regions. Currently, we are prioritizing noncoding variants in the linked intervals using functional annotation tools (e.g. ENCODE, Roadmap Epigenomics, GWAVA, CADD, VISTA Enhancer, and miRdSNP) and additional frequency-based databases for filtering (e.g. gnomAD). We are also considering alternative genetic models, including potential oligogenic contributions of variants in the linked interval(s) as well as increased frequencies of disease alleles. Once novel candidate genes and variants are identified, we will proceed with their validation and segregation analysis in additional family members. We anticipate that identification of causal genetic variant(s) in this family will identify relevant biological systems for strabismus. *We thank the Burroughs-Wellcome Fund/MD-GEM, NEI 2T32EY007143-21, and NHGRI 1U54HG006542 for support.*

**Linkage analysis and whole genome sequencing analysis in familial isolated strabismus.** X. Ye<sup>1,2,3</sup>, C. Shyr<sup>2,3</sup>, N. Roslin<sup>5</sup>, D. Giaschi<sup>4</sup>, C. Gregory-Evans<sup>4</sup>, M. Patel<sup>1,3</sup>, W.W. Wasserman<sup>1,2,3</sup>. 1) Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Centre for Molecular Medicine and Therapeutics, Vancouver, BC, Canada; 3) BC Children's Hospital Research Institute, BC, Canada, Vancouver, BC, Canada; 4) Ophthalmology and Visual Sciences, University of British Columbia, Vancouver, BC, Canada; 5) FORGE Canada Consortium.

Strabismus is a misalignment of the eyes, with prevalence as high as 5% in the general population. This complex condition has been associated with many environmental risk factors and genetic components, the latter having been demonstrated through twin studies and family studies. However, we still have limited understanding of strabismus genetics for isolated strabismus, the most common form. We report a seven-generation pedigree with an autosomal dominant pattern of isolated strabismus. We requested relevant clinical records of affected family members and/or arranged detailed phenotyping. Affected members have either esotropic or hypertropic, comitant or non-comitant, strabismus with varying severity. No other ocular or neurological abnormalities segregated in the pedigree. Fourteen family members from three generations were enrolled in total, with nine affected members. The most distantly related individuals are third-degree cousins. Thirteen were enrolled initially for linkage analysis, and an affected second-degree cousin of the index was enrolled later for whole genome sequencing. A high density genome-wide mapping study based on HumanOmni 2.5 SNP array data of thirteen individuals was undertaken and showed a maximum multipoint LOD score of 3.55 on chromosome 14q under parametric linkage models in MERLIN. The identified linkage region on chromosome 14 is a gene poor region, and a parallel whole exome sequencing study on a pair of third-degree cousins did not reveal potential protein-coding variants. To follow up, we conducted a whole genome sequencing study in three second-degree cousins. SNPs extracted from whole genome sequencing of the new participant were combined with the SNP array data and confirm the linkage region. A few non-coding variants were identified by a combination of bioinformatic analyses. The top candidate variants are being subjected to validation focusing on candidate genes associated with the altered regulatory regions. Gene expression levels in lymphoblastoid cell lines and gene knockdown effect in a zebrafish morpholino model are used to examine the candidate genes. Results will be reported at the meeting. Study of this rare family provides an opportunity to reveal genetics of isolated strabismus and suggest diverse strabismic phenotypes can be associated with the same genetic factor.

**A novel homozygous deletion in last exon of CYP1B1 gene cause primary congenital glaucoma in an Iranian female patient.** M. Noruzinia, A. Salehi, M. Ahmadvand, O. Bashti. Department of Medical Genetics, Tarbiat modares university, Tehran, GA.

Primary Congenital Glaucoma (PCG) is a serious eye disease that is responsible for 15% of blindness in the world. Generally, defects in the trabecular meshwork and anterior chamber angle lead to primary congenital glaucoma. The disease is severe, manifesting at birth or early infancy, associated with intraocular pressure (IOP), and enlarged cornea and globe (buphthalmos). The precise molecular basis of this disabling disease is unclear but some genetic pathogenic mutations are reported in PCG. Mutations in *CYP1B1* and *LTBP2* are two important explanations for PCG. The *CYP1B1* gene harbors more than 70 mutations leading to PCG in different ethnic groups and missense mutations assigned to most cases. Here we report a novel homozygote deletion of a "C" nucleotide at the last exon of *CYP1B1* gene in a female patient suffering from PCG. The patient born of a consanguineous marriage and her symptoms are typical for PCG. According to these representations, we employed targeted sequence analysis for genes associated with PCG (*ASB10*, *CYP1B1*, *FOXC1*, *LTBP2*, *MYOC*, *NTF4*, *OPA1*, *OPTN*, *TBK1*, *WDR36*). Obtained sequences were aligned to human reference genome (GRCh37/h19) using BWA program, analyzed by Picard and GTAK-Lite toolkit to identify variants in the targeted genes relevant to clinical indication. A novel mutation in exon 3 of *CYP1B1*. Linkage analysis further confirmed the absence of the mutation in healthy members of the family. This novel mutation is pathogenic and would be considered in genetic counseling and genetic testing in Iran. Phenotypes in this family and mechanism of mutation pathogenicity are discussed in this article.

**Identification of novel mutations of *POU3F4* in seven Chinese families with X-linked nonsyndromic hearing loss.** H. Yuan, J. Cheng, Y. Lu. Medical Genetics Center, Southwest Hospital, Chongqing, China.

DFNX2 deafness, accounting for 50% of X-linked nonsyndromic hearing loss, can be easily distinguished from the other X-linked hearing loss by the remarkable radiological features include partial hypoplasia of the cochlea and dilation of the internal auditory canal, often with a fistulous communication between its lateral aspect. *POU3F4* is the causative gene for DFNX2. We report 7 Chinese family with X-linked non-syndromic hearing impairment in which seven affected males demonstrated congenital profound sensorineural hearing loss. Computer tomography of the temporal bones showed bilateral dilation of the internal auditory canals and with a fistulous communication between its lateral aspect and the basal turn of the cochlea in two affected brothers and normal in their mother. Seven missense mutation in the *POU3F4* gene were identified in these families, and failed to detect in 3700 normal human control. The appropriate use of the genetic testing and prenatal diagnosis has great potential to reduce the recurrence risk in DFNX2 families with genetic defects.

**Next generation sequencing of three families with severe keratoconus identifies putative disease-causing variants.** S.E.M. Lucas<sup>1</sup>, B.J. McComish<sup>1</sup>, N.B. Blackburn<sup>1,2</sup>, E. Souzeau<sup>3</sup>, R.A. Mills<sup>3</sup>, J.E. Craig<sup>3</sup>, S.E. Staffieri<sup>4</sup>, D.A. Mackey<sup>5</sup>, J.C. Charlesworth<sup>1</sup>, K.P. Burdon<sup>1</sup>. 1) Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania, Australia; 2) South Texas Diabetes and Obesity Institute, School of Medicine, University of Texas Rio Grande Valley, Brownsville, Texas, USA; 3) Department of Ophthalmology, Flinders University, Adelaide, South Australia, Australia; 4) Centre for Eye Research Australia, Royal Victorian Eye and Ear Hospital, Melbourne, Victoria, Australia; 5) Lion's Eye Institute, Centre for Ophthalmology and Visual Sciences, University of Western Australia, Perth, Western Australia, Australia.

Keratoconus is an eye disease characterised by progressive thinning and protrusion of the cornea causing high myopia and irregular astigmatism. This severely affects vision and quality of life. Keratoconus has a strong genetic basis, but is typically considered a complex disease. Familial examples of Mendelian autosomal dominant and recessive transmission are reported; however, the genetic cause has not yet been identified in most families. Using whole exome (WES) and whole genome (WGS) sequencing, we aim to identify putatively functional variants that segregate with disease in three pedigrees with highly penetrant, severe keratoconus. Family 1 is an extended Australian pedigree with nine affected and seven unaffected family members across four generations. We previously reported two linkage regions, 1p36.23-36.21 and 8q13.1-21.11, and hypothesised a digenic mode of inheritance in this family. WES was obtained for all 16 family members and WGS data for four cases and two unaffected individuals. Family 2 is an extended pedigree from Jordan with eight cases and three unaffected relatives with autosomal dominant keratoconus. WGS was obtained for all 11 family members. Family 3 is an Australian family with autosomal recessive inheritance affecting two siblings from unaffected and unrelated parents. One of the cases has an unaffected child. WGS data were obtained for all five family members. We identified a potentially pathogenic variant in *VPS13D* within the 1p36.23-36.21 linkage region in Family 1. This c.1850C>T variant results in a p.(P617L) substitution, has a frequency of 0.00007 in ExAC, is predicted to be deleterious (CADD score of 34) and occurs at a highly conserved residue (GERP score of 6.07). Very little is known about the function of *VPS13D*. It may play a role in the regulation of IL-6, which has been reported to be increased in tears from keratoconic eyes. We have identified a putative keratoconus-causing variant in a novel gene, *VPS13D*. Analysis is continuing with the WGS data from all three families to elucidate a potentially functional variant on chromosome 8 in Family 1 and to identify linkage regions and candidate genes in Families 2 and 3. Identifying genes that contribute to keratoconus susceptibility would aid in identifying key biological pathways involved in the disease process. This is essential for developing novel non-surgical treatments with the potential to slow or prevent keratoconus progression.

**1100T****Identification of novel candidate genes for recessive visual impairment**

**by analyzing 132 consanguineous families.** M. Ansari<sup>1</sup>, M.T. Sarwar<sup>2</sup>, H. Shaikh<sup>3</sup>, P. Makrythanasis<sup>1</sup>, N. Batool<sup>1,2</sup>, K. Gul<sup>4</sup>, A.A. Khan<sup>4</sup>, A. Nazir<sup>5</sup>, S.A. Paracha<sup>6</sup>, J. Khan<sup>7</sup>, S. Qureshi<sup>5</sup>, S. Imtiaz<sup>2</sup>, Z. Iqbal<sup>6</sup>, E. Falconnet<sup>1</sup>, P.G. Ribaux<sup>1</sup>, Y.M. Waryah<sup>3</sup>, M. Guipponi<sup>1,4</sup>, C. Borel<sup>1</sup>, F.A. Santoni<sup>1,4</sup>, A.M. Waryah<sup>3</sup>, J. Ahmed<sup>2</sup>, S.E. Antonarakis<sup>1,4,7</sup>. 1) Department of Genetic Medicine and Development, University of Geneva, Geneva, Switzerland; 2) Institute of Basic Medical Sciences, Khyber Medical University, Peshawar, Pakistan; 3) Molecular Biology and Genetics Department, Medical Research Center, Liaquat University of Medical and Health Sciences, Jamshoro, Pakistan; 4) Service of Genetic Medicine, University Hospitals of Geneva, Geneva, Switzerland; 5) Department of Genetics, University of Karachi, Karachi, Pakistan; 6) Department of Neurology, Oslo University Hospital, Oslo, Norway; 7) iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland.

Populations that practice consanguinity have a higher prevalence of autosomal recessive disorders due to the extensive genomic regions of homozygosity that include alleles identical by descent. By studying runs of homozygosity (ROH) across the genome, we have observed that the average ROH size of 215 Mb in the offspring of consanguineous families is significantly larger than that of 25 Mb in outbred individuals. Using exome sequencing and genotyping, we have analyzed 132 highly consanguineous families from Pakistan (where consanguinity rate is > 60%), with undiagnosed likely autosomal recessive visual impairment (VI). For each family, there were at least 2 affected individuals; samples from both parents and offspring were collected after informed consent; there were 400 affected individuals in this study. Although the diagnostic yield in visual impairment families is considerably high, the study of consanguineous families continues to provide the opportunity to discover new recessive genes. In 62% of the VI families, we have identified known or novel likely pathogenic variants in genes which are already reported to cause visual impairment (in a similar number of consanguineous families with intellectual disability from the same geographical origin the diagnostic yield is approximately 28%). In 20% of the VI families, we failed to identify any causative or candidate variants in the coding regions covered by exome sequencing. However, in 18% of the VI families we have found likely damaging variants in 24 novel candidate genes. Some of the candidate genes are likely the targets for potential therapeutic interventions. All of the candidate genes/variants have been submitted to matchmaking efforts. We conclude that the discovery of novel autosomal recessive genes for visual impairment can be accelerated by analyzing large cohorts of consanguineous families. This has important implication in correct molecular diagnosis, family planning, and may reduce the incidence of autosomal recessive disorders in consanguineous couples. Gene discovery of novel candidates is the first step in understanding the molecular pathophysiology of a disease and may contribute to innovative treatment.

**1101F****Genomic analysis of inherited hearing loss in the Palestinian population.**

A.I. Abu-Rayyan<sup>1,2</sup>, L.A. Kamal<sup>1</sup>, C.J. Canavati<sup>1</sup>, Z. Brownstein<sup>2</sup>, S. Gulsuner<sup>3</sup>, T. Walsh<sup>3</sup>, M.C. King<sup>3</sup>, K.B Avraham<sup>2</sup>, M.N Kanaan<sup>1</sup>. 1) Biological Sciences, Bethlehem University, Bethlehem, Palestinian Territory; 2) Department of Human Molecular Genetics & Biochemistry, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 3) Department of Medical Genetics and Department of Genome Sciences, University of Washington, Seattle, WA, USA.

Childhood onset hearing loss (HL) in Palestine is more frequent than elsewhere, in part due to the high rate of consanguineous marriage in this population. The goal of our project is to estimate the proportion of childhood onset HL in Palestine that is genetic and to identify and characterize all the genes involved. Through schools and clinics for the deaf in the West Bank and Gaza, we enrolled 364 families with HL, confirmed by audiology, either syndromic (21 families) or non-syndromic (343 families). As a first screen, a deaf proband from each family was sequenced for GJB2 and 19 other mutations that are relatively common among Palestinians with HL. Only 11% of families (40) had mutations in GJB2, which is responsible for most inherited HL worldwide. HL in an additional 18% of families (65) was due to other founder alleles. Of the unresolved families, 120 were sequenced using our custom gene panel of 246 human and mouse deafness genes (PMID: 21917145). Novel candidate variants were evaluated by co-segregation with HL in fully sampled families and in Palestinian hearing controls. For genes expressed in accessible tissue, potential splice variants were evaluated by transcript analysis of participant RNA. All variants interpreted as causal were screened in the entire cohort of 364 families. Ultimately, HL in 45% of families (164) was explained by 74 different mutations, most not previously reported, in 29 genes. Results were submitted to LOVD and ClinVar. Genes responsible for non-syndromic HL were GJB2 (40 families), MYO15A (26), TRIOBP (14), MYO7A (11), TMPRSS3 (10), CDH23 (7), TECTA (6), OTOA (3); CACNA1D, CLDN14, ESRRB, ADGRV1, LOXHD1, MYO6, PJKV, PTRPQ, and PTRH2 (2 each); and EPS8L2, MYH9, PCDH15, POU3F4, TMC1, and TMHS (1 each). Genes responsible for syndromic or other HL phenotypes were SLC26A4 (Pendred signs, highly variable across families, 12 families), PAX3 (Waardenburg-1, 3), GPSM2 (CMCS, 2), OTOF (auditory neuropathy, 2), PTRH2 (IMNEPD, 2) and USH1G (RP, 1). The 38% of families (139) that are unsolved singleton cases provide an upper estimate for the proportion of hearing loss in the population that may be due to non-genetic causes. The 16% of families (60) with multiple deaf children and no pathogenic mutation in any known deafness gene represent a highly informative resource for identification and characterization of additional HL genes and of distant non-coding regulatory mutations. Supported by NIH R01DC011835 to KBA and MNK.

**Siblings with Perrault syndrome and *LARS2* mutation who presented with neurologic abnormalities.** R. Kosaki<sup>1</sup>, R. Horikawa<sup>2</sup>, E. Fujii<sup>3</sup>, K. Kosaki<sup>4</sup>.

1) Division of Medical Genetics, National Center for Child Health and Development, Tokyo, Japan; 2) Division of Endocrinology and Metabolism, National Center for Child Health and Development, Tokyo, Japan; 3) Department of Perinatal Medicine and Maternal Care, National Center for Child Health and Development, Tokyo, Japan; 4) Center for Medical Genetics, Keio University School of Medicine.

Perrault syndrome represents a genetically heterogeneous disorder characterized by sensorineural hearing loss in males and females and ovarian dysfunction in females. Causative genes include *HARS2*, *HSD17B4*, *CLPP*, *C10orf2*, and *LARS2*. Some patients with Perrault syndrome exhibit neurologic features including learning disability, cerebellar ataxia, and peripheral neuropathy and are classified as type 2 and are clinically separate from those without neurological symptoms other than a hearing loss (type 1). To date, all reported patients with *LARS2* mutations (15 patients in 8 families) have been classified as type 1. Here, we report female siblings with biallelic mutations in *LARS2*, p.Glu294Lys and p.Thr519Met, who were classified as type 2. The probanda developed progressive sensorineural hearing loss at 18 months and pervasive developmental disorder at 8 years, with repetitive behavior, insistence on sameness, attention deficit, tic, irritability, and an ataxic gait. At age 15 years, she was diagnosed as having primary amenorrhea with elevated FSH and LH and a decreased estradiol; ultrasound and magnetic resonance imaging examinations revealed a small uterus and no detectable ovaries. The probanda's younger sister presented with neonatal sensorineural hearing loss and a mild delay in motor and speech development. She was diagnosed as having primary amenorrhea with endocrinologic and radiographic findings that were comparable to those of her sister. She had difficulty with reading comprehension, and had trouble with open-ended test questions at 12 years of age. We concluded that Perrault syndrome patients with *LARS2* mutations are at risk for neurologic problems, despite previous notions otherwise. .

*KCNE1* encodes a regulatory subunit that can associate with the KCNQ1 voltage-gated potassium channel comprised of four subunits encoded by *KCNQ1*. *KCNE1* and *KCNQ1* appear to be necessary for both normal hearing and cardiac ventricular repolarization. Mutations in these two genes are associated with Jervell and Lange-Nielson syndrome (JLNS1, MIM 220400 and JLNS2, MIM 612347, respectively). JLNS is an autosomal recessive disorder characterized by congenital, bilateral profound sensorineural hearing loss and long electrocardiographic QT intervals (>500 milliseconds), and syncope events or sudden cardiac death in the first or second decade of life if left untreated. Heterozygous normal-hearing carriers can have long QT intervals as part of Romano-Ward syndrome. We ascertained a large consanguineous family (PKDF461) segregating non-syndromic deafness, which showed evidence for linkage to chromosome 21q. Whole genome sequencing identified a rare stop gain variant (p.Tyr46\*) of *KCNE1* (allele frequency of 0.000008123 in gnomAD) co-segregating with the deafness phenotype in this family. Family PKDF461 has four deaf individuals who are homozygous for the p.Tyr46\* allele, three normal-hearing heterozygous carriers and four normal-hearing individuals that are homozygous for the wild type tyrosine-46 residue. Biallelic null pathogenic variants in *KCNE1* have not been previously reported. In family PKDF461, homozygotes and heterozygotes for p.Tyr46\* have a normal QT interval and there have been no sudden unexplained deaths. The absence of a cardiac phenotype in the presence of a null allele of human *KCNE1* may be explained if in the heart (but not the ear), wild type *KCNQ1* can function adequately in the complete absence of a *KCNE1* beta-subunit, but does not function properly in the presence of a dominant negative or gain of function variant of *KCNE1*, which may negatively effect the *KCNQ1* function when biallelic, as in JLNS patients. We hypothesize that another member of the KCNE gene family may compensate for loss of *KCNE1* function in the heart but not the ear of our patients. Although several missense mutations of *KCNE1* are associated with JLNS2, our study indicates a more complex genotype-phenotype relationship, as a biallelic null variant of *KCNE1* is associated with non-syndromic deafness.

**Variation in *MERTK* in patients with retinal dystrophy.** C. Jespersgaard<sup>1</sup>, H.G. Gellert-Kristensen<sup>1</sup>, M. Fang<sup>2</sup>, M. Bertelsen<sup>1</sup>, X. Dang<sup>2</sup>, H. Jensen<sup>2</sup>, Y. Shen<sup>2</sup>, N. Bech<sup>2</sup>, I. Dai<sup>2</sup>, T. Rosenberg<sup>2</sup>, J. Zhang<sup>2</sup>, L.B. Moeller<sup>1</sup>, Z. Tümer<sup>1</sup>, K. Broendum-Nielsen<sup>1</sup>, K. Groenskov<sup>1</sup>. 1) Clinical Genetics Department, Kennedy Center, Rigshospitalet, Glostrup, Denmark; 2) BGI-Shenzhen, Shenzhen 518083, China; 3) The National Eye Clinic, The Kennedy Center, Department of Ophthalmology, Copenhagen University Hospital, Glostrup, Denmark.

Retinal dystrophy encompasses a range of diagnoses and modes of inheritance, and more than 250 genes have been associated so far. Pathogenic sequence variations in one of these, MER tyrosinase kinase protooncogene; *MERTK*, are known to cause retinitis pigmentosa type 38. *MERTK* associated retinitis pigmentosa comprise around 1 % of patients displaying a recessive inheritance. Previously 60 different disease causing or probably disease causing variants have been reported in HGMD® Professional 2017.1. Among these are four gross deletions and recently Evans et al reported an additional patient with a *MERTK* deletion encompassing exon 6 to 8. One of the reported gross deletions has been shown to be a founder in the Faroe Islands and is responsible for approximately 30 % of all retinitis pigmentosa cases within that population. In a study with targeted sequencing of 804 individuals clinically diagnosed with retinal dystrophy we found 6 individuals who were homozygous or compound heterozygous for variants in *MERTK*. The individuals had one of the following diagnoses: autosomal recessive retinitis pigmentosa; autosomal dominant retinitis pigmentosa; X-linked retinitis pigmentosa; Leber's congenital amaurosis; Usher syndrome; Bardet-Biedl syndrome; cone- or cone-rod dystrophy; unspecified macular dystrophy or Stargardt disease; congenital stationary night blindness or age-related macular degeneration. All individuals gave written informed consent for genetic analysis. We analyzed our patient cohort for *MERTK* variants by analyzing all the SNVs as well as analyzing the data looking for gross deletions or duplications to elucidate the contribution of *MERTK* within our patient population. We found gross deletions encompassing several exons in heterozygous as well as homozygous form in our patient cohort. This demonstrates that CNV screening of *MERTK* should be considered in cases displaying recessive inheritance.

**1105W**

**The NIH Oculocutaneous Albinism Natural History Study.** D.R. Adams<sup>1</sup>, W.M. Zein<sup>2</sup>, B.P. Power<sup>1</sup>, T. Nguyen<sup>3</sup>, C. Brewer<sup>1</sup>, C. Zalewski<sup>4</sup>, J. Bryant<sup>1</sup>, W.A. Gahl<sup>1</sup>, B.P. Brooks<sup>2</sup>. 1) NHGRI, NIH, Bethesda, MD; 2) NEI, NIH, Bethesda, MD; 3) Clinical Center, NIH Bethesda, MD; 4) NIDCD, NIH Bethesda, MD.

Oculocutaneous Albinism (OCA) is a syndrome of hypopigmentation and aberrant visual development resulting from decreased production of melanin. It is pan-ethnic and constitutes a significant minority of inherited vision impairments. While most isolated OCA is caused by mutations in two genes (*TYR* and *OCA2*), growing lists of additional loci have been described in recent years. Recent clinical trials and advances in the understanding of melanocyte biology have reinvigorated efforts to look for rational treatments of the visual manifestations of OCA. The OCA natural history study at the NIH Clinical Center enrolls individuals with albinism, seeking to expand understanding of the clinical manifestations and underlying biology. The study has four primary goals: 1) To clinically and comprehensively characterize known OCA types; 2) To use participants' cultured melanocytes to study pigment biology, variability in pigment formation related to genotype, and response to proposed treatments; 3) To recruit study participants with hypopigmentation not due to known albinism-causing genes; and 4) to evaluate methods of quantifying eye pigmentation, skin pigmentation and other clinical parameters that may serve as outcome measures in future treatment studies. To date, 125 persons with albinism have been enrolled. Clinical histories, biological specimens and laboratory testing have provided collect data for targeted aspects of OCA including vision, hearing, dietary vitamin D sufficiency, and visual adaptation. The presented work includes highlights from a current effort to collate data from the last 9 years of the study. These data refine the phenotype, contribute to the phenotypic presentation of novel genotypes, and lay the groundwork for future therapeutic studies and clinical guidelines.

## 1106T

**Novel *PXDN* mutations cause microphthalmia and anterior segment dysgenesis.** *N. Chassaing*<sup>1,2</sup>, *C. Zazo-Seco*<sup>2</sup>, *P. Bitoun*<sup>3</sup>, *O. Roche*<sup>4</sup>, *J. Plaisancié*<sup>1,2</sup>, *N. Ragge*<sup>5,6</sup>, *P. Calvas*<sup>1,2</sup>. 1) Department of Medical Genetics, Purpan Hospital, Toulouse, France; 2) UMR 1056 Inserm -Toulouse University, Toulouse, France; 3) SIDVA 91, Ophthalmic Genetics, 1 rue de la Cour de France, 91460 Juvisy s/orge, France; 4) Department of Ophthalmology, IHU Necker-Enfants Malades, Paris Descartes University, 75015 Paris, France; 5) Dept of Biological and Medical Sciences, Faculty of Health and Life Sciences, Oxford Brookes University, Oxford, UK; 6) West Midlands Regional Clinical Genetics Service and Birmingham Health Partners Birmingham Women's Hospital NHS Foundation Trust, Birmingham UK.

Anterior segment dysgeneses encompass a wide spectrum of developmental disorders, including iris corectopia, Peters and Rieger anomalies. Microphthalmia refers to a reduced axial length of the globe at least 2 standard deviations below the mean for age. Microphthalmia is classified as simple or, complex, when associated with anterior and/or posterior segment dysgenesis. Numerous genes have been shown to underlie these ocular developmental anomalies. Biallelic mutations in *PXDN* gene were first reported in 2011 in two consanguineous families affected by congenital cataract, corneal opacity, and developmental glaucoma and in one family affected by developmental glaucoma and severe corneal opacification. All affected family members displayed isolated ocular involvement. Since then, 5 individuals with *PXDN* mutations have been reported, expanding the phenotype to anterior segment dysgenesis and microphthalmia associated with developmental delay in two patients. We report herein, 3 novel patients with ocular involvement due to *PXDN* mutations. In a female patient suffering from microphthalmia and Peter's anomaly, whole genome sequencing identified a maternally inherited mutation affecting the initiation codon (c.1A>G [p.Met1?]) and a paternally inherited frameshift insertion (c.697\_698insCTCAG [p.Val223AlafsTer11]). In a second family, two brothers were affected by ocular developmental anomalies, one with congenital cataract, microcornea, and anterior segment dysgenesis, while the other had severe unilateral microphthalmia, with contralateral anterior segment dysgenesis. Targeted sequencing of a panel of 24 genes involved in ocular developmental anomalies led to the identification of a maternally inherited frameshift mutation (c.4216\_4225dup [p.Arg1409ProfsTer2]), and a paternally inherited missense mutation (c.2276C>T [p.Ser759Leu]). The missense variant was rare in the ExAC database (1/120.000 alleles), affected a very conserved amino-acid, and was considered by *in silico* analysis to be deleterious. Interestingly, although heterozygous carriers reported so far have been asymptomatic, the heterozygous mother of the two affected sibs had goniodysgenesis suggesting that *PXDN* mutations may lead to mild ocular developmental defects in the heterozygous state. In conclusion, we report herein 3 novel patients with compound heterozygous mutations of the *PXDN* gene highlighting the importance of screening this gene more widely in patients with anterior segment dysgeneses.

**Comprehensive analysis of CNVs in patients with congenital eye malformations by targeted next generation sequencing.** *M. Corton*<sup>1,2</sup>, *D. Aguilera-García*<sup>1</sup>, *L. Rodrigues Jacy da Silva*<sup>1,3</sup>, *M. Tarilonte*<sup>1</sup>, *P. Ramos*<sup>1</sup>, *A. Gomez*<sup>1</sup>, *C. Villaverde*<sup>1,2</sup>, *J. Rosell*<sup>4</sup>, *V. Lopez*<sup>5</sup>, *M.J. Ballesta*<sup>5</sup>, *E. Guillen*<sup>5</sup>, *M.J. Trujillo-Tiebas*<sup>1,2</sup>, *F. Blanco-Kelly*<sup>1,2</sup>, *C. Ayuso*<sup>1,2</sup>. 1) Genetics Department. IIS-Fundación Jimenez Diaz University Hospital, Madrid, Madrid, Spain; 2) Centre for Biomedical Network Research on Rare Diseases (CIBERER), ISCIII, Madrid; 3) University of Mogi das Cruzes, São Paulo, Brazil; 4) Genetics Department. University Hospital Son Espases. Palma de Mallorca, Spain; 5) Medical Genetics Department. University Hospital Virgen de la Arrixaca, Murcia, Spain.

**Introduction:** Congenital ocular malformations are very highly heterogeneous conditions displaying a wide spectrum of overlapping phenotypes that can occur isolated or taking part of syndromes. They include panophthalmic disorders such as microphthalmia, anophthalmia and coloboma (MAC) spectrum and aniridia, and anomalies restricted to the anterior or posterior segment. Mutational load in the associated genes is not well known due to lack of systematic molecular characterization of large cohorts. Our aim was to perform a comprehensive molecular screen for SNVs and CNVs in genes causing ocular malformations using a custom next-generation sequencing (NGS) gene panel in a large cohort of Spanish patients. **Material and Methods:** A cohort of 130 patients with several ocular phenotypes were analysed, including syndromic and isolated forms of MAC, aniridia, anterior segment dysgenesis, nerve optic hypoplasia and albinism that mostly were previously tested by Sanger sequencing and MLPA for the most prevalent genes. These includes control cases with previously known pathogenic variants and CNVs. A set of up to 260 genes were analyzed by means of custom gene panels (Haloplex and SureSelect), followed by sequencing in Illumina platforms. SNVs were analyzed following an in-house bioinformatic pipeline. CNVs identification was performed prioritizing statistically significant regions in the read depth. Custom Agilent CGH arrays were used to validate CNVs and to refine chromosomal breakpoints. **Results:** Currently we have findings for 88 patients with a variety of phenotypes and additional 48 patients are now being analyzed. A total of 19 pathogenic SNVs spanning 14 different genes and 13 additional VUS were identified, validated and segregated in the families. Our specific bioinformatic method in combination with the high depth of coverage (>400X) allowed the detection of 7 structural variants: a duplication of *GDF3*, complete deletions of *FOXC1*, *GJA8*, *HPS5* and *OTX2-SIX6* and multi-exon deletions of *PAX6*. **Conclusions:** Our study allowed the characterization of 24% of the patients (40% of the patients with MAC). Our results have shown that a NGS panel is a good strategy for the genetic analysis of these patients since it permits the co-detection of SNVs and CNVs in a single design when a homogeneous coverage between samples is ensured. **Grants:** ISCIII (CP12/03256), MINECO (SAF2013-46943-R), Fundación Mutua Madrileña.

**Purpose** Stargardt disease 1 (STGD1; MIM 248200), the most prevalent inherited macular dystrophy, is an autosomal recessive condition caused by pathogenic sequence variants in the *ABCA4* gene (ATP-binding cassette subfamily A member 4; MIM 601691). We describe the genetic characteristics of the cohort enrolled in the international multi-center progression of STGD1 study (ProgStar) and determine ethnic variations in allele frequency. **Methods** 275 subjects with a clinical diagnosis of STGD1 and harboring multiple pathogenic *ABCA4* variants were enrolled from nine centers in the USA and Europe. All the detected variants were assessed with *in silico* molecular genetic analysis. Subjects were classified into four ethnic subgroups (European/Middle Eastern, African, Asian, and Other/Unknown) based on questionnaire responses. Comparisons of allele frequency were performed with categorical testing of the independence of each prevalent allele. **Results** 195 pathogenic sequence variants were identified in the total cohort, including missense (123), splice site alteration (32), frame shift (19), stop (19), in-frame deletion (1), and large exonic deletion (1). 46 variants were novel. Exclusively missense variants were detected in 139 patients (50.5%). The cohort comprised 196 European/Middle Eastern patients, 18 African (by descent), 14 Asian and 47 with other/unknown ethnicity. The three most prevalent variants in the total cohort were p.G1961E (15.3%), p.G863A (7.3%), and c.5461-10 T>C (4.9%). The most prevalent variant in each ethnicity was p.G1961E (15.3%) in European/Middle Eastern, p.R2017H (13.9%) in African, and p.G1961E (39.3%) in Asian, respectively. The ethnic subgroup analysis revealed a statistically significant ethnic differences in the allele frequencies of p.G1961E, p.R2107H, p.E2096K, p.V1693I, c.4253+4C>T, c.2977\_2984delGACATTGA, p.G991R, p.V989A, p.V643M, and p.S95P. **Conclusions** The spectrum of *ABCA4* variants was documented in a well-characterized large cohort with STGD1. Approximately half of the cohort harbors only missense variants, which is in keeping with the relatively mild phenotype of the ProgStar cohort. Subgroup analysis reveals the distinct prevalent alleles in each ethnicity, although the number of subjects for some subgroups is limited.

## 1109T

**First systematic molecular analysis of 45 Greek patients with retinal dystrophies by next generation sequencing reveals 21 novel mutations in 30 genes and establishes a wide spectrum of distinct retinal degenerative diseases.** S. Kamakari<sup>1,5</sup>, V. Kokkinou<sup>1</sup>, G. Koutsodontis<sup>1</sup>, A. Anastasakis<sup>2</sup>, S. Koukoulas<sup>3</sup>, M.K. Tsilimbaris<sup>4</sup>, I. Datsis<sup>5</sup>. 1) OPHTHALMIC GENETICS UNIT, OMMA OPHTHALMOLOGICAL INSTITUTE OF ATHENS, ATHENS, Greece; 2) Athens Eye Hospital, Glyfada, Athens; 3) Ophthalmica Institute of Ophthalmology and Microsurgery, Thessaloniki; 4) Department of Ophthalmology, University of Crete School of Medicine, Heraklion; 5) OMMA Ophthalmological Institute of Athens, Athens.

**Purpose:** Hereditary retinal dystrophies (RD) are characterized by clinical variability and pronounced genetic heterogeneity. The aim of this study was to molecularly diagnose 45 Greek patients with different forms of hereditary retinal dystrophies. **Materials and Methods:** 45 unrelated Greek patients were analyzed by Next Generation Sequencing (NGS), 13 of them using a 105 retinal gene panel as described (Ellingford JM et al. J Med Genet 2016; 53:761-767) and 32 of them using whole exome sequencing comprising a 287 ophthalmic gene panel as described (Haer-Wigman L et al, Eur J Hum Genet 2017; 25:591-599). In addition, PCR and Sanger sequencing, MLPA and array CGH were used in 4 cases where no mutations or a single mutation was identified. **Results:** A total of 43 distinct mutations were detected in 30 RD genes in this cohort of 45 Greek patients including 21 novel potentially pathogenic mutations in the *ABCA4*, *CAPN5*, *PRPF31*, *SPATA7*, *MERTK*, *FAM161A*, *ALMS1*, *CDHR1*, *MYO7A*, *USH2A*, *CNGB1*, *CRX*, *LCA5* and *PROM1* genes. The detection mutation rates were 38.5% (5/13 patients) and 71.9% (23/32 patients) for the 105 and 287 gene panels, respectively. Furthermore, in 4 cases with no mutation or a single identified mutation, complete diagnosis was achieved using additional methods thus increasing the mutation detection rates for the two subgroups to 46.1% and 81.2%. Final diagnoses of participating subjects included retinitis pigmentosa (9 cases), Usher syndrome (4 cases), cone-rod dystrophy (4 cases), Leber congenital amaurosis (4 cases), Bardet-Biedl syndrome (2 cases) and 9 single rare cases of isolated or syndromic inherited retinopathy including a case of nephrotic syndrome type 9 due to mutations in the *ADCK4* gene and a case of Knobloch syndrome due to mutations in the *COL18A1* gene. Notably, genetic findings in several families were not consistent with the initial clinical diagnosis. **Conclusions:** This is the first systematic study to investigate the molecular identity of 45 Greek patients with various subforms of RD by the use of NGS technology targeting two panels of 105 and 287 RD genes and additional methods as required. The overall mutation detection rate was 71.1% (32/45 patients). A plethora of novel mutations was documented further expanding the genetic heterogeneity. The molecular identification established the complete diagnosis of the patients thus drastically contributing to family making decision, prognosis and candidacy to current and future treatments.

**1110F****Novel *RS1* gene mutations of X-linked retinoschisis Lithuanian patients.**

V. Kucinskas<sup>1</sup>, L. Ambrozaityte<sup>1,2</sup>, L. Cimbalistiene<sup>1,2</sup>, R. Strupaitė<sup>3</sup>, R. Asoklis<sup>3</sup>, A. Utkus<sup>1,2</sup>. 1) Dept. of Human and Medical Genetics, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 2) Center for Medical Genetics, Vilnius University Hospital Santaros klinikos, Vilnius, Lithuania; 3) Centre of Eye Diseases, Clinic of Ear, Nose, Throat, and Eye Diseases, Faculty of Medicine, Vilnius University.

X-linked juvenile retinoschisis (XLRs, MIM 312700) is a common early onset macular degeneration characterized by mild to severe loss in visual acuity, splitting of retinal layers, and a reduction in the b-wave of the electroretinogram (ERG). The prevalence of XLRs ranges between 1:5000 to 1:20000 males. The *RS1* gene (MIM 300839) associated with the disease encodes retinoschisin, that is expressed and secreted from photoreceptors and bipolar cells, and it binds strongly and specifically to the surfaces of many cells in the retina. Over 200 disease-causing mutations in the *RS1* gene are known with most mutations occurring as non-synonymous changes in the major protein unit, i.e. discoidin domain. First XLRs Lithuanian patients have been diagnosed due to clinical findings and confirmed molecular diagnosis. Comprehensive ophthalmological examinations, including best-corrected visual acuity (BCVA), color vision assessment with Ishihara plates, slit-lamp, fundus examination, spectral domain optical coherent tomography (SD-OCT) with fundus autofluorescence images and full-field electroretinography, have been performed. *RS1* gene (NM\_000330.3) has been Sanger sequenced for the three probands and pathogenic mutations identified. NM\_000330.3:c.599G>T (p.R200L) mutation was detected in one case, *in silico* analysis showing to be pathogenic (disease causing; deleterious; probably damaging). Human Genome Mutation Database (HGMD) involves three other different mutations at the same position (CM095237, CM981767, CM981768) supporting the pathogenicity of the identified variant. NM\_000330.3:c.(92\_97)insC (p.W33fs) mutation creating a frameshift was identified for another proband, again *in silico* analysis indicating the variant is possibly damaging. The third case was identified with a pathogenic mutation NM\_000330.3:c.422C>G (p.R141H), HGMD CM981753. The penetrance of XLRs is almost complete but clinical expression is highly variable, though Lithuanian XLRs patients are presented with similar phenotype. Functional studies would support the characterization of the specific identified variants on the effect of retinoschisin expression, subcellular localization, and protein structure.

**1111W****Genetic analysis of children and families with heritable retinal dystrophies in Costa Rica: Identification of an X-linked mutation.** D.J. Wolff,

I. Znojko<sup>1</sup>, W.B. Glen<sup>1</sup>, J. Martinez Arguedas<sup>2</sup>, R. Badilla-Porras<sup>3</sup>, M.M. Peterseim<sup>4</sup>. 1) Pathology/Lab Med, Med Univ South Carolina, Charleston, SC; 2) Ophthalmology, National Children's Hospital, San José, Costa Rica; 3) Clinical Genetics and Metabolism, National Children's Hospital, San José, Costa Rica; 4) Ophthalmology, Med Univ South Carolina, Charleston, SC.

The retinal dystrophies (RDs) are a group of diseases with phenotypic and genotypic heterogeneity with over 200 known disease-causing genes. Our study aimed to identify underlying genetic defects resulting in RD in the Costa Rica population that has known founder effects. Whole genome autozygosity mapping (Illumina 850K SNP microarray) was performed on 31 affected children from 23 families. Affected persons had a median 5% homozygosity with many known recessive RD genes mapping within homozygous regions. While no homozygous structural aberrations were detected involving autosomal genes, a 44 kb hemizygous deletion of the X chromosome (153,414,836-153,458,779) was detected in two brothers. Whole exome sequencing (Agilent SureSelect V6) confirmed that the deletion included exons 2 - 6 of *OPN1LW* and exons 1 - 4 of *OPN1MW*. The high level of homology between these genes predisposes to unequal recombination and deletion/hybrid gene formation. Loss of function of the *OPN1LW* (red) and *OPN1MW* (green) opsin photopigment genes results in blue cone monochromacy which is characterized by reduced vision, color vision impairment and variably, photophobia, myopia and nystagmus. The brothers had symptoms starting age 5 including nyctalopia but no nystagmus; both had subnormal vision (20/40-60; 20/150), some changes in retina appearance and myopia. The maternal grandfather was also reported to have a history of nyctalopia since childhood, retinal degeneration and severely impaired vision (20/200). Identification of this X-linked mutation shows the utility of our approach to identify recessive mutations in the Costa Rican population. Autozygosity mapping in conjunction with whole exome sequencing is ongoing for the 23 families to search for additional mutations with the ultimate goal of identifying pathogenic mutations to assist with better patient care and potentially identify individuals who may be candidates for vision-sparing therapies.

**1112T**

**Unclassifiable brachydactyly (brachydactyly E+A2) due to a novel missense mutation in *IHH*.** H. Numabe<sup>1,2</sup>, K. Yura<sup>3,4</sup>, T. Maeda<sup>2</sup>, Y. Morishima<sup>1</sup>, N. Inagaki<sup>1</sup>, M. Wakai<sup>1</sup>, S. Suzuki<sup>2</sup>, H. Kawashima<sup>1,2</sup>, G. Nishimura<sup>5</sup>. 1) Clinical Genetics Center, Tokyo Medical University, Shinjuku-ku, Tokyo, Japan; 2) Department of Pediatrics, Tokyo Medical University, Shinjuku-ku, Tokyo, Japan; 3) Faculty of Core Research, Ochanomizu University, Bunkyo-ku, Tokyo, Japan; 4) School of Advanced Science and Engineering, Waseda University, Shinjuku-ku, Tokyo, Japan; 5) Department of Radiology, Tokyo Metropolitan Children's Medical Center, Fuchu-shi, Tokyo, Japan.

The proband was an 11-year-old girl who was referred because of short digits and toes. She showed mild facial dysmorphism, including hypertelorism and a high arched palate as well as overt brachydactyly. The physical findings were otherwise unnoticeable. Her mother was similarly affected. Based on the Japanese standardized MCPP (metacarpo-phalangeal pattern profile), the brachydactyly was characterized by extreme shortness of metacarpals of 4<sup>th</sup> and 5<sup>th</sup> fingers, proximal phalanges of 1<sup>st</sup> fingers, middle phalanges of 2<sup>nd</sup> and 5<sup>th</sup> fingers, and distal phalanges of 1<sup>st</sup> and 3<sup>rd</sup> fingers. The pattern was classified into the combination of type E and type A2 on Bell's classification. Whole exome analyses of her and her mother's genomes revealed a heterozygous missense variant (c.G1222A; p.G408R) in Indian Hedgehog gene (*IHH*). The variant was likely to be pathogenic.

**1113F**

**A novel missense variant in *IRF6* gene implicated in causing Van der Woude syndrome.** N. AlDhaheeri<sup>1,4</sup>, N. Beck<sup>1,2,4</sup>, E. Davidson<sup>2,4</sup>, K. Seifert<sup>3,4</sup>, R. Redett<sup>3,4</sup>, J. Hoover-Fong<sup>1,2,4</sup>. 1) McKusick-Nathans Institute of Genetic Medicine; 2) Greenberg Center for Skeletal Dysplasias; 3) Department of Plastics and Reconstructive Surgery; 4) Johns Hopkins University School of Medicine, Baltimore, MD, United States.

**Background:** Orofacial clefts (OFC) are the most common craniofacial birth defect affecting ~ 1 in 700-1000 individuals worldwide. About 30% are syndromic and Van der Woude syndrome (VWS) is the most common monogenic OFC diagnosis accounting for ~ 2%. VWS is a dominant condition presenting with cleft lip and/or palate, bifid uvula, hypodontia and paramedian lower lip pits or a small cyst capping a sinus tract from a mucous gland. VWS has phenotypic variability ranging from an isolated lip pit to bilateral cleft lip and palate with multiple pits or cysts and hypodontia. Penetrance is estimated at 92%. Heterozygous loss of function mutations in the Interferon Regulatory Factor 6 gene (*IRF6*) are identified in ~70% of VWS patients; over 300 *IRF6* mutations have been described. Gain of function mutations in *GRHL3* account for another 5% of VWS patients with remaining cases without genetic etiology. **Case Report:** We report a patient prenatally diagnosed with cleft lip and palate. On postnatal exam, she also had a lower lip pit with sinus tract and negative family history for cleft lip/palate and lip pits. Molecular testing of *IRF6* and *GRHL3* revealed a novel missense variant c.232A>G (p.Lys78Glu) in exon 4 of *IRF6*, reported to be of uncertain significance. This variant is not present in ExAc or ClinVar and Polyphen predicted it to be 'probably damaging'. Analysis for the variant in the patient's unaffected parents revealed it was *de novo*, further supporting its pathogenicity. No functional studies exist for this variant. 90% of the mutations in *IRF6* causing VWS or an allelic condition known as popliteal pterygium syndrome are missense or truncation mutations with the remaining 10% creating a new start codons or affecting splicing. The frequency of missense mutations was significantly increased in the DNA-binding and protein-binding domains, encoded by exons 3-4 and 7-9, respectively, and these domains were highly conserved. Furthermore, *IRF6* variants rarely occur in control subjects, implying *IRF6* does not tolerate mutation burden. **Conclusion:** The novel missense mutation in a highly conserved domain of *IRF6* identified in our patient with strong clinical features of VWS strongly supports the pathogenicity of this variant. This report should allow reclassification of this variant from that of unknown significances to a pathogenic variant.

## 1114W

**Origin of *EIF4A3* pathogenic expansion, the causative mechanism of a craniofacial syndrome (RCPS).** G.S.P. Hsia, L. Alvizi, L.A. Brito, C.M. Musso, R.C.M. Pavanello, M. Zatz, M.R. Passos-Bueno. Centro de Pesquisa sobre o Genoma Humano e células tronco, Instituto de Biociências, Universidade de São Paulo, São Paulo, SP, Brasil.

Richieri Costa-Pereira syndrome (RCPS) is an autosomal-recessive acrofacial dysostosis, characterized mainly by midline cleft mandible and Robin sequence. RCPS patients can also show intellectual disability and speech impairment. Mutations in *EIF4A3*, mainly expansion at its 5'UTR region (UCSC Genome Browser on Human Feb. 2009 - GRCh37/hg19 - Assembly, chr17:78,109,013-78,120,982), cause RCPS. Sequencing analysis of this region showed multiple allelic patterns, which varies in number and organization of motifs: TCGGCAGCGGCAGCGAGG (CA-18nt), TCGGCAGCGGCACAGCGAGG (CACA-20nt) and TCGGCAGCGGCGCAGCGAGG (CGCA-20nt). RCPS patients present all 3 types of motifs within the same allele and a total of 14 to 16 motifs (CGCA-20nt is the most abundant). Unaffected individuals present lower number of motifs, however it is still unknown if they have CGCA-20nt motifs and which is the most prevalent allele pattern. To get insights in the arisen of this pathogenic expansion, we characterized *EIF4A3* allele variability in 380 samples of individuals unrelated to RCPS families (control sample, CS) by Sanger Sequencing method. The results revealed that almost 50% of our sample presented 7 or 8 motifs. Most of the individuals (85%) are heterozygous and follow the Hardy-Weinberg equilibrium. We identified 45 different allelic patterns (APs), being the most common compound by 4 motifs CACA-20nt followed by 1 CA-18nt, 1 CACA-20nt and 1 final CA-18nt. Furthermore, 8 heterozygous controls presented CGCA-20nt motifs (9 to 10), which previously was only reported in RCPS patients. Next, we analyzed the haplotype of 16 samples (4 controls; 5 with CGCA-20nt motif; United Kingdom RCPS patient and 6 Brazilian RCPS patients with different expansion structures) using 5 SNPs markers (rs11150824, rs2289534, rs3829612, rs10782008 and rs12943620) flanking *EIF4A3*. The results revealed two haplotypes associated with CGCA-20nt motif. Based on these results, we hypothesized that the pathogenic expansions might have arisen from an unequal crossing-over event between two alleles. The detection of alleles containing the CGCA-20nt motif in the control population suggests that pathogenic alleles can arise independently, and this expanded allele may not be specific of the Brazilian population. It is possible, therefore, that this disease is misdiagnosed in other regions of the world. FAPESP, CNPq.

## 1115T

**Craniosynostosis: Expanding the phenotype of 3 rare syndromes.** E.H. Zackai<sup>1</sup>, E. Bhoj<sup>1</sup>, J. Taylor<sup>2</sup>, D.M. McDonald-McGinn<sup>1</sup>, M.H. Harr<sup>1</sup>, K. Grand<sup>1</sup>, A. Santani<sup>3</sup>, D. Li<sup>3</sup>, C. McDougall<sup>1</sup>. 1) Division of Human Genetics; 2) Division of Plastic and Reconstructive Surgery; 3) Department of Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA.

Craniosynostosis affects 1/2250 births. An underlying genetic cause is identified in ~24% of cases with mutations in 6 genes (*FGFR2*, *FGFR3*, *TWIST1*, *TCF12*, *ERF*, and *EFNB1*). At least 52 other genes have been associated with craniosynostosis. Of these, 20 core genes have craniosynostosis as a common feature (>50% of patients). The remaining genes have craniosynostosis in a minority (Miller et al., 2017, J Med Genet). Utilizing whole exome sequencing (WES) in craniofacial clinic, we wish to add 3 diseases (Xia-Gibbs syndrome, Ayme-Gripp syndrome and *KMT5B*-related syndrome) to the latter category and expand their phenotypes to include craniosynostosis. Patient 1 is a 14 year old female with bicoronal craniosynostosis, developmental delay (DD), intellectual disability (ID), atrial septal defect, short stature, lumbar lordosis, joint laxity, and patellar dislocations. WES identified a heterozygous *de novo* pathogenic mutation in *AHDC1* (c.2473C>T;p.Q825X) consistent with Xia-Gibbs syndrome characterized by failure to thrive, hypotonia, DD, moderate ID and dysmorphic features. Two other patients with Xia-Gibbs syndrome had craniosynostosis – one with sagittal and the other with bicoronal and metopic (Yang et al., 2015, Cold Spring Harb Mol Case Stud; Miller et al., 2017, J Med Genet). Patient 2 is a 20 year old male with sagittal and coronal craniosynostosis, bilateral mixed hearing loss, ID and dysmorphic features. WES found a mutation in *MAF* (c.161C>T;p.S54L) causing Ayme-Gripp syndrome characterized by ID, sensorineural hearing loss, brachycephaly, flat facies, short stature, seizures and congenital cataracts. Another patient with Ayme-Gripp syndrome and coronal craniosynostosis has the same *MAF* mutation (p.S54L) as our patient (Ayme & Philip, 1996, Clin Dysmorphol; Niceta et al., 2015, Am J Hum Genet). Patient 3 is a 4 year old female with moderate global DD, autism, and sagittal and bilateral lambdoid craniosynostosis. WES identified a heterozygous *de novo* pathogenic mutation in *KMT5B* (c.598T>C;p.C200R) causing a newly described syndrome characterized by DD, ID, autism and seizures (Stessman et al., 2017, Nature Genet). We know of one additional patient with craniosynostosis who has a mutation in *KMT5B* (Personal Communication). Through the use of WES in the craniofacial clinic we have expanded the phenotypes of 3 rare syndromes to include craniosynostosis. Our cohort illustrates the utility of WES in ascertaining the etiology of craniosynostosis.

**1116F**

**Disorders of sexual development in genetics pediatrics. Three different ambiguous genitalia cases report from Hospital Para El Niño Poblano, México.** J. Aparicio<sup>1,2</sup>, F. Cuellar-López<sup>3</sup>, M.L. Hurtado-Hernández<sup>4</sup>, A. Atriano Ponce<sup>5</sup>, H. Marodan García<sup>6</sup>, S. Chatelain-Mercado<sup>6</sup>. 1) Genetics, Benemerita Universidad Autónoma de Puebla; 2) Genetics; 3) Urology and Pediatric Surgery; 4) Citogenéticos; 5) Endocrinology, Hospital para el Niño Poblano; 6) Biotechnology, Universidad Autónoma Metropolitana, México.

Five pediatric patients with three different disorders of sexual development are reported in this study; the first three male patients (16 years, 4 years and 2 months old, respectively) were diagnosed as having diphallia. These 3 patients had real diphallia, well developed penises, urinarius meatus, and both testicles and one of the case, vessel duplication was reported by urology. All the patients have normal cytogenetic analysis, 46XY. The fourth patient was 2 years old, with hyperplasic clitoris, hyperpigmented tissue similar to labia major (large lips) and internal female organs identified as vagina, uterus and both ovaries. A chimera with two different cells lines [46,XX (48%) and 46,XY (52%)] by cytogenetic studies was reported. And the last child was 2 years 8 months old patient with chromosome translocation, between chromosome Y and 7 chromosomes t(7;Y). Hypospadias peneescrotal, unilateral cryptorchidism, urinary meatus stenosis and malformed scrotum were diagnosed together with vessel duplication. Key words: Ambiguous genitalia, diphallia, hypospadias, cryptorchidism, chromosome translocation and chimera.

**1117W**

**Microdeletion of 17q21.31 causes a novel malformation syndrome.** K. Kurosawa, M. Minatogawa, T. Yokoi, Y. Enomoto, K. Ida, N. Harada, J. Nagai, Y. Tsurusaki. Kanagawa Children's Med Ctr, Yokohama, Japan.

17q21.31 deletion syndrome, also known as Koolen-De Vries syndrome or KANSL1-related disorder, was a genomic disorder characterized by distinctive facial appearance, intellectual disability, hypotonia, and characteristic behavior. It is usually caused by a recurrent 0.450–0.600 Mb deletion on chromosome 17q21.31, encompassing KANSL1. To date, excluding the KANSL1-related disorder, no syndromic genomic rearrangement was known in the 17q21.31. Here, we report a patient with intellectual disability, dysmorphic facial appearance, hydrocephalus, congenital heart defect, and epilepsy, associated with de novo 17q21.31 deletion, proximal to the critical region of KANSL1-related disorder. The patient was an 8-year-old boy, referred for multiple congenital malformations and severe developmental delay. He was born to non-consanguineous healthy parents at 38 weeks of gestation after uneventful pregnancy. His birth weight was 2450 g (-1.3 SD), length 47 cm (-0.9 SD), and OFC 30.5 cm (-2.0 SD). Developmental milestone was severely delayed, rolling over at 9 months, sitting and crawling at 1 year and 5 months, walking alone at 3 years. At age of 8 years, he spoke no meaning words. His weight was 19.0 kg (-1.5 SD), height 113.6 cm (-2.4 SD), and OFC 51.4 cm (0 SD). He exhibited distinct facial appearance including long face, ptosis, malformed ears, strabismus, and high arched palate. Microarray revealed 0.2 Mb deletion on 17q21.31 proximal to the large cluster of low copy repeats. The deletion interval encompassed 8 RefSeq genes including NAGS, TMEM101, LSM12, G6PC3, HDAC5, C17orf53, ASB16, and TMUB2. In the deleted genes, HDAC5, encoding histone deacetylase 5, is the only gene with a high score of pLI (1.0). HDAC5 plays an important role in transcriptional regulation, cell cycle progression and developmental events, which is likely to be consistent with the clinical phenotype of our patient. According to DECIPHER database, two individuals with ptosis and intellectual disability common to our patient were registered, but detailed clinical information was unavailable. These results suggested that haploinsufficiency of HDAC5 might cause distinct phenotype. Additional cases with loss of function mutation in HDAC5 are required for establishing a novel malformation syndrome.

**1118T****Phenotypic and genotypic spectrum in Richieri-Costa-Pereira syndrome.**

D. Bertola<sup>1,2</sup>, G. Hsia<sup>2</sup>, L. Alviz<sup>2</sup>, A. Gardham<sup>3</sup>, G.L. Yamamoto<sup>1,2</sup>, R.H. Honjo<sup>1</sup>, L.A.N. Oliveira<sup>1</sup>, R.C. Di Francesco<sup>4</sup>, B.A. Perez<sup>5</sup>, C.A. Kim<sup>1</sup>, M.R. Passos-Bueno<sup>2</sup>. 1) Pediatrics, Instituto da Criança, Sao Paulo, Brazil; 2) Centro de Pesquisas sobre o Genoma Humano e Células-Tronco, Instituto Biociências – Universidade de São Paulo, SP, Brazil; 3) North East Thames Genetics Service, Great Ormond Street Hospital, London, England; 4) Departamento de Otorrinolaringologia – Hospital das Clínicas da FMUSP – Universidade de São Paulo, SP, Brazil; 5) Departamento de Genética – Universidade Federal de São Paulo, SP, Brazil.

Richieri-Costa-Pereira syndrome (RCPS) is a rare autosomal recessive acrofacial dysostosis described mainly in Brazilian individuals. Cardinal features of this syndrome include Robin sequence, cleft mandible, laryngeal anomalies and limb defects. An expansion in both alleles of a complex repeated motif composed of 18 or 20 nucleotides in the 5' untranslated region of *EIF4A3* have been shown to cause this syndrome, commonly with 15 or 16 repeats. The only patient with mild clinical findings harbored a 14 repeat-expansion in one allele and a point mutation in the other allele. This proband is described here in more details, along with his affected sister, as well as 4 new individuals with RCPS, including a patient from England, of African ancestry. The clinical findings ranged from a severe infant, requiring tracheostomy and gastrostomy due to striking mandible compromise, to individuals showing mild facial dysmorphisms, dental and skeletal anomalies, and, sometimes, asymptomatic structural laryngeal anomalies. Although the most frequent mutation in the present study was the recurrent 16-repeat expansion in *EIF4A3*, there was an overrepresentation of the 14-repeat expansion. Even though the number of patients reported is small, the ones that showed mild clinical findings presented the shorter repeat-expansion in *EIF4A3*, suggesting that the number of these expansions could play a role in phenotypic delineation. It is possible that this syndrome has been underdiagnosed, especially in the cases in which the individuals do not present the full-blown phenotype. Moreover, the analysis of sequencing techniques, including next-generation sequencing, does not routinely detect expansions in the 5' untranslated region of a gene. In these mild cases, a clinical suspicion of RCPS should be taken in individuals presenting microretrognathia or Pierre-Robin sequence and an active search for subtle dental, acral and laryngeal anomalies should be performed. In order to confirm the clinical hypothesis, a targeted genetic analysis is required. FAPESP (2013/08028-1; 2015/21783-9), CNPq (302605/2013-4).

**1119F****Combination of *UBR1* and *UBR5* mutations in a severe form of Johanson-Blizzard Syndrome with total agenesis of lateral nasal process and situs inversus.**

A. Cetinkaya<sup>1</sup>, G. Akay Tayfun<sup>2</sup>, B. Erguner<sup>3</sup>, A. Tutun<sup>4</sup>, M.B. Mutlu<sup>1</sup>, N. Karadag<sup>4</sup>, G. Karatekin<sup>4</sup>, A. Karaman<sup>1</sup>, N.A. Akarsu<sup>5</sup>. 1) Medical Genetics, Zeynep Kamil Women and Children's Hospital, Uskudar, Istanbul, Turkey; 2) Pediatric Genetics, Zeynep Kamil Women and Children's Hospital, Uskudar, Istanbul, Turkey; 3) Advanced Genomics and Bioinformatics Research Center (IGBAM), The Scientific and Technological Research Council of Turkey (TUBITAK-BILGEM), Kocaeli, Turkey; 4) Neonatal Intensive Care Unit, Zeynep Kamil Women and Children's Hospital, Istanbul, Turkey; 5) Department of Medical Genetics, Gene Mapping Laboratory, Faculty of Medicine, Hacettepe University, Ankara, Turkey.

Johanson-Blizzard Syndrome (MIM 243800) is a rare autosomal recessive disorder characterized by hypoplasia/aplasia of alae nasi and impairment of exocrine pancreatic function. Oblique facial clefts have hitherto been defined as the most severe facial phenotype in this syndrome. Here, we present a newborn with total agenesis of facial structures originating from the embryonic lateral nasal process — resulting in bilateral oblique facial clefts which include medial portion of the lower eyelids, lateral nasal walls and nasolacrimal ducts. Additionally left atrial isomerism, laterality defects involving liver and stomach; and bilateral dysplastic kidneys have been observed. The newborn, whose parents were first degree relatives, died hours after birth due to severe congenital defects. A previously undefined homozygous mutation c.2380-1G>C in *UBR1* was identified by exome sequencing. This is predicted to disrupt the consensus splice acceptor site in intron 21, for which another pathogenic point mutation, c.2380-1G>A, has previously been reported [Sukalo M., et al. Hum Mutat. (2014) 35: 521-531]. The exceptionally severe phenotype reported here prompted us to look for another mutation in a possible modifier gene in the *UBR1* interactome. We utilized the exome sequencing data and STRING protein association networks to identify a heterozygous missense variant, c.2323A>G p.(Thr775Ala), in *UBR5* which is conserved during evolution and is "disease causing" according to Mutation Taster and "possibly damaging" according to Polyphen-2. The variant was not present in large population databases, 1000 Genomes Project, ESP, ExAC and IGBAM in-house database (n=1182 individuals). *UBR5*, like *UBR1*, encodes for a protein that functions in the N-end rule pathway, which directs proteins to ubiquitinylation and subsequent protein degradation by recognizing the amino acid residues and modifications in the N-terminal of polypeptides. The high expression of *UBR5* in the lateral wall of the snout during the embryonic development of mice may hint a cooperative action of *UBR1* and *UBR5* during embryonic development [Kinsella E., et al. PLoS One. (2016) 11: e0157079]. The conserved *UBR5* variant could be the first example to highlight the importance of modifier genes of N-end rule pathway in determining the wide phenotypic spectrum of individuals with Johanson-Blizzard Syndrome.

**1120W**

**SHOX duplication in a Kabuki syndrome patient: A possible effect on clinical phenotype.** A.P. Marques-de-Faria<sup>1</sup>, J.R.M. Prota<sup>1</sup>, C.R. Lincoln-de-Carvalho<sup>2</sup>, B.S. Carvalho<sup>2</sup>, I. Lopes-Cendes<sup>1</sup>. 1) Department of Medical Genetics – Faculty of Medical Sciences- University of Campinas (UNICAMP); 2) Department of Statistics - Institute of Mathematics, Statistics and Scientific Computing - University of Campinas (UNICAMP).

Kabuki syndrome (KS) is a multiple malformation syndrome usually caused by pathogenic variants in genes *KMT2D* or *KDM6A*. It is characterized by a typical facial gestalt, developmental delay and growth deficiency. The diagnostic suspicion is usually due to cardinal facial features such as elongated palpebral fissures with eversion of distal third of the lower eyelid, arched eyebrows, short columella with depressed nasal tip and prominent ears. After the first description, the Kabuki phenotype has been expanding as well as the mutational findings. In most cases the pathogenic variants are private and “de novo” consistent with sporadic occurrence. In general, the hypothesis of KS is unequivocal due to its peculiar facial signs despite the wide clinical spectrum. Recently, the expanding phenotype included microphthalmia and overlapped the CHARGE syndrome, which should be considered as a differential diagnosis. We describe a female child of healthy and non-consanguineous parents, birth weight 2935g, length 48.5 cm, with generalized hypotonia, microcephaly, unilateral microphthalmia, up-slanted and elongated palpebral fissures, laterally sparse eyebrows, anteverted nostrils, downturned corners of the lips, prominent ears, deep palmar creases and prominent finger pads. Patient evolved with adequate body weight and stature, neurodevelopmental delay, dysphagia and constipation. At first dysmorphological exam, KS was considered, despite the normal stature. However, in view of differential diagnosis, SNP-array was performed and detected Xq22.33 duplication, including only *SHOX* gene. As the latter is usually associated with tall stature and does not justify the Kabuki phenotype, an exome sequencing was performed and revealed a missense variant in *KMT2D*, previously registered as disease causing mutation, interpreted as pathogenic and also related with microphthalmia, confirming the initial hypothesis. The normal stature, which is uncommon in KS, although described in other cases, could be justified by *SHOX* duplication. Structural variants modulating a specific clinical sign of a monogenic syndrome are unusual and could represent an additional factor to consider in face of an atypical clinical phenotype. It is expected that after the increased use of exome sequencing and other diagnostic application of next generation sequencing associated with chromosomal microarray, these complementary genetic findings should be disclosed more frequently. .

**1121T**

**A novel mutation in *PDE3A* gene in a 7-year-old female patient with dysmorphic features, developmental delay, short stature, and unilateral brachydactyly without high blood pressure.** A. Alali, J. Greally. Pediatrics-Genetics, Montefiore Medical Center, Bronx, NY.

**Background:** The hypertension and brachydactyly syndrome, HTNB; OMIM 112410, is an autosomal dominant syndrome characterized by brachydactyly type E and severe salt-independent but age-dependent hypertension resulting from gain of function mutation in *PDE3A* gene. **Case report:** A 7 year-old female child first seen at the age of 5 years for dysmorphic features and developmental delay. Prenatal course was complicated with late poor weight gain (IUGR) of unclear etiology. Our patient was born at 36 weeks gestation to a 35 years old G3P2002 mother by caesarean section due to a concerning fetal heart tracing but with no further complications. Birth weight was 2085 grams. The family history was significant for a maternal aunt who had isolated brachydactyly. Our patient was diagnosed with congenital hypothyroidism and started on synthroid. She walked at the age of 12 months and had her first word also at the age 12 months. She spoke in full sentences at age of two but had fair academic performance in a special education class. Her length was consistently less than 3<sup>rd</sup> percentile. Her physical exam was significant for missing distal digital of first and second fingers and third finger brachydactyly, blue sclera bilaterally, low-set anteriorly rotated ears with her left ear more prominent than her right ear, wide mouth, thin upper lip, short moderately smooth philtrum, high nasal bridge, and bulbous nasal tip. The patient had surgeries for craniosynostosis at age of 2 years and hiatal hernia repair at age of 1 year. Her primary genetic work up including chromosomal analysis and array comparative genomic hybridization (CGH) was normal. On WES, she was heterozygous for the D359N variant of uncertain significance in *PDE3A* gene (c.1075 G>A) inherited from her mother who has no brachydactyly or high blood pressure. This variant is in exon 3 of the *PDE3A* gene, while all the six known mutation associated with hypertension and brachydactyly syndrome (HTNB) reported previously were in exon 4. A family history and blood pressure readings overtime were elucidated from PCP with most readings were within the range 95/65 mmHg to 92/52 mmHg. Her weight and stature are consistently less than 3<sup>rd</sup> percentile for age and gender. **Conclusion:** HTNB syndrome although rare, should be considered in any patient presenting with high blood pressure, especially at young age with brachydactyly and short stature. FH is a key point in the light of its different expressivity.

**1122F**

**A unique contiguous gene syndrome encompassing Potocki-Shaeffer syndrome and aniridia.** G. Delplancq<sup>1</sup>, M.-A. Boukebir<sup>2</sup>, D. Amsallem<sup>3</sup>, P. Kuentz<sup>4</sup>, L. Thines<sup>2</sup>, J.-L. Bresson<sup>4</sup>, L. Van Maldergem<sup>1</sup>. 1) Department of Human Genetics, Besançon University Hospital, Franche-Comté University, France; 2) Department of Neurosurgery, Besançon University Hospital, Franche-Comté University, France; 3) Department of Pediatric Neurology, Besançon University Hospital Franche-Comté University, France; 4) Department of Cytogenetics, Besançon University Hospital Franche-Comté University, France.

**Introduction:** Potocki-Schaeffer is a contiguous gene syndrome associated with deletions in the 11p11-p12 region. It combines *EXT2*-related multiple exostoses with *ALX4*-parietal foramina. Delayed milestones or intellectual deficiency, craniosynostosis and facial dysmorphism have also been described. A single patient with Potocki-Shaeffer syndrome plus *PAX6*-related aniridia has been described so far. We describe a second patient which confirms this specific contiguous syndrome and characterize the corresponding 30 Mb microdeletion alongside with expansion of the phenotype that encompasses both proximal p11 and *PAX6*. **Materials and methods:** A 9 month-old girl born prematurely at 32 week to Algerian non consanguineous parents was referred to our genetics department by the neurosurgeon because of an enlarged parietal foramina. Her parents aged 49 and 45 at the time of conception were healthy. She had bilateral aniridia and microphthalmia, a thin corpus callosum and delayed milestones. A brain CT-scan indicated a large pulsatile hole of 6 cms on both parietal bones. On the basis of the association of parietalis foramina and aniridia, a diagnosis of probable 11p11-13 microdeletion syndrome was made. Karyotype on lymphocytes confirmed segmental monosomy: 46,XXdel(11)(p11.2). Array-CGH indicated a 11p11.2 – 11p15.1: 18400975-48014598 30Mb deletion [hg19] arising *de novo*. **Conclusion:** The current observation confirms combined Potocki-Shaeffer-aniridia as a viable and specific new contiguous gene syndrome amenable at diagnosis on clinical grounds.

**1123W**

**Novel pathogenic variants of *EP300* in two Japanese patients with Rubinstein-Taybi syndrome type 2.** T. Kaname<sup>1</sup>, K. Yanagi<sup>1</sup>, M. Iso<sup>1</sup>, Y. Kuroki<sup>1</sup>, M. Minatogawa<sup>1</sup>, T. Tohma<sup>2</sup>, Y. Matsubara<sup>3</sup>. 1) Dept Gen Med, Natl Ctr Child Hlth Dev (NCCHD), Tokyo, Tokyo, Japan; 2) Wanpaku Clinic, Okinawa, Japan; 3) National Center for Child Health and Development, Tokyo, Japan.

**Background:** Rubinstein-Taybi syndrome (RSTS) is a rare autosomal dominant congenital disorder characterized by distinctive facial features, broad thumbs, postnatal growth deficiency and mental retardation. Patients bearing a mutation in *CREBBP* are diagnosed as RSTS 1 (OMIM #180849), who shows classical feature of RSTS. *CREBBP* is major cause of RSTS. *EP300* is another causative gene for RSTS (RSTS2; OMIM #180849). Mutation in *EP300* is minority in the patient of RSTS. Though clinical feature of RSTS2 seems milder phenotype than that of RSTS1, it has been unclear. We present two cases of RSTS2 with mild phenotype and severe mental retardation.

**Patients:** First patient is 2-yr old Japanese girl. Second patient is 8-yr old Japanese boy. Both patients have severe mental retardation, microcephaly, distinctive facial features with grimacing smile, broad thumbs and halluces. Epilepsy and ataxic gait are not observed in both patients. Postnatal growth deficiency is not observed in the first patient but second patient (-3SD). Clinical features are mild compare to typical RSTS. **Results of genetic testing:** Genomic DNA obtained from blood was examined by exome sequencing using a next generation sequencer. First patient has an A to G transition at splicing acceptor site of intron 25 of *EP300*. RT-PCR analysis showed the transition provoked non-canonical splicing in peripheral blood monocyte cells. Second patient has a missense variant in the exon 27 of *EP300*. SIFT and Polyphen predicted as disease causing. Both variants were not found in public database, dbSNP, 1000 Genome, ExAC, HGVD, integrative Japanese Genome Variation Database (<https://ijgvd.megabank.tohoku.ac.jp>), and in-house exome data. **Conclusion:** We found pathogenic variants in the *EP300* gene in the patients. They have mild phenotype, especially mild facial features, and have a grimacing smile. According to reports of patients with *EP300* variants, RSTS 2 has milder phenotype than RSTS 1 and grimacing smile might be one of the features of RSTS 2.

**1124T**

**Identification of *AFF4* missense mutation in a girl with Cornelia de Lange syndrome (CdLS) like phenotype and obesity.** E. Nishi<sup>1</sup>, N. Miyake<sup>2</sup>, N. Matsumoto<sup>2</sup>, N. Okamoto<sup>1</sup>. 1) Department of Medical Genetics, Osaka Women's and Children's Hospital, Osaka, Japan; 2) Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

CHOPS syndrome (MIM;616368) is a multiple congenital anomaly syndrome, phenotypically overlaps Cornelia de Lange syndrome (CdLS), characterized with cognitive impairment, coarse facies, heart defects, obesity, pulmonary involvement, short stature, and skeletal dysplasia, caused by heterozygous mutation in *AFF4* (MIM;604417) on chromosome 5q31 [Izumi, et al., 2015]. *AFF4* encodes a scaffold protein that functions as a core component of the super elongation complex (SEC), which is involved in transcriptional regulation during embryogenesis. In 3 unrelated children with CHOPS syndrome, 3 different *de novo* heterozygous missense mutations in *AFF4* (T254A, T254S, and R258W), all of which affected conserved residues in the ALF homology domain were identified [Izumi, et al., 2015]. Here we report a 7 years old girl with delayed psychomotor development with profound intellectual disability, short stature, obesity, spinal lipoma, and somewhat variable dysmorphic facial features, including round face, hypertelorism, thick eyebrows and hair, long eyelashes, short nose, and downturned corners of the mouth, clinically diagnosed Cornelia de Lange syndrome, who was found to have *de novo* heterozygous missense mutations in *AFF4*, R258W, by whole exome sequencing. Our case represents the fourth reported case of CHOPS syndrome due to *AFF4* mutations, and provides further evidence to support the notion that *AFF4* mutation cause CHOPS syndrome. Common clinical features among the patient described herein and the 3 patients previously described by Izumi et al. include IUGR, profound developmental delay/intellectual disability, short stature, obesity, congenital heart disease, brachydactyly, and somewhat variable dysmorphic facial features, including round face, hypertelorism, thick eyebrows and hair, long eyelashes, short nose, and downturned corners of the mouth. In our patient, hearing loss, cataract, and lipoma which was reported one by one in patients with CHOPS syndrome was found. So far, she have not showed the chronic lung disease which was found in the all three patients with CHOPS syndrome. This report would be important to further clarify the clinical picture of CHOPS syndrome.

**1125F**

**A novel genetic syndrome with *RAB11B* mutation.** N. Okamoto<sup>1</sup>, F. Miya<sup>2,3</sup>, T. Tsunoda<sup>2,3</sup>, M. Kato<sup>4</sup>, S. Saitoh<sup>5</sup>, M. Yamasaki<sup>6</sup>, Y. Kanemura<sup>7,8</sup>, K. Kosaki<sup>9</sup>. 1) Dept Medical Genetics, Osaka Women's and Children's Hospital, Izumi, Osaka, Japan; 2) Department of Medical Science Mathematics, Medical Research Institute, Tokyo Medical and Dental University; 3) Laboratory for Medical Science Mathematics, Center for Integrative Medical Sciences, RIKEN; 4) Department of Pediatrics, Showa University School of Medicine; 5) Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences; 6) Department of Pediatric Neurosurgery, Takatsuki General Hospital; 7) Division of Regenerative Medicine, Institute for Clinical Research, Osaka National Hospital, National Hospital Organization; 8) Department of Neurosurgery, Osaka National Hospital, National Hospital Organization; 9) Center for Medical Genetics, Keio University School of Medicine.

**[INTRODUCTION]** Rab (Ras-related in brain) proteins are included in the Ras superfamily of small GTPases. The Rab family proteins regulate variable intracellular membrane trafficking processes. They have critical roles in regulating exocytotic and endocytotic pathways. The isoforms Rab11a, Rab11b, and Rab11c/Rab25 constitute the Rab11 subfamily. *RAB11B* has 4 conserved domains important for GTP binding. Rab11b is highly expressed in brain, heart and testes. We report a boy with a novel pathogenic variant in *RAB11B*. **[CLINICAL REPORT]** The 6-year-old male was the first child of healthy and non-consanguineous Japanese parents. He was noted to have laryngomalacia after birth. He was hypotonic and his developmental milestones were markedly delayed. Brain MRI revealed hypoplasia of corpus callosum and cortical dysplasia of the frontal lobe. Physical examination identified microcephaly (-2.5SD) and dysmorphic features including epicanthal folds, flat nasal bridge, short philtrum and, high arched palate. His testes and penis were small. Endocrinological studies revealed hypogonadotropic hypogonadism. His fingers were short and slender. He showed spasticity of lower extremities. Ophthalmological investigation revealed strabismus and bilateral optic nerve atrophy. He showed severe intellectual disability and spoke a few meaningful words. His physical growth was within normal range. **[METHOD]** With the approval of our institutional ethics committee, the samples were analyzed using WES. Precise methods have been reported in another article (Okamoto et al. J Hum Genet 2014). **[RESULTS]** The patient had a *de novo* variant in exon2 of the *RAB11B* (NM\_004218: c.G64A:p.V22M). This variant is predicted to be pathogenic by *in silico* analyses. It was not found among public databases. **[DISCUSSION]** There have been no reports on the association of the *RAB11B* variant and genetic disorders. We suppose that abnormality of *RAB11B* causes a novel neurogenetic syndrome with characteristic facial features, cortical dysplasia, optic atrophy and hypogonadism.

**1126W****A case report of novel mutation in NSD1 gene, which causes Sotos Syndrome.**

*J. Prieto*<sup>1,2</sup>, *P. Sanchez*<sup>2</sup>, *A. Paredes*<sup>1</sup>. 1) Inst de Gen Humana, Univ Javeriana, Bogota D.C, Colombia; 2) Hospital La Victoria E.S.E, Bogotá D.C, Colombia.

**Introduction:** Sotos syndrome is characteristically identify as an autosomal dominant disorder of early overgrowth, caused by mutations in the NSD1 gene, located at chromosome 5q35.3, which encodes nuclear receptor-binding SET domain-containing protein 1, responsible of 90% cases. Patients presents length at or greater than 97th percentile usually during the first four years, associate with macrocephaly, dolichocephaly, bossing forehead, Malar flushing, prognathism, appearance of hypertelorism due to bitemporal narrowing, variable intellectual disability, phenotype changes in adulthood. The diagnosis is made by the identification of heterozygous NSD1 pathogenic variant. **Case presentation:** Patient of 8 year old, who was remitted to our service with diagnosis of high height since 1-year-old, bone age X-rays bone age 6, 5 years and chronological age 5 year 4 months. At physical examination is evident macrocephaly, frontal bossing, hypertelorism, prognathism, thorax pectus excavatum; extension studies reports progesterone: <0,03nmol/l, somatostatin C: 35,0ng/ml, growth hormone: 0,495ng/ml, ACTH: 11,4pg/ml, prolactin: 6.98ng/mmol, TSH: 1,23uIU/ml, T4L: 1,61ng/dl, estradiol: <5pg/ml, cortisol (am): 9,75ug/dl, Fasting glucose: 78,9mg/dl, RNM evaluates Turkish chair as normal, IQ 86. These findings suggest Sotos syndrome. Molecular study confirms the diagnosis, in the sequence analysis of the NSD1 gene, exons 2-23, found a heterozygous for the c.6437dupG, variant of uncertain significance, but resulting from a **Frameshift** mutation. **Discussion:** Sotos syndrome occurs in 1:14000 live births. The diagnosis is establish by the identification of a heterozygous pathogenic variant in NSD1 gene, the sequence analysis identify until 93% patients. NSD1 gene is located at 5q35.3 chromosome, encodes a histone methyltransferase, transcriptional intermediary factor. Mutations of this gene have been associated with Sotos and Weaver syndromes. At the moment more than 100 pathogenic variants have been published. The novel variant c.6437dupG identify in this patient, haven't been reported in the databases and was never found in ExAC nor 1000G. Therefore we propose a novel mutation, frameshift that causes a strongly truncated protein, result in a clear pathologic phenotype. **Conclusions:** Is the first time this variant is reported in a patient with the phenotype of Sotos syndrome. Functional studies will be necessary in future to confirm pathogenicity of this mutation.

**1127T****SATB2-associated syndrome: Differential diagnosis and genotype-phenotype correlations by detailed facial dysmorphism analysis using facial recognition technology in 38 individuals.** *Y. Zarate*. Arkansas Children's Hospital, Little Rock, AR.

**SATB2-associated syndrome (SAS, Glass syndrome)** is a multi-system disorder characterized by significant neurodevelopmental compromise and craniofacial anomalies. Despite the reported high frequency of subtle dysmorphic features, they are not thought to be distinctive enough to allow for a clinical diagnosis of SAS. To determine how recognizable this syndrome could be based on facial dysmorphism alone and to further delineate commonly shared dysmorphic features among affected individuals, an objective facial analysis using automated facial recognition technology was conducted on a large population of individuals diagnosed with SAS. 2D facial photographs were analyzed using Face2Gene (FDNA Inc; Boston, MA) technology to automatically detect and evaluate subtle craniofacial dysmorphism and compared to a previously established SAS mask generated from prior published cases. A total of 58 2D facial photographs of sufficient quality from 38 individuals (28 previously unreported) were analyzed using the facial recognition technology. Based on facial dysmorphism analysis alone, from a list of possible diagnoses, SAS was suggested in at least the at least the top 20 for 21 individuals (55%), at least the top 5 for 7 individuals (18%), and as the top choice in 2 individuals (5%). Some common dysmorphic features automatically detected by the facial technology analysis included anteverted nares, broad nasal tip, low nasal bridge, downslanted palpebral fissures, epicanthus, frontal bossing, hypertelorism, and long philtrum. When multiple photographs of the same individual at different ages were analyzed, the possibility of SAS to be suggested at least within the top 20 of possible diagnoses was higher (11/14=79%) compared to those with a single photograph analyzed (10/24=42%). Similarly, individuals with intragenic mutations were more likely to have SAS suggested at least within the top 20 list (15/25=60%) compared to those with large deletions (3/11=27%). Besides SAS, the next 2 most commonly suggested diagnoses in the differential by the facial photograph analysis were Cerebrocostomandibular syndrome and Mucopolipidosis type IV. In summary, this study provides evidence that SAS does have some common dysmorphic features that allow facial recognition technology to suggest this diagnosis within the top 20 of possible diagnoses in over half of individuals. Individuals with point mutations appear to have more recognizable features compared to those with large deletions.

**Noonan-like syndrome with loose anagen hair: Expanding the phenotype.** A. Belonis, D. Weaver. Department of Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN.

Noonan-like syndrome with loose anagen hair (NS/LAH) is a condition characterized by Noonan-like facies, congenital heart defects, darkly-pigmented skin, brittle nails, short stature, intellectual disability and sparse, thin, slow-growing hair that is easily plucked. The clinical phenotype is caused by a missense mutation in the *SHOC2* gene, c.4A>G, p.Ser2Gly, which is the only mutation reported to cause this condition. The patient is now a 4-year-old female who presented with a number of vascular abnormalities, including skin, hepatic, and extrahepatic hemangiomas, as well as vascular changes of the subdural membrane. These findings appear to expand the phenotype of this condition. At the time of the initial presentation, her genotype was not known, but it was later determined on whole exome sequencing: It identified a c.4A>G mutation in the *SHOC2* gene. She has a phenotype consistent NS/LAH, although she also has several features that have not been previously reported. An abdominal CT scan and an abdominal MRI both demonstrated findings consistent with multiple hepatic hemangiomas, hepatomegaly, and an extrahepatic, extra-adrenal mass suggestive of a hemangioma. At 6 months of age, she was hospitalized for increased intracranial pressure, with findings of papilledema and a bulging anterior fontanel. She required a decompression, followed by placement of an extraventricular drain (EVD), and later had a ventriculoperitoneal (VP) shunt placement. During her EVD placement, her visualized subdural membrane was described as thick, white, and riddled with distended veins. During VP shunt placement, an increased vascular pattern was noted on the surface of her liver. Additionally, the burr hole used for the initial decompression has not yet closed. There have been two patients with *SHOC2* c.4A>G mutation reported with hemangiomas. There is another reported patient with a familial *PTPN11* mutation c.1226G>C, p.Gly409Ala as well as the NS/LAH mutation in *SHOC2* (c.4A>G), who had characteristic features of NS/LAH and a hepatic hemangioma; the authors proposed that the atypical phenotype in this patient was the result of an additive effect, with *PTPN11* c.1226G>C mutation acting as a modifier. Our patient's hepatic hemangioma was initially diffuse and, with treatment, has decreased in size on follow-up imaging. Additionally, our patient's abnormal subdural membrane venous finding appears to be another intracranial vascular anomaly in this condition.

**A Japanese sporadic case of Adams-Oliver syndrome with a novel missense variant in *DLL4*.** M. Nagasaka<sup>1,2</sup>, M. Taniguchi-Ikeda<sup>2,3</sup>, H. Inagaki<sup>4</sup>, U. Ouchi<sup>4</sup>, M. Morioka<sup>2</sup>, T. Toda<sup>2</sup>, H. Kurahashi<sup>4</sup>, K. Iijima<sup>2</sup>. 1) Takatsuki General Hospital, Osaka, Japan; 2) Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; 3) Division of Genetic Counseling, Kobe University Hospital, Kobe, Japan; 4) Division of Molecular Genetics, Institute for Comprehensive Medical Science, Fujita Health University, Toyoake, Aichi, Japan; 5) Department of Neurology/Molecular Brain Science, Kobe University Graduate School of Medicine, Kobe, Japan.

Adams-Oliver syndrome (AOS, OMIM; 100300) is a rare genetic disease. Various clinical manifestations have been reported, including aplasia cutis congenita of the scalp, terminal transverse limb defects, and cutis marmorata with vascular anomalies such as congenital heart defects. The etiology of AOS has remained largely unknown but defective Notch signaling during vascular formation has been suggested. Here we describe a sporadic Japanese newborn case with clinically diagnosed AOS. The proband was born at 34 weeks, 4 days gestation with a birth weight of 1334 g (-2.7 SD), height of 39.6 cm (-2.2 SD), and occipitofrontal circumference of 26 cm (-2.5 SD). During pregnancy, fetal growth restriction and single umbilical cord artery were present. The patient was transferred to the neonatal intensive care unit at Kobe University Hospital soon after birth, presenting with bleeding around aplasia cutis congenita of the skull. Limb abnormalities, such as bilateral syndactyly of the lower extremities and brachydactyly, and cutis marmorata were also observed. Clinical presentation suggested a diagnosis of typical AOS. Trio whole-exome sequencing identified a *de novo*, novel, heterozygous missense variant in the *Delta-like 4 ligand* gene (*DLL4* c.572G>A, p.Arg191His) in the patient. *DLL4* functions as a requisite ligand for NOTCH1 receptor, which is essential for vascular formation. *DLL4* has recently been identified as a causative gene of an autosomal dominant type of AOS. Amino acid substitution of Arg 191 to His was predicted by molecular models to interfere with direct binding between *DLL4* and NOTCH1. The *in silico* variant analysis tools, SIFT and PolyPhen-2 produced scores of 0 (deleterious) and 1.0 (damaging), respectively. By modeling the *DLL4* structure and the R191H variant using MODELLER9v8, the side chain of histidine was shown to be shorter compared to that of arginine. Therefore, the Arg191His variant might lead to weakening of the electrostatic interaction between *DLL4* and the receptor and it may have reduced access to receptor binding site residues, resulting in the AOS phenotype. Variants in *DLL4* have been recently identified in several families, with these patients showing relatively mild phenotypes compared to autosomal recessive cases. The case described here showed gradual recovery from skull defects after birth, suggesting that mutation in *DLL4* has less effect after birth, leading to the milder phenotype of the case.

**1130T****Redefining phenotypic spectrum of constitutional *CDK13* mutations:**

**Three patients without cardiac defects.** T. Uehara<sup>1</sup>, H. Suzuki<sup>1</sup>, Y. Yamaguchi<sup>1</sup>, T. Takenouchi<sup>1,2</sup>, K. Kosaki<sup>1</sup>, K. Kurosawa<sup>3</sup>, S. Mizuno<sup>4</sup>. 1) Center for Medical Genetics, Keio University School of Medicine, Tokyo, Japan; 2) Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan; 3) Division of Medical Genetics, Kanagawa Children's Medical Center, Kanagawa, Japan; 4) Department of Pediatrics, Central Hospital, Aichi Human Service Center, Aichi, Japan.

Precise regulation of the cell cycle is a prerequisite for human development and growth. Cyclins and cyclin-kinases are key regulators of cell cycle and constitutional mutations in those molecules lead to developmental disorders. Recently, seven patients with de novo constitutional missense mutations in the *CDK13* gene from the cyclin-dependent kinase family were identified through trio exome analysis of a large cohort of 610 patients with congenital cardiac disease accompanied with intellectual disabilities and other extra-cardiac features. Here we report 3 patients with de novo constitutional missense mutations in the *CDK13*. These 3 patients had intellectual disabilities but did not have congenital heart diseases. Exome analysis of the patients and their parents revealed the following: Patient 1 was a 6-year-old male who had de novo heterozygous *CDK13* p.G717Q mutation. He showed severe intellectual disability, prenatal and postnatal growth retardation, craniosynostosis, long eyelashes, cupped ears, teeth anomalies, and strabismus. Patient 2 was a 5-year-old male who had de novo heterozygous *CDK13* p.G717Q mutation. He showed intellectual disability, cleft palate, dark skin, hypertrichosis, long and wide nose, posteriorly rotated ears, and hypertelorism. Patient 3 was a 1-year-old female who had de novo heterozygous *CDK13* p.A842S mutation. She showed intellectual disability, craniosynostosis, hearing impairment, down-slanting palpebral fissures, flat nose, low-set ears, and small chin. We here redefined the phenotypic spectrum of the *CDK13* constitutional defect. Cardiac defect is not an essential feature of the syndromic intellectual disability syndrome associated with constitutional *CDK13* mutations. Long or busy eyebrow and earlobe anomaly, and craniosynostosis may represent a diagnostic clue to this newly identified syndrome.

***IRF6* mutational screening in a sample of Mexican patients with non syndromic cleft lip palate.** J. Velazquez, B. Estandia-Ortega, M.A. Alcantara-Ortigoza, A. Gonzalez-del Angel. Genetics, Instituto Nacional de Pediatría, Mexico, Distrito Federal, Mexico.

Van der Woude Syndrome (VWS, MIM#119300) is caused by pathogenic variants (PV) on *IRF6* gene (~70% VWS cases). Clinical presentation includes cleft lip/palate and lower lip pits, but lower lip pits can be unnoticed or absent at clinical examination, which in some cases difficult its distinction from non-syndromic cleft lip palate (NSCLP). The VWS has been identified in the 0.4-3.7% of patients catalogued as NSCLP. The misdiagnosis of VWS had important implications for genetic counseling or as a confounder for NSCLP association studies. We screened for *IRF6*PV in Mexican mestizo NSCLP patients recruited for genetic association studies. 172 Mexican-Mestizo unrelated NSCLP patients evaluated for a clinical geneticist to exclude those with clinical data suggesting a syndromic form. The nine *IRF6* exons were PCR amplified and sequenced by Sanger method. Identified variants were searched in public databases. To date, complete *IRF6* sequencing has been achieved in 96 individuals, 76 patients sequencing has a progress of ~70%. No PV have been identified. 9 reported non-PV were identified, all in Hardy-Weinberg equilibrium, allelic frequencies 0.14-0.44 which did not show statistical differences with those reported in Mexican ancestry individuals from LA (1000 Genomes project). Screening of VWS in NSCLP patients have been performed in Asian, Caucasian, African and Latin-American populations, but it is the first report in Mexican mestizos and the largest in Latin-America. Although we have not yet completed sequencing, seems unlikely to identify the VWS in our sample, thus our results indicate that VWS could be infrequent in clinically catalogued NSCLP patients. This can be explained by the careful clinical evaluation in order to exclude any minimal expression of VWS. In similar studies, was reported that in *a posteriori* revision of NSCLP-catalogued cases with an *IRF6* PV, they have a minimal expression of lip pits (42%), besides that *IRF6* PV carriers has a pedigree suggesting autosomal dominant inheritance (42%), PV carriers with none of the last characteristics were 43%. In our sample only 5.8% had an affected first degree relative (5 of 10 cases with complete *IRF6* sequence and none with a PV). In our study, minimal expression of VWS was discarded from patients and the proportion of familial cases were low. This diminishes the possibility of assortment bias for NSCLP association studies performed in this sample and remarks the importance of a careful clinical evaluation.

**Urine-derived podocytes-like cells: From a diagnostic to a CRISPR/Cas9 gene therapy perspective in Alport syndrome.** A.M. Pinto<sup>1,2</sup>, S. Daga<sup>1</sup>, M. Baldassarri<sup>1,2</sup>, C. Lo Rizzo<sup>1,2</sup>, C. Fallerini<sup>1</sup>, V. Imperatore<sup>1</sup>, I. Longo<sup>1,2</sup>, E. Frullanti<sup>1</sup>, L. Massella<sup>3</sup>, C. Pecoraro<sup>4</sup>, G. Garosi<sup>3</sup>, F. Ariani<sup>1,2</sup>, M.A. Mencarelli<sup>1,2</sup>, F. Mari<sup>1,2</sup>, A. Renieri<sup>1,2</sup>. 1) Medical Genetics, Department of Medical Biotechnology, University of Siena, Policlinico 'Santa Maria alle Scotte', Siena, Italy; 2) Medical Genetics, Azienda Ospedaliera Universitaria Senese, Siena, Italy; 3) Division of Nephrology and Dialysis, Bambino Gesù Children's Hospital, IRCCS, Rome; 4) Pediatric Nephrology Unit, Santobono-Pausilipon Hospital, Naples, Italy.

Alport Syndrome (ATS) is a rare genetic disorder caused by mutations in collagen IV genes, leading to ultrastructural lesions of the Glomerular Basement Membrane (GBM) up to end-stage renal disease. Podocytes, the main cellular component of the glomerular structure, are the only cells able to produce the three collagens IV alpha chains and thus, they are key-players in ATS pathogenesis. However, transcripts-based diagnostic approaches and podocytes-targeted therapeutic strategies, have been hampered by their inaccessibility. Modifying previously established protocols for urine cells isolation, we were able to grow and isolate podocytes-like cells from ATS patients, in a totally non-invasive way. RT-PCR analysis indeed revealed *COL4A3*, *COL4A4* and *COL4A5* expression, for all the isolated cell lines. RNA studies performed on patients-derived podocytes harboring intronic variants of uncertain significance (VoUS) in *COL4V* genes, led to the identification of aberrant splicing patterns leading to premature stop codons and truncated proteins allowing us to define the pathogenic role in a number of VoUS involving +2, +5 positions and exon-intron deletions. We designed a podocytes-like cells co-infection with both a SV40NLS-dCas9-AAV2 and a gRNA-HDR-AAV2 (pAAV-COL4-HDR) construct harboring the homology arms, packed between a gRNA expression cassette and a GFP expression cassette to "snip out" the most frequent single nucleotide *COL4* genetic mutations and stably reverting the phenotype. We are currently running this approach on variants frequently observed in Eastern Europe: p.Gly1045Val, p.Gly1233Arg and p.Gly695Arg in *COL4A3*, p.Gly370Glu in *COL4A4* and p.Gly624Asp, p.Arg1410Cys in *COL4A5*. As proof of principle we demonstrated that it is possible to isolate podocytes-like cells from Alport patients urine samples thus providing a novel easily-available tool for a transcript-based diagnostic approach aiming to provide the family with a proper recurrence risk. In addition, we built on the availability of disease-relevant cell lines to engineer a gene therapy strategy opening up the possibility of a personalized transformative gene-based medicine.

**1133T**

**The expansion of heterotopic bone in fibrodysplasia ossificans progressiva is Activin A-dependent.** A.N. Economides<sup>1</sup>, J. Upadhyay<sup>1</sup>, L. Xie<sup>1</sup>, L. Huang<sup>1</sup>, N. Das<sup>1</sup>, R. Stewart<sup>2</sup>, M. Lyon<sup>2</sup>, K. Palmer<sup>2</sup>, S. Rajamani<sup>1</sup>, C. Graul<sup>3</sup>, M. Lobo<sup>2</sup>, T. Wellman<sup>2</sup>, E. Soares<sup>2</sup>, M. Silva<sup>2</sup>, J. Hesterman<sup>2</sup>, K. Nannuru<sup>1</sup>, V. Idone<sup>1</sup>, A.J. Murphy<sup>1</sup>, S.J. Hatsell<sup>1</sup>. 1) Regeneron Pharmaceuticals, Inc., 777 Old Saw Mill River Road, Tarrytown, NY; 2) InviCRO, LLC, 27 Drydock Avenue, Boston, MA 02210; 3) College of Holy Cross, 1 College Street, Worcester, MA 01610.

Fibrodysplasia Ossificans Progressiva (FOP) is a rare autosomal dominant disorder that is characterized by episodic, progressive, and cumulative heterotopic ossification (HO) in tendons, ligaments, and a subset of skeletal muscles over a patient's lifetime. FOP is caused by missense mutations in the type I Bone Morphogenetic Protein (BMP) receptor-encoding gene, *ACVR1*. We have shown that HO in FOP requires activation of mutant *ACVR1* by Activin A. Activin A – a BMP/TGF $\beta$  family member which is not osteogenic – induces formation of HO in FOP mice, whereas its inhibition blocks the formation of HO. Here we extend our previous studies by piecing together a 'natural history' of developing HO lesions, and determining where in the continuum of HO Activin A is required, using imaging (T2-MRI,  $\mu$ CT, <sup>18</sup>F-NaF PET/CT) coupled with pharmacologic inhibition of Activin A at different times during the progression of HO in FOP mice (MGI:5763014). As disease progresses, expansion of HO lesions comes about through growth and fusion of independent HO events that tend to arise within a neighborhood of existing lesions, indicating that already formed heterotopic bone lesions likely trigger the formation of new lesions. The process appears to be depended on Activin A, as inhibition of this ligand not only suppresses the growth (and can even cause partial regression) of nascent HO lesions but also stops the emergence of new HO events. These results provide evidence for a model where HO is triggered by inflammation, and where existing or developing HO lesions become 'self-propagating' by a process that may involve re-initiation of inflammation (by already formed heterotopic bone lesions) and that also requires Activin A. This new data extends the potential utility of prophylactic treatment with inhibitors of Activin A as a therapy for FOP that might not only stop the emergence of new lesions but also limit the growth and expansion of the heterotopic bone field in subjects with ongoing disease activity.

**1134F**

**Diamond Blackfan "anemia" due to *RPL26* mutation in a family with radial ray and congenital anomalies.** L. Mehta<sup>1</sup>, L. Karger<sup>1</sup>, B. Webb<sup>1</sup>, J. Liao<sup>1,2</sup>, L. Edelmann<sup>1,2</sup>. 1) Dept. of Genetics & Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Sema4, a Mount Sinai venture, Stamford, CT.

Heterozygous loss of function mutations in ribosomal protein genes cause Diamond Blackfan anemia (DBA). Typically DBA presents with hematological findings of pure red cell aplasia and macrocytic anemia. Growth retardation and congenital anomalies, commonly of limbs, heart or genitourinary system are present in 30-50% of patients with DBA. We evaluated a 63 yo man, with right triphalangeal thumb, right stenotic ear canal and high myopia, height 5'10", with no other significant medical history. His 52 yo brother had mildly hypoplastic left thumb. This brother's older son had preauricular pits, myopia, and learning disabilities; a younger son had bilateral hypoplastic thumbs and forearms with radioulnar synostosis, right congenital deafness, horseshoe kidney, short stature, and autism. A third brother, age 41 y, had a right triphalangeal thumb. The parents of the patient were not noted to have any anomalies. His 28 yo daughter was unaffected. Townes Brocks and Okihiro syndromes were considered, but *SALL1* and *SALL4* sequencing as well as chromosome microarray were normal. Whole exome sequencing showed a likely pathogenic frameshift variant in *RPL26*, c.341delA, p.D114Afs\*15 (NM\_000987.3), in the proband and his 41 yo brother, but not in the proband's daughter. Other affected family members declined genetic testing. The variant has not been reported in DBA patients, nor is it present in dbSNP, ESP or ExAC databases. Located in the last exon of the gene, it is likely to disrupt gene function due to changing the reading frame and protein truncation. The patient had normal blood counts, MCV and Hb electrophoresis and elevated erythrocyte deaminase (eADA) of 1083 mu/g Hb (ref range 400-900). He had a normal echocardiogram and renal sonogram. A *de novo* frameshift mutation in *RPL26* has been previously reported in a female infant with shortened forearms, absent thumbs, absent left kidney and absent/narrow external auditory meatus. This patient had severe anemia and neutropenia (Gazda et al, 2011). *RPL26* depletion in HeLa cells was observed to affect maturation of ribosomal RNA subunits. While our patient did not manifest hematological abnormalities he was found to have an elevated eADA. Mutations in ribosomal protein genes should be considered in the differential diagnosis of relevant congenital anomalies particularly of the forearms and radial ray, even in the absence of anemia. EADA may be a good screening test in such cases.

**A novel genetic disorder characterized by severe developmental delay and dysmorphism, recurrent pancreatitis, and organomegaly.** M. Morimoto<sup>1,2</sup>, X. Chepa-Lotrea<sup>1,2</sup>, M. Sincan<sup>1,2</sup>, D. Draper<sup>1,2</sup>, C.F. Boerkoel<sup>1,2</sup>, G. Golas<sup>1,2</sup>, D.R. Adams<sup>1,2</sup>, W.A. Gahl<sup>1,2,3</sup>, M.C.V. Malicdan<sup>1,2,3</sup>. 1) NIH Undiagnosed Diseases Program, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 2) Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 3) Section of Human Biochemical Genetics, Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

**Introduction:** The endoplasmic reticulum (ER), composed of a continuous membranous system, is vital for protein (rough ER) and lipid (smooth ER) synthesis and secretion, lipid bilayer assembly, carbohydrate metabolism, and calcium homeostasis. Disruption of the ER by either gene mutations or misfolding of cellular proteins can lead to neurodegeneration, metabolic or inflammatory disorders. Here we present a child with multisystem abnormalities and identify a gene encoding an endoplasmic reticulum transmembrane protein that may be associated with this novel genetic disease. **Methods:** Extensive clinical evaluation was performed on the patient through the NIH Undiagnosed Diseases Program (UDP). SNP array and whole exome sequencing analyses were performed and candidate variants were validated by Sanger sequencing. Expression analyses were performed in patient dermal fibroblasts using quantitative PCR, western blot, and immunocytochemistry. **Results:** A 5-year-old girl presented to the UDP with a complex multisystem clinical phenotype characterized by severe global developmental delay, hypotonia, recurrent bouts of pancreatitis, chronic liver inflammation, enlarged kidneys, and hepatosplenomegaly. She also exhibited dysmorphic features including brachycephaly, low-set ears, dental crowding, joint contractures, and club foot. Compound heterozygous nonsense mutations were identified in *CCDC47* in the patient. Expression studies in patient dermal fibroblasts showed nearly negligible expression of *CCDC47* mRNA and no protein expression compared to unaffected controls. These results, together with the previously described role of *CCDC47* in embryogenesis and endoplasmic reticulum-associated degradation (ERAD), suggest that the lack of *CCDC47* protein expression may be contributing to the pathogenesis of this disease through dysregulation of this pathway. **Conclusion:** We report the first patient with a novel genetic disease and hypothesize that biallelic mutations in the endoplasmic reticulum transmembrane protein encoding gene *CCDC47* may underlie the pathogenesis of this disease. We plan to further explore this hypothesis through further studies in neural progenitor cells derived from patient-specific induced pluripotent stem cells.

## 1136T

**A growing need for reverse clinical genomics: Demonstrated by phenotypic characterization of CDK13-related disorders.** B. Bostwick<sup>1</sup>, S. McLean<sup>1,11</sup>, J. Posey<sup>2</sup>, H. Historically, most disease gene discovery occurred *after* the gathering of a large cohort of individuals with a remarkably similar phenotype. It was common for a syndrome to be identified, named, and well-delineated prior to gene discovery. With the advent of next generation sequencing, many new gene discoveries are originating from large disease-specific sequencing cohorts often containing thousands of individuals. In these new studies, syndromes are identified first molecularly instead of phenotypically. This experimental design has created a new demand for 'reverse clinical genomics,' where disease-gene directed cohorts are then studied phenotypically to delineate the syndromic associations and appropriate medical management. Here, we use this approach to provide comprehensive phenotypic characterization of a newly described CDK13-related disorder. *De novo* missense variants in *CDK13* were first described in late-2016 as the cause of syndromic congenital heart defects in 7 individuals ascertained from a large congenital cardiovascular malformations cohort. We aimed to further define the phenotypic spectrum of this newly described disorder by recruiting 9 additional individuals with *CDK13* pathogenic variants detected by clinical or research exome sequencing. This approach minimized ascertainment bias as recruitment was non-phenotype driven. Our phenotypic characterization demonstrated greater than expected phenotypic heterogeneity, including 33% (3 of 9) of individuals without structural heart disease on echocardiogram. There was a high penetrance for a unique constellation of facial dysmorphisms, suggesting a potentially recognizable 'facial gestalt' with some resemblance to Kabuki syndrome. In addition, a wide variety of CNS anatomical abnormalities (91%), sacral abnormalities (44%) and renal anomalies (19%) were present. Global developmental delay was universal. Molecularly, two individuals had novel *de novo* *CDK13* variants (p.Asn842Asp, p.Lys734Glu), while the remaining 7 unrelated individuals had a recurrent, previously published p.Asn842Ser variant. Overall, our study demonstrates that extensive phenotyping using a genotype-first approach to subjects with pathogenic *CDK13* variants enables syndrome delineation and recognition of greater phenotypic heterogeneity than revealed by initial phenotype-driven cohort analysis. The aggregated clinical phenotyping information is used for the initial construction of clinical management guidelines.

## 1137F

**Phenotypic variability in a cohort of patients with VACTER-L association.** O.M. Moreno<sup>1</sup>, A.I. Sánchez<sup>1</sup>, A. Herreño<sup>1</sup>, Y. Vargas<sup>2</sup>, M. Olaya<sup>2</sup>, G. Giraldo<sup>1</sup>, J.C. Prieto<sup>1</sup>, A. Rojas<sup>1</sup>. 1) Instituto de Genética Humana, Pontificia Universidad Javeriana Bogotá, Bogotá, Colombia; 2) Hospital Universitario San Ignacio.

**Introduction:** VACTER-L association comprises different multisystem congenital malformations including vertebral anomalies, anal atresia, cardiac defects, trachea-oesophageal (TE) fistula with or without oesophageal atresia, renal malformations and limb defects. Prevalence is 1:7000 to 1:40000 individuals. This heterogeneous condition has many overlapping defects with other malformation syndromes and it is usually considered as a diagnosis of exclusion. Fanconi anemia (FA) patients often exhibit birth defects suggesting VACTERL association. Because of this, FA must be considered among one of the first differential diagnosis among VACTER-L patients. **Objective:** The aim of this study was to determine the frequency of VACTER-L characteristics in patients who met criteria for this condition and to identify abnormalities in genetic tests including conventional cytogenetics analysis, molecular cytogenetics (aCGH) and chromosome fragility. **Methods:** This is a prospective study. Data regarding clinical features was obtained by physical examination or from clinical reports, and then it was analyzed to describe all clinical aspects. Complete cytogenetic investigation based on at least 25 metaphases with G-band staining was performed in all patients, as well as chromosome fragility studies for FA using standard procedures. **Results:** We evaluated 18 patients who met criteria for VACTER-L association, 11 were female and 7 were male. Age range between 1 month and 16 years. Ten patients presented with vertebral anomalies. Anal atresia was evident in 6 patients. Congenital heart defects were seen in 13 patients. Oesophageal atresia was diagnosed in 9 patients, six of them having TE fistula. Eight patients had renal anomalies. Limb defects were evident in 7 patients. Normal karyotypes were reported for all patients. Chromosome fragility studies were negative. aCGH results are running. **Discussion and conclusion:** VACTER-L association is characterized as a heterogeneous condition with non-random pattern of defects. All patients in our study exhibit a wide clinical spectrum. Chromosome aberrations were ruled out in all of them and chromosome breakages and fragility for FA were negative. Because abnormalities in aCGH have been identified in patients with VACTER-L association, we are also performing this test, however results are still pending. More association studies are necessary for genotype-phenotype correlations to determine the genetic causes underlying this condition.

**1138W**

**Truncating *MAGEL2* mutations produce fetal lethality in mice and may recapitulate pathogenesis of Schaaf-Yang syndrome.** Y. Negishi<sup>1</sup>, D. Jeda<sup>1</sup>, T. Miyamoto<sup>2</sup>, I. Hori<sup>1</sup>, A. Hattori<sup>1</sup>, Y. Nozaki<sup>3</sup>, H. Komaki<sup>4</sup>, J. Tohyama<sup>5</sup>, K. Nagasaki<sup>6</sup>, H. Tada<sup>7</sup>, H. Oishi<sup>6</sup>, S. Saitoh<sup>1</sup>. 1) Department of Pediatrics and Neonatology, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 2) Department of Comparative and Experimental Medicine, Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; 3) Department of Pediatrics, Jichi Medical University, Tochigi, Japan; 4) Department of Child Neurology, National Center Hospital, National Center of Neurology and Psychiatry (NCNP), Tokyo, Japan; 5) Department of Child Neurology, Nishi-Niigata Chuo National Hospital Niigata, Japan; 6) Division of Pediatrics, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 7) Department of Pediatrics, Chibaken Saiseikai Narashino Hospital, Narashino, Japan.

*MAGEL2* is a paternally expressed gene located in 15q11-q13, which is responsible for Prader-Willi syndrome (PWS), and truncating mutations on the paternal allele of *MAGEL2* have recently been reported as a cause of Schaaf-Yang syndrome (SHFYNG). The mechanism underlying the disease is considered to be the loss of function of *MAGEL2*; however, the deletions of the entire paternal copy of *MAGEL2* appear to cause very mild phenotype, and there are many uncertainties regarding the role of *MAGEL2* in PWS phenotypes. We sequenced *MAGEL2* in 105 patients suspected PWS clinically, but without a genetic alteration specific for PWS, and detected truncating mutations in *MAGEL2* in 6 patients, including a pair of siblings. Of the 4 sporadic patients, 3 patients for whom samples were obtained from their parents were detected to have *de novo* mutations, and the mutation alleles were paternally derived in all 4 patients. For the 2 siblings, the father was a carrier and the father's mutation was maternally derived. The patients with *MAGEL2* mutations shared several features with PWS, such as neonatal hypotonia, poor suck, and obesity; however, there were also unique findings, including arthrogryposis and a failure to acquire meaningful words. Additionally, a history of cryptogenic encephalopathy was confirmed in 3 of the 6 patients, and this could be an additional feature of SHFYNG. Because *MAGEL2* is a single exon gene, nonsense mutation-mediated mRNA decay does not induced, and we hypothesized that the truncated protein was related to the pathogenesis. Consequently, we next produced transgenic mice that overexpressed the N-terminal of *Mage12* that was conserved in the patients. However, most of Tg-positive mice died in utero or in early neonatal period. While a single Tg-positive mouse was produced, it died several days after birth. These results suggest the possibility that truncated *MAGEL2* protein could have toxic effects resulting in mostly fetal lethality in mice, and may explain why SHFYNG shows much more severe phenotype than PWS.

**1139T**

**Case report Kleefstra syndrome in a Colombian patient.** A. Nova<sup>1</sup>, G. Giraldo<sup>2</sup>, J. Montoya<sup>2</sup>. 1) Instituto Genética Humana, Pontificia Universidad Javeriana, Bogotá, Colombia; 2) Servicio Genética Médica, Clínica Universitaria Bolivariana, Medellín, Colombia; 3) Servicio Genética Médica, Hospital Universitario San Vicente Fundación, Medellín, Colombia.

Kleefstra syndrome (KS), is caused by haploinsufficiency of the EHMT1 gene. And is one of the first clinically recognizable Subtelomeric Deletion syndrome. The syndrome is characterized by intellectual disability, hypotonia, and typical dysmorphisms, and may be associated with congenital heart, renal defects and epilepsy. The evolution of the behavioral profile of KS was one of the last described characteristics of the syndrome. In this report, the characterization of a patient with kleefstra syndrome by microdeletion, with molecular diagnosis by means of comparative genomic hybridization, and changes suggestive of MRI leukomalacia, from an early age, in whom no behavioral changes have yet been shown, described in other reports at later ages, in patients with brain alterations similar, confirming the neuroregressive picture of this syndrome and the participation of the EHTM1 gene as the cause of this syndrome. It is also highlighted by the case presented here, the need to report the cases found in our Colombian population, in order to be able to know more broadly the condition of this pathology, its epidemiology, its characteristics, natural history and forecast, in order to be able to carry out Comprehensive management of these patients.

**Acid ceramidase deficiency (Farber disease): A qualitative research study documenting the clinical impact of symptoms in a diverse population of patients and caregivers.** A. Solyom<sup>1</sup>, B. Johnson<sup>2</sup>, P. Tanpaiboon<sup>3</sup>, D. Tetzl<sup>4</sup>, K. Coyne<sup>5</sup>. 1) Enzyvant, Basel, Switzerland; 2) Roivant Sciences, Durham, USA; 3) Children's National Medical Center, Washington, DC, USA; 4) Enzyvant, New York, USA; 5) Evidera, Bethesda, USA.

**Introduction** Acid ceramidase deficiency (Farber disease; Farber lipogranulomatosis) is caused by mutations in the *ASAH1* gene and is considered an ultra-rare disease. Since 2014, Enzyvant has identified a cohort of patients from 30 countries on 6 continents, with a much broader phenotypic spectrum and demonstrating a potentially higher incidence than previously thought. The cardinal symptoms of acid ceramidase deficiency are: arthritis, subcutaneous nodules, and hoarseness. Farber disease is most often misdiagnosed as Juvenile Idiopathic Arthritis. **Objectives** Conduct a qualitative research study to understand the symptoms and impact of Farber disease from the perspective of patients and caregivers by conducting one-on-one interviews for concept elicitation, content validity, and patient interpretation of newly developed patient-reported outcome (PRO) tools. **Methods** This study consisted of two parts: semi-structured qualitative interviews to understand Farber disease symptoms and to evaluate new PRO measures to capture the impact of symptoms on patients including: subcutaneous nodules, voice, overall pain, arthritis, ability to move joints, ability to perform daily tasks, and level of fatigue. Participants were asked to rate the symptoms' impact on a scale of 0–10, with 0 meaning no impact and 10 meaning greatest impact. **Results** Eight interviews were conducted: 2 adult patients (attenuated phenotype); 1 caregiver of deceased child (severe phenotype); 1 transplanted adult patient (moderate phenotype); 1 caregiver of transplanted pediatric patient (moderate phenotype); 1 caregiver of a pediatric patient (moderate phenotype); and 1 caregiver/patient dyad of a non-transplanted pediatric patient (moderate phenotype). Interviews revealed the symptoms of acid ceramidase deficiency have measurable clinical impact across a broad spectrum of phenotypes and symptom severity. The symptoms with the highest-rated impact were the ability to move joints, average impact rating of 6.6 (range 1 to 10); the ability to perform daily activities and subcutaneous nodules, both rated 5.9 (range 1 to 10 for daily activities and 3 to 9 for nodules); voice impact was rated 5 (range of 3 to 9). **Conclusion** The information gathered provides a better understanding of methods useful for measuring symptom impact in Farber disease, potentially in the context of future therapeutic trials, and may allow better discussion of symptom impact between physicians, patients and caregivers.

**1141W**

**Natural history study design including retrospective and prospective components to address the lack of clinical data on acid ceramidase deficiency presenting as Farber disease.** D. Tetzl<sup>1</sup>, B. Johnson<sup>2</sup>, A. Solyom<sup>3</sup>. 1) Enzyvant, New York, USA; 2) Roivant Sciences, Durham, USA; 3) Enzyvant, Basel, Switzerland.

**Introduction** Mutations in both alleles of the *ASAH1* gene cause acid ceramidase deficiency (Farber disease; Farber lipogranulomatosis) and accumulation of the pro-apoptotic and pro-inflammatory sphingolipid, ceramide. A cohort of patients (some of whom are since deceased) from 30 countries on 6 continents has been identified since 2014, with clinical presentations indicating a much broader phenotypic spectrum and potentially higher incidence than previously thought. **Objectives and Methods** We developed a natural history study structure and design to enable systematic collection of information on living patients who have or have not undergone hematopoietic stem cell transplantation (HSCT), and on deceased patients using medical records. The study will also function to evaluate clinical assessment tools used for other diseases with similar symptoms, as well as those created specifically for Farber disease. The pre-existing clinical assessment tools include (among others) the Childhood Health Assessment Questionnaire (CHAQ), and Wong-Baker Faces Pain Rating Scale, 6-minute Walk Test, Pulmonary Function Testing, and Joint Range of Motion measurements. We developed a unique patient reported outcome measure related to Farber disease symptoms including physical impairment, pain, and emotional distress, and a method for the assessment of change in size of subcutaneous nodules. **Conclusion** Consideration of the broad spectrum of ages and heterogeneous phenotypes in a small population of patients available to participate in a study of the natural history of acid ceramidase deficiency led to the design of a cross-sectional cohort study with retrospective and prospective components. By including deceased patients and patients having undergone HSCT in the study design, the amount of data that can contribute to the understanding of this very rare disease is substantially increased. Furthermore, the specific prospective assessments will allow us to follow disease progression over time, and to evaluate the degree to which the assessment tools and techniques may be appropriate for registering change in certain symptoms over time. Enzyvant is developing enzyme replacement therapy for Farber disease, and it is our hope that the data collected will contribute to the selection of methods for measuring therapeutic efficacy in any future clinical trials.

**1142T**

**Rare syndrome: First reported Egyptian sibs with 3MC(1) syndrome and detection of novel *MASP1* gene mutation in the family.** A.N. Khalaf<sup>1</sup>, S.M. Kotb<sup>1</sup>, M.M. Fata<sup>1</sup>, E.M. Abdalla<sup>1</sup>, K.M. Nabil<sup>2</sup>, F.S. Alkurraya<sup>2</sup>. 1) Human Genetics, Medical Research Institute, Alexandria, Egypt; 2) KFSHRC, Riyadh, SA; 3) Ophthalmology Dept, Faculty of medicine, Alexandria, Egypt.

Here we are reporting the first Egyptian male sibs with the rare 3MC(1) syndrome. Two male sibs born to consanguineous parents, aged 4 and 2 years, presented with dysmorphic features, cleft lip and congenital heart disease. Pregnancy history and delivery history were irrelevant. Both patients showed motor and speech developmental delay. The elder brother had history of correction of bilateral inguinal hernia and cleft lip at age of 6 months. On examination, this patient showed bilateral microphthalmia with narrow palpebral fissures, severe ptosis and absent lid creases, distorted nose with wide nasal root and bridge, corrected incomplete right cleft lip, very long low-set ears, occipital whorl and abnormal irregular teeth with hypodontia. In addition, bilateral syndactyly of second and third toes and single crease on fifth left finger were also noted. Anthropometric measures were within normal percentiles. Echocardiography revealed PDA and VSD while ABR, CT brain and karyotype were normal. Ophthalmological examination showed mixed astigmatism, prominent schwalb line and alternating esotropia. For the younger similarly affected brother there was a history of congenital clenched hands and deformed feet which gradually improved till completely resolved. On examination, he showed dysmorphic features similar to his brother with corrected right oblique incomplete cleft lip and abnormal helical folding of left ear which is also distorted. Anthropometric measures were also normal. CT brain showed ectatic ventricles, ABR revealed serous otitis media and echocardiography showed PDA, VSD and ASD secundum. Most probable suspected diagnosis was 3MC(1) syndrome. This syndrome which was first described by Michels et al. with the eye lid triad of blepharophymosis, blepharoptosis and inverse epicanthus in association with limitation of upward gaze, hypertelorism, cleft lip and palate, Various skeletal anomalies, mild intellectual ability and mixed hearing loss. Those findings were greatly matched with our cases with the typical ocular findings, cleft lip and palate. Thereafter, molecular testing was requested for the whole family revealing a novel homozygote mutation in *MASP1* gene in the affected sibs while the parents were heterozygote for the same mutation, confirming our diagnosis. This aided us in giving proper genetic counseling and offering prenatal genetic testing in future pregnancies for the family. .

**1143F**

**Expanding the phenotype of *DST*-related disorder: A case report suggesting a genotype/phenotype correlation.** M. Pinelli<sup>1,2</sup>, G. Cappuccio<sup>1,2</sup>, A. Torella<sup>2,3</sup>, M. Alagia<sup>2</sup>, R. Auricchio<sup>2</sup>, A. Staiano<sup>2</sup>, V. Nigro<sup>2,3</sup>, N. Brunetti-Pierrri<sup>1,2</sup>. 1) Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli, Italy; 2) Department of Translational Medicine, Section of Pediatrics, Federico II University, Naples, Italy; 3) Department of Biochemistry, Biophysics and General Pathology, Università degli Studi della Campania 'Luigi Vanvitelli', Naples, Italy.

The gene *DST* encodes for the large protein BPAG1 involved in hemidesmosomes. Its alternative splicing gives rise to tissue-enriched isoforms in brain, muscle and skin. The few patients described so far with bi-allelic mutations in *DST* gene have either a skin phenotype of epidermolysis bullosa simplex (EBS) or a neurological phenotype. Here, we report a 17-year-old individual presenting with a complex phenotype with both skin and neuronal involvement, in addition to behavioral and gastrointestinal issues, iris heterochromia, cataract, hearing impairment, syringomyelia, osteoporosis, and growth hormone deficiency. Family-trio whole-exome sequencing revealed that she was a compound heterozygous for two variants in the *DST* gene with highly-predicted functional impact: c.3886A>G (p.R1296X) in exon 29 and c.806C>T (p.H269R) in exon 7. Interestingly, exon 7 is included in the neuronal isoform whereas exon 29 is expressed in both skin and neuronal isoforms. This individual herein described is the first case with a mutation affecting an exon expressed in both the neuronal and skin isoforms thus, potentially explaining the more complex and expanded phenotype, that includes several previously unreported findings in patients harboring *DST* mutations. .

### 1144W

**Genomic approaches to investigate children born small for gestational age (SGA) without catch up-growth.** B.L. Freire, T.K. Homma, M. Funari, A. Malaquias, R. Ronjo, G. Vasques, A. Canton, C. Kim, D. Bertola, A. Jorge. University of Sao Paulo, São Paulo, São Paulo, Brazil.

**Background:** Short stature is a complex and heterogeneous disorder influenced by genetic factors. It may be present in non-syndromic or syndromic forms, with a variable clinical spectrum making difficult the clinical diagnosis. **Aim:** We conducted a genomic approach to establish the etiology of growth disorder in children born SGA without catch-up growth. **Methods:** A total of 197 children born SGA were evaluated clinically, laboratory and radiologically by professionals with expertise in dysmorphology. Clinical diagnosis was unable to be obtained in 152 patients. According to the presence/absence of dysmorphic features, developmental delay or intellectual disability they were classified as syndromic (S=65) or non-syndromic (NS=87). We conducted SNP/CGH microarray analyses in 71 patients (S=48/NS=23) and whole exome (n=38)/targeted panel (n=58) sequencing in 96 patients (S=48/NS=48). Identified copy number (CNVs) and single nucleotide (SNVs) variations were classified according to ACMG guidelines. **Results:** Among Non-Syndromic patients, we did not find any pathogenic CNVs, however we identified 9 (19%) pathogenic SNVs using whole exome sequencing/target panel in *IGF1R* (2x), *IHH* (2x), *ACAN*, *NF1*, *NPR2*, *PTPN11*, *LTBP3* genes. Among syndromic group, we found 13 (27%) CNVs and 8 (16.5%) SNVs classified as pathogenic or probably pathogenic, including variants in *COL2A1* (2x), *SRCAP* (2x), *ANKRD11*, *NPR2*, *POC1A*, *BRCA1*. All identified SNVs are extremely rare or absent in public database, were predicted to be deleterious and segregated with the phenotype. The genes involved are associated with rare diseases (i.e. KBG syndrome), or genetic syndromes with high phenotypic variability (i.e. Noonan syndrome), which prevented their clinical recognition. Additionally, we identified novel candidate genes for short stature of prenatal onset: *DGCR8* and *RAB3IP*. The variants identified in these genes are loss-of-function, one of them was identified in homozygous state (*RAB3IP*) and one was a heterozygous de novo mutation (*DGCR8*). All novel candidate genes are involved in critical cellular function pathway and, based on ExAC database, they are intolerant to LoF variation. **Conclusion:** The great heterogeneity of short stature phenotype difficulties the clinical diagnosis of children born SGA. The genomic approaches are effective to establish the etiology of growth impairment of a larger number of previously undiagnosed children born SGA and also identified novel genes involved in this phenotype.

### 1145T

**Genetic diagnosis and clinical characteristic reviews in neonate patients of *KMT2D* gene mutation caused Kabuki syndrome.** B. Wu<sup>1,2</sup>, Y. Su<sup>3</sup>, H. Wang<sup>1</sup>, X. Dong<sup>1</sup>, P. Zhang<sup>1</sup>, W. Zhou<sup>1,2</sup>. 1) Molecular Diagnosis Laboratory of Children's Hospital of Fudan University, Shanghai Key Laboratory of Birth Defects, The Translational Medicine Center of Children Development and Disease of Fudan University, Shanghai 201102, China; 2) Key Laboratory of Neonatal Diseases, Ministry of Health, Shanghai 201102;; 3) Department of Neonatology, People's Hospital of Xinjinag Uygur Autonomous Region ,Urumqi 830001.

**Objective** To investigate the clinical and genetic features of Kabuki syndrome caused by *KMT2D* mutation. Summarize the clinical features in neonate. **Method** Using Whole-Exome Sequencing (WES) and Clinical panel deep sequencing, combined with data analysis pipeline established by molecular diagnostic center of Children's Hospital of Fudan University. We summarized the clinical and molecular features of 8 children with *KMT2D* mutations. Databases including PubMed, CNKI, and VIP were searched to collect literature of KS, which describe the clinical features of neonatal period from April 2012 to April 2017. **Result** Four males and four females were diagnosed in our laboratory. Mutations were located in exon 11, exon14, exon34, exon 39 (3cases), exon 51 and exon 53 respectively. The types of mutations were two stop gained, four missenses and two frameshifts. Mutation of c.C11119T (p.R3707X), c.12697C>T (p.Q4233X), c.16498C>T (p.R5500W) and c.16273G>A (p.E5425K) were reported as pathogenic mutations and had recorded in Human Gene Mutation Database (HGMD). Mutation of c.G4139T (p.C1380F), c.3495delC (p.Pro1165LeufsTer47), c.10881delT (p.Leu3627ArgfsTer31) and c.12560G>A (p.G418E) were novel, which predicted as harmful variants by SIFT, polyphen 2 and MutationTaster software. Seven of them were from new born baby to 4 months infant, all with de novo mutation confirmed with parents data. Only one 8 years female patient with congenital and development delay who have clinical Kabuki syndrome diagnosis. This patient was confirmed carried c.C11119T (p.R3707X) pathogenic mutation by using panel sequencing, and not yet test parent. A total of 18 literatures, involving 32 neonates were included. The most common clinical features are as follow: feeding problem in 18 cases, cardiac dysplasia in 18 cases, special appearance in 17 cases, skeletal dysplasia in 14 cases, hypoglycemia in 10 cases and hypotonia in 9 cases. **Conclusion** The typical clinical features of KS are not shown in the neonatal period. It's need to consider this disease when the newborn has feeding problem, abnormal cardiac morphology, special appearance and other clinical features. Genetic test can help to diagnose earlier in clinical. Early diagnosis can provide accurate information to clinic, may help patients to acquire appropriate treatment and family genetic counseling.

**1146F**

**De novo truncating mutations in X-linked *MED12* are associated with Hardikar syndrome in females.** D. Li<sup>1</sup>, E. Bhoji<sup>1</sup>, M. Harr<sup>1</sup>, J. Ebrahimzadeh<sup>2</sup>, J. Richards-Yutz<sup>2</sup>, A. Ganguly<sup>2</sup>, E. Rand<sup>3</sup>, J. Jaeken<sup>4</sup>, D. Cassiman<sup>5</sup>, P. Chow<sup>6</sup>, A. Hing<sup>7</sup>, S. Vergano<sup>8</sup>, M. Van Dyck<sup>9</sup>, E. Zacka<sup>9,10</sup>, H. Hakonarson<sup>7,9,10</sup>. 1) Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 2) Department of Genetics, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania, USA; 3) Division of Gastroenterology, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 4) Center for Metabolic Diseases, University Hospital Gasthuisberg, Leuven, Belgium; 5) Department of Paediatric Nephrology, University Hospital Gasthuisberg, Leuven, Belgium; 6) Division of Genetics, Seattle Children's Hospital, Seattle, Washington, USA; 7) Division of Craniofacial Medicine, Seattle Children's Hospital, Seattle, Washington, USA; 8) Division of Medical Genetics and Metabolism, Children's Hospital of The King's Daughters, Norfolk, Virginia, USA; 9) Department of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 10) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania, USA.

Hardikar syndrome (MIM 612726) is a multiple congenital anomaly syndrome characterized by hepatic or biliary anomalies, intestinal malrotation, genitourinary abnormalities, orofacial clefts, and pigmentary retinopathy. Hardikar syndrome is an extremely rare disorder of unknown etiology, with only four individuals being all females reported in the literature, suggesting X-linked dominant and lethality in males. Here we performed exome sequencing in two published patients and two additional previously unpublished patients with a clinical diagnosis of Hardikar syndrome, and identified three *de novo* novel nonsense and frameshift indels in *MED12* in three patients with all having cleft palate, congenital heart disease (i.e. ventricular septal defect, aortic coarctation, or patent ductus arteriosus), biliary abnormalities (i.e. cholestasis, dilated bile ducts, or choledochal cyst), renal abnormalities (i.e. hydronephrosis or absent gall bladder), and retinal pigmentation. Hemizygous missense mutations in *MED12* cause the *MED12*-related disorders of FG syndrome, Lujan syndrome, and Ohdo syndrome in males, whereas females carrying heterozygous missense mutations are most often unaffected. The pattern of X-inactivation was analyzed based on the methylation pattern at the androgen receptor locus on all four studied individuals with a clinical diagnosis of Hardikar syndrome, 3 of which harboring the *MED12* loss-of-function (LoF) mutation showed extreme skewed X-inactivation (99:1), suggestive of some genetic heterogeneity. These LoF *MED12* mutations identified in Hardikar syndrome raise suspicion for a male embryonic-lethal mechanism, accounting for the female preponderance of patients affected by this syndrome.

**1147W**

**A novel homozygous mutation in *MMP21* is associated with heterotaxia and cardiac defects.** L. Aspit<sup>1,5</sup>, O. Reish<sup>2,3</sup>, L. Benyamin<sup>2</sup>, V. Sheffield<sup>4</sup>, R. Parvari<sup>1,5</sup>. 1) Microbiology, Immunology and Genetics, Ben Gurion University of the Negev, Beer Sheva, Israel; 2) Genetic Institute, Assaf Harofeh Medical Center, Zerifin, Israel; 3) The Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel; 4) Department of Pediatrics, Division of Medical Genetics, University of Iowa, Iowa City, IA, USA; 5) National Institute of Biotechnology in the Negev, Ben-Gurion University of the Negev, Beer Sheva, Israel.

Introduction: Heterotaxia is a rare congenital autosomal recessive defect in which the major visceral organs are distributed abnormally within the chest and abdomen. The mixed organ orientation found in situs ambiguus often leads to severe complications mainly of the heart and/or lungs. We have characterized a consanguineous Bedouin family from Israel with 2 affected siblings with heterotaxia and complicated heart defects and detected a novel *MMP21* mutation. Materials and Methods: Genotyping of both patients and their parents was performed using Affymetrix microarrays and kinSNP analysis. Regions of homozygosity were identified. Exome sequencing was performed on 1 affected DNA. Results: Exome sequencing revealed 50 potential variations within the homozygous regions. Following bioinformatics predictions, segregation in the family and analysis of prevalence in the Bedouin population, one candidate remained - a homozygous variation in the *MMP21* gene that is involved in the breakdown of extracellular matrix for normal physiological processes, such as embryonic development, reproduction, and tissue remodeling. The variation causes an amino acid change that is predicted to be highly damaging. Conclusions: The novel *MMP21* mutation presented here, reinforce the role of this gene that only recently has been described with association to heterotaxia and is in line with an ENU-induced mutant mice with LR asymmetry and major cardiac defects. Further studies are required to verify whether this gene is a candidate for complicated heart defects without LR asymmetry.

## 1148T

**Exome-first approach identified two novel indels and gene deletions in Mowat-Wilson Syndrome cases previously diagnosed as clinical Angelman syndrome.** F. Gosso<sup>1,3</sup>, C. Rohr<sup>2,3</sup>, B. Brun<sup>2,3</sup>, G. Mejico<sup>1,3</sup>, F. Madeira<sup>1,3</sup>, F. Fay<sup>1,3</sup>, M. Klurfan<sup>4</sup>, M. Vazquez<sup>2,3</sup>. 1) Cibic S.A., Rosario, Santa Fe, Argentina; 2) INDEAR, Rosario, Santa Fe, Argentina; 3) Heritas, Rosario, Santa Fe, Argentina; 4) Casa Angelman, Buenos Aires, Argentina.

**Introduction** Mowat-Wilson Syndrome (MWS) is caused by haploinsufficiency of *ZEB2* (*ZFH1B*) on chromosome 2q22.3<sup>1</sup>. MWS resembles Angelman and other Angelman-like Syndromes (ALS) in that all individuals have moderate-to-severe intellectual disability with minimal speech. Microcephaly, seizures or EEG abnormalities have been observed in up to 90% of affected individuals. According to the Mowat-Wilson Syndrome Foundation, 213 patients worldwide received genetic confirmation so far. Since MWS is misdiagnosed with AS and other ALS during early infancy, it is very important to develop a first-tier single genetic testing that covers all types of genetic mutations including SNVs, INDELS and CNVs to distinguish between them. Whole-exome Sequencing (WES) or clinical-exome Sequencing (CES) was recently proposed as a first-tier clinical diagnostic test in children with intellectual disabilities<sup>2</sup>. We propose WES/CES as differential diagnosis for patients with clinical AS and normal methylation results. **Methods** Whole-exome sequencing (WES) was performed on genomic DNA extracted from venous blood sample from two patients after informed consent was obtained. WES was performed using a mean on-target coverage for both cases of 160X. **Results** Two novel pathogenic mutations were identified in both patients with clinical AS, whom tested normal for 15p11.2-q13 methylation assay. Patient 1: a novel truncating variant was identified (NM\_014795.3:c.2177\_2180delCTTT, NP\_055610.1:p.Ser726TyrfsTer7). Patient 2: a novel pathogenic deletion of 1.79 Mb (chr2:144209542-146007670) this result was also confirmed by comparative genomic hybridization (CGH) array. **Conclusion** WES/CES relevance as first-tier single test has been recently highlighted as differential clinical diagnostic test for a wide range of neurodevelopmental disorders. Using WES in two patients with clinical diagnosis of AS (normal 15p11.2-q13 methylation result) we were able to describe two novel mutations that unequivocally differentiate between MWS, AS caused by a mutations in *UBE3A* gene and ALS. Here we propose the use of WES/CES to diagnose and differentiate MWS from AS caused by SNVs, INDELS and CNVs and from other ALS in newborn/infants and young children with AS suspicion whom tested normal for 15p11.2-q13 methylation test. **References.** <sup>1</sup>Mowat DR *et al.* (1998). *J Med Genet*, 35:617-623. <sup>2</sup>Monroe GR *et al* (2016). *Genet Med*. 18:949-56.

**Homozygous truncating variants in *TMCO1* contribute to a spectrum of craniofacial, skeletal and neurodevelopmental abnormalities.** J. Ji<sup>1,2</sup>, C. Quindipan<sup>1</sup>, G. Raca<sup>1,2</sup>, X. Gai<sup>1,2</sup>, S. Saitta<sup>1,2</sup>, D. Schweitzer<sup>3,4</sup>. 1) Pathology and Laboratory Medicine, Children's Hospital Los Angeles, Los Angeles, CA; 2) Department of Pathology, Keck USC School of Medicine, Los Angeles, CA; 3) Craniofacial and Cleft Center, Division of Plastic and Maxillofacial Surgery, Children's Hospital Los Angeles, Los Angeles, CA; 4) Department of Medical Genetics, Children's Hospital Los Angeles, Los Angeles, CA.

*TMCO1* (transmembrane and coiled-coil domains protein 1) is expressed in multiple tissues and is critical to early fetal development. Pathogenic variants in *TMCO1* were first described in 11 individuals of Old Order Amish ancestry with craniofacial dysmorphism, skeletal anomalies, and intellectual disability. Since then, a few patients of Turkish ancestry have been described. We report 3 individuals from 2 unrelated consanguineous families with homozygous truncating variants in the *TMCO1* gene. Patient 1 is a 7 year-old Kuwaiti female with bilateral cleft lip and palate, facial features consistent with *TMCO1* dysmorphisms, cardiac defect, duplicated thumb and great toe, intellectual disability, brain structural abnormalities, anxiety and phobias. Trio-exome sequencing (Patient 1 and both parents) revealed a homozygous variant in *TMCO1*: NM\_019026.4:c.646\_647del (p.Ala216Profs\*53). Patients 2 and 3 are siblings of Mexican ancestry. Patient 2 is an 8 year old male with bilateral cleft lip and palate, dysmorphic features, profound bilateral sensory neural hearing loss (SNHL), severe pectus carinatum, scoliosis, segmental vertebral anomalies of several vertebral bodies, other skeletal anomalies, single kidney, cryptorchidism, strabismus, pulmonic stenosis, and severe intellectual disability with almost no expressive language currently. His younger brother, Patient 3 is a 17 month-old male with submucous cleft palate, imperforate anus, craniofacial dysmorphism, pectus excavatum, scoliosis, fusion of cervical vertebral bodies with rib anomalies, hydronephrosis, VSD, and motor and language delays. Chromosome microarray analysis showed multiple segments of absence of heterozygosity (total 81 Mb), consistent with consanguinity. Quad-exome sequencing of both brothers and parents showed a homozygous variant: NM\_019026.4:c.616C>T (p.Arg206\*). These cases expand *TMCO1* deficiency beyond the initial ethnic groups reported. Additionally, duplicated digits and periventricular leukomalacia with agenesis of the hippocampal commissure in Patient 1, profound SNHL in Patient 2, and imperforate anus in Patient 3, have not been previously reported in the *TMCO1*-related phenotypic spectrum. To date, only truncating *TMCO1* variants have been reported in association with disease. These mutations are distributed among different regions of the *TMCO1* gene, appear to mediate significant syndromic features and are now shown to be present across multiple ethnic groups worldwide.

## 1150W

**Robinow syndrome in an infant with multiple anomalies due to *DVL3* mutation: A lesson in detailed clues.** B. Keena<sup>1</sup>, C. Murali<sup>1</sup>, P. Liu<sup>2</sup>, E.H. Zackai<sup>1</sup>.

1) Clinical Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Baylor College of Medicine, Houston, TX.

We wish to report a patient with Robinow syndrome due to a *DVL3* mutation and emphasize the findings in an infant. Recent discovery of mutations in the *DVL3* gene resulting in autosomal dominant Robinow syndrome was reported by Janson White et al (Am J Hum Gen 98, 2016). The authors reported 5 patients ranging in age from 14 years to 38 years who were identified with *DVL3* mutations. These 5 patients were part of a total cohort of 34 patients with clinical diagnoses of Robinow syndrome who all were studied for known Robinow genes-*DVL1*, *WNT5A*, and *ROR2* along with *DVL3* which was a candidate gene at that time. We report a case of an infant who died at 3 months of age with multiple anomalies in 2012. The female infant was transferred to our hospital at 1 month of age for management of multiple anomalies-hypoplastic left heart, omphalocele, cleft lip and palate, choanal atresia, club feet, anorectal malformation, hypertelorism, and broad thumbs and great toes. Microarray testing was normal. X-rays showed bifid terminal phalanges in fingers 1 and 2 bilaterally. The baby died at 3 months of age from worsening apnea and cardiac complications without a specific diagnosis being made. Whole exome sequencing was initially performed while this patient was alive and did not identify a molecular etiology for her findings. Upon recent review, a heterozygous *de novo* mutation in *DVL3* (c.1592delC) was reported consistent with a diagnosis of Robinow syndrome which is thought to explain the patient's findings. Robinow syndrome is characterized by frontal bossing, hypertelorism, cleft lip/palate, mesomelia, genital hypoplasia, and distinctive facial features. Omphalocele, heart defects, and broad thumbs and toes have been reported. The finding of bifid terminal phalanges, which is distinctive and rare, has been reported in Robinow syndrome in the older literature (Kelly, T et al. Am J Dis Child, 129, 1975 and Giedion et al. Helf paediat 20, 1975). In retrospect, this could have been a major clue to this diagnosis in the patient's lifetime. This finding can be very useful in a child with multiple anomalies to lead one to a diagnosis.

Frontonasal dysplasias (FND) are rare facial malformations caused by abnormal development of the frontonasal process-derived structures. Several entities have been described, characterized by hypertelorism, median cleft and nasal anomalies. The association with facial skin polyps leads to the diagnosis of Pai, oculoauriculofrontonasal syndromes (PS, OAFNS), encephalocraniocutaneous lipomatosis (ECCL), or Sakoda complex (SC). In this work, we aim to better define the phenotypic spectrum of PS, OAFNS, ECCL and SC, discuss overlapping features and differential diagnosis for these syndromes, and identify the molecular basis of PS. We clinically reviewed 25 individuals referred for a syndromic frontonasal polyp. We performed trio or solo whole exome sequencing (WES) on blood-derived DNA from 10 individuals and whole genome sequencing (WGS) in one individual. Typical or atypical PS was clinically confirmed in respectively 9 (36%) and 2 individuals (8%). OAFNS was diagnosed in 9 individuals (36%). Syndrome overlaps were discussed in 5 patients: 3 (12%) met the criteria for both PS and OAFNS; one (4%) for PS and ECCL; one for PS and SC. We identified 3 *de novo* heterozygous variants in genes from the TGF $\beta$  pathway (*TGFBRAP1*, *PCSK7*) in PS patients, thus 12% of the series, and one inherited *GLI2* variant in a PS-ECCL patient. Based on the phenotypic overlap between these entities, we suggest that OAFNS, ECCL and SC should either be considered as differential diagnosis for Pai syndrome or part of the same spectrum. The identification of molecular bases will be the next step toward a better delineation of these entities.

**Treacher Collins syndrome 1: Extreme manifestations.** C. McDougall, A.R. Barone, N. Khalek, E. Schindewolf, L. Conlin, E.H. Zackai. Children's Hospital of Philadelphia, Philadelphia, PA.

Treacher Collins syndrome (TCS) is the most common and well known mandibulofacial dysostosis caused by mutations in at least 3 genes involved in pre-rRNA transcription (*TCOF1*, *POLR1D*, and *POLR1C*). Here we present a case with extreme findings who, on whole exome sequencing (WES), was found to have a heterozygous pathogenic mutation in *TCOF1* (c.4357\_4360delGAAA;p.Glu1453fs). No association between severity of the TCS phenotype and the location within the *TCOF1* gene has been observed. An infant female was born at 39 weeks gestation to a 25 year old G1P0->1 mother. Facial abnormalities were noted prenatally including cleft lip and palate, bilateral facial clefts, hypertelorism, possible colobomas, and micrognathia. Examination after delivery noted marked hypertelorism, a small right eye, midline cleft lip and palate, severe bilateral facial clefting, incompletely formed maxilla, and retromicrognathia. The patient was intubated and it was unclear if any external ear tissue was present. Extremities were normal. Ophthalmologic examination revealed bilateral chorioretinal colobomas with lack of normal optic nerve tissue as well as small palpebral fissure on the right with phimosis of the eyelids. Echocardiogram found a VSD and PDA. Given the respiratory failure and severity of the infant's anomalies including likely blindness and deafness, family elected comfort care and the infant expired. Microarray and WES were sent, with WES results as above. There have been two other extreme cases in the literature (Bauer et al., 2013. Am J Med Genet; Writzl et al., 2008. Am J Med Genet) who had molecular testing and were each found to have a heterozygous *de novo* pathogenic mutation in *TCOF1* (c.4355\_4356ins14;p.1456Thrfs\*18 and c.4321delG;p.E1441fs, respectively). These variants all fall within a region of *TCOF1* where many insertions and deletions are reported, emphasizing the lack of a genotype-phenotype correlation for this disorder. Several hypotheses were considered to explain the extreme manifestation, including some promoter effect on the gene, some position effect on the gene, a polymorphism elsewhere in the gene, a point mutation elsewhere in the gene, a polymorphism in another gene, or a point mutation in another gene such as *POLR1C* or *POLR1D* (Bauer et al). The fact that this individual had WES and a normal chromosomal microarray has eliminated a rare pathogenic mutation (copy number or SNV) in the other Treacher Collins genes as possible explanations.

**1153W**

**Triple diagnosis by whole exome sequencing.** Z. Yüksel<sup>1</sup>, J. Balazs<sup>1</sup>, M. Calvo<sup>1</sup>, A. Megarbane<sup>2</sup>, O. Brandau<sup>1</sup>, P. Bauer<sup>1,3</sup>, A. Rolfs<sup>1,4</sup>. 1) Centogene AG, Rostock, Germany; 2) Institut Jerome Lejeune, Paris, France; 3) Institute of Medical Genetics and Applied Genomics, University of Tübingen, Tübingen, Germany; 4) Albrecht-Kossel-Institute, University of Rostock, Rostock, Germany.

**Introduction:** Whole exome sequencing (WES) was performed only for the index in order to determine the possible genetic cause of symptoms for a 37-year-old Lebanese patient whose parents are consanguineous (2<sup>nd</sup> degree cousins). The index presented with hydrocephalus, delayed motor and language development, intellectual disability, abnormal gait, macrocephaly (56 cm), microphthalmos, teeth abnormality, early teeth loss, malformation of heart and great vessels, dysmorphic facial features, failure to thrive, short stature, undescended testis and micropenis. **Methods:** WES was performed on Illumina Platform for the index (Nextera Rapid Capture Exome Kit, ~95% of target bases were covered at 10x or higher). All disease-causing variants reported in HGMD®, in ClinVar or in CentoMD® (class 1), as well as all variants with minor allele frequency (MAF) of less than 1% in ExAc database were considered. Evaluation was focused on exons and intron boundaries +/-20 bps. All relevant inheritance patterns were considered and the provided family history and clinical information were used to evaluate eventually identified variants. Only variants related to the phenotype were reported after confirmation by Sanger sequencing. **Results:** Three variants associated with the patient's phenotype were detected. The first variant c.893del, classified as likely pathogenic, was detected in a homozygous state in the *THOC6* gene (NM\_024339.3). The *THOC6* gene is associated with Beaulieu-Boycott-Innes syndrome (OMIM #613680), an autosomal recessive neurodevelopmental disorder characterized by delayed development, moderate intellectual disability, and dysmorphic facial features. The second variant classified as likely pathogenic in the *PTCH2* gene (NM\_003738.4:c.528del) is associated with autosomal dominant Basal cell nevus syndrome (OMIM #109400), a genodermatosis characterized by multiple early-onset basal cell carcinoma (BCC), odontogenic keratocysts and skeletal abnormalities. The third variant classified as pathogenic in the *EDAR* gene (NM\_022336.3:c.486del), is associated with autosomal dominant Ectodermal dysplasia 10A, hypohidrotic/hair/nail type (OMIM #129490). **Conclusion:** Using WES as a diagnostic tool, three different diagnoses have been possibly confirmed for this patient with a complex phenotype.

**1154T**

**Ovotesticular DSD associated with a pathogenic mutation in the BMP15 gene.** S. Albanyan, D. Chitayat. The Hospital for Sick Children, Toronto, ON, Canada.

Ovotesticular disorders of sex development (DSD) are rare disorders of sex development that are characterized by the presence of both well-differentiated ovarian and testicular tissue co-existing in the same individual. A wide spectrum of atypical internal and external genitalia has been reported and the etiology in most cases is not known. We report a patient who presented with DSD including perineal hypospadias, left sided ovotestis with fallopian tube and a hemi uterus and a right sided testes). Chromosome analysis was 46 XX and microarray analysis was normal and female. Whole exome sequencing identified a missense variant in the *BMP15* gene - c.226C>T in a heterozygous state. The bone morphogenetic protein (BMP) family is part of the transforming growth factor-beta superfamily which includes large families of growth and differentiation factors. These proteins are synthesized as prepropeptides, cleaved, and then processed into dimeric proteins. In 1998 Dube et al. identified an additional member of the BMP family, *BMP15*, mapped to Xp11.22. The *BMP15* variants have been previously implicated in premature ovarian failure (POF) and ovarian dysgenesis can be seen as the most severe form of POF. There have been mouse models that revealed that *bmp15* mutants could result from a failure of primary sex determination or from a failure to maintain female sex during the juvenile and/or adult stages and in zebra fish, *Bmp15* was found to have no role in either primary or secondary female sex determination or differentiation. However, the role of *BMP15* in human gonadogenesis and sex development has not been determined. To our best knowledge this is the first reported case of ovotesticular DSD associated with *BMP15* variant pointing to the possibility that it may have a major role in female gonadogenesis with its variant being associated with testicular determination in 46,XX chromosome sex. Our study shows again the importance of whole exome sequencing in identifying the molecular etiology of disorders of sex development.

**A genotype-first approach identifies genes contributing to variable phenotypic presentations in a Smith-Magenis Syndrome cohort.** C. Zhang<sup>1</sup>, C.M.B. Carvalho<sup>1</sup>, C.R. Beck<sup>1</sup>, Z.C. Akdemir<sup>1</sup>, P. Liu<sup>1</sup>, B. Yuan<sup>1</sup>, M. Withers<sup>1</sup>, S.N. Jhangian<sup>2</sup>, D.M. Muzny<sup>2</sup>, R.A. Gibbs<sup>2</sup>, J.R. Lupski<sup>1,2,3,4</sup>. 1) Department of Molecular and Human Genetics, BCM, Houston, TX; 2) Human Genome Sequencing Center, BCM, Houston, TX; 3) Department of Pediatrics, BCM, Houston, TX; 4) Texas Children's Hospital, Houston, TX.

Smith-Magenis syndrome (SMS) is a developmental disorder caused by either a deletion or a pathogenic loss-of-function mutation in the dosage sensitive *Retinoic acid-induced 1 (RAI1)* gene. The majority of patients (~70-80%) with SMS carry a recurrent 3.6 Mb deletion of 17p11.2. The core clinical phenotypes of SMS include global developmental delay, cognitive impairment, craniofacial differences, and skeletal features. Some SMS phenotypes, such as seizures, sensorineural deafness, and scoliosis, affect < 70% of patients. Remarkably, these less frequent phenotypes are usually observed in patients with 17p11.2 deletions rather than *RAI1* variants. Therefore, we hypothesize that deletions unmask recessive mutations (including both common variants and rare variant alleles) in genes mapping proximal to *RAI1*. To test this hypothesis, we performed Whole Exome Sequencing (WES) in 28 patients carrying recurrent SMS deletions. We identified variants in the 53 protein-coding genes in this region based on inheritance models and database annotation; 21 genes were observed to contain variants after filtering. We performed a genotype-first approach by selecting genes with more than two patients presenting hemizygous variants and then evaluated these individuals for shared clinical phenotypes. Our preliminary analyses identified three genes (*FAM83G*, *DRC3* and *MYO15A*) for which a recessive model could potentially explain variable expressivity of certain clinical phenotypes. *FAM83G* functions in noncanonical bone morphogenetic protein signaling. Patients carrying variants in *FAM83G* have both heart and bone development abnormalities. In addition, *FAM83G* targets ASNS, which is an asparagine synthetase. Accumulation of aspartate and glutamate in brain may result in increased excitability and seizure activity, which was found in patients. *DRC3* is a key component of the nexin-dynein regulatory complex, which may be associated with defects in ciliary motility; remarkably, patients with *DRC3* mutation had ophthalmological and hearing deficiencies. *MYO15A* is a well-known deafness gene, and resides in the DFNB3 locus for recessive deafness. Aggregated analysis also showed variants in both *MYO15A* and *DRC3* in two patients (BAB1198 and BAB1361) who share a majority of the clinical phenotypes[CB1]. In summary, our data provide evidence for recessive variants in three genes that may act either individually or together to cause some of the less frequent clinical manifestations in SMS patients.

Chromosome 1q41-q42 deletions have recently been associated with a distinguishable neurodevelopmental disorder in early childhood (OMIM 612530). Features of this deletion syndrome span a small neurodevelopmental spectrum, likely depending on the inclusion or exclusion of specific genes in the 1q41-q42 deletion. Despite this, a predominant phenotype has emerged with core features of developmental delay (DD), intellectual disability (ID), epilepsy and distinct facial features including a depressed nasal bridge, widely-spaced teeth and gingival hyperplasia. In addition, it is also frequently accompanied with CT/MRI brain abnormalities, growth retardation, nail hypoplasia, mixed tone and limb/digit anomalies or contractures. Less frequently, congenital anomalies including diaphragmatic hernias, palate and cardiac defects have been seen. There has been significant interest in mapping the smallest region of overlap (SRO) for this syndrome to identify the pathological gene(s). To date, no definitive gene(s) have been directly attributed to the predominant 1q41-q42 microdeletion syndrome (MDS) phenotype as even the smallest deletions encompass at least 6 genes. Nevertheless recent reports have proposed *DISP1*, *TP53BP2* and particularly *FBXO28* to play roles in pathogenesis through studies of SRO and single gene murine models. Here we present a single-gene, loss-of-function (LoF) event in a 3 year-old female with global DD, ID, seizures, distinct facial features and other traits highly reflective of the overriding 1q41-q42 MDS phenotype. Through whole exome sequencing (WES) of the family trio, we identified a *de novo*, heterozygous *FBXO28* c.972\_973delACinsG (p.Arg325GlufsX3) 2 base-pair event in the female proband. The resulting frameshift and premature stop gain three amino acids downstream has not been reported in any genomic reference database and is the first report of a single-gene LoF event in the 1q41-q42 SRO causing the hallmark features of the syndrome's predominant phenotype. These new findings provide strong foundational evidence supporting *FBXO28*'s role as a novel monogenic neurodevelopmental disease gene and further establishes it as the causative gene contributing to the ID, seizure and dysmorphic phenotype previously proposed in 1q41-q42 MDS. In light of this evidence we suggest the name *FBXO28* Haploinsufficiency Syndrome in describing this predominant phenotype in combination with heterozygous *FBXO28* loss of function.

Amelogenesis imperfecta (AI) is a clinically and genetically heterogeneous group of diseases characterized by defects in enamel formation. A non-consanguineous Costa Rican family with hypoplastic amelogenesis imperfecta was identified, which apparently follows an autosomal recessive pattern of inheritance. Initially, four genes that have been reported to harbor disease-causing variants were excluded by Sanger sequencing: *ENAM*, *KLK4*, *MMP20*, and *WDR72*. As a next step, whole exome sequencing (WES) was performed for one affected individual, one healthy sibling, and their healthy parents in search for variants that segregate with the disease according to autosomal recessive inheritance. No homozygous variants were found in the affected individual. On the other hand, five candidate genes were identified for which the affected individual - but not his healthy sibling - is compound heterozygous, and each parent is heterozygous for one of the variants. Sequencing of these candidate genes in the rest of the family, as well as CNV analysis, are ongoing. It is worth mentioning that after WES, a search for variants in the affected individual was performed for other genes that have been reported to have disease-causing variants for autosomal recessive AI: *FAM20A*, *AMBN*, *ITGB6*, *SLC24A4*, and *C4orf26*. None of these genes had variants that segregated with the disease in the family. However, it was found that the affected individual is heterozygous for a nonsense variant, p.C552X, in *ITGB6*. A second mutation in the gene was not present. For this gene as well, a further analysis in order to detect a possible CNV at the second allele is ongoing.

Congenital diaphragmatic hernia (CDH) is one of the most common and often lethal birth defects, characterized by the incomplete formation of the diaphragm. CDH can occur as an isolated defect or in association with additional anomalies. Previous genetic studies of CDH using exome sequencing (WES) support a significant enrichment of coding *de novo* variants in a large number of risk genes, especially in complex cases. To further investigate the genetic architecture of CDH, we performed WES in 196 case-parents trios and whole genome sequencing (WGS) in 195 trios (28 with both WES and WGS), including 133 complex and 230 isolated cases. We observed a significant overall enrichment of likely-gene-disrupting (LGD) (enrichment=1.7, p-value=3e-4) and missense (enrichment=1.3, p-value=1e-5) *de novo* variants. In total, LGD and missense *de novo* variants explain about 25% of both complex and isolated CDH cases, which is larger than previous estimates from a smaller cohort and older sequencing approaches. Interestingly, isolated and complex cases have distinct patterns of LGD and missense variants burden. LGD burden in complex cases are all carried by genes highly expressed in developing diaphragm (mouse E11.5 pleuroperitoneal fold), but in isolated cases, the burden is spread across genes with a broader range of expression in the developing diaphragm. In complex cases, deleterious missense (d-mis, as predicted by CADD or metaSVM) burden is mostly located in haploinsufficient genes ("HIS", defined by ExAC pLI), whereas in isolated cases, d-mis variants in non-haploinsufficient (non-HIS) genes explain about twice as many cases as d-mis in HIS genes. This suggests that isolated CDH cases are more likely to be caused by mutations in non-HIS genes that are dominant negative or oligogenic compared to complex cases. We identified 4 LGD or d-mis *de novo* variants in *MYRF*, a significant association (p-value=2e-10) based on comparison with background mutation rate. *MYRF* is a transcription factor intolerant of mutations (ExAC pLI=1) and highly expressed in developing diaphragm and heart. We observed 2 genes with 2 LGD or d-mis variants: *TUBGCP6* and *WT1*. Finally, 6 genes carrying *de novo* LGD or d-mis variants are involved in post-transcriptional regulation through 3'UTR. In WGS data, we observed a moderate enrichment of noncoding *de novo* variants in 3'UTR regions of genes highly expressed in developing diaphragm, supporting a novel role of 3'UTR dysregulation in CDH.

1159W

**Clinical and molecular phenotypes of Coffin-Siris syndrome among UAE population.** F. Al Ali, M. Khalifa, F. Bastaki. Dubai Health Authority, Dubai, United Arab Emirates.

Coffin-Siris syndrome (CSS) is a genetically heterogeneous intellectual disability/dysmorphic features syndrome. So far 8 genes have been associated with CSS; *AIRD1B* is most prevalent with no obvious phenotype/genotype correlation. Since its first description in 1970, a significant number of additional and different findings have been reported expanding the phenotype from the "unusual facies, absent fifth finger- and toenails, and mental deficiency" original prototype. CSS is inherited in an autosomal dominant fashion, and all are *de Novo* with one exception of a mother child inheritance. Whole exome sequencing screening of Emirati children with DD/intellectual disability identified 8 patients; 5 males and 3 females in 6 families with CSS. Attached table shows the clinical and molecular characteristics of these patients. *AIRD1B* variants still is the most prevalent present in 5 patients followed by *AIRD1A* in 2 and *SMARCB1* in 1. All variants were novel and *de novo* 2/8 patients have nails changes, one of them had the characteristic feature of CSS. 6/8 have 'classical/type A' facial features; that include bushy eyebrows, broad nose, broad nasal tip, thick and fleshy lip. Cognitive and developmental delay existed in all cases. Several previously unreported findings as hepatomegaly (3/8), optic atrophy (1/8), transient neonatal hypocalcemia (1/8), and un-ossified fibroma (1/8) were seen among these patients. In addition, these families have the only reported gonal mosaicism associated with CSS where three affected siblings born to unaffected parents..

**Twelve novel *GUSB* mutations and genotype-phenotype correlation in mucopolysaccharidosis VII (MPS VII) patients.** Q. Abu Ali<sup>1</sup>, W. Song<sup>1</sup>, S. Daugherty<sup>1</sup>, A. Schatz<sup>1</sup>, H. Lau<sup>2</sup>, C. Dias da Costa<sup>3</sup>, T. Levade<sup>4</sup>, G. Touati<sup>5</sup>, D. Marsden<sup>1</sup>, C. Haller<sup>1</sup>. 1) Ultragenyx Pharmaceutical Inc., Novato, CA; 2) New York University Lagone Medical Center, New York, NY; 3) Centro Hospitalar Lisboa Norte EPE, Lisbon, Portugal; 4) Institut Fédératif de Biologie, CHU Toulouse, France; 5) Hôpital des Enfants, CHU Toulouse, France.

MPS VII is a clinically heterogeneous, ultra-rare, autosomal recessive lysosomal disease in which patients are deficient in beta-glucuronidase enzyme (GUS). Nearly fifty unique MPS VII-causing mutations in *GUSB* gene have been reported. In this study, we present twelve novel *GUSB* mutations and provide potential genotype-phenotype correlation. Twenty-three MPS VII patients were enrolled in early access programs and clinical studies investigating recombinant human GUS, vestronidase alfa (UX003), as a potential enzyme replacement therapy (ERT). *GUSB* testing results were available on 74% of patients (17/23). 65% (11/17) were male, 35% (6/17) female; 35% (6/17) were Hispanic, 29% (5/17) Caucasian, 18% (3/17) Asian, and 6% (1/17) each for African American, native Brazilian and unknown ethnicity. 65% of patients (11/17) were unrelated, in addition to three sets of non-twin siblings. All tested patients harbored at least two mutations. Overall, twenty different *GUSB* mutations were identified, all being missense. 60% (12/20) were novel mutations (c.1A>G, p.G97A, p.E141A, p.H142Y, p.W288L, p.N379S, p.M430T, p.S485F, p.V496L, p.G512R, p.W587S, p.I608M). 59% of patients (10/17), including two of three sibling pairs, were heterozygous for at least one novel mutation, and 30% of these patients (3/10) were compound heterozygous for two novel mutations. 82% of patients (14/17) harbored at least one previously published mutation. To assess potential genotype-phenotype correlation, an individual clinical assessment of disease severity at baseline was done, considering dysmorphic, clinical, diagnostic and functional assessments including walking ability and patient reported outcomes. All patients (4/4) heterozygous for these novel mutations: c.1A>G, p.G512R, p.W288L, p.S485F, p.V496L, p.W587S and p.I608M exhibited an overall severe phenotype. All patients (4/4) heterozygous for these novel mutations: p.M430T, p.G97A, p.E141A and p.H142Y exhibited an overall mild phenotype. One sibling pair harbored p.N379S novel mutation, and overall phenotype was mild for one sibling but severe for the other. Our results add twelve novel *GUSB* mutations to previously reported genotype data, and provide further evidence that genetic heterogeneity could contribute to MPS VII clinical heterogeneity. Genotype-phenotype correlation will benefit from future studies aimed at understanding possible role of various genotypes in potential response to investigational ERT in MPS VII patients.

**1161F**

**Clinical exome data analysis and novel variant identification for MPS VII disease in *GUSB* gene.** A. Bhattacharjee<sup>1</sup>, P. Ranganath<sup>2</sup>, A. Dalal<sup>1</sup>. 1) The Centre for DNA Fingerprinting and Diagnostics (CDFD), Hyderabad, India; 2) Nizam's Institute of Medical Sciences, Hyderabad, Telangana, India.

The deficiency of  $\beta$ -glucuronidase enzyme due to mutations in *GUSB* gene (OMIM#611499), leads to Mucopolysaccharidosis Type VII (MPS VII) (OMIM#253220), which is an autosomal recessive lysosomal storage disease characterized by highly variable phenotype, ranging from severe lethal hydrops fetalis to mild forms with survival into adulthood. At least 55 mutations in the *GUSB* gene have been found to cause MPS VII of which most are single nucleotide changes which reduce or eliminate the function of  $\beta$ -glucuronidase. We report a case of 26 years old female, at 18 weeks of pregnancy with nonimmune fetal hydrops. This was the second conceptus of a third degree consanguineous couple with a previous history of a female fetus terminated at 20 weeks with fetal hydrops. Enzyme analysis in amniotic fluid culture showed  $\beta$ -glucuronidase level of 0 nmol/hr/mg (Control – 84, normal: 75 – 650 nmol/hr/mg) suggestive of MPS VII. All other investigations including fetal karyotype, MLPA for  $\alpha$  – thalassemia and TORCH profile were normal. *GUSB* has large number of pseudogenes and hence molecular analysis by Sanger sequencing is very difficult. DNA sample was extracted from the amniotic fluid (AF) with the consent of the patient and the whole exome sequencing of the DNA was performed using Illumina HiSeq platform. Raw data was analysed using BWA-GATK pipeline and reads were aligned to the human reference genome GRCh37/hg19 to generate the variant call file (VCF) in the downstream analysis. Annotation was done using Annovar. A homozygous missense mutation in exon 5 of the *GUSB* gene (NM\_000181:c.893C>T; Depth: 48X) that results in amino acid change from Alanine to Valine at the 298<sup>th</sup> position (p.Ala298Val) was identified. This variant has not been reported as a normal variant in public databases like 1000 Genomes, Exome Variant Server (EVS), Exome Aggregation Consortium (ExAC), dbSNP, ClinVar and HGMD. *In-silico* pathogenicity prediction programs like Combined Annotation Dependent Depletion (CADD phred score 24.8) and Mutation taster predicted it to be disease causing and is assumed to be the cause of MPS VII in this fetus. This report signifies the importance of next generation sequencing technologies for analysis of patients with diseases with pseudogenes where Sanger sequencing is difficult.

**Mutations in the condensin II component NCAPG2 cause autosomal recessive neurodevelopmental syndrome.** T.N. Khan<sup>1</sup>, K. Khan<sup>1</sup>, H. Reynolds<sup>1,2</sup>, A. Sadeghpour<sup>1</sup>, M.T. McDonald<sup>3</sup>, R.N. Goldberg<sup>3</sup>, W.B. Gallentine<sup>3</sup>, N. Katsanis<sup>1</sup>, E.E. Davis<sup>1</sup>, Task Force for Neonatal Genomics. 1) Duke Center for Human Disease Modeling, Duke University, Durham, NC 27701; 2) Furman University, Greenville, SC 29613; 3) Department of Pediatrics, Duke University, Durham, NC 27710.

Neurodevelopmental disorders (NDDs) are clinically and genetically heterogeneous, and the number of known NDD-associated genes is rapidly expanding with the application of whole-exome sequencing in patients. Here we report on two unrelated pediatric cases presenting with overlapping central nervous system, ocular, renal and digit abnormalities. Both individuals had non-diagnostic chromosomal microarray results; female DM516 was array negative, and female DM074 harbored a maternally-inherited heterozygous *NPHP1* deletion. We performed trio-based whole exome sequencing in both families and, after variant filtration, we identified rare missense variants in *NCAPG2* segregating with disease in an autosomal recessive pattern of inheritance. *NCAPG2* plays an important role in chromosomal condensation and segregation during cell division. To investigate the functional relevance of *NCAPG2* to NDDs and the pathogenicity of missense variants identified in patients, we conducted morpholino-based suppression of this gene's sole zebrafish ortholog. The morphant zebrafish displayed patient-relevant phenotypes such as microcephaly and renal anomalies. These abnormalities were rescued by co-injecting the morpholino with wild type human *NCAPG2* mRNA, demonstrating morpholino specificity. Coinjection of morpholino with *NCAPG2* mRNA harboring the patients' specific missense variants did not rescue the head size and renal anomalies as efficiently as wild type *NCAPG2* mRNA, suggesting loss of function of *NCAPG2* as a plausible disease mechanism. Additionally, CRISPR-Cas9 editing of *ncapg2* in zebrafish recapitulated the microcephaly and renal anomalies. We also observed increases in apoptosis and in cell proliferation, as well as gross structural abnormalities of the central nervous system in *ncapg2* zebrafish morphants and CRISPR F0 mutants supporting further a role for *ncapg2* in clinical phenotype. Finally, we tested whether sensitization at the *NPHP1* locus, the most common contributor of juvenile nephronophthisis, could explain a more severe renal phenotype in DM074. *In vivo* co-suppression of *nphp1* and *ncapg2* in zebrafish resulted in significantly more dysplastic renal tubules in comparison to either gene model alone. Together, our genetic findings and subsequent functional modeling in zebrafish suggest that loss of function of *NCAPG2* results in a neurodevelopmental syndrome and highlight how multi-gene interactions can exacerbate endophenotypes in rare syndromes.

## 1163T

**Frequency of germline pathogenic variation in *NF1* and eight other RASopathy genes in the Exome Aggregation Consortium (ExAC) database: A pilot study.** A. Pemov, K. Jung, D.R. Stewart. NIH/NCI, Bethesda, MD.

ExAC is the largest public database of human variation, comprising high-quality variant calls across 60,706 human exomes. Importantly, the curators of the database "have made every effort to exclude individuals with severe pediatric diseases from the ExAC data set," which makes the database a valuable resource for studying variation in Mendelian disease genes in unaffected populations. The RASopathies are a group of inherited disorders caused by mutations in predominantly RAS-MAP kinase pathway genes. We downloaded all coding, non-synonymous germline variants in nine genes: *NF1*, *HRAS*, *KRAS*, *NRAS*, *BRAF*, *RAF1*, *SPRED1*, *MAP2K1* and *MAP2K2* from the database (excluding 7,601 The Cancer Genome Atlas (TCGA) samples). There were 1,188 mutations in the nine genes (range: 36 (*NRAS*) to 498 (*NF1*), of which almost half were found only once in the dataset and 76% had frequency below 0.01%. We then analyzed the variants using InterVar (ACMG/AMP 2015 guideline) method and phenotype-genotype databases to predict the pathogenicity of the variants. As expected, the majority of the variants were classified as "benign," "likely benign," and "variants with unknown significance." We also compared the ExAC variants with the variation annotated in the Human Gene Mutation Database (HGMD). In the nine genes, we found 60 variants present in both HGMD and non-TCGA ExAC. Forty-one variants were found in *NF1* alone, of which nine were loss-of-function or canonical splice-site mutations. After excluding variants for which the evidence of pathogenicity was less convincing (labeled "DM?" in HGMD), there were 28 disease-causing mutations in *NF1*. Assuming that there was one *NF1* mutation per individual, this observation implies that in ExAC the frequency of *NF1* variants associated with neurofibromatosis type 1, is  $28 / (60,706_{\text{Total}} - 7,601_{\text{TCGA}}) = 0.00053$  ( $\sim 1/1,900$ ), which is within the range of published *NF1* prevalence in the general population. There were eight "pathogenic" or "likely pathogenic" mutations in four genes (*H-*, *K-*, *NRAS* and *BRAF*), all of them were rare, with frequencies ranging  $8.2 \times 10^{-6}$  –  $2.5 \times 10^{-5}$ . **Conclusions:** In this pilot study of a large exome database, we found that prevalence of pathogenic variation in *NF1*, *BRAF*, *H-*, *K-* and *NRAS* is close to published estimates. Future work focuses on phenotype spectrum and penetrance of *NF1* and other RASopathies in large, exome-sequenced populations linked to an electronic medical record.

**Enhancement of hepatic autophagy increases ureagenesis and protects against hyperammonemia in a mouse model of ornithine transcarbamylase deficiency and other models of secondary hyperammonemia.**

*L. Soria<sup>1</sup>, G. Allegri<sup>2</sup>, D. Melck<sup>3</sup>, N. Pastore<sup>4</sup>, P. Annunziata<sup>1</sup>, D. Paris<sup>3</sup>, E. Polishchuk<sup>1</sup>, E. Nusco<sup>1</sup>, B. Thöny<sup>2</sup>, A. Motta<sup>3</sup>, J. Häberle<sup>2</sup>, A. Ballabio<sup>1,4,5</sup>, N. Brunetti-Pierri<sup>1,5</sup>.* 1) Telethon Institute of Genetics and Medicine, Pozzuoli, Naples, Italy; 2) Division of Metabolism, University Children's Hospital Zurich and Children's Research Center, Zurich, Switzerland; 3) Institute of Biomolecular Chemistry, National Research Council, Pozzuoli, Italy; 4) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA; 5) Department of Translational Medicine, Federico II University, Naples, Italy.

Ureagenesis is the main pathway for waste nitrogen removal in mammals. Ammonia crosses the blood-brain barrier and is neurotoxic at high concentration. Systemic ammonia is elevated in patients with inherited or acquired impairments of ammonia detoxification, such as urea cycle disorders, organic acidemias, or acute and chronic liver diseases. Regardless from its etiology, hyperammonemia may result in irreversible brain damage if not treated early and thoroughly. Current treatments are often inadequate. In this study, we show that hepatic autophagy is triggered in an mTOR-dependent manner by hyperammonemia and deficiency of autophagy impairs ammonia handling. Rapamycin is a drug already used in humans that is known to activate autophagy. Rapamycin reduced blood ammonia in C57BL/6 wild-type mice fed with ammonia enriched diet. Moreover, rapamycin treatment of abnormal skin and hair (*spf<sup>ash</sup>*) mice that have markedly reduced ornithine transcarbamylase (OTC) activity increased <sup>15</sup>N-labeled urea enrichment and normalized orotic acid concentration in whole blood/dried blood spots. In conclusion, these data show that autophagy is an important mechanism for ammonia detoxification and its enhancement has potential for therapy of both primary and secondary causes of hyperammonemia.

**1165W**

**Search for the mutation causing the ThoracoAbdominal Syndrome (TAS), an X-linked dominant disorder.** *P. Majdalani<sup>1,2</sup>, R. Parvari<sup>1,2</sup>.* 1) The Shraga Segal Department of Microbiology, Immunology & Genetics; Faculty of Health Sciences (A.B.), Ben-Gurion University of the Negev, Beer-Sheva, Israel; 2) National Institute of Biotechnology in the Negev, Ben-Gurion University of the Negev, Beer Sheva, Israel.

**Introduction:** The Thoracoabdominal Syndrome (TAS) is a very rare congenital X-linked dominant disorder presented only in one Jewish North African family. The features of the syndrome are ventral herniae (midline abdominal wall defect), antero-lateral diaphragmatic herniae (manifested almost exclusively in affected males), hypoplastic lung, and associated cardiac anomalies. The aim of this study is to identify and characterize the mutation causing TAS. **Materials and Methods:** The initial search for the mutation causing the syndrome was done by linkage analysis on the X chromosome using 27 individuals of the TAS family. Genome sequencing of two of the family members was performed on the identified TAS interval on chromosome X. **Results:** The TAS interval was localized to Chr:Xq27.1 in an interval of 1.06 Mb. Three genes and two miRNA are encoded in the interval. No mutation causing variants were identified in these sequences. Large deletions, insertions and translocations were negated by the sequence. Therefore, further search for indel variants in the non-coding DNA was pursued. Variations presenting in more than 1 person in the population databases and in Short Tandem Repeats (STR) regions were excluded, leaving 4 variations that are further characterized for the possibility of causing the TAS phenotype. **Conclusion:** Further analysis using the Chromosome Conformation Capture-on-Chip (4C-seq) technology will be held on the mutation causing variant for determining long-range chromatin interactions and the gene that may be affected.

**1166T**

Weaver syndrome (WS; MIM# 277590) is a rare congenital overgrowth disorder characterized by pre/postnatal overgrowth, accelerated osseous maturation, characteristic craniofacial features, intellectual disability, limb anomalies and susceptibility to cancer. To date, germline heterozygous mutations in *EZH2* (enhancer of zeste homolog 2; NM\_004456.4) and *EED* (embryonic ectoderm development; NM\_003797.3) have been reported in WS. *EZH2* and *EED* are core components of the polycomb repressive complex 2 (PRC2), which play a role in regulating epigenetic gene repression by catalyzing trimethylation of lysine 27 of histone H3 (H3K27me3). Here, we analyzed three probands with clinically suspected WS using whole-exome sequencing and identified three mutations: a 25.4-kb deletion partially involving *EZH2* and *CUL1*, a missense mutation (c.707G>C, p.Arg236Thr) in *EED* and a missense mutation (c.1829A>T, p.Glu610Val) in *SUZ12* (suppressor of zeste 12 homolog; NM\_015355.2) inherited from her father with a mosaic mutation. *SUZ12* is another component of PRC2, but germline mutations in *SUZ12* have never been reported in humans. To investigate the functional effects of the *EED* and *SUZ12* missense mutations, we performed rescue experiments to evaluate the H3K27me3 levels using the Tet-on system for 293 T-REx cells. Our results showed that the *EED* or *SUZ12* mutants failed to rescue and produced only similarly low levels of H3K27me3 as the mock transfections. These data indicate that loss-of-function mutations of PRC2 components are an important cause of WS. Interestingly, *SUZ12* at 17q11.2 is mapped approximately 560 kb downstream of *NF1*, whose mutations cause neurofibromatosis type 1 (NF1; MIM# 162200). 5-10% of NF1 patients exhibit 1.2–1.4 Mb microdeletions encompassing *NF1* and *SUZ12*. The clinical phenotypes of patients with the microdeletion are significantly different from those with *NF1* point mutations: overgrowth, learning disabilities and WS-like features (macrocephaly, prominent forehead, hypertelorism long philtrum, micrognathia, and large ears) have been often described in *NF1* microdeletion patients. Therefore, *SUZ12* deletions may possibly contribute to the unique phenotypes in *NF1* microdeletion.

**1167F**

**Functional analysis of a novel *TUBA1A* gene mutation associated with cerebral dysgenesis and cleft palate.** *R. Peretz<sup>1</sup>, S. Chung<sup>1</sup>, A. Derrick<sup>1</sup>, M. Rees<sup>1</sup>, R. Stratton<sup>2</sup>, C. Wang<sup>3</sup>.* 1) Department of Pediatrics, Driscoll Children's Hospital, Corpus Christi, TX; 2) Department of Medical Genetics, Driscoll Children's Hospital, Corpus Christi, TX; 3) Department of Neurology, Driscoll Children's Hospital, Corpus Christi, TX; 4) Neurology and Molecular Neuroscience Research, Institute of Life Science, Swansea University Medical School, South Wales, UK.

Tubulinopathies are a group of autosomal dominant brain malformations due to structural defects in microtubules caused by mutations in genes encoding tubulin subunits. Characteristic features of tubulinopathies include cortical dysgenesis - such as lissencephaly, pachygyria, and polymicrogyria - and malformations of the corpus callosum and basal ganglia. We report a newborn with severe lissencephaly, polymicrogyria, agenesis of the corpus callosum and cerebellum, and a unique extra-cranial manifestation of cleft palate. Genetic screening with a lissencephaly gene panel revealed a novel heterozygous missense mutation in the *alpha-tubulin 1A* (*TUBA1A*) gene: c.1169G>C, p.Arg-390Pro (R390P). This single amino acid substitution of a positively charged arginine with a neutrally-charged proline strongly suggests reconfiguration of the protein structure at this locus. Thus, we conducted FLAG-tagged site-directed mutagenesis of the wild-type *TUBA1A* construct to create a *TUBA1A* p.Arg-390Pro construct. Immunocytochemistry in HEK cells, in vitro polymerization assays, and protein expression studies were utilized to analyze the functional consequences of this novel mutation on alpha-tubulin. This study expands the clinical phenotypes of tubulinopathies and provides insight into the function of the protein domain spanning amino acid Arg390 of alpha-tubulin.

**1168W**

**A prospective study of natural history, physiology, and biochemistry of propionic acidemia.** O.A. Shchelochkov, J. Sloan, S. Ferry, C. Van Ryzin, J. Gagne, I. Manoli, C.P. Venditti. NHGRI/NIH, Bethesda, MD.

Propionic acidemia (PA) has a heterogeneous spectrum of laboratory abnormalities and multiorgan pathology. To define the genetic, laboratory, and clinical variables in PA, we initiated a prospective study of the natural history, physiology, microbiome and biochemistry of PA (ClinicalTrials.gov Identifier: NCT02890342). During protocol visits, patients receive clinical, nutritional, imaging, and laboratory evaluations, with biospecimen collection and banking. Since fall 2016, we have evaluated 8 PA patients, ages 3 – 52 years (4 females). Molecular confirmation was made in 7/8 (4 had mutations in *PCCA* and 3 in *PCCB*). Three patients had short stature ( $z$ -score  $\leq 2$ ), 3 patients were overweight or obese, one patient was underweight. On EKG, 4 patients had non-specific repolarization abnormalities and 2 patients had a QTcB interval greater than the age- and sex-specific cutoff. All had a normal ejection fraction (range 54-65%). Cystatin C-based glomerular filtration rate ranged from 43 to 103 mL/min/1.73 m<sup>2</sup>. In 5/6 patients, dual-energy X-ray absorptiometry showed bone density  $z$ -score  $\leq 2$ . Hearing loss was present in 4/8 patients. Eye evaluation revealed normal retina in all and subtle optic pallor in 2/8 patients. Epilepsy was reported in 3/8 patients. Four patients completed brain MRI revealing cerebral atrophy and non-specific T2 signals in white matter. Neurocognitive studies showed IQ in the normal range in 1/6 patients and moderate to severe intellectual disability in 5/6. Five of 8 patients were diagnosed with autism spectrum disorder. Six of 8 patients received medical foods and 4/8 had a G-tube. One patient underwent a liver transplant for metabolic instability and one received a kidney transplant for end-stage renal disease. To non-invasively assess the whole-body activity of propionyl-CoA carboxylase, we measured 1-<sup>13</sup>C-propionate oxidation in 7 patients. Patients with a clinically severe form of PA had depressed oxidation (7.04±3.38 % of dose metabolized), while two clinically milder patients were more variable (15.7% and 40.5%) compared to controls (47.7±4.5%). Thus, increased 1-<sup>13</sup>C-propionate oxidation rate appeared to correlate with a milder clinical course. In summary, our initial experience highlights that all PA patients are at risk for developing multi-organ involvement warranting prospective clinical surveillance and management, and identifies clinical and metabolic domains that could be useful to predict the course and assess new therapies.

**SOPH syndrome: Multisystem disorder with facial dysmorphism, skeletal dysplasia, episodic liver failure, immune dysfunction and intellectual disability.** A. Yadav, R.J. Hopkin, E.K. Schorry. Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

SOPH syndrome is an AR condition with skeletal dysplasia, brachydactyly, Pelger-Huet anomaly and episodic liver failure triggered by fever due to biallelic *NBAS* mutations. The *NBAS* protein (NAG) is a subunit in the syntaxin-18 complex implicated in ER/Golgi transport. Missense mutations in *NBAS* result in decreased protein product and render syntaxin-18 complex thermolabile. Hence, febrile illnesses may cause disordered ER/Golgi transport. Our proband presented at 16 years during her 4th episode of acute liver failure associated with acute renal failure. She had three prior episodes of liver failure. She was born at 26 weeks to a non-consanguineous Caucasian couple. She had intellectual disability (IQ 72). She had a triangular face, prominent forehead, pointed chin, long fingers, prominent PIP joints and short stature ( $Z$ -score -3). Skeletal survey showed long phalanges, thin long bones, anterior subluxation at C2-C3, right thoracic curvature, gracile ribs and narrow upper chest. NK cell function was decreased. Interestingly, IgG was low and normalized later while IgA was low during recovery. She was followed for failure to thrive & precocious puberty. She had hypothyroidism, insulin resistance and PCOS. Novel compound heterozygous missense mutations in the *NBAS* were found by whole exome sequencing. SOPH syndrome was first described by Maksimova et al (2010) in an isolated Yakut population. Clinical features in 33 patients included short stature, facial dysmorphism, senile appearance, brachydactyly, optic atrophy and Pelger-Huet anomaly. Homozygosity mapping found homozygous missense mutations in *NBAS*. Biallelic mutations in *NBAS* were found causative in infantile onset recurrent acute liver failure in a separate cohort of 11 German individuals by Haack et al (2015). Affected individuals had episodes of acute liver failure triggered by fever, with interval recovery of liver function. They did not have any features of SOPH syndrome. Soon after, Segarra et al reported two patients with biallelic *NBAS* mutations and multisystem disease that included progeroid appearance, recurrent acute liver failure, immune dysfunction, hypogammaglobulinemia, skeletal dysplasia with C1-C2 instability. Our case supports the theory that SOPH syndrome and recurrent episodes of liver failure may be part of the same spectrum and can coexist in some patients. In addition, she has unique features that raise questions for further functional studies of this fascinating condition.

**The genetic architecture of Bardet Biedl Syndrome.** *M. Kousi<sup>1</sup>, A. Ozan-turk<sup>1</sup>, S. Frangakis<sup>1</sup>, J. Muller<sup>2,3</sup>, A. Sadeghpour<sup>1</sup>, R.A. Lewis<sup>4,5</sup>, H. Dollfus<sup>2</sup>, E.E. Davis<sup>1</sup>, N. Katsanis<sup>1</sup>.* 1) Center for Human Disease Modeling, Duke University School of Medicine, Durham, NC; 2) Laboratoire de Génétique Médicale, Institut de Génétique Médicale d'Alsace, INSERM U1112, Université de Strasbourg, Fédération de Médecine Translationnelle de Strasbourg (FMTS), Strasbourg, France; 3) Laboratoire de Diagnostic Génétique, Hôpitaux Universitaires de Strasbourg, Strasbourg, France; 4) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas, USA; 5) Department of Ophthalmology, Baylor College of Medicine, Houston, Texas, USA.

The importance of genetic background on driver mutations is well established. However, understanding how such background interacts with Mendelian loci remains challenging. Bardet-Biedl syndrome (BBS) has been a useful model to study such phenomena. Mutations in >20 genes are necessary for pathogenesis, while numerous BBS patients have also been reported who, in addition to recessive drivers, bear *bona fide* pathogenic alleles in other BBS genes. Here, through sequencing and array analysis, we detected all rare alleles impacting the coding regions 17 BBS genes in two cohorts of BBS patients (201 families). We stratify the distribution of recessive mutations and report a new candidate BBS locus, *CEP76*. Further, we show that in a cohort of 74 families with diagnosed recessive alleles, there is significant enrichment of rare alleles (excluding diagnostic recessive variants) compared to controls (n= 380), with > 40% of BBS patients carrying 1-4 additional rare variants in BBS genes. This observation persisted when we restricted our analysis to likely pathogenic variants; was replicated in a second cohort of 101 recessive families; and enabled the generation of a mutational distribution network for BBS across 175 families. Importantly, this enrichment was restricted to BBS genes. We found no differences in an equivalent-sized set of genes mutated in primary ciliary dyskinesia, nor did we see signal when considering other functional particles in the ciliary apparatus. Taken together, our data inform the mutational architecture of BBS and intimate specificity in the network, where the effect of *trans* variation is enriched in BBS genes, but not the overall ciliary proteome. We propose that such architecture is unlikely to be unique to BBS and that focused analysis of first-order interactors in other pleiotropic genetic disorders will potentially reveal similar enrichment and distribution.

**1171W**

**Clinical and genetic characteristics of seven patients with Floating-Harbor syndrome.** *P. Castro<sup>1</sup>, R. Honjo<sup>1</sup>, G. Lopes<sup>1</sup>, L. Albano<sup>1</sup>, S. Sugayama<sup>1</sup>, D. Bertola<sup>1</sup>, T. Homma<sup>2</sup>, B. Freire<sup>2</sup>, A. Jorge<sup>2</sup>, C. Kim<sup>1</sup>.* 1) Genetics Clinic Unit, Child Institute, University of São Paulo School of Medicine, São Paulo, Brazil; 2) Developmental Endocrinology Unit (LIM/42), University of São Paulo School of Medicine, São Paulo, Brazil.

The Floating-Harbor syndrome (FHS) is a rare condition, with only about 50 confirmed individuals to date. It is characterized by a particular gestalt, with typical facial dysmorphisms, short stature with delayed bone age and speech delay. Our study included seven patients assisted at the Genetics and Endocrinology Services in Hospital das Clínicas, São Paulo - Brazil, between 1992 and 2017, with clinical and molecular diagnosis of FHS. Analysis of the clinical characteristics of the patients was carried out by a systematic survey of their medical records. The seven patients were 2 females and 5 males, with current ages ranging from 5-29 years old (mean 14.5y). All of them had proportionate short stature (mean SD: -3.14) and delayed bone age greater than 2SD. Six had characteristic facies, with triangular face, deep eyes, thin lips and wide mouth. The typical nose, narrow at the root and broad at the tip, with low-hanging columella and smooth philtrum was observed in five patients, though all of them had a somehow prominent nose. Intellectual disability and language delay were also universal findings ranging from severe cognitive impairment to isolated speech delay. Only three patients presented seizures. Motor development was normal in five patients and only slightly delayed in the remaining two. Microcephaly was reported in four patients. Recurrent ear infections, another common trait associated to FHS, was reported in only three patients. Hirsutism was present in three patients. Other structural anomalies, such as heart defects and cleft lip/palate were observed in isolated patients. Molecular testing revealed known pathogenic variants in *SRCAP* in all, except one case, which presented a novel variant. All mutations were located in exon 34, three in c.7330C>T and three in c.7303C>T, which lead to premature stop codons: p.Arg2444\* and p.Arg2435\*. These mutations were already reported in literature. The last patient had a novel mutation, a *de novo* 1-bp duplication at nucleotide 7262 causing a frameshift predicted to result in a premature termination codon (p.R2421fs). Overall, the clinical characteristics of our patients were similar to those previously reported cases. (SUPPORT: CNPQ).

**An integrated clinical program and crowdsourcing strategy for genomic sequencing and Mendelian disease-gene discovery.** A. Haghighi<sup>1,2,3,4,5</sup>, C. Cassa<sup>2,4</sup>, D. Vuzman<sup>2,4</sup>, A. Toth-Petrozy<sup>2</sup>, C. MacRae<sup>3</sup>, C. Seidman<sup>1,3,4</sup>, S. Sunyaev<sup>2,4</sup>, R. Maas<sup>2</sup>, J. Krier<sup>2</sup>, *Brigham Genomic Medicine*. 1) Department of Genetics, Harvard Medical School, Boston, MA; 2) Division of Genetics, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 3) Division of Cardiovascular Medicine, Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 4) Broad Institutes of Harvard and MIT, Cambridge, MA; 5) Partners HealthCare Laboratory for Molecular Medicine, Cambridge, MA.

Mendelian gene discovery is not only potentially beneficial to individuals with these rare disorders, but it also provides insight into more common forms of similar disease phenotypes. Here, we describe an integrated clinical program using whole exome and whole genome sequencing (WES/WGS) for Mendelian disease gene discovery as well as cutting edge science in genome analytics (including genome and exome sequencing) and biological models (mouse and zebrafish mutants, and human iPSCs) to: (1) discover the genetic cause of undiagnosed monogenic diseases, and (2) strategize improved or novel treatment for patients. This program includes specific case ascertainment parameters to select cases not solved by conventional clinical sequencing, a WES/WGS computational analysis pipeline that is optimized for Mendelian gene discovery with callers tuned to specific inheritance modes, an interdisciplinary crowdsourcing strategy for genomic sequence analysis, matchmaking for additional cases, and integration of the clinical findings regarding gene causality with the clinical management plan. Clinicians and research scientists review the clinical and genomic findings and to contribute to discussion about each open case, channeling the clinical and scientific expertise that resides within the local and extended biomedical communities into solving these challenging genetic cases. This efficient platform has promoted education and engagement of faculty and fellows throughout our affiliated academic medical centers and has served as a genomic sequencing re-analysis core for the Harvard Undiagnosed Disease Network clinical site and the NIDCR FaceBase Consortium. Examples of (published) BGM high impact discoveries of disease-associated genes (with different inheritance modes; i.e., autosomal dominant and recessive, X-linked and de novo mutations), include PIEZO2 (where we identified that gain-of-function missense mutations cause a subtype of distal arthrogyria, a musculo-skeletal contracture and respiratory disease), LOX (in which mutations cause familial aortic dissection), WISP3 (in precocious arthritis) and CHST11 (in T cell lymphoma with limb abnormalities). This integrated monogenic disease gene discovery model could be readily adopted by other academic medical centers, and effectively leverages existing clinical and research expertise in the task of diagnosing and treating these debilitating conditions.

**1173F**

**Insights from applying ClinGen framework in evaluating the clinical validity of 30 published studies of gene-disease relationship of monogenic disorders.** R. Attali, O. Farchy, A. Rafaeli, S. Tzur. Genomic Research Department, Emedgene Technologies, Tel Aviv, Israel.

The Clinical Genome Resource (ClinGen) has recently developed a framework for evaluating the clinical validity of gene-disease relationship in monogenic disorders. Using this semi-quantitative measurement framework, a scientist can evaluate the relevant genetic and experimental evidence for supporting a certain gene-disease relationship, and to calculate the strength of evidence based on qualitative classifications: "Definitive", "Strong", "Moderate", "Limited", "No Reported Evidence", or "Conflicting Evidence". In an attempt to assay this framework, we evaluated 30 studies (in journals with impact factor greater than 5) that described new gene-disease connections. The aim of our work was twofold: to evaluate the usability of the ClinGen framework and to estimate its power when applied to a single first gene-disease article. Overall, we confirm the usability and the importance of this framework approach in clinical validation of new gene-disease connections. The evaluation process is well detailed and accurate and therefore can be used as a powerful source for gene-disease validity assessment by multiple users. Potential drawbacks are the frequent inconsistencies between curators that will often require ClinGen expert decision, and the technical calculation of the segregation Lod-score for non-experts. Interestingly, in our review 40% of the evaluated articles were scored with "Strong" strength of evidences, whereas 42% were "moderate", and only 18% with "Limited" strength. This tends to show the high standards demanded by most editors and peer-reviewers. The generalized use of this framework will indescribably benefit scientists in building their research evidence, and it can also be used as a standard evaluation in peer reviewed journals for submitters and publishers. Particularly this framework could help defining a strict threshold for the recognition of a new gene-disease connection in databases such as OMIM.

## 1174W

**Evaluating the evidence available for associating genes of unknown significance (GUS) with disease phenotypes: Review of 100 studies.** S. Tzur, N. Mizrahi, E. Feldman, R. Attali. emedgene, Tel Aviv, Israel.

A large portion of unresolved exome-analysis cases in rare disease research are explained by mutations in genes of unknown significance (GUS). While various types of evidence are available for most human genes (biochemical function, protein interaction, expression, animal model, pathways, and gene family), it is unclear how often these can be used as indirect supportive data for the establishment of a new gene-disease relationship. We reviewed 100 recent publications from journals with an impact factor greater than 5 that described the discovery of new genes causing monogenic diseases. We listed the types of evidence that were available for each gene prior to the publication, and evaluated whether they could be used as indirect supporting evidence for connecting the GUS with disease phenotypes (i.e. a shared pathway with another gene causing disease, or an animal knockout model resulted with similar phenotype). We found that in 90% of the studies, biochemical function data was available for the gene under investigation. Most interestingly, in 73% of these cases the data could be used as supportive indirect evidence for the new gene-disease suggested relationship. Additional categories were also examined: Pathways (80% availability, in 76% as supportive), animal model (75% availability, in 76% as supportive), gene family (54% availability, in 50% as supportive), protein interactions (45% availability, in 70% as supportive). On average for each case, 4.3 different types of evidence were available, 2 were supportive for establishing the new gene-disease connection. This study quantifies for the first time how prior available evidence can contribute to the identification of new gene-disease association. These data demonstrate how basic scientific evidence is highly required to establish a gene-disease relationship, and pinpoints the importance of availability of basic molecular research data as well as knockout animal projects. The implementation of these insights in rare disease research protocols would improve the ability to obtain evidence needed for a new gene-disease relationship.

**Oral cavity findings in A2ML1-related otitis media.** R.L.P. Santos-Cortez<sup>1,2,3</sup>, M. Steritz<sup>1</sup>, J.P. Magno<sup>4</sup>, M. Pedro<sup>3</sup>, S.M. Lagrana-Villagracia<sup>3</sup>, T.K.L. Yarza<sup>3,4</sup>, M.L.C. Tantoco<sup>3,4</sup>, A.L. Chan<sup>3,4</sup>, M.R.T. Reyes-Quintos<sup>3,4,5</sup>, E.G.dV. Llanes<sup>3,4</sup>, A.T.R. Santos<sup>6</sup>, R.A.P. Santos<sup>6</sup>, R.A.Q. Rosanes<sup>7</sup>, C.M. Chiong<sup>3,4,5</sup>.

1) Department of Otolaryngology, University of Colorado School of Medicine, Aurora, CO; 2) Center for Children's Surgery, Colorado Children's Hospital, Aurora, CO; 3) Philippine National Ear Institute, University of the Philippines Manila - National Institutes of Health; 4) Philippine General Hospital, Manila, Philippines; 5) Newborn Hearing Screening Reference Center, University of the Philippines Manila - National Institutes of Health; 6) Nordhoff Craniofacial Center, Manila, Philippines; 7) College of Dentistry, University of the Philippines Manila.

Otitis media is the top reason for health care visits and antibiotic use among children. Previously the *A2ML1* variant c.2478\_2485dupGGCTAAAT (p.Ser-829Trpfs\*9) was identified to confer increased susceptibility (odds ratio 3.7) to early-onset otitis media of various types (chronic, acute, effusive, healed) in an indigenous Filipino population with a 50% otitis media prevalence. This variant is absent in public variant databases and in Filipino controls. The *A2ML1* gene encodes alpha-2-macroglobulin-like protein, which is highly similar to serine protease inhibitor alpha-2-macroglobulin. In *A2ML1* variant carriers with chronic otitis media, middle ears have increased relative abundance of *Fusobacterium*. In the head and neck, *F. nucleatum* is a common pathogen for gingivitis and periodontitis and has clonal similarity in nasopharynx and saliva. *F. nucleatum* produces serine protease fusolisin and its growth is inhibited by protease inhibitors. We hypothesize that the oral cavity is a potential source of pathogens for the middle ear. The oral cavities of 52 indigenous Filipinos were screened for dental caries, gum bleeding, gingivitis and periodontitis. Salivary DNA samples were Sanger-sequenced for the *A2ML1* variant. Gingivitis increases risk for otitis media (odds ratio 6.4, 95%CI: 1.3, 42.5,  $p=0.009$ ). There is no direct relation between the *A2ML1* variant and oral cavity status. However by multivariate regression analysis, both the *A2ML1* variant ( $p=0.02$ ) and gingivitis ( $p=0.002$ ) increase risk for otitis media. Age and sex were not significant in the regression model. Our dental screening suggests that the oral cavity is a potential source of middle ear pathogens, likely using the nasopharynx as the main route of spread. The lack of protease inhibition due to the *A2ML1* variant is hypothesized to alter the activity of bacteria which rely on serine proteases for growth. RT-PCR showed that the shorter *A2ML1* isoform is expressed in salivary gland. This study will also describe salivary RNA expression according to *A2ML1* genotype.

**Deep phenotyping for patients by patients: A lay-friendly version of the Human Phenotype Ontology.** M.A. Haendel<sup>1,7</sup>, N. Vasilevsky<sup>1</sup>, M.E. Engelstad<sup>1</sup>, E.D. Foster<sup>2</sup>, T. Groza<sup>2</sup>, J. McMurry<sup>1</sup>, C.J. Mungall<sup>6</sup>, C. Brownstein<sup>5,7</sup>, I. Holm<sup>3,7</sup>, C. Boerkoef<sup>2</sup>, K. Rageth<sup>2</sup>, M. Moore<sup>2</sup>, P. Robinson<sup>2</sup>, S. Köhler<sup>1</sup>. 1) Medical Informatics and Clinical Epidemiology, Oregon Health & Science University, Portland, OR; 2) Sanford Health Imagenetics, Sioux Falls, SD; 3) Jackson Laboratory of Genomic Medicine, CT; 4) Charite Hospital, Berlin, Germany; 5) Boston Children's Hospital, Boston, MA; 6) Lawrence Berkeley National Laboratory, Berkeley, CA; 7) Undiagnosed Disease Network; 8) Garvan Institute, Sydney, Australia; 9) Indiana University School of Medicine, Indianapolis, IN.

The Human Phenotype Ontology (HPO) has become the de facto standard representation of clinical "deep phenotype" data for computational comparison of abnormalities and for use in genetic disease diagnostics. The HPO enables non-exact matching of sets of phenotypic features (phenotype profile) against known diseases, other patients, and model organisms, and algorithms for inclusion of phenotype profiles. The algorithms based on HPO have been implemented into many variant prioritization tools and are used by the 100,000 Genomes project, the NIH Undiagnosed Diseases Program/Network, and thousands of other clinics, labs, tools, and databases. Patients themselves are an eager and untapped source of accurate information about symptoms and phenotypes - some of which may go unnoticed by the clinician. However, medical terminology is often perplexing to patients, making it difficult to use resources like the HPO. Since patient self-phenotyping is a critical complement to deep phenotyping performed by clinicians, we have created a 'layperson' translation of the HPO. We systematically reviewed all 12,000+ terms in the HPO and added layperson synonyms with approximately 60% being translatable into layperson terminology. We evaluated the quality of the lay-HPO to ensure lay profiles could be effectively used by variant prioritization tools such as Exomiser. Preliminary analyses suggest that the lay-HPO has the features required to be useful in a diagnostic setting, in that lay terms are: a) sufficiently specific and, b) well-represented in our disease-to-phenotype database that is utilized by the aforementioned tools for differential diagnostics. This patient friendly version of the HPO uses the same infrastructure as the primary HPO, so patient-generated phenotyping data can readily be combined with clinical phenotyping data to improve variant prioritization. New patient-centered tools are being developed to help patients to assist clinicians in creating robust computational phenotype profiles to improve molecular diagnostic rates and be active participants in their diagnostic odysseys. Finally, such tools can also assist in creation of patient generated phenotypic profiles for sharing in patient registries, forums, and on the Web for cohort definitions and community formation.

**1177W**

**Sporadic, isolated Fanconi syndrome due to a mutation of EHHADH.** E.G. Seaby<sup>1,2</sup>, D. Bunyan<sup>3</sup>, R.D. Gilbert<sup>2</sup>, S. Ennis<sup>1</sup>. 1) Genomic Informatics, University Hospital Southampton, Southampton, United Kingdom; 2) Southampton Childrens Hospital, University Hospital Southampton, United Kingdom; 3) Wessex Regional Genetics Laboratory, Salisbury, UK.

**Background:** Hereditary Fanconi syndrome has been described a handful of times in the literature, displaying variable Mendelian patterns of inheritance. Some cases segregate as autosomal dominant and may or may not be associated with renal failure, whilst other kindreds show recessive and X-linked recessive inheritance. In 2001, Lichter-Konecki et al identified the locus (chromosome 15q15.3) in a kindred with autosomal dominant Fanconi syndrome. In 2014, Klootwijk et al found a causal mutation in *EHHADH*, a gene involved in peroxisomal beta oxidation resulting in dominant Fanconi syndrome with preserved renal function in a black family. **Case Diagnosis/Treatment:** We applied whole exome sequencing technology to a Caucasian boy presenting with sporadic, idiopathic Fanconi syndrome. We identified a *de novo* mutation in *EHHADH*, the same variant as previously described by Klootwijk et al. This mutation has been observed to cause the protein encoded by *EHHADH* to mislocalise to the mitochondria, where it interferes with mitochondrial beta oxidation, the primary source of energy in renal proximal tubular cells. Aberrant mitochondrial beta oxidation starves the renal tubule cells of energy required to maintain electrochemical gradients, essential for solute reabsorption. **Conclusion:** Our finding describes the first Caucasian patient with a *de novo* mutation in *EHHADH* causing isolated Fanconi syndrome.

**1178T****A combinatorial approach for the selection of novel bioactive peptides.**

R.R. Handley, S.N. Lawrence, K. Ly, K. Lehnert, R.G. Snell. School of Biological Sciences, University of Auckland, Auckland, New Zealand.

The rapid discovery of rare mutations is revealing an enormous number of drug targets. As a result there is a requirement for almost bespoke molecular tools for understanding the pathophysiology of these conditions and ultimately also bespoke therapies. Our aim is to develop an inexpensive method for generating and screening novel bioactive compounds, using combinatorial randomised sequence generation by degenerate primer PCR amplification. The goal is that the approach will be applicable in any molecular genetics laboratory with particular disease expertise. As proof of concept we developed and tested this method in a modified toxin/antitoxin plasmid cloning system, where the plasmid contains a type II bacterial toxin 'cell death control' sequence *ccdB*, immediately downstream of its *ccdA* antitoxin sequence. To generate a diverse library for screening, PCR with degenerate primers was used to synthesise random DNA sequences in *ccdA*, with products subsequently incorporated as part of the antitoxin sequence of the plasmid. Sequence analyses revealed massive diversity of the libraries as expected. Functionality of modified toxin/antitoxin peptides was tested using a simple live/dead screen of transformed *E.coli*. Small scale sequencing of 16 selected colonies which grew revealed 8 clones containing novel *ccdA* modifications that may have enabled antitoxin function to be maintained. Large scale sequencing of further positive clones is underway. Overall, initial testing indicates that this simple, combinatorial method can generate very complex libraries and may function as an effective source for target specific, bioactive compounds. We are now in the process of identifying peptides that inactivate huntingtin (*HTT*) toxicity in *E.coli* and which may be useful for investigating Huntington's disease.

**1179F****Mouse models of human disease: How mouse model data can provide mechanistic insight into human disease etiology and development of therapeutics.**

M. Tomczuk, J.T. Eppig, C.L. Smith, the Mouse Genome Informatics Staff and Software Team. Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, ME.

Model organisms greatly aid in understanding the cause and development of human disease. Mice provide an excellent system for investigating rare disorders in which patient data may be lacking, for understanding congenital diseases as the mouse embryo is easily manipulated, and for designing and evaluating targeted therapies. The Mouse Genome Informatics (MGI, [www.informatics.jax.org](http://www.informatics.jax.org)) resource integrates mouse phenotype data from multiple sources such as published research, large scale mouse mutagenesis projects, the International Mouse Phenotyping Consortium's (IMPC) genome-wide phenotypic pipeline, and the newly added embryonic lethal data from Deciphering the Mechanisms of Developmental Disorders (DMDD) consortium, to facilitate links between known mouse phenotypes and human disease symptoms. Congenital diaphragmatic hernia (CDH) is a condition that affects 1:3,000 births and results in 30-50% mortality and abnormal embryogenesis. Only two human genes, *GATA4* and *ZFPM2*, are so far implicated in CDH and causes are largely unknown. We will show how MGI can be utilized to gain a deeper understanding of the pathogenesis of this defect by studying available mouse models and using these models to identify possible new candidate genes. A search for 'diaphragmatic hernia' displays all genetic mouse mutants with this phenotype. The results indicate 52 mutant alleles in 38 different genes that show this defect. The new Disease Ontology (DO) Browser, a standardized human disease vocabulary, with links to MesH, OMIM, and Orphanet, shows that 18 mutant alleles in 11 genes are reported to model CDH. Searching by extra phenotypes specific to signs observed in patients can help to identify genes responsible for different aspects of the condition. Links to specific alleles provide molecular descriptions about the mutation and genotypes associated with detailed descriptions of the mutant phenotypes. Embryonic abnormalities of these mutants can be analyzed to better understand how CDH develops in humans. Based on the most relevant phenotypic similarities between patient symptoms and phenotypes in mutant mice, a list of possible candidate genes can be generated. Detailed pages for each gene provide comprehensive information about the gene of interest, including biochemical function and process, sub-cellular localization, expression data, gene interactions, polymorphism, and gene homology that can aid in understanding disease pathology and guide discovery of therapeutics.

**1180W****Challenges in translating pharmacogenetic variants from Illumina's****Multi-ethnic Genotyping array into clinical practice.** *N. Rafaels<sup>1</sup>, K.**Crooks<sup>1,2</sup>, T. Phang<sup>1</sup>, T. Brunetti<sup>1</sup>, C.R. Gignoux<sup>1,3</sup>, Y.M. Lee<sup>1,4</sup>, A. Monte<sup>1,5</sup>, C.L.**Aquilante<sup>1,4,6</sup>, R.A. Mathias<sup>1,7</sup>, K.C. Barnes<sup>1</sup>.* 1) Colorado Center for Personal-

alized Medicine, School of Medicine, University of Colorado, Aurora, CO; 2)

Department of Pathology, School of Medicine, University of Colorado, Aurora,

CO; 3) Department of Biostatistics and Informatics, Colorado School of Public

Health, University of Colorado Anschutz Medical Campus, Aurora, CO; 4)

Skaggs School of Pharmacy and Pharmaceutical Sciences, Department of

Pharmaceutical Sciences, University of Colorado, Aurora, CO; 5) Department

ment of Clinical Pharmacy, University of Colorado, Aurora, CO; 7) Johns Hop-

kins Asthma and Allergy Center, School of Medicine, Johns Hopkins University.

The incorporation of pharmacogenetics into the clinical setting is becoming increasingly feasible with the availability of more affordable genetic sequencing technologies; however, many challenges still remain for clinical implementation. The Colorado Center for Personalized Medicine is using Illumina's Multi-Ethnic Genotyping Array (MEGA-Ex) with up to 300,000 variants of custom content to meet this challenge. Scraping databases from the Clinical Pharmacogenetics Implementation Consortium (CPIC) and PharmGKB, the base chip contains 2,778 of 3,274 (84.9%) of known pharmacogenetic variants, yet only 98 of 334 (29.3%) of known, clinically actionable, CPIC Level A variants. (The more recently released Illumina Global Screening Array contains 2,472 (75.5%) and 81 (24.3%) of known pharmacogenetics variants and CPIC Level A variants, respectively.) Work still needs to be done in public databases to trace 85 of 496 missing known pharmacogenetic variants and 5 of 236 missing CPIC Level A variants to rsID and base pair position. In addition, validation of HLA, copy number variant (CNV) and compound heterozygote calling, as well as design of indels, remain challenges (e.g., although 150 of 157 known *CYP2D6* variants can be identified, 21 variants are indels, 107 of 153 \* alleles contain multiple SNPs, and 15 \* alleles require CNV calling). Current GWAS array technology cannot provide all solutions for clinical pharmacogenetics implementation; however, with the ability to add custom content, it can provide an affordable solution to capture up to 444 of 479 (92.7%) of all CPIC Level A \* alleles.

**1181T****The ET-HPN highlights a potential ALS-related disease cluster.** *B.E.*

The identification of genes related to human phenotypes is important to understanding disease pathophysiology, but for complex disease this can be a difficult endeavor. We previously developed the ET-HPN, a method of filtering Human Phenotype networks based on the differential distribution of disease between populations and three-way comparisons of the possibly associated allele frequencies. Here we investigated Type 2 diabetes mellitus (T2DM) as an index disease, using ET to filter the HPN. Our sample populations were YRI, GIH and CEU, based on T2DM global prevalences. Our resulting network contained several T2DM related phenotypes, including Glucose and Glycosylated Hemoglobin A (HbA1c). Unexpectedly, we uncovered a link between Glucose, HbA1c and Amyotrophic Lateral Sclerosis (ALS). We confirmed, by a literature search, that T2DM is inversely related to ALS, but the underlying mechanism is unknown. However, our network results identified a series of common genes, and we found that T2DM is less common in the ALS population, with a better ALS prognosis and later onset in the presence of T2DM. In our present study, we also used a proteomic, pathway based analysis, with a focus on ALS in context of T2DM. We narrowed the genes examined to those shared by ALS and Glucose or HbA1c. Our examination uncovered three genes associated with KEGG pathways. *GRIN2B* is in the Huntington's (HD), ALS and Alzheimer's (AD) disease pathways. *NDUFA4* is in the AD, HD and Parkinson's (PD) pathways. *RYR3* is in the AD pathway. We also examined molecular, cellular and biological function of the gene products as defined by Gene Ontology and found a Neuron cell-cell adhesion function involving *CNTN4*, *NCAM2* and *NRXN3*. This cluster of T2DM, ALS, AD, PD and HD is very interesting, as T2DM is associated with HD, AD and PD, in addition to the aforementioned inverse relationship to ALS. Also, ALS and HD seem to occur together more than by chance. ALS shares disease features with HD, AD and PD as well as common GWAS hits. Dementia is rare in ALS, but ALS is more severe when dementia is present. All of this together suggests that these five conditions form a disease comorbidity cluster based on pleiotropic gene action. Some links were already known, but not this particular cluster. This study shows that the ET-HPN is a powerful tool for the rapid identification of links and comorbidity of disease and possibly predictive of novel disease clusters.

**1182F****The system biology concept applied to a secondary analysis of Body**

**Mass Index Genome Wide Association Study (BMI GWAS) data.** *E. Cirillo<sup>1</sup>, K. Watanabe<sup>2</sup>, M. Adriaens<sup>3</sup>, L. Parnell<sup>4</sup>, S. Coort<sup>1</sup>, C. Evelo<sup>1,3</sup>.* 1) Department of Bioinformatics – BiGCaT, Maastricht University, Maastricht, The Netherlands; 2) Department of Complex Trait Genetics, VU University Amsterdam, Amsterdam, The Netherlands; 3) Maastricht Centre for Systems Biology (MaCSBio), Maastricht University, Maastricht, The Netherlands; 4) Agricultural Research Service, USDA, Jean Mayer-USDA Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA.

The interpretation of GWAS results is crucial to understand the influence of SNPs in diseases. For instance, identifying genetic loci affected by actionable SNPs can guide functional genomics experimentation and drug target testing. Retrieving and combining the information available to describe the SNPs functionality and then place it in the larger context of a biological process, is a current challenge. Currently, many tools arrange different types of annotation related to variants, genes and pathways, but no single tool exists that provides all the diverse types of information simultaneously. Moreover, the output of multiple tools need to be harmonized and interpreted by the researchers. We present a secondary analysis of BMI GWAS results using several types of data, with the scope to combine different levels of complexity based on SNPs, genes and pathways information, towards the understanding of the obese condition. We performed FUMA to define 77 genomic risk loci containing 10,367 SNPs which are in Linkage Disequilibrium to one of the independent significant SNPs at  $r^2$  0.6. All the SNPs were mapped to genes, if they were closer than 10kb regardless of ANNOVAR annotation. We obtained 182 genes related to 89 coding SNPs, and 10,279 non-coding SNPs. This gene set was analyzed using pathway enrichment analysis and network analysis using the WikiPathways collection. The pathway role was evaluated in relation to both the effect of the coding variants on the genes that they present, and in the context of obesity with the literature support. In addition, all the non-coding variants were described using four online tools (FUMA, HaploREG, rVarBase and GWAVA) from which we considered only the epigenetics information related to chromatin state, histone modification and transcription factor binding sites. This output was then combined with eQTLs analysis based on GTEx data related to: adipose tissue, pancreas, liver, skeletal muscle, brain and thyroid. The preliminary results related to pathway, showed processes such as: energy metabolism and brain functionality that are in line with the pathophysiology of the obesity. However, further analysis is currently underway to elucidate which genes per tissue are regulated by the non-coding SNPs. Those genes will allow the identification of tissue specific pathways. With these results we aim to present an overview of tissue specific processes in which genes affected by BMI GWAS variants can influence the obesity condition.

**1183W**

**Causal gene prediction from type 2 diabetes susceptibility loci through integration of genetic association and functional annotation data.** J. Fernandez-Tajes<sup>1</sup>, J. Torres<sup>1</sup>, M. van de Bunt<sup>1,2</sup>, S. Thomsen<sup>3</sup>, W. Rayner<sup>3,4</sup>, M. Thurner<sup>5</sup>, K. Lage<sup>6</sup>, K. Gaulton<sup>1,7</sup>, M. McCarthy<sup>1,3</sup>, *DIAGRAM consortium, the T2D-GENES consortium, the GoT2D consortium.* 1) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, Oxfordshire, United Kingdom; 2) Global Research Informatics, Novo Nordisk A/S, Måløv, Denmark; 3) Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, United Kingdom, Hinxton, United Kingdom; 4) Department of Human Genetics, Wellcome Trust Sanger Institute, Wellcome Genome Campus; 5) Broad Institute of MIT and Harvard, Cambridge, MA, USA; 6) Department of Surgery, Massachusetts General Hospital, Boston, MA, US; 7) Department of Genetics, Stanford University, Stanford, CA, USA.

GWAS studies have identified ~100 loci influencing type 2 diabetes (T2D) risk. However, as most associated variants are non-coding, the genes through which causal variants act are mostly unknown. We aimed to identify the genes through which these risk variants act and protein interaction networks (PPI) in which these genes reside through integration of large-scale genetic and genomic annotation data. We developed a scheme to assign causal 'candidacy' scores to genes and applied it to all 1,511 genes within 500kb of 93 known T2D signals. This scheme integrated data from (a) fine-mapped localization of causal variants using Bayesian credible sets, (b) regulatory annotations from ENCODE and T2D-relevant tissues (eg pancreatic islets, adipose), (c) annotations linking regulatory elements to target genes (eg *cis* eQTLs), (d) coding variant T2D associations from exome sequence and array data and (e) biological annotations of gene function. We then normalized the resulting scores across all genes at each locus by partitioning the posterior probability of candidacy. This approach generated high candidacy scores for many established causal genes (eg *SLC30A8*, *MTNR1B*), and highlighted novel candidates (eg *NKX6-3* at *ANK1* locus). We then used these scores as seeds to build a PPI network, by solving an instance of a rooted weighted price-collecting Steiner tree problem, where the roots were the genes in a 500kb window region from the loci described in Wood et al (2017) and associated to both acute and peak insulin response. This approach allowed us to guide the network modeling to a likely islet-function specific network. The resulting network was significantly enriched for T2D association in DIAGRAM imputed to 1000 Genomes (Scott et al. 2017) (PASCAL, Fisher  $p=5 \times 10^{-8}$ ) after excluding GWAS genes from the enrichment. The most important steiner nodes (proteins that connect GWAS loci genes) in terms of both network connectivity and link to "causal" genes, were *YWHAG*, *SMAD4* and *EP300*, all with independent molecular evidence for a role in T2D. The top significant GO processes enriched in this T2D-specific network included endocrine pancreas development, glucose homeostasis, positive regulation of autophagy, and regulation of insulin secretion. These results suggest a high degree of functional inter-connectivity among causal genes influencing T2D. They provide a resource for experimental validation of causal gene targets at established loci and discovery of novel risk genes.

**1184T**

**LabWAS: A catalog of real-world associations between genetic variants and lab values.** J.A. Goldstein, L.A. Bastarache, P. Speltz, A. Gifford, D.M. Roden, J.C. Denny. Vanderbilt University Medical Center, Nashville, TN.

Laboratory testing underlies much of modern medicine. Genome-wide association studies (GWAS) on individual lab tests have been used to understand the biology of diseases in which those labs are abnormal. Using 24600 Caucasian adults with genotyping and linked electronic health record (EHR), including labs, we performed GWAS for 110 common lab tests. We summarized multiple measures based on the mean, median, first, minimum or maximum lab values. We also tested whether the patient ever had an abnormal high or low value. We compared our findings to previously reported associations. We replicated 354 of 462 testable associations (77%) previously identified in the GWAS catalog at  $p < 0.05$ . We replicated 60% of associations previously reported a single time, which increased to 100% when associations were previously reported at least 5 times. Probability of replication was also related to prior published P-value. We also identified 1216 putative novel associations for 61 labs at  $p < 5 \times 10^{-8}$ . For example, rs34856868 in *BTBD8*, previously associated with Crohn's disease, was associated with a 72 cell/uL increase in monocyte count ( $p = 3.6 \times 10^{-13}$ ). The largest number of new associations were identified using labs that have few previous significant findings from GWAS, such as eosinophil counts and oxygen saturation. We also identified variants associated with well-studied labs, such as blood glucose. Many of these blood glucose-associated variants were in genes in the HLA region known to be associated with Type I Diabetes Mellitus (T1D), including *BTNL2*, *HLA-DQA1*, and *HLA-DQB1*. The novelty of these associations likely reflects exclusion of patients with disease (such as T1D) from prior studies. We then tested whether SNPs associated with lab values were also associated with disease using phenome-wide association studies (PheWAS). We identified 329 lab:SNP:disease associations. Some, such as those noted above between glucose, HLA SNPs, and T1D were expected. Others, such as the association between basophil counts, rs35534614 in *CACNA1S*, and lower gastrointestinal congenital anomalies are surprising and may point to new disease biology. In a real-world cohort, we showed a high degree of replication of known associations and report novel SNPs associations with lab results. Some of these novel findings may occur exclusively in the context of disease. We are developing a public repository of all results at <http://www.phewascatalog.org/labwas>.

**1185F****Genome-wide prediction of susceptibility loci for complex diseases based on regulatory data.**

*T. Yang, S. Dong, Y. Guo, S. Yao, Y. Chen, M. He, X. Chen, J. Chen.* School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, Shaanxi, China.

Abstract Genome-wide association studies (GWASs) is an effective strategy to identify susceptibility loci for human complex diseases. However, missing heritability is still a big problem. Most GWASs SNPs are located in non-coding regions, Encyclopedia of DNA Elements (ENCODE) and Roadmap Epigenomics projects have provided rich resources in interpreting their biological functions. In this study, we developed a pipeline to identify novel susceptibility loci for complex diseases based on the interpretation of the functional features for known disease-associated variants with machine learning. We applied our pipeline to predict novel susceptibility SNPs for type 2 diabetes (T2D). The predicted SNPs could explain heritability beyond that explained by GWAS-associated SNPs. Functional annotation by expression quantitative trait loci (eQTL) analyses showed that the target genes of the predicted SNPs were significantly enriched in T2D related pathways. Our results suggest that combining previous GWASs results and regulatory data could identify additional functional susceptibility SNPs for complex diseases. We hope our pipeline could help to identify novel susceptibility loci for complex diseases and solve the missing heritability problem.

**1186W****The Type 2 Diabetes Knowledge Portal: Clearing a path from genetic associations to disease biology.**

*B. Alexander, M. Costanzo, M. DUBY, C. Gilbert, T. Green, M. von Grotthaus, R. Koesterer, P. Singh, K. Yuksel, J. Flannick.* Medical Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA.

Genetic research on type 2 diabetes (T2D) and complex traits in general has reached an inflection point where the central challenge has shifted from discovering new loci to understanding disease biology. However, major barriers separate the statistical experts who analyze genetics data and the biologists who might profitably learn from them. Here, we demonstrate the value of a new data sharing initiative, the T2D Knowledge Portal (T2DKP) produced by the Accelerating Medicines Partnership in T2D, for breaking down these barriers. The T2DKP draws from a harmonized database of 39 million variants, 48 traits, and 11 million epigenetic annotations and provides a freely available website (<http://type2diabetesgenetics.org>). This resource provides a wide variety of interactive tools, including custom association analysis with dynamic sample filtering, covariate specification, and conditional analysis, while enabling sophisticated analytics of sensitive genetic data and ensuring patient privacy. Using this framework, known results that previously took consortium-level coordination can be identified in seconds. A search of the MTNR1B gene displays an integrated table of all variants associated across all traits, notably fasting glucose and T2D, as well as an interactive "LocusZoom" plot of the genomic loci. Displaying credible sets, rather than associations, immediately prioritizes a single variant as likely causal for the signal, with further evidence for a regulatory effect in pancreatic islets based on epigenomic results integrated within the display; these results replicate the results of a 2015 genetic analysis that required over 100 authors (Gaulton KJ et al., 2015, Nat Genet. 47:141). Additionally, investigators without previous access to these data can for the first time use them in their own analyses. A study that characterized the impact of variants in HNF1A (Najmi LA et al. (2017), Diabetes 66:335) was able to validate the significant association of functionally important variants based on lookups in the T2DKP. Similarly, a study that identified associations between ANGPTL4 and coronary artery disease (Dewey FE et al. (2016), N Engl J Med. 374:1123) was able to query the T2DKP for T2D associations, suggesting a novel effect on T2D from this gene. These results provide a platform that removes a major barrier impeding genetic data sharing and demonstrate the potential scientific value of providing broad access to genetic data.

**1187T**

**Retrospective electronic medical record analysis to identify patients at risk of hypophosphatasia.** C. Peroutka<sup>1</sup>, M. Marzinke<sup>4</sup>, N. Parikh<sup>2</sup>, A. Alade<sup>1,2</sup>, J. McGready<sup>3</sup>, K. Schulze<sup>2,3</sup>, J. Hoover-Fong<sup>1,2</sup>. 1) McKusick Nathans Inst of Gen Med, Johns Hopkins, Baltimore, MD; 2) Greenberg Center for Skeletal Dysplasias, Johns Hopkins, Baltimore, MD; 3) Bloomberg Sch of Public Health, Johns Hopkins, Baltimore, MD; 4) Clinical Pharmacology Analytical Laboratory, Johns Hopkins Hospital, Baltimore, MD.

**Introduction:** Hypophosphatasia (HPP) is a pleiotropic metabolic condition caused by variants in tissue-nonspecific alkaline phosphatase (*TN-SALP/ALPL*), manifesting as perinatal lethal or throughout life with fractures, early tooth loss, osteoporosis, seizures, chronic pain, fatigue and/or respiratory compromise. Low serum alkaline phosphatase (AP) is a key biochemical indicator of HPP, but is often unrecognized as pathologic. Given a broad disease spectrum and under-recognized indicator, HPP is likely underdiagnosed. Misdiagnosis as idiopathic osteoporosis may lead to treatment with bisphosphonates, which counteracts available asfotase alpha enzyme replacement therapy for HPP. We conducted a risk prevalence study for HPP by query of a large, hospital-based electronic medical record (EMR), demonstrating that EMR query may be used to identify rare disease. **Methods:** The Johns Hopkins (JH) IRB approved this protocol under a waiver of consent. JH patients from all clinical sites with  $\geq 1$  AP level reported from Jan 2013-Dec 2015 were compiled by patient medical record number (MRN). Site and ICD-9 codes were merged to MRNs with  $\geq 1$  low AP based on age- and sex-specific AP norms. MRNs with hematologic, oncologic, drug and/or transplant codes associated with low AP were excluded. Remaining charts were prioritized for review. **Results:** There were 983,458 AP levels from 156,459 patients, with 45,233 (22,175 patients  $\leq 19$ yo) low AP levels from 11,730 patients. Exclusion by ICD-9 and clinical codes yielded 642 patients for review, with data from 45 patients presented. Medical history is suggestive of HPP in 28(62%) patients: 3 of 45(6%) with adult premature tooth loss, 4(8%) excessive caries, 6(13%) nephrolithiasis, 10(22%) muscle pain, and 27(60%) chronic pain. 6(13%) have osteoporosis; 2 received bisphosphonates and 1 received a PTH analog. Multiple specialists provide care: 5(11%) endocrinology, 8(17%) orthopedics, 4(8%) rheumatology, 3(6%) genetics, and 2(2%) pain management. HPP was not on the differential for patients with low AP, though 5(11%) had molecular testing for other conditions. **Conclusions:** This study provides evidence that EMR query of a large patient population can identify those who warrant further investigation for rare, treatable genetic conditions like HPP. Following chart review, we will obtain IRB approval to contact patients at risk of HPP to offer genetic counseling, molecular testing, and treatment to those affected.

**Evaluation of genetic sequencing to improve newborn screening for VLCAD disease.** B. Cai<sup>1</sup>, R. Jain<sup>1</sup>, D. Lee<sup>1</sup>, T. Bergquist<sup>1</sup>, C. Bock<sup>1</sup>, V. Pejaver<sup>1</sup>, R. Gallagher<sup>2</sup>, P. Kwok<sup>2</sup>, J. Puck<sup>3</sup>, S.D. Mooney<sup>4</sup>, B. Carrier<sup>5</sup>. 1) Department of Biomedical Informatics and Medical Education, University of Washington, Seattle, WA, USA; 2) Institute of Human Genetics, University of California, San Francisco, California, CA, USA; Cardiovascular Research Institute, University of California, San Francisco, CA, USA; Department of Dermatology, University of California, San Francisco, CA, USA; 3) Department of Pediatrics, Division of Allergy, Immunology, and Blood and Marrow Transplantation, University of California San Francisco, San Francisco, CA, USA; 4) Genetic Disease Screening Program, California Department of Public Health, Richmond, CA, USA; 5) Department of Pediatrics, Medical Genetics, University of California San Francisco, San Francisco, CA, USA.

**Background:** Very-long-chain acyl-CoA dehydrogenase deficiency (VLCAD) is currently screened for as part of newborn screening programs in all 50 states in the US. We assessed the incorporation of genetic sequencing of the *ACADVL* gene to assess the overall utility of incorporating genetic information by comparing screening true positives (affected= TP) and screening false positives (unaffected but screened positive= FP) samples. **Methods:** The screening results within the study population were refined via Mayo Clinic Collaborative Laboratory Integrated Reports (CLIR) Tool Runner using the tools for VLCAD and VLCAD(het), i.e. heterozygote VLCAD carriers. We performed exome sequencing on 600 individuals and applied a computational pipeline to identify pathogenic variants on the *ACADVL* gene. This study population included the 16 TP and 45 FP for VLCAD identified by the California Newborn Screening Program, which were resolved as not disease during follow-up by metabolic clinics. **Results:** The results are summarized in the table below. In the 16 TP (affected) individuals, 11 had two potentially pathogenic variants identified and the other 5 each had one variant identified. Review of case history in these 5 suggested that that at least 2 were heterozygous carriers. Of the 44 FP, 3 had two variants identified, 31 had one variant identified and 13 had no variants identified. In the clinical follow-up, of the 14 cases called indeterminate by the CLIR tools, 3 were identified as VLCAD. Of these indeterminate cases, 2 had two pathogenic variants, and 1 had one, 6 were clinically identified as carriers, 5 had 1 pathogenic variant, and 1 had none. 3 were clinically identified as “No Disorder”, 2 had no variants, and 1 had one. **Conclusion:** This initial study suggests that sequencing *ACADVL* together with the CLIR-based tools can significantly refine newborn screening for VLCAD. Table: Comparison of clinical resolution, CLIR refinement of screening results, and sequencing results among VLCAD screen positive cases in California.

NBS resolution for VLCAD Screen Positive	CLIR Dual Scatter Plot Evaluation	Number of Cases	# of ACADVL Variants		
			Two	One	None
True Positive (TP)	VLCAD	10	9	1	0
	VLCAD heterozygote (carrier)	3	0	3 (*)	0
	Indeterminate	3	2	1	0
False Positive (FP)	VLCAD	3	1	0	2
	VLCAD heterozygote (carrier)	30	2	21	7
	Indeterminate	11	0	8	3

(\*) Two of these cases were reclassified as carriers (i.e. FP screening tests) following several years of uneventful clinical follow-up by metabolic specialists.

**1189W**

**Using automatic adipose measures from electronic health record based imaging data for discovery.** E.D.K. Cha<sup>1</sup>, Y. Veturi<sup>1</sup>, C. Agarwal<sup>2</sup>, M. Arbabshirani<sup>1</sup>, S.A. Pendergrass<sup>1</sup> on behalf of the DiscovEHR collaboration. 1) Biomedical and Translational Informatics Institute, Geisinger Health System, Danville, PA; 2) Department of Electrical and Computer Engineering, University of Illinois at Chicago, Chicago, IL.

Using advanced methods for extracting measures from imaging data within electronic health records offers an opportunity for new research, such as investigating the impact of subcutaneous and visceral adipose tissue levels on risk factors and exploring genetic associations with those traits. The location and type of adipose tissue is an important factor in metabolic risk for diseases such as diabetes, hyperlipidemia, hypertension, and atherosclerosis. Visceral adipose tissue (VAT) levels are believed to have a more negative impact on metabolic outcomes over subcutaneous adipose tissue (SAT) levels. Evaluating visceral and subcutaneous fat levels has been pursued through computed tomography (CT). There is a unique opportunity to use existing abdominal CT imaging data for large-scale research without necessitating the enrollment of individuals in a new imaging study. As proof of principle, we pulled ~2000 CT studies from Geisinger Health System PACS and used "greedy snakes", a method in computer vision, to quantify VAT, SAT, total adipose tissue (TAT) and adipose-ratio volumes. After controlling for age and sex, we performed logistic regression analyses to evaluate these adipose measures for association with more than 1000 disease diagnoses (using ICD-9 codes to define cases and controls for each diagnosis). While SAT was more strongly associated with some obesity-related ICD-9 codes (e.g. localized osteoarthritis), we found a number of significantly stronger associations between VAT and metabolic syndrome diagnoses such as type II diabetes ( $p=1.5E-58$ ; 95% CI = [2.85, 2.87]) and obstructive sleep apnea ( $p=7.7E-37$ ; 95% CI = [2.32, 3.16]), which shows the increased impact of VAT on these traits. We also performed linear regression with 35 continuous clinical lab measures, finding stronger associations and consistent effect direction for VAT with lipid levels and white blood cell counts. The same tests stratified by sex revealed stronger associations for many diagnoses and clinical lab measures for women than men, suggestive of an increased impact of VAT in women. Finally, we performed a GWAS between adipose measures and genetic variants identified some suggestive associations for VAT and SAT measures. Our future work will include increasing the sample size for a larger study, including common and rare variant genetic associations with these adipose measures to further elucidate their impact on disease risk, comorbidities and the underlying genetic architecture.

**1190T**

***In-silico* characterization of cell-type composition in adipose tissue: Implications for 'omic analyses and associations to adiposity measures.** C.A. Glastonbury<sup>1,2</sup>, J.S. El-Sayed Moustafa<sup>1</sup>, A.C. Alves<sup>1</sup>, K.S. Small<sup>1</sup>. 1) Department of Twin Research and Genetic Epidemiology, King's College London, London, UK; 2) Big Data Institute, University of Oxford, Oxford, UK.

Adipose tissue is the largest endocrine organ in the body and has a role in the development of cardio-metabolic disorders. Adipose tissue is comprised of a heterogeneous array of cell types which can differentially affect disease phenotypes. Cellular heterogeneity is a well established confounder of 'omic analyses in blood, but has rarely been taken into account in analysis of solid-tissue transcriptomes. We used CIBERSORT to estimate the relative proportions of four cell types (adipocytes, macrophages, CD4+ t-cells, Micro-Vascular Endothelial Cells (MVEC)) in bulk subcutaneous adipose RNAseq from TwinsUK volunteers (N =766) and GTEx post-mortem donors (N=326). We confirmed deconvolution accuracy *via* simulations and visual consistency with GTEx histology images. Cell-type composition was markedly different between the two cohorts (adipocyte, macrophage, MVEC medians: TwinsUK =0.82, 0.02, 0.15, GTEx = 0.62, 0.08, 0.30), reflecting differences in the collection protocols, biopsy location (abdomen vs leg) and cohorts. In TwinsUK, cell-type proportion, in particular macrophage proportion, was correlated with BMI ( $R^2=0.22$ ,  $P=2 \times 10^{-8}$ ), with even stronger associations to DXA-derived measurements of body-fat distribution including visceral fat ( $R^2=0.29$ ,  $P=4 \times 10^{-15}$ ) and android/gynoid ratio ( $R^2=0.36$ ,  $P=2 \times 10^{-16}$ ), suggesting macrophage infiltration plays a prominent role in body-fat distribution. By contrast, cell-type proportion was not associated with age ( $R^2=-0.02$ ). Heritability of adipocyte, macrophage and MVEC proportion was 17%, 30% and 21% respectively. We assessed the effect of cell-type composition on a range of 'omic analyses. Expression levels of 43% of protein-coding genes were associated with BMI (FDR 5%); 20% of these were no longer significant after adjusting for cell-type proportion, indicating a substantial portion of BMI-expression associations are independent of cell-type proportion. WCGNA co-expression networks were heavily associated with cell-type proportion, including the MEMN module and macrophage proportion ( $R=0.68$ ,  $P=2 \times 10^{-16}$ ). Adjusting for cell-type proportion in *cis*-eQTL analysis achieved a modest increase in eQTL yield (2.3%), but no difference after correction for latent factors. G x Cell Type Proportion interaction models identified 20 cell-type specific eQTLs (12 macrophage, 10 MVEC, 4 adipocyte), demonstrating the potential of *in silico* deconvolution of bulk tissue to identify cell-type restricted regulatory variants.

**1191F**

**Non-additive SNP effect discovery from GWAS with LAMP.** J. Sese<sup>1,2</sup>, A. Terada<sup>3,4</sup>, M. Koido<sup>2</sup>, M. Akiyama<sup>2</sup>, M. Kubo<sup>5</sup>, Y. Kamatani<sup>2,6</sup>. 1) Artificial Intelligence Research Center, National Institute of Advanced Industrial Science and Technology; 2) Laboratory for Statistical Analysis, RIKEN Center for Integrative Medical Sciences; 3) PRESTO, Japan Science and Technology Agency; 4) Dept. of Computational Biology and Medical Science, The University of Tokyo; 5) RIKEN Center for Integrative Medical Sciences; 6) Center for Genomic Medicine, Kyoto University Graduate School of Medicine.

Genome-wide association studies (GWASs) have uncovered thousands of disease related SNPs, and recent very large-scale GWASs unveiled the importance of additive effects among the SNPs to understand the mutations related to especially common diseases. These analyses also showed the existence of remaining missing heritability with the traits. One possibility to explain the gap is to consider non-additive effects among multiple SNPs. However, only a few non-additive effects can be found because of the lack of the statistically valid method to detect the effects. Therefore, we developed a statistical method to detect the combinatorial effect of multiple features, called Limitless Arity Multiple-testing Procedure (LAMP) [PNAS 2013], and made a new software named LAMPLINK which incorporates LAMP in widely-used statistical genetic software PLINK [Bioinformatics 2016]. We here show the results of the application of LAMPLINK to a part of the BioBank Japan Project data including 200,000 patients with 47 target diseases. The results revealed the candidate novel non-additive combinations of SNPs related to diseases including Graves' diseases and rheumatoid arthritis. Furthermore, the joint analysis workflow of LASSO with LAMPLINK confirmed that the SNP combinations cannot be explained by the additive effect of SNPs.

**1192W**

**The grid-interpolation algorithm: A novel approach for fast and efficient mixed model analysis of high-dimensional phenotype data.** J.R. O'Connell. Program for Personalized and Genomic Medicine, University of Maryland, Baltimore, Baltimore, MD.

High-dimensional phenotype data represents a new and significant analytical and computational challenge for emerging large scale multi-omics and imaging datasets. Two examples of high-dimensional phenotype data include epigenome-wide analysis (EWA) of a complex trait using the 850,000 probes on the Illumina EPIC methylation chip and voxel-wise analysis of cognitive function using 100,000 voxels from Human Connectome project brain images. Using regression variable names we call the analysis of many dependent variables the big Y problem and many independent variables the big X problem. An example of big X is genome-wide association analysis (GWA) of sequence data. Both the above big Y examples require mixed model methods to incorporate random effects to account for genetic relatedness and/or batch effects. Many optimized mixed model algorithms and software exist for efficient GWA analysis, but to date no such tools exist for mixed model EWA analysis. Current options are extremely inefficient: run a separate GWA mixed model for each phenotype. We present a simple solution to the big Y mixed model problem that is thousands of times faster than the current single-phenotype approach and can scale to samples sizes in the tens of thousands. The algorithm, called the grid-interpolation algorithm, relies on evaluating the mixed model likelihood on a set of fixed parameter values, called a grid, then interpolating the likelihood function using Lagrange polynomials to find the maximum value. The computational cost of the grid step is of order  $N^3$ , where  $N$  is the sample size, then grid likelihood evaluation is of order  $P^*N^2$ , where  $P$  is the number of phenotypes. The single-phenotype approach has cost of order  $P^*N^3$ . To examine performance, we simulated 100,000 phenotypes (random normal deviates) on 8000 subjects who had available age, sex, lipid traits, and a genetic relationship matrix. The runtime for a single lipid trait against 100,000 phenotypes was under 30 minutes, while the single-phenotype analysis was estimated to take 25 days based on the runtime for 5000 phenotypes. Our software supports both cluster and cloud computing, outputs both maximum likelihood (ML) and restricted ML (REML) estimates, standard errors and p-values of all fixed and random effects, and can output a file of the residuals for each phenotype for input to other analyses. We will also demonstrate extensions of our algorithm to big Y analysis of genetic data and multiple random effects.

**1193T****Identification of genes alternatively spliced in HIV-infected CD4+ T-cells.**

S. Han, S. Byun, Y. Lee \*. Biomedical Informatics, University of Utah, Salt Lake City, UT., Select a Country.

**Introduction:** The most effective treatment for patients infected with human immunodeficiency virus 1 (HIV-1) is the complete elimination of T-cells harboring the latent form of the virus. However, specific targeting of the latently infected T-cells is a major obstacle in such treatment. **Motivation:** Alternative splicing (AS), using different combinations of exons, is a major mechanism for gene regulation and protein diversity. AS patterns (exon skipping, alternative splice sites) are known to occur in specific genes related to T-cell immune processing (e.g. CD44, CD45, CTLA4). However, there is no study yet that has systematically examined differential exon skipping events in HIV-infected T-cells. We hypothesized that immune-related genes have differentially expressed exons in HIV-infected T-cells. We analyzed alternative splicing in RNA-seq data to discover immune-related genes that produce differentially skipped exons between HIV-infected and non-infected T-cells. **Methods:** We downloaded RNA-seq data from the Sequence Read Archive (run IDs SRR5071107-SRR5071122), which consisted of *in vitro* HIV-infected (n=4) and non-infected (n=12) T-cells. Raw data was mapped onto the human reference genome (GRCH37.75) using Tophat. The R package *IMAS* was used to identify differentially skipped exons. Gene Ontology (GO) term enrichment was analyzed using the program GSEA to determine the functional roles of genes. In addition, we searched PubMed for studies documenting genes with roles relating to transmembrane protein and T-cell function. **Results:** We identified 145 genes with differentially expressed exons. Among these genes, the term "Immune Processing Process" was significantly enriched ( $p=1.75e-8$ ,  $q=7.75e-5$ , GO:0002376), represented by 19 genes (e.g. NCK1, STK11, CTSL). Thirty-one of the AS genes are known transmembrane proteins, of which 14 are related to immune function (e.g. FCGR1B, FCGR3A, LILRB2). In addition, we found 20 genes that are related to T-cell function (e.g., ITK, CD200, TMEM176B). **Conclusion:** We identified a number of genes with roles relating to immune and T-cell function which produce differentially expressed exons in HIV-infected T-cells. These findings suggest that an assay for alternative splicing may contribute to improved detection of latently infected T-cells.

**1194F****Depression and mental illness affect pre and post multiple sclerosis diagnosis.**

C. Gardner<sup>1</sup>, M. Davis<sup>1</sup>, J. Denny<sup>2</sup>. 1) Department of Microbiology and Molecular Biology, Brigham Young University, Provo, UT; 2) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN.

Multiple sclerosis (MS), is an autoimmune disease resulting in the demyelination of the myelin sheath in the central nervous system (CNS). Currently, there are approximately 2.3 million people worldwide affected by MS, with an increased incidence in those with European heritage. The disease course for each individual case of MS is unique and unpredictable with a wide array of symptoms and disabilities following diagnosis. As the disease progresses, the quality of life the individual decreases, often leading to depression. Studies have shown that up to 50% of those diagnosed with MS will suffer from depression or anxiety in addition to the physical symptoms and disabilities. Evidence recently suggests that there may be a stronger relationship between MS and depression and anxiety in which having depression and anxiety increases risk of MS. We investigated this through data extracted from de-identified electronic medical records (EMRs) and genetic data from the BioVU database from Vanderbilt University Medical Center, based on ICD9 and ICD 10 codes for MS, depression and anxiety. We then created four groups (one control group, and three case groups) from the extracted individuals based on criterion of diagnosis dates of both diseases. Controls were defined as individuals diagnosed with MS and never diagnosed with depression or anxiety (n=746). The three case groups were defined as 1) having MS and being diagnosed with depression or anxiety (n=118), 2) having MS and being diagnosed with depression or anxiety pre-MS diagnosis (n=78), and 3) being diagnosed with depression or anxiety post-MS diagnosis (n=40). We [MD1] then preformed a logistic regression for each of the case groups against the control group while adjusting for age and gender to identify genetic variants that may be associated with depression or anxiety in MS patients. We saw no SNPs that reached genome-wide significance for any of the analyses, but some results were borderline significant. Seven intronic SNPs across three genes (ANKRD55, RPS6KA2, WDY4) showed association with depression or anxiety in either pre- or post-MS diagnosis ( $p < 1 \times 10^{-4}$ ), but not in the other ( $p > 0.05$ ).

**A haplotype assembly workflow for HLA and KIR typing from next-generation sequencing data.** S. Tian<sup>1</sup>, H. YAN<sup>1</sup>, S. McDonnell<sup>1</sup>, W. Ding<sup>2</sup>, E. Klee<sup>3</sup>, S. Baheti<sup>4</sup>, N. Ihrke<sup>3</sup>, M. Kalmbach<sup>3</sup>, J. Olson<sup>4</sup>, J. Cerhan<sup>4</sup>, S. Slager<sup>1</sup>.

1) Division of Biomedical Statistics and Informatics, Department of Health Sciences Research, Mayo Clinic, Rochester, MN 55905, USA; 2) Division of Hematology/Medical Oncology, Department of Internal Medicine, Mayo Clinic, Rochester, MN 55905, USA; 3) Division of Research and Education Support Systems, Department of Information Technology, Mayo Clinic, Rochester, MN 55905, USA; 4) Division of Epidemiology, Department of Health Sciences Research, Mayo Clinic, Rochester, MN 55905, USA.

The human leukocyte antigen (HLA) is a super-locus of genes that encode for cell-surface proteins that regulate the immune system. HLA and the Killer Immunoglobulin-like Receptors (KIR) region it interacts with play critical roles in organ transplant and disease. Determining gene sequences (typing) is crucial for defining immune epitope repertoires in cancer immunotherapy and for predicting adverse drug effects. Classical HLA typing with serology- or PCR-based methods is labor-intensive, time-consuming, and ambiguity-prone. From next-generation sequencing data, the two well-performed algorithms Optitype and Polysolver can only type class I (HLA-A, -B, and -C) but not class II (HLA-DRB1, -DQA1, and -DQB1) genes that are more complex. In fact, results from several bioinformatics algorithms showed considerable discordance compared to the Sanger sequencing-based typing, the current gold standard. At the four-digit resolution, the overall prediction accuracy in typing HLA classes I and II ranges from 7 to 66%, 26 to 77% and 20 to 81%, respectively, for whole-genome (WGS), whole-exome (WES), and RNA sequencing data in the 1000 Genomes Project. These studies highlight the need to develop novel analytical systems for more accurate typing in HLA and other complex regions. We previously developed SGVar, a *de novo* assembly workflow for haplotype-based variant discovery from WGS and WES, which is particularly sensitive to the HLA region. Here, we aimed to improve typing accuracy and success rate by utilizing SGVar assembled haplotigs. Specifically, we optimized the selection of reads to be used in assembly and the allele inference from haplotig-reference alignments. We selected 13 WGS (2x250bp) and 24 WES (2x100bp) data sets from 1000 Genomes Project that had the gold standard PCR-verified HLA genotype information. Our pipeline achieved an accuracy of 92.3% and a success rate of 94.7% for class I and 90.4% accuracy and success for class II in WGS. For WES, the accuracy was 87.3 and 86.4% and the success rate was 87.9 and 86.4% for class I and II genes, respectively. We are currently using the pipeline to type the HLA and KIR genes from 1000 WGS in Mayo Clinic biobank samples. The allele frequency information gained from such a large collection of controls will be particularly useful for the discovery of immune and autoimmune risk alleles in disease susceptibility studies.

**A high-throughput deep sequencing approach for CRISPR off-target assessment in therapeutic genome editing applications.** A. Ajetunmbi<sup>1</sup>, A. Hendel<sup>2</sup>, V. Dillard<sup>1</sup>, R. Doyle<sup>1</sup>, N. Humphries-Kirilov<sup>1</sup>. 1) Clinical Services, Desktop Genetics, London, London, United Kingdom; 2) Bar-Ilan University, Ramat Gan, Israel.

Presented is a multiplexed deep sequencing approach for investigating off-target effects in CRISPR genome-editing experiments. This approach involves the design of Tru-Seq Custom Amplicon (TSCA) primers for multiplexed target amplification and deep sequencing of predicted off-target sites. Specificities of sgRNAs were assessed in K562 myelogenous leukaemia cells and CD34+ human pluripotent stem cells. 3000 amplicons across 24 samples were pooled for parallel sequencing on a single Mi-Seq run. Results show limited cross-hybridization across TSCA primers indicating high specificity to the target loci. Over 80% of amplicons achieve uniform coverage, negating target region bias across the 125 predicted sites. CRISPR editing events were detected at the predicted on-target site as well as several predicted off-target sites. Mutations in the population were detected to a sensitivity of 0.1% minor allele frequency. This approach presents a scalable option for discovering, validating, and assessing the off-target profile of genome-editing modifications.

**High throughput BCR sequencing of the thymus and blood B cell repertoire in myasthenia gravis patients pre and post thymectomy.** R. Jiang<sup>1</sup>, E. Dimalanta<sup>2</sup>, R.J. Nowak<sup>3</sup>, S.H. Kleinstein<sup>4,5</sup>, K.C. O'Connor<sup>2</sup>. 1) Immunobiology, Yale University, New Haven, CT, USA; 2) New England Biolabs, Inc. Ipswich, MA USA; 3) Department of Neurology, Yale School of Medicine, New Haven, CT, USA; 4) Interdepartmental Program in Computational Biology and Bioinformatics, Yale University, New Haven, CT, USA; 5) Departments of Pathology and Immunobiology, Yale School of Medicine, New Haven, CT, USA.

Thymectomy along with glucocorticoid treatment has long been part of the standard of care for nonthymomatous myasthenia gravis (MG); thymic hyperplasia has been demonstrated on pathology in the vast majority of patients with MG, particularly those with circulating anti-AChR antibodies. Transplantation of thymic biopsies from patients with proven thymic hyperplasia in the context of MG is known to elicit an MG phenotype in immunodeficient mice (SCID) associated with the production of anti-AChR antibodies. Furthermore, previous studies have demonstrated correlative evidence between the efficacy of thymectomy and the presence of tertiary lymphoid structures in the thymus. While previous studies have used low throughput techniques to attempt to study the role of the thymic B cell compartment in MG, we sought to evaluate the heavy chain repertoire of both the thymic and blood compartments from thymectomy patients at a high depth of sequencing. Using samples from patients that had been treated by thymectomy at Yale-New Haven Hospital, we investigated both their thymic and blood repertoires using high-throughput heavy chain B cell receptor (BCR) sequencing. We applied a method developed for the accurate reconstruction of VDJ constructs from RNA extracted from B cells. Unique molecular identifier (UMI) sequencing combined with novel computational techniques was also applied to resolve sequencing error and to maximize the number of sequences that could be extracted from these samples. Our results demonstrate significant abnormalities in the thymic compartment of these patients relative to the blood as well as shifts in the repertoire pre and post thymectomy. We also attempted to identify similarities across thymic samples from these patients both in terms of broad repertoire level analysis and more closely in terms of the structural identities of the heavy chains representing the repertoires. This study better defines these repertoire abnormalities with a goal towards offering new paradigms for the earlier diagnosis and more definitive prognosis of MG.

**PheWAS and permutation analyses indicated involvement of the *CLEC16A* locus in immune-related phenotypes.** M.E. March<sup>1</sup>, F.D. Mentch<sup>1</sup>, K. Thomas<sup>1</sup>, C. Hou<sup>1</sup>, C.E. Kim<sup>1</sup>, P.M.A. Sleiman<sup>1,2</sup>, H. Hakonarson<sup>1,2</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania.

The *CLEC16A* locus has been implicated as a region of interest in multiple genome-wide association studies examining autoimmune-, immunodeficient-, or inflammation-related diseases. Associated conditions include (but are not limited to) type 1 diabetes, combined variable immunodeficiency, asthma, atopic dermatitis, multiple sclerosis, and systemic lupus erythematosus. To investigate the potential role of *CLEC16A* in other phenotypes, an approach was developed using phenome-wide association studies (PheWAS). The genotypes for the entire PheWAS cohort from the Center for Applied Genomics at CHOP were imputed against the Haplotype Research Consortium reference panel, and the approximately 2,200 LD-pruned SNPs from the *CLEC16A* region on chromosome 16 were extracted as allele doses. The allele doses were run through our standard PheWAS pipeline, and suggestive results ( $p < 1E-5$ ) were extracted and analyzed. Twenty-five immunity- and infection-related phenotypes were identified in the suggestive results. To determine if this accumulation of phenotypes represented an enrichment, the SNPs from the *CLEC16A* region were permuted into multiple hundreds of collections. Each permuted collection was run through the PheWAS, and the results were scanned for occurrences of the 25 identified phenotypes. The distribution of occurrences in the permutations indicated that the 25 phenotypes found with the original genotypes is a significant enrichment. A second permutation analysis performed with an irrelevant gene of similar size to *CLEC16A* did not uncover a similar enrichment, suggesting that our PheWAS analysis of the *CLEC16A* locus provides additional evidence for the role of *CLEC16A* in immune-related phenotypes, several of which are novel.

**Understanding chronic fatigue syndrome using immune cell specific RNA-seq in a time series after an exercise perturbation.** P. Comella, N.D. Beckmann, A. Cohain, G.E. Hoffman, E.E. Schadt. Department of Genetics and Genomic Sciences, Icahn Institute for Genomics and Multiscale Biology, Icahn School of Medicine at Mount Sinai, New York, NY.

Chronic Fatigue Syndrome (CFS) is a disease resulting in extreme fatigue without any known underlying medical condition. CFS often presents in patients following a viral infection and patients may appear to have slightly impaired immune systems. With no positive diagnostic, CFS is often misunderstood and misdiagnosed. A pilot clinical study was established to give further insight into the immunological role of CFS. This pilot study included 15 CFS patients and 15 age and sex matched controls undergoing cardiopulmonary exercise testing (CPET). Blood was extracted at four time points - immediately before, 1 day after, 2 days after and 3 days after. Five immune cell types were sorted from whole blood collected from each participant, and RNA was extracted and sequenced for each cell type, as well as whole blood, at each time point. Additionally, each participant underwent extensive clinical surveys and questionnaires. To discover genetic drivers of CFS, we generated differential gene expression (DE) signatures, constructed gene co-expression networks to identify coherent modules of co-regulated genes, and then carried out gene ontology enrichments on the signatures and modules. Using all cell types, we were able to identify B cells as the most CFS informative cell type, with the DE signature and network modules constructed from the B cell data containing the most disease specific information across all time-points. We identified components of DE signatures that were specific to a given time point, with some time points having larger DE signatures than others, suggesting such time points may be more informative in further studies of CFS.

**Finding NEMO: *De novo* mutation detection in the *IKBKG* gene.** Z.

Deng<sup>1</sup>, A. Almeida de Jesus<sup>2</sup>, R. Goldbach-Mansky<sup>2</sup>, R. Siegel<sup>1</sup>, E. Hanson<sup>1</sup>.

1) NIAMS, National Institutes of Health, Bethesda, MD; 2) NIAID, National Institutes of Health, Bethesda, MD.

NEMO (NF- $\kappa$ B Essential Modulator, encoded by the *IKBKG* gene) is an important regulator of host defense and inflammation. Mutations in the NEMO gene have been shown to cause a range of human diseases including embryonic lethality, Incontinentia Pigmenti in females, and Anhidrotic Ectodermal Dysplasia with Immune Deficiency. Detecting mutations in *IKBKG*, therefore, is of paramount clinical importance, however this has been difficult due to its location in a segmental duplication region on human chromosome Xq28. The duplication covers *IKBKG* after intron 2 and extends 36kb with near perfect sequence identity. Standard variant callers such as GATK and SAMTOOLS among others are ill-suited for mutation detection in duplicated regions because NGS reads have ambiguous mapping locations. We have developed a bioinformatics method to identify potential *de novo* mutations in *IKBKG* from whole genome sequencing data. We first extract reads in the duplicated regions from whole genome BAM files which are then converted to pileup format to identify variants. Next, a series of parameters including coverage and allele fraction are tested and optimized to filter out false variants. Lastly, potential mutations are manually inspected using IGV. We applied this method to screen a cohort of 69 patients with suspected monogenic autoinflammatory disease and their 123 unaffected parental controls. We identified two *de novo* mutations at the splice sites for exon 5. One mutation is chrX 153,788,776 T>G that disrupts the +2 consensus donor splice site (GT to GG) within intron 6. Another mutation is chrX 153,788,779 G>A, 3 bp away from the first mutation at +5 splice site. Both mutations are predicted to affect exon 5 splicing. We confirmed exon 5 skipping in mRNA from both patients and protein expression of a NEMO isoform (NEMO- $\Delta$ ex5). Both patients identified by this method are phenotypically similar to a previously studied NEMO- $\Delta$ ex5 patient. In conclusion, we have developed a bioinformatic method capable of mutation detection in highly similar segmental duplication regions that led to the identification of 2 *de novo* mutations in *IKBKG*. As there are more than 25 disease genes that, like *IKBKG*, are located in so-called NGS dead zones, our method may also enable detection of mutation in these other genes.

**Exome sequencing by NimbleGen kit is not suitable for SOX2 and SOX3 molecular screening due to bald spot.** A.F.F. Benedetti<sup>1</sup>, J.M. Silva<sup>1</sup>, J.L.O. Madeira<sup>1</sup>, Q. Ma<sup>2</sup>, J.Z. Li<sup>2</sup>, A.B. Oze<sup>2</sup>, B.B. Mendonca<sup>1</sup>, I.J.P. Arnhold<sup>1</sup>, S.A. Camper<sup>3</sup>, A.C. Tahira<sup>3</sup>, L.R.S. Carvalho<sup>1</sup>. 1) Unit of Developmental Endocrinology, Laboratory of Hormones and Molecular Genetics/LIM42. Clinics Hospital, University of Sao Paulo Medical School (HC-FMUSP), Sao Paulo, Sao Paulo, Brazil; 2) Department of Human Genetics, University of Michigan, Ann Arbor, USA; 3) Medical Investigation Laboratory from Institute of Psychiatry/LIM23. University of Sao Paulo Medical School (FMUSP), Sao Paulo, Sao Paulo, Brazil.

SOX2 and SOX3 genes are members of the SOX (SRY-related HMG-box) family of transcription factors involved in the pituitary development. Mutations in both genes were previously associated with congenital idiopathic hypopituitarism (CIH). The aim of this study was to determine SOX2 and SOX3 coverage in the whole exome sequencing (WES) for variants screening in a cohort of twenty-six patients (15 males) with CIH. Genomic DNA was isolated from blood leukocytes by standard techniques and then used to produce exome captured sequencing library by NimbleGen SeqCap EZ v3.0 kit, following manufacturer's protocol. Paired-end exome-sequencing was done using the Illumina HiSeq2000 System. Raw reads were aligned to the 1000 Genomes Phase 1 reference and mapped to GRCh37 using BWA v0.5.9. Single nucleotide variants, insertions and deletions were called using GATK Haplotype Caller v3.3. Variants were annotated using ANNOVAR. Lastly, the coverage of exomic regions corresponding to SOX2 and SOX3 genes were explored using the software Integrative Genomics Viewer (IGV), as well as the coverage suite from bedTools (coverageBed). The GC-rich single exon of both SOX2 and SOX3 were amplified by polymerase chain reaction using in-house designed primers. Amplicons were sequenced using the ABI Prism BigDye Terminator Cycle Sequencing Ready Reaction Kit and placed on the ABI PRISM 3100 sequencer. No variants in SOX2 and SOX3 were identified by WES. However, SOX3 poly alanine tract and other parts of the coding region in both genes displayed low coverage, with less than a minimum of twenty reads per base. SOX3 analysis by Sanger sequencing revealed the allelic variant p.P103T (c.307G→T, rs201101913) in heterozygous state in three patients. In silico analysis and variant population frequency was performed using the prediction sites Mutation Assessor, Mutation Taster, Polyphen2, Human Splicing Finder 3.0, ExAC, and 1000g and the variant was classified according to the American College of Genetics and Genomics (ACMG) as benign. It was previously demonstrate that WES by NimbleGen capture system showed a poor coverage of genes with high GC contents, such as SOX2 and SOX3. Despite the rarity of SOX2 and SOX3 mutations, it is important for them to be screened since defects in these genes were associated to CIH. Thus, the screening of these genes in patients with CIH should be done by Sanger sequencing instead of using NimbleGen.

**1202T**

**Hunting rare variants in chronic kidney disease.** S.R. Cameron-Christie<sup>1</sup>, E. Groopman<sup>2</sup>, C. Wolock<sup>2</sup>, J. Fleckner<sup>1</sup>, R. March<sup>1</sup>, A. Platt<sup>1</sup>, D. Goldstein<sup>3</sup>, A. Gharavi<sup>3</sup>. 1) Centre for Genomics Research, Astrazeneca LTD, Melbourn, Royston, United Kingdom; 2) Department of Medicine, Columbia University, 635 W 165th St, New York, U.S.A; 3) Institute for Genomic Medicine, Hammer Health Sciences, 701 W 168th St, New York, U.S.A.

Whole-exome sequencing (WES) has been successfully used to identify rare or private variants that dramatically increase the risk for common or complex disorders, helping to bridge the gap between the highly-penetrant mutations identified in families with Mendelian disorders and the common, low-risk polymorphisms that can be detected by genome-wide association studies. Case-control assessment of the gene-level burden of rare variants of large effect have provided insight into the molecular basis of complex disorders such as amyotrophic lateral sclerosis, inflammatory bowel disease, and idiopathic pulmonary fibrosis. However, to our knowledge, this framework has yet to be applied to the study of chronic kidney disease (CKD). To this aim, we performed a gene-based collapsing analysis using WES data from 2,710 CKD cases and 12,218 healthy or non-CKD controls. CKD cases included adults recruited from the nephrology clinics at Columbia University Medical Center (CUMC) (n=1,569), and the Astrazeneca-AURORA study (n=1141). The cohort was comprised largely of adults and was ethnically diverse (29.5% of patients were of self-declared non-white ancestry). Patients presented common clinical phenotypes, including glomerular, cystic, diabetic, and hypertensive kidney disease, making it broadly representative of all-cause CKD. We first excluded sites that had unbalanced sequence coverage between cases and controls, then used collapsing analysis to identify genes enriched in cases for rare variants predicted to be protein-damaging. We ran analyses under dominant and recessive inheritance models and using different allele frequencies, functional categories of variants, and with or without exclusion of diabetic and hypertensive phenotypes. We used principal component analysis to identify population stratification within and between the cases and controls, and performed ancestry-stratified and whole-population analyses. Preliminary analyses demonstrate enrichment in cases with concordant phenotypes for rare, deleterious variants in multiple genes known to cause Mendelian forms of nephropathy, such as COL4A5 and TRPC6. In addition to known genes for nephropathy, the analysis yielded novel candidate genes for further investigation. Our findings support the potential of WES to elucidate the genetic architecture of CKD, inform understanding of its molecular pathogenesis and help facilitate the development of novel, targeted diagnostics and therapeutics.

**BREATH: An open-access database and website of normal human and mouse lung development generated by the Molecular Atlas of Lung Development Program (LungMAP).** *R.F. Clark<sup>1</sup>, N.C. Gaddis<sup>1</sup>, J.L. Levy<sup>1</sup>, M. Duparc<sup>1</sup>, H. Pan<sup>1</sup>, G.P. Page<sup>1</sup>, J.A. Whitsett<sup>2</sup>, S.M. Palmer<sup>3</sup>, LungMAP Data Coordinating Center.* 1) RTI International, Research Triangle Park, NC; 2) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 3) Duke Clinical Research Institute, Duke University School of Medicine, Durham, NC.

The lung is a complex organ with high cellular heterogeneity, and research is needed to define the interactive gene networks and dynamic crosstalk among multiple cell types that coordinate normal lung development. Significant knowledge gaps exist in the understanding of lung development from late fetal to perinatal stages and through early childhood, a critical period when the diverse lung cells go through terminal differentiation and maturation and when alveoli form. Coordination of information from disparate assays and experimental approaches is critically needed to help the pulmonary research community uncover the molecular determinants of lung development. The goal of LungMAP is to build an open-access resource providing a comprehensive molecular atlas of late-stage lung development in humans and mice, making otherwise dispersed data, reagents, and protocols freely available to the research community. We have created the Bioinformatics Resource Atlas for the Healthy lung (BREATH) database, applying novel data management and bioinformatics approaches to manage high-throughput multidimensional experimental data. BREATH is built on a triplestore database backbone, integrated with anatomical ontologies for lung development, and provides access to novel web-based tools for the analysis and visualization of data generated by the four Research Centers and Human Tissue Core of the LungMAP Consortium. The current version of BREATH contains confocal immunofluorescence images, *in situ* hybridization images, histological images, nano-DESI, and 3D Vibra-SSIM confocal and uCT images of developing mouse and human lungs at several time points, as well as single-cell RNAseq, multi-cell RNAseq, microRNA, MeDIP-seq, proteomic, lipidomic, and metabolomic data from mouse and human lung cells. The LungMAP website ([www.lungmap.net](http://www.lungmap.net)) provides an entry portal to the BREATH database and tools for exploring and interacting with the lung images and omics data. Future versions of BREATH will incorporate additional data types and novel tools for cross-datatype analysis. A better understanding of the basic molecular pathways that regulate normal lung development will enable development of innovative therapies that advance treatment of lung injury repair and regeneration.

**1204W**

**An unbiased, genetic-data-driven benchmarking strategy for gene and variant prioritization algorithms.** *R. Fine<sup>1,2,3</sup>, T.H. Pers<sup>4,5</sup>, Y.H. Hsu<sup>1,2,3</sup>, J.N. Hirschhorn<sup>1,2,3</sup>.* 1) Department of Genetics, Harvard Medical School, Boston, MA; 2) Division of Endocrinology and Center for Basic and Translational Obesity Research, Boston Children's Hospital, Boston, MA; 3) Broad Institute of MIT and Harvard, Cambridge, MA; 4) Novo Nordisk Foundation Centre for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark; 5) Department of Epidemiology Research, Statens Serum Institut, Copenhagen, Denmark.

Determining the causal genes or variants from genome-wide association studies (GWAS) loci remains a daunting challenge. Many algorithms have been developed to prioritize causal genes/variants within associated loci, but benchmarking the relative success of these methods is not straightforward. A common approach is to assess whether known, "gold-standard" disease-related genes are preferentially prioritized. However, this method relies heavily on prior knowledge of disease etiology and is biased toward better-studied genes in well-characterized biological pathways. A better benchmarking approach would rely only on unbiased data, such as the genetic results themselves, rather than drawing on alternative sources of information whose relevance and comprehensiveness are uncertain. To address this need, we have developed Benchmarker, a leave-one-chromosome-out approach to perform a more robust benchmarking that uses the GWAS data as a gold standard: the GWAS serves as its own, unbiased control. From a GWAS data set, Benchmarker (1) removes the results from all SNPs from one chromosome, (2) applies the gene/variant prioritization method to the remaining GWAS data, and (3) determines if the prioritized variants or the SNPs in prioritized genes on the withheld chromosome are enriched for low p-values in the original GWAS. Benchmarker also generates a permutation-based p-value for the comparison of any two prioritization strategies. We applied our method to DEPICT, an algorithm which prioritizes genes from GWAS results based on shared biological functions, and show that across several well-powered GWASes, DEPICT's gene prioritization performs substantially better than chance. As a proof of principle, we used Benchmarker to show that DEPICT strongly outperforms a prioritization based on gene length only ( $p < 0.002$ ). We also compared DEPICT's gene prioritization performance based on either (1) shared gene set membership or (2) shared patterns of tissue expression. We found that using gene set membership was more effective than tissue expression for height and schizophrenia, while the reverse was true for inflammatory bowel disease and rheumatoid arthritis. Benchmarker can be used to fine-tune existing prioritization strategies, rigorously compare two different prioritization strategies, and compare the efficiency of prioritization based on different data types (e.g. GWAS vs ExomeChip). It thus provides a useful framework for future development of these algorithms.

**1205T****The gene expression signature associated with rheumatoid arthritis is altered during pregnancy.** *D. Jawaheer<sup>1,8,11</sup>, D. Goin<sup>1,2</sup>, M. Smed<sup>3</sup>, L. Pachter<sup>2,4</sup>, E. Purdom<sup>2</sup>, J.L. Nelson<sup>5,6</sup>, B. Ottesen<sup>3</sup>, J. Olsen<sup>7,8</sup>, M. Hetland<sup>9,10</sup>, V. Zoffmann<sup>3,10</sup>, H. Kjærgaard<sup>3</sup>.*

1) UCSF Benioff Children's Hospital Oakland Research Institute, Oakland, CA, USA; 2) University of California, Berkeley, Berkeley, CA, USA; 3) Juliane Marie Centeret, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; 4) Caltech, Pasadena, CA, USA; 5) Fred Hutchinson Cancer Research Center, Seattle, WA, USA; 6) University of Washington, Seattle, WA, USA; 7) University of California, Los Angeles, Los Angeles, CA, USA; 8) Aarhus University, Aarhus, Denmark; 9) DANBIO Registry and Copenhagen Centre for Arthritis Research, Rigshospitalet, Glostrup, Denmark; 10) University of Copenhagen, Copenhagen, Denmark; 11) University of California San Francisco, San Francisco, CA, USA.

**Goal:** To identify gene expression signatures associated with rheumatoid arthritis (RA) before pregnancy and to determine whether the signatures are altered during pregnancy, when disease activity naturally improves or worsens. **Methods:** Global gene expression profiles before pregnancy (T0) and at the third trimester (T3) were generated from 11 women with RA and 5 healthy women using RNA sequencing (RNA-seq). Disease activity scores were used to assess improvement or worsening of RA during pregnancy. Pseudo-alignment and quantification of transcripts were performed using kallisto. Differential expression (DE) analysis of normalized gene-level counts was performed using edgeR comparing (a) each RA subset (RA<sub>improved</sub> or RA<sub>worsened</sub>) vs. healthy women at each time-point, and (b) T3 vs T0 profiles within each group of women. Functional enrichment analysis was performed using WebGestalt. **Results:** Among the women with RA, 8 improved during pregnancy and 3 worsened. In the RA<sub>improved</sub> vs healthy analysis at T0, 94 genes had expression patterns associated with RA. These were enriched in various immune-related gene ontology processes. At T3, when disease activity improved, the majority of these genes (79 of 94) had expression patterns that were no longer associated with RA. These included several genes that have been previously reported as part of RA expression signatures. Their loss of DE at T3 was due to changes in expression (from T0 to T3) in RA and/or healthy women such that expression profiles became comparable between the 2 groups by T3. When the RA<sub>worsened</sub> group was compared to healthy women, 83 genes were differentially expressed at T0. There was little overlap (13 genes) between these baseline signature genes and those identified among RA<sub>improved</sub> women. Further, only 38 of the 83 genes (46%) lost their DE by T3 when RA worsened. Interestingly, an additional set of 240 genes became differentially expressed at T3 as might be expected with increasing differences in clinical phenotype between the RA<sub>worsened</sub> and healthy groups as RA worsened. **Conclusions:** In our pilot data, when disease activity improved during pregnancy, expression profiles of numerous RA signature genes became comparable between RA and healthy women. On the other hand, when disease activity worsened, there was an increase in differentially expressed genes during pregnancy.

**1206F****The accuracy of whole genome sequencing and the Platypus variant caller in identifying genetic variation within the structurally challenging epidermal differentiation complex.** *C. Malley<sup>1</sup>, M. Boorgula<sup>2</sup>, S. Chavan<sup>2</sup>, N. Rafaels<sup>2</sup>, D. Leung<sup>3</sup>, K. Barnes<sup>2</sup>, R. Mathias<sup>1</sup>.* 1) Division of Allergy and Clinical Immunology, Johns Hopkins University, Baltimore, MD; 2) Colorado Center for Personalized Medicine, University of Colorado, Department of Medicine, Aurora, CO; 3) Pediatric Allergy and Clinical Immunology, National Jewish Health, Denver, CO.

**Rationale:** Segmental duplications and tandem repeats in the Epidermal Differentiation Complex (EDC; chr1:151972910-153642037) present challenges to sequencing approaches. Within the Atopic Dermatitis Research Network (ADRN), whole genome sequencing (WGS) is available on ~800 subjects. Given the implications of the EDC in development and severity of atopic dermatitis (AD), increased genotype resolution leveraging WGS will aid the search for disease-associated genes. Here, we apply the Platypus variant caller to integrate the calling of structural variants and single nucleotide polymorphisms within a single framework, and evaluate the accuracy of variant calling within the EDC. **Methods:** Three sets of genetic data were available on N=799 European American subjects from the ADRN: 1) 30X WGS generated on the Illumina HiSeq; 2) the OMNI 2.5 GWAS array; and 3) TaqMan genotypes on a set of four variants in the Filaggrin (FLG) gene of prior clinical interest (R501X, 2282del4, R2447X, and S3247X). The Platypus variant caller was run on all subjects to create multi-sample variant call files (VCF) containing both SNPs and indels. Only sites that passed the variant caller flags and genotypes with coverage and/or read quality >7 were retained for analysis. All platypus SNP calls were compared to the OMNI and TaqMan genotype data to determine concordance. This similar pipeline was run on three additional gene regions without known segmental duplication and tandem repeat issues of equal length as the EDC for comparison. **Results:** There were 15,636 SNPs passing QC filters in the EDC with Platypus with mean total coverage per variant of 30,971 (range: 337-46,696). We found a mean of 99% (range: 98-100%) genotype concordance between Platypus and OMNI, from a subset of 850 non-monomorphic transition overlapping SNPs called in both the OMNI and WGS data. Additionally, there was 98% (787 of 799) genotype concordance with TaqMan called FLG variants. Overall coverage and variant calling statistics were comparable to the three other gene regions. **Conclusions:** The Platypus variant caller provides high quality variant calls from whole genome sequencing data rife with structural variation, which has led to unreliable or impossible calls in the past. Platypus-called genotypes are highly concordant with older-generation genotyping array and qPCR data. We are confident in the quality of the software's joint calling for generating squared-off multi-sample VCFs of both SNPs and indels.

**1207W**

**Somatic mutation hunting: The search for the genetic architecture of linear localized scleroderma.** R.G. Higgins<sup>1,2</sup>, M. Theiler<sup>1,3</sup>, A. Smith<sup>1,3</sup>, R. Wächli<sup>1,3</sup>, L. Weibel<sup>1,3</sup>, A.A. Navarini<sup>1,2</sup>. 1) Department of Dermatology, Universitätsspital Zürich, Switzerland; 2) Department of Dermatology, University of Zurich, Switzerland; 3) Kinderspital Zürich, Zürich, Switzerland.

Linear localized scleroderma (LLS) is a rare connective tissue disorder (2.7/100'000 per year) characterised by chronic inflammation and massive accumulation of collagen. This results in hardening and thickening of the lesion leading to the affected areas to cave in from atrophy. The sharply delimited and linear lesions, can affect patients throughout the body and more rarely the face in the clinical subtypes *en coup de sabre* and Parry-Romberg syndrome. This leads to terrible disfigurement. The disease affects mostly children and is limited in treatment options, which are most often unsatisfactory. Very little is understood about the condition in terms of genetic and clinical aetiology. There is evidence that LLS might be based on genetic alterations in affected tissues. Blaschko's lines are the patterns of cell migration and proliferation during embryological development. Multiple skin conditions have been shown to follow Blaschko's lines including LLS. Several of these diseases have been demonstrated to be caused by genetic factors such as a *de novo* somatic mutation causing a cutaneous mosaicism. Here we test the hypothesis that LLS is caused by a somatic genetic mutation. Blood and affected skin taken from 19 confirmed LLS patients was Whole Exome Sequenced (WES). Library preparation and hybridization was performed using the SureSelectXT Reagent kits (Agilent Technologies). Sequence analysis was performed as per GATKv3.5. Somatic mutations were called using 3 somatic callers. All SNPs and indels were analysed and no rare and damaging mutation was found in common. 5 patients had damaging germline SNP mutations in *PRSS3*, a gene involved in metabolism and the immune system. No minor allelic frequency data is available for any of the *PRSS3* mutations found so comparison with internal controls has shown 2 of 5 to be truly rare. An analysis of the 3 somatic callers revealed that an increase in read depth (DP) allowed for a more sensitive detection of mutations at low allelic fraction. To this end 4 patients with similar lesions were chosen for deep sequencing (DP of >300). However, somatic analysis of these samples revealed no suitable causative mutation. CGH was performed on 3 patients to find large scale chromosomal aberrations too large to be detected by WES. Samples were compared with 3000 control karyotypes. No rare aberrations were found in common between patients. Taken together, our analysis revealed the absence of genetic mosaicism in LLS.

***In silico* screening for potentially aberrant novel essential splice sites (PANESS) created by single nucleotide variants (SNVs) in the human genome.** C.C. Bruels<sup>1</sup>, T. Mendoza<sup>2</sup>, J. Khan<sup>2</sup>, H.M. Reddy<sup>1</sup>, E.A. Estrella<sup>2</sup>, M. Lek<sup>4,5,7,8</sup>, B.B. Cummings<sup>4,5,6</sup>, E. Valkanas<sup>4,5</sup>, D.G. MacArthur<sup>1,5</sup>, L.M. Kunkel<sup>3</sup>, F. Modave<sup>2</sup>, P.B. Kang<sup>1,9,10</sup>. 1) Division of Pediatric Neurology, Department of Pediatrics, University of Florida College of Medicine, Gainesville, FL; 2) Department of Health Outcomes & Policy, University of Florida College of Medicine, Gainesville, FL; 3) Division of Genetics & Genomics, Boston Children's Hospital and Harvard Medical School, Boston, MA; 4) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA; 5) Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; 6) Program in Biological and Biomedical Sciences, Harvard Medical School, Boston, MA; 7) School of Paediatrics and Child Health, University of Sydney, Sydney, Australia; 8) Institute for Neuroscience and Muscle Research, Kids Research Institute, The Children's Hospital at Westmead, Sydney, Australia; 9) Department of Molecular Genetics & Microbiology, and Department of Neurology, University of Florida College of Medicine, Gainesville, FL; 10) Genetics Institute and Myology Institute, University of Florida, Gainesville, FL.

The muscular dystrophies are inherited, progressive muscle disorders characterized by destruction and wasting of muscle tissues. Although genetic mechanisms for numerous muscular dystrophies are well defined, many affected patients remain undiagnosed. Whole exome (WES) and whole genome (WGS) sequencing are commonly used to discover pathogenic mutations underlying rare genetic disorders. WES of limb girdle muscular dystrophies (LGMDs) typically identifies pathogenic mutations in approximately 40% of cases. Although exons remain the most common sites of causative mutations, recent studies are increasingly focusing on the identification and characterization of pathogenic mutations in regulatory regions, including canonical RNA splice sites. *In silico* tools currently available for identifying RNA splicing effects examine variants only in or near canonical splice sites at intron/exon boundaries. Whole transcriptome sequencing (RNA-seq) can identify splice sites created outside these boundaries; however, not all cases are amenable to this approach. *In silico* evaluation of existing WES/WGS data can identify potentially aberrant novel essential splice sites (PANESS). We developed a pipeline that uses the ANNOVAR software tool for data file conversion and annotation, and uses code written in Python v.2.7.6 to evaluate the potential effect of SNVs. We used the ExAC v.0.3.1 dataset of human protein-coding genetic variants to validate the pipeline. We applied the validated pipeline to sequence data from two families with uncharacterized neuromuscular disorders. The first family has several individuals affected with LGMD. The pipeline identified 189 low frequency ( $\leq 0.001$ ) variants that formed PANESS on the chromosome containing a previously identified linkage peak, of which 13 variants were within the actual linkage peak. The proband in the second family is affected with myotonia congenita. The pipeline identified 536 variants that created PANESS in 480 genes, 18 of which are involved in other neuromuscular disorders. Further analysis is ongoing to identify the causative mutations in both families. Although specifically designed to assess SNVs that might be involved in neuromuscular disorders, the pipeline is broadly applicable to any disease category. The list of affected genes can be used in pathway, gene ontology, and other *in silico* analyses to prioritize the list of candidate variants prior to laboratory characterization of the effect of the variants.

**1209F**

**Computational prediction and molecular validation of novel therapeutic targets for potent splicing modulators.** D. Gao<sup>1,2,3</sup>, E. Morini<sup>1,2</sup>, M. Salani<sup>1,2</sup>, C. Montgomery<sup>1,2</sup>, S. Erdin<sup>1,2,3</sup>, M.E. Talkowski<sup>1,2,3,4,5</sup>, S.A. Slaugenaupt<sup>1,2,5</sup>. 1) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA; 2) Department of Neurology, Harvard Medical School, Boston, MA; 3) Program in Medical and Population Genetics and Stanley Center for Psychiatric Research, Broad Institute, Cambridge, MA; 4) Departments of Psychiatry and Pathology, Massachusetts General Hospital, Boston, MA; 5) Psychiatric and Neurodevelopmental Genetics Unit, Department of Psychiatry, Massachusetts General Hospital, Boston, MA.

While Mendelian genetics has seen remarkable advances in recent years in the discovery of novel genes and pathogenic mechanisms, therapeutic development remains incremental. One strategy is to discover novel targets for known compounds, and therapeutic targeting of splicing defects is one area in which progress has been made. Here, we applied a combination of computational and molecular approaches to identify such targets. We demonstrate that the pathogenic mechanism underlying familial dysautonomia (FD), namely skipping of exon 20 in the *IKBKAP* gene, is partially rescued by the plant cytokinin kinetin, which improves exon inclusion and increases protein both *in vitro* and *in vivo*. We have developed other kinetin-like splicing modulator compounds (SMCs) to improve drug efficiency and pharmacokinetic properties. However, to what extent SMCs influence splicing across the transcriptome is unclear. We thus conducted a transcriptome-wide *in silico* analysis to identify the sequence signatures that determine response to treatment and to extend the therapeutic usefulness of SMCs. Six independent human fibroblast cell lines from healthy individuals were treated with kinetin and a more potent SMC, BPN-15477. From RNA-seq of these, we investigated splicing by assessing all plausible exon 'triplets' (three consecutive exons) genome-wide. For each triplet, we calculated the Percentage of Splice-in (PSI,  $\psi$ ), or the frequency of inclusion of the middle exon. This analysis revealed 97 events where  $\psi$  changed in response to kinetin and 242 events in response to BPN-15477. We then trained a machine learning approach based on genomic feature enrichment within  $\pm 100$ bp of the middle exons with the most significant  $\psi$  changes and with no  $\psi$  changes. We found that fourteen sequence features were sufficient to distinguish these two groups of middle exons (ROC=0.89). We are using these signatures to predict which disease-causing splice mutations will likely respond to treatment. Our study is an example of coupling machine learning strategies with classic transcriptome analysis to determine potential genomic drug targets.

**Alterations of transcriptome landscaping in head trauma-related human brain disorders.** H. Cho<sup>1,2</sup>, T. Stein<sup>5,6,7</sup>, J. Lee<sup>5,6</sup>, N. Kowall<sup>5,6</sup>, A. McKee<sup>5,6,7</sup>, J. Shin<sup>1,3</sup>, H. Ryu<sup>4,5,6</sup>, J. Seo<sup>1,2,3</sup>. 1) Genomic Medicine Institute, Medical Research Center, Seoul National University, Seoul, 110-799, South Korea; 2) Department of Biomedical Sciences, Biomedical Science Building 117, Seoul, South Korea; 3) Life Science Institute, Macrogen Inc., Seoul, 153-781, Korea; 4) Center for Neuromedicine, Brain Science Institute, Korea Institute of Science and Technology, Seoul, 02792, Korea; 5) VA Boston Healthcare System, Boston, MA, 02132, USA; 6) Boston University Alzheimer's Disease Center and Department of Neurology, Boston University School of Medicine, Boston, MA, 02215, USA; 7) Boston University Chronic Traumatic Encephalopathy Center and Department of Pathology, Boston University School of Medicine, Boston, MA, 02215, USA.

Chronic Traumatic Encephalopathy (CTE) is a neurodegenerative disease that is associated with traumatic brain injury. CTE and Alzheimer's disease (AD) are known to share similar neuropathological features, which mainly consist of the presence of neurofibrillary tangles and hyperphosphorylated tau, but they have generally been described as distinct entities. To better understand the neuropathological mechanism of CTE and AD, we conducted transcriptome sequencing analysis of post-mortem human brain tissue. Moreover, in order to characterize unique or common transcriptome signatures among head trauma-related disorders, we also included postmortem brains with chronic traumatic encephalomyelopathy (CTEM), an amyotrophic lateral sclerosis (ALS)-like disorder, and CTE/AD in the RNA sequencing analysis. Using the weighted gene co-expression network analysis (WGCNA) and principal component analysis (PCA), we found a clear distinction between CTE and CTEM and as well as similar distributions of CTE and AD. Our systematic and comprehensive analysis serves as a framework to reveal important transcriptome signatures that will be useful for the diagnosis of disease progression and the design of therapeutic strategy in head trauma-related neurodegenerative disorders.

**1211T****NIA Genetics of Alzheimer's Disease Data Storage Site (NIAGADS)**

**Genomics Database.** E. Greenfest-Allen<sup>2,4</sup>, P. Gangadharan<sup>2,4</sup>, A. Kuzma<sup>1,2</sup>, L. Qu<sup>1,2</sup>, O. Valladares<sup>1,2</sup>, Y.Y. Leung<sup>1,2,3</sup>, A. Naj<sup>5</sup>, G.D. Schellenberg<sup>1,3</sup>, C.J. Stoeckert Jr.<sup>2,4</sup>, L. Wang<sup>1,2,3</sup>. 1) Penn Neurodegeneration Genomics Center, Department of Pathology and Laboratory Medicine, University of Pennsylvania Perelman School of Medicine; 2) Institute for Biomedical Informatics, University of Pennsylvania Perelman School of Medicine; 3) Institute on Aging, University of Pennsylvania Perelman School of Medicine; 4) Department of Genetics, University of Pennsylvania Perelman School of Medicine; 5) Department of Epidemiology, University of Pennsylvania Perelman School of Medicine.

**Statement of Purpose:** NIAGADS is a national genetics data repository that facilitates access of genotypic data to qualified investigators for the study of late-onset Alzheimer's disease (AD) and related neuropathologies. The GenomicsDB is a searchable annotation resource that provides public access to genome-wide association study (GWAS) summary statistics datasets deposited at NIAGADS. These data are linked to variant and gene annotations and functional genomics datasets, allowing AD researchers to easily identify and interpret interesting genomic regions via detailed record pages, interactive search strategies, and a genome browser. **Methods:** The GenomicsDB is powered by the Genomics Unified Schema (GUS), a relational database system comprising a modular schema capturing sequence data, functional genomics data, and rich descriptions of methodology and study design. GUS uses OBO Foundry ontologies to annotate all captured datasets and associated meta-data, facilitating data harmonization and integration. The GUS system underlying the NIAGADS GenomicsDB is served via an open-source PostgreSQL 9.5 database, optimized for big-data storage and querying. The website is built using the Strategies-WDK system, which provides both a back-end web development kit and a front-end "strategy"-based graphical search interface for functional genomics databases. "Strategies" are interactive graphical workflows that enable sophisticated data-mining of the GWAS summary statistics datasets via filtering, Boolean logic, and comparisons to sequence annotations or uploaded user-data via colocation queries. Strategy results can be saved and shared with other researchers. Searches can be made for specific record types (e.g., variants, genes, genomic regions) and then combined or transformed (e.g., variants to genes) using the Strategies interface. The NIAGADS GenomicsDB also provides a genome browser, built on the GMOD:JBrowse framework, allowing users to visually inspect NIAGADS deposited tracks and compare against personal data. **Results:** As of June 2017, the NIAGADS Genomics Database (<https://www.niagads.org/genomics>) makes available summary statistics from eight NIAGADS GWAS accessions (35 datasets; >150 million variant annotations) for interactive exploration and data-mining. With a newly redesigned search interface and comprehensive record pages linking the summary statistics to variants and genes, the GenomicsDB is a rich resource and valuable tool for AD research.

**1212F****Integrated causal network analysis of genomic and epigenomic data.**

Z.X. Hu<sup>1,2</sup>, N. Lin<sup>2</sup>, P.P. Wang<sup>1</sup>, Y. Zhu<sup>2</sup>, J.Y. Zhao<sup>3</sup>, D.A. Bennett<sup>4</sup>, L. Jin<sup>1</sup>, M.M. Xiong<sup>1</sup>. 1) School of Life Science, Fudan University, Shanghai, China; 2) Department of Biostatistic, Health Science Center at Houston, TX, US; 3) Division of Genetic Epidemiology at the College of Public Health and Health Professions and the College of Medicine at the University of Florida; 4) Rush Alzheimer's Disease Center, Rush University Medical Center, Chicago, IL 60612, USA.

The generation of large multiscale omic data requires new methods for integration with phenotypic data in terms of breadth and depth. Many extant approaches perform analyses individually and separately. The traditional analytic platforms for analyzing biological datasets use association or correlation analysis. However, systematic omic data analysis needs to uncover causal relationships among various molecular components, which form complex biological systems. How to identify the causal relationship inherent in multiscale omics and clinical phenotypes and perform integrated analysis of WGS, other omics data, and clinical data is a key issue to the analysis. Deep analyses of high dimensional and heterogeneous types of correlated omic and clinical data pose huge challenges. We develop a unified analytical framework for systematic causal decomposition through novel statistical methods of trans-omic networks integrating heterogeneous genomic, environmental, RNA-seq, DNA methylation and phenotypic data into multilayer networks underlying disease and health. The proposed method was applied to genetic and epigenetic studies of five diseases: hypertension, obesity, type 2 diabetes, Alzheimer's disease (AD), and Lewy Body disease to infer causal genotype-environment-expression-phenotype-disease networks. The inferred network consists of **58,207 nodes** and **192,939 edges**. We found that **960 Genes** were directly connected to phenotype nodes, **1501 genes** to the disease nodes in the causal networks and that **395 genes** and **2088 methylated genes** were connected to **609 gene expression nodes**. **14,368 paths** were identified from these genes to diseases. Several notable features emerge. 1) Several genes such as *HLA-DRB6*, *HLA-DQA1 / HLA-DQB1*, *NFKB1* and *POU3F2 (Bm2)* that play an essential role in AD via expression and methylation causal networks were identified. 2) **Half of the edges** in the signaling pathways were consistent with the pathway structure in the KEGG pathway database. 3) Several diseases appear to share common disease risks, pathways and genes. For example, the *HLA-DRB5* gene, its expression, and methylation, all had direct effects on AD, hypertension, and obesity, and AD share gene *CREBBP*, and hypertension, obesity and Lewy body disease share gene *KMT2C*. 4) Causal omic network analysis can identify the causal pathways from gene to disease via environment, gene expression and phenotype (risk factors) that was supported by literatures.

**FGWAS: Functional Genome Wide Association Analysis.** C. Huang<sup>1</sup>, P. Thompson<sup>2</sup>, Y. Wang<sup>3</sup>, J. Zhang<sup>1</sup>, D. Kong<sup>4</sup>, R. Colen<sup>5</sup>, R. Knickmeyer<sup>6</sup>, H. Zhu<sup>1</sup>. 1) Department of Biostatistics, The University of Texas MD Anderson Cancer Center, Houston, TX and University of North Carolina at Chapel Hill, Chapel Hill, NC, USA; 2) Imaging Genetics Center, Stevens Institute for Neuroimaging and Informatics, University of Southern California, Marina del Rey, CA, USA; 3) School of Computing, Informatics, and Decision Systems Engineering, Arizona State University, Tempe, AZ, USA; 4) Department of Statistical Sciences, University of Toronto, Toronto, Ontario, Canada; 5) Department of Diagnostic Radiology, The University of Texas MD Anderson Cancer Center, Houston, TX, USA; 6) Department of Psychiatry, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

**Introduction:** Functional phenotypes (e.g., subcortical surface representation), which commonly arise in imaging genetic studies, have been used to detect putative genes for complexly inherited neuropsychiatric and neurodegenerative disorders. However, existing statistical methods largely ignore the functional features (e.g., functional smoothness and correlation). **Methods and Results:** The aim of this paper is to develop a functional genome-wide association analysis (FGWAS) framework to efficiently carry out whole-genome analyses of functional phenotypes. FGWAS consists of three components: a multivariate varying coefficient model, a global sure independence screening procedure, and a test procedure. Compared with the standard multivariate regression model, the multivariate varying coefficient model explicitly models the functional features of functional phenotypes through the integration of smooth coefficient functions and functional principal component analysis. Statistically, compared with existing methods for genome-wide association studies (GWAS), FGWAS can substantially boost the detection power for discovering important genetic variants influencing brain structure and function. Simulation studies show that FGWAS outperforms existing GWAS methods for searching sparse signals in an extremely large search space, while controlling for the family-wise error rate. We have successfully applied FGWAS to large-scale analysis of data from the Alzheimer's Disease Neuroimaging Initiative for 708 subjects, 30,000 vertices on the left and right hippocampal surfaces, and 501,584 SNPs. **Conclusion:** Three key advantages of FGWAS have been discovered: (i) the spatial correlation structure of imaging data and variability of multiple phenotypic measurements considered in the multivariate varying coefficient model; (ii) much lower computational complexity compared to standard functional GWAS, and (iii) a parallel computing strategy that makes FGWAS feasible for super large-scale genetic data. Our FGWAS is a valuable statistical toolbox for fast, large-scale imaging genetic analysis.

**NIA Genetics of Alzheimer's Disease Data Storage Site (NIAGADS): Update 2017.** H. Lin<sup>1,2</sup>, O. Valladares<sup>1,2</sup>, A. Kuzma<sup>1,2</sup>, E. Greenfest-Allen<sup>2,4</sup>, P. Gangadharan<sup>1,2</sup>, D. Childress<sup>1,2</sup>, R. Cweibel<sup>1,2,3</sup>, C. Zhong<sup>1,2</sup>, Y. Zhao<sup>1,2</sup>, L. Qu<sup>1,2</sup>, Y. Leung<sup>1,2,3</sup>, A. Naj<sup>1,5</sup>, C. Stoeckert Jr.<sup>1,2,4</sup>, G. Schellenberg<sup>1,3</sup>, L. Wang<sup>1,2,3</sup>. 1) Penn Neurodegeneration Genomics Center, University of Pennsylvania, Philadelphia, PA; 2) Institute for Biomedical Informatics, University of Pennsylvania, Philadelphia, PA; 3) Institute on Aging, University of Pennsylvania, Philadelphia, PA; 4) Department of Genetics, University of Pennsylvania, Philadelphia, PA; 5) Department of Epidemiology, University of Pennsylvania, Philadelphia, PA.

**Statement of Purpose:** NIAGADS is a national genetics data repository that facilitates access of genotypic data to qualified investigators for the study of the genetics of late-onset Alzheimer's disease (AD) and other neurological diseases. Collaborations with large consortia such as the Alzheimer's Disease Genetics Consortium (ADGC) and the Alzheimer's Disease Genome Sequencing Project (ADSP) allow NIAGADS to lead the effort in managing large AD datasets that can be easily accessed by the research community and utilized to their fullest extent. **Methods:** Since 2012, NIAGADS has been supported by National Institute on Aging (NIA) under a cooperative agreement (U24 AG041689). All data derived from NIA funded AD genetics studies are expected to be deposited in NIAGADS or another NIA approved site. NIAGADS has partnered with the database of Genotypes and Phenotypes (dbGaP) and the Sequencing Read Archive (SRA) in this effort. NIAGADS is continually developing new databases to facilitate neurodegenerative research. The redesigned NIAGADS Genomics Database is a searchable annotation resource that links published AD studies to AD-relevant sequence features and genome-wide annotations. Based on INQuery developed by CNDR at Penn, the redeveloped genotype/phenotype database allows qualified users to log in and filter for subjects with a particular phenotype and genotype and see if there is a DNA sample available at the National Cell Repository for AD (NCRAD). **Results:** As of June 2017, NIAGADS houses 44 datasets with >55,000 samples and over 24 billion genotypes. With the completion of the Discovery Phase of ADSP, qualified investigators can retrieve sequencing data with ease and flexibility using the ADSP website and data portal (collaboration with dbGaP/SRA). The ADSP project has completed whole-exome sequencing of 10,939 subjects and whole-genome sequencing of 4,036 subjects; raw data as well as quality controlled VCF files for the Discovery Phase are available through the ADSP portal and dbGaP. **Conclusions:** NIAGADS is a rich resource for AD researchers. Datasets, guidelines, and new features are available on our website at <https://www.niagads.org>.

**Statement of Purpose.** The Alzheimer's Disease Sequencing Project (ADSP) was established in 2012 as a key initiative to meet the goals of the National Alzheimer's Project Act (NAPA) to prevent and effectively treat Alzheimer's disease (AD) by 2025. Developed jointly by National Institute on Aging (NIA) and the National Human Genome Research Institute (NHGRI), the aims of the ADSP are to: 1) identify protective genomic variants in older adults at risk for AD, 2) identify new risk variants among AD cases, and 3) examine these factors in multi-ethnic populations to identify therapeutic targets for disease prevention. **Methods.** The ADSP Data Flow Work Group (DFWG) and the NIA Genetics of Alzheimer's Disease Data Storage Site (NIAGADS) support data production, sharing and management for the ADSP, and facilitation of data access to the community. Samples are contributed by the AD Genetics Consortium (ADGC) and Cohorts for Heart and Aging Research in Genomic Epidemiology consortium (CHARGE). Sample plating and shipping is coordinated by the National Cell Repository for AD (NCRAD). Whole-exome (WES) and whole-genome (WGS) sequencing data were generated by three NHGRI funded Sequencing Centers and quality controlled by the ADSP. The DFWG maintains the ADSP web site, providing study design, cohort information, news releases, and application instructions for ADSP access. The ADSP Data Portal is a collaboration with the Database of Genotypes and Phenotypes (dbGaP), Sequence Read Archive (SRA), and NIAGADS. The portal allows users to explore the ADSP project data archived at dbGaP with NIH iTrust user authentication. Approved investigators identify data and download files using a customizable filtering system and check-out cart function. **Results.** The ADSP has completed whole-exome sequencing of 10,939 unrelated cases and controls, whole-genome sequencing of 892 members from 159 families, and whole-genome sequencing of 3,144 unrelated cases and controls. All newly sequenced genomes are being processed on GRCh38 by the Genome Center for AD (GCAD) and are expected to be available in late 2017. Accompanying each sample are phenotypes that were harmonized according to ADSP protocols. **Conclusion.** The DFWG provides support to all ADSP Work Groups for data related issues, coordinates with dbGaP for data transfers, and reviews, posts, and notifies members of new results generated by other Work Groups. Find additional information at the ADSP website ([www.niagads.org/adsp](http://www.niagads.org/adsp)).

**1216W****Personalized and cell-specific pathway score computations from risk alleles and regulatory information in 2370 subjects with multiple sclerosis.**

L.R. Madireddy<sup>1</sup>, K. Kim<sup>1</sup>, S.J. Caillier<sup>1</sup>, S.L. Hauser<sup>1</sup>, J.R. Oksenberg<sup>1</sup>, S.E. Baranzini<sup>1,2</sup>. 1) Department of Neurology, Weill Institute for Neurosciences, University of California San Francisco, San Francisco, USA; 2) Institute for Human Genetics, University of California San Francisco, San Francisco, USA.

More than a decade of successful GWA studies on Multiple Sclerosis (MS) has revealed close to 200 genetic loci associated with MS. However, progress on functional characterization, cell type specificity, and prioritization of genes within each of these loci has been very limited. To address these biologically important questions, we developed a novel bioinformatics and network based pipeline where the most functionally associated gene per region and cell type are identified, leveraging multiple sources of evidence including ENCODE and Roadmap Epigenomics Project. Gene regulatory data were scraped from RegulomeDB website for SNPs that passed a p-value threshold of  $10^{-4}$  in a large meta-analysis with ~ 47,000 patients and for the SNPs tagging them. We then grouped experiments into 10 cell type buckets of potential interest for MS. In addition, we classified histone modifications into 3 broad categories representing transcriptional promotion/quiescence/repression. We computed normalized weights for each SNP based on number of times the SNP is shown to be associated with a particular regulatory activity in that particular cell type. These weights were summed across SNPs to compute sum of weighted weights per gene per region across cell types. We ascribed a gene to a region per cell type based on the gene that has highest absolute sum of weighted weights score in that cell type in that region. We next overlapped the gene regulatory potential with an existing protein interaction network, and performed a topological analysis from the resulting sub networks at each cell type. We observed a significant enrichment of interactions across prioritized genes at various cell types compared to the number of connections from randomly generated networks. Finally, we computed individual regulatory burden scores across genes and cell types for 2782 samples from UCSF and observed individualized cell-specific association patterns. This method is relevant for prioritization of genes within a region, and for individualized risk stratification, where networks of associated genes in different cell types can be potentially used to inform therapeutic approaches or disease management strategies. This novel approach will open new avenues to integrate past and future GWA studies with publicly available regulatory information and shines more light on the functional aspects of disease etiology and on the use of individual genetic scores to discover associations with additional phenotypes.

**Omic-based machine learning modeling of monogenic neurological diseases.** J.A. Botía<sup>1,2</sup>, S. Guelfi<sup>1</sup>, K. D'sa<sup>1,3</sup>, J. Vandrovčova<sup>1</sup>, H. Houlden<sup>1</sup>, J. Hardy<sup>1</sup>, M. Ryten<sup>1,3</sup>. 1) Molecular Neuroscience, University College London, London, United Kingdom; 2) Departamento de Ingeniería de la Información y las Comunicaciones, Universidad de Murcia, Spain; 3) Medical and Molecular Genetics, King's College London, United Kingdom.

Dysfunction of the central and peripheral nervous system is a feature of around 50% of all rare diseases. Yet we know relatively little about why some genes give rise to human brain diseases, whereas others do not. In order to address this question we used machine learning (ML) to model genes associated with neurological diseases from their omics-based features. These features, which are used as predictors, included: i) gene-based measures of mutational constraint generated by ExAC (e.g. probability of intolerance to loss of function or missense variants); ii) gene complexity measures derived from GENCODE (e.g. gene length, and number of transcripts per gene); and iii) tissue-specific gene expression and co-expression metrics generated using GTEx V6 gene expression data covering 47 human tissues (e.g. adjacency for global hubbiness and module membership for local connectivity). We used the Genomics England Panel App to obtain expertly curated lists of genes associated with a range of neurological and neurodevelopmental disorders. Non-disease genes, were defined as all genes not currently known to be linked to any disease. We developed a bootstrapped decision tree model (BDTM) of  $n=200$  trees for each disease gene panel containing  $>10$  genes ( $n=23$ ). This led to the construction of 23 classifiers, one for each disease type, with an additional classifier, which used all genes associated with any neurological or neurodevelopmental disorder. Using this approach the BDTM created using all neuro-genes predicted 276 new neuro-genes (threshold of 99% agreement on trees within the BDTM). Interestingly, using the Mouse Phenotype Database, we found that this gene list was significantly enriched for genes associated with abnormal neuron morphology ( $p\text{-value} = 1.39 \times 10^{-6}$ ) and abnormal synaptic transmission ( $p\text{-value} = 1.79 \times 10^{-6}$ ) amongst other phenotypes. Furthermore, using DisGeNET, a database of genotype-phenotype associations including those generated through genome-wide association studies, we identified 14 disease-specific enrichment signals including addiction related disorders ( $p\text{-value} = 4.53 \times 10^{-13}$ ), glioblastoma ( $p\text{-value} = 1.11 \times 10^{-7}$ ), autism spectrum disorders ( $p\text{-value} 2.63 \times 10^{-4}$ ), schizophrenia ( $p\text{-value} = 3.56 \times 10^{-2}$ ) and Alzheimer's disease ( $p\text{-value} = 7.08 \times 10^{-3}$ ). Thus, we demonstrate both the predictive and explanatory power of ML-based models in the context of neurological and neurodevelopmental diseases.

**Identification of tolerated reading-frame changes induced by stop-lost and frame-shift variants in Alzheimer's disease.** M. Butkiewicz, J.L. Haines, W.S. Bush for the Alzheimer's Disease Sequencing Project. Epidemiology and Biostatistics, Case Western Reserve University, Cleveland, OH.

**Background:** With increasing life expectancy, Late Onset Alzheimer's disease (LOAD) is affecting an expanding population of elderly individuals and is a growing sociological and financial burden on society. Genetic variants that contribute to a 'change-of-function' character for gene transcripts are of interest with respect to disease pathogenesis. Here, we aim to identify tolerated reading-frame changes within a cohort of well-aged individuals, and to then prioritize variants within a cohort of late onset Alzheimer's disease. **Methods:** We analyzed a whole-genome sequencing (WGS) dataset, comprised of 578 individuals from 111 European Caucasian and Caribbean Hispanic families, from the Alzheimer's Disease Sequencing Project (ADSP), an initiative to identify genetic variation associated with LOAD risk. As a control, we accessed WGS called variants from the Welllderly study, a cohort of 511 successfully aged individuals, older than 80 years, without significant medical conditions. Both datasets were analyzed by COCOS, a recently published plugin for the Ensembl variant effect predictor (VEP), which provides information about the altered reading frame and the translated protein sequence changes resulting from stop-lost variants and small insertions and deletions (InDels). We determined whether these variant-induced reading-frame changes would affect functional domains within the translated protein sequence using the Pfam database, as well as sequence similarity compared to the unaltered protein sequence. **Results:** Applying the COCOS VEP plugin, we identified reading-frame altering variants in the ADSP (9,593 InDels, 352 stop-lost) and the Welllderly (11,450 InDels, 428 stop-lost) datasets. An overlap of 986 InDels was observed for the ADSP (986/9,593=10%) when compared to the Welllderly (986/11,450=9%). 55% (542/986) of the overlapping ADSP InDels induced reading-frame changes leading to a disruption in at least one Pfam domain, and exhibited an average sequence similarity of 16% compared to the original protein sequence. Also, 83 stop-lost variants were overlapping between the Welllderly (83/428=19%) and ADSP (83/352=24%). Overlapping InDels and stop-lost variants can be seen as a reduction in number of variants to test with respect to AD. **Conclusions:** Considering the Welllderly cohort as a source for seemingly more tolerated variation, the overlap of reading-frame changing variants between the ADSP and Welllderly cohorts suggests a reduced significance to AD risk.

**Missense variant interpretation based on mutational burden at analogous amino acid positions across gene family members.** E. Perez-Palma<sup>1</sup>, P. May<sup>2</sup>, P. Nürnberg<sup>3</sup>, M. Daly<sup>2,4,5</sup>, A. Palotie<sup>3,4,5,6</sup>, D. Lal<sup>1,3,4,5</sup>. 1) Cologne Center for Genomics, University of Cologne, Cologne, NRW, Germany; 2) Luxembourg Centre for Systems Biomedicine, University Luxembourg, Luxembourg; 3) Massachusetts General Hospital, Boston, MA, USA; 4) Harvard Medical School, Boston, MA, USA; 5) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, USA; 6) Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland.

Missense variants are the most frequent disease-associated mutations, but also the most challenging to interpret. Current *in silico* methods are imperfect in predicting their functional consequences and potential disease trajectories. Ultra large exome aggregation approaches such as gnomAD have allowed to identify and score genes and exons intolerant for missense variants. However, these do often not show high enough accuracy and the number of variants is still too low to calculate intolerance with amino acid resolution. We have recently shown that paralogous conserved amino acids are more likely than non-conserved residues to give risk to disease when mutated. In the present work, we propose a novel framework using the total amount of variants of the whole gene family to calculate gene-specific local constrained scores with amino acid resolution. We hypothesize that paralogous amino acid positions across the whole gene family are essential when never mutated in individuals from the general population. Gene families and paralog definition were retrieved from the maximum likelihood phylogenetic gene trees provided by Ensembl. For each gene, the longest CCDS isoform was considered. Non-coding genes and genes without a HGNC symbol were excluded. All alignments were performed using the multiple sequence comparison by log-expectation (MUSCLE) software. Mutations from the general population were extracted from the genome Aggregation Database (gnomAD, version 2.0), neurodevelopmental disorders (NDDs) mutations were extracted from ClinVar database (March 15, 2017). In total, we generated 2,871 gene families with at least 80% identity in their amino acid sequence comprising a total of 9,991 genes. We were able to map 2,219,811 and 97,391 missense mutations from gnomAD and ClinVar, respectively, into these alignments. Gene-specific local constrained scores were generated using a sliding window approach evaluating the proportion of gnomAD variants found among the alignments of each gene family. Our approach allowed to identify mutation-constrained paralog domains enriched for *de novo* variants from 11,000 trios with NDDs and ClinVar variants. Our derived gene-specific scores identify sites in proteins which are never mutated in the general population at the same position across proteins from the same gene family. In particular, in large gene families, such as ion channels, our approach will facilitate variant interpretation and identify functionally essential domains.

**Evaluation of basic massive parallel sequencing parameters in relation to true/false positivity's findings of rare variants from an isolated population from South-Eastern Moravia in the Czech Republic with high incidence of Parkinsonism.** R. Vodicka<sup>1</sup>, R. Vrteš<sup>1</sup>, K. Kolarikova<sup>1</sup>, M. Prochazka<sup>1</sup>, K. Mensikova<sup>2</sup>, P. Kanovsky<sup>2</sup>. 1) Department of Medical Genetics, University Hospital, Olomouc, Czech Republic; 2) Department of Neurology Faculty of Medicine and Dentistry, Palacky University, University Hospital, Olomouc, Czech Republic.

Introduction: Massive Parallel Sequencing (MPS) in 16 genes known to be associated with Parkinsonism including coding DNA, intron/exon boundaries and UTRs loci was used to find rare variants in 30 patients and 12 healthy controls from an isolated population of South-Eastern Moravia in the Czech Republic. Epidemiological data show significantly increased prevalence of Parkinsonism (2.9%). Aim of the study: To evaluate true/false positivity ratio in relation to the basic MPS sequencing parameters (coverage, type of mutation – SNV/INDEL, percentage of rare variants in case of heterozygosity, +/- strand bias and length of homopolymers) in the 16 genes associated with Parkinsonism (ADH1C, ATP13A2, EIF4G1, FBXO7, GBA + GBAP1, GIGYF2, HTRA2, LRRK2, MAPT, PARK2, PARK7, PINK1, PLA2G6, SNCA, UCHL1 and VPS35). Study was supported by MH CZ – DRO (FNOI, 00098892). Method: Final filtered out rare variants were obtained from the Ion Torrent platform with workflow as following: Torrent Suite - Base calling and BAM mapping; IonReporter - Variant calling and rare variant filtering. True from false positivity findings were distinguished by Sanger confirmation sequencing. Results: In total, there were found 36 rare variants (MAF < 1 %) from which 50 % of them were confirmed as true positive. In case of SNV, the probability of false positivity is 11.7 % while in INDEL the false positivity proportion is 84 %. Very interesting indicator of true positivity could be high correlation in strand biases of reference and rare variants in heterozygous findings. Variants were then filtered using following parameters: AQ > 20; Read coverage > 10; MAF < 0,01; SIFT: 0 - 0,05 and/or PolyPhen-2: 0,2 - 1. The most important and Sanger confirmed variants: three missense mutations were found in LRRK2 gene: rs33995883 in 6/0 patients/control (p/c), rs33958906 in 1/1p/c, rs781737269 in 3/0p/c, one missense mutation in MAPT gene rs63750072 in 6/1p/c and one mutation in HTRA2 gene rs72470545 in 3/1p/c. Conclusion: Our findings could contribute: 1) to the improvement of NGS data analysis with respect to false positivity from true positivity variant calling recognition 2) to further understanding of molecular pathogenesis of Parkinsonism 3) to the creation of clinically applicable diagnostic procedure.

**1221F**

**A statistical inference framework to improve functional prediction of missense variants in neurodevelopmental disorders.** J. Du<sup>1</sup>, E. Pérez-Palma<sup>2</sup>, P. May<sup>2</sup>, P. Nuernberg<sup>1,3,4</sup>, M. Daly<sup>5,6,7</sup>, A. Palotie<sup>5,6,7,8</sup>, D. Lal<sup>1,5,6,7</sup>. 1) Cologne Center for Genomics, Cologne, NRW, Germany; 2) Luxembourg Centre for Systems Biomedicine, University Luxembourg, Esch-sur-Alzette, Luxembourg; 3) Cologne Excellence Cluster on Cellular Stress Responses in Aging-associated Diseases (CECAD), University of Cologne, Cologne, NRW, Germany; 4) Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, NRW, Germany; 5) Massachusetts General Hospital, Boston, MA, USA; 6) Harvard Medical School, Boston, MA, USA; 7) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, USA; 8) Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland.

Many *in silico* methods have been recently developed to predict the effect of missense variants. However, these prediction algorithms do not accurately distinguish between functional and neutral missense variants. In addition, each gene has a different evolutionary and population constraint and the distribution of variant scores is gene-specific. Current pathogenicity prediction methods score each variant without informing whether the observed variant score is similar to or significantly different from the expected score in individuals of the general population. The inability to evaluate whether the observed variant score is exceptional minimizes the interpretation power of the available methods. Therefore, in this study, we present a statistical inference framework to guide functional prediction of missense variants using various variant prediction tools. **Methods and Results:** The genome Aggregation Database (gnomAD, version 2.0), encompassing 4,483,391 missense variants in 138,632 individuals, was used as a reference set for genetic variants in the general population. All missense variants were annotated to the corresponding canonical transcripts. Established methods for variant interpretation such as SIFT, GERP, CADD and EIGEN were employed together with novel prediction tools developed in our group. Based on these measures we developed a one-sided testing framework that scores missense variants of interest and calculates the likelihood for observing variants with such scores in the gnomAD reference set. Currently, the framework is applied to *de novo* missense variants identified in our cohort (N = 11k) of patients with neurodevelopmental disorders and disease databases (including ClinVar and HGMD). Our approach provides a novel statistical framework for leveraging large population data to easily identify exceptional disease variant scores across a large range of variant prediction tools. The method will allow ranking thousands of variants from a whole exome data set of an individual patient to bring only a few highly significantly different variants to our attention. The framework is implemented in Python and will be freely available as an online tool.

**Assessment of lesion-associated gene and variant pathogenicity in focal human epilepsies.** L.M. Neupert<sup>1</sup>, P. May<sup>2</sup>, K. Kobow<sup>2</sup>, M. Nothnagel<sup>1</sup>, P. Nürnberg<sup>1</sup>, T. Freiman<sup>4</sup>, P. Harter<sup>4</sup>, K.M. Klein<sup>4</sup>, Y. Weber<sup>5</sup>, M. Daly<sup>6,7,8</sup>, A. Palotie<sup>6,7,8,9</sup>, I. Blümcke<sup>3</sup>, D. Lal<sup>1,6,7,8</sup>. 1) Cologne Center for Genomics, Cologne, NRW, Germany; 2) Luxembourg Centre for Systems Biomedicine, University Luxembourg, Luxembourg; 3) University Hospital Erlangen, Germany; 4) Epilepsy Center Frankfurt Rhine-Main, Germany; 5) Hertie Institute for Clinical Brain Research, Germany; 6) Massachusetts General Hospital, Boston, MA, USA; 7) Harvard Medical School, Boston, MA, USA; 8) Stanley Center for Psychiatric Research, Broad Institute of MIT and Harvard, Cambridge, MA, USA; 9) Institute for Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland.

Germline and brain-specific somatic variants have been reported as an underlying cause in patients with epilepsy-associated neuropathologies, including focal cortical dysplasias (FCDs) and long-term epilepsy associated tumors (LEAT). However, evaluation of identified neuropathology-associated variants in genetic screens is complex since not all observed variants contribute to the etiology of neuropathologies not even in genuinely disease-associated genes. Here, we critically reevaluated the pathogenicity of 12 previously published disease-related genes and of 88 neuropathology-associated missense variants listed in the PubMed and ClinVar databases. We (1) assessed the evolutionary gene constraint using the *pLI* and the missense *z* score, (2) used the latest American College of Medical Genetics and Genomics (ACMG) guidelines, and (3) performed bioinformatic variant pathogenicity prediction analyses using PolyPhen-2, CADD, and GERP. Constraint analysis classified only seven out of 12 genes to be likely disease-associated. Furthermore, 35 (40%) of 88 neuropathology-associated missense variants were classified as being of unknown significance (VUS) and 53 (60%) as being likely pathogenic (LP1). Pathogenicity prediction yielded a clear discrimination between LP1 variants and a milder discrimination for VUS compared with rare variant scores from individuals present in the Genome Aggregation Database (gnomAD). In summary, our results demonstrate that interpretation of variants associated with neuropathologies is complex while the application of current ACMG guidelines including bioinformatic pathogenicity prediction can help improving variant evaluation. Furthermore, we will augment this set of literature-identified variants at the conference by results from our variant screen using self-generated deep sequencing data in >150 candidate genes in >50 patients not yet analyzed.

**Accurate identification of de novo structural variants in a trio using a reference agnostic, rapidly queryable format to reduce the proportion of unsolved cases.** *S.N. Shekar<sup>1</sup>, L. Herta<sup>1</sup>, W.J. Salerno<sup>2</sup>, A.C. English<sup>1,2</sup>, C.A. Brownstein<sup>4,5</sup>, J. Gonzalez-Heydrich<sup>1</sup>, A. Mangubat<sup>1</sup>, J. Bruestle<sup>1</sup>, E. Boerwinkle<sup>1,3</sup>, R.A. Gibbs<sup>1</sup>.* 1) Fabric Genomics, Oakland, CA; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, Texas, USA; 3) Human Genetics Center, University of Texas Health Science Center, Houston, Texas, USA; 4) Boston Children's Hospital, Boston, MA; 5) The Manton Center for Orphan Disease Research, Division of Genetics and Genomics, Boston Children's Hospital, Boston, MA.

Detecting structural genetic changes (SVs) that are de novo could reduce the proportion of unsolved cases. Currently, SV callers can exhibit upwards of a 50% false discovery rate (English et al, 2015) with ambiguity in the breakpoint coordinates. This makes it difficult to compare calls between the proband and the parents. Here, we detect de novo variants using the Biograph Analysis Format (BAF), a method of indexing NGS data that is reference agnostic and rapidly searchable. To show consistency of calls using this Format, we confirm SV identified by the caller Pindel using overlap assembly in a Ashkenazi Jewish Trio from the Personal Genome Project. Of 1,195 calls that showed evidence in the reads of at least one individual, all except for 25 (2.1%) were consistent with mendelian inheritance. In all cases that the variant was called in multiple samples, the variant was reported exactly the same. For variants that did not follow mendelian inheritance, there was insufficient coverage in regions flanking the breakpoint in at least one individual. In a further case where the proband and both parents genomes were sequenced at 30x coverage using an Illumina HiSeq, we used Anchored Assembly on the proband sample, a caller that uses read overlap assembly to detect variants (English et al, 2015). We called 2,383 genetic changes that were either an insertion or deletion (> 50 base pairs) in the proband. To confirm whether there was evidence of each of these variants in the parents, we search for the count of reads that contain the 50mer that is unique to the breakpoint junction. Of the 2,383 variants, 98 showed, prima facie, evidence of being de novo. 18 of these variants were heterozygous in the proband. Although there was no evidence for the variant in either parent, at least one parent showed a drop in coverage. Of the remaining 80 variants that were homozygous in the proband, the variant was present in at least one parent with the other parent either having no coverage at that location (68 variants) or low reference (12 variants, < 9 reads). Overall, this is suggestive that these variants are more likely to be due to a lack of coverage than true de novo variants. This analysis was completed in 18 hours. Although, we didn't confirm a true de novo SV, calling with a low FDR and rapid search of read data can be used to detect and rule out candidate de novo variants quickly.

**1224F**

**A single-cell transcriptome atlas of mouse hypothalamus: Identification and characterization of high-fat diet and GLP-1 responding arcuate nucleus cell types.** *P.N. Timshel, M.A. Bentsen, J. Lee, T.H. Pers.* Novo Nordisk Foundation Center for Basic Metabolic Research, University of Copenhagen, Copenhagen, Denmark.

**Background:** A key challenge for gaining biological insights from genetic associations is to identify etiological cell types and pathways. Genome-wide association studies (GWAS) have identified numerous genetic variants associated with body mass index (BMI). Functional studies using gene expression data of genes in BMI-associated genetic loci have emphasized the role of the brain in predisposition to obesity. However, these studies have been conducted at the brain area level as opposed to the cell-type level. Key appetite regulating brain nuclei reside within the hypothalamus. The arcuate nucleus is one of the key areas and importantly, it has recently been shown that an approved weight-loss drug, liraglutide (a GLP-1 analogue), acts in the ARC. Yet our understanding of the molecular mechanisms behind the effects of GLP-1 analogue treatment remains incomplete. **Data:** We used droplet-based single-cell RNA sequencing (10x Genomics protocol) to construct transcriptional atlases of mouse ARC cell types from four groups of C57BL/6J mice: 1) diet-induced obese (DIO) fed ad libitum, 2) DIO treated with 400 mg/kg liraglutide for three weeks, 3) pair-fed vehicle control and 4) chow fed control. In total, we profiled > 60,000 single-cell transcriptomes. **Methods:** We developed and applied a computational method to integrate single-cell transcriptomic data with GWAS summary statistics, to prioritize cell types and cell-type specific pathways. Our method uses matrix factorization models to decompose the biological components and cellular heterogeneity captured in our ARC cell atlases. **Results:** Liraglutide treated mice lost 17±2% weight from baseline, pair-fed lost 10±2%, whereas DIO mice fed ad libitum lost 2±1% and chow fed mice gained 1±1%. We compared cell types across each group of mice, and identified GLP-1 and high-fat diet responsive cell types. Using our computational method and BMI GWAS data, we prioritized BMI-relevant cell types and pathways. **Conclusion:** Single-cell transcriptomic profiling of the ARC enable identification of brain cell types responding obesity relevant physiological regimes. Finally, we show that integrating genetic data with single-cell transcriptomics is a powerful way of gaining cell-type and pathway etiological insights for human complex traits.

**1225W**

**The GCAD workflow for processing 5000 whole genomes and 11,000 whole exomes from the Alzheimer's Disease Sequencing Project using Amazon cloud.** Y.-F. Chou<sup>1,2</sup>, Y.Y. Leung<sup>1,2</sup>, O. Valladares<sup>1,2</sup>, A.B. Kuzma<sup>1,2</sup>, L. Cantwell<sup>1</sup>, L. Qu<sup>1,2</sup>, H.-J. Lin<sup>1,2</sup>, P. Gangadharan<sup>1,2</sup>, Y. Zhao<sup>1,2</sup>, J. Malamon<sup>1</sup>, A.D. Sequencing Project (ADSP)<sup>1</sup>, A. Naj<sup>1</sup>, W.J. Salerno<sup>3</sup>, G.D. Schellenberg<sup>1,2</sup>, L.-S. Wang<sup>1,2</sup>. 1) Penn Neurodegeneration Genomics Center, Department of Pathology and Laboratory Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 2) Institute for Biomedical Informatics, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX.

Late-Onset Alzheimer's Disease (AD) is a devastating disease that will affect 16 million Americans by 2050. Established in 2016, the Genome Center for Alzheimer's Disease (GCAD) aims to coordinate the integration and meta-analysis of all available AD relevant genetic data with the goal of identifying AD risk and eventual therapeutic targets. It involves the collaboration of diverse scientists within the Alzheimer's disease sequencing project (ADSP) and GCAD. With the vision to minimize data heterogeneity and to efficiently process thousands of genomes, GCAD has built an Amazon cloud-based pipeline that is 1) fully designed and optimized for large scale production of WGS/WES data; 2) interactive with a tracking database that can display a variety of quality metrics instantly; and 3) developed in coordination with other NIH programs including TOPMed and the CCDG. This pipeline takes an input FASTQ/BAM file and re-maps to the hg38 genome assembly using BWA. Supplementary alignments are retained for downstream SV optimization. It then performs duplicate marking, base recalibration, indel-realignment and quality score binning using GATK 3.7. Next, it performs SNV genotype calling using GATK. All individual gVCFs from WES and WGS are scaled and aggregated to a project level file by joint genotype call. The final output contains all possible sites for every genotype position, allowing for easy comparison across genomes from other sequencing projects. Together with the pipeline, a live statistics page is built and supported by a database which stores >100 quality metrics on each sequenced sample. These include information on how the sequencing is performed, processing time, metrics on BAM quality and genome-wide statistics of the called SNPs and indels. On average, the workflow can process a complete genome in <30 hours. The pipeline is available through bitbucket ([https://bitbucket.org/GCAD/SNV\\_pipeline/](https://bitbucket.org/GCAD/SNV_pipeline/)) and as an Amazon image (ami-e6df35f0). To date, we have processed 5,000 WGS and 11,000 WES from 26 different cohorts of European, Caribbean Hispanic, and African American descent, which are deeply sequenced across 5 sequencing centers at mean depth 30X (WGS) and 75% of targeted regions at >20x coverage for WES. From the WGS data, 21M novel SNPs were discovered across these sequenced individuals. Among the discovered, 23% were singletons present in a single individual. 39.6M SNPs has reached 99.8% sensitivity tranche threshold, of which 42% of these are novel.

**1226T**

**Neuron-squared (N<sup>2</sup>): An industrial-scale iPSC disease-modeling project for neuropsychiatric disorders.** R. Randhawa, A. Kaykas, B. Bilican, K. Worringer, C. Ye, B. Altshuler, T. Kulkarni, K. Chan, S. Kommineni, D. Fletcher, B. Henry, K. Theriault, D. Ho. Neuroscience, Novartis Institutes for BioMedical Research, Cambridge, MA.

The majority of neuroscience drug discovery in the last 3 decades has yielded very few new drugs. One of the major challenges we face is rodent models of neuropsychiatric and neurodegenerative disorders have shown limited success in identifying compounds that are effective in clinical trials. Traditionally, industry has relied on transformed or genetically-engineered heterologous systems to develop cellular assays for drug discovery. Stem cells offer distinct opportunities to establish genetically and functionally faithful neurological disease models, potentially bridging a significant gap in new target identification, validation and drug discovery. However, a major challenge in the field is establishing standardized differentiation protocols that yield human neurons with disease-relevant phenotypes at a truly industrial scale, in both quantity and screening format. To this end, we established a fully automated human pluripotent stem cell (PSC) maintenance and excitatory cortical neuronal differentiation platform that enables parallel phenotyping of many different lines at once. We have generated over 100 iPSC lines from normal and psychiatric disease patients using non-integrating reprogramming technology. We are currently running these lines through automated differentiation platform and collecting genomic & phenotypic data. We have subjected all patients to whole genome-sequencing and are collecting epigenomic and transcriptomic data at the pluripotency, neuronal precursor and neuronal phases of differentiation. We are collecting high content imaging data on the neurons to capture neuronal morphology and synaptic formation and FDSS/calcium imaging as a proxy for network activity. This large data set will allow us to look at reproducibility and technical noise at unprecedented levels and allow us to correlate the clinical phenotypes of patients, genotype, transcriptional networks and cellular phenotype. Further analysis of this large dataset may yield new targets for psychiatric disease and/or cellular phenotypes that could be used for high-throughput screening. This human disease-modeling platform is being integrated into Novartis' lead discovery pipeline to identify new targets, molecules, and to shed light on the cellular aspects of human neuronal biology.

**Towards translating genetic findings of polygenic diseases to personalized drug development: Proof-of-concept study for drug combinations to target multiple genes.** I.S. Vlachos<sup>1,2,3</sup>, B. Kaskow<sup>1,2,3</sup>, G. Wong<sup>1,2,3</sup>, P. de Jager<sup>1,2,3</sup>, W. Elyaman<sup>1,2,3</sup>, N.A. Patsopoulos<sup>1,2,3</sup>. 1) Ann Romney Center for Neurological Diseases, Brigham & Women's Hospital, Boston, MA, USA; 2) Harvard Medical School, Boston, MA, USA; 3) Broad Institute of MIT and Harvard, Cambridge, MA, USA.

**Background** One of the main promises of genetics is the discovery of new targets for drug discovery. However, two main limitations can arise: i) the vast majority of disease-associated loci fall in non-coding parts of the genome, ii) there are hundreds of genes that can be prioritized in common diseases. Here, we perform a proof-of-concept study by integrating personalized genetic information, expression data, and drug-screen signature. We create and experimentally test a framework to identify compound combinations that can target multiple disease-related genes, given an individual's genome.

**Methods** We perused a cohort of 215 healthy subjects to identify pairs of individuals that are extreme homozygotes for multiple MS-associated variants. We used expression data of CD4+ naïve T cells from the same individuals, to prioritize pairs bearing MS variants that were *cis*-eQTLs for one or more genes. Having pairs of individuals, that are expected to have extreme gene expression for the given set of genes, we leveraged the Connectivity Map (CMAP) data to identify combinations of compounds that could reverse the MS-specific gene expression signature. We isolated CD4+ naïve T cells from the selected pairs and treated them with the prioritized compounds. We used SCRBS-Seq, a low-input library preparation to measure genome-wide gene expression. **Results** We prioritized 2 pairs of individuals (n=4) for a total of 3 MS-associated variants that were *cis*-eQTLs for 4 genes. Perusing the CMAP data, we prioritized 13 chemical compounds, combinations of which were predicted to reverse the MS-specific gene signatures. We sequenced CD4+ T naïve cells, from the above individuals, treated for the 13 compounds and 6 pair-wise combinations. We also included untreated and DMSO-only CD4+ naïve T cells for comparisons. We report the success to replicate the CMAP data and the ability to predict the effect of the drug combinations given their single-drug effect. Finally, we report the extent to which the by disease-specific genetic variation controls the response of gene expression to the compounds treatment. **Discussion** We present a comprehensive methodology that aims to develop a genetic-guided and personalized combinatorial drug regimen to simultaneously target several disease related genes. We discuss feasibility, issues, and results and we elaborate on next steps towards created personalized drug prioritization approaches.

**SV<sup>2</sup>: Accurate structural variation genotyping and de novo mutation from whole genomes.** D. Antaki<sup>1,2,3,4</sup>, W.M. Brandler<sup>1,2,3</sup>, J. Sebat<sup>1,2,3</sup>. 1) Beyster Center for Genomics of Psychiatric Diseases, University of California San Diego, La Jolla, CA; 2) Department of Psychiatry, University of California San Diego, La Jolla, CA; 3) Department of Cellular and Molecular Medicine and Pediatrics, University of California San Diego, La Jolla, CA; 4) Biomedical Sciences Graduate Program, University of California San Diego, La Jolla, CA.

Structural Variation (SV) is a major contributor to human genetic variation with 13% of the human genome defined as structurally variable, and is also implicated in a variety of human diseases. In particular, *de novo* structural mutations (those in offspring and not in parents) contribute significant risk for idiopathic autism and intellectual disability. Therefore, family-based studies of rare and *de novo* SVs have become a widely implemented approach for gene discovery in neurodevelopmental disorders. However, SV detection from short-read whole genome sequencing is error prone, presenting significant challenges for population or family-based studies of disease. Here we present SV<sup>2</sup> (support-vector structural-variation genotyper), a machine-learning algorithm for genotyping deletions and duplications from paired-end sequencing data. SV<sup>2</sup> rapidly integrates variant calls from multiple structural variant discovery algorithms into a unified call set with high genotyping accuracy and capability to detect *de novo* mutations. As a proof of concept, SV<sup>2</sup> was implemented in a genetic study of autism (3,169 individuals, 829 families), where 123 *de novo* deletions and duplications were resolved, implicating novel autism gene candidates. Likewise, SV<sup>2</sup> was pivotal in our novel discovery of over-transmission of rare paternally-inherited SVs that disrupt promoters or UTRs of haploinsufficient genes to autistic children and not to their typically-developing siblings (P= 0.0013). In conclusion, the utility of SV<sup>2</sup>'s accurate genotyping benefits any structural variation association study, making SV<sup>2</sup> a palpable solution for genetic association and *de novo* mutation discovery. SV<sup>2</sup> is an open-source software available for download at <http://github.com/dantaki/SV2>.

**1229T****Novel pathway transcriptomics method greatly increases detection of molecular pathways associated with the trait.** C. Chatzinakos<sup>1</sup>, A. Docherty<sup>2</sup>, V. Vladimirov<sup>1</sup>, T. Bigdeli<sup>3</sup>, T. Webb<sup>1</sup>, K. Kendler<sup>1</sup>, S. Bacanu<sup>1</sup>.

Genetic signal detection in genome-wide association studies (GWAS) is improved by pooling information from multiple single nucleotide polymorphism (SNP), e.g. across genes or pathways. Because many genes influence trait via gene expression, it is of interest to combine information from Quantitative Trait Loci (eQTLs) in a gene or genes in the same pathway. Such type of methods, denoted as transcriptomics, already exists for gene analysis. They use eQTLs to infer the association between trait and predicted expression of gene under study. Among the many transcriptomics based methods/software, our group proposed Gene-level Joint Analysis of functional SNPs in Cosmopolitan Cohorts (JEPEGMIX). However, due to the  $O(n^2)$  computational burden for computing linkage disequilibrium (LD) between numerous ( $n$ ) SNPs across large regions (even chromosome arms) transcriptomics methods are not yet applicable to arbitrarily large pathways/gene sets. To overcome this obstacle, we propose JEPEGMIX2, a novel  $O(n)$  transcriptomics method, which 1) computes LD for gene statistics and 2) uses LD and GWAS summary statistics to rapidly test for the association between trait and expression of genes even in the largest pathways. It first computes chromosome arm pathway  $\chi^2$  tests as Mahalanobis statistics of Z-scores for genes in the pathway and chromosome arm. Subsequently, due to variants on different chromosome arms being quasi-independent, JEPEGMIX2 pathway  $\chi^2$  statistic and degrees of freedom are simply the sum of their chromosome arm counterparts. Simulations indicate that JEPEGMIX2 controls the type I error at or below nominal rates both for i) the entire set of genes/pathways and each gene/pathway separately. Being written in C++, JEPEGMIX2 takes less than 3.5 hours to compute all gene- and pathway-level statistics. To underline its potential for greatly increasing the power to uncover genetic signals over existing (non-transcriptomics) pathway methods, we applied JEPEGMIX2 to summary statistics from several large meta-analyses. For instance, while current methods found only nominally significant pathways for Psychiatric Genetics Consortium Schizophrenia phase 2, JEPEGMIX2 uncovered around one hundred pathways that were statistically significant after adjusting for multiple testing. Surprisingly, most such significant pathways seem not to be mostly involved in the activity of the central nervous system, but rather in the well-functioning/maintenance of cell/entire organism.

**1230F****Gravity: A tool to analyze genetic variants in individuals using gene networks.** F. Cliquet<sup>1,2,3,4</sup>, A. Mathieu<sup>1,2,3,4</sup>, T. Kergrohen<sup>1,2,3,4</sup>, T. Rolland<sup>1,2,3,4</sup>, R. Delorme<sup>1,2,3,4,5</sup>, B. Schwikowski<sup>4</sup>, T. Bourgeron<sup>1,2,3,4</sup>.

1) Institut Pasteur, Human Genetics and Cognitive Functions Unit, Paris, France; 2) CNRS UMR 3571 Genes, Synapses and Cognition, Institut Pasteur, Paris, France; 3) University Paris Diderot, Sorbonne Paris Cité, Paris, France; 4) C3BI, Institut Pasteur, Paris, France; 5) Department of Child and Adolescent Psychiatry, Robert Debré Hospital, APHP, Paris, France.

For many complex traits such as psychiatric disorders or cancer, patients display a highly heterogeneous genetic architecture. In some cases of autism spectrum disorders (ASD), a single *de novo* deleterious mutation is causative, but in the vast majority, a combination of multiple common and rare variants increases disease risk (Bourgeron, T. *Nat Rev Neurosci* 2015). Even within families with more than one affected child, causative mutations can be different from one sibling to another (Yuen, R.K. *Nat Med* 2015). The causative variants are usually detected by progressive filtering of sequencing data, but practical means for the rapid inspection of multiple variants potentially affecting different genes (multiple hits) in functional networks are missing. Here, we present GRAVITY <http://gravity.pasteur.fr/>, a tool that allows efficient visualization and analysis of all exonic variants, including single nucleotide polymorphisms and copy-number variants, by mapping them onto a protein-protein interaction or co-expression network (Rolland, T. *Cell* 2014). Designed as an app for Cytoscape and highly customizable, it facilitates data analyses; either specifically oriented towards pathways known to be involved in the phenotype (e.g., the glutamatergic synapse pathway in ASD, or sets of candidate genes previously associated with cancer), or by exploring the whole exome. GRAVITY allows regular trio analysis (a patient with his parents) to identify *de novo* mutations, recessive mutations, or Mendelian errors, as well as the visualization of the mutation burden on a gene or a group of genes for an individual. For cancer research, it allows the analysis of the somatic mutations together with the constitutive genetic background of the patient. Finally, it provides customizable options for the identification in a group of patients of all individuals carrying mutations in a given gene or cellular pathway, thereby assisting clinicians to build and validate hypotheses. GRAVITY was developed using Gemini, a flexible, widely used, database to store genetic data that can include pedigree information and potentially more than one phenotype. GRAVITY enables researchers and clinicians to visualize and analyze multiple hits directly from sequencing data, towards a better understanding of how complex mutation profiles translate into diversity and severity of ASD symptoms in patients. GRAVITY is easily adaptable to other neurodevelopmental disorders and other complex human diseases.

**1231W****GWAS-based machine learning approach to predict duloxetine response in major depressive disorder.** *M. Maciukiewicz<sup>1</sup>, V.S. Marshe<sup>1,2</sup>, A.-C. Hauschild<sup>3,4,5</sup>, J.A. Foster<sup>5,6</sup>, S. Rotzinger<sup>5,7</sup>, J.L. Kennedy<sup>1,2,7</sup>, S.H. Kennedy<sup>2,5,7,8</sup>, D.J. Müller<sup>1,2,7</sup>, J. Geraci<sup>9</sup>.*

**Background:** Major depressive disorder (MDD) is one of the most prevalent psychiatric disorders and is commonly treated with antidepressant drugs. However, large variability is observed in terms of response to antidepressants. Machine learning (ML) models may be useful to predict treatment outcomes.

**Patients and Methods:** A sample of 186 MDD patients received treatment with duloxetine for up to 8 weeks were categorized as "responders" based on a MADRS change >50% from baseline; or "remitters" based on a MADRS score ≤10 at end point. The initial dataset (N=186) was randomly divided into training and test sets (70% and 30% respectively), resulting in ten different training and test set pairs. We performed genome-wide logistic regression to identify potentially significant variants related to duloxetine response/remission and extracted the most promising predictors using LASSO regression. Subsequently, classification-regression trees (CRT) and support vector machines (SVM) were applied to construct models, using ten-fold, repeated cross-validation. **Results:** For the response, LASSO regression suggested twenty SNPs for prediction models. Calculated models achieved accuracy of 63.43% for CRT and 78.93% for SVM. For the remission, LASSO filtering suggested five SNPs. Best models were characterized by an accuracy of 65.45% with a sensitivity of 69.31% and specificity of 61.43%. **Discussion and Conclusions:** In this study, the potential of using GWAS data to predict duloxetine outcomes was examined using ML models. These models managed to capture a fraction of responders and remitters (i.e. moderate sensitivity), but failed to filter out non-responders and non-remitters (i.e. low specificity). Inclusion of additional non-genetic variables to create integrated models may help improve prediction results.

**1232T****The Registry of Candidate Regulatory Elements: Integrating human and mouse epigenomic data to fine map and annotate genetic variants.** *J. Moore, M. Purcaro, H. Pratt, Z. Weng.*

Program in Bioinformatics and Integrative Biology, University of Massachusetts Medical School, Worcester, MA.

Genome wide association studies (GWAS) and whole genome sequencing projects have identified thousands of genetic variants associated with human disease. However, understanding how these variants contribute to disease remains a challenge as the majority are in non-coding regions of the genome. To address this problem, we created the Registry of candidate Regulatory Elements (cREs), a collection of putative regulatory regions across human and mouse. We curated this registry by integrating DNase hypersensitive sites with H3K27ac, H3K4me3 and CTCF ChIP-seq signals. We incorporated data from 620 human and 138 mouse cell/tissue types, utilizing experiments from the Encyclopedia of DNA Elements (ENCODE) and Roadmap Epigenomics projects. In total, the registry contains 1.3M human cREs and 430k mouse cREs each annotated with promoter-like, enhancer-like, or CTCF-only signatures. We validated our approach using complementary data such as transcription factor ChIP-seq peaks and experimentally validated enhancers from the VISTA database. These cREs are publically available on our interactive database SCREEN (Search Candidate Regulatory Regions by ENCODE) at [www.screen.umassmed.edu](http://www.screen.umassmed.edu). To aid in variant annotation and fine mapping, we integrated SCREEN with variants from the NHGRI-EBI GWAS catalog. SCREEN allows users to simultaneously investigate human and mouse regulatory regions, enabling them to (1) prioritize variants in orthologous cREs (i.e. cREs conserved across human and mouse) and (2) survey data from a greater number of cell types. To demonstrate SCREEN's utility, we analyzed variants associated with neuropsychiatric disorders. By comparing cRE activity with corresponding RNA-seq data across human and mouse, we identified over 50 potentially causal cREs. The majority of these cREs have promoter-like or enhancer-like signatures, several of which are primarily active during brain development. For example, *AGAP1* contains an intronic cRE that overlaps a schizophrenia associated variant. Due to the limited scope of fetal brain data, we are unable to annotate this cRE using only human datasets. By incorporating mouse data, we observe that the orthologous cRE has enhancer-like signatures only in embryonic brain tissue suggesting that this cRE regulates *AGAP1* only during brain development. In the future, we can apply this same methodology to fine map and annotate variants associated with other diseases, particularly those associated with human development.

**Bayesian multivariate analysis of RNA sequencing data to identify brain-specific protein-protein interactions.** S. Muller<sup>1,2</sup>, T. Li<sup>1,2</sup>, A. Kim<sup>1,2</sup>, C. Hart<sup>3</sup>, E. Malolepsza<sup>1,2</sup>, K. Lage<sup>1,2</sup>. 1) Massachusetts General Hospital, Boston, MA; 2) Broad Institute, Cambridge, MA; 3) University California Los Angeles, CA.

Human protein-protein interaction (PPI) studies have empowered the understanding of biological mechanisms involved in diseases. Although the human interactome is providing useful information on the mediation of biological processes, it is very sparse and likely to be specific to a tissue or cell type. Undercovering the biological processes leading to a brain disease through PPI networks rely therefore on the amount of information available on human brain proteins, which is poor due to the difficulty of uniformization of experiments across tissues. To try to tackle this gap in literature, we hypothesize that the physical PPI in the brain can be learnt from tissue-specific RNA sequencing data. In this study, we propose a new algorithm based on multivariate Bayes theory that aims at inferring a significant differential expression network that is specific to a tissue (e.g. the brain). The algorithm prioritizes genes that have a significant higher or lower co-expression in a given tissue. It assumes that a physical interaction between two proteins in a specific tissue is the consequence of the whole genes expression signature in that given tissue. This type of multivariate inference, particularly suited for small sample size studies, insures that the model learns the putative regulatory effects between the expression of the genes and how, as a whole, gene expression in a given tissue will modulate the protein interactions. From tissue specific RNA sequencing data, we identified a set of 55 brain-specific genes with a significant differential expression network. The expression patterns observed in the network are reproducible in other datasets (in vitro, neuronal-induced cells, in-house RNA sequencing) and in vivo. The obtained network is highly enriched for physical PPI ( $p=0.003$ ). The characterization of the network reveals significant lower and higher expression clusters of interacting genes both at the RNA and protein levels. Globally, we show that genes in the predicted network are more translated in the brain than in other tissues. Finally, we demonstrated that brain related diseases are significantly more associated to genes in the predicted network than random. The predicted gene network accumulates evidences that it is underlying biological mechanisms specific to the brain. Further in vitro biological validation is planned.

**1234W**

**Tissue-specific gene expression inference.** K. Vervier, J.J. Michaelson. Psychiatry, University of Iowa, Iowa City, IA.

Gene expression varies by tissue, and projects like Gene-Tissue Expression (GTEx), have enabled the systematic quantification of such variation. Wheeler *et al.* (2016) estimated tissue-specific gene expression with the use of “local heritability” only, noting that current sample sizes in GTEx do not allow for the integration of distal heritability. In this study, we propose to filter predictor variants based on a tissue-specific functional score (Vervier *et al.*, 2017) and then train predictive models on a large dataset from whole blood samples (Battle *et al.*, 2014). Reducing the number of functional input variables also lowers the features-to-observations ratio, thus enabling the use of both local and distal information. Transfer learning is used to extrapolate from whole blood to other tissues, such as human brain and heart. We demonstrate that tissue-specific predictive models are more consistent at identifying disease-related genes than tissue-agnostic methods such as PrediXcan (Gamazon *et al.*, 2015) and SLINGER (Vervier *et al.*, 2016). On the WTCCC bipolar disorder case-control cohort, differentially expressed genes predicted by a brain-specific model show a significant enrichment in calcium channel complexes, which are known players in bipolar disorder. Notably, this finding was not observed using generic, tissue-agnostic methods.

**1235T****Augmenting multi-ethnic image signals to enhance schizophrenia**

**prediction.** H. Qin<sup>1</sup>, Y. Li<sup>1</sup>, Y.-P. Wang<sup>1,2</sup>. 1) Department of Global Biostatistics and Data Science, Tulane University School of Public Health and Tropical Medicine, 1440 Canal Street, New Orleans, LA 70112, USA; 2) Department of Biomedical Engineering, Tulane University School of Science and Engineering, New Orleans, LA 70118, USA.

Identifying predictive brain voxels is a critical, but currently difficult, task in multi-ethnic biomedical image studies of schizophrenia. Susceptible voxels are highly correlated with adjacent voxels and can interact with latent environmental factors. Classical voxel wise method (e.g., LIMMA), exploits mean heterogeneity between case and control groups only, assuming dispersion homoscedasticity. The dogmatic assumption of homoscedasticity severely violates the strong intra-voxel correlation and latent interaction effects. As such, we proposed a double moderate Welch test (DMWT) to integrate the mean and second order heterogeneities of a voxel after calibrating the mean and dispersion effects of confounders in a generalized linear mixed model. By extensive simulations, the proposed method properly controlled type I error rates and appeared strikingly more powerful than mean heterogeneity test. The novel method displayed particular utility in analyzing biomedical fMRI data of 104 multi-ethnic controls and 80 multi-ethnic schizophrenia cases. The DMWT and the LIMMA identified 4 and 3 significant voxels, respectively. The four voxels identified by the DMWT displayed 33% prediction accuracy over those three identified by the LIMMA; and the improvement proved significant ( $p = 0.016$ ). In summary, we have paved an effective avenue to integrate voxel wise high-order informative heterogeneities while adjusting for heteroscedastic background confounders. Our results have demonstrated the tremendous potential gain of explicitly handling higher-order heterogeneities in multiethnic image data. This work was supported by Carol Lavin Bernick Faculty Grant (632119), Tulane's Committee on Research fellowship (600890), and Innovative Programs Hub (I2PH) Grants Award of Tulane (632037).

**1236F****A statistical framework of mapping risk genes from *de novo* mutations in whole-genome sequencing studies.**

Analyzing *de novo* mutations (DNMs) from sequencing data of nuclear families has identified risk genes of a variety of complex diseases, especially neurodevelopmental and psychiatric disorders. Such efforts have been mostly focused on mutations targeting protein-coding sequences. Non-coding regions harbor important regulatory information and play important roles in human diseases, as evidenced by the finding from genome-wide association studies (GWAS) that most disease loci are located in non-coding sequences. Extending the DNM-based gene mapping approach to non-coding regions is thus an important direction to advancing our understanding of complex psychiatric disorders. Unlike coding sequences, however, we do not have a "genetic code" that allows us to easily predict the functional consequence of noncoding mutations, and as a result, how to interpret DNM data from whole genomes remains a major challenge. In this study, we developed a statistical framework for analyzing DNMs from whole-genome sequencing (WGS) data of parent-child trios. Built upon on our earlier TADA model for DNM analysis, the new method allows us to combine coding and non-coding mutations at the gene level to detect risk genes. It incorporates various genomic annotations in the model, such as conservation scores and epigenomic marks. The model learns from data which annotations are informative of pathogenic mutations, and utilizes such knowledge to better identify causative non-coding mutations. An additional benefit of the model is that it enables meta-analysis that combines multiple DNM studies, while adjusting for study-specific effects on mutation rates (e.g. difference of sequencing depth). Application of this new method, which we name TADA-Annotations, to WGS data of ~300 autism family trios (combining five studies) increases the power of disease gene mapping and predicts a number of new genes with possible roles in ASD.

**1237W**

**Comparison of different approaches to detect CNV from SNP genotyping array and whole-exome sequencing.** B. Chaumette<sup>1</sup>, Q. He<sup>2</sup>, G. Huguet<sup>2</sup>, D. Spiegelman<sup>1</sup>, A. Dionne-Laporte<sup>1</sup>, P. Dion<sup>1</sup>, G.A. Rouleau<sup>1</sup>, L. Xiong<sup>2</sup>. 1) Neurology and Neurosurgery, McGill University, Montréal, Quebec, Canada; 2) Centre de recherche, Institut universitaire en santé mentale de Montréal, Université de Montréal, Montréal, Quebec, Canada; 3) CHU Sainte-Justine, Université de Montréal, Montréal, Quebec, Canada.

The detection of Copy Number Variants (CNV) from large datasets remains challenging due to variable sensitivity and specificity offered by different programs and approaches. While comparative studies have been published, those comparing CNV calls from whole-genome genotyping data (SNP chip) and whole-exome sequencing data (WES) are scarce. We present a comparison between CNV calls from SNP chip and from WES in a large dataset (n=243 individuals). We illustrate this comparison with the specific results from a multiplex family with autism spectrum disorder (ASD). ASD is a neurodevelopmental condition defined by altered social interaction and communication, restricted interests and repetitive behaviors. The heritability is estimated to 80% and some pathogenic CNV have been identified. First, we used three programs - PennCNV, QuantiSNP and cnvPartition - to detect CNV from SNP chip. Second, we used the WES data from the overlapped samples to detect CNV using two programs - Conifer andXHMM. Concordance between programs and datasets were determined using CNVision program. The multiplex family design was useful to detect true positives called by each program, based on the familial segregation. In our genotyping dataset, 16.5% of the CNV were found by the three algorithms with a comparable concordance rate for duplication and deletion. Adjusting the quality control parameters (quality score, minimal number of SNP) increased this concordance to 40%. In the WES dataset, Conifer called 72.8% of the CNV that were also called by XHMM but the inverse gives 7.8% concordance. Only 2.3% of the CNV were concordant between WES and SNP genotyping data. As an example, in our SNP chip data, we found a 11q22.1 deletion encompassing the *CNTN5* gene and segregating in all three affected male siblings in a multiplex family. This deletion is inherited from the unaffected father and shared by one sibling with learning disabilities. This deletion in *CNTN5* gene has been previously identified as a strong candidate in autism and could be considered as a positive control. Interestingly, the deletion was impossible to identify in the WES data because the region was out of the capture-kit targets. This comparison, as well as this example, sheds light on the importance of a complementary approach from different datasets to efficiently detect CNV. Our design helped us to determine the sensitivity and the specificity of the different methodologies and to optimize the parameters of each program.

**1238T**

**Exomerate: A machine-learning approach to identify high-confidence CNVs from exome sequencing data.** V. Pounraja, G. Jayakar, M. Jensen, N. Kelkar, S. Girirajan. Department of Biochemistry and Molecular Biology, The Pennsylvania State University, PA.

Most studies that detect copy-number variants (CNVs) from exome-sequencing data employ algorithms that model the sequence read distribution across the genome. Each of these algorithms employ different criteria to filter noise from signal, with almost no consensus between the CNV calls. Their performances are often estimated by either validating only a subset of predictions or comparing them against calls made by an alternate algorithm. Therefore, an objective method that borrows strengths from multiple callers is necessary to address these issues. We propose a machine-learning framework, *Exomerate*, that learns to segregate true CNVs from false positives based on the ability of individual callers. We first tested the feasibility of the proposed framework with two sets of independent samples, 134 samples from the 1000 Genome Project (1KG) and 503 samples from the Simons Variation in Individuals Project (SVIP), for which biological validations were available. We analyzed both sets of samples using five different exome CNV callers, including Conifer, CODEX, Canoes, Exomedepth and XHMM, and obtained 69,254 (1KG) and 143,619 (SVIP) CNV predictions. Each prediction was then labeled either 'True' or 'False' based on the presence of overlap with at least one biologically validated CNV. Since the likelihood of CNVs vary across the genome based on the regional context, we chose to leverage GC content, mappability, exome probe counts and aggregate RVIS (Residual Variation Intolerance Score) as features for our algorithm. We supplemented CNV predictions made by individual exome CNV callers with these variables, and trained random forest classifiers to assign prediction scores to each call based on its likelihood of being a true CNV. The models built independently on both datasets attained substantially high precision rates (65-70%) and recall rates (35-40%). Our framework assigned high confidence even to those true calls lacking consensus across multiple exome CNV callers that would have otherwise been discarded. Our results indicate that a dynamic framework with a small set of biologically validated CNVs could help differentiate true CNVs from false positives from exome sequencing data. Our framework addresses several limitations of existing exome CNV callers and potentially helps making cautious and yet meaningful interpretations of the identified CNVs.

**Improving pathogenicity prediction of structural variation in neurodevelopmental disorders: A machine learning approach.** *P.T. Tandon, O.S. Shanta, D.A. Antaki, W.B. Brandler, M.K. Kleiber, O.H. Hong, J.S. Sebat.* University of California, San Diego, San Diego, CA.

Structural Variants (SVs) consist of changes in the copy number or arrangement of DNA sequences (> 50 bp) in the genome and include deletions, duplications, and inversions. Gene-disrupting SVs contribute to elevated risk for a variety of psychiatric disorders including Autism Spectrum Disorders (ASD) and schizophrenia (SCZ) (Malhotra and Sebat 2012; Walsh et al. 2008). Despite continued success in identifying SVs that confer risk, current analytical approaches have been limited to investigations of the genome-wide burden of SVs or the enrichment of large gene-disrupting SVs at individual loci. Limited progress has been made in identifying smaller causal variants within individual genes or in non-coding regions of the genome that may be pathogenic. This study seeks to develop more accurate pathogenicity prediction and functional interpretation tools for SVs using a machine learning approach. The study develops a machine learning pipeline to fuse multiple biological functional annotations into a single pathogenicity score for a structural variant to assess risk for neurodevelopmental disorders. The trained classifier can distinguish deleterious SVs from neutral variants on a variety of data types including next-gen, whole genome sequencing, and clinical microarray data. On ClinVar data, the trained predictor can leverage multiple functional constraint predictors to predict the pathogenicity of an SV accurately for many sizes of SV, even when its ExAC probability of loss of function (pLI) score is on the margin (i.e. pLI=0.5). The developed SV pathogenicity scoring system is used to investigate the unexplained genetic basis of psychiatric disease in ASD and SCZ. The predictor is more accurate than previous methods for medium to large ( $10^2$ - $10^6$  bp) deletions in the Psychiatric Genomics Consortium (PGC) data, after controlling for known covariates via logistic regression and filtering known loci (Wilcox  $p < 0.01$ ). Emphasis in our study is placed on exploring the contribution of SVs that overlap non-coding regulatory elements to disease risk. The predictor utilizes fetal brain enhancer and promoter overlaps to improve predictions for non-exonic SVs. We have also seen supporting evidence for a "female protective effect" in SCZ by computing Bayesian person-level risk scores. Female cases display a stronger risk score enrichment over female controls ( $p=3.605 \times 10^{-6}$ , Odds Ratio=1.2381) compared to the males ( $p=2.8959 \times 10^{-4}$ , Odds Ratio=1.0256).

**1240W**

**Biological pathways and drug gene-sets: Analysis and visualization.** *H.A. Gaspar<sup>1,2</sup>, C. Hübel<sup>1,2</sup>, G. Breen<sup>1,2</sup>.* 1) King's College London, Institute of Psychiatry, Psychology and Neuroscience, MRC Social, Genetic and Developmental Psychiatry (SGDP) Centre, UK; 2) National Institute for Health Research Biomedical Research Centre, South London and Maudsley National Health Service Trust, UK.

**Introduction** Here, we use summary statistics from genome-wide association studies (GWAS) to find significant biological pathways, disease pathways, drug targets and drug gene-sets in schizophrenia, BMI, body fat % (BF%), and fat-free mass (FFM). We introduce a workflow encompassing data collection and curation, pathway analysis of drug gene-sets and biological pathways, drug class enrichment analysis, and visualization of "pathway landscapes".

**Materials and Methods** We used the latest schizophrenia GWAS from the PGC, and new GWASs of BMI, BF% and FFM based on UK Biobank data. We curated drug/gene interactions from various databases (DGIdb, DSigDB, Ki DB, PHAROS, ChEMBL). Biological pathways were collected from MSigDB (GO and canonical pathways) and disease pathways from the Open Targets platform. The software MAGMA was used to produce gene-wise and pathway-wise associations, and MetaXcan together with GTEx data (Genotype-Tissue Expression project) to predict gene expression levels in different tissues. The enrichment of drug classes was estimated by labelling drugs by ATC code (Anatomical Therapeutic Chemical) and estimating the enrichment using a Wilcoxon-Mann-Whitney test and the AUC (area under the enrichment curve). Pathway landscapes were generated using the Generative Topographic Mapping (GTM), a probabilistic dimensionality reduction algorithm. **Results** Results show new Bonferroni-significant pathways in schizophrenia. Antipsychotics and antiepileptics are enriched in the latest and largest schizophrenia GWAS from the PGC(1). Different disease pathways are found in BMI and BF% - e.g., "binge eating" and "age at menarche" for BMI. 47 disease pathways and 24 biological pathways are significantly associated with FFM - related to bone, height, etc. Pathway landscapes reveal that many significant pathways overlap in "pathway clusters". **Conclusion** A comprehensive approach is necessary to investigate drug repurposing opportunities and biological pathways using GWAS results. Two key issues are data availability (drug/target affinities, gene annotations) and sample sizes for GWAS studies. Growing public databases and increasing sample sizes will help us to improve our understanding of the genetic etiology of complex diseases. ## 1241T

**A paradigm for using human GWAS summary statistics to accurately test gene expression correlation networks derived from model organisms or post-mortem tissues.** S. Bacanu, V. Vladimirov, C. Chatzinakos. Virginia Commonwealth University, Richmond, VA.

Due to the direct assessment of biologically relevant variables, gene expression experiments are very powerful in detecting genes and pathways associated with traits. Unfortunately, in humans very rarely researchers can assay the tissue of interest, e.g. brain tissues for psychiatric disorders. Nevertheless, such experiments are easily performed in animal models and post-mortem human tissues. However, the main issue for such experiments is their perceived lack of generalizability to their homologues in living human subjects. First, the correlation networks derived from animal models might not be relevant for humans. Second, post-mortem tissue experiments are beset by the gene expression differences/correlations not being causal to disease but occurring due to the medication, changes in nutrition post disease onset, tissue decomposition after death, etc. To validate these potentially high powered but "softer" hypotheses, researchers must confirm them using firmer human data, e.g. summary statistics from Genome-Wide Association Studies (GWAS) for relevant traits. To this end we propose a three-step procedure that is based on our **Gene-level Joint Analysis of functional SNPs in Cosmopolitan Cohorts (JEPEGMIX)** transcriptomics method, which uses Quantitative Trait Loci (eQTLs) to infer the association between trait and predicted expression of the gene under study. First, it decomposes the gene correlation matrix into  $m$  principal components (PCs), which can include all PCs or only the most "important" ones. Second, it uses GWAS summary statistics to obtain a novel, fast Z-score statistic that tests for the significance of the association between trait and linear combination of expression for human orthologous genes associated with each PC. Third, it combines the Z-scores for each of the PCs in an overall  $\chi^2_m$  pathway test. Simulations indicate that our method is fast and controls the false positive rates at nominal rates. We applied JEPEGMIX to summary statistics from large meta-analyses for several psychiatric traits, e.g. schizophrenia and bipolar disorders. As softer hypotheses needing validation we used gene expression correlation networks derived from postmortem brain expression studies involving tissues donated by the Stanley Medical Research Institute from normal subjects and subjects with schizophrenia and bipolar disorders. More than half of the PCs associated with these networks were found to be significant after validation using GWAS statistics.

**Ultra-accurate complex disorder prediction: Case study of neurodevelopmental disorders.** L. Huynh<sup>1</sup>, F. Hormozdiari<sup>2,3</sup>. 1) Genome Center, UC Davis, Davis, CA; 2) MIND institute, UC Davis; 3) Department of Biochemistry and Molecular Medicine, UC Davis.

Early prediction of complex disorders (e.g., autism and other neurodevelopmental disorders) is one of the fundamental goals of precision medicine and personalized genomics. An early prediction of these disorders can have a significant impact on increasing the effectiveness of interventions and treatments in improving the prognosis and, in many cases, enhancing the quality of life in the affected patients. Considering the genetic heritability of neurodevelopmental disorders, we are proposing a novel framework for utilizing rare coding genetic variation for early prediction of these disorders. We provide a novel formulation for the Ultra-Accurate Disorder Prediction (UADP) problem and develop a novel combinatorial framework for solving this problem. The primary goal of this novel framework, denoted as Odin (Oracle for Disorder prediction), is to make an accurate prediction for a subset of affected cases while having virtually zero false positive predictions for unaffected samples. Note that in the Odin framework we will take advantage of the available functional information (e.g., pairwise coexpression of genes during brain development) to increase the prediction power beyond genes with recurrent variants. Application of our method accurately recovers an additional 8% of autism cases with LoF variants not disrupting recurrent mutated genes in the training set. Note that our approach has less than 0.5% false positive prediction based on our analysis of unaffected controls. We also extended the Odin method to predict genes that severe variants will potentially cause neurodevelopmental disorder with high probability. Utilizing this approach, we also predicted a set of 391 genes that severe variants in these genes can cause autism or other neurodevelopmental disorders. These 391 genes were not only significantly enriched in known autism genes (10-fold enrichment,  $p < 0.001$ ), but also in reported *de novo* variants in autism probands. Furthermore, we observed that the genes which were predicted can also help in dissecting some of the phenotypes and predicting potentially more severe subtypes of autism. Finally, we observed that the probands which were accurately predicted by Odin had significantly smaller male to female gap than expected. Odin is publicly available at <https://github.com/HormozdiariLab/Odin>.

**Sample-specific background correction leveraging vast historical patient cohort maximizes sensitivity of noninvasive prenatal screening.** D. Muzzey, J. Tratner, K.M. D'Auria, K.E. Kaseniit, D.H. Hite, G.J. Hogan, C.B. Oyolu, C. Haverty, K.R. Haas. Counsyl, South San Francisco, CA.

**Background:** Noninvasive prenatal screening (NIPS) using whole-genome sequencing (WGS) identifies fetal chromosomal aneuploidies by measuring larger-than-expected deviations in the depth of sequenced cell-free DNA. A key determinant of test quality, therefore, is an accurate expectation of the disomic depth distribution, such that significant deviations are properly detected. Early implementations of the WGS method calculated expected disomic depth in a simple "one-dimensional" manner, using either the average depth of other "reference" chromosomes in the same sample or the average of the single chromosome of interest across the other 50-100 samples in the batch. These approaches have two drawbacks: (1) limited background observations (e.g., only 23 chromosomes), and (2) insufficient accounting for systematic biases—e.g., GC bias and total depth—between samples and chromosomes. Here we present a strategy for determining an accurate expected disomic depth that is multidimensional, accounts for sources of bias, uses all chromosomes, and utilizes tens of thousands of samples. **Methods:** WGS data from 34,000 anonymized clinical NIPS samples was featurized by three values: the depth, the GC-bias profile, and the chromosome-bin-depth medians. Applying K-means clustering to the resulting dataset yielded 200 "background clusters", each with 500 samples. Each newly sequenced sample was next assigned to the closest background cluster. Aneuploidy calling used the chromosome's z-score, which reflects the extent of depth deviation from the background cluster. A regression model leveraging all chromosomes and all samples of the background cluster predicted the expected disomic depth for the chromosome of interest in the given sample. Sensitivity was calculated by developing a modeling framework that uses (1) the fetal-fraction distribution and (2) the relationship between z-scores and fetal fraction to predict the proportion of aneuploid samples expected to be called positive. **Results & Conclusions:** Our algorithm appreciably increased sensitivity relative to standard algorithms, notably yielding a two-fold reduction in the expected false-negative rate for chromosomes 13, 18, and 21. Though our work showcases sample-specific background correction for NIPS, we expect that harnessing multidimensional data from thousands of historical samples will improve other large-scale clinical genomic assays as well.

**1245F****Identification of homozygous deletions from exome sequencing data.**

*M. Kohda*<sup>1,2</sup>, *T. Hirata*<sup>2</sup>, *T. Fushimi*<sup>3</sup>, *H. Harashima*<sup>4</sup>, *K. Murayama*<sup>3</sup>, *A. Ohtake*<sup>4</sup>, *Y. Okazaki*<sup>1,2</sup>. 1) Intractable Disease Research Center, Juntendo University, Bunkyo-ku, Tokyo, Japan; 2) Research Center for Genomic Medicine, Saitama Medical University, Saitama, Japan; 3) Department of Metabolism, Chiba Children's Hospital, Chiba, Japan; 4) Department of Pediatrics, Saitama Medical University, Saitama, Japan.

Exome sequencing are routinely used to identify single nucleotide variations and small insertion/deletions. In addition to this, many tools have been developed to detect copy number variations (CNVs) using depth of coverage data. Most tools work efficiently for finding of relatively large and heterozygous CNVs. There are few tools, however, for detecting relatively small (single or several exons) and homozygous deletions. On the other hand, variations of loss of function (LoF) has attracted attention in the field of disease genetics and population genetics, because it's interesting to decipher the relationship between biallelic LoF and human phenotypes. In this study, we report newly developed tool (named HomDel) that identify putative homozygous deletion regions from exome sequencing data through its depth of coverage. We tested HomDel for the detection of homozygous deletions in our 284 cases with suspected mitochondrial diseases. HomDel could identify multi-exonic deletions in known cases, and also could detect putative homozygous deletion in the *ATAD3* gene cluster region where harboring segmental duplications. The homozygous deletion approach has a potential to find complete LoF gene from patient's exomes. Especially, in patients with recessive traits, this strategy could identify missing causative genes by normal exome analysis pipelines. We will present our approach and evaluations at the meeting.

**1246W****Comparison of pipelines and databases for detection and annotation of mitochondrial variants from whole-exome sequencing data.** *J.C. Tsai*<sup>1,2</sup>, *B. Chaumette*<sup>1,2</sup>, *A. Dionne-Laporte*<sup>2</sup>, *Q. He*<sup>1</sup>, *G.A. Rouleau*<sup>2</sup>, *L. Xiong*<sup>1,2</sup>. 1) Centre de Recherche, Institut Universitaire en Santé Mentale de Montréal, Université de Montréal; 2) Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada.

Introduction: Detecting mitochondrial (MT) variants in human diseases has garnered interest in recent years. In the last decade, Whole-Exome Sequencing (WES) has become a research standard due to its decreasing cost, availability and manageable data output. While panels are designed to capture and sequence the entirety of an individual's nuclear exons, off-target regions, like the MT genome, are also captured based on sequence similarity to the capture probes. Bioinformatic tools can be used to analyze the off-target sequences thus providing a unique and additional data source for investigations. Our primary objectives are to investigate the best bioinformatic pipeline and technology platform to detect, evaluate, annotate and validate the mitochondrial variants from off-target WES captures, as well as to explore the implication of MT variants in various cohorts with neuropsychiatric disorders. Methods: Two alignment procedures were tested: alignment with BWA to a reference MT genome and inputting the cleaned exomic capture into two programs: MitoSeek and MToolbox. These pipelines were chosen for their ability to align WES data to the MT genome and were used to detect MT variants with various filtering criteria. A literature comparative screening was conducted to determine the best reference databases to be implemented by ANNOVAR. Input parameters were manipulated to ensure comparable results. In our pilot study, WES data from 243 individuals suffering from major psychiatric disorders was used for testing these pipelines. Calls between pipelines were compared using GATK tools. Interesting variants will be further confirmed by re-sequencing. Preliminary Results: Both tools align WES data to a reference MT genome without discrepancy. A total of 601 variant calls were made in 243 WES data, 251 have associated dbSNP IDs and are considered as true positive. Further investigation of the validity and the utility of MT variant calls from WES data are underway. Conclusions: There are clear advantages and drawbacks for each tool, and features unique to each program. We herein present a comprehensive pipeline to detect and annotate mitochondrial variants for various disease cohorts where mitochondrial variants are likely to play a role. The long-term objective of this project is to develop and implement the "best-tool" from this pilot study to a larger WES dataset (4000+ exomes with neuropsychiatric disease phenotypes) to identify potential disease associated MT variants.

**Assessment of the performance of splicing predictors at non-canonical intronic sites and implications for variant classification.** *D.H. Tran, H.P. Kang, R. Mar-Heyming, S. Guha, 4. Counsyl, South San Francisco, CA.*

**Genetic variants that disrupt or alter normal splicing are important factors underlying many genetic disorders. The appropriate clinical classification of these variants represents a challenge that could be assisted by accurate *in silico* predictors and comprehensive population-genetic information. Here we leveraged the Counsyl variant database to evaluate the general features of intronic-variant interpretation, and assessed the performance of *in silico* predictors. We focused on “non-canonical” intronic variants, those located more than 2bp from a splice junction rather than the nearly invariant “canonical sites”. 30,646 curated, intronic SNPs alleles comprised our initial dataset. When we compared the allele frequencies to Exome Aggregation consortium (ExAC) frequencies, our internal allele frequencies correlated with those in ExAC (r-squared of 0.8739,  $p < .00001$ ), suggesting our sample cohort is concordant with an ostensibly general population. 13,132 intronic variants resided within 20bp of the splice junction. 1326 variants at canonical sites were excluded from further analyses. Among the non-canonical variants: 58 alleles were classified as deleterious/likely deleterious by literature/database curation of patient cases and/or functional studies, 476 alleles were classified benign/likely benign, and 9539 alleles were designated as variants of unknown significance (VUS). Comparing ExAC allele frequencies for this cohort, non-canonical pathogenic variants averaged an allele frequency of  $0.019 \pm 0.00036\%$  ( $n=38$ ), benign variants  $18.53 \pm 0.85\%$  ( $n=471$ ), and VUS variants  $0.10 \pm 0.0013\%$  ( $n=9539$ ). Next we partitioned sites into 5' and 3' intronic regions, and analyzed the performance of MaxENT, NNsplice, and SpliceSiteFinder predictions. MaxENT had the best overall performance, as estimated by the area under the receiver-operator characteristic curves (5' AUC = 0.95,  $n = 322$ ; 3' = 0.86,  $n = 267$ ), followed by NNsplice (5' AUC = 0.95,  $n = 302$ ; 3' = 0.68,  $n = 222$ ), and SSF (5' AUC = 0.88,  $n = 328$ ; 3' = 0.77,  $n = 266$ ). The overall sensitivity and specificity for these tools were higher for non-canonical intronic variants in the 5' region than variants in the 3' region. In summary, our analyses show that outside of the canonical sites, these tools, while providing a useful estimation of potential splicing defects, need additional lines of evidence for accurate classification.**

**Chromosomal sequencing analysis: Assessing the performance of copy number variant analysis by next generation sequencing compared to traditional clinical microarray analysis.** *S.P. Strom, W. Scaringe, C.Y. Lee, M. Li, H. Yen, Y. Xue, Y. Shen, H. Gao. Fulgent Diagnostics, Temple City, CA.*

**INTRODUCTION:** Chromosomal Sequencing Analysis (CSA) is the detection of structural variants using Next Generation Sequencing (NGS). We have developed a highly sensitive CSA pipeline using a combination of low-pass whole genome NGS and capture based targeted NGS. This screen, when combined with orthogonal confirmation enables high performance CSA with high sensitivity and specificity. In this study, we compare the types of genetic alterations clinically validated as detectable using this method in comparison with the gold standard clinical approach, Clinical Microarray Analysis (CMA). **METHODS:** Whole genome sequencing was performed with an average coverage under 1x and large copy number variants (CNV) were called using CNVgenome™. Target capture NGS was performed and exon-level CNV were called using CNVexon™. Results for were analyzed by at least two licensed molecular geneticists and compared with known positive and negative controls previously tested by CMA or other standard methods. **RESULTS:** CNV were detected with sensitivity and pre-confirmation specificity ranging from >99% and >99.9%, respectively, for CNV affecting multiple exons or larger regions down to 97% and 94% for CNV affecting only two exons. **CONCLUSIONS:** Chromosomal Sequencing Analysis has a higher resolution than SNP-based CMA, with the ability to detect much smaller deletions and duplications, and has equivalent ability to detect microdeletions and microduplications >100kb. CMA offers better resolution at detecting absence of heterozygosity (AOH). Combined with the benefit of potential reflex testing to sequence variant analysis, this test may be a resource-efficient alternative front-line test. Turn-around time for large CNVs is competitive with CMA (estimated at 2 weeks). Deeper whole genome sequencing and additional bioinformatics tools are required to detect copy neutral structural variants such as balanced translocations, and is not yet validated.

**A Bayesian network approach for *de novo* variant calling and its application on rare Mendelian disorders.** A. Toth-Petroczy<sup>1</sup>, A.K. Mohanty<sup>1</sup>, L. Francioli<sup>2,4</sup>, C.A. Cassa<sup>1</sup>, N. Carmichael<sup>1</sup>, D. Vuzman<sup>1</sup>, R. Maas<sup>1</sup>, J. Krier<sup>1</sup>, S. Sunyaev<sup>1,2</sup>, *Brigham Genomic Medicine*. 1) Division of Genetics, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA; 2) Department of Biomedical Informatics, Harvard Medical School, Boston, MA, USA; 3) Broad Institute of Harvard and MIT, Cambridge, MA, USA; 4) Massachusetts General Hospital, Boston, MA, USA.

A growing number of studies focus on the analysis of *de novo* mutations detected by sequencing of parent-offspring trios. *De novo* mutations are a predominant cause of sporadic dominant monogenic diseases and play a significant role in genetics of complex neuropsychiatric disorders. *De novo* mutation studies inform population genetics models and shed light on biology of DNA replication and repair. However, there is room for improvement with regards to the accuracy of *de novo* mutation calling. We designed the novoCaller variant calling algorithm to detect *de novo* mutations in trio sequencing data. novoCaller is a Bayesian method that uses the information from both read-level data in the pedigree and unrelated samples. The method was extensively tested using large trio sequencing studies. We also applied the algorithm to 22 cases of suspected rare Mendelian disorders including an affected proband and unaffected parents as part of the Brigham Genomic Medicine gene discovery initiative. The caller performed with 98% specificity and 91% sensitivity on a set of validated variants. Its application resulted in a significant reduction in the resources required for manual inspection and experimental validation of the calls. Further, four *de novo* variants were found in known genes associated with rare disorders leading to a genetic diagnosis for the probands. novoCaller is available for the biomedical community to further aid diagnostics of rare genetic disorders. .

**MiRMed: Therapeutic recommendation and drug repositioning framework for rare and common diseases using micro-RNA signatures.** K. Shameer<sup>1</sup>, B.S. Glicksberg<sup>1</sup>, B. Readhead<sup>1</sup>, K.W. Johnson<sup>1</sup>, M.A. Badgeley<sup>1</sup>, M.S. Tomlinson<sup>1</sup>, A. Laganà<sup>1</sup>, C. Becker<sup>1</sup>, K.K. Yadav<sup>2</sup>, B.A. Kidd<sup>1</sup>, P. Mukherjee<sup>3</sup>, A.K. Tewari<sup>2</sup>, R. Bhattacharya<sup>3</sup>, J.T. Dudley<sup>1</sup>. 1) Biomedical Informatics, Genetics and Genomic Sciences, Institute of Next Generation Healthcare, Mount Sinai Health System, New York, NY, USA; 2) Department of Urology, Mount Sinai Health System, New York, NY, USA; 3) Peggy and Charles Stephenson Cancer Center, University of Oklahoma Health Science Center, Oklahoma, OK, USA.

Micro-RNAs (miRNAs) regulate gene expression of target genes and act as key players of pathophysiology pathways of various diseases. Over the last decade, miRNAs were used as therapeutic agents and has shown great promise in altering tumor progression, immune responses, and heart failure. Oligonucleotides based anti-miR have shown therapeutic efficacy by inhibiting the function of miRNAs in the setting of viremia, cancer, and autoimmune diseases. Gene knockout studies have shown that for disorders such as cancer, perturbing targets of multiple miRNAs have a higher therapeutic impact than targets of a single miRNA. Irrespective of experimental evidence, the delivery of miRNAs for therapeutic purposes is still a challenge. To address this problem, we present MiRMed - a computational drug discovery framework that uses vast compendium of published miRNA-disease signatures integrated with systematic drug repositioning data from RepurposeDB (<http://repurposedb.dudleylab.org>) to find compounds based on miR-disease signatures. MirMed uses meta-expression signature of miRNAs associated with a disease and targets the consensus sub-network of the target genes to find drugs that can impart the synergistic or antagonistic effect as miRNAs. To illustrate the utility of the framework, we have applied MirMed to 240 diseases covering various genetic diseases, including cancers, cardiovascular diseases, infectious diseases, and autoimmune diseases. Systematic analyses of the dataset of 240 disease signatures with 423 miRNAs and 11, 551 target genes reveal core biological functions, pathway cross-talks, and functional modules driving miRNA-based gene regulation. Using MirMed, we have identified therapeutic recommendations and drug repositioning opportunities for common cancers (ovarian cancer and prostate cancer), rare types of cancer (Waldenström Macroglobulinemia and Sézary syndrome), cardiovascular diseases (hypertrophic cardiomyopathy and heart failure), autoimmune diseases (systemic lupus erythematosus and Sjogren's Syndrome) infectious diseases (sepsis and lupus vulgaris) and genetic diseases (fragile X syndrome, Gerstmann-Straussler-Scheinker Disease, and Multiple Hamartoma Syndrome). Pre-clinical studies, experimental and electronic medical based validations combined with clinical trials using the lead compounds identified using MirMed would further improve drug development for several conditions without currently available treatments.

**Examining age, tissue, and genetic effects on RNA splicing with allele-specific resolution in a diverse mouse population.** *D.A. Skelly, N. Raghupathy, K. Choi, A. Srivastava, G.A. Churchill.* The Jackson Laboratory, Bar Harbor, ME.

Alternative splicing is a ubiquitous feature of gene expression that generates a wide variety of transcript isoforms from a relatively small number of protein-coding genes. Variation in splicing is increasingly being recognized as a contributor to complex traits, including human disease. We used RNA-Seq to examine splicing patterns associated with genotype, age, tissue, and sex in a diverse multi-parent mouse population that provides powerful and precise dissection of the genetic contribution to splicing variation. We used the RNA-Seq data to reconstruct the diploid genomes of individual mice and obtained estimates of allele-specific splice junction usage by aggregating transcript abundance across shared haplotypes. Differences in splice junction usage are widespread, and we identify numerous examples of age-, tissue-, and sex-specific splicing patterns. We mapped quantitative trait loci that drive variation in splice junction usage (sQTL). We found that sQTL are common, primarily local, and concordant across tissues. We examined conserved donor and acceptor splice site sequences but found few examples of variants that could explain the sQTL. This observation suggests that the regulation of splicing is genetically complex and may be dependent on as yet uncharacterized DNA elements. Our results highlight the power of multi-parent populations for genetic analysis of molecular phenotypes and shed new light on the role of genetic diversity as a driver of variation in transcript structure.

**Exomic variants of an elderly cohort of Brazilians: ABraOM database.**

*M.S. Naslavsky<sup>1,2</sup>, G.L. Yamamoto<sup>1,3</sup>, T.F. Almeida<sup>1</sup>, S.A.M. Ezquina<sup>1</sup>, D.Y. Sunaga<sup>1</sup>, N. Pho<sup>4</sup>, D. Bozoklian<sup>1</sup>, T.O.M. Sandberg<sup>1</sup>, L.A. Brito<sup>1</sup>, M. Lazar<sup>1</sup>, D.V. Bernardo<sup>5</sup>, E. Amaro Jr<sup>2,6</sup>, Y.A.O. Duarte<sup>7,8</sup>, M.L. Lebrão<sup>7</sup>, M.R. Passos-Bueno<sup>1</sup>, M. Zatz<sup>1</sup>.* 1) Human Genome and Stem Cell Research Center, University of Sao Paulo, Sao Paulo, SP, Brazil; 2) Hospital Israelita Albert Einstein, São Paulo, SP, Brazil; 3) Department of Clinical Genetics, Children's Hospital, Medical School, University of São Paulo, São Paulo, SP, Brazil; 4) Department of Biomedical Informatics, Harvard Medical School, Boston, MA, United States of America; 5) Laboratório de Estudos em Antropologia Biológica, Bioarqueologia e Evolução Humana. Instituto de Ciências Humanas e da Informação. Universidade Federal do Rio Grande, Rio Grande, RS, Brazil; 6) Radiology Institute, Medical School, University of São Paulo, São Paulo, SP, Brazil; 7) Department of Epidemiology, Public Health School, University of São Paulo, São Paulo, SP, Brazil; 8) School of Nursing, University of São Paulo, São Paulo, SP, Brazil.

We hereby present the SABE609, a collection of exomic variants from 609 elderly from a São Paulo city census-based cohort deposited in ABraOM (Online Archive of Brazilian Mutations at [abraom.ib.usp.br](http://abraom.ib.usp.br)), a web-based publicly available database. Age-related phenotypes and their underlying biology are a focus of research worldwide and components driving healthy aging are largely unknown. Comprehensive repositories of phenotypic and genotypic information are essential for variant interpretation by allele frequency filtering. Elderly individuals are less likely to harbor pathogenic mutations for early and adult-onset diseases, therefore such variant databases are of great interest. São Paulo population is highly admixed, with parental populations from Europe, Africa and Asia, underrepresented in major public databases. Among the over 2.3 million variants, 1,282,008 are high-confidence calls. We identified more than 200 thousand variants absent from major public databases. 9,791 variants with potential loss of function consequence were identified, with an average of 300 mutations per individual. Pathogenic variants on clinically relevant genes (ACMG) were found in 1.15% of the individuals. These observations illustrate the relevance of collecting data from different populations. Datasets of census-based of aged individuals are extremely valuable to improve the interpretation of variant pathogenicity.

**1253T****Age-related changes in abundance of extracellular RNA in human serum.**

*D.F. Dluzen<sup>1</sup>, S. De<sup>2</sup>, W.H. Wood<sup>2</sup>, K.G. Becker<sup>2</sup>, A.Z. Zonderman<sup>1</sup>, T. Tanaka<sup>2</sup>, L. Ferrucci<sup>2</sup>, N. Noren Hooten<sup>1</sup>, M.K. Evans<sup>1</sup>.* 1) Laboratory of Epidemiology and Population Sciences, National Institute on Aging, NIH, Baltimore, MD; 2) Laboratory of Genetics and Genomics, National Institute on Aging, NIH, Baltimore, MD; 3) Translational Gerontology Branch, National Institute on Aging, NIH, Baltimore, MD.

Extracellular RNAs (exRNAs) are cell-free RNAs found in human serum and other bodily fluids and can be used as biomarkers for disease. Profiling exRNAs in a readily-accessible biofluid such as serum may help identify biomarkers of healthy aging or age-related disease. However, previous studies are limited either by profiling one type of RNA biotype or by RNA size (small or large). As a result, there has never been a single comprehensive analysis of total exRNA profiles in the context of healthy aging. We hypothesized that age-related changes in exRNAs are important for normal aging and age-related degenerative processes. Here, we sequenced both large and small RNAs from human serum under one comprehensive and novel protocol. Total RNA was isolated from serum from 13 young (30-35 yrs) and 10 old (80-85 yrs) healthy, African American females from the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) and the Baltimore Longitudinal Study of Aging (BLSA) studies. RNA-seq was performed on the Ion Torrent Proton and reads were aligned to the human genome (v19) using separate scripts to identify linear, micro-, and circular RNAs. There was an average of 8.4 million reads per individual. We identified over 30,000 unique RNA transcripts, of which almost 9,000 were shared between young and old. We sequenced varying RNA transcript biotypes, including: messenger, micro-, long non-coding, ribosomal, small nuclear and nucleolar, transfer-, Y-, and circular. The total number of unique transcripts varied by individual. We found that transcript abundance of total small nuclear RNAs significantly decreased with age and abundance of mitochondrial transfer-RNAs increased with age significantly. We identified 142 linear transcripts in at least 90% of our samples, 38 of which were present in every individual. There were significant age-related changes in serum abundance for 10 of these transcripts: *HBB*, *MT-TL1*, *SNORD69*, *RNY4P8*, *MTRNR2L9*, *MT-TM*, *RNU2-59P*, *MTRNR2L6*, *GNL3*, and *MT-ND1*. We identified 454 unique miRNAs throughout the entire cohort and observed age-dependent changes in serum abundance for 11 of them, including: miRs -320a, -3653, -145-5p, -6087, -425, -1307-5p, 3607, -301a-5p, -191-5p, -2110, and -30d-5p. Our novel approach provides evidence of an extensive, age-related exRNA transcriptome present in human serum.

**1254F****Mixture models reveal multiple positional bias types in RNA-seq data and lead to accurate transcript concentration estimates.** *J. Aleksejeva, A. Tuerk, G. Wiktorin, S. Güler.* Lexogen, Vienna, Austria.

Accuracy of transcript quantification with RNA-Seq is negatively affected by positional fragment bias. *Mix<sup>2</sup>* (rd. "mixquare") is a transcript quantification method which uses a mixture of probability distributions to model and thereby neutralize the effects of positional fragment bias. The parameters of *Mix<sup>2</sup>* are trained by Expectation Maximization resulting in simultaneous transcript abundance and bias estimates. We compare *Mix<sup>2</sup>* to Cufflinks, RSEM, eXpress and PennSeq; state-of-the-art quantification methods implementing some form of bias correction. On four synthetic biases we show that the accuracy of *Mix<sup>2</sup>* overall exceeds the accuracy of the other methods and that its bias estimates converge to the correct solution. We further evaluate *Mix<sup>2</sup>* on real RNA-Seq data from the Microarray and Sequencing Quality Control (MAQC, SEQC) Consortia as well as the ABRF NGS study. On MAQC data, *Mix<sup>2</sup>* achieves improved correlation to qPCR measurements with a relative increase in  $R^2$  between 4% and 50%. *Mix<sup>2</sup>* also yields repeatable concentration estimates across technical replicates with a relative increase in  $R^2$  between 8% and 47% and reduced standard deviation across the full concentration range. We further observe more accurate detection of differential expression with a relative increase in true positives between 74% and 378% for 5% false positives. In addition, *Mix<sup>2</sup>* reveals 5 dominant biases in MAQC data deviating from the common assumption of a uniform fragment distribution. On SEQC data, *Mix<sup>2</sup>* yields higher consistency between measured and predicted concentration ratios. A relative error of 20% or less is obtained for 51% of transcripts by *Mix<sup>2</sup>*, 40% of transcripts by Cufflinks and RSEM and 30% by eXpress. Titration order consistency is correct for 47% of transcripts for *Mix<sup>2</sup>*, 41% for Cufflinks and RSEM and 34% for eXpress. We, further, observe improved repeatability across laboratory sites with a relative increase in  $R^2$  between 8% and 44% and reduced standard deviation. On the ABRF data we study repeatability under different types of RNA degradation and for libraries generated with either poly(A) enrichment or rRNA depletion. We ran *Mix<sup>2</sup>* and Cufflinks and found an average increase in  $R^2$  of 28.23% for *Mix<sup>2</sup>* over Cufflinks. When correlating FPKM and qPCR fold changes between UHR and HBR for variable conditions, *Mix<sup>2</sup>* achieved an average increase in  $R^2$  of 48.36% leading to improved ROC curves in our classification experiments of differentially expressed isoforms.

**1255W****A novel clustering model for droplet-based single cell transcriptomic data.**

W. Chen<sup>1,2</sup>, Z. Sun<sup>1</sup>, T. Wang<sup>2</sup>, K. Deng<sup>3</sup>, R. Lafyatis<sup>4</sup>, M. Hu<sup>5</sup>. 1) Department of Biostatistics, University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; 2) Division of Pulmonary Medicine, Allergy and Immunology; Department of Pediatrics, Children's Hospital of Pittsburgh of UPMC, University of Pittsburgh, Pittsburgh, PA; 3) Center for Statistical Science, Tsinghua University, Beijing, China; 4) Department of Medicine, Division of Rheumatology and Clinical Immunology, University of Pittsburgh School of Medicine, Pittsburgh, PA; 5) Department of Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, Ohio.

Single cell transcriptome sequencing (scRNA-Seq) has become a revolutionary tool to study cellular and molecular processes at single cell resolution. Among existing technologies, the recently developed droplet-based platform enables efficient parallel processing of thousands of single cells efficiently. Despite the technology advances, statistical methods and computational tools are still lacking for analyzing droplet-based scRNA-Seq data. Model-based approaches for clustering large-scale single cell transcriptomic data are not well studied. We developed DIMM-SC, a Dirichlet Mixture Model for clustering droplet-based Single Cell transcriptomic data. This approach explicitly models Unique Molecular Identifier (UMI) count data from scRNA-Seq experiments and characterizes variations across different cell clusters via a Dirichlet mixture prior. An expectation-maximization algorithm is used for parameter inference. We further extended the model to incorporate heterogeneity across multiple individuals. We performed comprehensive simulations to evaluate DIMM-SC and compared it with existing clustering methods such as K-means, CellTree and Seurat. In addition, we analyzed public scRNA-Seq datasets with known cluster labels and in-house scRNA-Seq datasets from a study of systemic sclerosis with prior biological knowledge to benchmark and validate DIMM-SC. Both simulation studies and real data applications demonstrated that overall, DIMM-SC achieves substantially improved clustering accuracy and much lower clustering variability compared to other existing clustering methods. More importantly, as a model-based approach, DIMM-SC is able to quantify the clustering uncertainty for each single cell, facilitating rigorous statistical inference and biological interpretations. DIMM-SC has been implemented in a user-friendly R package with a detailed tutorial available on [www.pitt.edu/~wec47/singlecell.html](http://www.pitt.edu/~wec47/singlecell.html).

**1256T****CookHLA: Accurate, efficient, and memory-efficient HLA imputation.**

S. Cook<sup>1,2</sup>, X. Jia<sup>3</sup>, P. Bakker<sup>4,5</sup>, S. Raychaudhuri<sup>6,7,8,9</sup>, B. Han<sup>1</sup>. 1) Department of Convergence Medicine, University of Ulsan College of Medicine & Asan Institute for Life Sciences, Asan Medical Center, Seoul, Republic of Korea; 2) Department of Biomedical Science and Engineering, University of Ulsan College of Medicine, Seoul, Republic of Korea; 3) Department of Neurology, University of California–San Francisco, San Francisco, CA, USA; 4) Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht, The Netherlands; 5) Department of Genetics, Center for Molecular Medicine, University Medical Center Utrecht, Utrecht, 3584 CX, The Netherlands; 6) Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, University of Manchester, Manchester, UK; 7) NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester Foundation Trust and University of Manchester, Manchester Academy of Health Sciences, Manchester, UK; 8) Department of Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, Massachusetts, USA; 9) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, Massachusetts, USA.

**Motivation:** Human leukocyte antigen (HLA) genes in the major histocompatibility complex (MHC) region influence many disease phenotypes. However, in order to thoroughly investigate MHC and identify disease-driving HLA variations, HLA typing in a large number of individuals is required, which can be costly. To overcome this challenge, we previously developed an HLA imputation method called SNP2HLA, which helps investigators to impute HLA alleles and amino acid residues using the intergenic SNP markers. To date, SNP2HLA has been widely used in the community to define disease-driving HLA alleles and amino acids for many disease phenotypes. However, SNP2HLA has several limitations; (1) The imputations are often inaccurate, (2) The computational cost is prohibitively high for a large reference panel ( $N > 10,000$ ), and (3) The memory requirement is high for large sample. **Results:** In this study, we developed a new HLA imputation method, CookHLA. CookHLA differs from previous approaches in that it learns the pseudo genetic distance between the binary markers and utilizes this information for imputation. This strategy dramatically improved the imputation accuracy; in the simulation experiment where we used a European reference panel to impute HLA of HapMap CEU data and measured the average 4-digit imputation accuracy of 6 HLA genes, CookHLA superbly achieved 97.4% accuracy, whereas SNP2HLA and HIBAG achieved 91.2% and 93.1% accuracy, respectively. A wide range of different simulation experiments including the Asian data analysis showed similar relative performances between the methods. CookHLA is more computationally efficient than any other competing methods, consumes minimal memory, and supports multi-core computation. Utilizing the largest-to-date reference panel (Chinese,  $N=10,689$ ) takes only 3 hours of computation time and 3Gb memory in CookHLA, even when using a single core. .

**A novel Word2vec based tool to estimate semantic similarity of genes by using gene ontology terms.** *D. Duong<sup>1</sup>, J. Li<sup>2,3</sup>, E. Eskin<sup>1,3</sup>.* 1) Computer Science, University of California, Los Angeles; 2) Statistics, University of California, Los Angeles; 3) Human Genetics, University of California, Los Angeles.

The Gene Ontology (GO) database contains GO terms that describe biological functions of genes and proteins. A GO term contains one or two sentences describing a biological aspect. One application of the GO database is the comparison of two genes or two proteins by first comparing semantic similarity of the GO terms that annotate them. Previous methods for this task have relied on the fact that GO terms are organized into a tree structure. In this old paradigm, the locations of two GO terms in the tree dictate their similarity score. In this paper, we introduce a new solution to the problem of comparing two GO terms. Our method uses natural language processing (NLP) and does not rely on the GO tree. In our approach, we use the Word2vec model to compare two words. Using this model as the key building-block, we compare two sentences, and definitions of two GO terms. Because a gene or protein is annotated by a set of GO terms, we can apply our method to compare two genes or two proteins. In addition, we also train the Doc2vec model using the descriptions of genes from [ncbi.nlm.nih.gov](http://ncbi.nlm.nih.gov), so that the gene names not seen in open accessed Pubmed articles are converted to vectors. These vectorized gene names are used to directly measure semantic similarity between genes. We validate our method in two ways. In the first experiment, we measure the similarity of genes in the same regulatory pathways. In the second experiment, we test the model's ability to differentiate a true protein-protein network from a randomly generated network. Our results are equivalent to those of previous methods which depend on the GO tree. This gives promise to the development of NLP methods in comparing GO terms.

**Systematic assessment of joint genotyping.** *U. Evani, R. Musunuri, A. Abhyankar.* New York Genome Center, New York, NY.

Today we routinely see designing of projects that involve sequencing of tens of thousands of individuals. To obtain better sensitivity and specificity in variant calling, a joint genotyping strategy is generally recommended. This strategy typically involves multiple steps to be run on a large cohort of samples. Although this strategy has been used in a lot of large-scale projects, to date we have not seen a study that systematically characterizes the benefits or limitations of the joint genotyping strategies. The process is computationally intensive and beyond the capacity of most research labs, so we think such an assessment would be beneficial to the community. To that end, we performed whole genome sequencing on HapMap sample NA12878 on Illumina HiSeqX platform and pre-processed the data using GATK best practices recommendations. The resulting gVCF was jointly genotyped along with gVCFs from other samples sequenced and analyzed using the same protocol. NA12878 was jointly genotyped with these additional samples in batch sizes ranging from 2 to 4500 samples. After joint genotyping, we analyzed the resulting variant calls for NA12878 in each batch to, (1) measure the change in sensitivity and specificity of variant calling in comparison to confident callset provided by Illumina as part of Platinum genomes effort, (2) evaluate the effect of joint genotyping batch sizes on the individual genotype calls and the variant parameters that affect the called genotype. We also analyzed the effect of large batch sizes on genotyping extremely rare variants.

**Improving sequence read mapping and allele calling for the polymorphic *PRDM9* gene using a reference graph approach.** H. Gibling<sup>1,2</sup>, A. Ang Houle<sup>1,2</sup>, J.T. Simpson<sup>1,3</sup>, P. Awadalla<sup>1,2</sup>. 1) Informatics, Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 2) Molecular Genetics, University of Toronto, Toronto, Ontario, Canada; 3) Computer Science, University of Toronto, Toronto, Ontario, Canada.

Mapping high-throughput sequencing reads to a haploid linear reference genome is useful for identifying small variants, but is problematic for regions of high genetic polymorphism, particularly in repetitive loci. One consequence of this is a mapping bias where reads with variant alleles might not map to the reference genome. This leads to the underestimation of non-reference variants, resulting in a limited estimate of human genetic diversity. The polymorphic gene *PRDM9* is difficult to map with current methods due to its minisatellite-like zinc finger (ZnF) repeats. Typically only expressed during meiosis, *PRDM9* is involved in recruiting machinery that initiates double-stranded DNA breaks during recombination. The ZnF repeats that determine its DNA-binding sites show extensive allelic variation across different populations, with more alleles observed in Africans than in Europeans. Rare alleles that diverge greatly from the reference allele are more likely to be subject to mapping biases, and additional Sanger sequencing is currently necessary to accurately genotype samples. To overcome the challenges with mapping high-throughput sequencing reads from the *PRDM9* locus, we use a sequence graph to create a flexible population-based reference, incorporating ZnF repeat arrays from 36 known *PRDM9* alleles. We used the graph to align sequencing reads from the 1000 Genomes Project. Many reads from samples of both African and European populations had higher alignment scores compared to when mapped to the GRCh37 reference. Additionally, a greater proportion of reads had improved alignment scores in the African samples than in the European samples, suggesting our reference graph captures more of the *PRDM9* genetic diversity present in the African samples than does the GRCh37 reference. We are developing a Hidden Markov Model approach to call alleles from sequencing reads aligned to our *PRDM9* graph, and are validating it with simulated data. We are then calling alleles for samples from the Pan Cancer Analysis of Whole Genomes (PCAWG) project. Our lab previously found an association between rare *PRDM9* alleles and pediatric acute lymphoblastic leukemia, and is currently investigating aberrant *PRDM9* expression in several PCAWG cancer samples. This allele-calling approach will help elucidate the relationship between *PRDM9* and some cancers, and will provide a resource for genotyping samples that diverge from the reference allele.

**Comprehensive benchmarking of error correction methods for next generation sequencing via unique molecular identifiers.** B.L. Hill<sup>1</sup>, S. Mangul<sup>1</sup>, I. Mandric<sup>2</sup>, R. Littman<sup>1</sup>, D. Yao<sup>1</sup>, H. Yang<sup>1</sup>, K. Hsieh<sup>1</sup>, L. Chen<sup>1</sup>, P. Ingle<sup>1</sup>, A. Nguyen<sup>1</sup>, S. Gill<sup>1</sup>, N. Wu<sup>3</sup>, R. Sun<sup>1</sup>, J. Schroeder<sup>1</sup>, P. Skums<sup>2</sup>, A. Zelikovskiy<sup>2</sup>, E. Eskin<sup>1</sup>. 1) University of California Los Angeles, Los Angeles, CA; 2) Georgia State University, Atlanta, GA; 3) The Scripps Research Institute, La Jolla, CA; 4) Walter and Eliza Hall Institute of Medical Research, Parkville, Melbourne, Victoria, Australia.

Error correction is an important computational technique that promises to deliver highly accurate sequencing calls and improve the results of next-generation sequencing (NGS) analysis. While errors in data sets are a concern for any NGS-based application, they mostly affect applications that use variants at frequencies similar to the frequencies of errors. Currently, a plethora of error correction methods based on different computational approaches is available. The optimal choice of error correction method for users of NGS platforms is often unclear, because we lack standardized comparison platforms and 'gold standard' benchmark data sets. For this reason, NGS-based applications cannot adopt today's most accurate and efficient error correction techniques. In this paper, we provide the first comprehensive assessment of error-correction algorithms (n=15) based on high-quality sequencing data derived from heterogeneous populations, the most challenging population on which to apply error correction methods. We use two case studies; one consists of a population of viral genomes, and the other consists of a population of T cell receptor clonotypes. Such heterogeneous populations of distinct, but closely related, clonotypes pose a serious challenge to error-correction algorithms due to the comparable level of artificial sequencing noise (i.e., errors) and true low-frequency genetic intra-population diversity. We used the UMI-based high-fidelity sequencing protocol (safe-SeqS) to eliminate errors from the sequencing data. Using raw reads and high fidelity reads obtained with the protocol, our approach provides an accurate and robust baseline for performing realistic evaluation of error correction on sequenced genomes. The most challenging reads to perform error correction on are derived from heterogeneous samples composed of highly similar, yet distinct, genomic variants, such as viral and T cell populations. We apply different methods to reads from such communities in order to assess whether error correction affects the ability of the assembly method to identify low frequency variants. We present the assessment criteria we used in the study to allow the user to make an informed choice of the most suitable software for specific NGS projects. Scripts for computing the accuracy of error-corrected reads and the 'gold standard' data are publicly available at <https://smangul1.github.io/ec/>, allowing users to easily benchmark any new error-correction algorithm.

**ART\_PacBio: A fast and accurate simulator for PacBio sequencing platforms.** *W. Huang<sup>1</sup>, L. Niu<sup>2</sup>.* 1) NERL, EPA, Cincinnati, OH; 2) Department of Environmental Health, University of Cincinnati, OH.

In the last couple of years, PacBio SMRT long-read sequencing technology has been drastically increasingly used for *de novo* whole genome sequencing, metagenomics studies, full-length transcription studies, survey large population for structural variants, and many others. Such fast expansion of PacBio sequencing applications is largely due to the drastically improved PacBio sequencing systems with markedly improved base accuracy, substantial higher throughput, and much shorter sequencing time needed. To facilitate biomedical research using PacBio sequencing system, we are developing a new sequencing simulator ART\_PacBio to support the latest PacBio sequencing system (e.g., Sequel System), and to support the newest sequencing chemistries (e.g., Sequel 2.0), which currently are not supported by the available simulation tools. ART\_PacBio also supports the previous PacBio system PacBio RS II, allowing users to simulate data from the popular old system. In order to generate realistic simulated PacBio data, we evaluated substitution, insertion, and deletion sequencing error rates from multiple latest PacBio datasets. In addition, we developed a new Gamma-based distribution to model raw read length generated from zero-mode waveguides (ZMWs) of PacBio SMRT Cell, and use a Gaussian distribution for the original DNA fragment length or eventual consensus sequence length. Furthermore, ART\_PacBio can directly use empirical distributions generated from real PacBio sequencing data for simulation. ART\_PacBio, implemented in C++, will be freely available to the public once it is released.

**A high-throughput pipeline for genotyping within primary health care to enable precision prevention.** *S. Jai Kumar Ahuja, M. Soe, L. Fricke, J.M. Lubieniecka, S.D. Bennett, K.P. Lubieniecki, C.F. Boerkoel, R. Pyatt, M. Sincan, C-H. Chan, P.F. Cherukuri.* Genomic & Molecular Medicine, Sanford Imagenetics, Sioux Falls, SD.

Implementation of large-scale genotyping within primary health care for purposes of precision prevention remains problematic in part due to high costs of genetic testing. We hypothesized that SNP chip genotyping using Illumina's Infinium® Global Sequencing Array with 660,000 markers in 24-sample format, provides a cost effective first line genotyping for pharmacogenetics and some disease predisposing alleles deemed medically actionable by the American College of Medical Genetics (ACMG) and Sanford clinicians. To test this hypothesis, we developed a high-throughput laboratory and a set of bioinformatics tools that are tightly integrated with the electronic medical record. In this context, we are able to offer pharmacogenetics and some predisposition testing to all individuals within the health care system at the time of a visit to their primary care physician. We launched this as part of a precision prevention initiative within a rural primary health care setting. We present the process and logic underlying this as well as our initial results on patient response, clinician response, and educational initiatives encouraging uptake of the tool.

**Reducing reference bias in whole-genome variant calling using reference graphs.** *M. Kallberg, M. Popovic, G. Rakocevic, M. Suci, K. Ghose, Y. Li, J. Browning, P. Komar, V. Semenyuk, A. Jain, J. Spencer, D. Kural.* Seven Bridges Genomics, 1 Main St, Cambridge, MA 02142.

The linear reference genome conventionally used when aligning reads from a sequencing experiment represents a single consensus haplotype derived from a small genetically homogenous cohort. Consequently, the range of known genetic variants in human subpopulations cannot be taken into account during sample analysis. This so-called "reference bias" causes alignment to variant-rich genome regions to become increasingly inaccurate because the applicable sample cohort diverges from the reference. Ultimately this reduces the number of aligned reads which leads to decreased sensitivity in detection of sample variation. Here we present a graph-based genomic reference structure capturing both the linear reference and known variants, thereby enabling the simultaneous representation of several common population haplotypes. Using our graph-aware aligner, we demonstrate how utilizing known variations can significantly improve alignment quality while maintaining compute-cost lower than that of standard linear aligners. Further, we evaluate the variants called from the graph alignments through several orthogonal experiments using both simulated and real data. We demonstrate that our graph-based analysis pipeline achieves higher accuracy than standard variant-processing workflows when benchmarked against public variant truth-sets. Finally, we establish that using a reference graph enables detection of common structural variants well-beyond a single read-length in size. Our methods can be readily applied to large sample cohorts and become increasingly accurate as the reference graph is enriched with cohort unique variants, thus enabling the construction of application specific variant-calling pipelines.

**Integrating networks and comparative genomics reveals retroelement proliferation dynamics.** *B.A. Knisbacher<sup>1</sup>, O. Levy<sup>2</sup>, S. Havlin<sup>2</sup>, EY. Levanon<sup>1</sup>.* 1) The Mina & Everard Goodman Faculty of Life Sciences, Bar-Ilan University, Ramat Gan, Israel; 2) Department of Physics, Bar-Ilan University, Ramat Gan, Israel.

Retroelements (REs) are transposable elements that multiply and spread throughout genomes by a copy-and-paste mechanism. These parasitic elements promote diversity, cause disease and accelerate evolution in virtually all eukaryotes, including humans. Due to their high copy number and similarity, studying their activity and tracking their proliferation dynamics is a challenge. It is particularly complicated to pinpoint the few REs in a genome that are still active in the haystack of degenerate and suppressed elements. Here, we present a computational framework based on RE similarity networks that tracks the path of RE proliferation throughout evolution and highlights the most probable currently active communities and elements. Integrating biological data into the networks (e.g., comparative genomics, RE expression during embryonic development, population data) enhances the ability to track the course and tempo of RE proliferation. We use SVA, the youngest RE family in human, to demonstrate the potential of this approach. SVA insertions are associated with multiple hereditary diseases, but remain poorly characterized. By constructing and comparing SVA networks from human and other hominids, we identify the genomic locus of specific elements that most probably played pivotal roles in SVA proliferation. Our analysis identifies active SVA communities in hominids and predicts the most probable sources of *de novo* insertions in the human population, which promote diversity and genomic disease. Beyond SVA, the application of biological characteristics specific to LTR and non-LTR retrotransposons in other genomes will be discussed. For example, how footprints of DNA editing by APOBECs can enhance network-based retroelement ancestry inference.

**Limits of indel detection using CLC alignment and variant calling.** *T. Koganti*<sup>1,2</sup>, *Z. Tu*<sup>1,2</sup>, *A. McDonald*<sup>1</sup>, *P. Lundquist*<sup>1</sup>, *Z. Niu*<sup>1,4</sup>, *D. Babovic-Vuksanovic*<sup>1,4</sup>, *C. Klein*<sup>1,3,4</sup>, *E. Klee*<sup>1,2,4</sup>. 1) Department of Laboratory Medicine and Pathology, Mayo clinic, Rochester, MN; 2) Department of Health Sciences, Mayo clinic, Rochester, MN; 3) Department of Neurology, Mayo clinic, Rochester, MN; 4) Department of Clinical Genomics, Mayo clinic, Rochester, MN.

**Introduction:** Variant calling is an important step in bioinformatics analysis of patient sequencing data to report pathogenic variants. Most variant calling software packages can detect Single Nucleotide Polymorphisms (SNP) very reliably but the same is not true when it comes to detecting insertions and deletions (indels). In this study, we evaluated the exact indel size at which insertions, deletions and duplications can be detected at 95% accuracy using CLC pipeline on Illumina Hiseq 2500 data. **Methods:** Samples were processed through library preparation and targeted enrichment using SureSelect hybridization methods. Prepared library was sequenced on Illumina Hiseq 2500 instrument using 101 paired-end reads. An NGS pipeline using CLC software was used to generate alignment files. 500 synthetic insertions and deletions of size 1-50 and 500 synthetic duplications of size 1-30 were artificially inserted in the sample BAM file. These BAM files were converted to fastq files and the entire bioinformatics pipeline was repeated to generate new alignment and variant files. These files were scanned for artificially inserted indels and the indels identified were categorized into 1) Indels identified with same size in output; 2) Indels identified at same start location but different indel size; 3) Indels identified in neighboring regions 4) No indels identified. This procedure was repeated for insertions, deletions and duplications. **Results:** We found that insertions of less than 30 base pairs were detected at an accuracy rate of 95%, deletions less than 27 base pairs were detected at the same rate. Even though duplications are a type of insertions, performance of insertions was far better compared to duplications. Duplications less than 18 base pairs were detected at 95% accuracy. Our study not only helps show the limits of detection size of indels for NGS pipeline but also demonstrates that insertions and duplications need to be assessed individually.

**1266F**

**Comparison of short tandem repeat estimation methods with various conditions.** *K. Kojima*, *Y. Kawai*, *K. Misawa*, *T. Mimori*, *M. Nagasaki*. Integrative Genomics, Tohoku University, Sendai, Japan.

In the estimation of repeat numbers in a short tandem repeat (STR) region from high-throughput sequencing data, two types of strategies are mainly considered: a strategy based on counting repeat patterns included in sequence reads spanning the STR region and a strategy based on estimating the difference between the actual insert size and the insert size inferred from paired-end reads. The quality of sequence alignment is crucial, especially in the former approaches although usual alignment methods have difficulty in STR regions due to insertions and deletions caused by variations of repeat numbers. lobSTR and RepeatSeq were applied to three types of aligned reads: synthetically generated sequencing reads aligned with BWA-MEM, those realigned with STR-realigner, those realigned with ReviSTER, and those realigned with GATK IndelRealigner. From the comparison of root mean squared errors between estimated and true STR region size, the results for the dataset realigned with STR-realigner are better than those for other cases. For real data analysis, we used a real sequencing dataset from Illumina HiSeq 2000 for a parent-offspring trio. RepeatSeq and lobSTR were applied to the sequence reads for these individuals aligned with BWA-MEM, those realigned with STR-realigner, ReviSTER, and GATK IndelRealigner. STR-realigner shows the best performance in terms of consistency of the size of estimated STR regions in Mendelian inheritance. Root mean squared error values were also calculated from the comparison of these estimated results with STR region sizes obtained from high coverage PacBio sequencing data, and the results from the realigned sequencing data with STR-realigner showed the least (the best) root mean squared error value.

**1267W****A graph method for population genotyping of structural variants. P.**

*Krusche<sup>1</sup>, E. Dolzhenko<sup>2</sup>, N. Johnson<sup>2</sup>, M.A. Bekritsky<sup>1</sup>, A. Gross<sup>2</sup>, B.R. Lajoie<sup>2</sup>, V. Rajan<sup>2</sup>, Z. Kingsbury<sup>1</sup>, S.J. Humphray<sup>1</sup>, S.S. Ajay<sup>2</sup>, R.J. Taft<sup>2</sup>, D.R. Bentley<sup>1</sup>, M.A. Eberle<sup>2</sup>.* 1) Illumina, Saffron Walden, United Kingdom; 2) Illumina Inc., San Diego, CA.

Accurate detection and annotation of structural variants (SVs) is a critical component of clinical variant calling pipelines. A significant challenge with SV calling is that the breakpoints of the same event are often represented differently from sample to sample. Nearby variants and sequence instability around the breakpoints of the SVs can further complicate these issues. As a result, SVs can be difficult to aggregate across samples leading to errors, such as underestimation of variant frequencies. We have developed a joint genotyping method for SVs based on re-aligning sequence reads to breakpoint graphs. Using this method, we are able to evaluate breakpoints uniformly across many samples and genotype SVs jointly in a population. Furthermore, we can optimize our genotyping parameters based on population analysis to improve genotyping accuracy in individual samples. A distinguishing feature of this method is that we can account for repetitive sequence around the breakpoints and produce consistent results across all samples even when small variants occur close to the breakpoint. As a demonstration of this method we have identified 185,395 putative insertions and deletions identified from a variety of sources including individual SV calls made on >2,500 samples sequenced to high depth. We jointly genotyped these variants in a cohort of over 220 WGS samples from the Polaris cohort (available at ENA as PRJEB20654 and PRJEB19931), as well as in the Platinum Genomes pedigree. Of these variants 183,098 were biallelic in at least one of these samples. We are able to confirm the accuracy of 37,878 of the variants that are bi-allelic in the Platinum Genomes pedigree using Mendelian inheritance (plus an additional 100,154 variants that are monomorphic in the pedigree). Additionally, we identified 71,505 common (MAF>5%) variants are not significantly out of Hardy-Weinberg equilibrium (HWE) in the population data. Combined we are able to validate that 70,009 of these variants pass both of these tests indicating that they are accurately genotyped in these samples. We will continue to investigate the remaining rare variants using HWE in 3,000 additional samples. The variant calls for all these samples and the joint alignment and genotyping software will be publicly available for comparison and method development. Further work will identify and solve the problems with the variants that failed our quality requirements and apply this method to more SVs.

**1268T****Accurate radiation biodosimetry through automation of metaphase cell image selection and chromosome segmentation. Y. Li<sup>1</sup>, J. Liu<sup>2</sup>, B. Shirley<sup>1</sup>,**

*R. Wilkins<sup>3</sup>, F. Flegal<sup>4</sup>, J.H.M. Knoll<sup>1,2</sup>, P.K. Rogan<sup>1,2</sup>.* 1) CytoGnomix Inc, London, Ontario, Canada; 2) University of Western Ontario, London, Ontario Canada; 3) Health Canada, Ottawa, Ontario, Canada; 4) Canadian Nuclear Laboratories, Chalk River, Ontario, Canada.

The dicentric chromosome (DC) assay is a standardized method that is recommended for determination of biologic radiation exposure<sup>1,2</sup>. Software to fully automate this assay has been developed in our laboratory<sup>3</sup>. This method relies on high quality microscope-derived images of metaphase cells to reduce the rate of false positive (FP) DCs. We present image processing methods to eliminate suboptimal metaphase cell images based on novel quality measures and to reclassify FPs by analyzing their morphological features. A set of chromosome segmentation thresholds selectively filtered out FPs, arising primarily from extended prometaphase chromosomes, sister chromatid separation and chromosome fragmentation. This reduced the number of FPs by 55% and was highly specific to the abnormal structures (≥97.7%). Image segmentation filters selectively remove images with consistently unparseable or incorrectly segmented chromosome morphologies, while image ranking sorts images according to their qualities and enables selection of optimal images in samples. Overall, these methods can eliminate at least half of the FPs detected by manual image review. By processing data to derive calibration curves and to assess samples of unknown exposures with the same image selection models, average dose estimation errors were reduced from 0.6 Gy to 0.3 Gy, without requiring manual review of DCs. During this presentation, we will use our software to demonstrate that metaphase image filtering and object selection constitute a reliable and scalable approach for biodosimetry, resulting in more accurate radiation dose estimates. 1. **WGSA 07: Updated annotation pipeline for human genome sequencing studies.** X. Liu<sup>1,2</sup>, R. Gibbs<sup>3</sup>, E. Boerwinkle<sup>1,2,3</sup>. 1) Human Genetics Center, School of Public Health, University of Texas Health Science Center at Houston, Houston, TX, USA; 2) Department of Epidemiology, Human Genetics and Environmental Sciences, School of Public Health, University of Texas Health Science Center at Houston, Houston, TX, USA; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, USA.

Large-scale sequencing technologies have made unprecedented progress during the recent years. We are witnessing an exciting era when genetic variants—including single nucleotide variant (SNV) and insertion-deletion variants (indels)—in both healthy human subjects and those with Mendelian or complex diseases can be comprehensively identified by re-sequencing studies. Unfortunately, there is a large gap in the ability to ascertain enormous amounts of variants and the ability to understand their functionality. This gap will grow even wider as we transition from whole exome capture sequencing to whole genome sequencing (WGS). As a first step to narrow this gap, we developed WGSA Annotator (WGSA), an annotation pipeline for human genome sequencing studies, to facilitate the functional annotation step of WGS. WGSA supports the annotation of SNVs and indels locally without remote database requests, so it can be scaled up for large studies. Since its first release in 2015, significant updates have been made. Here are a few highlights of the current version WGSA 07: 1. We integrated annotations from 3 popular annotation tools (ANNOVAR, SnpEff and VEP) versus 3 popular gene model databases (Ensembl, RefSeq and UCSC knowGene). As the consequence prediction of a variant often varies depending on the underlying gene model and the annotation tool used, it is suggested to obtain annotations from multiple tools across multiple databases for a complete interpretation of the variants. Here we provide a one-stop resource to achieve that goal. 2. To enable scalability, we precomputed the annotations for all potential human SNVs (a total of 8,584,031,106 and 8,812,967,043 based on human references GRCh37 and GRCh38, respectively) and use them local databases. Multithreading further speeds up the query 3-fold faster. 3. We integrated many annotation resources for both coding and non-coding variants, including functional prediction scores (CADD, DANN, Eigen&Eigen PC, FATHMM-MKL, genoCanyon, fitCons, Funseq&Funseq2, RegulomeDB, etc), population allele frequencies (1000G, ESP6500, ExAC, UK10K, GnomAD, etc), conservation scores, mappability, and annotations from epigenomic projects (ENCODE, Roadmap, FANTOM5, BLUEPRINT, etc). 4. To provide convenience to a broader community, we have built an Amazon Machine Image for running WGSA on the cloud from Amazon Web Services, in addition to a downloadable version. More information can be found at <https://sites.google.com/site/jpopgen/wgsa>.

**PoolHap2: Inferring within-host haplotype frequencies from pathogen next-generation sequencing data.** Q. Long<sup>1</sup>, J. Wang<sup>2</sup>, L. Mak<sup>1</sup>, C. Cao<sup>1</sup>, K. Ye<sup>3</sup>, D. Jeffares<sup>4</sup>. 1) Biochemistry and Molecular Biology, University of Calgary, Calgary, AB, Canada; 2) Electrical and Computer Engineering, Illinois Institute of Technology, Chicago, USA; 3) Department of Automation, Xi'an Jiaotong University, Xi'an, China; 4) Department of Biology, University of York, York, UK.

There is a burgeoning demand for tools capable of analyzing the composition and evolution of a mixture of microbes within a patient. The emergence of affordable next-generation DNA sequencing allows researchers to explore the genetic variation and dynamics of microbial genomes at increasingly precise scales. However, when microbe DNA of multiple strains is collected from host tissues, the microbes are sequenced together in pools as isolating and culturing single strains of microbes is frequently a difficult and expensive task. We present PoolHap (version 2.0), a tool that makes use of advanced statistical models to accurately infer the identity and frequency of individual strains (haplotypes) from pooled sequencing *in silico*. In clinical settings, it is expected that accurate inference of pathogenic haplotypes in a heterogeneous population will facilitate targeted, strain-specific treatment. Beyond mixed pathogen analysis, this tool has a broad range of applications such as the approximation of single-cell sequencing outcomes using only conventional pooled sequencing protocols.

**LRSim: A linked reads simulator generating insights for better genome partitioning.** *R. Luo*<sup>1,2</sup>, *F. Sedlazeck*<sup>1</sup>, *C. Darby*<sup>1</sup>, *S. Kelly*<sup>3</sup>, *M. Schatz*<sup>1,2,4</sup>. 1) Johns Hopkins University, Department of Computer Science, Baltimore, MD; 2) Johns Hopkins University School of Medicine, Center for Computational Biology, Baltimore, MD; 3) New York University School of Medicine, Center for Health Informatics and Bioinformatics, New York, NY; 4) Cold Spring Harbor Laboratory, Simons Center for Quantitative Biology, New York, NY.

Haplotype-resolved or phased genomes are essential for studying allele-specific regulation and expression, and other important genomic features. However, most of the genomes assembled to date are only a single haploid 'consensus' sequence with parental alleles merged arbitrarily. 10X Genomics recently invented a low-cost, labor-efficient library preparation protocol to obtain phased genomes. The protocol ligates adapters to reads which will be sequenced on an Illumina instrument; the adapters allow each read to be traced back to its progenitor molecule. The so-called linked reads, spanning tens to hundreds of kilobases, offer an alternative to long-read sequencing for de novo assembly, haplotype phasing and other applications. However, there is no available simulator, making it difficult to measure their capability or develop new informatics tools for linked reads. Our analysis of 13 real human genome datasets of 10X Chromium linked reads revealed their characteristics of barcodes, molecules and partitions. The first "linked read" simulator we wrote, named LRSim, generates simulated linked reads by emulating the library preparation and sequencing process with highly customizable parameter settings. We compared the simulated results from LRSim to NA12878 to illustrate a high concordance between the simulated and real data. We concluded that from the phasing results of 6 simulated datasets with different mean molecule lengths and a real dataset of NA12878 that if constrained at a certain sequencing depth, the best molecule size to achieve the best phase block size needs to be meticulously chosen. This can be done by wet-lab experiments, but would be more efficient with a simulator in silico. We also performed experiments on 6 simulated *A. thaliana* datasets with a different number of partitions and demonstrated a substantial degradation in assembly performance with an improper number of partitions, which leads to insufficient cover-age per molecule. Finally, we concluded an appropriate sequencing depth needs to be chosen for different applications and species before sequencing to achieve the best performance out of linked-reads.

**1272F**

**Genetic correlations as a tool for finding new biomarkers for female reproductive health phenotypes.** *R. Magi*<sup>1</sup>, *T. Laisk*<sup>2,3</sup>, *A. Salumets*<sup>2,3</sup>, *A. Metspalu*<sup>1</sup>. 1) Estonian Genome Center, University of Tartu, Tartu, Estonia; 2) Department of Obstetrics and Gynecology, Institute of Clinical Medicine, University of Tartu, Tartu, Estonia; 3) Competence Centre on Health Technologies, Tartu, Estonia.

Together with the personalised medicine revolution and the continuously decreasing cost of large-scale genotyping, a lot of attention has been focused on genomic biomarkers, which are robust and reliable and in theory could be used for screening, diagnosing and monitoring the activity of a disease, but also for personalised counselling and treatment regimens, or for assessing therapeutic responses. A genetic component has been identified for many common diseases, including those affecting female fertility and well-being. New methodologies have made it possible to analyse the genome-wide genetic correlations across diseases and phenotypes by comparing the association analysis summary statistics. These methods are not only useful for understanding the genetic background and etiology of studied traits but could also serve as a tool for finding new prognostic biomarker candidates. Comparison of the GWAS summary statistics of age at menopause and nuclear magnetic resonance (NMR) metabolites has revealed several NMR metabolites, which are genetically correlated with age at menopause and could be tested as predictive biomarkers. Based on genetic correlation analysis, five metabolites had nominally significant correlations ( $p < 0.05$ ) with the age at menopause. Out of these five, concentrations of chylomicrons and extremely large very-low-density lipoprotein (VLDL) particles, as well as the average number of methylene groups in a fatty acid chain have previously been associated with menopausal status, as has been docosahexaenoic acid, corroborating the view that these metabolic biomarkers could be associated with the timing of menopause. Furthermore, the remaining two metabolites from our analysis, the ratio of bis-allylic groups to total fatty acids and average number of double bonds in a fatty acid chain, are novel biomarker candidates for menopause age, and have previously been associated with body weight change. Before testing these novel biomarker candidates in the clinical setting, further in silico testing will be undertaken to verify the predictive properties of potential biomarkers.

**Privacy preserving Fisher's exact test for GWAS.** *K. Misawa<sup>1,2</sup>, S. Hasegawa<sup>3</sup>, K. Hamada<sup>3</sup>, K. Chida<sup>3</sup>, S. Ogishima<sup>1,2</sup>, M. Nagasaki<sup>1,2</sup>.* 1) Tohoku Medical Megabank Organization, Tohoku University, Miyagi, Japan; 2) Graduate School of Medicine, Tohoku University, Miyagi, Japan; 3) NTT Secure Platform Laboratories, Tokyo, Japan.

A genome-wide association study (GWAS) is a method for identification of genetic variations that are statistically significantly associated with a particular disease. Because a GWAS requires not only genomic data from the participants but also their health condition, it is necessary to keep the data private. Secure multiparty computation (MPC) protocols allow a set of participants to perform calculations privately. In this study, we developed algorithms of Fisher's exact test for a GWAS using MPC, because Fisher's exact test is widely used for GWAS. We conducted Fisher's exact tests for all possible tables with the given total sample size. On the basis of the results of these tests, a decision tree was constructed. We then developed an algorithm utilizing the decision tree by means of MPC. We devised a function,  $f(\mathbf{X})$ , that always yields a smaller value than the  $p$  value of Fisher's exact test, where  $\mathbf{X}$  is a  $2 \times 2$  contingency table intended to reduce computational time. We measured the computational time with sample sizes varying between 100 and 4,000. We found that the new algorithm can carry out Fisher's exact test in a shorter period in comparison with the previous algorithm.

**1274T**

**The predictive power of RNA-Seq: Modeling blood chemistry and hematology test results.** *M. Naymik, A. Siniard, M. De Both, A. Wolfe, M. Huetelmann.* Neurogenomics Division, Translational Genomics Research Institute (TGen), Phoenix, AZ.

Blood chemistry and hematology tests are common for diagnosing disease, tracking disease progression, or as an assessment of an individual's health. These tests generally involve a venous blood draw of several milliliters in volume. We are interested in developing methods that can measure these quantities using small volumes or alternative bio specimen types. To facilitate this we explored the potential use of RNA signatures as effective correlates. In this experiment we attempted to use simple and multiple linear regression to predict a panel of 59 blood tests using gene expression from 3 different bio specimen types. Whole blood (1 ml), plasma (1 ml), and dried blood spot (DBS) (30  $\mu$ l) samples were collected from 50 individuals and RNA sequencing was performed along side the blood panels. Each blood test was examined for correlation with a single gene followed by a more complex analysis where subsets of up to 5 genes were selected to model the blood test results. We considered models with an  $r$ -squared greater than 0.7 to have good predictive power. Using simple regression we identified 5 tests that correlated with a single gene in the whole blood including Eosinophils (0.81), Neutrophils (0.8), Lymphocytes (0.79), PSA (0.71), and Monocytes (0.74). In DBS specimens PSA (0.81) was the only test that passed the cutoff. In plasma there were no tests that passed the cutoff. With multiple linear regression 6 tests passed the cutoff using whole blood specimens including Lymphocytes (0.87), Monocytes (0.79), Neutrophils (0.77), Aspartate Aminotransferase (0.74), Cholesterol (0.72), and Eosinophils (0.72). For plasma specimens no models passed the cutoff. For DBS specimens 5 models passed the cutoff including Non HDL Cholesterol (0.84), Eosinophils (0.78), RBC (0.76), Absolute Neutrophils (0.73), and T7 Index (0.73). Finally, we attempted to combine multiple specimen types by using predictors from whole blood and plasma which improved the  $r$ -squared over 3 whole blood only models including RDW (0.57 to 0.68), T7 Index (0.61 to 0.65), and MCHC (0.54 to 0.62). Our results suggest good correlates can be found between gene expression and blood panel tests and in the future it may be possible to use RNA expression instead of the current tests for the blood panel. Our results also suggest most of the predictive power lies in the cellular fraction of the whole blood and not in extracellular plasma.

**Quality comparison of whole exome sequencing data by different types of specimen.** *K. Park, C. Fung, H. Kwon, C. Park, S. Lee, S. Park, D. Seo.* MacroGen Corp, Rockville, MD.

Nowadays, there are many researches and clinical studies performed using next-generation sequencing (NGS) data to detect genetic variations from samples. As a sequencing service provider, we have many experiences handling different types of specimens and noticed that their qualities of sequencing results are affected from different types of specimens. To examine these types of biases, we investigated mapping rate, percent of non-redundant, and off-target rate with 600 whole exome sequencing (WES) data including 200 gDNA, 200 blood, and 200 saliva samples that passed our initial QC criteria. From these comparisons, we observed off-target rates across all three types of specimens were comparable, but mapping rates and proportions of non-redundant rates in saliva samples showed much lower efficiency than the other two types of samples. Based on this study, we conclude that gDNA or the blood samples will warrant a better quality results of WES than saliva samples.

**ClinGen Pathogenicity Calculator 2.0: New features and lessons learned from the data mining of 2,400 variant interpretations according to ACMG/AMP guidelines.** *R. Patel, N. Shah, A. Jackson, P. Pawliczek, S. Paithankar, S. Milosavljevic, S. Plon, A. Milosavljevic.* Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

ClinGen Pathogenicity Calculator is a web service for assessing pathogenicity of genetic variants (Genome Medicine, 2017, 9:3). The service has been open to the public since October 2015. As of May 2017, the Calculator has more than 600 registered users. During the month of May 2017 more than 2300 page visits were generated by users from 41 countries. Based on the experience gained, Calculator was updated to include several new features to better assist and manage the variant interpretation process. Updates include a reconfigured dashboard that facilitates navigation by gene, interpretation, and phenotype. Prediction charts from key pathogenicity predictors, conservation scores, pooled allele frequency information, and link-outs to two additional sources (VarSome and InterVar) are included to assist the interpretation process. We evaluated usage patterns for the American College of Medical Genetics and Genomics and the Association of Molecular Pathologist (ACMG/AMP) guidelines using both user-contributed interpretations in the Pathogenicity Calculator and those imported from published articles reporting variant interpretations based on the guidelines. From a combined dataset of 2400 interpretations, we derived key statistics such as ACMG/AMP guidelines code usage, upgrades and pathogenicity assessment patterns for variants in 73 genes having > 10 interpretations (BRCA1, BRCA2, ATM and EFHC1 with the largest number of interpretations). Although the Calculator supports customization of variant interpretation guidelines, most users employ the published ACMG/AMP guidelines without any customization. The three most widely used variant interpretation codes on the combined dataset are BS4 (Non-segregation with the disease), PM2 (Absent in population databases) and PP2 (Missense mutation in the gene with a low rate of benign missense variants) ACMG codes. When only user-contributed assessments are considered, the most widely used codes were PP4 (Patient's phenotype or family history highly specific for the gene), PM2 and PP3 (computational evidence supports a deleterious effect). Other analysis results and lessons learned from this evaluation of ACMG/AMP guideline usage patterns to date will be presented during the meeting. The Pathogenicity Calculator is publicly available upon registration at <https://calculator.clinicalgenome.org>. This work was funded by the NIH National Human Genome Research Institute grants U01 HG007436-01 and U41HG006834.

**Indexcov: Whole-genome coverage in <1 second per BAM.** B.S. Pedersen, A.R. Quinlan. Human Genetics, University of Utah, Salt Lake City, UT.

Comparing consecutive file offsets indicated in a BAM or CRAM index allows one to estimate the number of alignments per genomic region without parsing the BAM. By leveraging the BAM/CRAM index in this way, as a proxy for coverage, **indexcov can analyze a 60X human genome dataset in ~1 second and thousands of samples in minutes.** This gives a coarse (~16KB resolution) whole-genome coverage estimate that, for the most part, closely tracks the actual depth. This represents a substantial improvement in the time required to profile coverage with existing methods and a valuable, early quality-control measure. The output of indexcov is an interactive HTML page that facilitates the **detection of sex chromosome anomalies, large copy-number variants, high-variance samples, batch effects, and other coverage anomalies.** *Indexcov* infers sample sex from coverage on the sex chromosomes and outputs metrics in a simple text files for filtering and custom visualization. In addition to coverage plots for each chromosome, it outputs a summary plot that simplifies finding outlier samples. *indexcov* is available as an executable from: <https://github.com/brentp/goleft/releases> with source-code available under the MIT license.

**Variants impact on splicing regulatory element determination pipeline.** N. Prodduturi, G. Oliver, Y. Li, E. Klee. Mayo Clinic, Rochester, MN.

**ABSTRACT Background:** Misregulation in the splicing component is linked to multiple hereditary diseases[1]. Many disease-causing variants disrupt splicing mechanism which affects splice sites or splicing regulatory sites in humans[2]. Splicing regulatory elements (SREs) are of different types i.e. splice sites, splicing silencers, and splicing enhancers and causal variants can impact these elements. Available DNA-based methods predict variants that affect these regulatory sites but applying them to mRNA level leads to a significant number of false positive events predicted as pathogenic mutations. Existing RNA-based tools also give large numbers of false positive candidate events. Despite available tools, a comprehensive Workflow to identify splice variants is still needed. **Method:** We have developed an integrative rule-based pipeline to annotate cis-acting variants in SREs and splice sites that cause splicing aberrations based on DNA-Seq and RNA-Seq data. BAM file with RNA-seq reads, mutations from RNA-seq and DNA-Seq (variant calls from DNA-Seq are optional), junction read counts and exon and gene level expression data are inputted into the workflow. Optional modules like gene expression sample filtering and variant calling are also included. The pipeline filters the mutations to the local vicinity Junctions, integrates different genomic input data, summarizes them to mutation level and annotates them as variants causing partial or whole exon exclusion or intron retention, and the deletion or insertion of splicing sites using a rule-based method. Where reference expression data exist, the workflow has an option to predict affect of splicing aberration on a relative gene or exon level expression. **Results:** With this workflow, aberrant splice mutations can be detected with high sensitivity and which can be applied to transcriptomics and genomics studies. We have used this workflow to detect disease causal genetic mutations affecting various splicing events in unsolved diagnostic odyssey cases. **References:** Lim, KH; Ferraris, L; Filloux, ME; Raphael, BJ; Fairbrother, WG (2011). **Working through heterozygous variants in NGS screenings: The DOMINO algorithm allows recognizing potentially dominant genes by machine-learning.** M. Quinodoz<sup>1</sup>, B. Royer-Bertrand<sup>1,2</sup>, K. Cisarova<sup>1</sup>, S.A. Di Gioia<sup>1</sup>, A. Superti-Furga<sup>2</sup>, C. Rivolta<sup>1,3</sup>. 1) Département de Biologie Computationnelle, Université de Lausanne, Lausanne, Switzerland; 2) Division of Genetic Medicine, Lausanne University Hospital (CHUV), Lausanne, Switzerland; 3) Department of Genetics, University of Leicester, Leicester, United Kingdom.

**Introduction:** In contrast to recessive conditions with biallelic inheritance, identification of dominant (monoallelic) mutations in novel disease genes is more difficult, because of the abundance of benign heterozygous variants that act as massive background noise (typically, in a 400:1 excess ratio with respect to pathogenic mutations). **Methods:** To reduce this overflow of false positives in Next-Generation Sequencing (NGS) screens, we developed DOMINO, a tool assessing the likelihood for a gene to harbor dominant changes. Unlike commonly-used predictors of pathogenicity, DOMINO takes into consideration features that are proper of genes, rather than of variants. It uses a machine-learning approach to extract discriminant information from a broad array of features, including: genomic data, intra- and interspecies conservation, gene expression, protein-protein interactions, protein structure, etc. DOMINO's iterative architecture includes a massive input of gene-associated properties (432, in total), a training process on 985 disease genes with well-established inheritance patterns, and repeated cross-validation that optimizes its overall discriminant power. **Results:** When validated on all newly-discovered disease genes published in the *AJHG* and in *Nat Genet* over a 15-month period, the algorithm displays an excellent final performance, with the receiver operating characteristic (ROC) function giving values for the area under the curve (AUC) higher of 0.91 and 0.92 for training and validation respectively. **Conclusion:** DOMINO is a robust and reliable tool that can predict dominance of candidate disease genes with high sensitivity and specificity, making it a useful complement to any NGS pipeline dealing with the analysis of the morbid human genome.

**Precision phenotyping of sample biopsies of kidney transplants by leveraging public microarray data and cell types enrichment analysis.** D. Rychkov<sup>1,2</sup>, T. Sigdel<sup>2</sup>, M. Sarwal<sup>2</sup>, M. Sirota<sup>1</sup>. 1) Institute for Computational Health Sciences, UCSF, San Francisco, CA; 2) Department of Surgery, UCSF, San Francisco, CA.

Acute Rejection (AR) still remains the driving cause of renal failure within one year after transplantation. The access to publicly available transcriptomic data provides a great opportunity for meta-analysis enlightening new diagnostic and therapeutic strategies. However, the data can have phenotypic annotations that don't truly reflect biological process going on in transplant, since a histological diagnosis can vary among pathologists. To reduce variance in analyses, we developed a new approach for precision phenotyping of allografts. We leverage the publicly available microarray data from the NCBI GEO from 38 datasets of human kidney allograft biopsies. After data quality control and filtering procedures, we ended up with the 1,734 samples, down from 2,973 samples. For each sample, we first used the phenotypes as they are described in the original publications: stable (1,061), chronic allograft nephropathy (CAN) (239) (including interstitial fibrosis/tubular atrophy and calcineurin inhibitor toxicity), and AR (434) (including antibody and T-cell mediated rejection, Mixed, and AR+CAN). Next, by taking advantage of a new tool for cell type enrichment analysis xCell (D. Aran et.al, 2017), we identified unique signatures of 45 cell types ( $p$ -value < 0.05) for each phenotype. Adopting this as training data we applied machine learning techniques to carry out sample phenotype prediction. This allows us to precisely select samples based on their biological functionality and thus strengthen the overall gene expression signal for a given phenotype. Also, this new approach can be applied as an independent *in silico* validation for a patient diagnosis and warn about possible future allograft rejection. We reserve three independent longitudinal cohorts with 217 samples (STA (157) and others (60)) for validation of our results. Further, we performed a statistical analysis on re-phenotyped samples to identify a more robust gene expression signature associated with acute rejection resulting in several hundred significant genes. Among them there are up-regulated genes that are involved in the immune response, T- and B-cell activation, and cytokine signaling in immune system. The proposed approach for sample control and diagnostic validation offers a robust analytical design for identification molecular signatures in acute kidney rejection, that can lead to better understanding biological mechanisms of allograft injury and increase the graft survival rate.

**Cloud-based quality measurement of whole-genome cohorts.** *W. Salerno<sup>1</sup>, O. Krasheninina<sup>1</sup>, W. Nasser<sup>1</sup>, J. Farek<sup>1</sup>, A. Mansfield<sup>1</sup>, D. Ames<sup>2</sup>, A. Carroll<sup>2</sup>, F.J. Sedlazeck<sup>1</sup>, Z. Khan<sup>1</sup>, G. Metcalf<sup>1</sup>, D.M. Muzny<sup>1</sup>, E. Boerwinkle<sup>1,3</sup>, R.A. Gibbs<sup>1</sup>. 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 2) DNAnexus, Mountain View, CA, 94040; 3) Human Genetics Center, University of Texas Health Science Center, Houston, TX, 77030.*

Large-scale human disease sequencing programs such as the Centers for Common Disease Genomics (CCDG), Trans-Omics for Precision Medicine (TOPMed), and Alzheimer's Disease Sequencing Project (ADSP) each have generated whole genome sequence (WGS) data sets derived from tens of thousands of phenotyped individuals. These samples also serve as a resource to the Precision Medicine community, providing the foundation for variant and genome annotation, method and technology development, and sequencing best practices. Cost-optimized processing, management and quality assessment remain technical and logistic challenges. We assessed the data quality of more than 25,000 WGS samples, reflecting multiple sequencing protocols and NIH cohorts, a 20x range in sequence coverage, a variety of multiplexing strategies, three sequencing platforms and the effects primary analysis harmonization. Both sample-level and project-level assessments were performed, including generation of GRCh38-specific variant and genome quality control metrics, structural variant (SV) yield-sensitivity to these metrics, and replicate-based protocol comparisons. All analyses utilized updated workflows deployed on the DNAnexus platform, including an NIH-compliant FASTQ-to-CRAM workflow optimized with Sentieon software, >200 FASTQ and CRAM metrics with the HGSC's AlignStats app, and a multi-method variant calling method parallelized in a single application, Parliament (PMID:25886820). This infrastructure allows for rapid and inexpensive harmonization of other data sets with existing NIH cohorts. These assessments also leverage project-specific features to isolate data bias that can confound downstream analysis. For example, in a multi-institution study, replicate-based SV analysis of 584 WGS samples across 111 families showed strong platform and institution batch effects, and removal of protocol-specific events (49%) did not resolve the heterogeneity. However, a novel PCA replicate harmonization identified a smaller SV set (17%) that did resolve the batch effects when removed: the remaining data properly clustered the replicate samples and reflected the underlying family structure. Taken together, these results and infrastructure describe a scalable model for WGS data harmonization.

**Ultra-rapid detection of identity-by-descent tracts for biobank-scale inference.** *R. Shemirani<sup>1</sup>, G.M. Belbin<sup>2</sup>, E.E. Kenny<sup>2</sup>, C.R. Gignoux<sup>3</sup>, J.L. Ambite<sup>1</sup>.* 1) Information Sciences Institute, University of Southern California, Marina del Rey, CA; 2) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Colorado Center for Personalized Medicine, University of Colorado, Aurora, CO.

The identification of identity-by-descent (IBD) tracts is a standard step in many pipelines for genome-wide studies in both population and medical genetics. With novel mega-scale initiatives ongoing from biobanks and nation-wide resources there is an ongoing need for efficient methods to detect these IBD segments for identification of cryptic relatedness, population linkage, and demographic inference. While IBD detection has been a topic of vigorous development, existing algorithms scale poorly, exhibiting emergent quadratic or higher order run time as study size becomes large and IBD segments become commonplace. This makes integration into large studies such as across health systems or national biobank initiatives intractable. Here, we present a novel algorithm for mega-scale IBD detection via partitioning and locality sensitive hashing, allowing close-to-linear time scaling and enabling IBD segment detection genome-wide in studies of hundreds of thousands of samples and beyond. Our algorithm, called I-LASH (Ibd by LocAlity Sensitive Hashing), provides a pipeline-ready approach to IBD detection, uses standard file formats, and contains flexible tuning parameters for arrays or sequencing. By leveraging parallelism and our computationally efficient design I-LASH allows entire mega-scale studies to be analyzed on a standard multi-core machine. We benchmark I-LASH on simulated datasets and across reference datasets including the ethnically diverse >51,000 individuals genotyped in the PAGE-II Consortium. While maintaining similar precision and recall metrics to the standard GERMLINE method, I-LASH provides a >40-fold speedup compared to GERMLINE with 50,000 samples. We anticipate that I-LASH will empower IBD inference for the next generation of medical and population genetic studies.

**Collective feature selection to identify important variables for epistatic interactions.** S. Verma<sup>1,2</sup>, A. Lucas<sup>2</sup>, X. Zhang<sup>1</sup>, Y. Veturli<sup>2</sup>, S. Dudek<sup>2</sup>, B. Li<sup>1</sup>, R. Li<sup>3</sup>, D. Kim<sup>2</sup>, M. Ritchie<sup>2</sup>. 1) Huck Institute of Life sciences, The Pennsylvania State University, University Park, PA; 2) Biomedical and Translational Bioinformatics Institute, Geisinger Health System, Danville, PA; 3) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Machine learning (ML) methods have gained popularity and practicality in identifying linear as well as non-linear effects of genetic variants associated with complex disease traits. Genotype data (used as input variables for ML methods) generally consists of ~100,000 or more common variants (MAF>20%) after quality control. Detection of epistatic interactions for 100K or more variants still remains a challenge, thus leading to the so-called "curse of dimensionality" problem. The efficiency of ML methods can be increased by limiting the number of input features. Thus, it is essential to perform variable selection before searching for epistasis. Many methods have been previously proposed to perform feature selection; but all methods do not follow "one method fits all" approach. We tested a wide range of parametric, non-parametric, and data mining approaches to select variables with epistatic effects in a simulation study. In our simulated data analysis, we found that data mining approaches like Multifactor Dimensionality Reduction (MDR) performs best in identifying true positives with epistatic as well as additive effects but in other published simulation studies, it is observed that other parametric and nonparametric methods select features with smaller type 1 error rates. Thus, we propose a collective feature selection approach to select variants that are in the "union" of the best performing methods. Since the scoring algorithms for all methods are different, we propose the use of a user-defined percentage of top-ranking features from all methods and then proceed with these collectively selected features for downstream analysis. In this study, we demonstrate in extensive simulation datasets that this collective feature selection method maintains high power to detect the true positive signals in the simulated datasets. We present collective feature selection as a powerful approach in identifying biologically pertinent epistatic features for discovery analysis.

**PipelineDog: A simple and flexible graphic pipeline construction and maintenance tool.** J. Xing<sup>1</sup>, A. Zhou<sup>1</sup>, Y. Zhang<sup>1</sup>, Y. Sun<sup>2</sup>. 1) Dept of Genetics, Human Genetic Institute of New Jersey, Rutgers Univ, Piscataway, NJ; 2) New Jersey Center for Science, Technology & Mathematics, Kean University.

Data manipulations and analyses are essential components of bioinformatics research. An analysis pipeline defines an analysis workflow by specifying the order and configuration of various analysis tools, and their input/output data. Although pipelines can be coded in a scripting language such as BASH or python, such scripts usually suffer from limited readability and poor reusability. For enhanced reusability, a design that allows clear decoupling and easy reassembly of individual steps is needed. Several attempts have been made to address these challenges, such as the Common Workflow Language (CWL) and Workflow Description Language (WDL). However, most existing pipeline management system or workflow engines are too complex for rapid prototyping needs, and a lightweight, user-friendly, and flexible solution is thus desirable. We developed a pipeline construction and maintenance tool, PipelineDog (<http://pipeline.dog/>), to deliver both simplicity and flexibility. PipelineDog is a comprehensive web-based integrated development environment (IDE) with a modern web graphical user interface (GUI). It offers cross-platform compatibility, project management capabilities, code formatting and error checking functions, and online repositories. It uses an easy-to-read/write script system that encourages code reuse, and with an online repository, it also encourages sharing of pipelines, which enhances analysis reproducibility and accountability. For most users, PipelineDog requires no additional software installation. Overall, this system provides a way to rapidly create and easily manage *ad hoc* pipelines.

**Bayesian multiple eQTL detection with control for population structure and sample relatedness.** B. Zeng, G. Gibson. Georgia Institute of Technology, Atlanta, GA.

Expression quantitative loci, or eQTL, are widely used as a tool to interpret GWAS results. There is increasing evidence that gene expression is often controlled by multiple *cis*-eQTLs (Wen et al, 2015; Hormozdiari et al, 2017). A battery of recent methods, frequentist and Bayesian, are being developed to detect such multiple eQTL, and there is some evidence that the latter (CAVIAR, FMQTL, DAP, FINEMAP) have increased power to resolve independent effects of closely linked sites. However, most of the available packages ignore the effects of sample relatedness due to population and family structure. Ignoring these phenomena can be detrimental, as they may lead to false positives or loss of resolution when fine-mapping the multiple causal eQTL variants. Here we describe MeQTLPolyG (*Multiple eQTL detection controlling for PolyGenic background*), a package for identifying and estimating complex eQTL effects while controlling for potential population structure and relatedness. This package first performs sequential conditional analysis to detect independent peak signals, then integrates a genetic relatedness matrix to remove the influence of structure. For each peak signal, a Bayesian-based multiple eQTL detection pipeline is used to estimate the number of causal variants and choose most plausible candidate list. We apply the method to two large blood gene expression data sets, CAGE and Framingham, both of which include relatives and population diversity, and quantify the increased detection of multiple *cis*-eQTL.

**Robust and accurate estimation of DNA sample contamination agnostic to genetic ancestry.** *F. Zhang<sup>1,3</sup>, H.M Kang<sup>2,3</sup>*. 1) Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 2) Department of Biostatistics, School of Public Health, University of Michigan, Ann Arbor, MI; 3) Center for Statistical Genetics, University of Michigan, Ann Arbor, MI.

Detecting and estimating DNA sample contamination has been established as a critical step to ensure high quality sequence reads and reliable downstream analysis. Our verifyBamID software tool has been run over 2 million samples to date from multiple sequencing centers. The current method relies on externally provided allele frequency information to estimate estimation of contamination levels, and misspecified allele frequencies result in substantial bias in contamination estimates. Our experiment demonstrates that current methods may fail to screen highly contaminated samples (~10%) at a stringent contamination threshold (~3%) when the genetic ancestry is misspecified. However, correctly specifying population allele frequencies in early stage of sequence analysis is cumbersome or sometimes even impossible for large-scale sequencing centers that simultaneously process samples from multiple studies across diverse populations. We propose a robust statistical method that accurately estimates DNA contamination agnostic to genetic ancestry of the intended or contaminating samples. Our method integrates the estimation of genetic ancestry and DNA contamination in a unified likelihood framework by leveraging individual-specific allele-frequencies projected from reference genotypes onto principal component coordinates. As a result, our method not only estimates contamination accurately, but also estimates genetic ancestry of both intended and contaminating samples. Our experiments show that our method robustly corrects for the bias in both contamination level estimates and genetic ancestry estimates under different scenarios of contamination. In the experiment with *in-silico* contaminated samples constructed from the 1000 genomes samples, our new method resulted best estimation accuracy and least bias compared to the current method across all different settings. With current method, the contamination levels were most severely underestimated for African American samples, and overestimated when intend and contaminating samples originate from different continental populations. In experiment with real dataset, we observed that that 18 of 1,000 deeply sequenced genomes are marked as contaminated with new method at 3% threshold, even though all of them were estimated to have <3% contamination with the current methods. Our method is publicly available at <https://github.com/statgen/verify-BamID2>.

**Predicting exposure to ionizing radiation by biochemically-inspired genomic machine learning.** *J.Z.L. Zhao, E.J. Mucaki, P.K. Rogan*. Biochemistry, University of Western Ontario, London, Ontario, Canada.

Analyzing gene expression in peripheral blood mononuclear cells reveals profiles that predict radiation exposure in humans and mice by logistic regression (PLoS Med. 4:e106; PLoS ONE. 3:e1912). Using biochemically-inspired methods (Mol. Onc. 10:85-100), we derive gene signatures to predict the level of radiation exposure with improved accuracies. DNA repair genes responsive or differentially expressed upon radiation exposure and orthologs highly expressed in species resilient to radiation exposure (n=998) were analyzed by two-sampled t-tests comparing expression in individuals unexposed and exposed to radiation (150-200 cGy: humans or 50-1000 cGy: mice). Significance thresholds for including a gene in developing a signature were adjusted based on radiation dose, from  $p < 0.01$  (50 cGy) to  $< 1E-14$  (1000 cGy), equivalent to ~10% of genes. Support Vector Machine (SVM) signatures were derived by backward feature selection (BFS) or minimum-redundancy-maximum-relevance (mRMR) and validated using leave-one-out cross validation (LOOCV) and external datasets. GEO datasets GSE6874 and GSE10640 were used for training and testing. Signatures derived by BFS from the human patients of GSE6874 (n=78) included  $\alpha$  *GADD45A*, *GTF3A*, *TNFRSF4*, *XPC* and  $\beta$  *ATR*, *GADD45A*, *GTF3A*, *IL2RB*, *MYC*, *NEIL2*, *RBM15*, *SERPINB1*, *XPC*, which both distinguished irradiated from unirradiated individuals with 98% sensitivity and 100% specificity in LOOCV. Validating these signatures on the human patients of GSE10640 (n=71) confirms that  $\alpha$  and  $\beta$  are both 92% sensitive and, respectively, 94% and 96% specific. mRMR found the 10 "best" genes from the murine samples of GSE10640 (n=104) to create a signature at each radiation dose; several genes were common among signatures. Signature  $\delta$  (50 cGy) included *PHLDA3*, *BAX*, *NBN*, *CCT3*, *CDKN1A*, *CCNG1*, *POLK*, *ERCC5*, *GCDH*, and *RAMP1*. Signature  $\epsilon$  (200 cGy) included *PHLDA3*, *LIMD1*, *CCT3*, *BAX*, *MS4A1*, *GLIPR2*, *BLNK*, *BCAR3*, *CDKN1A*, and *TFAM*. Signature  $\zeta$  (1000 cGy) included *CCT3*, *SUCLG2*, *EI24*, *CNBP*, *PHLDA3*, *TPST1*, *HEXB*, *FEN1*, *CDKN1A*, and *BLNK*. When validated on the murine samples of GSE6874 (n=14), each signature correctly predicted the exposure status of all mice. Our approach produces signatures with higher accuracies in cross- and external validation datasets than prior logistic regression models, with significantly improved sensitivities in detecting radiation exposure in humans. This will be useful in identifying nearly all radiation-exposed individuals in a mass casualty.

**1289T**

**Leveraging allele-specific expression to refine fine-mapping for eQTL studies.** *J. Zou<sup>1</sup>, F. Hormozdizari<sup>2</sup>, J. Ernst<sup>1</sup>, J. Sul<sup>1</sup>, E. Eskin<sup>1</sup>.* 1) University of California, Los Angeles, Los Angeles, CA; 2) Harvard University, Boston, MA.

Many disease risk loci identified in genome-wide association studies are present in non-coding regions of the genome. It is hypothesized that these variants affect complex traits by acting as expression quantitative trait loci (eQTLs) that influence expression of a nearby gene. This indicates that many causal variants for complex traits are likely to be causal variants for gene expression. Hence, identifying causal variants for gene expression is important for elucidating the genetic basis of not only gene expression but also complex traits. However, detecting those variants is challenging due to complex genetic correlation among variants known as linkage disequilibrium (LD) and the presence of multiple causal variants within a locus. Although several fine-mapping approaches have been developed to overcome these challenges, they may produce large sets of putative causal variants when true causal variants are in high LD with many non-causal variants. In eQTL studies, there is an additional source of information for fine-mapping called allele-specific expression (ASE) that measures imbalance in gene expression due to different alleles. In this work, we develop a novel statistical method that leverages both ASE and eQTL information to detect causal variants that regulate gene expression. We illustrate through simulations and application to the Genotype-Tissue Expression dataset that our method identifies the true causal variants with higher specificity than an approach that uses only eQTL information.

**The role of CTCF and cohesin complex in chromatin looping and higher-order organization of human genome.** *D. Plewczynski<sup>1</sup>, M. Kadlof<sup>1</sup>, P. Szalaj<sup>1</sup>, M. Lazniewski<sup>1</sup>, M. Sadowski<sup>1</sup>, Z. Tang<sup>2</sup>, Y. Ruan<sup>2</sup>.* 1) Centre of New Technologies, University of Warsaw, Warsaw, Mazovia, Poland; 2) Jackson Laboratory for Genomic Medicine, CT, USA.

The recent genomic and bioimaging insights in the higher order chromatin organisation in human nucleus motivated us to propose novel simulation method aimed at the effective prediction of three-dimensional human genome structure. We applied an advanced long-read Chromatin Interaction Analysis by Paired-End Tag Sequencing (ChIA-PET) experimental strategy [1] combined with computational modelling [2] to comprehensively map higher-order chromosome folding and specific chromatin interactions mediated by CCCTC-binding factor (CTCF), cohesin and RNAPII with haplotype specificity and nucleotide resolution in different human cell lineages [3]. We demonstrate the effectiveness of biophysical modeling in building 3D genome models at multiple levels, including the entire genome, individual chromosomes, and specific segments at megabase (Mb) and kilobase (kb) resolutions of single average and ensemble structures. We find that CTCF/cohesin-mediated interaction anchors serve as structural foci for spatial organization of constitutive genes concordant with CTCF-motif orientation, whereas RNAPII interacts within these structures by selectively drawing cell-type-specific genes towards CTCF-foci for coordinated transcription. Furthermore, we show that haplotype-variants and allelic-interactions have differential effects on chromosome configuration influencing gene expression and may provide mechanistic insights into functions associated with disease susceptibility [1]. 3D-genome simulation suggests a model of chromatin folding around chromosomal axes, where CTCF is involved in defining the interface between condensed and open compartments for structural regulation [2]. Our 3D-genome strategy thus provides unique insights in the topological and thermodynamical mechanisms [4] of human variations and diseases. **References** [1] "CTCF-Mediated Human 3D Genome Architecture Reveals Chromatin Topology for Transcription" Tang Z, Luo OJ et al., Plewczynski D, Li G, Ruan Y. *Cell*. 2015 [2] "An integrated 3-Dimensional Genome Modeling Engine for data-driven simulation of spatial genome organization" Szalaj P, et al., Ruan Y, Plewczynski D. *Genome Res*. 2016 [3] "3D-GNOME: an integrated web service for structural modeling of the 3D genome" Szalaj P, et al., Ruan Y, Plewczynski D. *Nucleic Acids Res*. 2016 [4] "Free energy based high-resolution modeling of CTCF-mediated chromatin loops for human genome" Dawson W and Plewczynski D (bioRxiv 2017).

**Weighted gene co-expression network analysis using peripheral blood of patients with 22q11.2 deletion syndrome.** A.G. Dantas<sup>1</sup>, M.L. Santoro<sup>2</sup>, C.A. Kim<sup>3</sup>, D.C.Q. Soares<sup>3</sup>, V.A. Meloni<sup>1</sup>, N.R. Nunes da Silva<sup>1</sup>, S.I. Belangero<sup>1,2</sup>, G.G. Carnevali<sup>1</sup>, M.I. Melaragno<sup>1</sup>. 1) Department of Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, SP, Brazil; 2) Department of Psychobiology, Universidade Federal de São Paulo, São Paulo, SP, Brazil; 3) Genetics Unit, Universidade de São Paulo, São Paulo, SP, Brazil.

22q11.2 deletion syndrome (22q11.2DS) results from hemizygous deletions of chromosome 22, being the 3 Mb deletion between the LCR22A-D the most frequent one. Even though most patients have the same size deletions, the phenotype is highly variable among individuals and different mechanisms has been described to justify this variability. During the years, the genes responsible for clinical conditions have been delineated from gene expression data sets, where differentially expressed genes are correlated to the phenotype. Recently, a new system biology approach has been developed to analyze gene expression data. The WGCNA (weighted gene co-expression network analysis), a R analytical package, identify groups of probes that have similar expression in the sample and produces a set of modules. Each module is a group of genes with strongly shared co-expression relationships. The WGCNA analysis on microarray gene expression data set from 11 22q11.2DS patients and 14 controls identified a total of 50 modules of different sizes in terms of gene number, which were labelled by different colors according to WGCNA package functions, and a gene ontology (GO) enrichment analysis was performed. Eight modules were correlated with the patients' phenotype (correlations ranging from -0.51 to 0.96,  $p < 0.03$ ). The tan module was enriched in neuronal functions and cellular processes such as nucleolus organization and DNA repair; the turquoise module in neuron development, differentiation and neurotransmitter secretion; plum2, in protein modification processes and negative regulation of glutamate metabolic process; white, in uridine and borate transport and regulation of cell motility; thistle1, in cellular processes and cell differentiation; royal blue, in cerebellar cortex morphogenesis, telomere maintenance and organization; magenta, in immune cell response, and red module was enriched in regulation of imprinting and methylation, cell-substrate and cell-matrix adhesion, mesenchymal cell development and GABA signaling pathway. Our data show that the WGCNA is able to indicate the enrichment of GO terms associated to the pathology observed in patients with 22q11.2DS, providing the possibility of searching for genetic modifiers that were not previously observed in gene expression studies. The study of gene networks allowed us to do more than single gene comparisons, but also identify relationships between genes, pathways and phenotypes. Financial support: FAPESP, Brazil.

Babb<sup>10</sup>, ClinGen Consortium Data Model Working Group and the Monarch Initiative. 1) Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Medical Informatics and Clinical Epidemiology, Oregon Health and Science University, Portland, OR; 3) Laboratory for Molecular Medicine, Partners Healthcare Personalized Medicine, Cambridge MA; 4) Health Sciences Research, Mayo Clinic, Rochester MN; 5) Pediatrics-Oncology, Baylor College of Medicine, Houston, TX; 6) Harvard Medical School, Boston MA; 7) Geisinger Autism and Developmental Medicine Institute, Lewisburg PA; 8) Biomedical Informatics, University of Utah, Salt Lake City UT; 9) Renaissance Computing Institute, University of North Carolina at Chapel Hill, Chapel Hill NC; 10) GeneInsight, a SunQuest company, Boston MA.

Determining the clinical relevance of a genetic variant requires detailed evaluation of diverse data. Resources that share simple statements of variant pathogenicity, alone or in combination with unstructured metadata, do not provide sufficient detail for reanalysis in light of new information or for adjudication of discordant interpretations. While the recently published ACMG-AMP guidelines encourage a more systematic assessment of pathogenicity, they fundamentally rely on the synthesis and evaluation of the evidence for pathogenicity in the context of individual criteria. Comparisons of interpretations performed by different laboratories demonstrate that there is still considerable variability in how these criteria may be applied. Further, our knowledge is constantly changing through updating of existing disease and molecular resources, collection of new data and data types, and redefinition of diseases and phenotypes. It is therefore necessary to develop a robust model of evidence that can be leveraged to provide for consistent interpretation of variant pathogenicity and to rapidly incorporate new knowledge in real time. The Clinical Genome resource (ClinGen) and the Monarch Initiative have created a robust informatics foundation for tools to support knowledge integration and interoperability regarding verifiable and updatable interpretations of variant pathogenicity. ClinGen provided domain knowledge in the methods and evidence types used for variant interpretation. This included development of structured representations of over 95 examples documenting the application of the ACMG-AMP guidelines. The Monarch Initiative contributed the Scientific Evidence and Provenance Information Ontology (SEPIO), a generalizable semantic model for linking scientific assertions to underlying lines of evidence and provenance metadata. SEPIO provides a unified and flexible representation of evidence for assertions that supports data integration across diverse biomedical databases. The result is a structured but practical approach to representing variant pathogenicity assertions with evidence. This approach addresses the imperative for structured and granular sharing of variant interpretations and supporting evidence.

**1293F****Supervised enhancer prediction with epigenetic pattern recognition and targeted validation across organisms.**

*M. Gu<sup>1</sup>, A. Sethi<sup>1,2</sup>, E. Gumusgoz<sup>3</sup>, L. Chan<sup>3</sup>, K. Yan<sup>1,2</sup>, K. Yip<sup>4</sup>, J. Rozowsky<sup>1,2</sup>, R. Sutton<sup>6</sup>, L. Gerstein<sup>1,2,5</sup>.* 1) Program in Computational Biology and Bioinformatics, Yale University, New Haven, CT; 2) Molecular Biophysics and Biochemistry, Yale University, New Haven, CT; 3) School of Medicine, The Chinese University Hong Kong, China; 4) Department of Computer Science, The Chinese University Hong Kong, China; 5) Department of Computer Science, Yale University, New Haven, CT; 6) Department of Internal Medicine, Section of Infectious Diseases, Yale University School of Medicine, New Haven, CT; 7) Functional Genomics Department, Lawrence Berkeley National Laboratory, Berkeley, CA.

*Cis*-regulatory elements (CREs) are difficult to characterize both experimentally and computationally. With only a few validated mammalian enhancers, it is difficult to properly train statistical models for their identification. Instead, postulated patterns of genomic features were used heuristically for prediction. More recently, a large number of massively parallel assays for characterizing enhancers have been developed. Here, we use them to create shape-matching filters based on enhancer-associated metaprofiles in epigenetic features. We then combine different features with simple, linear models and predict enhancers in a supervised fashion. Using *in vitro* transduction-based reporter assay in human H1 hESC cell line, as well as *in vivo* transgenic mouse enhancer assays in 6 different tissues, we show that our model is able to accurately predict enhancers in different species without re-parameterization between cell lines and even between organisms. Finally, we predict enhancers in cell lines with many transcription-factor binding sites. In turn, this highlights distinct differences between the type of binding at enhancers and promoters, enabling the construction of a secondary model discriminating between these two.

**1294W****Novel high-resolution multi-ethnic HLA imputation reference panels constructed based on high-coverage whole-genome sequencing data.**

*Y. Luo<sup>1,2</sup>, M. Gutierrez-Arcelus<sup>1,2</sup>, A. Metspalu<sup>3</sup>, J.G. Wilson<sup>4</sup>, S. Kathiresan<sup>5</sup>, T. Esko<sup>2,3</sup>, S. Raychaudhuri<sup>1,2</sup>, the TOPMed project.* 1) Division of Genetics and Rheumatology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; 2) Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 3) Estonian Genome Center, University of Tartu, Tartu 51010, Estonia; 4) Physiology and Biophysics, University of Mississippi Medical Center; 5) Center for Genomic Medicine, Massachusetts General Hospital.

The human leukocyte antigen (HLA) region harbors genes that are crucial to a wide range of human diseases. However it has been challenging to identify and fine-map HLA associations from GWAS data. HLA imputation approaches have been restricted by limitations in reference panels to European populations and to amino acid (4-digit) resolution. Here, we infer HLA types from large scale whole-genome sequencing (WGS) data, and built the first multi-ethnic high resolution HLA reference panels. These references can be applied to a wide range of worldwide data sets, where HLA imputation was not previously possible. The computational strategies that we present can also be applied in any high coverage WGS data, thereby allowing users to build their own HLA reference panels. First, we present a computational strategy that takes advantage of the recent rapid development of WGS technology to infer a set of alleles that encode the same protein sequence for the peptide binding sequence of an HLA molecule (i.e., 6-digit). We applied this strategy to 2,244 Estonian and 3,027 African-American WGS samples with coverage  $\geq 25\times$ . We observed that the frequencies of inferred HLA alleles are highly consistent with publicly available data within the same population group (Pearson  $r^2$  of 0.96 and 0.98 respectively). Next, we constructed a 4- and 6- digit HLA reference panel of the 5,271 WGS samples, and a 4-digit panel combining these with samples from a perviously published 4-digit panel based on data from 5,225 individuals in the Type 1 Diabetes Genetics Consortium (T1DGC). To evaluate performance of these panels, we imputed HLA alleles with each of them into a multi-ethnic cohort of 2,291 individuals genotyped on the ImmunoChip array. The average imputation  $r^2$  at 4-digit resolution is 0.96 compared to 0.90 using the T1DGC panel. For individuals of African descent,  $r^2$  improved to 0.92 in the combined panel. To further assess the accuracy of the imputed HLA types we analyzed data obtained from 26 individuals by the gold-standard sequencing method. Of 520 alleles tested in the five classical HLA genes (HLA-A, B, C, DQA1, and DRB1), 100%, 96.9% and 94.2%, respectively, were correctly imputed at 2-, 4- and 6-digit resolution. We subsequently demonstrate how imputation and association testing at 4- and 6-digit resolution could facilitate discovery and fine-mapping of HLA association signals, giving specific examples from psoriasis in 50K individuals from the Estonian Biobank.

**Detecting copy number variants in 200,000 individuals: The Department of Veterans Affairs Million Veterans Program (MVP).** *M. Li<sup>1,2</sup>, Y. Shi<sup>1</sup>, S. Pyarajan<sup>1,3</sup> on behalf of the VA Million Veteran Program.* 1) VA Boston Healthcare System, Boston, MA; 2) Division of Nephrology, University of Utah School of Medicine, Salt Lake City, UT; 3) Harvard Medical School, Boston, MA.

Copy number variants (CNVs) are one of the most important genomic sources of variability that have not been comprehensively evaluated for association with complex diseases or human traits in the GWAS era. The Million Veteran Program (MVP), sponsored by the Department of Veterans Affairs, is partnering with Veterans to establish one of the world's largest databases of genomic, clinical, lifestyle and military exposure information. With the goal of enrolling one million participants, MVP has enrolled over 570,000 Veterans as of June 2017. In phase 1 200,845 samples have been genotyped using the Affymetrix Axiom MVP 1.0 Custom array and data quality assessment completed. In order to systematically assess the contribution of CNVs to complex diseases or traits, we aim to develop a map of human CNVs informed by hybridization intensity data generated from the Affymetrix Axiom MVP 1.0 array. CNV calls were obtained using Affymetrix Power Tools and PennCNV software. We "trained" a hidden markov model (hmm) file on 96 HapMap samples genotyped on the MVP 1.0 array, using the available Affymetrix Axiom hmm file as a template in PennCNV. The reference CNV database combined previously identified CNV regions from the HapMap3 project, the 1000 Genomes Project, and the Exome Aggregation Consortium (ExAC). We examined the population frequency of CNVs that are a) within the reference CNVs; b) outside of the reference CNVs. In total, we identified 4,665 autosomal CNVs, 50% of them reside within the reference CNVs. Among 2,334 novel CNVs, 14 are common genic CNVs ( $\geq 2\%$  frequency) and 2,283 are rare genic CNVs ( $<0.5\%$  frequency). Our results open the door for new opportunities such as conducting genome-wide association study for CNVs or burden of rare CNVs with different diseases or traits in MVP. We plan to extend the CNV map with genotype data from the entire MVP cohort.

**1296F**

**A graph-based Arab reference genome using whole read overlap assembly.** *Y. Mokrab<sup>1</sup>, A.C. English<sup>2</sup>, J. Bruestle<sup>2</sup>, S.N. Shekar<sup>2</sup>, K.A.M. Fakhro<sup>1</sup>.* 1) Systems Biology and Bioinformatics, Sidra Medical and Research Centre, Doha, Qatar; 2) Fabric Genomics, 1611 Telegraph Avenue, Suite 500, Oakland, CA 94612, USA.

Recent exploration of ancestral populations' genomes has shown that the widely used Human reference genome (GRCh37/GRCh38) lacks the diversity needed to represent populations of specific ethnicities (Fakhro et al. 2016. Hum Genome Var. 3:16016). By incorporating Single Nucleotide Variants (SNVs) and indels found by alignment-based variant calling into GRCh37, a population-representative reference can be created which increases the proportion of alignable reads from an individual of the same population. Incorporating structural variants (SVs) would further improve alignment. Here, we look at the prevalence of SVs in a cohort of 100 individuals with Qatari ancestry to further enhance the Arab reference genome (Fakhro et al. 2016. Hum Genome Var. 3:16016) with SVs having a high population frequency. The detection of SVs with short-read data is difficult due to inaccurate breakpoints, unresolved insertion sequences and high false discovery rate (English AC, et al. 2015. BMC Genomics. 16:286). To characterise SVs in this cohort, we run the BioGraph variant caller - a graph-based caller combining extended BWT and FM index to create a graph structure of the reads while allowing for rapid query of all possible assembly paths. Using this graph-genome representation, BioGraph detects SVs with high sensitivity, low false discovery rate and exact sequence of breakpoints and insertions (Parikh H et al 2016. BMC Genomics. 17:64). In a study of SVs within a family using BioGraph, over 97% of the detected SVs were shown to follow mendelian inheritance (Shekar et al, 2016 unpublished). In a preliminary analysis, the BioGraph variant caller was run on the caucasian HapMap individual NA12878 and two individuals of Arab ancestry (SRR2098185 and SRR2098177). Approximately 4,000 SVs were identified in each of these individuals. Of these, 104 (2.6%) were Arab-specific, identical between the Arab individuals but absent from NA12878. These results suggest this method enables accurate, reproducible SV detection across samples. Here, we will show characteristics of SVs that have a high allele frequency in the Qatari population as well as comparisons of BioGraph results against other graph-based and linear SV detection methods, including long-read single molecule sequencing.

**1297W**

**DUP-OE: A new tool to discovery the origin and expansion of duplication.** X. Zhuang. HKU, HK, Hong Kong.

Copy number variation (CNV), including deletion and duplication, has been proved to be associated with a lot of human diseases. Researchers have developed lots of tools to detect CNV. Read-Depth, Pair-end and Split-read methods are the widely used principle for discovering CNV. The detection of deletion is easier than that of duplication, and the concordance of deletion among different tools are quite high. However, there exists high preference in duplication when using different tools, as the derivation of duplication is complex, which includes ectopic recombination, replication slippage and retrotransposition. Moreover, the detection of duplication on complex genomic region, such as repeat and GC-content unusual regions might be more challenge. Most of the current tools only give the results of the duplicated locations. However, in most cases, the duplicated genes would not just stand next to the duplication region. On the contrary, it may inserted to other genomic regions. In these cases, if we have not realised where the duplicated gene expanse, we might just focus on the function discovery of the original region. However, the duplicated region might be normal, and it is the expansion region that been disrupt and causing certain kinds of diseases. Based on the above reasons, we develop a new method: DUP-OE, to discovery both the origin and the expansion of duplication. It can be used to detect the CNV based on the whole genome sequence. DUP-OE performs well on both the simulated data and the real clinical samples.

**Illuminating the Druggable Genome (IDG): An NIH Common Fund program.** J. Baker<sup>1</sup>, C. Colvis<sup>2</sup>, A. Pawlyk<sup>1</sup>. 1) National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, M.D. 20892; 2) National Center for Advancing Translational Sciences, National Institutes of Health, Bethesda, M.D. 20892.

The Pilot Phase of the **Illuminating the Druggable Genome (IDG)** was launched as an NIH Common Fund program in 2014. The pilot program supports a Knowledge Management Center (KMC) and a consortium of 7 projects for the Adaptation of Scalable Technologies to Illuminate the Druggable Genome (TechDev). The Pilot Phase was intended to provide feasibility of the approaches to identify and study understudied **G protein-coupled receptors, protein kinases, ion channels, and nuclear receptors**. The Implementation Phase of the IDG is expected to launch in 2018 and run through 2023. The NIH has issued RFAs for **Data and Resource Generation Centers** (RFA-RM-16-026), a **Knowledge Management Center** (RFA-RM-16-024), and a **Resource Dissemination and Outreach Center** (RFA-RM-16-025). Applications were due on March 14<sup>th</sup>, 2017 and awards will be made in late 2017. The experimental arms of the Implementation Phase of the IDG will focus on understudied members of the **G protein-coupled receptors, ion channels, and protein kinases** while informatics efforts will extend across the proteome. Its overall goal will be to generate, aggregate, analyze, and disseminate knowledge and tools around understudied proteins. These new knowledge and tool sets are intended to equip the scientific community, including small businesses and the pharmaceutical industry, with the ability to explore previously understudied biology with the potential to rapidly impact human health.

**Enhancing discoverability and reusability of 1.2 million human genomic datasets.** *M. Corpas, N. Kovalevskaya, R. Shaw, C. Whicher, A. Alexa, F.G.G. Nielsen.* Repositiv Ltd, Cambridge, United Kingdom.

Publicly-funded human genome studies require their data to be catalogued and deposited in internationally recognized repositories. As sequencing data generation explodes, a rising number of data repositories are being created to accommodate the increasingly divergent data types and regulated sharing environments. This makes finding and accessing genomic datasets more cumbersome for users, who ultimately may choose to generate their own data rather than reusing the existing data (even if that means duplicating efforts). Repositiv (<https://repositiv.io/?ASHG>), a free online portal for finding and accessing human genomic datasets, is a centralized platform currently indexing over 1.2M datasets from 47 data sources. Repositiv harbors a community of >2000 users, actively engaged in crowdsourcing the annotation of registered datasets via Repositiv's powerful social networking features. By following or favoriting Repositiv's datasets, users can track a dataset's user activity and connect with other users interested in the same dataset, hence seeding potential new collaborations. To facilitate the search, datasets are further organized into collections, which aggregate meaningful dataset classifications and specific search criteria according to data types: e.g., population studies, microbiomes, methylomes and other NGS-derived data of human origin. By using the Repositiv platform, researchers are able to find all publicly available (restricted or open access) human genomic datasets, acquire a global overview of the genomic data landscape and forge new collaborations, drastically enhancing their dataset discoverability and reusability for further research advancement.

**Semantic web technology accelerates integration of genetic and phenotypic information in biomedical databases.** *T. Katayama, S. Kawashima, Y. Yamamoto.* Database Center for Life Science, Kashiwa, Chiba, Japan.

The Database Center for Life Science is a Japanese national institute for the development of technologies on database standardization and integration. We have been developing an integrated genome database, named as TogoGenome, which incorporates genome and gene/protein annotations with the Semantic Web technology. To effectively integrate genetic and phenotypic information in the genome database, we have developed Resource Description Framework (RDF) version of major public biomedical databases such as MedGen, ClinVar and ExAC, where RDF is a standard for data exchange in the Semantic Web which is standardized by the World Wide Web consortium (W3C). While a lot of important biomedical databases are available, integrated use of them is still hard because of lacking in standards for data formats, identifiers and common vocabularies among them. This has laid a heavy burden on both database developers and users working in research institutes and pharmaceutical companies. RDF can effectively resolve the integration issues and also provide the semantics of original data explicitly with the help of ontologies. Once the databases are represented as RDF data, those are interlinked and also linked to external RDF resources. In the case of biomedical data, genetic variation can be seamlessly linked to genomes, transcripts, proteins, diseases, drugs, pathways and literature information. To date, most of major life science databases are already provided or are being developed as RDF datasets such as 1) genome annotations (Ensembl), 2) DNA sequences and annotations (GenBank/ENA/DDBJ and RefSeq), 3) protein sequences and annotations (UniProt), 4) protein structures (PDB), 5) chemical and drug related information (PubChem, ChEMBL, NIKKaji) 6) biological pathways (Reactome), 7) gene expressions (Expression Atlas, RefEx), 8) taxonomy, 9) literature (PubMed, MeSH), and omics data including cancer genomics, toxic genomics, orthologies, epigenetics, proteomics, glycomics along with many biomedical ontologies mainly hosted at the National Center for Biomedical Ontologies (NCBO). To fully utilize those kinds of valuable information for human genetics, here we report our work on RDF versions of the biomedical databases which are going to be integrated to the TogoGenome application. The application and the RDF datasets are publicly available so that biomedical researchers and application developers can make use of them without suffering from incompatibilities.

**Controlled-access databases for genetic and phenotypic human data in Japan.** Y. Kodama<sup>1</sup>, A. Fukuda<sup>1</sup>, J. Mashima<sup>1</sup>, M. Minowa<sup>2</sup>, M. Kawashima<sup>2</sup>, K. Miyazaki<sup>2</sup>, N. Mitsuhashi<sup>2</sup>, E. Kaminuma<sup>1</sup>, O. Ogasawara<sup>1</sup>, K. Okubo<sup>1</sup>, Y. Nakamura<sup>1</sup>, T. Takagi<sup>1,2</sup>. 1) DDBJ Center, National Institute of Genetics, Mishima, Shizuoka, Japan; 2) National Bioscience Database Center, Japan Science and Technology Agency, Tokyo, Japan.

The Japanese Genotype-phenotype Archive (JGA, <http://trace.ddbj.nig.ac.jp/jga>) serves as one of centralized repositories providing authorized access to individual-level phenotype and genotype data in collaboration with our partner institute, the National Bioscience Database Center (NBDC, <http://humandbs.biosciencedbc.jp>) of the Japan Science and Technology Agency. JGA is the Japanese counterpart of the dbGaP (database of genotypes and phenotypes) and EGA (the European Genome-phenome Archive) at NCBI and EBI, respectively. NBDC in Japan established guidelines and policies compliant with the amended Act on the Protection of Personal Information and ethical guidelines fully put into effect on May 30, 2017. The Data Access Committee (DAC) at NBDC reviews and makes decisions about data submission to JGA and usage requests from researchers. JGA accepts metadata in which personal identifiers have been removed by submitters. Acceptable data types include raw and processed data from array-based and next-generation sequencing platforms, clinical images, and phenotype data associated with data samples. Upon receipt, JGA archives the original data files in encrypted form in the database. JGA data are organized in the hierarchical JGA data model based on that of EGA. JGA assigns stable, unique identifiers prefixed by 'JGA' to studies and subsets of metadata from those studies. Approved user can download permitted datasets with secure transfer software after granted by DAC. To enhance collaboration by providing workspace for sharing and analyzing pre-publication data, we have started a new service 'DDBJ Group Cloud (DGC)' since February 2017. As the first use case, we provide 'AMED Genome Sharing Database (AGD)' for sharing pre-publication human genomic data from AMED-funded researches. Because AGD and JGA use the same data model, users can smoothly transfer the AGD data to JGA when their papers are published. Summaries of available studies are listed on the JGA (<https://ddbj.nig.ac.jp/jga/viewer/view/studies>) and NBDC websites. As of 31 May 2017, 53 studies are available at JGA. In the poster, we present contents, system and recent developments of JGA.

**DASHR 2.0: Database of small non-coding RNAs in normal human tissues and cell types.** P.P. Kuksa<sup>1,2</sup>, Y.Y. Leung<sup>1,2</sup>, A. Amlie-Wolf<sup>1,2,3</sup>, O. Valladares<sup>1,2</sup>, L.-S. Wang<sup>1,2,3</sup>. 1) Penn Neurodegeneration Genomics Center, University of Pennsylvania, Philadelphia, PA; 2) Institute for Biomedical Informatics, University of Pennsylvania, Philadelphia, PA 19104, USA; 3) Genomics and Computational Biology Graduate Group, University of Pennsylvania, Philadelphia, PA.

DASHR is a database developed at the University of Pennsylvania with the most comprehensive information on ~48000 human small non-coding RNAs (sncRNA) genes and mature sncRNA products in 187 smRNA high-throughput sequencing (smRNA-seq) datasets from multiple public sources. We present the updated DASHR 2.0 database with an improved preprocessing workflow, more samples and tissue types, more sncRNA classes and availability in both hg19 and hg38 genome builds. Beyond small RNA-seq data sets in DASHR 1.0, we have incorporated >150 high quality short total RNA-sequencing and miRNA-sequencing data sets from ENCODE, as well as ~500 single cell small RNA-seq data into DASHR 2.0. The full collection of DASHR 2.0 contains 800 samples across 55 tissues, 33 cell types including 6 stem cells types, and 8 cell lines. In addition to the seven existing small RNA classes (microRNAs, Piwi-interacting RNAs, small nuclear, nucleolar, cytoplasmic RNAs, transfer and ribosomal RNAs), DASHR 2.0 includes other functional sncRNAs such as tRNA-halves, tRF -1, -3, -5, long non-coding RNAs-derived small RNAs, updated annotations for snoRNAs, piRNAs and Y-RNAs. More importantly, we have included all the previously unannotated sncRNAs identified in the datasets described, thus allowing researchers to use our database to perform in silico validation on their own data. All the datasets have been processed using an updated small RNA-seq pipeline (SPAR, <http://lisanwanglab.org/SPAR>) with additional features, including conservation scores, consistency of mature products and read accumulation relative to the genomic background. These new features, especially the conservation scores should greatly increase the convenience of studying these sncRNAs. All annotations are viewable as tracks on the UCSC genome browser so researchers can integrate with other existing omics data easily. DASHR 2.0 is a valuable resource for researchers to query and characterize their small RNAs of interest. Users can access DASHR 2.0 at <http://lisanwanglab.org/DASHR/v2>.

**Predicting genetic ancestry for 805,482 patients using clinical data from electronic health records.** *N. Tatonetti<sup>1</sup>, T. Lorberbaum<sup>1</sup>, K. Quinnes<sup>1</sup>, R. Vanguri<sup>1</sup>, H. Qi<sup>2</sup>, W. Chung<sup>2</sup>, D. Goldstein<sup>3</sup>.* 1) Biomedical Informatics, Columbia University, New York, NY; 2) Pediatrics, Columbia University, New York, NY; 3) Institute for Genomic Medicine, New York, NY.

Genetic ancestry is essential for studies aiming to discover variants with clinical significance. Dimensionality reduction techniques, such as principal components analysis, make shared ancestry in complex populations easily identifiable. Unfortunately, genetic data are not available for most patients in clinical and research settings. Clinical data, like those stored in electronic health records (EHRs), are vast but do not directly capture ancestry information. Here, we present a novel method for inferring genetic ancestry using only variables routinely captured in the EHR. Using 1,161 patients that have both genetic and clinical information at Columbia University/NewYork-Presbyterian Hospital, we trained and validated a machine learning model that uses clinical data to estimate genetic ancestry. We conducted principal components analysis on 3,154 samples from 1000 Genomes and HapMap and applied the learned principal components (PCs) to the genetic data of 1,161 consented patients at Columbia. We then trained a random forest regressor model on demographic and billing code (ICD-10) data from these patients to predict their PC1 and PC2 values; we evaluated model performance using out-of-bag estimates against the genetic reference standard. Top predictive features included the self-reported race/ethnicity information, diseases of the nervous system, and congenital malformations. We found that merging related ICD-10 codes up to the Chapter level (21 condition features and 12 demographic features) achieved the greatest Pearson correlation (0.609) and lowest RMSE (68.29) for PC2 with only a small change in performance for PC1 (Pearson correlation = 0.600, RMSE = 36.66). We also found that the tree ensemble standard deviation was significantly correlated with the absolute error for both PC1 (Pearson correlation = 0.847,  $P < 1E-100$ ) and PC2 (Pearson correlation = 0.849,  $P < 1E-100$ ) and therefore could be used to estimate confidence of the predicted ancestry. 805,482 patients had sufficient data to predict their genetic ancestry from the clinical data stored in their EHRs. We applied our trained model to these patients to predict PC1 and PC2 values for patients that otherwise have no genetic data available. Our approach uses a minimal set of commonly collected data to accurately infer genetic ancestry and is a new tool for genetic screening in EHR research.

**Improved phenotype-based computational methods to support diagnosis of genetic disease.** *J. Chen<sup>1</sup>, H. Xu<sup>2</sup>, A. Jegga<sup>1</sup>, K. Zhang<sup>1</sup>, P. White<sup>1</sup>, G. Zhang<sup>1</sup>.* 1) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) University of Cincinnati Medical Center, Cincinnati, OH.

Clinical diagnosis of genetic diseases is often difficult because patients usually exhibit many clinical features that are not readily recognizable as known genetic syndromes. The Human Phenotype Ontology (HPO) provides a structured and standardized vocabulary of phenotypic abnormalities of human disease and it has been widely used for differential diagnostics, phenotype-driven analysis of genetic testing results. The main challenges of these approaches include how to efficiently extract the diagnostic information embed in the phenotypic ontology and to make correct and robust diagnosis when the query phenotypes are not specific or imprecise. Here we introduce two new methods to prioritized diagnosis of genetic diseases based on integrated semantic similarity (Method 1) or ontological overlap (Method 2) between the phenotypes expressed by a patient and phenotypes annotated to known diseases. Using simulated and real patients' data, we showed that these two methods were computationally efficient and exhibit better performance than previous methods in correctly prioritizing candidate diseases. We implemented our methods in a freely available web application to aid diagnosis of genetic diseases.

**Quantification of transplant-derived circulating cell-free DNA in absence of a donor genotype.** *E. Sharon*<sup>1,2,9</sup>, *H. Shi*<sup>3</sup>, *S. Kharbanda*<sup>3</sup>, *W. Koh*<sup>4,5</sup>, *L.R. Martin*<sup>4,5</sup>, *K.K. Khush*<sup>6</sup>, *H. Valentine*<sup>7</sup>, *J.K. Pritchard*<sup>1,2,4,9</sup>, *I. De Vlamincck*<sup>8,9</sup>. 1) Department of Genetics, Stanford University, Stanford, CA, 94305, USA; 2) Department of Biology, Stanford University, Stanford, CA 94305, USA; 3) Pediatric Stem Cell Transplantation, Lucille Packard Children's Hospital, Stanford, California 94304, USA; 4) Howard Hughes Medical Institute, Stanford University, Stanford, CA 94305, USA; 5) Departments of Bioengineering and Applied Physics, Stanford University, Stanford, California 94304, USA; 6) Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford, CA 94305, USA; 7) National Institutes of Health, Bethesda, MD 20892, USA; 8) Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY 14853, USA; 9) Corresponding authors.

Quantification of cell-free DNA (cfDNA) in circulating blood derived from a transplanted organ is a powerful approach to monitoring post-transplant injury. Genome transplant dynamics (GTD) quantifies donor-derived cfDNA (dd-cfDNA) by taking advantage of single-nucleotide polymorphisms (SNPs) distributed across the genome to discriminate donor and recipient DNA molecules. In its current implementation, GTD requires genotyping of both the transplant recipient and donor. However, in practice, donor genotype information is often unavailable. Here, we address this issue by developing an algorithm that estimates dd-cfDNA levels in the absence of a donor genotype. Our algorithm predicts heart and lung allograft rejection with an accuracy that is similar to conventional GTD. We furthermore refined the algorithm to handle closely related recipients and donors, a scenario that is common in bone marrow and kidney transplantation. We show that it is possible to estimate dd-cfDNA in bone marrow transplant patients that are unrelated or that are siblings of the donors, using a hidden Markov model (HMM) of identity-by-descent (IBD) states along the genome. Last, we demonstrate that comparing dd-cfDNA to the proportion of donor DNA in white blood cells can differentiate between relapse and the onset of graft-versus-host disease (GVHD). These methods alleviate some of the barriers to the implementation of GTD, which will further widen its clinical application.

**Copy number variation detection and variant curation improves interpretation of exomes for inborn errors of metabolism.** *S.E. Brenner*<sup>1</sup>, *A.N. Adhikari*<sup>1</sup>, *Y. Wang*<sup>1</sup>, *R.C. Gallagher*<sup>2</sup>, *R.L. Nussbaum*<sup>2</sup>, *Y. Zou*<sup>1</sup>, *U. Sunderam*<sup>3</sup>, *J. Shieh*<sup>2</sup>, *F. Chen*<sup>2</sup>, *B.A. Koenig*<sup>2</sup>, *M. Kvale*<sup>2</sup>, *S.D. Mooney*<sup>4</sup>, *R. Srinivasan*<sup>2</sup>, *P.-Y. Kwok*<sup>2</sup>, *J.M. Puck*<sup>2</sup>, *The NBSeq Project*. 1) University of California, Berkeley, CA, USA; 2) University of California, San Francisco, CA, USA; 3) Tata Consultancy Services, Hyderabad, TS, India; 4) University of Washington, Seattle, WA, USA; 5) Invitae, San Francisco, CA, USA.

The NBSeq project is evaluating effectiveness of whole exome sequencing (WES) for detecting inborn errors of metabolism (IEM) for newborn screening (NBS). De-identified archived dried blood spots from MS/MS true positive and false positive cases previously identified in the California NBS were studied. 26 out of 145 affected individuals lacked two rare potentially damaging single nucleotide variants or short indels in genes responsible for their Mendelian disorders. The sensitivity of causal mutation detection in 145 NBSeq exomes varied across disorders; all affected PKU cases were predicted correctly, but several cases of other IEMs were missed. Deeper analysis of the data from these 32 individuals was undertaken to assess sources of discrepancy between sequencing results, MS/MS call, and clinical diagnosis. Copy number variation (CNV) calling tools were evaluated on NBSeq exomes for ability to resolve some of these exome false negatives. CNV tools can both miss CNVs in exomes and report them spuriously. We optimized tools for our data and filtered out genes (PRODH, HCFC1, ETFA) harboring common CNVs (identified from CNV calls on the 1000 genomes project exomes). This identified deletions in the correct genes for 4 of the 32 exome false negatives using XHMM: 2 isovaleric acidemia cases, 1 methylmalonic acidemia case and 1 OTC deficiency case. Our initial pipeline reported any variant in IEM genes with annotation of pathogenic or likely pathogenic by HGMD or ClinVar with allele frequency <5%. However, critical re-assessment of the primary literature for 59 variants with MAF >0.1% found that only 18 were reportable, including 1 dominant variant. The resulting curated inclusion/exclusion variant list reduced both false positives and false negatives, while highlighting the clinical heterogeneity among monogenic IEMs. Incorporation of CNV detection and variant curation into our analysis pipeline improved overall accuracy from 81.32% to 85.16% on the initial 145 affected NBSeq samples. This updated pipeline will be run on additional NBSeq exomes to assess the potential role for WES in NBS. While still not sufficiently specific alone for screening of most IEMs, WES can facilitate timely and more precise case resolution.

**QRank: A novel quantile regression tool for eQTL discovery.** X. Song, G. Li, Z. Zhou, X. Wang, I. Ionita-Laza. Columbia University, New York, NY.

**MOTIVATION:** Over the past decade, there has been a remarkable improvement in our understanding of the role of genetic variation in complex human diseases, especially via genome-wide association studies. However, the underlying molecular mechanisms are still poorly characterized, impeding the development of therapeutic interventions. Identifying genetic variants that influence the expression level of a gene, i.e. expression quantitative trait loci (eQTLs), can help us understand how genetic variants influence traits at the molecular level. While most eQTL studies focus on identifying mean effects on gene expression using linear regression, evidence suggests that genetic variation can impact the entire distribution of the expression level. Motivated by the potential higher order associations, several studies investigated variance eQTLs. **RESULTS:** In this paper, we develop a Quantile Rank-score based test (QRank), which provides an easy way to identify eQTLs that are associated with the conditional quantile functions of gene expression. We have applied the proposed QRank to the Genotype-Tissue Expression project, an international tissue bank for studying the relationship between genetic variation and gene expression in human tissues, and found that the proposed QRank complements the existing methods, and identifies new eQTLs with heterogeneous effects across different quantile levels. Notably, we show that the eQTLs identified by QRank but missed by linear regression are associated with greater enrichment in genome-wide significant SNPs from the GWAS catalog, and are also more likely to be tissue specific than eQTLs identified by linear regression. Intriguing by heterogeneous eQTLs on gene expression, we have further extended the QRank approach to maximize the identification of heterogeneous effects.

**A novel set of 96 indices for accurate sample demultiplexing on Illumina platforms.** B. Carrion, J. RosaFigura, S.K. Sandhu, J. Irish, L. Kurihara, T. Harkins, V. Makarov. Swift Biosciences Inc., Ann Arbor, MI.

The ability to uniquely and correctly assign sequencing reads to the appropriate sample is essential for all next generation sequencing projects. Recent publications have highlighted sequencing reads being misassigned due to index hopping on the Illumina pattern flow cell platforms. In addition, there is a growing demand for new indices to eliminate errors associated with certain index combinations on Illumina's 2 and 4-channel technologies. These errors are mostly due to insufficient separation of the hamming edit distances (the minimum number of base substitutions required to change one index sequence to the other) among index sequences with equal length. We have observed bleed-through index collisions among Illumina TruSeq HT indices at a frequency up to 1.5%. To remedy these issues, we have developed 96 single (i7) indices with a minimum hamming distance of at least three bases between all 96 indices, allowing proper discrimination of distinct index bases for sample identification during demultiplexing. These 8 nt i7 indices are compatible with Illumina's TruSeq HT i5 index sequences, enabling up to 768 high through-put dual combinations. To ensure there are no bleed-through index collisions, we co-sequenced indexed libraries containing unique non-overlapping inserts on both 2- and 4-channel instruments. Using this method, we were able to identify the presence, the extent, and the source of any observed bleed-through. Sample bleed-through was not observed at rates >0.1%. Also, it has been recently demonstrated that index hopping occurs on patterned flow cells as DNA library strands can have index misassignment due to carryover indexing PCR primers or adapters during the exclusion amplification (ExAmp) reaction, that is part of cluster generation. We have developed both wet lab protocols and unique dual indices (UDIs) to minimize this issue and where it does happen, the misassigned sequencing reads are rendered undetermined, eliminating any sequencing reads from being assigned to the incorrect indexed sample. Using this strategy, there is a minimum of 96 UDI combinations used for sequencing on patterned flow cells. Good laboratory practice suggests using different 96 indices from sequencing run to run to eliminate any possible carry-over, a possible third source for sequencing reads to be misassigned.

**1309W**

**Gene-based tests using imputed genotype dosages showed increased statistical power than using best-guessed genotypes.** *M. Hwang, Y. Kim, D. Shin, S. Moon, B. Kim.* Division of Genome Research, Korea National Institute of Health, Cheongju-si, South Korea.

Recently, imputation analysis is widely used in genome-wide association studies to gain increased statistical power and enhanced mapping resolutions, especially for low frequency variants. Association analysis using imputed data is more powerful considering genotype uncertainty by using probabilistic dosages of predicted genotypes. While imputed genotype dosages (DS) have frequently been used for single variant association tests, gene-based association tests often use best-guess genotypes (GT) that is the imputed genotypes with maximum posterior probability. The approach using DS for gene-based tests is limited because 1) only one imputation software, Minimac3, support VCF format with DS as an output, 2) no tool convert the output from other imputation software to VCF format with DS, which is generally used for tools supporting gene-based association tests, and 3) significant amount of time is required for conversion process using in-house scripts. Therefore, the conversion tool and study on advantages in using DS for gene-based tests are warranted. In this study, we developed a software Converting Imputation output to VCF format(CIV) with GT, Genotype Posterior Probabilities (GP), and DS information. And we compared gene-based association results of GT and DS. Imputation analysis was performed using IMPUTE v2 software with 1,000 Genomes project phase 3 data as a reference panel. SKAT-O was used for gene-based association analysis. Association for TCHL was tested using chromosome 1 data of imputed genotypes from about 7,000 genotyped samples (Korea Biobank Array). During conversion process, CIV showed more than approximately 2-3 times faster than qctool v1.4, only support GT and GP output, and in-house python script. In gene-based association tests, DS approach could test about 9.3% more genes than GT approach. In overall, for commonly discovered genes, DS showed slightly increased statistical power over GT. Our study showed that gene-based tests using DS is more powerful than using GT and CIV facilitated the approach using DS followed by imputation analysis in terms of faster conversion time and support for various variables of imputed genotypes.

**1310T**

**User-driven prioritisation of study addition to the NHGRI-EBI Genome-Wide Association Study (GWAS) Catalog.** *J.A.L. MacArthur<sup>1</sup>, A. Bu-niello<sup>2</sup>, T. Burdett<sup>1</sup>, M. Cerezo<sup>1</sup>, H. Coley<sup>2</sup>, P. Hall<sup>2</sup>, L. Harris<sup>1</sup>, L.A. Hindorff<sup>2</sup>, C. Malangone<sup>1</sup>, A. McMahon<sup>1</sup>, A. Milano<sup>1</sup>, J. Morales<sup>1</sup>, D. Welter<sup>1</sup>, F. Cunningham<sup>1</sup>, P. Flicek<sup>1</sup>, H. Parkinson<sup>1</sup>.* 1) European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Cambridge, United Kingdom; 2) National Human Genome Research Institute (NHGRI), NIH, Bethesda, MD.

The importance of GWAS in identifying associations between genetic loci and traits or diseases is well established. GWAS produce a vast amount of data; we estimate that well over 15 billion variant-phenotype associations have been assayed in published GWAS to date. The GWAS Catalog ([www.ebi.ac.uk/gwas](http://www.ebi.ac.uk/gwas)) summarises this information into a structured, freely available and user-friendly resource. The Catalog contains the most significant associations, with p-value  $<1 \times 10^{-5}$ , from all published GWAS assaying at least 100,000 variants genome-wide. As of June 2017 this represents over 40,000 SNP-trait associations covering more than 2,300 unique traits from 2,900 publications. The volume of eligible data continues to grow with an 85% increase in associations from 2015-2016 publications compared to 2013-2014. This trend is likely to continue with many studies now analysing multiple complex phenotypes. Currently, eligible studies are curated into the GWAS Catalog in publication date order. Here, we propose alternative strategies to ensure data with the highest relevance and utility to users is available in the Catalog as quickly as possible. We have identified a series of metrics that can be used to assess the utility of GWAS, including sample size, extent of genome-wide coverage, relevance of trait, execution of a replication stage, inclusion of ancestrally diverse populations and the availability of summary statistics. We have surveyed users of the GWAS Catalog to help us identify which of these metrics are most valued by the community. We are optimising an algorithm to allow us to prioritise curation of GWAS studies according to these criteria, with each study characteristic weighted according to its relative importance. Prioritisation of the Catalog queue according to this algorithm will require triage of each publication as soon as it is identified as eligible. To maintain transparency of the Catalog methods, the queue of eligible GWAS publications will be made publicly accessible. The algorithm also takes into account requests for specific studies by Catalog users and therefore the interface will include the functionality for users to "up-vote" an eligible publication in the queue. These proposed changes to Catalog data acquisition will ensure the maximal value of the data available through the Catalog and sustainability into the future. We welcome feedback from the user community on these improvements and any other changes they would like to see.

**1311F****GRASP v3: An updated GWAS catalog and contrast to similar catalogs.**

B.A.T. Rodriguez<sup>1</sup>, C. Zellmer<sup>1,2</sup>, J. Li<sup>1,3</sup>, A. Panda<sup>1,4</sup>, N. Jenssen<sup>1</sup>, J.P. Lien<sup>1</sup>, J.D. Eicher<sup>1</sup>, A.D. Johnson<sup>1</sup>. 1) Population Sciences Branch, Division of Intramural Research, National Heart, Lung and Blood Institute, Framingham, MA; 2) University of Wisconsin, Madison, WI; 3) The Ohio State University, Columbus, OH; 4) Carnegie Mellon University, Pittsburgh, PA.

**Background:** Access to the expanding number of GWAS studies is a vital tool to biomedical research, providing opportunity for novel scientific discovery, identification of targets for functional assessment and mechanistic insights into disease biology. Current GWAS catalogs each have unique design features as well as limitations. The goal of GRASP (<https://grasp.nhlbi.nih.gov/>) is to provide a simple, intuitive means for the scientific community to query a centralized repository of reported SNP associations ( $P \leq 0.05$ ) with human traits, including studies of methylation and expression QTL. Current challenges to developing and maintaining GWAS databases include: (1) data sharing, (2) non-standardized formats, annotation practices across GWAS, (3) human curator study search, review and extraction strategies, and (4) criteria for inclusion. Here we describe efforts toward the release of GRASP v3. **Results:** The v3 update increases the total number of studies to >3,300. To facilitate results sharing summary statistics are now included in the GRASP web portal. To investigate differences among widely used catalogs, we contrast GRASP and the NHGRI-EBI. The latter catalog was downloaded May 5, 2017 and limited to results with clear SNPids. Random studies (n=50) common to both were selected for comparison. At a genome-wide significant threshold ( $P \leq 5e-8$ ) there was marked variation between the catalogs with respect to the studies' results. There were 656 SNP-association results unique to GRASP and 8 results unique to NHGRI-EBI. Focusing on 373 SNPs common to both we characterized consistency in associations for the studies. While most were consistent, differences in phenotype nomenclature were frequent. In general, GRASP contained more results for specific sub-phenotypes per SNP (e.g., sex-specific results, disease sub-classification). When comparing P-value associations for identical SNPs/publication/phenotype only a small number of associations (n=14/373) deviated by >1 log(P-value) unit, with others being highly correlated (r=0.99). Sampling of 50 more studies yielded similar results. **Conclusions:** Study exclusion criteria and data extraction methods vary between catalogs and likely account for many differences. However, our results indicate marked heterogeneity across popular GWAS results catalogs and researchers may be best served by querying multiple resources instead of relying on a single one. Further characterization and analysis of GRASP v.3 will be presented.

**1312W****Reinterpreting genetic studies of kidney disease with integrated analysis of kidney-cell specific chromatin accessibility and transcriptomics data.**

K. Sieber<sup>1</sup>, S. Akilesh<sup>2</sup>. 1) Target Sciences, GlaxoSmithKline, King of Prussia, PA; 2) Department of Pathology, University of Washington, Seattle WA.

It is now evident that genetic variants identified by genome wide association studies (GWAS) largely map to non-coding regulatory DNA elements that in turn drive cell-type specific gene transcriptional programs. Regulatory DNA elements are efficiently identified genome-wide by chromatin accessibility assays such as DNase-seq. However, such maps are not available for rare or difficult to isolate cell types, which often play a critical role in human diseases. Specifically, the lack of cell-type specific chromatin-accessibility maps has limited the evaluation of GWAS of complex phenotypes such as chronic kidney disease, which affects ~10% of adults worldwide. Thus far, chromatin accessibility maps have only been generated for kidney tubule cells and endothelial cells and maps for a key component cell of the kidney filter, the glomerular podocyte, have been lacking. Therefore, to address this deficit, we generated high resolution chromatin accessibility (DNase-seq) and gene expression (RNA-seq) data for primary cultures of human podocytes (n=4) and tubular epithelial cells (n=3). Integrated analysis of these chromatin accessibility data with transcriptomic information enables us to map genetic variants associated with kidney disease to specific kidney cell types, a critical step in understanding biology and pathophysiology. Of the 63 replicated kidney loci identified by CKDGen in their 2015 and 2017 publications, 53 of the loci are within 5kb of open chromatin (DNase hypersensitive sites) in our data sets. For example, the *WNT7A* locus has numerous tubule-specific open chromatin regions which correlate with high expression of the *WNT7A* gene in tubule cells. The rs6795744 genetic variant associated with chronic kidney disease maps within 2kb of two tubule-specific DNase-hypersensitive sites. Increased *WNT7A* expression is associated with renal fibrosis in animal models. Therefore, this approach is the first use of cell type specific genomic data to functionally connect genetic variants for kidney disease to specific regulatory DNA elements. Extension of these approaches to other genetic variants is ongoing and will uncover novel therapeutic target genes and pathways affecting specific kidney cell types.

**1313T**

**Genomic multilateration.** *K. Kim<sup>1</sup>, H. Baik<sup>2</sup>, E. Eskin<sup>3,4</sup>, B. Han<sup>1</sup>.* 1) Department of Convergence Medicine, University of Ulsan College of Medicine & Asan Institute for Life Sciences, Asan Medical Center, Seoul 05505, Republic of Korea; 2) Department of Mathematical Sciences, KAIST, 291 Daehak-ro, Yuseong-gu, Daejeon 34141, Republic of Korea; 3) Department of Computer Science, University of California, Los Angeles, Los Angeles, CA 90095, USA; 4) Department of Human Genetics, University of California, Los Angeles, Los Angeles, CA 90095, USA.

Multilateration is a surveillance technique used to locate sensor nodes in wireless sensor networks. Using multilateration, the spatial coordinates of an unknown node can be estimated from its distances to reference nodes at known positions. For example, GPS analyzes radio signals received from satellites to pinpoint user position. Our motivation is to implement the concept of multilateration with genomic data. Specifically, we map individual data with  $K$  SNPs to a node in  $K$ -dimensional space, where each coordinate represents each SNP. In this space, pairwise Euclidean distance represents the genetic distance between two individuals. Using public data such as HapMap as our satellites, we investigate whether the distances to the satellites can uniquely determine the position of an individual in the  $K$ -dimensional space. Here, we analytically show that a minimum of  $K+1$  satellites are required, which is not satisfied in many practical situations in which the number of satellites (public data) is smaller than  $K$ . However, we show that the distance from an individual to a set of satellites (distance vector) can have wide utility in genetic studies. First, the distance vectors can be used to detect duplicate individuals among multiple association studies in a meta-analysis without transferring genotype data. In a meta-analysis, detecting duplicate individuals is important to avoid spurious associations, but is often difficult because sharing genotype data is prohibited due to privacy issues. Our method can determine duplicate individuals by comparing distance vectors without breaching privacy and can be easily shared among studies. Second, the distance vectors can be used to group individuals into distinct populations. In simulations using the 1000 Genomes Project data as our satellites, our method based on  $k$ -means clustering successfully distinguishes HapMap individuals into distinct populations. Third, the distance vectors can be used to map individuals in a 2-D map. Previous studies used principal component analysis (PCA) on genotype data to geographically map individuals. We show that, without genotype data but with distance vectors only, we can approximate the mapping of POPRES data using the 1000 Genomes Project data as the satellites. Our estimated projection resembles the plot based on the PCA result of the corresponding POPRES data and the geographical map of the Europe.

**Estimating incidence of inborn errors of metabolism from the frequency of variants in general population.** *I. Mihalek, O. Bodamer.* Boston Children's Hospital, Boston, MA.

Inborn errors of metabolism (IEM) constitute a large class of genetic diseases, specific in that many of them are amenable to (nutritional) treatment, especially if detected early. As the first-line screening moves from metabolite to genetic, it opens new possibilities for the number of diseases that can be screened for, which in turn may bring them to the attention of the medical and nutrition industry - the existence of effective treatment currently being one of the prerequisites for the IEM to be included in the screening panel. Collecting data about the incidence of the IEM on the national level is a difficult process, and not systematically pursued. However, the information about human genetic variation is becoming available (e.g. ExAC database) on the scale that enables us to put a bracket on the expected incidence of all recognized IEMs with monogenic origin. We are collecting that information in a publicly available place (monogenic.org). In this presentation we discuss our current experience in using data integration - modeling of the related protein structure, evolutionary conservation, known disease causing variants, and the genetic variability in the protein coding regions of the genome, stratified across ethnic sub-populations - to put an upper limit on the expected incidence of IEMs. In 75% of the cases for which the information about the IEMs prevalence on the US national level we can make a reasonable prediction on its upper limit. The remaining cases, discussed here, bring to the attention the need to collect the information on a deeper genetic level, perhaps extend the definition of some diseases to include polygenic origin, and hopefully motivate the need for further systematic reporting on the IEMs detected through newborn screening.

**A novel computational strategy for DNA methylation prediction.** *F. Yu, H.W. Deng, S. Hui.* Center for Bioinformatics and Genomics, Department of Global Biostatistics & Data Science, School of Public Health and Tropical Medicine, Tulane University, New Orleans, LA, USA.

Whole-genome bisulfite sequencing (WGBS) is the most comprehensive, unbiased method for characterization of genome-wide DNA methylation profiles, but is still too expensive to apply for large-scale studies. On the other hand, the Illumina HumanMethylation450 BeadChip (450K) array is a cost-effective and the most widely used method for DNA methylation analysis. Previous epigenomic studies have generated millions of 450K array data on various samples to study the methylation patterns associated with various diseases/traits. However, the 450K array only measures <2% of all the 28 million CpG sites in the human genome, which considerably limited the scope of the DNA methylation analysis in those studies. In this project, we developed a novel computational strategy to expand the existing 450K data by predicting DNA methylation levels at the unassayed CpG sites based on local DNA methylation patterns and other epigenomic functional annotations. Specifically, we first explored the co-methylation region based on the correlation pattern in a reference WGBS data. Then within each region, we trained a linear regression model of radial basis functions (RBFs) to predict a DNA methylation local score using the local upstream and downstream DNA methylation information. Finally, we incorporated the local score with other functional annotation information in a random forest classifier to predict the DNA methylation levels at unmeasured CpG sites. We found that the proposed prediction strategy using RBFs outperforms some existing methods, which use the methylation value of one nearest upstream and one nearest downstream CpGs as one kind of the input information for prediction, in terms of correlation between the predicted and true methylation values without any significant loss of area under the ROC curve. A potential extension by using the mixture of regression models of RBFs to estimate the local score are expected to improve the performance of our strategy by considering the bimodal distribution of methylation data. By application, this strategy will allow us to expand the existing 450K data and uncover new disease-related epigenetic signals without re-analyzing those samples by WGBS with high cost.

**1316T**

**Scaling workflows for growing microbiome applications.** *J. Lai.* Labcyte Inc, San Jose, CA.

16S ribosomal RNA (rRNA) sequencing has long been a technique employed by microbial ecologists to identify and compare bacteria present within a given sample. It is a well-established method for garnering a sense of organism identity and diversity from complex microbiomes and environments that are difficult to culture or study otherwise. As our understanding of microbiomes grows, we have become increasingly aware of the implications these communities have in areas such as hospital ecology, human health, and metagenomic discovery efforts. Thus, the utility and applications for 16S rRNA sequencing are growing. Unlike PCR-based approaches or capillary sequencing, next-generation sequencing (NGS) has already enabled the analysis of entire microbial communities that are unable to be cultured or studied in the lab. Furthermore, NGS enables the capacity and throughput to perform the method as a routine procedure. The reagent cost, however, can still be prohibitive. We demonstrate that the 16S rRNA amplicon sequencing library preparation procedure for the Illumina platform can be miniaturized 10-fold while providing equivalent amounts of data at equivalent quality levels. This reduces the cost for a technique that is essential to microbiome projects and spurs the technique's feasibility for other projects. As microbiome applications continue to grow, more information is becoming necessary to answer the questions researchers are asking, involving biovars, pathogenicity, and fungal diversity. Here, to address these requirements, we show that whole genome sequencing can be performed at a 10-fold reduced scale to provide much more information and context for microbiome studies than 16S rRNA sequencing, while increasing throughput and reducing costs.

**1317F**

**Deriving disease signatures using data driven approaches on microbiome.** *K. Poorey, L. Whitmore, D. Ray, C. Ball.* Systems Biology, Sandia National Laboratory, Livermore, CA.

Human body comprises 100 trillion microbial cells which make up 90% of total cells. They comprise 90% of our immune system, our digestive system, our second brain. Disruption of microbiome has been correlated to many of the diseases and also in some cases re-establishing a healthy microbial flora is key to restoring normal bodily functions. This puts research and understanding of human microbiome highly relevant in perspective of human health and diseases. Although, until recently the research in human microbiome research and its relation to human health have been limited due to lack of tools and resources. With the availability of Human Microbiome Project 1 and 2 (iHMP) data from individuals with disease and healthy gives us an opportunity to apply sophisticated machine learning and data-driven approaches to understand the role of microbiome in human health. Also, can it be used to identify key biomarkers of diseases for early detection and intervention? We have developed a state of the art Metagenomics and Amplicon sequencing Pipeline (MAGPie) to analyze the NGS data generated from the iHMP project. We combine these datasets with available metadata of individuals to use ensemble machine learning methods and deep learning to understand the dynamics of microbial community and how it changes in diseases. Our ensemble machine learning pipeline included hierarchical clustering approaches to cluster microbes to identify core communities, which reduces the feature space to apply ensemble methods with deep learning to build a predictive model of onset of disease. We find that the reduced feature model reduces the prediction error by 75% in the validation dataset. We apply this methodology on three datasets of Onset of Inflammatory Bowel Disease (IBD), Preterm Birth and, type 2 diabetes. These machine learning models also measure feature importance which is key to identify biomarkers of diseases and health. Which can be used to design a microbial consortium that can be used to counter related health problems. We intend to expand this study to incorporate metabolic modeling using the metatranscriptomics dataset in these systems to model and understand the functional changes happening in diseases.

**Noninvasive reconstruction of fetal methylome by sequencing of maternal plasma DNA.** *K. Sun, F.M.F Lun, R.W.K Chiu, Y.M.D Lo, H. Sun.* The Chinese University of Hong Kong, Hong Kong, Hong Kong.

The placental tissue plays key roles during the human pregnancy process and its DNA methylation profile is tightly related to the normal growth and development of the fetus, therefore possesses high clinical value in prenatal diagnosis. The discovery of cell-free fetal DNA in maternal plasma and the fact that these cell-free fetal DNA molecules mainly originate from the placental tissue promises the feasibility of noninvasive fetal/placental methylomic analysis using the plasma DNA. In a previous study, our group had demonstrated that the fetal methylome could be assessed through maternal plasma DNA. However, the deduced fetal methylome suffered from low resolution and accuracy thus limited its clinical applications. To this end, in this work we propose a novel algorithm, which we named Femer, to reconstruct the fetal methylome by sequencing of plasma DNA. Femer is completely noninvasive and control-free. We demonstrate that Femer could achieve high accuracy as well as high resolution and could correctly recover the Partially Methylated Region (PMD) pattern of the placental tissue, thus provides us a high-quality view of the fetal methylome from the maternal plasma interface. In addition, Femer could also deduce the fetal methylation profile of the CpG islands with extremely high accuracy and demonstrates potential clinical utility in monitoring of the key genes for placental development during the pregnancy process. Our work thus moves one step forward of the noninvasive fetal methylomic analysis using maternal plasma DNA for potential clinical utilities.

**Stargazer: A software tool for calling star alleles from next-generation sequencing data using *CYP2D6* as a model.** S. Lee<sup>1</sup>, R. Dalton<sup>2</sup>, M.M. Wheeler<sup>1</sup>, K. Patterson<sup>1</sup>, S. McGee<sup>1</sup>, A. Gaedigk<sup>3</sup>, T.A. Thornton<sup>4</sup>, K.E. Thummel<sup>5</sup>, E.L. Woodahl<sup>5</sup>, D.A. Nickerson<sup>1</sup>. 1) Department of Genome Sciences, School of Medicine, University of Washington, Seattle, WA, USA; 2) Department of Biomedical and Pharmaceutical Sciences, University of Montana, Missoula, MT, USA; 3) Division of Clinical Pharmacology, Toxicology and Therapeutic Innovation, Children's Mercy Kansas City, Kansas City, MO, USA; 4) Department of Biostatistics, School of Public Health, University of Washington, Seattle, WA, USA; 5) Department of Pharmaceutics, School of Pharmacy, University of Washington, Seattle, WA, USA.

Many enzymes play a role in pharmacological responses. One important enzyme is Cytochrome P450 2D6 (*CYP2D6*), which metabolizes nearly 25% of all prescription drugs. Prescription of such medications without the knowledge of a patient's *CYP2D6* phenotype status can lead to adverse drug reactions or a loss of efficacy due to inappropriate drug choice and/or dosing. Enzyme activity varies considerably between individuals due to the highly polymorphic nature of the *CYP2D6* gene locus. There are over 100 defined *CYP2D6* haplotypes (designated as star alleles); these are characterized by single nucleotide variants (SNVs), insertion-deletion variants (indels), and structural variants (SVs) that include gene deletions, duplications, and conversions. However, genotype analysis of *CYP2D6* is complex due to a number of reasons including the presence of a highly related non-functional paralog, *CYP2D7*, positioned upstream of *CYP2D6*. We have recently developed a novel tool named Stargazer that uses next-generation DNA sequence reads and a customized computational pipeline to call SNVs, indels, and SVs from targeted or whole genome sequences. To call SVs, Stargazer calculates paralog-specific copy number by leveraging nucleotide differences unique to each paralog. Genotyping of 32 ethnically diverse trios by Stargazer was 98% concordant with data obtained by Sanger sequencing, long-range PCR, TaqMan assays, or a combination of the former. Stargazer accurately called SVs, including *CYP2D6/CYP2D7* hybrids, all of which segregated according to expectations in the trios. In one case, Stargazer detected a duplication event missed by the orthogonal methods. We also assessed the correlation between Stargazer's genotype calls and *in vitro* measurements of *CYP2D6* abundance and activity in a large collection of human liver tissue samples ( $n > 300$ ). To improve interpretability, we translated the samples' genotype information into a standard unit of predicted phenotype called activity score (AS). The AS predicted by Stargazer was strongly correlated with *CYP2D6* abundance ( $r = 0.72$ ) and activity ( $r = 0.69$ ). This study demonstrates that *CYP2D6* genotype is the most important single factor explaining the large interindividual variability of *CYP2D6* abundance and activity. We are currently extending Stargazer to genotype novel *CYP2D6* star alleles and other pharmacogenes.

**Construction of Japanese reference genome and Japanese reference panel of thousands of individuals in Tohoku Medical Megabank Project.** M. Nagasaki<sup>1,2,3</sup>, F. Katsuoka<sup>1,2</sup>, Y. Kuroki<sup>1,2,4</sup>, T. Shibata<sup>1,2</sup>, T. Mimori<sup>1,2</sup>, Y. Kawaji<sup>1,2,3</sup>, N. Minegishi<sup>1,2</sup>, A. Hozawa<sup>1,2</sup>, S. Kuriyama<sup>1,2,5</sup>, Y. Suzuki<sup>1,2</sup>, H. Kawame<sup>1,2</sup>, F. Nagami<sup>1</sup>, T. Takai-Igarashi<sup>1</sup>, S. Ogishima<sup>1</sup>, K. Kojima<sup>1,2,3</sup>, K. Misawa<sup>1,2</sup>, O. Tanabe<sup>1,2</sup>, N. Fuse<sup>1,2,6</sup>, H. Tanaka<sup>1</sup>, N. Yaegashi<sup>1,2,6</sup>, K. Kinoshita<sup>1,3</sup>, S. Kure<sup>1,2,6</sup>, J. Yasuda<sup>1,2</sup>, M. Yamamoto<sup>1,2</sup>, TMM Japanese Reference Panel Project. 1) Tohoku Medical Megabank Organization, Tohoku University, Sendai, Japan; 2) Graduate School of Medicine, Tohoku University, Sendai, Japan; 3) Graduate School of Information Sciences, Tohoku University, Sendai, Japan; 4) National Research Institute for Child Health and Development, Tokyo, Japan; 5) International Research Institute of Disaster Science, Tohoku University, Sendai, Japan; 6) Tohoku University Hospital, Tohoku University, Sendai, Japan.

We have been conducting one of the largest prospective genome cohort studies in Japan. One of our missions is to set up the genome infrastructure in Japan for the promotion of personalized healthcare and genome medicine. Towards this mission, we have developed a whole-genome reference panel consisting of the 1,070 Japanese individuals (1KJPN) with short read Illumina sequencers. With this effort, we have succeeded in cataloging more than 20 million variants. However, at the same time we realized difficulties in cataloging long insertions ranging from one hundred to around ten thousand bases. To overcome this difficulty, we undertook *de novo* assembly of a Japanese genome using a deep long-read sequencer and successfully cataloged ten thousand of long insertions missing in the current international reference assembly. While there are efforts of *de novo* assembly in Korea and China in which one each individual sequence was determined by the similar approach to that employed in our study, we for the first time are able to extensively analyze and characterize these insertions in comparison with more than one thousand international individuals by using the whole-genome sequencing results from our 1KJPN (1,070 Japanese individuals) and 728 individuals from available from international consortium database. Most of the insertions we have identified in this study are shared among populations, such that parts of these sequences are found in the genomes of Denisovan, Neanderthal and chimpanzee. This fact suggests that many common insertions are originated from primitive anthropoids. We also have discovered almost one hundred insertions reside in all international individuals we have analyzed, demonstrating that these insertions are the strongly preferred sequences to complement to the latest international reference assembly. More accurate reference sequence is critically important for current clinical sequencings, given that an increasing number of patients are getting diagnosed by clinical whole-genome or -exome sequencings. In this regard, we provide a decoy Japanese reference genome (decoyJRGv2). The decoyJRGv2 improves the alignment ratio of unmapped sequencing data by more than 10% on average, as well as decreases the miss-called variants in coding regions. With the Japanese reference assembly, we are reconstructing the Japanese reference panel of thousands individuals from short-read sequencers in ToMMo dataset to catalog more accurate variants.

**1321W****SPACE, a tool for dynamic exploration of principal component analyses.**

*N.D. Berkowitz<sup>1</sup>, D.A. Turissini<sup>1</sup>, E. Elyashiv<sup>1</sup>, K.A. Rand<sup>1</sup>, Y. Wang<sup>1</sup>, E.L. Hong<sup>1</sup>, C.A. Ball<sup>1</sup>, K.G. Chahine<sup>2</sup>.* 1) Ancestry, San Francisco, CA; 2) AncestryDNA, Lehi, UT.

Principal component analysis (PCA) is frequently used in studies of human genetic diversity to study variability among a set of hundreds of thousands of single nucleotide polymorphisms (SNPs). PCA transforms this highly dimensional data into a new dimensional space, prioritizing the dimensions that capture the greatest variance. While powerful, PCA results can themselves be challenging to interpret, often involving arduous data manipulation and figure generation. We present SPACE, a PCA exploration tool that can be run from a web browser. SPACE, implemented in R using the package Shiny, allows users to dynamically scale, label, subset and transform data with a simple interface. In addition, users can examine metadata for a single sample or a collection of samples solely by pointing and clicking. We have designed SPACE to empower population geneticists to efficiently mine their data and get the most out of their analyses.

**1322T****Quickly determining subject ancestries in large datasets using genotypes of dbGaP fingerprint SNPs.**

*Y. Jin, M. Feolo, S.T. Sherry.* National Center for Biotechnology Information, National Institutes of Health, Bethesda, MD.

Genotypes and phenotypes of more than a million human individuals have been released by dbGaP. One researcher can now access the genotypes of hundreds of thousands of individuals from different dbGaP studies, but the data across studies is typically obtained using different genotyping and sequencing methods. It is therefore essential, but challenging, to systematically determine the ancestries, or population structures of all subjects in large, combined datasets. Numerous methods have been developed to determine subject ancestries from genotypes, including model-based approaches like STRUCTURE, and model-free, usually PCA-based method such as EIGENSTRAT. Many methods work well for small or medium sized datasets with low genotype missing rates. However, no existing methods can be applied to large datasets with genotypes collected using different methods, like the datasets combined from many dbGaP studies. At dbGaP, we extract genotypes of a fixed set of 10,000 SNPs from each study, and use these genotypes to find subject overlaps among different studies. We have also developed a method called GRAF (Genetic Relationship and Fingerprinting) to determine subject relationships using these "fingerprint SNPs". In order to determine subject ancestries, we first divide dbGaP subjects into subpopulations based on the self-reported ancestries and calculate the allele frequencies of the fingerprint SNPs for each subpopulation. Then for each subject we calculate the values of a statistical metric that reflect the distances between this subject and every subpopulations, and use these values to predict which subpopulation this subject belongs to, or if this subject is a mixture of several subpopulations. This method, called GRAF-pop, is very quick, running in linear time relative to the number of subjects. It is also accurate, with 99% of the subjects predicted as European, Asian, and African American match the self-reported ancestries. GRAF-pop is also robust, tolerating high genotype missing rates up to 99%. When only 100 of the 10,000 SNPs have genotypes, GRAF-pop can still be used to separate Europeans, Asians and Africans from one another with 95% accuracy. GRAF-pop can be applied to genotype datasets obtained using diverse methods, and the results are comparable between different dbGaP studies, and any other datasets. In this presentation I will describe GRAF-pop in more detail, and how it is used as a QC tool at dbGaP to find errors in self-reported ancestries.

**1323F**

**PubCases: A diagnosis assistant tool for rare diseases based on disease-phenotype associations extracted from published case reports.** T. Fujiwara<sup>1,2</sup>, Y. Yamamoto<sup>1</sup>, J.D. Kim<sup>1</sup>, T. Takagi<sup>2</sup>. 1) Database Center for Life Science, Joint Support-Center for Data Science Research, Research Organization of Information and Systems; 2) Department of Computational Biology and Medical Sciences, Graduate School of Frontier Sciences, The University of Tokyo.

Recently, next-generation sequencing (NGS)-based diagnostic tests, which particularly employ whole-exome sequencing (WES), have been attempted for diagnosis of patients with rare diseases. Usually, a run of WES identifies more than 30,000 variants, among which tens or hundreds remain after filtering out common variants and prediction of their pathogenicity. For further narrowing down to a handful number of variants to be manually evaluated, a phenotype-driven diagnosis assistant tool such as Phenomizer is often used. Note that the performance of a tool like Phenomizer relies on its underlying database such as Orphanet, and that manually curated databases like Orphanet inherently show a limited coverage. We present PubCases (<https://pubcases.dbcls.jp>), a new diagnosis assistant tool which employs a text mining-based approach to improve the coverage of Orphanet. More than one million case reports were harvested from PubMed, and they were annotated for concepts of rare diseases and phenotypes. For the annotation, ConceptMapper was used with Orphanet Rare Disease Ontology (ORDO) and Human Phenotype Ontology (HPO). A co-occurrence of a ORDO term and a HPO term within a sentence was treated as a signal for association between them. PubCases exploits the database of disease-phenotype associations sourced both from Orphanet and our result, to assist a diagnostic process: for a set of phenotypes (HPO terms) as input, it suggests a ranking of diseases based on phenotypic similarity. The performance of PubCases was evaluated in comparison with Phenomizer, using the 114 clinical cases retrieved from MyGene<sup>2</sup>, with “recall at ranks” (fraction of cases where the correct result appears in top 1, top 5, top 10, and top 100) as the evaluation metric. Orphanet had 6,233 rare diseases, among which 2,323 were associated with HPO terms. Our method could find phenotype-associations for 3,100 rare diseases, of which 52% did not have an association in Orphanet. PubCases showed the recall rate, 0.24@1, 0.30@5, 0.34@10, and 0.67@100, while Phenomizer showed 0.13@1, 0.29@5, 0.36@10, and 0.54@100. The experimental results support that our approach is effective in improving the coverage of the disease-phenotype associations, and PubCases performs better than Phenomizer in terms of average recall, enlightening a promising path to improving the diagnosis rate of NGS-based approaches.

**1324W**

**MVP: A deep neural network method of predicting pathogenicity of missense variants enables novel genetic discoveries.** Y. Shen<sup>1,2</sup>, H. Qi<sup>1,3</sup>, J.J. Long<sup>3</sup>, N. Zhu<sup>1,4</sup>, W.K. Chung<sup>4,5</sup>, Y. Guan<sup>6</sup>. 1) Department of Systems Biology, Columbia University, New York, NY; 2) Department of Biomedical Informatics, Columbia University, New York, NY; 3) Department of Applied Physics and Applied Mathematics, Columbia University, NY; 4) Department of Pediatrics, Columbia University, New York, NY; 5) Department of Medicine, Columbia University, New York, NY; 6) Departments of Pediatrics and Molecular and Human Genetics, Baylor College of Medicine.

Missense variants are the most abundant type of coding mutations in patients with cancer, birth defects, and neurodevelopmental disorders. However, the phenotypic consequence (pathogenicity) of missense variants are largely unknown, a major barrier in genetic studies and clinical testing. Previously published *in silico* prediction methods have facilitated the interpretation of missense variants, but have limited performance due to a few major issues. First, conventional statistical approaches are sub-optimal in leveraging large amount of training data or many correlated predictors. Second, databases of pathogenic variants are known to have substantial rate of false positives that limit the performance of supervised learning methods. Here we describe a new method (MVP) to leverage large training sets with correlated predictors. We use a deep residual network method in which a hierarchical structure increases model expressiveness without making it excessively large. Besides predictors commonly used in other methods, we included additional predictors at the variant-level (e.g. probability of being in protein interaction interface) and gene-level (e.g. protein complex formation and dosage sensitivity, which can modulate the *pathogenicity* of deleterious missense variants). We obtained large curated pathogenic variant datasets as positives and random rare missense variants from populations as negatives for training. MVP achieved superior area under the receiver operating characteristic curve (AUC) compared with other methods in cross-validation. To benchmark real-world performance, we compiled known cancer somatic mutation hotspots as positives, and random somatic missense as negatives, and showed that MVP had much better AUC. Additionally, we collected germline *de novo* mutations in ~6000 exome sequencing samples from recent studies of developmental disorders. Since such data do not have ground truth, we used the excess of predicted pathogenic missense variants in cases compared to controls as proxies of sensitivity and specificity. We showed MVP achieved 30-100% better sensitivity under a reasonable specificity compared with other methods, and implicated a number of new candidate risk genes for diseases with low reproductive fitness (e.g. *GLRA2*, *MINK1*, *CUL1*, *CAMK1D*, *ROBO2*, *PPP4C*, and *CTNND1*). These results using actual disease associated data suggest that MVP can improve diagnostic yield and power of detecting novel risk genes in genetic studies.

**1325T**

**Search Candidate Regulatory Elements by ENCODE (SCREEN): A web-based tool for visualizing genomic annotations.** *H.E. Pratt, M.J. Purcaro, J.E. Moore, Z. Weng.* Program in Bioinformatics and Integrative Biology, Department of Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Worcester, Massachusetts 01605, USA.

The Encyclopedia of DNA Elements (ENCODE) Consortium and Roadmap Epigenomics Consortium have generated thousands of genomic datasets with the goal of annotating the functional elements in the human and mouse genomes. The ENCODE Data Analysis Center has integrated these datasets to create a collection of annotations termed the ENCODE Encyclopedia. The Encyclopedia includes ground level annotations such as DNase hypersensitivity sites (DHSs) and peaks called for each dataset, and integrative level annotations, the core of which form a registry of candidate regulatory elements (cREs) anchored on DHSs in roughly 200 human and 50 mouse cell types. Here we present SCREEN, a web-based tool for searching and visualizing the cREs and their interactions with ground-level annotations. SCREEN is divided into three “apps”. The core app is the cRE-centric search, where the user can filter cREs by various characteristics and identify interaction with genomic features such as transcription factor binding sites, SNPs, and topologically-associated domains. The gene-centric app plots RNA-seq data, and, for mouse data, plots differentially-expressed genes and differential cRE activity across cell types and developmental time points. Finally, the SNP-centric GWAS app intersects cREs with SNPs from more than 50 published GWAS studies and presents associated analysis. We have used the Encyclopedia and SCREEN to characterize several novel regulatory elements. For example, SCREEN identified a candidate enhancer in GM12878, a lymphoblastoid cell line, overlapping SNP rs1250568 from a multiple sclerosis GWAS study; ground-level annotations revealed that this candidate enhancer lies in a binding site for transcription factor ELF1, a player in the IL-2 and IL-23 immune pathways which have been previously implicated in multiple sclerosis. SCREEN has also identified several candidate promoters and enhancers which may drive increased Ogn expression during mouse limb development, and several candidate enhancers overlapping SNPs from a schizophrenia GWAS study which may influence transcription factor SP3 binding during human and mouse brain development. Together, the Encyclopedia and SCREEN provide powerful tools for addressing a wide array of biological questions, such as predicting enhancer-gene interactions, comparing gene expression profiles across cell types and developmental time points, and annotating genetic variants and possible functional roles in disease.

**1326F**

**SinCCE (Single-Cell Cluster Ensemble): Cluster ensemble for single-cell RNA-seq data.** *Y. Yang<sup>1</sup>, R. Huh<sup>2</sup>, H. Culpepper<sup>1</sup>, Y. Li<sup>1,2</sup>.* 1) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Accurately identifying and characterizing cell type from a mass of heterogeneous cells is a crucial step for downstream analysis of single-cell RNA-seq data. Recently, multiple algorithms have been developed for this purpose. However, different clustering methods, utilizing different characteristics of data for clustering, typically yield different numbers of clusters and different cluster assignment. In this study, we present **Single-Cell Cluster Ensemble (SinCCE)** for highly accurate and robust single-cell clustering. SinCCE starts with clustering results from any existing clustering methods and builds one consensus clustering. We performed extensive evaluations across over 20 datasets with number of clusterings ranging from 3 to 14, and number of single cells ranging from 49 to 32,695. Specifically, single cells are first clustered using four state-of-the-art methods, SC3, CIDR, Seurat and t-SNE + k-means; and individual solutions are then combined into one consensus cluster using three hypergraph-based partitioning algorithms hypergraph partitioning algorithm (HGPA), meta-cluster algorithm (MCLA) and cluster-based similarity partitioning algorithm (CSPA). In our evaluations, SinCCE generates high-quality clustering, in terms of both cluster number and shapes, across various datasets. Moreover, SinCCE is computationally efficient to accommodate large datasets. For example, it takes < 5 minutes to process a data set of 28,733 cells.

**1327W**

**Improving quality of variant calling by integrating whole genome and whole exome sequencing from same samples.** X. Li<sup>1</sup>, L. Gauthier<sup>1</sup>, A.V. Segré<sup>1</sup>, M. Lek<sup>1</sup>, E. Gelfand<sup>1</sup>, G. Getz<sup>1,2</sup>, K. Ardlie<sup>1</sup>, D. MacArthur<sup>1,3</sup>. 1) Broad Institute, Cambridge, MA; 2) Department of Pathology, Massachusetts General Hospital, Charlestown, MA, USA; 3) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA, USA.

Whole genome sequencing (WGS) and whole exome sequencing (WES) are two important genotyping technologies, which provide high density ascertainment of variants in different/overlapping genomic regions, suitable for various downstream analyses. As the price of Next Generation Sequencing goes down, more and more studies may employ both technologies to get optimal variant calling in coding regions. To fully utilize the sequencing information from both technologies, while reconciling differences of genotype calls among them, we extended the current variant calling framework of Genome Analysis Toolkit (GATK) to enable variant calling and genotyping by integrating WGS and WES data from same samples within a cohort. Instead of merging at the raw sequencing reads level, our method directly merges the Phred genotype likelihood scores, making the integration much easier when GVCFs were generated. To evaluate our method, we generated high confident call sets from WGS and WES data of 147 individuals in GTEx dbGaP release v6, using our latest variant calling and sample and variant quality control tool set we developed. Comparing the integrated WGS and WES call set in exome intervals with WGS or WES alone, we found that our integrative method led to the discovery of an additional ~5,544 variants per sample in exome regions compared to the WES call set (27% of WES calls), while keeping a similar concordance rate with array genotyping technology as the WGS and WES separate call sets. The increase in sensitivity was most pronounced among low frequency variants. Our method also greatly improved genotype quality score (GQ) of on average 80% of WES calls and 0.4% of WGS calls (~16,000 variants per sample). Moreover, we found our method could help reconcile effects of different technologies, such as Illumina HiSeq2000 versus Illumina HiSeqX, and Agilent versus Illumina's Capture Exome (ICE). We further evaluate whether our method might introduce ascertainment bias of variant calling in coding versus noncoding regions, as this may have an effect on genome-wide analyses. In all, our method for integrating WGS and WES calls from the same donor, generated higher sensitivity and quality of variant calls in coding regions, in particular compared to the WES call set, while harmonizing the differences among sequencing technologies.

**The Mega2R suite of R packages: Tools for accessing and processing common genetic data formats in R.** D.E. Weeks<sup>1,2</sup>, R.V. Baron<sup>1</sup>, J.R. Stickele<sup>1</sup>. 1) Department of Human Genetics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; 2) Department of Biostatistics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA.

The standalone C++ Mega2 program has been facilitating data-reformatting for linkage and analysis programs since 2000. Support for more analysis programs have been added over time, though this has required software developers keenly knowledgeable in the Mega2 internals. Currently, Mega2 converts data from several different genetic analysis data formats (including PLINK, VCF, BCF, IMPUTE2) into the specific data requirements for over 40 commonly used linkage and association analysis programs (including Mendel, Merlin, Morgan, SHAPEIT, ROADTRIPS, MaCH/minimac3, etc.). Recently, Mega2 has been enhanced to use a SQLite database as an intermediate data representation. Additionally, Mega2 now stores biallelic genotype data in a highly compressed form, much like that of the GenABEL R facility and the PLINK binary format. Concurrently, the R community and Bioconductor community have developed a variety of genetic analysis programs complementary to the programs available through Mega2. We have now made it easy to load SQLite3 Mega2 databases directly into R as data frames to use these R facilities. In addition, we have developed C++ functions for R to decompress needed subsets of the genotype data, on the fly, in a memory efficient manner. We created the base Mega2R package that loads and manipulates data frames. We have also created several more R packages that illustrate how to use the data frames as well as perform useful functions: the Mega2pedgene package to run the pedgene R package to carry out gene-based association tests on family data using selected marker subsets, the Mega2VCF package to output the Mega2R data as a VCF file and related files (for phenotype and family data), and the Mega2GenABEL package to convert the data frames into GenABEL R `gwaa.data-class` objects. The Mega2R program enhances GenABEL since it supports additional input data formats (such as PLINK, VCF and IMPUTE2) not currently supported by GenABEL. The Mega2 program and the Mega2R R package are both open source and are freely available, along with extensive documentation and a 'quick-start' tutorial, from our <https://watson.hgen.pitt.edu/register> web site. This work was supported by NIH grant R01 GM076667 (PI: Weeks). Earlier contributions to our code base were made by Nandita Mukhopadhyay, Lee Almasy, Mark Schroeder, and William P. Mulvihill.

**An iterative strategy to improve the power of epistasis analysis.** *J. Wen, C. Nadzak, X. Shi.* Department of Bioinformatics and Genomics, University of North Carolina at Charlotte, Charlotte, NC.

Epistasis is an important genetic component in human diseases and quantitative traits whereby non-additive interactions of genes result in varied phenotypic effect. Many studies show that epistasis helps elucidate the genetic foundation for modeling human traits and evolution. However, a major challenge for epistasis analysis arises with the advent of high throughput sequencing and omics data, which the number of features (genetic variants) is usually much larger than sample size and produces an over-saturated model. To address this challenge, we propose an iterative pipeline based on an empirical Bayesian elastic net (EBEN) method that increases the power and accuracy in genomic studies of epistasis. First, we screen each single feature with the phenotype using a simple statistical procedure where features passing a predefined threshold are kept in the model, and then an estimation of the significant features with marginal effect is produced using EBEN. The resulting significant features from EBEN are then used to correct the raw phenotype. Second, a screen on the pairwise epistatic interactions of features is performed using the same statistical procedure and we use EBEN again to estimate the significant pairwise features against the corrected phenotype. Third, we put all the significant features, including the marginal and epistatic effect output by EBEN in Step 2 and 3, into a complete EBEN model to conduct parameter estimation. Significant marginal and epistatic variants are then selected from the complete EBEN model. Monte Carlo simulations verify that the power for epistasis detection is improved using our strategy. We apply our pipeline to a yeast data set and identify the marginal and epistatic effect of SNPs on indoleacetic acid levels, which provides a more comprehensive understanding of the molecular mechanism of yeast fitness via pathway and enrichment analysis.

**Telomere length estimation and analysis on large scale whole-genome sequencing data.** *M.A. Taub<sup>1</sup>, K. Iyer<sup>2</sup>, J. Weinstock<sup>3</sup>, L.R. Yanek<sup>4</sup>, H.M. Kang<sup>5</sup>, T. Blackwell<sup>6</sup>, A. Correa<sup>5</sup>, S.L. Salzberg<sup>6</sup>, D. Vaidya<sup>4</sup>, D.M. Becker<sup>4</sup>, J.G. Wilson<sup>7</sup>, L.C. Becker<sup>8</sup>, G. Abecasis<sup>5</sup>, A. Reiner<sup>8</sup>, R.A. Mathias<sup>1</sup>.* 1) Department of Biostatistics, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD; 2) Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD; 3) Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, MI; 4) The GeneSTAR Program, Johns Hopkins School of Medicine, Baltimore, MD; 5) Department of Medicine, University of Mississippi Medical Center & Jackson Heart Study, Jackson, MS; 6) Departments of Computer Science and Biomedical Engineering, and McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 7) Department of Physiology and Biophysics, University of Mississippi Medical Center, Jackson, MS; 8) Department of Epidemiology, University of Washington, Seattle, WA.

Telomere length (TL) is a hallmark of aging, and has been associated with a range of diseases. Variation in TL is linked to exposures such as smoking and stress, and to genetic factors. TL is also considered a measure of "biological age", a concept that disengages the calendar age of an individual from their physical age. While some prior studies have assessed these relationships, the advent of large-scale whole-genome sequencing (WGS) studies in diverse populations has created new resources to expand knowledge of the role of TL in aging and disease. The optimal method for estimating TL from WGS data is still unknown. In a pilot analysis of 574 samples from the GeneSTAR study, we compared three methods (TelSeq, Computel, and a hexamer counting method), and observed strong correlation among methods (0.94 and above within a batch) but wide differences in computational efficiency (ranging from a few hours to a few days to process one sample, on one core). To date, only small-scale comparisons between WGS-based estimates and low-throughput estimates, such as flow-FISH or qPCR have been done. Preliminary analysis of 19 samples with flow-FISH estimates from two cell types (lymphocytes and granulocytes) show consistent correlation between 0.7 and 0.8 with all methods considered, indicating that computational efficiency is likely to be a more important consideration as all methods perform otherwise similarly to one another. Samples from the pilot were processed in two batches using two different sequencing centers, to similar depth (~30x). We saw striking differences in the distribution of TL estimates from these batches, with TelSeq estimates on the first batch of samples showing a median of around 5kb (interquartile range 4.2kb to 5.5kb), and the second batch of samples showing a median of around 2.8kb (IQR 2.5kb to 3.1kb). For large scale sequencing studies, with samples likely to be processed in batches, concerns about the ability to combine data generated separately are clearly warranted for these TL estimates. Ongoing work involves estimation on an additional 2500 samples from the Jackson Heart Study through the TOPMed program, for which Southern Blot TL estimates calculated on blood from the same collection point are available for comparison. This will aid in determining the optimal TL estimation method and investigating how to detect and adjust for batch effects to enable effective analyses of the influence of TL on health outcomes.

**1000 Genomes Project data and additional openly consented data resources can be accessed via the International Genome Sample Resource (IGSR).** S. Fairley, P. Harrison, E. Lowy, D. Richardson, I. Streeter, G. Yordanova, H. Zheng-Bradley, L. Clarke, P. Flicek. European Molecular Biology Laboratory, European Bioinformatics Institute, Hinxton, United Kingdom.

The International Genome Sample Resource (IGSR) provides continued access to the resources created by the 1000 Genomes Project, while also expanding and updating those resources. Resources from the 1000 Genomes Project have been updated to the current reference genome. Data from phase three of the Project has been aligned to GRCh38, an assembly mapping-based "liftover" of the call set has been made available and the alignments to GRCh38 are being used to create a new call set directly on GRCh38. FreeBayes, GATK and Samtools have been used to call on GRCh38, while working toward creation of an integrated call set. New populations have been added to those sampled by 1000 Genomes. An example of this is data from the Gambian Genome Variation Project (GGVP). This project sampled an additional 100 individuals from the same Gambian population that was sampled in the 1000 Genomes Project. Further, GGVP sampled 100 individuals from each of three further Gambian populations, making three new populations and 400 new samples available. These data have also been aligned to GRCh38. New data generated on samples from 1000 Genomes is also made available. In particular for samples included in the work of the Human Genome Structural Variation Consortium (HGSVC), a wealth of data types are available, including PacBio, 10X, TruSeq, Strand-seq, high-coverage PCR-free Illumina data and others. Among the work that IGSR does to facilitate the availability of open genomic data is data coordination work, assistance in ethical review and alignment of sequence data. IGSR is open to establishing new collaborations for projects with openly consented genomic data. As a means of improving access to the data in IGSR, a data portal was added to the project website. This provides a number of ways to view the available data and we continue to develop this to meet users' needs. This, combined with the ability to browse the data in genomic context in Ensembl, provides users with a range of mechanisms for accessing the available data.

**1332F**

**An alignment-based approach for sensitively detecting SVs using optical maps data.** X. Fan<sup>1,2</sup>, J. Xu<sup>3</sup>, A. Delcher<sup>4</sup>, L. Nakhleh<sup>1</sup>, F. Yue<sup>3</sup>, K. Chen<sup>1,2</sup>, Human Genome Structural Variation Consortium. 1) Department of Computer Science, Rice University, Houston, Texas; 2) Department of Bioinformatics and Computational Biology, The University of Texas M.D. Anderson Cancer Center, Houston, Texas; 3) Department of Biochemistry and Molecular Biology, Pennsylvania State University, State College, Pennsylvania; 4) Nathans-McKusick Institute of Genetic Medicine, Johns Hopkins University, Baltimore, Maryland.

Structural variation (SV), although associated with genetic diseases and population diversity, has not been comprehensively studied due to limited sequencing length in widely used Next Generation Sequencing (NGS) data. Emerging new technologies such as the Optical Maps (OM) generated by Bionano Inc. produce much longer reads (between 100kbp to 250kbp), making it possible to detect SVs in large repetitive regions that have been missed in current studies. However, OM reads lack precise sequence-level information and often contain errors. Current methods attempt to perform whole genome assembly to reduce random errors in individual reads. Such methods, however, require deep coverage and are insensitive to detecting subclonal SVs in heterogeneous cancer genomes. In this abstract, we present a novel alignment-based approach that can sensitively detect somatic SVs in heterogeneous cancer OM data. Starting from the global alignment of Optical Map reads, we develop a dynamic programming algorithm to perform local re-alignment around the breakpoints. This algorithm takes into consideration the three types of errors in Optical Maps (additional and missing labels, sizing error), and thus can effectively improve the alignment accuracy. To enhance specificity, an SV is called only when a cohort of reads supports it, where the cohort size depends on the sequencing coverage, estimated variant allele fraction and tumor purity. We evaluated our algorithm using a public dataset, NA12878, and compared it with two previous approaches. We found that our sensitivity is twice that of the method published in Genetics'16, and 15% greater than that of the Irys program. Our FDR is much lower than Irys when compared against results derived from 10X genomics data. Our unique calls appear to be enriched in repetitive regions, confirming the advantage of our method. We also applied our algorithm to a chronic myeloid leukemia cell line K562. We detected some validated SVs that Irys missed, in addition to the majority of those that Irys detected. In all, our method is the first to combine global and local re-alignment to effectively utilize Optical Maps to detect SV, and thus further improves the detection of SV and, consequently, advances translational research. .

**Leveraging unique molecular identifiers to improve low-frequency variant calling in QIASeq V3 panels.** B. Vilhjalmsón<sup>1</sup>, D. Thomsen<sup>1</sup>, J. Hill<sup>1</sup>, R. Rhode<sup>1</sup>, D. Kamaev<sup>1</sup>, J. Vesterstrøm<sup>1</sup>, T. Rask<sup>1</sup>, P. Nielsen<sup>1</sup>, M. Christensen<sup>1</sup>, J. Nielsen<sup>1</sup>, R.G. Madsen<sup>1</sup>, M. Hussong<sup>2</sup>, S. Rullif<sup>2</sup>, L. Husted<sup>1</sup>, A. Materna<sup>1</sup>, R. Samara<sup>2</sup>, M. Simonsen<sup>1</sup>, A.-M. Hein<sup>1</sup>, Z. Wu<sup>2</sup>, E. Lader<sup>2</sup>. 1) QIAGEN, Aarhus, Risskov, Denmark; 2) QIAGEN, Frederick, Maryland, USA.

Unique molecular indices (UMIs) have in recent years become a standard practice in sequencing. UMIs are random molecular barcodes that are attached to the original DNA or RNA molecules at an early stage before amplification. The benefit of this technology is two-fold: 1) it provides a more accurate snapshot of the original DNA or RNA fragments before amplification; 2) it enables to correct for some PCR and sequencing errors (Xu *et al.*, BMC Genomics 2017). To take advantage of UMIs, we developed an integrated Sample-to-Insight approach encompassing proprietary chemistry (QIAseq targeted panels) to incorporate UMIs into library construction and three different bioinformatics workflows processing UMI-containing reads in the QIAGEN Biomedical Genomics Workbench (version 4.1) for different data types: one for estimating mRNA expression levels, one for variant detection, and one for detecting fusion gene expression. All three workflows make use of UMIs to either provide more accurate expression level estimates, or to improve the effective sequencing fidelity and thus variant calling accuracy. This is achieved through two key algorithms, one that identifies UMI groups, and one that merges reads within a UMI group to produce a consensus UMI read. A UMI group consists of reads that both map to the same position, and have an identical UMI, while accounting for errors. A consensus UMI read is obtained by maximizing the likelihood for each base, accumulating statistical evidence across multiple reads within the same UMI group. In practice, this corrects for PCR and sequencing errors, [RS-Q1] thereby increasing the average estimated per-base Q-scores substantially. We evaluated the benefit of using UMIs, by comparing the three different types of workflows to corresponding workflows where UMIs were ignored. We applied these to several different QIAseq targeted panel datasets and a GIAB (genome in a bottle) dataset for NA12878, where we estimated expression levels, variant frequencies, and empirical Q-scores. We found that UMIs provide a significant increase in the estimated empirical Q-scores, as well as providing more accurate variant frequency estimates overall. These two benefits are particularly relevant for low-frequency variant calling, highlighting UMIs as a promising technology for improving variant detection in cancer applications.

**Multi-sample isoform quantification from RNA-seq for known and novel transcripts.** A.E. Byrnes<sup>1,2</sup>, F. Aguet<sup>2</sup>, T. Sullivan<sup>2</sup>, A. Bloemendaal<sup>1,2</sup>, J.M. Mall-er<sup>2</sup>, C. Churchhouse<sup>1,2</sup>, B.M. Neale<sup>1,2</sup>. 1) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA; 2) Stanley Center for Psychiatric Research, Broad Institute, Cambridge, MA; 3) Genomics plc, Oxford, UK.

Alternative splicing is critical for the regulation and diversity of most human genes. The ability of a single gene to give rise to several diverse transcripts, and subsequently proteins, has been implicated in a wide range of processes and disorders from brain function to cancer proliferation. However, most RNA-seq transcript quantification methods rely upon existing lists of possible transcripts that may be incorrect or incomplete. Our field has long considered the problems of transcript discovery and quantification separately; however, we advocate evaluating both simultaneously to improve performance. We propose a 2-step, multi-sample method for discovery and quantification of transcript isoforms, both known and novel, from RNA-seq data. Our method aims, first, to maximize inference on splicing behavior by combining information from all aligned RNA-seq samples to construct a graph representing all possible transcripts, similar to Cufflinks' approach, but on all samples pooled together. In graph-building we weight each possible junction between exons by the number of junction reads observed across all samples. We represent each isoform as a possible path through the graph which provides an empirically derived list of transcripts that may be present in our samples and a preliminary estimate of their respective frequencies. After constructing a list of all possible isoforms, we aim to quantify relative levels of transcription for each isoform in each sample. In order to do so, we conduct a comparison of existing isoform quantification methods, including Cufflinks, Kallisto and RSEM, in addition to our own expectation-maximization (EM) algorithm which explicitly models many of the biases endemic to RNA-seq data by using Alpine. This second step allows us to characterize the isoforms present in any individual and quantify their respective transcription for each sample separately. The isoforms with very low or zero frequency estimates can be pruned from the anti-conservative list in the first step, providing a reliable list of isoforms likely to exist in nature. We demonstrate robust re-identification of many annotated transcripts, novel identification of additional transcripts not previously identified in Ensembl and several annotated transcripts with no evidence of expression in our data. We will discuss the details of this method and the relative performance of the above methods. Our results have clear implications for future work in alternative splicing.

**PennSeq2: Efficient quantification of isoform-specific gene expression from RNA-seq data using weighted likelihood method.** *Y. Hu, M. Li.* Department of Biostatistics, Epidemiology and Informatics, University of Pennsylvania, Philadelphia, PA.

The emergence of RNA-Seq has provided a powerful tool to study gene regulation at isoform levels. We previously developed PennSeq (Hu et al., 2014 *Nuc Acids Res* 42(3):e20), a statistical method for isoform-specific gene expression estimation by modeling non-uniform read distribution. However, in addition to the accuracy of estimated isoform expression, efficiency, which measures the degree of estimation uncertainty is also an important factor for downstream analysis. Here we developed PennSeq2, a successor of PennSeq, which employs a weighted likelihood framework to improve estimation efficiency. Briefly, for each read, PennSeq2 assigns a weight based on the number of compatible isoforms to assure that more informative reads (with less compatible isoforms) are given more weight in the likelihood function. PennSeq2 then employs an EM algorithm to estimate isoform-specific gene regression by maximizing the weighted likelihood. Compared to PennSeq, PennSeq2 has several advantages. First, the EM algorithm converges faster than PennSeq. Second, the efficiency of isoform expression estimation is significantly improved, which lays the groundwork for downstream analysis. Third, PennSeq2 yields equally accurate isoform expression estimation compared to PennSeq, even though this weighted likelihood approach theoretically trades bias for efficiency. To verify these advantages, we conducted simulations and compared its performance with PennSeq. We simulated 10 million 76-bp paired-end reads and mapped them to the reference genome using Tophat. Then, isoform relative abundances from 1455 genes were estimated using PennSeq and PennSeq2, respectively. Squared Pearson correlations between the ground truth and estimated relative expression demonstrate good estimation accuracy for both PennSeq ( $R^2=0.933$ ) and PennSeq2 ( $R^2=0.926$ ). Meanwhile, compared to PennSeq, on average, PennSeq2 reduces estimation uncertainty by 76% and the number of iterations in EM algorithm by 36%. Additionally, the running time of PennSeq2 is reduced by 10 times compared to PennSeq. These results indicate performance improvement of PennSeq2 without sacrificing estimation accuracy. Currently, we are performing extensive simulations and real RNA-Seq data analysis to verify the benefits of PennSeq2 estimates for differential expression and differential splicing analysis. As estimation efficiency improves, we expect downstream analysis based on PennSeq2 to have improved power.

**VariantFX: An open-source framework for aggregation, visualisation and analysis of Mendelian disease cohort sequence data.** *M. Ahmad<sup>1,2</sup>, E. Mazaika<sup>1,2</sup>, R. Govind<sup>1,2</sup>, N. Whiffin<sup>1,2,3</sup>, E. Edwards<sup>1,2</sup>, B. Weisburd<sup>4,5</sup>, M. Solomonson<sup>4,5</sup>, A. Harper<sup>2</sup>, R. Walsh<sup>1,2</sup>, X. Zhang<sup>1,2</sup>, A. Wilk<sup>1,2</sup>, A. O'Donnell-Luria<sup>4,5</sup>, H. Najgebauer<sup>1,2,3</sup>, P.J.R. Barton<sup>1,2</sup>, S.A. Cook<sup>1,2,3</sup>, D. MacArthur<sup>4,5</sup>, J.S Ware<sup>1,2,3</sup>.* 1) National Heart and Lung Institute, Imperial College London, London, United Kingdom; 2) Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom; 3) MRC London Institute of Medical Sciences, Imperial College London, London, United Kingdom; 4) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, MA; 5) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA.

Genomic reference datasets such as gnomAD have been transformative in clinical genome interpretation. However, the integrated presentation and analysis of equivalent data from cases with genetic diseases is challenging. Existing repositories that aggregate single variants do not preserve critical case allele frequency data, and case aggregation is likely best undertaken in a distributed manner by experts in each disease domain. VariantFX provides an open-source web framework comprising a variant database to host aggregated case data, an integrated API, a built-in web front-end for visualisation and quantitative analysis alongside the gnomAD reference dataset. We use Docker as a containerization platform, to create a downloadable resource with multiple complimentary components. Separate containers house each of the three main components of VariantFX; the database, associated API and front-end web scripts. The decoupling of the services into these distinct parts supports easy software upgrade, simplifies debugging, avoids software conflicts and supports adaptability. All the containers are managed by a single *docker-compose.yml* file. The database container hosts sequence data stored within a NoSQL MongoDB, which supports highly efficient queries for unstructured data. The database is shipped with sample seeded data. Users can easily upload their own data which is automatically imported to the database and presented in the front-end via the API. The second container hosts an API, configured through GraphQL, to serve data from the MongoDB database to the front-end and external web services. GraphQL queries have low over-head compared to the traditional REST API, resulting in low bandwidth consumption and flexible front-end coding. The final container hosts the front-end, developed in JavaScript using a React library for efficient rendering of data-rich pages. It uses the React virtual-DOM to render the front-end, providing highly interactive and responsive user experience. VariantFX is portable and can run on all major operating systems with Docker installed. We have provided all the scripts and full instructions on how to download and customise VariantFX on Github (<https://github.com/ImperialCardioGenetics/variantfx>). Our live implementation of VariantFX combining gnomAD with >10,000 cardiomyopathy cases can be found at <http://cardiac.variantfx.org>.

**NGS based CNV calling in a clinical diagnostic setting.** *D. Becker, M. Ziegler, Y. Dinçer<sup>1,2</sup>, K. Pindl, J. Schulz, K. Mayer, S.H. Eck, HG. Klein<sup>1</sup>.*  
1) Center for Human Genetics and Laboratory Diagnostics (AHC), Martinsried, Germany; 2) Chair of Social Pediatrics, Technical University of Munich, Munich, Germany.

The implementation of Next Generation Sequencing (NGS) in a clinical diagnostic setting opens vast opportunities through the ability to sequence all genes contributing to a certain indication simultaneously at a cost and speed that is superior to traditional sequencing approaches. Furthermore, these data allow the identification of small to medium sized copy number variations (CNVs). While the detection of single nucleotide polymorphisms (SNVs) and small insertions and deletions (InDels) is very straight forward, the reliable detection of CNVs from NGS enrichment data still poses several problems during data analysis. Here we present an approach for CNV calling in a clinical diagnostic setting as part of our multicentric Multiple Integration and Data Annotation Study (MIDAS). To call CNVs with sufficient sensitivity and specificity it seems impossible to rely on only one tool. Therefore, we combined different tools into an analysis pipeline and tried to find a combination of their respective results to optimize our calls. We incorporated ExomeDepth, CoNVaDING, XHMM, Canoes and VisCap in our current pipeline. The primary data in bam file format was produced by CLC Genomics Workbench as part of the primary data analysis. Interval files, GC-content or tables containing the coverage per region for the samples were produced by custom developed R and shell utility scripts. Results came in various formats and had to be normalized and condensed. There are different ways to combine data from the different tools. A union of the calls or a majority vote would improve the sensitivity but in routine diagnostics, specificity was the pressing requirement. The intersection of different tools removed the majority of false positives while true positives were called by all tools and remained in the final call set. Our approach contains a normalization of the scores given by each tool and a workflow to produce the final, scored calls based on unions and intersections of the primary results. Since some tools perform better than others for deletions or duplications (cite Canoes), a pipeline should be able to differentiate and use other combinations of the intermediate results. The assembly of the final calling and scoring mechanism varies therefore between different types of CNVs.

**A generalized non-parametric genotype caller using an EM-like algorithm.** *T.A. Benaglia<sup>1</sup>, B.S. Carvalho<sup>1,2</sup>.* 1) Department of Statistics, State University of Campinas, Campinas, SP, Brazil; 2) Brazilian Institute of Neuroscience and Neurotechnology / BRAINN, Campinas, São Paulo, Brazil.

Current biomedical research makes constant use of high-throughput technologies for genotyping. Microarrays and, more currently, sequencing experiments provide information at millions of variant sites, which are later investigated for association with a phenotype of interest. Prior to this association assessment, genotyping algorithms quantify the allele-specific abundance and classify subjects into genotype clusters. The series of statistical procedures involved in the aforementioned quantification and classification steps is complex and includes strong hypotheses on the distribution of the data. Models for microarray data assume that intensity signals follow an Exponential distribution combined with Gaussian error, while count data from sequencing are seen as results of a Negative-Binomial processes. We propose an alternative genotype caller that does not rely on assumptions regarding the distribution of the data. Our method uses a non-parametric approach combined with an adapted Expectation-Maximization (EM-like) algorithm to determine the membership likelihoods of each subject at every *loci*. Following this strategy, we use the maximum posterior probability to accurately perform genotype calling and consider the use of this statistic as genotype dosage, which can be used later for association studies, providing a strategy to account for genotype errors in data modelling.

**1339W**

**Phenotype-specific information improves prediction of functional impact for noncoding variants.** C. Bodea<sup>1,2</sup>, A. Mitchell<sup>1</sup>, H. Runz<sup>1</sup>, S. Sunyaev<sup>2</sup>. 1) Merck Research Laboratories, Boston, MA; 2) Brigham and Women's Hospital, Boston, MA.

A myriad of noncoding variants and association signals in the human genome are currently awaiting assignment of a function or the identification of causal alleles. Here, we introduce the computational framework PINES (Phenotype-Informed Noncoding Element Scoring) which evaluates the functional impact of noncoding variants in an unsupervised setting by integrating epigenetic annotations from diverse sources in a phenotype-dependent manner. A unique feature of PINES is that analyses may be customized towards genomic annotations of the highest relevance to phenotypes of interest. We show that PINES identifies functional noncoding variation more accurately than methods that do not use phenotype-weighted knowledge. To demonstrate its versatility, we show how PINES can be applied to systematically distinguish variants in enhancer regions from background variation; to delineate high-penetrance noncoding variants leading to Mendelian phenotypes; or to pinpoint epigenetic signals underlying noncoding alleles at GWAS loci. We further show how PINES can complement fine-mapping approaches and predict novel causal alleles from GWAS on Parkinson's and inflammatory bowel disease. Its flexibility and ease of use through a dedicated web portal establish PINES as a powerful new *in silico* method to prioritize and assign functions to noncoding genetic variants.

**1340T**

**Faster genotype phasing and imputation for large-scale data.** B.L. Browning<sup>1,2</sup>, S.R. Browning<sup>2</sup>, X. Tian<sup>2</sup>. 1) Department of Medicine, Division of Medical Genetics, University of Washington, Seattle, WA; 2) Department of Biostatistics, University of Washington, Seattle, WA.

We present new methods for genotype phasing and genotype imputation that have high accuracy and fast compute time for large-scale data. Both methods make use of a dynamic model state space for each target sample that is constructed from a set of reference haplotypes that continuously evolves across the genome. The genotype phasing method employs a novel approach that models haplotypes without modeling diplotypes. We compared our new genotype phasing method to Eagle2 (v2.3.2), the current state of the art, on UK Biobank data (n=150,000) for chromosomes 1, 5, 10, 15, and 20. Using current default settings, our phasing method reduced per-chromosome switch error rates and compute times by 23-36% and 23-39% respectively relative to Eagle2. In order to assess the performance of our genotype imputation method with very large reference panels, we made use of recent advances in demographic modeling and simulation methods to simulate 3 million UK European samples. The simulated data incorporate recurrent mutation and have a near-saturated marker density of 1 non-singleton single-nucleotide variant per 5 bases. Relative to Beagle 4.1, the current state of the art for reference panels with millions of samples, our new imputation method reduces compute time by a factor of 9 with no loss in accuracy when imputing 1000 target samples from 3 million reference samples in binary reference (bref) format. Extrapolating to a 3000 Mb genome, we estimate that the compute time for genome-wide imputation from 3M reference samples is < 12 min per sample on a 2.4 GHz compute server with 12 CPU-cores. Our new genotype phasing and imputation methods will be incorporated in Beagle version 5 (<http://faculty.washington.edu/browning/beagle/beagle.html>).

**1341F**

**Fast and easy pipeline for quality control and assurance for GWAS.** *T.M. Brunetti<sup>1</sup>, M. Campbell<sup>1</sup>, N. Rafaels<sup>1</sup>, T. Phang<sup>1</sup>, M. Boorgula<sup>1</sup>, S. Chavan<sup>1</sup>, M. Daya<sup>1</sup>, A. Shetty<sup>1</sup>, R.A. Mathias<sup>1,2</sup>, K.C. Barnes<sup>1</sup>.* 1) Colorado Center for Personalized Medicine, University of Colorado, Denver, CO; 2) Johns Hopkins Asthma & Allergy Center, School of Medicine, Johns Hopkins University, Baltimore, MD.

Genome-wide association studies (GWAS) tend to have a high degree of variability which can be attributed to both biological and technical confounders. Although biological variation is generally addressed in most GWAS during the downstream analysis of the data, the technical variation needs to be addressed prior to any downstream analysis to ensure significant results are due to true biological differences rather than unwanted technical aberrations. These technical factors can often arise from the improper handling of quality assurance measures within the initial dataset such as poorly performing SNPs and samples. For example, failures can arise due to poor cluster separation, large batch effects, low genotyping rates, and gender discrepancies. For these reasons, we have designed an automated, high-throughput, customizable pipeline implemented in Python, for assessing the quality and filtration of genotyping data for GWAS. The pipeline has been tested and optimized using the Multi-Ethnic Global Array (MEGA) from Illumina which contains over 1.7 million SNPs. We tested this pipeline across 1,667 samples and produced thorough results with an average run time of ~7 minutes on a standard laptop. The pipeline outputs a set of deliverables that contain detailed PDF reports and files, as well as PLINK and VCF files populated with metrics for a wide range of analyses, including CNV analysis. These files can be used directly in downstream analysis. The pipeline filters out poorly performing SNPs and samples, and reports which metrics the SNPs and samples fail and the value of each failure. In addition, several summary statistics of passing samples and SNPs with both quantitative and visual results are published. Due to its speed and ability to be easily customizable, the user has the ability to change, optimize, and run the pipeline several times or in parallel to determine what thresholds may be most optimal for their experiment, although carefully chosen defaults have been selected should the user not want to optimize the pipeline. The automated quality control and assurance pipeline is being implemented at the Colorado Genetics Research Facility and the Colorado Center for Personalized Medicine at the University of Colorado Anschutz Medical Campus.

**An empirical strategy to screen markers on case-control genomic studies.** *B.S. Carvalho<sup>1,3</sup>, B. Henning<sup>2,3</sup>, M.R. Rodrigues<sup>2,3</sup>, F. Ross<sup>2,3</sup>, T.A. Benaglia<sup>1</sup>, I. Lopes-Cendes<sup>2,3</sup>.* 1) Department of Statistics, State University of Campinas, Campinas, SP, Brazil; 2) Department of Medical Genetics, State University of Campinas, Campinas, SP, Brazil; 3) Brazilian Institute of Neuroscience and Neurotechnology, BRAINN, Campinas, SP, Brazil.

The development of Precision Medicine (PM) depends strongly on the statistical comparison of genomic data from control subjects to patients of the phenotype of interest. Next-generation sequencing is one of the most used technologies for this task and, due to its nature of massive parallel sequencing, downstream analysis methodologies should be able to handle thousands, if not millions, of comparisons. The multiple comparison problem is a well-known issue in statistical genetics, as it affects significantly the power to detect association between markers and phenotypes. We present a strategy that combines the latest developments in machine learning with high-throughput sequencing data to identify smaller sets of candidate markers that show evidences for association with the phenotype of interest. More specifically, we call variants in control subjects and epilepsy patients using the Best Practices for GATK, after mapping the reads using BWA to the genome reference HG38. Later, we train a random forest (RF) on 70% of our data and optimize the parameters using the remaining 30%. On our dataset, containing 199 healthy individuals and 203 epilepsy patients, we found that the best model for discrimination between case and control statuses in our dataset resulted from a random forest built with 100 decision trees and 16 variables as the maximum depth. On both training and optimizing samples, we obtained MSE=0.24 and AUC=0.63. The error rate was 42% on the training dataset and 38% on the optimizing dataset. Although this strategy shows a low discrimination rate between cases and controls, we use this optimized RF to compute the variable importance for each of the markers used as predictors. Given a threshold for the cumulative percentage of variability explained by the RF, we can then select a subset of markers that are potentially associated to the phenotype and study its overall effect on the response via techniques like enrichment. This subset can be also used by the researcher to generate hypotheses that will be then assessed via specific statistical models. When selecting markers that are responsible for only 10% of the explained variance, we identified 146 markers (out of 297) that were significantly associated with the phenotype at the FDR level of 10%.

**Accurate quantification of allele-specific methylation from genetically diverse population.** *K. Choi, A. Srivastava, R. Korstanje, G. Churchill.* The Jackson Laboratory, Bar Harbor, ME.

Quantifying genome-wide hyper and hypo-methylation is crucial for characterizing the regulatory landscape of gene expression. Recent advances in next-generation sequencing technologies, such as reduced representation bisulfite sequencing (RRBS), enable investigators to assess methylation status at single CpG dinucleotide resolution. In RRBS, unmethylated cytosines are converted to uracil, which requires read aligners to efficiently process higher number of mismatches. But, since the performance of Burrows-Wheeler-based aligners quickly degrades as the number of mismatches increases, many existing methods align to four separate three-letter reference genomes — C-to-T and G-to-A converted genomes for both strands. Although this strategy is generally adequate, it does not perform well when investigators seek to quantify allele-specific methylation (ASM). This is because the alignments of each read to four different reference genomes must be post-processed in order to identify the allelic origin of the read. We propose a novel ASM quantification pipeline, **asmtools**, in which we reconstruct individualized diploid genomes by incorporating annotated polymorphisms into the reference genome. Individualized diploid genomes identify the allelic origin of reads automatically and reduce the overload of increased mismatches for read aligner programs. Our method aligns reads to the digested regions of the individualized genomes, efficiently disregarding C-to-T or G-to-A mismatches. This implies our approach does not require the creation of three-letter converted genomes or three-letter converted reads and subsequent post-processing of alignments. Our method also minimizes the information loss caused by discarding multi-mapping reads as we developed a statistical model that disambiguates the origin of each read. Since a probability is assigned to each alignment and consequently to all the mismatches in it, we can evaluate *expected* ratio of methylated probe for each allele of CpG sites. We evaluated the performance of our pipeline using a kidney RRBS data sampled from Diversity Outbred (DO) mice, a genetically diverse population consisting of three different age groups (6, 12, and 18-month) of both sexes. In the QTL analysis, we found thousands of ASM sites are local methylation-QTLs, on which our approach generated higher LOD scores than other existing methods in most cases. These results represent the effectiveness of our pipeline for allele-specific methylome survey.

**Development of a framework for laboratory information tracking in support of research and clinical operations.** *B. Craig, B. Tibbils, K. Topper, S. Griffith, L. Watkins, K. Doheny.* Center for Inherited Disease Research (CIDR), Johns Hopkins Genomics (JHG), IGM, JHU-SOM, Baltimore, MD.

The Center for Inherited Disease Research (CIDR) provides high quality next generation sequencing (NGS), genotyping and statistical genetics consultation to investigators working to discover genes that contribute to disease. CIDR's current genotyping Laboratory Information Management System (LIMS) was designed to handle the tracking of detailed information for large numbers of samples going through specific genotyping assays. This LIMS has over time become difficult to maintain and extend as newer resources and NGS services have emerged. A third party LIMS was selected for NGS applications that addressed the widely different set of tasks and information to be stored for sequencing services. Annual licensing costs and requirements to re-write custom code and upgrade to newer releases to maintain support add to the difficulty of sustaining two LIMS deployments. These deficiencies combined with the expansion of research and clinical genomic services at JHG ([jhgenomics.jhmi.edu](http://jhgenomics.jhmi.edu)) have highlighted the need to create a new LIMS to support the breadth of current and future protocols. These rapidly changing laboratory protocols require reliable tracking of large amounts of workflow information including a record of sample movements, identification of robot resources, reagent association and user comment tracking. Here we describe the development of a MySQL database backed Java framework consisting of tools to reduce disruption to lab processing with module hot swapping, limit database schema complexity and increase reusable graphical user interface (GUI) components to flexibly build and extend workflows for any protocol driven technology.

**1345W**

**A new method for analysis of sequencing reads without reference genomes.** *H. Dai<sup>1</sup>, Y. Guan<sup>1,2</sup>*. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) USDA/ARS Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX.

The mapping-to-a-reference-genome based approach to analyze sequencing data has two challenges. One is limited ability to map short sequencing reads associated with INDELs, structural variants and repetitive regions. The other is incompleteness/unavailability and low quality of reference genomes. Here we present Nubeam (nucleotide be a matrix), a method to quantify difference between sets of sequencing reads without reference genomes. In the method, a nucleotide is represented by a matrix, a read is the product of a sequence of matrices, and a number, which is the trace of the product matrix, is assigned to the read. Since matrix multiplication preserves the order, similar sequences are represented by similar numbers. The difference between sets of reads can be quantified by the distance between empirical distributions formed by corresponding numbers. We first used simulations to demonstrate that Nubeam can reconstruct true phylogeny. We simulated sets of reads from trees representing different degrees of sequence divergence and assessed the accuracy of phylogeny reconstruction. We validated that the distance between empirical distributions could measure the genetic distance between samples. We then applied Nubeam on human microbiome project (HMP) WGS metagenomics samples collected from various body habitats. Using mapped reads, dimension reduction of resulted pair-wise distance matrix showed the primary clustering of samples is by body habitats, comparable with the results in published HMP studies. Interestingly, using unmapped reads only, oral and gastrointestinal samples showed less distinct clustering, while skin, nasal and, particularly, urogenital samples displayed much greater variation. Our analysis revealed the contribution of unmapped reads in metagenomics studies. We also applied Nubeam on the developmental transcriptome RNA-seq data of social amoeba *Dictyostelium discoideum*. Dimension reduction of resulted pair-wise distance matrix revealed that developmental transcriptome showed gradual changes interspersed with a few large shifts, indicating the slow change of transcriptome in certain developmental stages followed by rapid change of gene expression when the developmental stages switched. Our analysis recapitulated the findings of the original study. The applicability of Nubeam on the datasets demonstrated the method's efficiency in capturing the characteristic of sequence and ability in investigating the genetic contribution of unmapped reads.

**1346T**

**Gene identifiers: More than just a number.** *P. Denny, B. Braschi, K. Gray, R. Seal, S. Tweedie, B. Yates, E. Bruford*. HUGO Gene Nomenclature Committee (HGNC), EMBL-EBI, Hinxton, United Kingdom.

The HUGO Gene Nomenclature Committee (HGNC, [www.genenames.org](http://www.genenames.org)) is the only organisation worldwide assigning standardized gene symbols and names to all genes in the human genome. As human genomics increasingly becomes a key aspect of clinical practise it is critical that everyone knows exactly which gene they are referring to. In this context not only are gene symbols indispensable for everyday communication, stable gene identifiers (IDs) are also very important for cataloguing and datamining. As well as assigning a gene symbol and name the HGNC also creates a unique HGNC ID for every gene, in the format HGNC:#. While specific circumstances can result in a change in gene symbol, e.g. updating an uninformative placeholder symbol when the function of the encoded protein is elucidated (e.g. C14orf169 > RIOX1, ribosomal oxygenase 1), this would not result in a change in the HGNC ID (HGNC:20968) which is intrinsically linked to the gene locus and sequence. The HGNC ID is also a very reliable way to link between other major genomic resources; while these resources also aim to have stable gene IDs, changes for example in genome assembly, gene models and coding status can trigger a new ID being created for the same gene, which would not result in a change in the HGNC ID. Only in the rare circumstances of a gene merge or split would an HGNC ID potentially be altered; even in such a case the previous ID would remain fully traceable and linked to the new ID(s). Links between HGNC IDs and external resources are regularly updated by both automated quality control and manual curation, and HGNC IDs are widely referenced in biomedical resources. As such, we believe HGNC IDs are the most stable and practicable human gene IDs available. We strongly advise authors to reference the HGNC ID in article metadata (or at least once in the abstract/introduction) when publishing on a human gene. This policy is also being advocated by the UK Wellcome Trust funded Transforming Genetic Medicine Initiative (TGMI, [www.thetgmi.org/](http://www.thetgmi.org/)), and we plan to contact journals and publishing houses to promote the utility of HGNC IDs, and model organism database gene IDs in general, in all articles. Not only would using these IDs give readers an immediate link to databases with specific information on the gene(s) in question alongside multiple links to external resources, they would also serve to clarify exactly which species were being discussed, a common ambiguity in many publications.

**1347F****Cohort based precise interpretation algorithms of copy number variants detected by exome sequencing on individuals of severe disorders. X.**

Dong<sup>1</sup>, B. Liu<sup>1</sup>, L. Yang<sup>2</sup>, H. Wang<sup>2</sup>, B. Wu<sup>2</sup>, R. Liu<sup>2</sup>, H. Chen<sup>2</sup>, X. Chen<sup>2</sup>, S. Yu<sup>2</sup>, F. Xia<sup>3</sup>, W. Zhou<sup>1,2</sup>, Y. Lu<sup>1,2</sup>. 1) Children's Hospital & Institutes of Biomedical Sci, Fudan University, Shanghai, Shanhai, China; 2) Children's Hospital of Fudan University, Shanghai Key Laboratory of Birth Defects, The Translational Medicine Center of Children Development and Disease of Fudan University, Shanghai, Shanghai, China; 3) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, USA.

Background Copy number variations (CNVs) is a major cause of severe genetic disorders. Various algorithms have been developed to solve the estimation strategy or statistical model of CNV detection from WES data. However, lack of clinical phenotype integration or the ability to combine CNV analysis with SNV have made these tools not available for clinical-relevant CNVs evaluation. A more comprehensive variation detection and analysis pipeline is desirable to cover both CNVs and SNVs in clinical practice. Methods We established a pipeline for clinical NGS-involved CNV detection (PICNIC) to assist identifying potential disease-causing (PDC) CNVs and provided an SNV and CNV integrated (SCI) strategy for combinational CNV and SNV analysis. PICNIC used depth-based algorithm to detect CNV from BAM files, then annotated and filtered candidate variants with gene function, literature annotation and HPO-standardized clinical phenotype. The SNV and CNV Integrated (SCI) strategy could provide combinational potential disease causing (PDC) variants based on gene's inheritance model, zygosity of variants, and clinical phenotype matching details. Results The PICNIC and SCI strategy were applied to assist clinical diagnoses in a large Chinese pediatric cohort with sever genetic disorders, including 861 patients and 1,304 related pedigree samples. Altogether, 16,081 raw CNV calls were analyzed, including 3,610 duplications (DUPs) and 12,471 deletions (DELs). After PICNIC refinement, 1,024 CNVs (669 DELs, 355 DUPs) remained for further SCI analysis. Finally, 70 PDC CNVs (47 DELs, 23 DUPs) were identified, including 52 CNVs larger than 1 Mb (32 DELs, 20 DUPs), 10 CNVs smaller than 1 Mb covering multiple genes (7 DELs, DUPs) and 8 DELs covering single gene. These PDC CNVs were found in 63 patients (7.3%), including 50 SNV-negative cases. Specially, compound heterozygous SNV-CNVs were identified in 7 cases, and 25 out of 28 randomly selected PDC CNVs were confirmed with other test. Altogether, an increase of 6.6% diagnostic rate was achieved by PICNIC and SCI compared with traditional WES-SNV analysis. Conclusion In this study, our pipeline is important for the identification of PDC-CNVs and PDC compound heterozygous (CH) which were not covered in previous WES analysis. The combinatorial analysis could improve the positive diagnosis rate of rare genetic disorders. In the rapid development of clinical genetic testing, both PICNIC and SCI strategy deserve a widespread application.

**1348W****Fabric Genomics' Opal variant interpretation platform enables rapid, whole genome analysis turnaround in under an hour. A.P. Fejes, B. Stade, E.S. Kiruluta, M.G. Reese. Fabric Genomics, Oakland, CA.**

Opal Clinical is well suited for use in clinical applications, supporting delivery of rapid diagnostic outcomes on whole genome data. NGS-based diagnostics are poised to revolutionize the way clinical labs identify and interpret inherited or de novo diseases. However, the long sequencing and processing times make it difficult to incorporate into existing workflows. For diagnostics purposes, a raw sample must be sequenced, aligned to the reference genome, called for variant bases, annotated and interpreted. While large-scale sequencing for 30x whole genomes, suitable for diagnostic purposes, continues to improve, accurate genome annotation and interpretation remains one of the most challenging and time consuming components of the end-to-end process. To solve this issue, Fabric Genomics has designed a platform that performs variant annotation for a whole genome in ~8 minutes. It provides an interface for interpretation that can yield immediate results for many diseases and enables deep genome interrogation and interpretation. The quality of the annotations is ensured through robust regression testing. As each data source is upgraded, or source code is modified, data annotation tests are performed to ensure the accuracy of the annotations is not compromised. This ensures that Fabric Genomics' platform remains both up to date and accurate in its predictions. We discuss here some of the benchmarks of our complete genome annotation platform, as well as some of its key features and design principles. The annotation engine is currently in use widely, including in the UK's 100,000 Genomes Project. It is also in use at Rady's Children Hospital, where they are launching a rapid genome service to return results for babies in the newborn intensive care unit (NICU) and pediatric intensive care unit (PICU) in 24 hours.

**1349T****Minerva & Me: Public participation in research: Crowdsourcing for computational phenotyping method development.**

*M. Ferlaino<sup>1</sup>, M. Alvi<sup>2</sup>, J. Barret<sup>3</sup>, M. Dawson<sup>2</sup>, J. Diprose<sup>3</sup>, R. Esnouf<sup>6</sup>, N. Hallowell<sup>6</sup>, G. Baynam<sup>3,4</sup>, H. Brunner<sup>5</sup>, D.R. FitzPatrick<sup>5</sup>, A. Zisserman<sup>2</sup>, C. Nelläker<sup>7</sup>, Minerva Consortium.*

1) Big Data Institute, Li Ka Shing Centre for Health Information and Discovery, University of Oxford, UK; 2) Visual Geometry Group, University of Oxford, UK; 3) Genetic Services of Western Australia, King Edward Memorial Hospital, WA, Australia; 4) Western Australian Register of Developmental Anomalies, King Edward Memorial Hospital, WA, Australia; 5) Department of Human Genetics, Radboud University Medical Center, Nijmegen, The Netherlands; 6) MRC Human Genetics Unit, IGMM, University of Edinburgh, Western General Hospital, Edinburgh, UK; 7) Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, UK; 8) Wellcome Trust Centre for Human Genetics, University of Oxford, UK; 9) Ethox Centre, Nuffield Department of Population Health, University of Oxford, UK.

The Minerva Consortium is an open academic consortium that has been formed to allow computational phenotyping development together with clinician researchers. The mission is to enable research into the use of image analysis for the diagnosis of diseases, prevent data siloing, and foster further healthy competition between various image phenotyping approaches. There is huge potential for new deep phenotyping and machine learning approaches to have significant impact in health care pathways. However, big data machine learning approaches are reliant on having access to large data sets. Here we present Minerva & Me, which allows families, patients with rare diseases, and the broader public to directly participate in a research project into computational phenotyping. A dynamic consent model allows participants persistent granular control of how their data can be used in research. All data contributed remain under the users' control, including the ability to delete the data. The information to participants has been formulated in an easy to read version to allow active consent as broadly as possible. Our aim is to build on recent developments in using computer vision approaches in the context of rare disease phenotyping. Approaches such as the Clinical Face Phenotype Space have great potential to provide diagnosis decision support, statistical support for causative variants, and to augment current undiagnosed patient matchmaking. All such methods are vulnerable to implicit biases if the underlying data sets for the research are biased in terms of equitable representation of ancestral backgrounds, ages and genders. It is thus critical for the success of deep phenotyping approaches that platforms for collecting data sets from around the world are built. Minerva & Me has been built to have the requisite ethical, data security, and legal frameworks to allow open participation. It has been built to evolve to be able to allow other research projects to add consent and participation questions – and modular to allow additional data inputs in future. To regulate and control such developments an Advisory Board has been assembled with members from patient representative groups Unique, Rare Disease UK, and Rare Voices Australia, clinical genetics, legal, as well as data security experts. Together, the Minerva Consortium will be the means through which computational phenotyping is developed as part of the clinical pathway and ultimately to patient benefit in health care settings.

**1350F****Prediction of gain-of-function and loss-of-function mutations using Combined Annotation Dependent Depletion (CADD).**

*A. Ghosh<sup>1,2</sup>, A. Navarini<sup>1,2</sup>.*  
1) Department of Dermatology, University Hospital Zurich, Zurich, Switzerland; 2) Competence Center Personalized Medicine UZH/ETH, Zurich, Switzerland.

Introduction: Next generation sequencing (NGS) technologies can identify on average 20,000 missense variants per exome, out of which very few can be held responsible for causing the underlying disease. Therefore, it is very important to interpret the functional significance of these variants. A number of in silico bioinformatics tools have been already developed for the similar purpose, out of which CADD, SIFT (Sorting Intolerant From Tolerant) and PolyPhen2 (Polymorphism Phenotyping v2.0) are most commonly used. While SIFT and PolyPhen2 predict the deleteriousness of variants, CADD scores the variants based on a supervised machine learning approach (Support Vector Machine). The aim of this study is to utilize the CADD score to predict whether the variant causes a gain-of-function or loss-of-function at the protein level. Material and Methods: A large number of mutations was extracted from public databases ClinVar and DisGeNET, namely 435 gain-of-function (GOF) and 3,350 loss-of-function (LOF) variants. All of these variants have supporting evidence of their functional significance in terms of literature texts, clinical reports and research projects. Results: Our results show two peaks of mean CADD scores across GOF and LOF variants ( $p < 0.05$ ) indicating a non-random difference. This difference along with the CADD score distribution over all the variants helped us to choose a cut-off score of GOF and LOF variants. The cut-off scores, in combination with either SIFT or PolyPhen2, resulted in correct prediction of 71% GOF and 75% LOF variants. Discussion: Therefore, these CADD cut-off scores can be useful to predict the functional significance of a missense variant. However, they should be used more as an indicator as they need to be interpreted with further evidence on pathogenicity. .

**Efficient pipeline for whole genome simulation and summary statistic calculation with flexible demographic models.** A.L. Gladstein<sup>1</sup>, C.D. Quinto-Cortes<sup>2</sup>, J.L. Pistorius<sup>3,4</sup>, M.A. Skodiak<sup>5</sup>, L.K. Gantner<sup>6</sup>, A.E. Woerner<sup>7</sup>, J.C. Watkins<sup>3,8</sup>, M.F. Hammer<sup>3,8</sup>. 1) Ecology and Evolutionary Biology, University of Arizona, Tucson, AZ; 2) National Laboratory of Genomics for Biodiversity, Irapuato, Guanajuato, Mexico; 3) BIO5 Institute, University of Arizona, Tucson, AZ; 4) CyVerse, University of Arizona, Tucson, AZ; 5) School of Information, University of Arizona, Tucson, AZ; 6) Department of Mathematics, University of Arizona, Tucson, AZ; 7) Department of Genetics, University of Arizona, Tucson, AZ; 8) ARL Division of Biotechnology, University of Arizona, Tucson, Arizona.

Approximate Bayesian Computation (ABC) has become a widely used method for demographic inference. In order to use ABC millions of simulations per model and summary statistics of the data are required and small loci are usually used. We have developed a pipeline that utilizes the coalescent simulator MaCS and calculates a variety of genomic summary statistics in Python. In order to reduce storage requirements we bypass all printing by MaCS. We are able to simulate a complex demographic model of 100's of samples of whole chromosomes and calculate summary statistics in a runtime as little as a few seconds and an average of 1hr, with max memory use of 4Gb. This means that we are able to optimally run our pipeline in parallel on high throughput computers, to complete millions of complete chromosome simulations in a few weeks and use little storage. We conveniently read in a user input file containing model parameters and priors, allowing for our pipeline to be easily applied to any demographic model. We provide the option to model ascertainment bias so that ABC can be used on SNP array data. Our pipeline will be publically available on GitHub. We also provide a framework for rigorous testing and debugging in case users would like to add their own functions.

**The European Variation Archive: A repository for short and structural genomic variation.** C.Y. Gonzalez Garcia, G. Saunders, J. Kandasamy, J.M. Mut Lopez, P. Arce Garcia, S. Venkataraman, T. Smith, T. Keane. Archive Infrastructure, EMBL - European Bioinformatics Institute, Cambridge, United Kingdom.

The European Variation Archive (EVA, <https://www.ebi.ac.uk/eva>) is a primary open repository for archiving, accessioning, and distributing genomic variation data including single nucleotide variants, short insertions and deletions, and larger structural variants in any species. Since their launch in 2014, the EVA and its sister project the Database of Genetic Variants Archive (DGVA) have archived more than 520 million unique variants across more than 200 studies, containing approximately 300,000 samples across 27 species. A key function of the EVA as a long term data archive is to guarantee that study metadata and submitted VCF files are valid, and hence useful for data analysts. All VCF files are checked using the EVA VCF Validation Suite, which supports all 4.x versions of the VCF specification. We are committed to maintain and improve the VCF specification as part of our collaboration with the Global Alliance for Genomics and Health (GA4GH). The EVA also provides stable identifiers so that discovered variants and alleles can be referenced in publications, cross-linked between databases and integrated with successive reference genome builds. The EVA currently peers with the NCBI-based dbSNP and dbVar databases to form a worldwide network for exchanging and brokering submissions. From Q4 2017, issuing and maintaining locus identifiers will be divided by taxonomy: dbSNP will be responsible for human locus accessioning, and EVA responsible for all non-human loci. The EVA provides a comprehensive view of all these data through its website, mainly through the study browser and the variant browser. The study browser allows users to explore all archived datasets and download them via FTP. The variant browser allows fine-grained queries based on annotation generated using Ensembl's Variant Effect Predictor, protein substitution scores from SIFT and PolyPhen, and allele frequencies. Data can be downloaded at study, file or variant level, in VCF and TSV formats. More recently, we have been working on displaying variant data filtered by the user for a specific annotation version, and implementing a web services API for advanced search of structural variation. Future plans involve improving the integration with other EMBL-EBI services such as the European Genome-phenome Archive (EGA), to support browsing of controlled-access human datasets. All our software is open-source, licensed under Apache 2 and freely available in GitHub (<https://github.com/ebivariation/>).

**1353F**

**The analysis of negative selection with heterogeneous Mendelian models in coding, as well as noncoding regions for cohorts of diverse undiagnosed diseases.** *F. Gu, M. Gordon, T. Markello, S. Macnamara, L. Vlahos, D.A. Adams, W.A. Gahl.* National InstituteOffice of the Clinical Director, NHGRI, and NIH Undiagnosed Diseases Network and Program, NIH, Bethesda MDs of Health, Washington, DC.

A previous study of negative selection shows excess deleterious de novo variants in the affected cohort compared to healthy control siblings, but that analysis was done solely for the de novo model and for a single disease (autism). To assess the overall fitness landscape of an individual of any given disease, we developed an agnostic diagnostic pipeline that allows high confidence genotyping in low-coverage regions and permits analysis on coding and noncoding regions for various Mendelian models including homozygous recessive, de novo dominant, compound heterozygous recessive, x-linked, deletion with transmission, and novel deletion in very well-sequenced positions. This agnostic diagnostic pipeline presumes nothing about phenotype or molecular causes of these diseases. It was performed forwardly on affected probands, and again backwardly on their healthy siblings reversing the affectedness-statuses. The cohort consists of 96 non-consanguineous quartets or quintets in the Undiagnosed Disease Program of the intramural NIH, all with one affected proband and one or two unaffected siblings. Deleterious appearing candidates were assessed primarily by CADD and population frequency statistics. A combined score for compound heterozygous pairs strongly weighted towards equality in the deleteriousness of the two alleles was used to assess overall deleteriousness of that compound heterozygous pair. The only non-automatic part of the pipeline is the manual curation of the bam files. The analysis showed a higher number of disease-causing variants in the affected probands compared with their healthy controls. This demonstrates power of the current variant analysis relative to chance alone as represented by nonequality of deleterious variants in probands versus unaffected sibling controls and suggests the candidate variants generated from this agnostic genetic analysis are likely to contain the true causal variant.

**Graphtyper: Population-scale genotyping using pangenome graphs.**

*B. Halldorsson<sup>1,3</sup>, H. Eggertsson<sup>1,2</sup>, H. Jonsson<sup>1</sup>, S. Kristmundsdottir<sup>1,3</sup>, E. Hjartarson<sup>1</sup>, B. Kehr<sup>1</sup>, G. Masson<sup>1</sup>, F. Zink<sup>1</sup>, A. Jonasdottir<sup>1</sup>, A. Jonasdottir<sup>1</sup>, I. Jonsdottir<sup>1,4</sup>, D. Gudbjartsson<sup>1,2</sup>, P. Melsted<sup>1</sup>, K. Stefansson<sup>1,4</sup>.* 1) deCODE genetics, Reykjavik, IS, Iceland; 2) School of Engineering and Natural Sciences, University of Iceland, Reykjavik, Iceland; 3) School of Science and Engineering, Reykjavik University, Reykjavik, Iceland; 4) Faculty of Medicine, School of Health Sciences, University of Iceland, Reykjavik, Iceland.

A fundamental requisite for genetic studies is an accurate determination of sequence variation. While human genome sequence diversity is increasingly well characterized, there is a need for efficient ways to utilize this knowledge in sequence analysis. Here we present Graphtyper, a publicly available novel algorithm and software for discovering and genotyping sequence variants. Graphtyper realigns short-read sequence data to a pangenome, a variation-aware graph structure that encodes sequence variation within a population by representing possible haplotypes as graph paths. Our results show that Graphtyper is fast, highly scalable, and provides sensitive and accurate genotype calls. Graphtyper genotyped 87.9 million sequence variants in whole-genomes of 28,075 Icelanders using less than 100,000 CPU days, including detailed genotyping of six human leukocyte antigen (HLA) genes. We show that Graphtyper is a valuable tool in characterizing sequence variation in population-scale sequencing studies.

**PathwayMatcher: Direct mapping of omics data to the Reactome pathway knowledgebase.** L.F. Hernández Sánchez<sup>1,4</sup>, O. Helgeland<sup>1,3</sup>, B. Burger<sup>5,7</sup>, H. Barsnes<sup>5,7</sup>, S. Johansson<sup>1,4,6</sup>, A. Fabrega<sup>6</sup>, P.R. Njølstad<sup>1,3</sup>, H. Hermjakob<sup>2</sup>, M. Vaude<sup>1,4</sup>. 1) K.G. Jebsen Center for Diabetes Research, Department of Clinical Science, University of Bergen, Norway; 2) European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Wellcome Trust Genome Campus, Hinxton, Cambridge, United Kingdom; 3) Department of Pediatrics, Haukeland University Hospital, Bergen, Norway; 4) Center for Medical Genetics and Molecular Medicine, Haukeland University Hospital, Bergen, Norway; 5) Proteomics Unit, Department of Biomedicine, University of Bergen, Norway; 6) K.G. Jebsen Centre for Neuropsychiatric Disorders, University of Bergen, Norway; 7) Computational Biology Unit, University of Bergen, Norway.

Many studies performed in biomedical and clinical sciences is to uncover the biological mechanisms responsible for a phenotype, to provide the means to prevent or cure diseases. Identification of the underlying mechanism remains often elusive, and consequently the cause of the clinical observation cannot be confidently assessed. It is now possible to associate a disease condition with genetic variants, gene expression levels, abundances of proteins, their posttranslational modification states or other biochemical compounds. Here, we present PathwayMatcher, an open source bioinformatics tool to map clinical omics data to the Reactome knowledgebase (reactome.org). Reactome is a free, open-source, open-data, curated and peer-reviewed knowledgebase of biomolecular reactions and pathways. PathwayMatcher is written in Java under the Apache licence 2.0. The input Omics data can be gene names, Single Nucleotide Polymorphisms (SNPs), peptides sequences, protein accessions, and peptides or proteins carrying posttranslational modifications (PTMs). Variant effects are inferred using the Ensembl Variant Effect Predictor (VEP), and protein level data are mapped directly to the Reactome Neo4j graph database installed locally. In the future it will be possible to integrate these new types of mapping to the online Analysis Service of Reactome. PathwayMatcher is available as Docker container image, which is a standalone executable package with all the necessary libraries, including the latest version of VEP and Reactome. It can run offline and does not require the installation of dependencies besides Docker itself. It is possible to integrate PathwayMatcher in genomics bioinformatics pipelines, retrieving biochemical reactions and pathways that can be affected by SNPs and Copy Number Variation (CNV). The functional results can be used to inspect variant distributions among pathways, identify upstream and downstream processes, and design functional assays. In the case of proteomics experiments, it is further possible to map the peptide or protein level results to Reactome, including PTMs, without gene-centric summarization. Results can be visualized in the graphical interface of Reactome to see how the expression patterns of the proteins vary over time or between conditions, allowing visually distinguishing the regions of highest variation and guiding the design of future experiments.

**Development and organization of genomics metadata by ENCODE.** B. Hitz, C. Sloan, U. Baymuradov, E. Chan, C. Davis, I. Gabdank, A. Narayana, K. Onate, J. Hilton, T. Dreszer, J.S. Strattan, F. Tanaka, K. Dalton, J.M. Cherry. Genetics, Stanford University, Palo Alto, CA., United States.

The goal of the Encyclopedia of DNA Elements (ENCODE) project is to annotate functional regions in the human and mouse genomes. Functional regions include those that code protein-coding or non-coding RNA gene products as well as regions that could have a regulatory role. To this end, the project has surveyed the landscape of the human genome using over 40 high-throughput experimental methods in more than 400 different cell and tissue types, resulting in over 8500 experiments. These datasets have been supplemented with over 4500 complementary assays from other projects; the Roadmap for Epigenomics Consortium, the Genomics of Gene Regulation project, and our sister projects modENCODE and modERN comprising genomics experiments in *Drosophila* and *C. elegans*. A description of these datasets, collectively known as metadata, encompasses, but is not limited to, the identification of the experimental method used to generate the data, the sex and age of the donor from whom a tissue sample was taken, and the software used to align the sequencing reads to a reference genome. Defining and organizing the set of metadata that is relevant, informative, and applicable to diverse experimental techniques is challenging. Here we describe how metadata are organized at the ENCODE DCC and define the metadata standard. A metadata standard encompassing key experimental variables as well as software versions, parameters, and quality metrics determined from uniform processing of genomics data is critical to the comparability and reproducibility of the results and findings of these experiments and computational analyses. Understanding the principles and data organization will help improve the accessibility of the ENCODE datasets as well as provide transparency to the data generation processes. This understanding will allow integration of the diverse data within the ENCODE consortium as well as integration with related assays from other large-scale consortium projects and individual labs.

**Compare HLA typing by next generation sequence methods: An example in Taiwan Biobank database.** C. Hsiung<sup>1,2</sup>, M. Su<sup>1,2</sup>, H. Chu<sup>1,2</sup>, C. Shen<sup>1,2</sup>. 1) Taiwan Biobank, Academia Sinica, Taipei, Taipei, Taiwan; 2) Institute of Biomedical Sciences, Academia Sinica, Taipei, Taipei, Taiwan.

Human leukocyte antigens (HLA) genes play an important role in organ transplantation and are associated with autoimmune and infectious diseases. The gene family contains the most polymorphic variation in humans. Current DNA genotyping methods, such as the Sanger sequencing-based typing (SBT) and sequence-specific oligonucleotide (SSO) method which are extensively used in HLA typing, generally result in ambiguous typing results because of the limitations of oligonucleotide probe design or phasing ambiguity of HLA allele assignment. Next Generation Sequencing (NGS) Technology performs massively parallel sequencing, which leads to reconstruct allele sequences from overlapping gene fragments, and to identify the primary structure, providing the region phasing information. Currently, several NGS platforms, such as Ion Torrent, PacBio and whole genome sequence, which use different sequencing chemistry and technologies may be expected to solve the phase ambiguity problem. In order to compare the HLA typing accuracy obtained from different platforms, we conduct a pilot study by using the Taiwan Biobank database. The Taiwan biobank database has collected information from over 80,000 participants and whole-genome sequence has been performed in 1,000 individuals. We randomly selected 20 participants, whose sequences have whole genome-wide sequenced by illumina Hiseq 2500 sequencer, are typed by two different NGS platforms, including Ion Torrent and PacBio, and SBT method. We use SBT method as the gold-standard to estimate the accuracy of HLA typing at 2-digit, 4-digit and a super-high resolution (formerly known as the 8-digit level of resolution). The results show that the accuracy for HLA class I typing at 2-digit and 4-digit resolution, are not significantly difference between these three NGS methods, but the accuracy which is used BWA analysis of whole genome sequence data of the HLA-A typing at 8-digit resolution shows much lower (20%). In HLA class II, the accuracy of which is measured by HLA-DQB1 and HLA-DRB1 typing at 2-digit and 4-digit, is not different between the three NGS methods, but in HLA-DQB1 at 8-digit resolution the accuracy from PacBio analysis pipeline is lower. Our finding suggests that HLA typing at 2-digit and 4-digit resolution by the use the three NGS methods may widely use in clinical and laboratory application, but at 8-digit Ion Torrent HLA typing is a better method.

**Target Gene Notebook: Connecting genetics and drug discovery through enabling computational and logistical tools.** J. Hutz<sup>1</sup>, J. Wierzbowski<sup>1</sup>, A. Kirby<sup>2</sup>, J. Heymont<sup>1</sup>, M. Daly<sup>2</sup>, M.P. Reeve<sup>3</sup>. 1) Eisai, 4 Corporate Drive, Andover, MA 01810; 2) Analytic and Translational Genetics Unit, Department of Medicine, Department of Neurology and Department of Psychiatry Massachusetts General Hospital, Boston, MA; 3) 3309 Bayview Dr, #B, Manhattan Beach, CA 90266.

Genetic studies have generated a surfeit of robust associations in recent years, providing potential insights into the causal mechanisms of many human diseases. While many browsers and databases provide access to unfiltered genome annotations and genetic results, very few of these facilitate the development of therapeutic hypotheses due to limitations in the presentation and interpretation of functional and molecular information. Linking associations to functional biological information is essential to translating genetic insights to drug discovery; however, there is currently no way to maintain group curation of relevant genetic and functional information and to integrate it with proprietary experimental data. We introduce an e-notebook to facilitate the organization of results and provide freely-available software, Target Gene Notebook, for the purposes of assisting therapeutic target evaluation and creating durable institutional or public knowledge bases. With a gene or locus as the focal point, the software identifies candidate published associations and allows the user to review and store an assessment of each finding. Qualitative assessments are pre-computed via an automated assessment of statistical robustness and the variants' known or predicted functional. These analyses utilize published LD patterns across global populations derived from reference panels and derive 'credible sets' of variants. Public resources of relevance to target evaluation (e.g., variation patterns in ExAC/GnomAD, expression patterns in GTEx) are also presented. In addition, eQTLs as defined from GTEx and other sources are included as associations (complete with credible set definition) for visual assessment of phenotype – eQTL overlaps. The notebook can be extended to include other association modalities (e.g., protein-QTLs) and variant types (e.g. Mendelian disease mutations). Implementation is such that private instances can be shared across groups or sites as needed - potential users include pharma (for tracking knowledge of targets) and disease consortia for collating results and interpretations. Target Gene Notebook will be released in Fall of 2017.

**A graph-based pipeline to evaluate common structural variations based on haplotypes and reassembly.** S. Ji, L. Li, G. Demir, P. Komar, D. Kural. SBGD Inc., Cambridge, MA.

Structural variations (SV) are a greater source of human genetic variation than single nucleotide variants (SNVs). However, due to the complex nature of these events, complicated downstream processing and multiple algorithms are required after initial alignment of sequenced reads. The human genome reference in its linear form cannot represent these events in their native form. Recently, multiple methods that apply a graph-based approach by representing genetic variants as distinct paths through the graph have been proposed, but mostly focused on SNVs. Here, we aim to build a graph-based SV genotyping pipeline that aligns reads originating from known SVs directly to their native positions and genotypes them. For this purpose, we first established a pipeline that evaluates common SVs and resolves SV breakpoints prior to inclusion in the graph. This is due to inconsistent breakpoints negatively affecting the graph-aligner's performance. In order to select SVs with consistent breakpoints originating from single evolutionary events, we devised multiple metrics to identify SVs common in the population (>5%) with well-defined haplotypes. An initial set of SVs in Hardy-Weinberg equilibrium with tagging SNPs ( $r^2 > 0.9$ ) were collected from samples of the 1000 Genomes Project phase 3. These SVs were evaluated against the Database of Genomic Variants (number of studies, platforms, algorithms, frequency in cohort, etc.), as well as SVs from the Genome of the Netherlands and the Icelandic non-repetitive, non-reference sequences (based on concordance between frequency of SV and their tagging SNPs). For each SV region, reads were sampled from individuals with tag-SNPs suggesting a homozygous SV and reassembled per individual. Scores based on consistency of breakpoints in reassembled contigs across individuals and consistent haplotypes were then collated with other metrics to provide a quantitative measure of confidence regarding the breakpoints of each SV. The pipeline can also evaluate a custom list of SVs through these steps including the 1000 Genomes SVs as one of the reference dataset. Using Illumina short read sequences from the 1000 Genomes Project and the Simons Genome Diversity Project, we show that SVs not reported in the original studies can be well genotyped through our SV-aware graph pipeline. In addition, we demonstrate that false positive variant calls that arise due to microhomology within SV regions can be rescued through this approach.

**Rapid whole-genome annotation and search in the cloud: SeqAnt enables easy identification of alleles for traits of interest.** A. Kotlar<sup>1</sup>, M. Zwick<sup>1</sup>, D. Cutler<sup>2</sup>, T. Wingo<sup>2,3</sup>. 1) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA; 2) Division of Neurology, VA Medical Center, Atlanta, GA; 3) Department of Neurology, Emory University School of Medicine, Atlanta, GA.

While genome-wide association studies (GWAS) and whole-exome sequencing (WES) remain important components of human disease research, the future lies in whole-genome sequencing (WGS), as it inarguably provides more complete data. Genetic disease studies require thousands of samples to obtain adequate power, and the resulting WGS datasets are hundreds of gigabytes in size and contain tens of millions of variant alleles. Describing, prioritizing, and selecting alleles from whole-genome sequencing experiments at this scale is technically challenging, and has to date required computer science expertise. SeqAnt 2.0 (<https://seqant.emory.edu/>) is the first web application that make these tasks accessible to non-programmers, even for large data sets. It comprehensively describes (annotates) alleles using public data (e.g., RefSeq, dbSNP, ClinVar, CADD, PhasCons, and PhyloP), and introduces the first natural-language search engine that can locate the alleles of interest in a user's experiment in milliseconds. Instead of relying on specific terms, the SeqAnt 2.0 search engine understands English grammar, similar to modern Internet search engines like Google and Bing. To use SeqAnt 2.0, users simply upload their experimental alleles in VCF format to the SeqAnt web application, wait for the data to be processed, and then type experiment-related terms, such as gene names, diseases, or allele frequencies into the provided search bar. The alleles matching any search query can be exported for downstream analysis, and each step is automatically recorded for reproducibility. To test SeqAnt 2.0, we submitted all autosomal coding alleles from gnomAD (2.6GB). SeqAnt annotated the  $4.7 \times 10^6$  variant alleles in 3.47 minutes online. To test the search engine, we then queried "breast cancer pathogenic expert-reviewed maf < .001 cadd > 20" in SeqAnt's web interface. This query returned rare predicted-deleterious gnomAD alleles associated with breast cancer that had "Pathogenic" ClinVar records reviewed by an expert panel (.02 seconds, 93 alleles). SeqAnt provides these capabilities for numerous species, including *homo sapiens*, *m. musculus*, *d. melanogaster*, *c. elegans*, and *s. cerevisiae*. As sequencing becomes more prevalent in a diversity of research settings, and as the size of individual experiments grows, SeqAnt's capabilities will become increasingly critical in lowering barriers to effective sequencing experiment data analysis by researchers and clinicians alike.

**High-performance whole genome sequence variant analysis in the TOPMed project using cloud environments.** *R. Kuraisa, S. Gogarten, X. Zheng, C. Laurie, D. Levine.* Department of Biostatistics, University of Washington, Seattle, WA.

The NHLBI TOPMed project is expected to sequence >120,000 whole genomes. We are developing a high-performance analysis pipeline for computing population structure, kinship and association testing of all samples combined based around GENESIS, an R/Bioconductor package for statistical analysis of samples with genetic relatedness. Since TOPMed consists of many different studies from a wide range of populations, including family studies with extended pedigrees, characterizing and accounting for these relationships is crucial in association testing. The large scale of TOPMed requires parallel processing on either a local compute cluster or the cloud. Here we present an overview of the pipeline design as well as a comparison of using it in local and cloud computing environments. We first ported our pipeline from an in-house compute cluster to Amazon Web Services (AWS) using native Amazon Machine Images (AMI) and CfnCluster, a tool used to build and manage high-performance computing (HPC) clusters using different AWS job schedulers. We then evaluated AWS Batch, a newer offering that provides cluster-like services for running batch computing jobs encapsulated in Docker containers. AWS Batch dynamically provisions the compute resources required by a job, thereby subsuming many tasks that previously needed to be managed manually. Finally, we evaluated the portability of our pipeline using the batch services model and Docker containers to Microsoft Azure and Google Cloud Platform. To enable our pipeline to run in multiple compute environments, we create cluster objects in Python that define all aspects of the environment. This allows us to separate the analysis code from the batch computing and job scheduling. Providing cost-effective access to the heterogeneous compute resources necessary to run the different steps in our pipeline in the cloud was the most challenging technical obstacle we faced. Cloud vendors tend to scale their offerings such that memory and computational performance increase proportionally, which may not map readily to the needs of different pipeline steps. The batch services model using Docker containers simplified many administrative and configuration issues and allowed us to define a virtual compute environment that better supported the needs of our pipeline for heterogeneous compute resources. Our pipeline is hosted on GitHub for collaborators and the genetics community to adapt to their needs.

**Improved access to variant-centric data in ClinVar.** *M.J. Landrum, J.M. Lee, M. Benson, G. Brown, C. Chen, S. Chitipiralla, L. Geer, L. Han, J. Hart, D. Hoffman, A. Irving, W. Jang, K. Katz, C. Liu, Z. Maddipatla, A. Malheiro, K. McDaniel, A. Mercado, M. Ovetsky, G. Riley, A. Sethi, G. Song, R. Villamarin-Salomon, G. Zhou, B. Holmes, B. Kattman, D.R. Maglott.* NCBI/NIH, Bethesda, MD.

ClinVar is the public archive at NCBI for interpretations of genetic variants relative to a disease or phenotype. The database includes >486,000 interpretations for >318,000 variants. Interpretations in ClinVar have been provided by more than 700 submitters from 59 countries, including clinical testing laboratories, research laboratories, OMIM and GeneReviews, and expert panels. The initial data model for ClinVar focused on the variant-disease relationship. This model was reflected in the ClinVar XML file, which is the archival form of the ClinVar dataset. However, many ClinVar users prefer to review all data for a variant, regardless of the disease. This is relevant when a gene has been associated with more than one disease, and when a disease may have several different forms, such as breast cancer. We are introducing several new representations of the ClinVar dataset that are focused on the variant, for any reported disease. First, we have developed a new XML file that is focused on the variant, rather than on variant-condition. Each variant record will be assigned an accession number with a VCV prefix. Accession numbers will be versioned, so that we can maintain a history of changes to the variant's interpretation and evidence. The variant-centric XML represents variants for which we have an explicit interpretation as well as variants that have only been reported as part of a haplotype or genotype ("included" variants). Second, a new format for the ClinVar VCF file is now available. The previous VCF file was organized around the rs number, and thus was limited to variants that were in dbSNP. In addition, for some cases data for more than one variant was reported on the same row, making parsing of the data more complicated. The new format for the VCF file is allele-specific such that each row represents a single allele. It includes any variant in ClinVar with a precise location, even if it has not yet been accessioned in dbSNP or dbVar. The new VCF format also represents both variants with explicit interpretations and "included" variants. Third, the variant-centric web display for ClinVar is being updated. The new display includes the VCV accession number so that records may be cited. It makes the aggregate and submitted interpretations for each disease more accessible. It also provides more data about individuals observed with the variant, such as their zygosity and indication for testing, and provides information about submitted experimental evidence.

**1363W**

**Bioinformatics and Elasticsearch: The perfect combination to unify and visualize life sciences massive data.** *M. Leclercq, R. Ongaro-Carcy, A. Droit.* Faculté de médecine, Université Laval, Québec, QC, Canada.

Since few years, biological datasets have grown exponentially in size and complexity, hence entering into the world of big data. DNA/RNA/Protein sequences, biomolecules structures and functional information generated by cancer and omics research (e.g. genomics, metagenomics, transcriptomics, proteomics, and metabolomics...) now represent petabytes of data. To organize and make available these data, hundreds of bioinformatics repositories are currently available, but they are disparate and biologists constantly navigate from a database to another to perform their analyses. They also have to adapt their data through various mediums (i.e. software, platforms etc.) to prepare inputs into the various available online services. Moreover, free online resources to analyze data generated by last generation technologies, such as gene expression combined with clinico-pathological and phenotype data, and link them easily with online knowledge are still lacking. To answer this need, we have developed Kibio.science, a new portal dedicated to the biology and bioinformatics scientific communities. In one view, it can provide a mean to visualize the overall content or search queries results within many repository simultaneously, such as Pubmed, ChEMBL, GTEX, TCGA, and many others. Kibio.science is based on Elasticsearch search engine, and Kibi, a plugin which uses Kibana visualization tool and creates the relational searches between Elasticsearch indexes (i.e. databases). This environment, once distributed on clusters of servers, makes Kibio.science very fast and flexible. Kibio.science takes care of converting any repository in Elasticsearch format and re-organize the structure of the information. Designed to be user-friendly, it offers a great user experience to play with bioinformatics knowledge, by using advanced filtering and dynamic web visualizations where everything is clickable. Simultaneous searches between many databases are possible and each selection updates automatically all graphs, heatmaps or statistical information built in every linked databases. To enhance the analytical power of kibio.science, specialized visualizations dedicated to medical or research purpose will be implemented. In the near future, Kibio.science will allow users to import their own datasets, connect them to the desired repositories and create their own visualizations. We aim to make Kibio.science a great resource for exploring, visualizing, and analyzing multidimensional Omics data.

**1364T**

**A graph remapping framework for in silico adjudication of SNVs, indels, and structural genetic variants from genetic sequencing data.** *D.H. Lee, G.T. Marth.* Human Genetics, University of Utah, Salt Lake City, UT.

Several state-of-the-art, easy to use tools are available both for short-variant detection (e.g. GATK, FREEBAYES), and structural variant (SV) detection (e.g. LUMPY, MANTRA, DELLY), but these tools often produce divergent variant calls, especially INDELS, and it is very difficult to reconcile such variants into a single, accurate set. Furthermore, while it would be highly desirable to also detect larger, structural variants (SV), existing SV detector packages are typically difficult to integrate, highly resource-intensive to run, and result in call sets that require expert manual review to reduce false positive detection rate. Our algorithm, GRAPHITE (<https://github.com/dillonl/graphite>) requires as input a collection of variant calls, made by one or more short-variant or SV detection tools. Typically, this starting set is high sensitivity (i.e. inclusive), but low specificity (i.e. have a high false discovery rate). We then apply a novel "variant adjudication" procedure to discard false positives, while keeping true positive calls. This is accomplished by constructing a graph from these variants (the Variant Graph) representing allelic variants as graph branches, in addition to the branches formed by the current, linear genome reference sequence. Using a graph mapping algorithm (GSSW, a graph extension of the Smith-Waterman alignment algorithm) we developed earlier, we re-map all reads from each of the samples contributing to the candidate calls. We retain candidate variants confirmed by mappings to those branches in the graph that represent the corresponding variant allele, and discard those candidates that were not confirmed by such mappings. This procedure results in a highly specific callset that also maintains the high sensitivity of the inclusive starting callset constructed by multiple primary variant calling methods. Here we present the application of this method for cross-validating structural variants calls from Pacific Biosciences data by remapping deep Illumina WGS read sets to Variant Graphs constructed using the candidate Pacific Biosciences variants, as part of the Human Genome Structural Variation Consortium (HGSVC) data analysis project. We also present GRAPHITE's application to improving the accuracy of allele frequency measurement in tumor sequencing data, which is essential for the accurate reconstruction of subclonal evolution in longitudinal tumor samples.

**SAV (Sparse Allele Vectors): Efficient variant file format that scales to analysis of millions of deep genomes.** *J. LeFaive, H.M. Kang, G. Abecasis.* Center for Statistical Genetics, Department of Biostatistics, University of Michigan School of Public Health, Ann Arbor, Michigan, USA.

As the number of deeply sequenced genomes grows at an unprecedented rate, efficient storage formats that scale sublinear to the number of genotypes are essential. We have designed a format for storing very large sets of genotypes and genotype probabilities that produces small file sizes and is optimized for fast association analysis. The design supports fine-level random access to variants, with no limitations on variant annotation, sample size, ploidy level or genome length. Our format capitalizes on the sparsity of genetic variation at a given locus to both compress data and reduce deserialization overhead. In addition to the I/O and computational efficiency attributed to reduced storage footprints, further computational efficiency can be achieved through sparse matrix operations. Since the proportion of rare variants continually increases with sample size, the compression ratio and efficiency of our format both improve as study sizes grow. When comparing to BCF files with sample sizes of 2,504, 9,109 and 19,879 individuals, our format reduces the storage footprints by up to 70%, 74% and 80% respectively. Accompanying our format is a C++ programming library for interfacing with it and other file formats. This library was designed for efficient association analysis and provides a mechanism to plug in linear algebra and numerical libraries, which reduces the overhead of copying data and lowers the memory footprint. Our format specification is publicly documented to allow for custom integrations. Additionally, the programming library is open source. Both can be found at <https://github.com/statgen/savvy>.

**Pathview Web: User friendly pathway visualization and data integration.** *W. Luo, G. Pant, Y.K. Bhavnasi, S.G. Blanchard, C. Brouwer.* Department of Bioinformatics and Genomics, UNC Charlotte, Kannapolis, NC.

Pathway analysis is widely used in omics studies. Pathway-based data integration and visualization is a critical component of the analysis. To address this need, we recently developed a novel R package called Pathview. Pathview maps, integrates and renders a large variety of biological data onto molecular pathway graphs. Pathview quickly became a leading tool in pathway visualization, and has been widely adopted by tens of thousands of scientists and dozens of dependent applications worldwide. Here we developed the Pathview Web server, as to make pathway visualization and data integration accessible to all scientists, including those without the special computing skills or resources. Pathview Web features an intuitive graphical web interface and a user centered design. We also provide a comprehensive online help system and multiple quick-start example analyses. Even with no special computing training and resources, users may still accomplish pathway based data visualization and integration independently. The server not only expands the core functions of Pathview, but also provides many useful features not available in the offline R package: 1) The results graphs are interactive and hyperlinked to abundant external annotation data online; 2) The server provides the latest, most complete and accurate pathway definitions and graphs by regular synchronization with KEGG source databases; 3) Users can review, replicate and share their analyses easily with free registered user accounts, which enable collaborative research and reproducible science; 4) Useful user engagement features allow users make comments and suggestions, or ask for help in designated pages. Importantly, the server presents a comprehensive workflow for both regular and integrated pathway analysis of multiple omics data. In addition, the server also provides a RESTful API for programmatic access and conveniently integration in third-party software or workflows. Pathview Web is openly and freely accessible at <https://pathview.uncc.edu/>.

**Optimal workflow for next generation sequencing data processing using existing technology.** *J.E. Martin<sup>1</sup>, A. Larionov<sup>1,2</sup>, G. Clark<sup>1,3</sup>, E.R. Maher<sup>1,3</sup>.* 1) Department of Medical Genetics, University of Cambridge CB2 0QQ, UK; 2) Statistics and Computational Biology Laboratory, Cancer Research UK Cambridge Institute; 3) Cambridge NIHR Biomedical Research Centre, Cambridge CB2 0QQ, UK.

**Introduction** Next Generation Sequence (NGS) instruments are becoming the standard tool in genetics, however, this process has not been accompanied by the development of a "gold standard" pipeline for germline NGS data processing. Our goal in the present study is to determine the optimal workflow in the specific case of whole exome sequencing (WES) to maximize the cost-efficiency of the process. **Material and Methods** For our analysis, we selected a cohort of 200 individuals sequenced for WES. All the samples considered were processed using sixteen different workflows composed of the different algorithms and software available. We selected up to ten quality parameters and indices to discern the best possible workflow. **Results** Using *bwa mem* for the alignment compared to using *bwa sampe* improved the number of aligned reads by roughly a 10%. When performing and not performing BQSR and indel realignment, there were no significant differences in the number of variants called or the quality of those, but there was an increase of computing time (4:32 versus 2:24). Regarding the variant calling, there were no significant differences in the number of variants called or their quality between algorithms, while the depth of read was significantly higher in unified genotyper (73.63 versus 53.83). Also, the computational time was significantly lower for unified genotyper (2:24 versus 11:13). **Conclusions** Our results indicate an optimal workflow for the processing of NGS WES germline data which can cut the time per sample down to a tenth while maintaining the quality of the results produced.

**1368F**

**Harnessing the power of linked data: Using semantic annotations on pediatric and adult datasets to enable cross-search.** *M. Mattioni, J. Radenkovic, A. Stanojevic, N. Vukosavljevic, J. DiGiovanna, V. Mladenovic, B. Davis-Dusenbery.* Seven Bridges, Cambridge, MA.

Advances in Next Generation Sequencing have allowed the generation of huge amounts of genomic data. At the same time, an increased amount of clinical metadata has been recorded, usually in various formats and with different methods. These metadata are becoming the compass researchers use to find and discover cohorts for further analysis. The possibility to cross-search different datasets coming from different investigations can speed data discovery and also yield to statistically significant results due to the ability to marshal a higher number of samples; moreover, researchers are empowered to ask deep queries about the data and create cohorts which intersect adult and pediatric cases at the same time. We have created an overarching data model which can represent the different metadata found in different pediatric and adult datasets, and we have harmonized the metadata using this model. We also have developed the Data Browser, a graphical interface to create deep queries in genomic data, which support cross-database search. Cross search enables users to easily explore phenotypic data in pediatric and adult datasets, to create hypothesis driven cohorts, and then to identify the connected files, which can be accessed according to the dataset's access policy they belong to.

**1369W**

**Representing the human genome with synthetic spike-in controls.** *T. Mercer<sup>1,2</sup>, I. Deveson<sup>1</sup>, S. Hardwick<sup>1</sup>, J. Blackburn<sup>1</sup>, T. Wong<sup>1</sup>, B. Kanakamedala<sup>1</sup>, C. Barker<sup>1</sup>, A. Martins Reis<sup>1</sup>.* 1) Garvan Institute of Medical Research, Sydney, NSW, Australia; 2) Altius Institute for Biomedical Science, Seattle, WA, United States.

Due to its directionality (from 5' to 3'), the human genome is a chiral object that can be reversed by a mirrored plane. For example, the 5'-TGAC-3' sequence is mirrored by the chiral 5'-CAGT-3' sequence. This chiral sequence is distinct from the original human sequence, yet retains many identical properties, including the same nucleotide content, repetitiveness, sequencing and alignment properties. These chiral sequences can thereby act as synthetic DNA or RNA standards to represent almost any feature of the human genome. We term these reference standards, *sequins* (sequencing spike-ins). We have developed *sequins* to represent instances of common and disease-associated genetic variation, including germline, somatic and structural rearrangements, repeat DNA, and immune receptor recombination. We have also released RNA *sequins* that represent alternatively spliced isoforms and fusion genes. These RNA and DNA standards are mixed to form reference ladders and emulate quantitative features of genome biology, such as genotypes, mutation frequencies, clonal cell populations, gene expression and splicing. *Sequins* are typically added at a fractional concentration directly to the patient's DNA sample before library preparation, and are then sequenced together, with a proportional fraction of resultant reads deriving from the *sequins*. The alignment of the library to both a human and mirror genome partitions *sequin* reads from the accompanying sample, and allow their use as internal quantitative and qualitative controls at each step of the NGS workflow without contaminating the accompanying sample. We have demonstrated the use of *sequins* with tumor and normal patient samples as internal quantitative and qualitative controls during sequencing and diagnosis. We have demonstrated the use of *sequins* in a range of clinical applications, including whole genome sequencing in Mendelian disease diagnosis, targeted panel sequencing of tumor samples, and the diagnosis of fusion genes with RNA sequencing. *Sequins* can be used to empirically measure diagnostic performance and quantitative accuracy of each individual NGS library. *Sequins* can also act as scaling factors by which to normalize between multiple samples, and thereby enable more accurate comparisons, more efficient data-sharing and standardized clinical database aggregation.

**1370T**

**Use of a metadata-driven architecture for tools and techniques to enhance methods for data sharing and facilitate meta-analysis for genetic association.** *M.C. O'Leary<sup>1</sup>, R. Whitley<sup>1,2</sup>, K.J. Sims<sup>1</sup>, R.B. McNeil<sup>3</sup>, E.R. Hausler<sup>1,2</sup>, C.D. Williams<sup>1,2</sup>, D. Provenzale<sup>1,2</sup>.* 1) VA Cooperative Studies Program Epidemiology Center, Durham VA Health Care System, Durham, NC; 2) Duke University, Durham, NC; 3) Center for Clinical Research Network Coordination, RTI International, Durham, NC.

**Objectives:** The VA Cooperative Studies Program Epidemiology Center-Durham (CSPEC-Durham) manages a repository that contains data and specimens from multiple IRB-approved studies. We aimed to increase efficiency of repository data management by eliminating repetitive and error-prone manual steps through a metadata-driven architecture for our data management lifecycle. Specifically, we built a common set of variable descriptors (metadata) across studies and used those descriptors to generate: 1) application code for data entry and validation, 2) data dictionaries, and 3) data extracts for sharing data with approved researchers. **Methods:** We created a SQL Server database comprised of metadata tables with descriptors for each variable, including variable name, survey question, value description, minimum and maximum possible values, and other metadata. We populated the tables with variables from each study. These tables were used to generate application code for data validation, data extracts, data dictionaries, and other documentation for specific studies. We retain data maintenance history logs, snapshots of data extracts, and a history of all source code to ensure data provenance. **Results:** The metadata tables enabled the rapid generation of high-quality applications capable of automated data validations, as well as the creation of data extracts to address specific research questions or requests. Using the same tables, we have the ability to automatically extract HTML and PDF data dictionaries for whole datasets and subsets for specific research projects. Indicators flag personally identifiable information (PII) and exclude this information from extracted datasets and corresponding dictionaries as needed. **Conclusions:** We demonstrated that metadata-driven concepts related to data management and creation of study documentation can be applied to many datasets. This process will result in similarly high quality products for future researchers. We intend to monitor the use of these tools and techniques to ensure continuous quality improvement in data and documentation integrity. **Impact Statements:** We created a foundation for the automated management of data throughout its lifecycle across all studies in our repository. These metadata methods have significantly reduced the potential for errors, eliminated repetitive data management steps, and fostered a robust and secure sharing environment to facilitate future data sharing and meta-analysis for genetic association.

**Improving SNP array copy-number variant calling using site-specific variance models and windowed intensity normalization.** *T. Poterba*<sup>1,2,3</sup>, *C. Seed*<sup>1,2,3</sup>, *J. Bloom*<sup>1,2,3</sup>, *D. Howrigan*<sup>1,2,3</sup>, *C. Churchhouse*<sup>1,2,3</sup>, *B. Neale*<sup>1,2,3</sup>. 1) Stanley Center for Psychiatric Research, Broad Institute of Harvard and MIT, Cambridge, MA; 2) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA; 3) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston 02114, MA, USA.

Both common SNPs and rare, large copy-number variants (CNVs) have been shown to harbor substantial risk for heritable diseases. However, the overall contribution of CNVs to disease risk is not well understood. Recent SNP array datasets with hundreds of thousands of individuals can offer insight into the prevalence and impact of small CNVs, but existing tools to call CNVs suffer from sensitivity to noise and fail to model common error modes well. As a result, unavoidable variance in sample quality has required strict sample curation and CNV-size thresholding, reducing power to detect smaller CNVs. In order to create high-quality call sets from large cohorts, we have developed a new hidden Markov model (HMM) for CNV calling on microarray data. Spurious CNV calls usually result from either low quality SNPs or low quality samples, so we have modeled both of these error modes explicitly. The model includes per-SNP variance terms to weight emission probabilities by site quality, which reduces the false positive rate while preserving power to detect real events. We also model sample quality to dynamically adjust global priors on call probabilities, dramatically cutting the false positive rate in low quality samples and rescuing real CNVs by permitting more inclusive sample filtering. Our model is implemented using Hail, an open-source framework for statistical genetics built on Apache Spark to easily scale to hundreds of thousands of samples. Using a cohort of 1800 trios and benchmarking sensitivity and specificity against the leading method in the field, PennCNV, we demonstrate comparable CNV transmission rates for large events and improved performance for small events. This improvement will enable us to examine the role of small CNV events in contributing to the genetic burden of disease.

**LUBA: A software toolbox for efficiently manipulating and analyzing NGS data.** *A. Ryutov*<sup>1</sup>, *M. Bootwalla*<sup>1</sup>, *A. Govindarajan*<sup>1</sup>, *J. Buckley*<sup>1,2</sup>, *D. Maglinte*<sup>1</sup>, *J. Ji*<sup>1,2</sup>, *X. Gai*<sup>1,2</sup>. 1) Center for Personalized Medicine, Department of Pathology & Laboratory Medicine, Children's Hospital Los Angeles, California, USA; 2) Keck School of Medicine, University of Southern California, California, USA.

The need for robust bioinformatics algorithms to efficiently process Next-Generation Sequencing (NGS) data continues to grow. Here we present LUBA (Lightweight Utility for Bioinformatics Analysis), a suite of command line tools for handling NGS data that include modules for phasing, coverage analysis, copy number variation (CNV) detection and calling somatic variants.

**Phasing:** a computational algorithm for resolving the phase of heterozygous variant pairs in a gene from Whole-Exome Sequencing (WES) data. The algorithm assembles and connects heterozygous variants within individual reads or read pairs into "heterozygosity islands". The phase of two heterozygous variants can be directly resolved if they fall into the same "island". If not, their phase may be potentially determined from linkage disequilibrium data. The phasing algorithm was tested with our trio-WES data. For variants within the same gene, phase can be determined for 33% of all heterozygous variant pairs with 94% accuracy from the proband only exome data. **Depth:** an algorithm for generating coverage statistics from a BAM file. It is 3-7 and 3-4 times faster than SAMtools and Sambamba, respectively. The algorithm utilizes either a minimum heap or a circular array to process alignments efficiently, and has a small memory footprint. As a result, it can process more than 100 WES BAM files in two hours on a LINUX workstation. **CNV:** an algorithm to detect CNVs from WES data. The algorithm builds a baseline coverage profile for a sequencing platform by normalizing a batch of samples prepared and sequenced the same way. An input sample coverage is then normalized; and an average per-exon coverage is compared to the reference baseline to make CNV calls using a p-value cutoff. The algorithm was tested with chromosomal microarray CNV calls, and performed very well. **VAR:** a tool to make somatic variant calls from cancer WES data with high sensitivity. Comparison of LUBA VAR with several publicly available somatic variant callers such as VarDict and MuTect2 has yielded favorable results. Similarly to other LUBA tools, VAR is memory-efficient, which is especially suitable for high sequencing depth needed for oncology samples. In addition, LUBA has various general-purpose tools built with the same framework, i.e., tools for variant filtering, concordance analysis, BAM/VCF/BED processing. Our custom suite of LUBA NGS tools has demonstrated great utility in both germline and somatic diagnostic tests.

**1373T****Hail: Scaling statistical genetics to tens of thousands of whole genomes.**

*C. Seed*<sup>1,2,3</sup>, *J. Bloom*<sup>1,2,3,4</sup>, *J. Goldstein*<sup>1,2,3</sup>, *D. King*<sup>1,2,3</sup>, *T. Poterba*<sup>1,2,3</sup>, *B. Neale*<sup>1,2,3</sup>.

1) Stanley Center for Psychiatric Research, Broad Institute of Harvard and MIT, Cambridge, MA; 2) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston 02114, MA, USA; 3) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA 02142, USA; 4) Department of Mathematics, Massachusetts Institute of Technology, Cambridge, MA 02139, USA.

Advances in high-throughput sequencing offer unprecedented power to discover the genetic basis of disease. However, the scale and complexity of the data are increasingly making even simple analyses cumbersome or intractable. To address this challenge, we developed Hail (<https://hail.is>), an open-source framework for statistical genetics that has been used to efficiently analyze tens of thousands of whole genomes and hundreds of thousands of exomes. Hail is a Python library that uses Apache Spark to provide scalability and fault-tolerance for genetic analyses. Consequently, analysts can run the same code on a laptop or large cluster without the need to manually chop up the data or manage job failures. Hail provides a flexible query language to express complex quality control and analysis pipelines with concise, readable code that reflects genetics concepts; as a result, code is less prone to error and easily shared. Hail imports data from the VCF, PLINK, and BGEN (including v1.2 of UK Biobank) formats and includes natively distributed algorithms for common variant association (linear / logistic / mixed regression, TDT, eQTL, ...), rare variant association (linear / logistic / exact burden tests, SKAT, ...), kinship, LD, principal components, and synthetic data generation. Hail has been the primary analysis platform for dozens of major studies at the Broad Institute, Oxford, Michigan, Sanger, Stanford, and UCSF. Daniel MacArthur's group used Hail to iteratively clean and analyze the gnomAD dataset of 15k whole genomes and 125k exomes in the week before ASHG 2016. Ben Neale's group used Hail to demonstrate that ultra-rare disruptive and damaging mutations influence educational attainment (Ganna et al., *Nat. Neuro.*, 2016). Sekar Katherisan's group used Hail to analyze 16k whole genomes and 40k exomes for lipid and MI phenotypes. In 10 minutes, the initial GWAS on 8125 TOPMed genomes derived the kinship matrix, fit a linear mixed model, and computed statistics for 25M variants, compared to 2 weeks in practice with other tools. They then used Hail for programmatic, iterative fine mapping to identify independent signals at the LPA locus. Hail also enables on-the-fly analyses for online portals and will soon power a new platform for rare disease genomics. As we prepare Hail's infrastructure for a million whole genomes with deep phenotypes, we welcome the scientific community to leverage this open-source project to develop and share new methods at scale.

**1374F****IMSindel: An accurate intermediate-size indel detection tool incorporating de novo assembly and gapped global-local alignment into split reads.**

*D. Shigemizu*<sup>1,2,3</sup>, *F. Miya*<sup>2,3</sup>, *S. Akiyama*<sup>1</sup>, *S. Okuda*<sup>4</sup>, *K.A. Boroevich*<sup>3</sup>, *A. Fujimoto*<sup>5</sup>, *H. Nakagawa*<sup>6</sup>, *T. Tsunoda*<sup>2,3</sup>.

1) Department for Medical Genome Sciences, Medical Genome Center, National Center for Geriatrics and Gerontology, Obu, Aichi, Japan; 2) Department of Medical Science Mathematics, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan; 3) Laboratory for Medical Science Mathematics, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; 4) Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; 5) Department of Drug Discovery Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 6) Laboratory for Genome Sequencing Analysis, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan.

Insertions and deletions (indels) have been implicated in dozens of human diseases through radically altered gene functions by short frameshift indels as well as long indels. However, the accurate detection of these indels from next-generation sequencing data is still challenging, particularly for intermediate-size indels ( $\geq 50$ bp), due to the short DNA sequencing reads. In this study, we developed a new method that predicts these intermediate-size indels using BWA soft-clipped fragments (unmatched fragments in partially mapped reads) and unmapped reads. We report a performance comparison of our method, GATK HaplotypeCaller and PINDEL, using whole exome sequencing data from the same DNA samples. False positive and false negative counts were determined through Sanger sequencing of all predicted indels across these three methods. The harmonic mean of the recall and precision, F-measure, was used to measure the performance of each method. Our method achieved the highest F-measure of 0.82 in one sample, compared to 0.53 for HaplotypeCaller and 0.59 for PINDEL. Similar results were obtained in the second sample, demonstrating that our method was superior to the other two methods for detecting intermediate-size indels. We believe that this methodology will contribute to the discovery for long indels associated with human diseases.

**ENCODE Portal: A cohesive collection of genomic assays towards discovery of functional elements.** *C.A. Sloan, B. Hitz, E. Chan, C. Davis, J.S. Strattan, J. Hilton, A. Narayanan, M.K. Onate, I. Gabdank, F. Tanaka, T. Dreszer, U. Baymuradov, K. Dalton, J.M. Cherry.* Genetics, Stanford University, Palo Alto, CA.

The Encyclopedia of DNA Elements (ENCODE) project is an international collaboration of research groups funded by the National Human Genome Research Institute (NHGRI). The goal of ENCODE is to build a comprehensive parts list of functional elements in the human genome, including elements that act at the protein and RNA levels, and regulatory elements that control cells and circumstances in which a gene is active. As the DCC (the data coordination center) it is our task to collect, curate and disseminate the results, methods and raw data for a variety of complex assays and analyses that have been performed toward that goal. To that end, we have created the ENCODE portal ([www.encodeproject.org](http://www.encodeproject.org)). At this site, scientists can search, visualize, and download both raw and processed data. They can delve into the details of the experiment including the antibody and biosample validation results, the protocols, the software code, and provenance of a file. And, finally we provide insight into the methods, pipelines and standards that the consortium has developed. In addition to the ENCODE funded data, at the portal we also have data from modENCODE, mouse-ENCODE, modERN, GGR (Genomics of Gene Regulation) and Roadmap Epigenomics Mapping Consortium (ROADMAP). For the core assays like ChIP-seq, RNA-seq, and Dnase-seq, we have worked with these other projects to harmonize methods and in some cases we have provided new processing to enable integrated analysis. With over 18,000 experiments released, this is a powerful resource for the exploration of genomic assays toward the discovery of functional elements.

**1376T**

**Cloud computing environment for hosting federated genomic databases.** *W. Souza<sup>1</sup>, B.S. Carvalho<sup>2</sup>, C. Rocha<sup>1</sup>, I. Lopes-Cendes<sup>1</sup>.* 1) Department of Medical Genetics, UNICAMP, Campinas, Brazil; 2) Department of Statistics, UNICAMP, Campinas, Brazil.

Federated databases consist in using local resources for hosting data instead of submitting to centralized services. This concept facilitates sharing genomic data with restricted access to sensitive information such as individuals' data, and avoids legal issues associated to data protection. However, hosting data locally leads to difficulties in data integration from different databases because each provider may implement its own non-standard interface for sharing genomic data. Also, research groups require specialized technical assistance for configuring complex and keeping secure local databases. The Global Alliance for Genomics and Health (GA4GH) was formed to help accelerate the potential of genomic medicine to advance human health. The GA4GH Data Working Group developed data model schemas and application program interfaces (API) for standardized genomics data exchange. Software containers such as Docker, facilitates deployment of multiple services across computers. It increases security of sensitive data by isolating software solutions into standalone and lightweight images. As part of the Brazilian Initiative on Precision Medicine (BIPMed) project, we developed a containerized computing environment composed by GA4GH-based data servers and software clients. Our cloud environment provides easy deployment of one or more GA4GH reference implementation servers for hosting genomic data, GA4GHshiny application for interactive access via user-friendly graphical web interface and Beacon servers. Using the popular Docker solutions, our cloud-based computing environment allows researches groups to easily and securely host their own genomic data using local computing resources or internet services. All Docker images and documentation are freely available at <https://github.com/labcbcb/federated-genomic-databases>.

**The ENCODE annotation pipeline: Repeatable software tools for ChIP-seq, RNA-seq, DNase-seq, and whole-genome bisulfite experiments.** *J.S. Strattan<sup>1</sup>, T.R. Dreszer<sup>1</sup>, B.C. Hitz<sup>1</sup>, U.K. Baymuradov<sup>1</sup>, E.T. Chan<sup>1</sup>, I. Gabdank<sup>1</sup>, J.A. Hilton<sup>1</sup>, O.A. Jolanki<sup>1</sup>, C.A. Sloan<sup>1</sup>, Z. Weng<sup>2</sup>, A. Kundaje<sup>1</sup>, J.M. Cherry<sup>1</sup>, ENCODE Data Coordinating Center.* 1) Stanford University School of Medicine, Department of Genetics, Stanford, CA; 2) University of Massachusetts Medical School, Program in Bioinformatics and Integrative Biology, Worcester, MA.

The ground-level annotations ENCODE applies to the epigenome and the transcriptome are produced by defined cloud-based computational pipelines that anyone can use. By standardizing the computational methodologies for analysis and quality control, results from multiple labs can be directly compared and integrated into higher-level annotations, such as ENCODE Candidate Regulatory Elements (CREs). The ENCODE Data Coordinating Center (DCC) have deployed the pipelines to a cloud-based computing environment so that the computational load can be distributed across scalable resources. Because the exact software pipelines the ENCODE DCC uses are available for anyone to run, researchers can produce analysis results and quality-control metrics from their own data that are directly comparable to ENCODE's annotations. Pipelines are available for the analysis of ChIP-seq, RNA-seq, DNase-seq, and whole-genome bisulfite experiments. The pipelines are open-source, easy to use, and require minimal pre-requisites. The ENCODE DCC codebase is at <https://github.com/ENCODE-DCC> ENCODE analyses are distributed through the ENCODE Portal at <https://www.encodeproject.org/> The pipelines are also available as "ENCODE Uniform Processing Pipelines" at <https://platform.dnanexus.com/projects/featured> .

**Quantitative assessment of the feasibility of using whole-genome sequencing data at common single nucleotide polymorphism positions to reproduce high-confidence genotype calling and copy number variation detection results from SNP microarray data.** *N.S. Ten, B. Pusey, K. Chao, D. Adams, W. Gahl.* NIH Undiagnosed Diseases Program, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

The NIH Undiagnosed Diseases Program (UDP) was established in 2008 with the goal of conducting research for patients whose significant illnesses remain undiagnosed despite extensive medical workups. A specific focus of the UDP bioinformatics is the re-analysis of previously inconclusive clinical genetic studies with specialized exome, genome, and single nucleotide polymorphism (SNP) microarray sequencing analyses. SNP microarrays are utilized extensively by the UDP. Uses include recombination mapping, reconstructing missing parent genotypes from sets of siblings, and detecting copy number variations, regions of homozygosity, uniparental disomies, and mosaicisms. SNP microarrays are frequently used for quality control of next-generation sequencing (NGS) data because whole-genome sequencing should theoretically genotype the same SNPs selected in a SNP microarray. Standard commercial SNP microarrays employ redundant sampling of every SNP across multiple sites on a chip, and the fluorescence dynamic range produces high-confidence genotype calls for copy number quantitation from zero to four. For NGS data, results can have disparate coverage depths because of allele skew and high PCR amplification in library preparation for cluster generation, making copy number genotype calling difficult for exome data but within reach for low-PCR whole-genome sequencing. We tested the genotyping sensitivity of whole-genome sequencing at positions genotyped in SNP microarrays. Our comparison of SNP microarray and whole-genome sequencing-derived genotypes at over 940,000 SNPs in the Illumina OmniExpress SNP microarray suggests complete genotyping matching at 99.6% of these common positions. For discrepant or missing genotypes in SNP microarray data, we looked at differences in recombination mapping calls in nuclear family pedigrees with multiple siblings and found only minor differences. In the future, we plan to perform additional work conducting similar comparisons with other microarray-based analyses that require even more quantitation of alleles in NGS genotype calling. Concerning integer analyses of genotype calling and copy number variation, current whole-genome sequencing in the UDP appears to achieve the same quality and reliability for these specific results as that seen in SNP microarray analysis.

**1379T****GA4GH Genomic Beacon Network: Security challenges and mitigation.**

S. Ur-Rehman<sup>1</sup>, J.D Spalding<sup>1</sup>, S. Scollen<sup>2</sup>, J. Rambla Di Argila<sup>2</sup>, I. Lappalainen<sup>3</sup>, ELIXIR-SE, ELIXIR-BE, ELIXIR-FR, ELIXIR-NL, GA4GH Software Security, GA4GH Beacon Project. 1) European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Wellcome Trust Genome Campus, Hinxton, Cambridge, CB10 1SD; 2) Centre for Genomic Regulation (CRG), Dr. Aiguader 88, Barcelona 08003, Spain and Universitat Pompeu Fabra (UPF), Barcelona, Spain; 3) CSC IT Center for Science, Life Science Center Keilaniemi, Keilaranta 14, Espoo, Finland; 4) ELIXIR Hub, Wellcome Trust Genome Campus, Hinxton, Cambridge, CB10 1SD.

As the number of human genomes sequenced increases, there is a need for researchers to contextualise the genetic variation discovered against the efforts of all previously sequenced individuals to facilitate genotype to disease phenotype discoveries. The Global Alliance for Genomics and Health (GA4GH) Beacon Project in partnership with ELIXIR has created an open sharing platform for human genetic data to be discoverable. Beacons are a service that return a yes/no response when queried about the presence of a particular allele in a given chromosomal location. This allows a researcher to determine if a particular allele has been seen within a particular dataset as a precursor to applying for access to the complete dataset while respecting the privacy of the individual. Beacons can implement a tiered access model, public (anonymous user), registered (known user), and controlled. It has been shown that it is possible to re-identify an individual (determine if a particular individual's genome exists in a beacon) if the individual's genome is known a priori. In essence this involves querying multiple alleles from an individual's genome ranked in order of increasing allele frequency. Three mitigation techniques have been developed to prevent re-identification via Beacon but are only applicable to single Beacons. In order to maximise the utility of Beacons, a network of Beacons has been developed that allows search over all multiple Beacons from a single query. There are currently over 60 Beacons that include more than 200 global datasets, including 7 ELIXIR Beacons (Finland, Switzerland, Belgium, Spain, Netherlands, Sweden and EMBL-EBI - the beacon hosted at the European Genome-phenome Archive). As current mitigation techniques against re-identification only work on individual beacons, we present methods to extend the current method preventing re-identification to a Beacon network. These include the implementation of a registry, the communication of the individual(s) who are at risk of re-identification, and the mitigation techniques which are currently being deployed. We also make use of the ELIXIR AAI to track the source of queries for registered level queries. By reducing the possibility of re-identification with both individual and networked Beacons, we aim to attract more stakeholders with sensitive datasets to the Beacon Network. We are also working to improve the 'hand-off' between a positive Beacon response and other GA4GH access and data delivery services.

**1380F****UDPICS, a laboratory-medical informatics system for improving translational research in the NIH Undiagnosed Diseases Program.** Z.M. Valivulah, S. Sadozai, G. Yu, D. Draper, D. Mosbrook-Davis, D.R. Adams, W.A. Gahl. Undiagnosed Diseases Program, NHGRI, Bethesda, MD.

The Undiagnosed Diseases Program (UDP) is a translational medicine initiative based in the NIH Clinical Center which aims to diagnose patients with mysterious conditions and study unique and rare genetic disorders. The program has received over 10,000 inquiries, reviewed 3,500 applications, and seen almost 900 patients. Patient presentation is heterogeneous and our evaluation process initially treats each patient as independent. Therefore, managing patient and research data became increasingly difficult after the first years of the UDP. To allow clinicians and researchers to seamlessly collaborate on UDP cases, we built a web-based workflow management system called the Undiagnosed Diseases Program Integrated Collaboration System (UDPICS). The system is based on a commercial Ruby on Rails platform, which we expanded and customized for translational research. UDPICS integrates external biobanking, model organism, and genome analysis systems for easy access. Furthermore, we incorporated the open source tools PhenoTips for ontological patient phenotyping and Phenogrid for phenotype-genotype comparisons in humans and model organisms. UDPICS has allowed us to track patients and associated research from application to followup. Benefits of the system include rapid transit of records and tasks, reduced error in workflows, and ease of collaboration. By implementing complex process management, genomic analysis, biospecimen management, ontological phenotyping, and electronic laboratory notebooks, UDPICS has become a scalable collaborative workspace for research, clinical, and bioinformatics staff. The system is a mechanism for efficient, transparent, and scalable translational research and addresses many of the scientific and logistical problems of the NIH UDP.

**1381W****Improving clinical exome interpretation using lab internal cohort data.**

C. Wu<sup>1</sup>, S. Baker<sup>1</sup>, K. Cao<sup>1</sup>, B. Krock<sup>1,2</sup>, M. Sarmady<sup>1,2</sup>. 1) Division of Genomic Diagnostics, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Pathology & Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Workflow complexity and high-throughput nature of NGS is prone to producing false positive variants. Many of such artifacts are in low complexity regions of the genome, or specific to the sequencer, instruments, bench and bioinformatics processes used to yield the data. Clinical variant classification is a labor-intensive step and the presence of artifacts adds hands-on time. A common approach to reduce variants to be manually analyzed is to remove variants that are present at a high frequency in a cohort of internally sequenced and processed samples, the 'internal cohort'. This approach would remove common variants in lab-specific patient population as well as recurring technical artifacts. Here we present the essential role of using internal cohort data to remove false positive and common variants as well as challenges involved in effective removal of artifacts. In this study, VCF files from 665 unaffected and unrelated clinical exome sequencing samples at the Children's Hospital of Philadelphia were compiled to build the cohort. The individual vcf files were parental samples generated as part of the familial exome bioinformatics pipeline. The individual variant call sets were then combined into a single vcf file using *GATK* package. Subsequently, population (cohort) allele frequency (CHOP\_AF) of each variant in the cohort was calculated based on the genotypes. This design enables addition of new samples without the need to recall variants on the entire cohort. To annotate patient's variants against with CHOP\_AF, a python package was developed. The process compares all patient's variants to the variants in the cohort by matching chromosome, position, reference, and alternate alleles to determine whether to retain or filter out the variant using the pre-defined cut-off (i.e. 1%). On average, 41,927 raw variants across 11 clinical samples of different batches were observed in our validation samples. After internal cohort filtration of the variants, only 3,231 variants were retained on average, indicating that over 90% of the raw variants were removed from further analysis due to being too common or artifacts. We presented an efficient method to build internal cohort using unaffected samples in a clinical lab, as well as a bioinformatics strategy to filter any variant sets against the cohort. The overall approach is effective in detecting artifacts and common variants, removing over 90% of the raw variants and therefore improves the efficiency of the clinical tests.

**1382T****Integrated breakpoint analysis and structural variation detection using sequencing reads from multiple sequencing technologies for an Ashkenazi trio.** C. Xiao, S. Sherry. NIH/NLM/NCBI, Bethesda, MD.

Structural variations (SVs) play important roles in human genome organization and contribute to phenotypic diversity of human populations and diseases. Recent advancement of next generation sequencing (NGS) technologies has greatly facilitated the analysis of genomics structural variants. However, accurately detecting such structural variations with correct sizes and precise breakpoints remains a challenge. Existing structural variant detection methods mostly depend on reference-specific alignment tools or *de novo* assemblies that require intricate platform-specific workflows and significant amount of computation and storage resources. Here we introduce a novel structural variation discovery method, BreakScan, which does not rely on pre-aligned tools or pre-constructed assemblies. Instead, BreakScan models insertion and deletion events in reference sequence with breakpoint junctions observed in NGS reads, then subsequently compiles evidence for those junctions from the sequencing reads generated by multiple platforms such as Illumina, 10X Genomics, and Pacific Bioscience. The predicted structural variants are generated from event models and ranked by their supporting evidence. We have applied this method to the son of the Ashkenazi trio from Genome-in-a-Bottle (GIAB) project (<ftp://ftp-trace.ncbi.nlm.nih.gov/giab/ftp/data/AshkenazimTrio>) and delivered a callset to the GIAB consortium (<ftp://ftp-trace.ncbi.nlm.nih.gov/giab/ftp/data/AshkenazimTrio/analysis/>). Comparative analysis with other structural variant callsets has also been performed and will be discussed.

**1383F****Exploiting the co-localization of trait-associated SNPs and eQTLs to identify potential biological mechanisms underlying complex diseases.**

T. Xu, Z. Qin. Emory University, Atlanta, GA.

Genome-wide association studies (GWASs) have successfully identified a large number of disease-associated variants. However, the majority of these identified variants is non-coding, which makes functional interpretation extremely challenging. Instead of directly affecting the protein, it is likely that these variants affect the phenotype through transcription regulation. Since expression quantitative trait loci (eQTL) provide direct evidence on how genetic mutations affect gene expression, eQTL has long been recognized as an important resource for functional annotation of noncoding variants. In the present study, we proposed a novel strategy to utilize the rich eQTL information that has been accumulating in the public domain to annotate GWAS findings. To be specific, for a specific disease, we investigate whether eQTLs associated with a particular pathway are enriched around loci that harboring GWAS-identified variants. We first convert a set of GWAS variants into a set of genes through eQTL, then we conduct test similar to the gene set enrichment analysis to see if any pathway is overrepresented by the list of genes. Our method enjoys two key advantages over existing methods: first, we no longer need proximity to link a variant to a gene which has shown to be unreliable; second, eQTL allows us to identify the tissue type in which the dysregulation likely to affect the disease phenotype the most. We have implemented our strategy into an easy-to-use R package that performs functional enrichment analysis by associating non-coding genomic regions to the co-localized eQTLs. We applied our method to eQTL collections from the Genotype-Tissue Expression (GTEx) project and pathway collections from MSigDB. Using disease-related genomic regions as query, our method successfully identifies highly-relevant biological pathways for immune-related diseases and age-related neurological diseases. Tissue specificity analysis of associated eQTLs provide additional evidence of the distinct roles of different tissues in the disease mechanisms. Our tool is flexible to be applied to customized eQTL sets and pathways.

**1384W****ALEC: Amplicon Long-read Error Correction for targeted long-read**

**sequencing.** Y. Yang<sup>1,2,3</sup>, W. Qiao<sup>1,3</sup>, M. Delio<sup>3</sup>, L. Edelman<sup>1,3</sup>, S.A. Scott<sup>1,3</sup>. 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY 10029; 2) Icahn Institute for Genomics and Multi-scale Biology, Icahn School of Medicine at Mount Sinai, New York, NY 10029; 3) Sema4, a Mount Sinai venture, Stamford, CT 06902.

Long-read sequencing platforms [i.e., Pacific Biosciences (Pacbio) and Oxford Nanopore] have average read lengths of ~10-15 kb, which can be useful for interrogating structural variation, *de novo* genome assembly, variant phasing, and sequencing challenging gene regions with homologous pseudogenes. However, their single-pass error rates (~10-20%) are significantly higher than short-read error rates, particularly for insertion/deletion (indel) artifacts. Although the accuracy of PacBio single molecule real-time (SMRT) sequencing is improved by using multiple-pass circular consensus sequencing (CCS) reads, performance and output depth are limited by library length and number of passes. As such, error correction tools are typically necessary for analysis of single-pass long-read data. A common long-read sequencing correction strategy employs a hybrid assembly with high depth short-reads to identify and correct long-read errors. However, given that this strategy results in increased sequencing costs and cannot adequately interrogate non-unique regions, we developed Amplicon Long-read Error Correction (ALEC) as an informatics correction tool for targeted long-read sequencing analysis. ALEC identifies sequencing errors from SAM/BAM files generated by BWA-MEM by calculating per base substitution and indel allele frequencies, and subsequently corrects alleles below predefined or customized thresholds to their consensus nucleotide at each targeted base. Additionally, ALEC implements a linear formula to determine homopolymer allele frequency thresholds, as a linear correlation between homopolymer length and deletion error frequencies was detected in both Pacbio and Oxford Nanopore data. ALEC performance was tested on long-read amplicon data from the *CYP2D6* (~5 kb), and *RYR2* (~9.2 kb) genes derived from the PacBio RS II platform, as well as *CYP2D6* (~5 kb) amplicon data derived from the Oxford Nanopore MinION platform. Importantly, application of ALEC to PacBio data improved subread substitution errors from 1.5% to 0.05% and indel errors from 10.6% to 0.05%, and application of ALEC to Oxford Nanopore data improved substitution errors from 4.2% to 0.05% and indel errors from 20.8% to 1.4%. These data indicate that ALEC is a useful correction tool that can improve long-read sequencing accuracy, which subsequently can facilitate the incorporation of the widely used BWA-GATK pipelines for these third-generation sequencing platforms.

**An alignment-based method to trim adapter and filtrate low-quality reads from pair-end FASTQ files.** *R. Ye, P.C. Sham.* Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong.

As next generation pair-end sequencing is widely used around the world, cleaning up of raw FASTQ data is much more important than we thought before. Here we present FASTQ cleaning program (fqclean), a novel and efficient alignment-based method that trims adapter and filtrates low-quality reads from pair-end FASTQ files. Compared with previous published tools, "fqclean" does not need adapter sequence as an input parameter and has the ability to trim even 1bp-length adapter contamination. Accurate trimming and filtrating of raw data can improve sensitivity and specificity of downstream variation detection, especially single nucleotide variation, virus integration and structural variation. During trimming and filtrating, "fqclean" can also fetch barcodes which attached to 5'-end of reads and split big FASTQ files to small pieces to accelerate alignment based on Map-Reduce method.

**1386F**

**A statistical framework for longitudinal genomic data integration.** *Y. Zhang<sup>1</sup>, Z. Ouyang<sup>2</sup>.* 1) University of Connecticut, Storrs, CT; 2) The Jackson Laboratory for Genomic Medicine, Farmington, CT.

Recent advances in genomic medicine resulted in accumulated longitudinal genomic data, where patients were monitored over time, their biological samples were collected at multiple time points, and the corresponding molecular profiles were measured through high-throughput assays. Longitudinal high-dimensional datasets from genomic and biomedical research may have complicated correlation structures or irregular covariance structures. Consequently, such characteristics raise challenges on dimension reduction and feature selection of longitudinal genomic data. We present a new statistical method to integrate multiple sources of information for better knowledge discovery in diverse dynamic biological processes. We demonstrate the utility of our method through simulations and applications to gene expression data of the mammalian cell cycle and longitudinal transcriptional profiling data in response to influenza viral infections.

**SOAPgaea: A Hadoop/Spark based computing framework for bioinformatics in big data.** Y. Zhang, S. Li, Z. Huang, W. Hu, Y. Li, W. Chen, X. Liu, L. Fang. BGI-Shenzhen, Shenzhen 518083, Guangdong, China.

Big data is a new normal for bioinformatics in properties of volume, variety and velocity. And three computing issues are most concerned: 1) rapidly analyze the individual sample data, 2) analyze each sample of a large dataset in a resource efficient way, 3) enable the analysis of large scale samples together in one model like population variant calling. Multiple solutions came out, including hardware accelerator and cloud computing technology. And the big data technology, built on Apache Hadoop as the core, is also gradually adopted in bioinformatics. But a sophisticated solution for all the three computing issues is never really achieved. SOAPgaea, which started at 2011 to support the big data computing at BGI, utilized the Hadoop/Spark as the core technology to solve these problems. SOAPgaea is mainly developed using Java 1.8 with C/C++ involved. New unstructured file storage (HDFS) and structured table storage (HBase, etc.) have been utilized in SOAPgaea to accelerate the data access process. Hadoop MapReduce API and Spark API were adopted for parallel processing of multiple NGS data analysis functions, including pair-end reads aggregation, window based aggregation, duplicate reads aggregation. Based on the fundamental work, SOAPgaea implements one-stop solution for NGS data analysis including variant calling and annotation and variant frequency computation. Meanwhile, SOAPgaea optimized the parallel strategy to enable the multi-sample running mode to reduce the runtime cause by the task scheduling and load unbalance. SOAPgaea completed the variant calling pipeline and annotation in 2 hours for a 30X WGS sample, from GIAB NA12878 dataset and usually takes more than 2 days, on 16 nodes (24 cores in 2\*Intel Xeon E5645, 128G memory and 12\*4T disk for each node) of Hadoop clusters at BGI, with sensitivities of 99.68% and 95.26% for germline SNVs and indels. Moreover, we applied SOAPgaea to 100 WES samples with 834GB gzip compressed FASTQ file from 1000 genomes project in the modes of 1/run, 10/run, 20/run, 50/run and 100/run. And it takes 50, 18, 17, 14 and 11 hours, respectively, nearly 5 times faster than single sample mode. Furthermore, we applied SOAPgaea in the joint variant calling of 1000 WES CRAM files from 1000 genomes project of phase 3, which reached a data size of 3.2 TB data in total. And SOAPgaea finished in less than 12 hours on the same cluster in one job, instead of traditional way which takes days to split and compute the data manually.

**1388T**

**Gene set comparison analysis using both first and second moment information.** L. Zhang, W. Tang, HW. Deng. Tulane University, New Orleans, LA.

**Background:** Gene set analysis (GSA) aims to determine whether a priori defined gene set, in which the genes share some common biological function, is correlated with a particular phenotype. Numerous GSA methods have been proposed to explore how the gene regulatory network differs between two or more disease status. However, most methods are developed with respect to a particular scenario, either focusing on differential mean patterns or differential co-expression patterns. Here, we present a novel method that can capture both mean and variance-covariance information regarding the association between gene sets and phenotypes of interest. **Result:** Our method tests the null hypothesis that for a pre-defined gene set, there is no difference in both first and second moment information of the genes between case and control groups. We compared the type I error and power of our method with two existing prevailing GSA methods through simulation studies. We found that our method can control the type I error rate at the pre-specified significant level, and it has an improved power to detect gene sets in various situations, especially when difference in both mean and variance-covariance features between case and control group is large. **Conclusions** In summary, we proposed a new gene set comparison test that could detect significant changes in both mean and variance-covariance patterns between two different biological conditions. Since our approach is able to capture more information regarding the association between gene sets and relevant phenotypes, it may help to find broader gene regulatory networks or biological pathways essential for disease development and progression.

**1389F**

**A new diagnostic platform (Genomic Intelligence®) improves accuracy of whole exome and genome sequencing diagnosis in rare disease.** A. Fisher, Y. Rachmany, H. Neerman, N. Meeks. Variantyx Inc., Framingham, MA.

**Background:** Whole exome (WES) and genome sequencing (WGS) is becoming the standard of care for diagnosis of rare disease. Reports show a diagnostic yield of approximately 25-40 percent in published cases. This leaves a majority of cases undiagnosed even after testing and analysis. The lack of diagnosis may be multifactorial including variants not detected due to lack coverage, synonymous, intronic or intergenic variants for which there is no known interpretive data or variants missed due to a lengthy and cumbersome curation process. **Methods:** A new diagnostic platform (Genomic Intelligence®) has been developed to improve accuracy and timeliness of diagnosis for those variants that may be missed due to the cumbersome curation process. Using FASTQ data, this web-based platform allows curation of each variant at the variant, gene and protein level. It collates information from common mutation databases (HGMD, ClinVar, OMIM) as well as incorporates in silico prediction programs and publicly-available allele frequencies to allow efficient and accurate curation of variants. Previously-undiagnosed cases of whole exome and whole genome sequencing were re-processed using this diagnostic platform. This included singletons as well as trio cases. Each case was reviewed and variant curation was performed by an ABMGG-certified Geneticist. The results were discussed individually by phone with the ordering clinicians to confirm a plausible diagnosis. **Results:** 55 previously-undiagnosed whole exome and whole genome cases were re-processed with a new possible or confirmed diagnostic rate of 55 percent. In trios the rate was 22/36 (61 Percent). In single patients, the rate was 8/18 (44 percent). In WGS, the rate was 5/7 (75 percent). In WES, the rate was 25/48 (52 percent). **Conclusions:** Genomic Intelligence allows for improved diagnosis of whole exome and genome sequencing as it automates a cumbersome, error-prone and time-consuming process. These results are particularly significant in that these cases were previously-undiagnosed and yet in more than half of cases, the platform discovered a diagnosis. It also demonstrates the importance of re-processing of previously un-diagnosed cases. This tool allows geneticists to focus their time and expertise on variant curation and literature review instead of information gathering. This increases the yield of genetic diagnosis allowing for better patient care.

**Uncovering the genetic architecture of complex traits: A Kalman filter approach.** D. Palmer<sup>1,2</sup>, B. Neale<sup>1,2</sup>, N. Patterson<sup>2,3,4</sup>.

1) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Richard B. Simches Research Center, 185 Cambridge Street, CPZN-6818, Boston, MA 02114; 2) Stanley Center, Broad Institute, 75 Ames Street, Cambridge, MA 02142; 3) Department of Genetics, Harvard Medical School 77 Avenue Louis Pasteur, New Research Building, Boston, MA 02115; 4) Radcliffe Institute for Advanced Study, Harvard University, 10 Garden Street, Cambridge, MA 02138.

Methodological approaches have been invaluable in increasing our knowledge of the genetic contribution to complex traits. Approaches using GWAS summary statistics are particularly useful, as such data are readily available from across a raft of diseases and traits. An example of such an approach is LDscore regression [1], which has been wildly successful. The method hinges on an elegant relationship between marginal effect sizes and the smeared tagging effects of LD in that population. Extensions to the method are already highly cited in the literature (give an number here). These include examinations of the correlation between genetic architectures as well as partitioning the genome to determine the relative contribution of constituent parts to variance in phenotype [2-3]. Despite these existing extensions, in general it is not obvious how to extend LDscore to more complex models relating genetics to phenotype. We present a complementary approach, which, in the first instance, is based on Fisher's infinitesimal model. Our method has the added benefit of being readily extendable to more complex underlying models of the impact of genetics on phenotype, and naturally allows for the incorporation of priors in a well-studied statistical framework. By exploiting the approximately banded nature of LD, we can construct a Kalman filter in which true effect sizes are the hidden states. Such an approach can be used to estimate heritability, as well as the underlying true effect sizes under the model. These estimates, which account for the correlation structure imposed by LD, have a natural application in generating polygenic risk scores which may explain a greater proportion of phenotypic variation when applied across human populations. [1] Bulik-Sullivan *et al.*, 2015. LD score regression distinguishes confounding from polygenicity in genome-wide association studies. [2] Bulik-Sullivan *et al.*, 2015. An atlas of genetic correlations across human diseases and traits. [3] Finucane *et al.*, 2015. Partitioning heritability by functional annotation using genome-wide association summary statistics.

**1391T****Organize and share your bioinformatics analysis with the R package**

**workflow.** *J.D. Blischak<sup>1</sup>, P. Carbonetto<sup>1,2</sup>, M. Stephens<sup>1,3</sup>.* 1) Department of Human Genetics, University of Chicago, Chicago, IL; 2) Research Computing Center, University of Chicago, Chicago, IL; 3) Department of Statistics, University of Chicago, Chicago, IL.

With rapid advances in sequencing technologies, a geneticist can quickly amass large amounts of complex data. Analyzing massive data sets requires organization and planning, which is especially challenging when juggling multiple projects at once. For example, it can be difficult to recall which version of the data or code was used to produce a particular figure. This is the motivation for our R package, *workflow*: managing and organizing research projects is a complex task, and practitioners need all the help they can get. *workflow* improves management of computational projects by suggesting a “workflow” designed to promote best practices for data management and code development. We chose R because it is a popular programming language for data analysis in science and particularly Human Genetics. Any researcher that is familiar with R can instantly start using *workflow*. *workflow* includes four key features to promote effective project management: (1) *workflow* automatically creates subdirectories to separate data, code, and results files; (2) *workflow* uses the revolutionary version control system Git to track the code as each individual analysis is completed without the user needing to understand the complexities of Git; (3) to support reproducibility, *workflow* provides a custom R Markdown template that combines the code, figures, and explanatory text into a single HTML file per analysis and also automatically displays the version of the code that produced the results and; (4) *workflow* provides instructions for transferring the HTML files online to facilitate sharing with labmates and colleagues. As a proof of concept, we previously used this framework to manage a large project investigating the technical sources of variation in single-cell RNA-sequencing data, and the results of this project can be viewed at <https://jdblischak.github.io/singleCellSeq/analysis/>. Our goal is that any scientist using *workflow* will find it easier to write well-documented, reproducible code. Documentation and source code for *workflow* are available at <https://github.com/jdblischak/workflow>.

**1392F****TeraPCA: A fast and scalable method to study genetic variation in tera-scale genotypes.**

*A. Bose<sup>1</sup>, V. Kalantzis<sup>2</sup>, E. Kontopoulou<sup>1</sup>, M. Elkady<sup>1</sup>, P. Paschou<sup>3</sup>, P. Drineas<sup>1</sup>.* 1) Department of Computer Science, Purdue University, West Lafayette, IN; 2) Department of Computer Science and Engineering, University of Minnesota, Minneapolis, MN; 3) Department of Biological Sciences, Purdue University, West Lafayette, IN.

One of the significant challenges in population genetics is the growing size of terabytes of data with close to one million genotyped humans. Principal Component Analysis (PCA) serves as a key tool in capturing population stratification, as it maps the genetic variation inferred from SNPs. However, a key limitation of PCA is its scalability and computational complexity when applied on tera-scale data, e.g. about one million individuals at one million SNPs. To address this issue, we propose TeraPCA, ie. we compute the top Principal Components (PCs) of tera-scale matrices using a method known as Randomized Singular Value Decomposition (RandSVD). After computing the mean-centered matrix, we invoke RandSVD to approximate, under a user-specified accuracy, the dominant PCs. Our implementation is based on multithreaded libraries such as LAPACK, BLAS and MKL, and it can handle datasets which might exceed the amount of available system memory by performing out-of-core computations. We ran our algorithm on publicly available data sets such as the Human Genome Diversity Panel (HGDP), which we replicated to create data sets containing two thousand individuals and 1.4 million SNPs. Our implementation of TeraPCA outperforms state-of-the-art methods such as EIGENSOFT's *smartpca*, while producing similar qualitative results when ran on the same computing system. As a brief illustration, *smartpca* required 61.2 mins to compute the top 10 PCs exploiting 20 threads, whereas TeraPCA required 14.7 mins and 11.5 mins exploiting 1 and 20 threads, respectively. TeraPCA was also faster than *smartpca*'s fastmode which converged in 15.6 mins. We also applied TeraPCA on simulated genotyped data, generated by the Pritchard-Stephens-Donnelly (PSD) model for ten thousand individuals and ten million SNPs, leading to tera-size data sets and tera-sample-size scales. TeraPCA is an implementation which targets the handling of tera-scale data while combining the accurate capturing of genetic variation of the samples with a low computational overhead, and with the ability to take advantage of current multiprocessor architectures by being implemented on top of established multithreaded linear algebra routines.

**1393W**

**Performance optimization of a genomic variant store for genotype-phenotype correlation in PhenoTips software.** P. Buczkowicz<sup>1</sup>, S. Mastromatteo<sup>2</sup>, T. Nguyen<sup>1</sup>, S. Stanisor<sup>1</sup>, D. Gross<sup>1</sup>, M. Brudno<sup>1,2</sup>. 1) Gene42 Inc., Toronto, Canada; 2) Department of Computer Science, University of Toronto, Toronto, Canada.

Whole-genome and whole-exome sequencing have increased the discovery of the genetic basis for thousands of Mendelian phenotypes, thereby establishing a causal link between genotypes and phenotypes. However, even with the influx of big datasets from genome-wide sequencing efforts, approximately half of Mendelian phenotypes still have no known underlying genetic partner. This represents a large gap in the knowledge of genotype-phenotype correlation and has a significant impact on the diagnostic odysseys in medical genetics and rare disease research. A Variant Call Format (VCF) file is a standard file type used to store human genomic data and contains a list of DNA positions or segments that differ from a reference sequence. However, a VCF file for a single individual could be larger than 1 gigabyte and as a result performing queries on data from any non-trivially sized population introduces significant computational challenges. Here, we introduce a comprehensive genomic variant store compatible with open source PhenoTips software for the enhanced storage and querying of genomic data from VCF files, and capable of advanced genotype-phenotype correlation mapping. In order to interact with VCF data in real-time, it is necessary to design an effective system to store and quickly retrieve large amounts of variant data. We created a set of benchmark tests to empirically compare the performance of different data storage and processing paradigms with respect to VCF data. The storage architectures were compared based on compression ratio, query latency, and upload time in addition to the scalability across all these dimensions. We considered a variety of different open-source tools including an indexed search engine, a distributed processing system, columnar and document databases. Using the results of the benchmark tests, we chose the best performing architecture to construct a PhenoTips-integrable variant store. We show that this tool can help in providing additional insight into the study design and analytical strategies for big data storage and analysis associated with genome-wide sequencing and genotype-phenotype correlation.

**1394T**

**From quantity to quality: A population-based approach for building reference panel imputation.** M. Cocca<sup>1</sup>, D. Toniolo<sup>2</sup>, P. Gasparini<sup>1,4</sup>, M. Mezzavilla<sup>1,2</sup>. 1) Medical Genetics, Institute for maternal and child health IRCCS "Burlo Garofolo", Trieste, Italy; 2) Division of Experimental Genetics, Sidra Medical and Research Center, Doha, Qatar; 3) San Raffaele Scientific Institute, Division of Genetics and Cell biology, Genetics of common disorders Unit, Milan, Italy; 4) Department of Medical, Surgical and Health Sciences, University of Trieste, Trieste, Italy.

Imputation is widely used to infer genotypes in a target population using a denser scaffold of known haplotypes (Reference Panel) and has been useful to improve the results of genome-wide association studies (GWAS). The use of a custom reference panel, containing genomes from the target population, can improve imputation quality in particular in the low and rare frequency spectrum. However, this blind approach can lead to a costly procedure in terms of time and resources, since the tendency is to build bigger reference panels to increase the variation captured. Our aim is to provide a population-based approach which rely on genetic distance (Fst) between reference and target population, to create a reference panel based on specific characteristic of the population included. We generated 4 different panels subsampling the main 1000G Phase 3 reference. Our target population is composed by 1785 individuals from Val Borbera in North Italy. The study genotypes were phased using the SHAPEIT2 software and imputation was performed using the IMPUTE2 software. We compared two IMPUTE2 statistics across the 4 panels: concordance between imputed and real genotype (r<sup>2</sup>) and info score. The panels contain from 398 to 408 samples, but have different mean Fst from the target population. One panel is composed by African populations, one only East Asian, one only European and one composed by two European populations one African and one East Asian (admixed panel). Our results show that the panel with highest r<sup>2</sup> for variants with MAF<2% has an Fst mean of 0.005 and is the one composed by only Europeans. This panel is also the one with the highest percentage of rare variants with info score >0.4 (a common threshold to select high quality variants for GWAS studies). Moreover, the panel with lowest mean Fst to the target has 68% of rare variant that could be used in GWAS studies, in opposition to the panel with only Africans, which has Fst of 0.14 and only 44% of the imputed rare variants are informative enough for GWAS. The East Asian panel with Fst of 0.1 has the 48% of rare variants with info score >0.4 and the admixed panel with Fst of 0.05 has the 62% of the variants exploitable for GWAS analyses. Our results demonstrate also that building a population specific reference panel could be a good choice in terms of resources and time needed for the imputation process, and the inclusion of population with extreme values of Fst in a reference panel does not improve the overall imputation.

**1395F**

**A framework for using protein structure specific features to elucidate ambiguous non-synonymous single nucleotide variants.** *J.B. Jespersen<sup>1,2,3</sup>, K. Davidsen<sup>2,3</sup>, K. Lage<sup>1,2</sup>*. 1) Department of Surgery, Massachusetts General Hospital, Boston, MA, USA; 2) Medical and Population Genetics, Broad Institute, Cambridge, MA, USA; 3) Department of Bioinformatics, Technical University of Denmark, Lyngby, Denmark.

When assessing genetic variants, some end up without interpretation due to ambiguity, and get marked 'Variant of Uncertain Significance' (VUS). This method particularly aims to elucidate missense mutations, which otherwise, would not be interpreted. The importance of single amino acids based on their known experimental structure, and a variety of features, both extracted from PDB as well as calculated from the protein structures. Genomic coordinates are in a robust and protein isoform specific manner, mapped to single amino acids in PDB files. Hence, the method is limited to only being able to inform on variants that has an experimentally solved protein structure, which passes a quality threshold. All data has been pre-calculated, and will be accessed when an inquiry is made on particular variant. The input format can be a VCF-file and will be returned as enriched with information on all variants that has protein structural information available.

**1396W**

**Genoppi: A web application for interactive integration of experimental proteomics results with genetic datasets.** *A. Kim<sup>1,2</sup>, E. Malolepsza<sup>1,2</sup>, J. Lim<sup>1,3</sup>, K. Lage<sup>1,2</sup>*. 1) Broad Institute of MIT and Harvard, Cambridge, MA; 2) Massachusetts General Hospital, Department of Surgery, Boston, MA; 3) Massachusetts Institute of Technology, Cambridge, MA.

Integrating protein-protein interaction experiments and genetic datasets can lead to new insight into the cellular processes implicated in diseases, but this integration is technically challenging. Here, we present Genoppi, a web application that integrates quantitative interaction proteomics data and results from genome-wide association studies or exome sequencing projects, to highlight biological relationships that might otherwise be difficult to discern. Written in R, Python and Bash script, Genoppi is an open source, user-friendly framework easily deployed across Mac OS and Linux distributions and freely available at <https://github.com/lagelab/Genoppi>.

**1397T****A unified web platform for network-based analyses of genomic data.**

Regev<sup>1,10</sup>, K. Lage<sup>1,2,9</sup>. 1) Broad Institute of MIT and Harvard, Cambridge, MA; 2) Department of Surgery, Massachusetts General Hospital, Boston, MA; 3) Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, Cambridge, MA; 4) Department of Medical Oncology, Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA; 5) Howard Hughes Medical Institute and Department of Molecular Biology, MGH, Boston, MA; 6) Department of Statistics, Harvard University, Cambridge, MA; 7) University of California, San Diego, CA; 8) Center for Immunology and Inflammatory Diseases, Massachusetts General Hospital, Boston, MA; 9) Harvard Medical School, Boston, MA; 10) Howard Hughes Medical Institute, Department of Biology, Massachusetts Institute of Technology, Cambridge, MA.

With significant technological advances in epigenetics, proteomics and RNA sequencing, it is now possible to generate an unprecedented amount of tissue- and cell-type-specific functional genomics data that can be conveniently represented as gene networks. Integrating these networks with exome-sequencing data, or genome-wide association studies, is a cost-efficient and scalable way to identify draft cellular circuits that are enriched for genetic risk in a particular disease. However, different networks vary considerably in terms of how noisy they are and their global and local biological signals. Therefore, a major bottleneck in network-based analyses of genomic data is the quantitative comparison of biological signal in different networks to identify the optimal network dataset for a particular biological question. To address these barriers, we developed a unified web platform "Broad Institute Web Platform for Genome Networks (GeNets)". We designed a machine learning algorithm (Quack) that can learn the topological patterns of any pathway set in any network defined by users, allowing them to make detailed comparisons of the global and local biological signals of different networks. We trained Quack on 853 canonical pathways on five networks, which exhibited high area under the receiver operating characteristics curve (AUC, median 0.81) when predicting pathway membership, suggesting broad utility of Quack across different types of functional networks. To illustrate typical GeNets workflows, we analyzed 65 genes implicated in autism spectrum disorders (ASD). We chose the human protein-protein interaction network InWeb because it performed optimally in learning pathway relationship across 306 neuronal pathways compared to the other four networks. InWeb-trained Quack model identified 31 candidates topologically related to 65 ASD genes. Using GeNets visualization features, we found a significant overlap (3 genes) between the 31 candidates and genes implicated in schizophrenia and neurodevelopmental delay. Among the three genes, we discovered that *NAGA* has a brain-specific eQTL, and mutations in *NAGA* can cause Schindler disease which has overlapping symptoms with ASD, suggesting that *NAGA* could be an interesting ASD candidate gene. Overall, GeNets is a scalable and uniquely enabling computational framework for expert and non-expert users alike to perform, manage, and share analyses of genetic datasets using heterogeneous functional genomics networks.

**1398F****Quantitative transcription factor occupancy across cell types, conditions, and genetic variants.** K. Luo<sup>1,2,3,4</sup>, J. Zhong<sup>1,2,3</sup>, A. Saff<sup>2,5</sup>, L. Hong<sup>2,5</sup>, A. Tewari<sup>6</sup>, L. Song<sup>2,5</sup>, T. Reddy<sup>1,2,7,8,9</sup>, L. Ma<sup>1,10</sup>, G. Crawford<sup>1,2,5</sup>, A. Hartemink<sup>1,2,3,11</sup>. 1)

Computational Biology & Bioinformatics Graduate Program, Duke University, Durham, NC; 2) Center for Genomic & Computational Biology, Duke University, Durham, NC; 3) Department of Computer Science, Duke University, Durham, NC; 4) Department of Human Genetics, University of Chicago, Chicago, IL; 5) Department of Pediatrics, Duke University Medical Center, Durham, NC; 6) Department of Internal Medicine, Beth Israel Deaconess Medical Center, Boston, MA; 7) Department of Biostatistics & Bioinformatics, Duke University Medical Center, Durham, NC; 8) Department of Biomedical Engineering, Duke University, Durham, NC; 9) Department of Molecular Genetics & Microbiology, Duke University Medical Center, Durham, NC; 10) Department of Statistical Science, Duke University, Durham, NC; 11) Department of Biology, Duke University, Durham, NC.

Thousands of different transcription factors (TFs) bind with varying occupancy across the human genome. Chromatin immunoprecipitation can profile occupancy genome-wide, but one TF at a time, limiting our ability to comprehensively observe the TF occupancy landscape, let alone how it changes. We developed TOP, a Bayesian hierarchical regression framework to profile genome-wide quantitative occupancy of many TFs using data from a single DNase-seq experiment. TOP is supervised, but its hierarchical structure allows it to predict the occupancy of any sequence-specific TF, even those without training data. We used TOP to profile the quantitative occupancy of nearly 1500 TFs, and examined how their occupancy changed genome-wide in a number of contexts: across 178 human cell types, over 12 hours of exposure to different hormones, and across the genetic backgrounds of 70 individuals. TOP enables cost-effective exploration of quantitative changes in the landscape of TF binding.

**1399W****PHESANT: A tool for performing automated phenome scans in UK**

**Biobank.** L.A.C. Millard, N.M. Davies, T.R. Gaunt, G. Davey Smith, K. Tilling. MRC Integrative Epidemiology Unit (IEU), School of Social and Community Medicine, University of Bristol, UK.

Epidemiological cohorts typically contain a diverse set of phenotypes such that automation of phenome scans is non-trivial, because they require highly heterogeneous models. For this reason, phenome scans have to date tended to use a smaller homogeneous set of phenotypes that can be analysed in a consistent fashion. We present PHESANT (PHENome Scan Analysis Tool), a software package for performing comprehensive phenome scans in UK Biobank, including phenome-wide association studies (pheWAS) and Mendelian-randomization phenome-wide association studies (MR-pheWAS). PHESANT tests the association of a specified trait with all continuous, integer and categorical variables in UK Biobank, or a specified subset. PHESANT uses a novel rule-based algorithm to determine how to appropriately test each trait, then performs the analyses and produces plots and summary tables. We report results using PHESANT to search for the causal effects of body mass index, using the MR-pheWAS approach.

**1400T****Comparative analysis of methods for discovery of germline copy-number**

**variants from exome data.** B.D. O'Fallon<sup>1</sup>, J. Durtschi<sup>1</sup>, T. Lewis<sup>2</sup>, W. Donahue<sup>2</sup>, S. Reading<sup>2</sup>, S. Dames<sup>2</sup>, D. Close<sup>2</sup>, H. Best<sup>2,3</sup>, E. Gee<sup>2</sup>. 1) Biocomputing, ARUP Labs, Salt Lake City, UT; 2) ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT; 3) Department of Pathology, University of Utah Health Sciences Center, Salt Lake City, UT.

**Purpose** Sensitive and specific identification of copy number variants (CNVs) in human exomes remains a significant computational challenge, particularly for events spanning only one or two capture targets. We present a comparative analysis of six CNV detection tools, including CLAMMS, ConVadig, GATK (v4.1), Conifer, ExomeDepth, XHMM, and CODEX, and evaluate their performance on the detection of CNVs spanning 10 or fewer exons in germline exome data. **Methods** 44 human exomes were captured with IDT xGen Exome Research Panel v1.0 and sequenced on an Illumina HiSeq 4000 instrument. Reads were aligned with BWA MEM (v0.7.12) and duplicate marked using Picard Tools (v2.9). Nonoverlapping deletion and duplication CNVs spanning 1,2,3 and 10 exons were introduced into alignment (BAM) files by removing or duplicating reads, respectively. Caller performance was assessed by tabulating the sensitivity, specificity, and positive predictive value (PPV) at the quality threshold that maximized the  $F_1$  statistic for each test sample. We investigated the effect on sensitivity and PPV of the number of control samples used and, by downsampling both control and test samples, the mean sample read depth. We also examined reproducibility as measured by simulated CNV call concordance from three sets of internally replicated samples. **Results** Sensitivity and PPV increased with increasing CNV size across all callers. However, we found substantial variability among methods, with differences becoming more pronounced with decreasing CNV size. For single exon CNVs, mean sensitivities ranged from 0-85% across callers, while PPV varied between 20-90%. For 3- and 10-exon deletions, sensitivity and PPV varied from 60-90% and 80-100%, respectively, for most methods. Using mean  $F_1$  across all batches as a measure of overall accuracy, 3 of the 6 callers demonstrated increasing accuracy as the number of control samples was increased from 15 to 35. Mean  $F_1$  for all callers improved as read depth increased from 50 to 200, although the magnitude of the effect varied considerably. Reproducibility ranged from 44-96% across methods and increased with CNV size, with nearly all callers achieving 90% or greater concordance for 10-exon CNVs. **Conclusions** These results are consistent with earlier work demonstrating limited accuracy and precision of small CNV detection from targeted NGS data, but suggest that increasing read depth and the number of control samples may increase accuracy considerably for some methods.

**DNA sequence and quality value accuracy for a new Sanger sequencing instrument.** *S.J. Schneider, S.R. Berosik, J. Bodeau, Y. Chu, A. Gerstner, P. Ma, D. Rodriguez, R. Schaeffer, D.C. Woo.* Thermo Fisher Scientific, South San Francisco, CA.

Sanger Sequencing with capillary electrophoresis is a cost-effective and time-efficient DNA sequencing method to generate high quality and highly accurate DNA sequence information to interrogate DNA for both Mendelian variants and now minor variants present at 5% or greater, using Minor Variant Finder software. With the introduction of the new easy-to-use Applied Biosystems SeqStudio Genetic Analyzer, with a new polymer, new spectral auto-calibration algorithm, updated KB Basecaller, and long-, medium-, or short- read sequencing options, it is important to test the accuracy of basecalls and Quality Values of SeqStudio sequence data. Development of a new capillary electrophoresis DNA analysis platform includes the development and validation of the basecalling capability. Dye-labeled DNA fragment mobility correction as well as the capability of generating high-quality, highly-accurate sequencing content is essential for successful sequencing projects. We describe the process used to evaluate the performance of this new system, including validation of the updated KB™ Basecaller basecalling algorithm. The process starts with the creation of the mobility correction file content and includes the data generation and validation of the pure- and mixed-basecalling abilities of the KB™ Basecaller for the system using millions of bases of both genomic and FFPE-derived DNA generated on multiple SeqStudio instruments to maximize sequence variability and instrument variability.

**Genotype array missing variant imputation with 78 batches comprising ~84,000 individuals.** *I.B. Stanaway<sup>1</sup>, J. Jackson<sup>2</sup>, B. Mapes<sup>3</sup>, M.R. Palmer<sup>4</sup>, A. Gordon<sup>5</sup>, F. Lin<sup>4</sup>, Y. Joo<sup>4</sup>, M.G. Hayes<sup>4</sup>, A. Gharavi<sup>5</sup>, M.D. Ritchie<sup>6</sup>, E.A. Rosenthal<sup>3</sup>, B. Namjou-Khales<sup>7</sup>, M. Andrade<sup>8</sup>, K. Kiryluk<sup>8</sup>, G.P. Jarvik<sup>8</sup>, D.R. Crosslin<sup>1</sup>.* 1) Biomedical Informatics Medical Education, University of Washington, Seattle, WA; 2) eMERGE Network, Coordinating Center Nashville, TN; 3) Medical Genetics, University of Washington, Seattle, WA; 4) Northwestern, Chicago, IL; 5) Columbia University Department of Medicine, New York, NY; 6) Geisinger Health System, Danville, PA; 7) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 8) Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN.

The Electronic Medical Records and Genomics (eMERGE) Network comprises 12 medical centers with electronic health records (EHR) linked to genotype data for ~84,000 participants. To create a shared resource to perform association analyses with phenotypes derived from the EHR, we imputed 78 genotype array batches against the Haplotype Reference Consortium 1.1 using the Michigan Imputation Server (MIS). A total of 5,166,562 variants were directly genotyped in any one or more array batches. We analyzed the missing genotype imputation efficiency of the various genotype arrays using the R-square (Rs<sub>q</sub>) metric reported by the MIS at 39,131,578 variants genome wide. For each array batch, we calculated the mean Rs<sub>q</sub> (range:0.089-0.68). A total of 51 array batches had a mean Rs<sub>q</sub> >0.3. We constructed a linear model using the variables, batch sample count (range:4-9,315) and the count of directly genotyped variants (range:50,911-3,410,557). Both the log of array batch sample count ( $p < 2 \times 10^{-16}$ ) and the log count of directly genotyped variants ( $p \sim 5.6 \times 10^{-6}$ ) were significantly associated with the array batch imputation performance measured using the array mean Rs<sub>q</sub>, and explained 62% and 21% of the variance, respectively. The averages of each variant's Rs<sub>q</sub> across chips had 21,924,838 variants with a mean >0.3, and 17,294,872 variants with a median >0.3. PCA ancestry analysis using imputed genotypes from chromosome 22 showed concordance with self-reported race and displayed the canonical European, African and Asian ancestry sample groupings without evidence of gross batch effects in the first two principal components. Our metrics of Rs<sub>q</sub> summaries, principal components, and identity-by-descent will assist in performing association analyses with the rich eMERGE phenotype data derived from electronic health records.

**Graph embedding and visualization of genetic data using paired factor analysis.** *G.T. Wang<sup>1</sup>, K.K. Dey<sup>2</sup>, M. Stephens<sup>1,2</sup>.* 1) Department of Human Genetics, University of Chicago, Chicago, IL; 2) Department of Statistics, University of Chicago, Chicago, IL.

Many problems in genetics -- from characterizing gene-expression dynamics in single cell development, to inferring human population migration and admixture -- can be viewed as constructing graph embedding of high dimensional data. Currently a number of non-model based computational tools, eg Monocle, TSCAN, Slingshot, have been developed for discovering developmental trajectory in single cell data. To better understand their relative merits we have developed a Dynamic Statistical Comparison (DSC) benchmark using different types of simulated trajectories (tree, cycle and other planar graphs). We evaluated single cell specific methods as well as a number of generic approaches to dimensionality reduction and manifold learning. Our benchmark illustrates situations when certain types of noise can undermine detection power of some methods. In particular we have observed trade-off in their capability to recover global and local pattern for complex problems. In order to exploit the local linear structure in data we propose a model based approach called Paired Factor Analysis (PFA), which assigns grades of memberships to each sample with the constraint that a sample can have memberships in at most two clusters. Consequently, a graph can be embedded with factors being the nodes and samples aligning to edges. Statistical evidence for graph edges can be obtained to impose sparsity when desired, creating visualizations that automatically reveal trajectories in high dimensional space when they are present. Under the DSC benchmark, PFA is capable of recovering simulated trajectories, and is more resilient to certain noise types compared to principal component analysis. We have applied PFA to publicly available genetic data-sets including single cell RNA-seq data and genotype data of admixed individuals, providing visualizations that reflect core features in both data types. Our method is available as an R package at <https://github.com/gaow/pfar>.

**Polaris: A collection of 220 publicly available whole genomes for sharing validated structural variants.** *M.A. Bekritsky<sup>1</sup>, P. Krusche<sup>1</sup>, N. Johnson<sup>2</sup>, E. Dolzhenko<sup>2</sup>, A. Gross<sup>2</sup>, B.R. Lajoie<sup>2</sup>, V. Rajan<sup>2</sup>, N. Gonzaludo<sup>2</sup>, Z. Kingsbury<sup>1</sup>, S.J. Humphray<sup>1</sup>, S.S. Ajay<sup>2</sup>, R.J. Taft<sup>2</sup>, D.R. Bentley<sup>1</sup>, M.A. Eberle<sup>2</sup>.* 1) Illumina Cambridge Ltd., Chesterford Research Park, Saffron Walden, Essex, CB10 1XL, United Kingdom; 2) Illumina Inc., 5200 Illumina Way, San Diego, CA, 92122, USA.

Structural variant (SV) calling is an essential component of a clinical genomics pipeline. However, benchmarking SV caller accuracy is difficult due to the scarcity of well-defined validation methods and a dearth of sufficient whole genome sequencing (WGS) data to robustly test calling methods. Furthermore, once WGS data has been generated, researchers may be unable to share their data with others without compromising genetic privacy. We seek to address these challenges by combining publicly available WGS data with an extensive population and Mendelian genetic validation framework to facilitate sharing and benchmarking common SVs. The Polaris dataset is a collection of 220 unrelated Coriell samples, with full consent for posting of personally identifiable genetic information. The individuals within the cohort are from diverse ethnic origins and includes 70 samples from the Genetic Testing Reference Material Coordination Program (GeT-RM). Each sample has been sequenced to 35x coverage on the Illumina HiSeqX platform with 2x150 bp reads generated from a TruSeq PCR-Free library. Complete sequence data for these samples is available from the European Nucleotide Archive (PRJEB20654 and PRJEB19931). To accompany the raw WGS data, we are also releasing an initial set of >70,000 SVs that are observed in at least one Polaris sample and are consistent with population and Mendelian genetics. Candidate SVs include large deletions and insertions identified using a variety of inputs, including previously published insertions and SVs identified in the Platinum Genomes pedigree. These SVs were jointly re-called on the Polaris samples using either graph-based or depth-based structural variant calling methods. Each variant is in Hardy Weinberg Equilibrium in the Polaris dataset and an additional cohort of 3,000 samples, and satisfies pedigree consistency in the Platinum Genomes. Many of these events are also in linkage disequilibrium with nearby SNPs, providing further genetic confirmation of their validity. This data marks the beginning of a community resource to share and validate common SVs and more complex structural rearrangements that will continue to expand as more samples and further analyses are added. We hope to engage other members of the research community in our pursuit of a constantly improving and robust truth-set, and a widely accessible validation and coordination framework.

**1405W**

**CNVs in clinical WGS: Deployment and interpretation for rare and undiagnosed disease.** *A.M. Gross, S.S. Ajay, V. Rajan, C.M. Brown, K. Bluske, N. Burns, A. Chawla, A.J. Coffey, A. Malhotra, A. Scocchia, E. Thorpe, N. Johnson, E. Dolzhenko, B. Lajoie, J. Belmont, D.L. Perry, M.A. Eberle, R.T. Hagelstrom, D.R. Bentley, R.J. Taft.* Illumina, San Diego, CA.

Here we describe the deployment of a copy-number variant (CNV) detection pipeline as a component of a clinical whole genome sequencing diagnostic test for rare and undiagnosed genetic disease (RUGD). Since late 2016 a total of 79 RUGD cases have been assessed in the context of SNVs, indels and CNVs (>10kb) in the Illumina Clinical Services Laboratory. All cases included a detailed review of medical history followed by sequencing on the HiSeq X (2 x 150 bp) and analysis using a bioinformatics pipeline that includes automated filtering, annotation, and visualization. Copy number calls that passed automated prioritization were submitted to manual quality control and variant curation before being compiled into reports. On average, we found 2.5 benign, 3 VUS-likely benign, and 4 VUS CNVs were reported per case. In 15% (11/79) cases, we reported out variants with pathogenic or likely pathogenic classifications, across a diverse set of patient phenotypes. In addition to these CNVs, our pipeline also detected a full chromosome mosaic trisomy, and a uniparental isodisomy of chromosome 15. CNVs can be the result of simple or more complex genomic rearrangements. To understand better the mechanism of the event leading the copy-number change, our pipeline integrates depth-based CNV calls with split-read based structural variants. Additionally, we assess the parent of origin of a deleted or duplicated haplotype via joint analysis of a pedigree, using inheritance patterns of small variants when a CNV arises de-novo. In practice, we used these tools to identify copy-number gains as tandem- or dispersed- duplications and link CNVs within an individual as part of chromosomal rearrangement events. We highlight the case of unbalanced translocation in an unaffected parent leading to large copy number changes in a diseased proband. Lastly, mosaic CNVs represent a unique class of variants, which are difficult to distinguish from sequencing noise. To address this we leverage data across a population of more than 3000 genomes to distinguish true copy-number changes from baseline sequencing depth variation. Among our cohort we highlight three mosaic CNVs, a 23kb deletion of a imprinted promoter, an unbalanced translocation, and a full chromosome trisomy. In conclusion, we report considerable success deploying CNV calling on top of an existing WGS assay. These results show the utility of WGS as an extendable platform for exploring the diversity of variation in RUGD.

**The quantity of detected copy number variation (CNV) deletions substantially increases when coverage of whole-genome sequencing (WGS) data increases from 30x to 91x.** *Y.S. Huang<sup>1</sup>, C.Y. Tang<sup>1</sup>, C.K. Liu<sup>1</sup>, C.Z. Lo<sup>2</sup>, Y.C. Lin<sup>1</sup>, C.H. Chen<sup>2</sup>, L.H. Li<sup>2</sup>, A. Yao<sup>1,2</sup>.* 1) National Center for Genome Medicine (NCGM), Academia Sinica, Taipei, Taiwan, R.O.C; 2) Institute of Biomedical Sciences (IBMS), Academia Sinica, Taipei, Taiwan, R.O.C.

The correlation between copy number variation (CNV) and many human diseases has been established, especially in mental disorders, such as autism and schizophrenia. With advances in genome sequencing technologies, studies of CNV detection from whole-genome sequencing (WGS) data have accumulated. However, little is known about the correlation between coverage of WGS data and detected CNV events. In this study, we created a 30x and a 64x NA12878 WGS data by sampling pair-end reads from a 91x NA12878 WGS data; the 30x WGS data was a subset of the 64x counterpart. We focused on detecting CNV deletions with sizes between 10,000 and 100,000 base pairs in these NA12878 WGS data using Delly, a structural variant detector with a concise user interface, configurable genomic references, and continuous maintenance. The results indicated that the quantity of detected CNV deletions substantially increased when the coverage increased from 30x to 91x. Meanwhile, the increment of detected CNV deletions has not reached a plateau yet. To examine whether the number of detected CNV deletions in a WGS sample would approach a maximum when coverage of WGS data increases, we are currently working on creating WGS samples with various coverage by sampling pair-end reads from a 300x NA12878 WGS data and expect to present the results in the conference.

**1407F****Full-spectrum copy number variation detection by high-throughput**

**DNA sequencing.** Y. Jiang<sup>1,2</sup>, K. Nathanson<sup>3,4</sup>, N. Zhang<sup>5</sup>. 1) Department of Biostatistics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) Division of Translational Medicine and Human Genetics, Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4) Abramson Cancer Center, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 5) Department of Statistics, The Wharton School, University of Pennsylvania, Philadelphia, PA.

Much effort has been devoted to elucidating the role of Copy number variations (CNVs) on human diseases and phenotypes. Such efforts have met with mixed success, with setbacks arising from the lack of reliable methods for sensitive and robust CNV profiling. In particular, in studies where it is desirable to attain deep coverage, or where the cohort is very large, whole-exome sequencing (WES) and targeted sequencing are often preferred methods, and there is a lack of reliable CNV detection tools for these platforms. For example, the Exome Aggregation Consortium has sequenced the exomes of 60,706 individuals and many cancer genomic studies use deep targeted sequencing to find low-frequency mutations within specific genomic regions. Here we propose a new method, CODEX2, to remove technical noise and improve CNV signal-to-noise ratio for all sequencing platforms including WES and targeted sequencing. A limitation shared by all current methods, highlighted by multiple independent benchmarking studies, is the lack sensitivity for common variants. CODEX2 is improved over existing methods with high sensitivity for both common and rare CNVs, thus allowing full-spectrum CNV detection. CODEX2 can be applied to two scenarios: the case-control scenario to detect CNVs that are enriched in the cases, and the scenario where control samples are not available and the goal is simply to profile all CNVs. CODEX2 is benchmarked against existing methods in three ways. First, we reanalyze the WES of the HapMap samples from the 1000 Genomes Project, where a set of experimentally validated CNVs from microarrays are used to assess performance. CODEX2 is shown to markedly improve both sensitivity and specificity over existing methods. Second, we apply CODEX2 to targeted sequencing data of melanoma cancer cell lines, where CODEX2 detects CNVs with recurrence rates that are highly concordant with those obtained from a separate cohort studied by the Cancer Genome Atlas. Finally, we perform extensive simulations benchmarking existing methods and elucidating how key variables, such as population frequency, influence sensitivity. CODEX2 is currently being applied to 12,000 WES samples in the Penn Medicine BioBank and 10,000 WES samples in the Alzheimer's Disease Sequencing Project. With increasing sequencing capacity, and increasing need to profile CNVs as a non-negligible source of genetic variation, we believe CODEX2 can be a helpful tool for the genetic and genomic community.

**1408W****A clinically validated whole genome pipeline for structural variant detection and analysis.** A. Kaplun. Variantyx Inc., Framingham, MA.

With the cost of whole genome sequencing (WGS) continuing to decrease we are fast approaching the point of inflection where WGS testing will become more economically feasible, facilitating broader access to the benefits that are helping to define WGS as the new diagnostic standard. Many benefits are inherent in the sequencing technology itself. PCR-free DNA preparation methods eliminate amplification-related issues producing better coverage of amino acid coding regions. In addition comprehensive coverage of intronic and intergenic regions ensures the identification of potentially relevant transcription factor binding site, enhancer and other regulatory variants. Importantly, WGS provides unique opportunities for detection of structural variants, but such analyses have not previously made their way into clinical practice. We have developed a clinically validated WGS pipeline for highly specific and sensitive detection of structural variants. Using a combination of breakpoint analysis, read depth analysis and *de novo* assembly of tandem nucleotide repeats and tri-nucleotide tandem repeats, the pipeline identifies structural variants down to single base pair resolution. False positives are minimized using calculations for loss of heterozygosity and bi-modal heterozygous variant allele frequencies to enhance heterozygous deletion and duplication detection respectively. To facilitate clinical interpretation, identified variants are annotated with phenotype information derived from HGMD® Professional and population allele frequencies derived from DGV. Single base pair resolution enables easy visual inspection of potentially causal variants using the IGV genome browser as well as easy biochemical validation via PCR. Patient cases demonstrating clinical utility of the pipeline will be presented.

**Robust identification of deletions in next generation trio sequence data based on clustering of Mendelian errors.** *K.B. Manheimer<sup>1</sup>, N. Patel<sup>1</sup>, F. Richter, J. Gorham<sup>2</sup>, A. Tai<sup>2</sup>, J.G. Seidman<sup>2</sup>, C.E. Seidman<sup>2</sup>, B.D. Gelb<sup>1,3,4</sup>, A.J. Sharp<sup>3</sup>.* 1) Mindich Child Health and Development Institute, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Department of Genetics, Harvard Medical School, Boston, MA; 3) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 4) Department of Pediatrics, Icahn School of Medicine at Mount Sinai, New York, NY.

Identification of structural variation is important as they contribute to many types of disease including autism, schizophrenia and congenital heart disease. Next generation sequencing (NGS) data can be used to identify CNVs, often relying on changes in read depth as implemented by various tools such asXHMM for whole exome sequencing (WES) and CNVnator for whole genome sequencing (WGS). These tools have limited sensitivity, however, primarily because coverage is inherently variable across the genome. Here, we present an orthogonal method to identify deletions from NGS data based on the clustering of Mendelian errors (MEs). Hemizygous loci (due to an underlying deletion) are assigned homozygous genotypes by variant callers. With the availability of trios, these loci can be detected as MEs. We developed the ME method (MEM) to identify deletion CNVs in 2600 WES trios and 350 WGS trios from the Pediatric Cardiac Genomics Consortium (PCGC). We compared MEM to XHMM and CNVnator for *de novo* deletion detection in WES and WGS, respectively. From 2600 WES trios, MEM identified 171 putative deletions. Digital droplet PCR confirmed 91/104 for a positive predictive value of 87.5%, better than the 80% rate achievable with XHMM. Using MEM and XHMM, 74 *de novo* deletion CNVs were called: 37 by both tools, 4 MEM only, and 33 XHMM only. MEM false negatives were attributable to insufficient numbers of MEs, principally related to small deletion size (<30 kb). An additional strength of MEM was its ability to detect other sources of MEs: DNA contamination (n=6), broken trios (n=20), and uniparental disomy (n=8). From 350 WGS trios, MEM identified 6676 putative deletions (19.1 deletions/proband), of which 11% were exonic. Using MEM and CNVnator, 33 *de novo* deletions were called: 9 by both tools, 8 MEM only, and 15 CNVnator only. MEM WGS false negatives were primarily for deletions smaller than 10 kb. Robustness of MEM for calling deletion CNVs from WGS was assessed using the trio from Genome in a Bottle for which PacBio long-read sequencing was available; MEM called 26/29 deletions (90%), although the boundaries for 2 true positive calls were inaccurate. In conclusion, MEM is a robust method for calling inherited and *de novo* deletion CNVs from WES and WGS trio data. As it is orthogonal to read depth-based methods, it can obviate the need for PCR-based confirmations. MEM also detects UPD, which is missed by other NGS-based callers.

**Automated parameter tuning for more accurate CNV calling in WES/WGS data.** *M. Wiewiórka<sup>1</sup>, W. Kuśak&acute;mirek<sup>1</sup>, M. Okoniewski<sup>2</sup>, T. Gambin<sup>1</sup>.* 1) Institute of Computer Science, Warsaw University of Technology, Warsaw, Mazowieckie, Poland; 2) Scientific IT Services, ETH Zurich, Zurich, Switzerland.

**Background:** Accurate detection of CNVs from sequencing data is required to provide a comprehensive molecular diagnosis. However, there is still a lack of best practices developed for germline CNV calling pipelines and therefore both implementation and tuning of such a pipeline in a diagnostic lab is a challenge for a number of reasons. First of all, a great selection of algorithms and contradictory conclusions from CNV calling benchmarks makes it difficult to choose the most suitable method for a given dataset. Additionally, different target designs and coverage profiles may greatly impact the accuracy of a particular tool. Furthermore, there are no clear recommendations for the optimal selection of control samples that are required for joint-calling algorithms. Finally, a fine-tuning of the specific CNV caller parameters is problematic without access to a golden standard call set. **Methods:** To address these issues we developed a method capable of automated parameter tuning for the most popular CNV calling algorithms, including XHMM and CODEX. The main idea behind our approach is to modify read coverage profiles of an user dataset to imitate existence of additional rare CNVs that we further use for accuracy assessment. Their coverage characteristics (i.e. relative changes in depth of coverage), allele frequencies, lengths and genomic locations are derived from the set of validated CNVs in 1000 Genomes samples and corresponding sequencing data. Since the processing of BAM files, required to obtain high resolution coverage profiles, is a time consuming problem, we used Apache Spark, i.e. a distributed computing framework. In addition, we proposed a novel columnar data format for storing precomputed read depth to further speed up calculations. **Results:** We demonstrated the utility of our framework on both publicly available subset of 1000 Genomes data and locally available dataset. Results indicated that our solution can substantially improve the CNV calling performance of state-of-the-art methods when compared to their default settings. Concluding, proposed approach simplifying CNV calling pipelines implementation may give rise to higher adoption of CNV analysis from sequencing data in clinical laboratories.

**1411W****Integrative DNA copy number detection and genotyping from sequencing and array-based platforms.** Z. Zhou<sup>1</sup>, W. Wang<sup>2</sup>, L. Wang<sup>2</sup>, N. Zhang<sup>3</sup>.

1) Graduate Group in Genomics and Computational Biology, University of Pennsylvania, Philadelphia, PA; 2) Department of Pathology and Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3) Department of Statistics, The Wharton School, University of Pennsylvania, Philadelphia, PA.

Copy number variations (CNVs) are gains and losses of DNA segments that have been shown to be associated with disease. Previously, many large disease cohorts perform CNV analysis with data from SNP-array. However, with the cost of Next Generation Sequencing (NGS) dropped dramatically, those large cohorts redo their CNV analysis with technologies such as whole exome sequencing (WES) and whole genome sequencing (WGS), where both SNP-array data and NGS data are available. An integrated analysis is expected to improve resolution and accuracy, yet there is a lack of tools that efficiently combines data from both platforms, nor has there been a systematic study of the expected accuracy improvement achievable by integration. Here we propose a statistical framework, integrated Copy Number Variation Analysis (iCNV), which can be applied to multiplatform study designs: WES only, WGS only, SNP array only, or any combination of SNP and sequencing data. iCNV allows platform specific normalization to remove platform specific biases, uses allele specific reads from sequencing and B-allele frequency from array data to improve detection sensitivity and genotyping accuracy, and achieves fast computation through a Hidden Markov Model (HMM). Using iCNV, we compare CNV calling integrating multiple platforms versus simply performing intersection or union of detections made by the two platforms and show that properly integration across platforms increases sensitivity and specificity. We further compare CNV detection sensitivity between single platform versus joint platforms by an *in silico* spike-in study and find that array data greatly improves detection power when added to WES, while not too much when added to WGS. Finally, we compare iCNV to other commonly used CNV calling methods when analyzing solely WGS data on a cohort containing related individuals, where Mendelian concordance-based quality metrics show that iCNV improves upon existing methods owing to its improved normalization pipeline and utilization of allele-specific reads.

**1412T****CNVs from targeted NGS data: Building a cohort for validation and semiautomatic regression testing in a diagnostic setting.** M. Ziegler, D.

Becker, Y. Dinçer, S. Eck, K. Pindl, K. Mayer, K. Gemmeke, HG. Klein. Center for Human Genetics, Martinsried, Germany.

The validation of custom-made bioinformatics analysis systems in a GxP regulated setting is a major challenge due mostly to lack of reference material as well as to system complexity. Reference material for CNVs with exon level resolution is not available at all. Therefore, we set up a patient cohort, which underwent both targeted NGS analysis (Agilent QXT, NextSeq500) and further specification via MLPA (multiplex ligation-dependent probe amplification). The cohort consists of 277 patients with various phenotypes (e.g. Long QT syndrome, Marfan syndrome, cystic fibrosis, familial hypercholesterolemia) who underwent more than 420 MLPA analyses. Probes from 19 MLPA kits were lifted from hg18 to GRCh37p13 and GRCh38p10 coordinates and linked to patient specific probe signals. The matrix was transferred to patient specific files in browser extensible data format (BED) in order to generate a dataset that can be evaluated semi-automatically. The dataset consists of about 20,000 probe positions encompassing 1.2 Mb of analyzed region. Genomic regions of interest were enriched and sequenced for all cohort individuals. For enrichment, we used seven different targeted panels with an average region size of about 300 kb per panel. FASTQ files were demultiplexed and mapped to the reference genome (GRCh38p10) via Picard tools. The resulting binary alignment map files (BAM) were sorted for enrichment version and gender, and stored for subsequent CNV analysis. Since the resulting file format of our custom-made CNV pipeline is BED, MLPA and NGS results are semi-automatically comparable. Therefore, we set up a comparison script to determine key figures for analytical quality (sensitivity, specificity, accuracy and precision). The MLPA dataset also allows fast and precise change management of the CNV pipeline.

**Towards “gold standard” sequence-resolved structural variants in benchmark human trio reference samples.** *J.M. Zook<sup>1</sup>, L. Chapman<sup>1</sup>, N.F. Hansen<sup>4</sup>, F.J. Sedlazeck<sup>5</sup>, M. Salit<sup>3,5</sup>, Genome in a Bottle Consortium.* 1) Material Measurement Laboratory, National Institute of Standards and Technology, Gaithersburg, MD; 2) Material Measurement Laboratory, National Institute of Standards and Technology, Palo Alto, CA; 3) Department of Pathology, Stanford University, Palo Alto, CA; 4) Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, Rockville, MD; 5) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX.

The Genome in a Bottle Consortium (GIAB) has characterized an Ashkenazi trio from the Personal Genome Project (NIST Reference Material 8392) with 12 short, long, and linked read sequencing and mapping methods. Datasets are public without embargo for analysis and methods development by the community. We have characterized ~3.7 million small variants as well as reference calls for ~90% of the genome with estimated errors of ~2 FPs and 2 FNs per million variants. To extend this characterization to larger indels and structural variants, we collected analyses of variants  $\geq 20$  bp from 33 bioinformatics methods and five technologies. Nineteen discovery and refinement methods produced sequence-resolved calls using local or global assembly or split reads, giving a precise prediction of deletion breakpoints, inserted sequences, and complex changes. These methods produced at least one sequence-resolved call in 82,386 of 88,348 candidate SV regions where we merged all candidate SV calls within 1000bp. We designed three different integration approaches to address challenges in comparing large variants, which are frequently in tandem repeats ( $>50\%$  of all calls) and not precisely characterized. (1) We compared the sizes of deletions predicted in each candidate region and found 20,218 deletions in the trio where  $\geq 2$  technologies had size predictions within 20%. (2) We used SURVIVOR to compare predicted breakpoints and found 27,304 deletions, 14,045 insertions, and 117 inversions where  $\geq 2$  technologies had variants of the same type and breakpoints within 1000bp. (3) We used SVcomp to compare sequence-resolved calls, accounting for differing representations in repetitive regions. SVcomp found 30,493 (matched exactly), 33,533 ( $\leq 2\%$  different using three distance metrics), and 45,667 ( $\leq 10\%$  different) variants of all SV types supported by  $\geq 2$  technologies. Current work includes evaluating these potential benchmark calls using genotyping/evaluation methods, machine learning, experimental confirmation, and crowd-sourced manual curation of visualizations. These results represent a significant step in GIAB work towards improved benchmarking of large variants in research and clinical settings.

**A simple, flexible and EHR-agnostic platform for rapid cohort identification and characterization in a large and diverse biobank environment.** *F. Mentch<sup>1</sup>, H. Qiu<sup>1</sup>, M. March<sup>1</sup>, J.J. Connolly<sup>1</sup>, L. Hermannsson<sup>1</sup>, P.M.A. Sleiman<sup>1,2</sup>, H. Hakonarson<sup>1,2</sup>.* 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA.

Data to support many as yet undiscovered gene-disease and gene-disease-environment associations is very likely already captured in large biobanks set up for that purpose. One limiting factor in realizing these discoveries is the effort required to identify hundreds of clinically consistent patient cohorts using complex EHR records. Within our biobank environment with tens of thousands of genotyped subjects with full patient EHR records, we have developed a framework that standardizes and automates a significant percentage of the cohort selection effort while not requiring any particular EHR data schema. Schema independence facilitates augmenting our data sources with deep phenotype data not captured in the institution-wide EHR when it is available directly from clinicians. We have currently used this platform for over 300 distinct cohort searches from 160 data sources encompassing more than 7,000 unique diagnosis, medication, procedure and other search terms. Search metadata is permanently stored and full search results are stored in an associated data warehouse for as long as needed. As a benchmark, we find that this platform automates from 60-90% of the effort required to implement phenotype algorithms we have run that were developed by the eMERGE consortium. Other benefits of this platform include ready reuse or refinement of all or selected components of an existing search, the ability to apply extensions developed for one search to all past and future searches, and the ability to query across search metadata and results.

**ClinGen Allele Registry: Linking information about human genetic variation across the web.** P. Pawliczek<sup>1</sup>, R. Patel<sup>1</sup>, A. Jackson<sup>1</sup>, N. Shah<sup>1</sup>, C. Bizon<sup>4</sup>, T. Nelson<sup>5</sup>, S. Dwight<sup>2</sup>, M. Wright<sup>7</sup>, S. Harrison<sup>2</sup>, T. Strande<sup>6</sup>, B. Powell<sup>6</sup>, R. Freimuth<sup>8</sup>, L. Babb<sup>3</sup>, P. McGarvey<sup>3</sup>, H. Rehm<sup>2</sup>, S. Plon<sup>1</sup>, A. Milosavljevic<sup>1</sup> on behalf of the ClinGen Resource. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Laboratory of Molecular Medicine, Partners HealthCare Personalized Medicine; 3) GeneInsight a Sunquest Company, Boston, MA; 4) Department of Health Sciences Research, Mayo Clinic, Rochester, Minnesota; 5) Geisinger autism and developmental medicine, Lewisburg, PA; 6) University of North Carolina, Department of Genetics, Chapel Hill, North Carolina; 7) Stanford University, School of Medicine, Stanford, CA; 8) Georgetown University Medical Center, Washington, DC.

The Clinical Genome Resource (ClinGen) project developed the ClinGen Allele Registry (CAR) to enable layering of information about nucleotide and amino acid variants across the Web. More than 650 million currently registered variants are linked to >1.2 billion variant records in public databases including ClinVar, ExAC, gnomAD, dbSNP, MyVariant.info, and UniProtKB. A relatively small (~1,500) but growing number of variants is registered individually by users via the web interface (reg.clinicalgenome.org). The interface includes a number of web apps including both query tools and tools supporting contribution of new layers of variant information. Variants may be registered by batch upload (up to 50M variants per request) using HGVS identifiers or VCF files, registration of ~4M variants from a typical single whole-genome sequencing run taking a few minutes. In contrast to the Data Warehousing approach where variants are de-duplicated and assigned locally unique identifiers as part of the Extract-Transform-Load process, CAR provides canonical identifiers ("CA IDs") and globally unique dereferencable URIs serving variant information via Linked Data standards (including RDF). Robust, reliable and well-documented JSON-LD APIs (reg.clinicalgenome.org under button "API specification") enable linking of variant information across the Web and use of CAR services by applications such as the ClinGen Pathogenicity Calculator (Genome Med. 2017;9(1):3) and ClinGen variant curation interface. Using the Allele Data Model defined by the ClinGen Data Model Working Group, CAR tracks variants across >500K reference sequences (genomic, transcripts, and amino-acid), including NCBI36, GRCh37, and GRCh38 genome builds as well as most RefSeq, ENSEMBL, and LRG transcript reference sequences. A highly optimized alignment-based index maps variants of size <10Kb across genomic, transcript, or amino acid reference sequences, producing corresponding HGVS identifiers and variant URIs. The CAR resolves the identity of a wide range of variants such as indels, retroposon insertions, duplications, and haplotypes. The CAR tracks relations between nucleotide and amino acid variants, thus helping pool evidence for or against pathogenicity across nucleotide variants with similar effects on protein function that would otherwise have been fragmented and poorly accessible. This work was funded by the NIH National Human Genome Research Institute (NHGRI) grants U01 HG007436-01 and U41HG006834.

**Finding possible missed variant candidates through coverage comparison among varying sequencing technologies.** H. Fauni, C. Adams, K. Chao, T. Ten, C. Lau, B. Pusey, D. Adams, W. Gahl. NIH Undiagnosed Diseases Program, NHGRI, National Institutes of Health, Bethesda, MD.

The NIH Undiagnosed Diseases Program (UDP) was started in 2008 with the goals of making diagnoses and conducting research for individuals with serious medical illnesses remaining undiagnosed despite extensive evaluation. Next-generation sequencing, both exome and genome, have been important tools for a subset of these families. Since the start of the UDP, more than 700 families have been studied with these techniques. Less than 10% of cases yield a clear diagnosis, a success rate that is expected given the extensive prior evaluations (often including clinical exome sequencing) of study participants. Exome sequencing has evolved substantially from the time it was first employed for clinical diagnostics. Adequate coverage rates for genes known to be associated with human disease have improved from 80-85% to over 95%. Some improvements have been due to techniques that specifically target genes associated with known diseases. Other techniques have the potential to improve coverage of the remaining genes in the exome. We posited that exome coverage has improved during the last 5 years in the UDP. We sought to quantify the number of exonic base positions that remained undiagnosed due to poor coverage in older UDP cases compared with the current cases. Such positions represent a potential pool of sources for new diagnoses in older UDP cases. We calculated the exome coverage of individuals that were sequenced using different exome capture kits. We evaluated coverage in 30,522 hg19 UCSC transcripts and stratified the number of transcripts into three categories: no coverage,  $0 < x < 20$  mean coverage, and  $\geq 20$  mean coverage. Here we will provide summary data that describe and quantify the missed bases in our older cases and discuss the relative merits of rerunning those older cases to obtain improved coverage and aid new diagnoses.

**1417W**

**Diagnostic variant prioritization using a statistical framework for patient genome interpretation.** N. Stong<sup>1</sup>, T.J. Hayeck<sup>1</sup>, B. Copeland<sup>1</sup>, V. Aggarwal<sup>1</sup>, K. Wang<sup>1</sup>, D. Goldstein<sup>1</sup>, A. Allen<sup>1,2</sup>. 1) Columbia University Medical Center, New York, NY; 2) Duke University, Durham, NC.

A central challenge of diagnostic sequencing is judging the “exceptionalism” of individual variants, and therefore, their potential to severely affect a patient’s phenotype. The current variant prioritization paradigm relies on the application of a series of filters designed to enrich for pathogenic variants. Such filters include variant frequency, impact of the variant on the ultimate gene product (e.g., polyphen, sift, etc.), intolerance and/or conservation of the region in which the variant is found, etc. Each of these filtering steps require a threshold, which, though informed by experience and other considerations, is still, fundamentally ad hoc. Here we present a statistically principled framework for quantifying the exceptionalism of individual variants. Our scoring system (the **surprise index**) characterizes the probability of seeing a variant as extreme or more extreme than the test variant in terms of a series of annotations (frequency, deleteriousness, intolerance, conservation, etc.) if the variant were randomly sampled from a large population control dataset, e.g. gnomAD. The population controls constitute a null distribution, and, as such, the probability we compute is analogous to a p-value. To illustrate the framework’s utility, the surprise index was calculated for SNVs in individuals with previously identified pathogenic *de novo* mutations. In a ranking of functional SNVs (7939-9237 qualifying variants per trio) the surprise index ranks the pathogenic variant as the top variant in 1 trio, in the top 10 in 4 trios, and in the top 100 in all 7. These results are especially notable, given: (1) the framework does not explicitly use trio information, i.e. it is naïve to which variants are actually *de novo*; and (2) phenotype has not been incorporated in the prioritization. A subsequent refinement, in which phenolyzer scores are used to identify genes of interest, further improves performance: the surprise index ranks the pathogenic variant as the top variant in 2 trios, in the top 10 in 5 trios, and in the top 20 in all 7 trios. These results suggest that the proposed framework effectively prioritizes pathogenic variants in the context of individual patient genomes.

**Insights into the performance of whole-exome sequencing technologies.** Y. Yu, H. Hu, J. Fowler, Y. Ye, M. Hildebrandt, H. Zhao, P. Scheet, X. Wu, C. Huff. Epidemiology, UT MD Anderson Cancer Center, Houston, TX. 1) Department of Epidemiology, The University of Texas MD Anderson Cancer Center.

A number of new technologies have been developed to support whole-exome capture and sequencing, presenting researchers with many configuration options when designing whole-exome sequencing (WES) experiments. To evaluate the relative performance of available technologies, we conducted a series of WES experiments varying the following design options: genome fragmentation (sonication vs. enzymatic), average DNA fragment length, library preparation vendor (Kapa vs. Agilent), exome capture product (Agilent Clinical Research Exome, or CRE, vs. Nimblegen MedExome, or ME), and whether to PCR amplify libraries prior to target capture. All sequencing was performed on an Illumina HiSeq 4000 using 2x150bp paired-end (PE) reads with eight samples pooled per lane, which on average generated ~45 million read pairs per sample. Our results demonstrate that under optimal conditions, the CRE and ME products provided comparable exome coverage, on average covering of 94.5% and 92.6% of coding DNA sequence (CDS) based on RefSeq annotation at  $\geq 20\times$  for CRE and ME, respectively. Further, we found that sonication fragmentation using Covaris-sheared DNA generated ~20% more unique fragments compared to enzymatic fragmentation (KAPA HyperPlus), and smaller DNA fragment sizes of 200bp average length produced ~10% greater coverage than larger fragment lengths due to increased on-target coverage. To investigate the relationship between coverage depth and variant identification accuracy, we evaluated the proportion of detectable variants that could be accurately called as a function of sequencing coverage. Here, we define detectable variants as those can be identified when we pool all data from different libraries together (~50 million read pairs per sample). Pooling eight samples onto one HiSeq 4000 lane, which generated a depth of ~250X per sample, we were able to identify 99.97% and 99.85% of all detectable variants for CRE and ME, respectively. We also found only 0.62% of all detectable variants were discordant between CRE and ME, nearly all of which could be filtered by applying additional variant QC. Through permutation analysis, we found 99.7% and 99.01% of all detectable variants could be identified for CRE and ME, respectively, if 16 samples were pooled into one lane. In our study, we evaluated most recent WES technologies and proposed an optional design for a WES protocol, which balances the sensitivity and specificity of genotyping and experiment cost.

**Hepatic eQTL meta-analysis leads to identification of novel *cis*-eQTL in pharmacogenes.** A.S. Etheridge<sup>1</sup>, P.J. Gallins<sup>2</sup>, D. Jima<sup>2</sup>, C. Molony<sup>3</sup>, F. Wright<sup>2</sup>, Y.H. Zhou<sup>2</sup>, F. Innocenti<sup>1,4</sup>. 1) Eshelman School of Pharmacy, Univ of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Bioinformatics Research Center, North Carolina State University, Raleigh, NC; 3) Computational Biomedicine, Pfizer, Inc., Cambridge, MA; 4) Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Given the importance of the liver in drug absorption, disposition, metabolism, and excretion (ADME), as well as in drug response and toxicity, hepatic expression quantitative trait loci (eQTL) studies are crucial for elucidating how genetic variation influences inter-individual variability in therapeutic outcomes and may help guide strategies to obtain maximal efficacy and safety for patients. We performed a meta-analysis, combining microarray data and imputed genotype data from four human liver eQTL studies (n=1180), in order to increase statistical power to identify novel hepatic *cis*-eQTL. Within each study we tested for associations between genotype and gene expression, with sex, age, genetic ancestry, and experimental factors as covariates. A meta-t-statistic was calculated from the SNP/gene pair t-statistics for each liver study and p-values were generated using the normal distribution. After adjusting for multiple testing, the 1405 genes with significant *cis*-eQTL (adjusted p-value < 7.7 E-9) were filtered for relevance to ADME processes and drug response using a gene set compiled from the PharmGKB knowledge base. At a Bonferroni level of 7.7 E-9, 130,055 significant *cis*-eQTL were identified. We have identified genetic variants, not previously reported in the literature, that associate with the expression of genes important in the disposition of drugs that demonstrate a narrow therapeutic index and/or wide variability in pharmacokinetics or pharmacodynamics. Among these novel associations is rs4239798 in carbonyl reductase 1 (*CBR1*; adjusted p-value 7.8 E-25), an enzyme involved in the metabolism of the widely used chemotherapeutic doxorubicin. *CBR1* is the predominant hepatic enzyme catalyzing the reduction of doxorubicin to the less antineoplastic, but more cardiotoxic, metabolite doxorubicinol. rs4239798 was associated with increased *CBR1* expression (magnitude of effect = 11.3), indicating the potential for increased metabolism of doxorubicin and offering a possible mechanism for the up to 10-fold interpatient variability in doxorubicin plasma concentrations. Additionally, increased production of doxorubicinol may help explain acute cardiotoxicity that occurs in approximately 11% of doxorubicin treated cancer patients. Additional studies are needed to verify the role of rs4239798 in patient response to doxorubicin.

**Detecting sex specific mRNA and miRNA – eQTLs: Insight into sex biased gene regulation.** J.J. Shen, W.L. Yang. University of Hong Kong, Hong Kong, Hong Kong.

Despite sex being an important epidemiological and physiological factor, not much is known about how sex works to interact with genotypes to result in different phenotypes. Both messenger RNA (mRNA) and microRNA (miRNA) may be differentially expressed between the sexes in different physiological conditions. Using data from the Geuvadis consortium, we use whole transcriptome lymphoblastoid cell line (LCL) data from 338 European samples to look for sex-specific expression quantitative trait loci (eQTLs). We use both mRNA and miRNA expression data to search for genotypes that are differentially associated with mRNA and miRNA between sexes, which we call sex specific eQTLs (ss-eQTLs). Using linear regression, we uncover 72 mRNA ss-eQTL and 4 miRNA ss-eQTLs at genotype minor allele frequency (MAF) cutoff of 0.05 and a further set of 12 mRNA ss-eQTLs of higher confidence at genotype MAF cutoff of 0.2. We present the data in an easy to search eQTL browser at [http://147.8.193.83/ss\\_eQTL](http://147.8.193.83/ss_eQTL). We believe the ss-eQTLs presented will assist researchers in uncovering the basis of sex-biased gene expression regulation and ultimately help us understand the genetic basis of differences in phenotypes between sexes.

**Factorbook: ENCODE ChIP-seq and DNase-seq data visualizer.** *M. Purcaro, H. Pratt, J. Moore, Z. Weng.* Program in Bioinformatics and Integrative Biology, Department of Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Worcester, Massachusetts 01605, USA.

The goal of the Encyclopedia of DNA Elements (ENCODE) project has been to characterize all the functional elements of the human genome. These elements include expressed transcripts and genomic regions bound by transcription factors (TFs), occupied by nucleosomes, occupied by nucleosomes with modified histones, or hypersensitive to DNase I cleavage, etc. Chromatin Immunoprecipitation (ChIP-seq) is an experimental technique for detecting TF binding in living cells, and the genomic regions bound by TFs are called ChIP-seq peaks. ENCODE has performed and compiled results from tens of thousands of experiments, including ChIP-seq, DNase, RNA-seq, Hi-C, ChIA-PET, and eCLIP-seq. Factorbook is a web-based analysis tool that integrates all public ENCODE ChIP-seq TF, histone, and DNase-seq data. Factorbook is peak-centric, with peak data being summarized and displayed in several different manners. For TFs, aggregation plots display average histone mark signals in a +/-2kb regions centered on TF peak summits. Nucleosome profiles show the effect of TF binding on the location of nucleosomes using MNase-seq data, and peaks are similarly split into proximal and distal by TSS distance. For all ChIP-seq experiments, we performed de novo motif discovery using the MEME-ChIP software suite. Discovery is performed on 100-basepair regions centered on the summits of the top 500 ChIP-seq peaks as determined by signal rank; up to five motifs are discovered for each set of 500 regions. Motifs are assessed for quality using the FIMO tool from the MEME software suite; motifs not meeting both an FDR threshold and an occurrence threshold are considered to have failed quality assessment and are grayed out on final display. Using kmedoid clustering, we have also grouped motifs together to produce averaged motifs. These averaged motifs are indexed to allow a full-text search for motifs of interest, and clicking on an individual motif provides a list of the most similar motifs discovered in other experiments.

**1422F**

**Prioritizing phenome-wide associations using epigenome fine-mapping.** *M.D. Ritchie<sup>1,2</sup>, A. Verma<sup>1,2</sup>, Y. Zhang<sup>3</sup>.* 1) Biomedical and Translational Informatics, Geisinger Health System, State College, PA; 2) The Huck Institutes of the Life Sciences, The Pennsylvania State University, University Park, PA; 3) Department of Statistics, The Pennsylvania State University, University Park, Pennsylvania 16802, USA.

Phenome-wide association studies enable us to investigate genetic associations across many complex human diseases. However, it is still challenging to prioritize associations with genetic variants in high linkage disequilibrium (LD) and ultimately identify causal variants from association studies. Genetic impact of the variants has been addressed by using the predicted effect of variants from tools like Variant Effect Predictor (VEP), SNPeff, PolyPhen or functional annotation of non-coding regions from Roadmap Epigenome. But, such approaches are limited to answer the functional implication of the variants and tissue-specific effect on gene expression. Here we propose a method to prioritize genetic associations within LD haplotype blocks by using epigenetic functional annotations and gene expression data simultaneously. We used a 20-chromatin state model generated by the IDEAS method in 127 Epigenomes within 200 base pair window of a genomic region. We overlaid the SNP coordinates with Epigenome regions and annotated SNPs with the predicted chromatin state. We also utilized RNA-seq data on 56 Epigenomes provided by Roadmap Epigenome Consortium. We calculated the correlation between the chromatin state in 200 base pair windows and RPKM measures from 56 Epigenomes for each gene. We then used the correlation metric ( $r^2$ ) to prioritize association results within LD haplotype blocks for each phenotype/trait. The correlation measure suggests the effect of chromatin state on gene expression and hence the impact of variants within that 200 base pair window. Using chromatin state, we can infer functional consequence of the variants mapping to those states, and the correlation metric takes us one step further to narrow down the variants potentially impacting gene regulation. Our approach is broadly applicable to many genome and phenome-wide association studies to prioritize genetic associations in a high-throughput manner.

**New statistical tools to simulate, analyze, and assess the performance of CRISPR regulatory screens.** *G. McVicker, P. Fiaux, H. Chen, I. Luthra, C. O'Connor.* Salk Institute for Biological Studies, La Jolla, CA.

CRISPR regulatory screens are a powerful new approach for the systematic identification of functional regulatory sequences in the human genome. In a regulatory screen, single guide RNAs (sgRNAs) are designed to target potential regulatory sequences of target genes for mutation, silencing, or activation. Cells that express sgRNAs are sorted into low- and high-expression pools, such that cells containing sgRNAs that reduce the target gene's expression are more likely to end up in the low-expression pool. After sorting, the sgRNAs in each pool are sequenced and the differences in sgRNA frequencies between pools are analyzed to identify putative regulatory regions. Several analysis methods have been used to analyze screening data, however the performance of these methods has not been rigorously assessed, mainly because there is no test dataset with known regulatory and non-regulatory sequences. To address these limitations, we have developed a generative model that can be used to simulate data from CRISPR regulatory screens under a variety of realistic experimental conditions. We have used this simulation framework to generate screening datasets and to assess the performance of existing methods. In general, while we find that ranked statistics from existing methods perform well (the top hits are usually true positives), the p-values are poorly calibrated and it is unclear what threshold should be used to consider a putative regulatory sequence 'significant'. We are using the results from this simulation framework to guide experimental design and to develop new analysis methods with informative p-values. In addition, we have conducted our own regulatory screen for sequences that regulate the gene *GATA3* in the Jurkat T cell line using a paired-guide design that tiles deletions over a 2MB region surrounding the target gene.

**1424T**

**CRISPinator: A web-based sgRNA design tool that accounts for post-transcriptional influences on protein translation.** *Y. Yeu<sup>1</sup>, R. Tuladhar<sup>2</sup>, J.R. Clemenceau<sup>1</sup>, J.T. Piazza<sup>2</sup>, L. Lum<sup>2</sup>, T. Hwang<sup>1</sup>.* 1) Dept. of Quantitative Health Sciences, Cleveland Clinic, Cleveland, OH; 2) Dept. of Cell Biology, University of Texas Southwestern Medical Center, Dallas, TX.

The CRISPR/CAS9 genome editing tool has transformed our approach to gene interrogation and genomic medicine. Targeting of Cas9 to specific genomic sequences is achieved by a single-guide RNA (sgRNA) that pairs with a complementary DNA sequence preceding a protospacer adjacent motif. Whereas much effort has been devoted to the development of computational approaches for minimizing the off-targeting activities of sgRNAs, a systematic approach to predicting perturbations in DNA-encoded epigenetic regulatory mechanism that contribute to CRISPR/Cas9 induced changes in protein translation is lacking. Here we have developed a web-based tool called CRISPinator that not only provides off-target predictions for sgRNAs but also anticipates their propensity for generating foreign proteins either as a consequence of compromising mRNA splicing elements found within exonic sequences (Exon Splicing Enhancers) or altering the coding frame of pseudo mRNAs. We discuss the power and limitations of CRISPinator for gene deletion and rescue campaigns.

**Pioneering an efficient migration of 10,000 whole genomes: Catching up with the latest human genome assembly.** S. Graf<sup>1,2,3</sup>, M. Haimel<sup>1,2,3</sup>, B. Tolhuis<sup>4</sup>, T. Karten<sup>4</sup>, O. Shamardina<sup>1,3</sup>, C. Penkett<sup>1,3</sup>, K. Stirrups<sup>1,3</sup>, F.L. Raymond<sup>1,5</sup>, W. Ouwehand<sup>1,3</sup>, J. Karten<sup>4</sup>, *NIHR BioResource - Rare Diseases (NIHRBR-RD) consortium.* 1) NIHR BioResource - Rare Diseases, Cambridge University Hospitals, Cambridge Biomedical Campus, Cambridge, United Kingdom; 2) Department of Medicine, University of Cambridge, Cambridge, United Kingdom; 3) Department of Haematology, University of Cambridge, Cambridge, United Kingdom; 4) GENALICE B.V., Harderwijk, The Netherlands; 5) Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom.

It has been three years since the Genome Reference Consortium (GRC) released the latest version of the Human genome assembly GRCh38. Many large scale genome sequencing projects, however, still work with the even older version from 2009 as reference to base their analysis on, due to computationally intensive short read alignment and variant calling approaches. The NIHRBR-RD study has sequenced over 10,000 subjects diagnosed with rare diseases since 2013 using Illumina's 100bp, 125bp and 150bp read length PCR free whole genome sequencing (WGS) biochemistry at 30x on average. In order to evaluate potential gains by moving onto GRCh38 we selected 1036 samples for a pilot study to assess factors including read length bias, samples sequenced in duplicate or triplicate, parent-offspring trios, carriers of known disease causing variants, and unexplained cases. To assess differences between GRCh37 and GRCh38 we deployed the Genallice monolithic secondary analysis suite to align WGS data from 1036 samples and call aggregated variants for each reference. We determined the robustness of the migration process by looking at compute and storage footprints, quality of alignments and variant calls, and identification of known causative variants. The short reads from binary alignment/map (BAM) files are aligned to the respective reference genome and stored in Genallice Aligned Read (GAR) format. On average, alignment takes 17 minutes and variant calling 3 minutes per sample. The size of a GAR file is 5% of the original BAM. Compared to GRCh37 0.25% more reads are mapped. The Population Calling module aggregates variants into a random access Genallice Variant Map (GVM), from which one compressed 57 GB multi-sample VCF file is exported. The number of unique autosomal variants increases from GRCh37 to GRCh38 by 8.8% for SNPs and by 1.5% for INDELS. All 426 disease causing variants previously identified in rare disease patients were recovered with both GRCh37 and GRCh38. We assessed the quality of variants using common (Ts/Tv ratio, INDEL length distribution) and population specific (Hardy-Weinberg equilibrium) metrics, which are in keeping with other large scale sequencing projects like GnomAD for GRCh37. When extrapolating to 10,000 samples, as the process scales linearly, the realignment to GRCh38 and variant calling is estimated to take only 2 weeks while reducing the storage requirements and maintaining alignment and variant calling quality.

**1426W**

**Finding associated variants in genome-wide associations studies on multiple traits.** L. Gai<sup>1</sup>, E. Eskin<sup>1,2</sup>. 1) Computer Science, UCLA, Los Angeles, CA; 2) Human Genetics, UCLA, Los Angeles, CA.

Many variants identified by genome-wide association studies (GWAS) have been found to affect multiple traits, either directly or through shared pathways. There is currently a wealth of GWAS data collected in numerous phenotypes, and analyzing multiple traits at once can increase power to detect shared variant effects. However, the vast majority of studies consider one trait at a time. Studies that do analyze multiple traits are typically limited to sets of traits already believed to share a genetic basis. Traditional meta-analysis methods for combining studies are designed for use on studies in the same trait. When applied to dissimilar studies, meta-analysis methods can be underpowered compared to univariate analysis. This is major limitation as the degree to which a pair of traits share effects is often not known. Here we present a flexible method for finding associated variants from GWAS summary statistics for multiple traits. Our method estimates the degree of shared variant effects between traits from the data. Using simulations, we show that our method properly controls the false positive rate and increases power at varying degrees of relatedness between traits. We then apply our method to real datasets in a wide variety of disease and medically relevant traits.

**1427T**

**A map of highly constrained coding regions in the human genome.** *J. Havrilla, B. Pedersen, R. Layer, A. Quinlan.* Department of Human Genetics, University of Utah, Salt Lake City, UT.

Interspecies sequence conservation summarizes the degree of genetic constraint over vast evolutionary periods. In contrast, catalogs of genetic variation from thousands of exomes and genomes enable the inference of more recent constraint from extreme paucities of genetic variation. While existing techniques such as pLI and RVIS summarize constraint for entire genes, it is clear that single metrics do not capture the variability in constraint that exists with each protein coding gene. Therefore, to address this limitation, we have devised a linear model to identify significantly constrained regions across the entire protein coding exome by leveraging the deep resource of genetic variation observed among 60,706 exomes in the Exome Aggregation Consortium (ExAC). Constrained coding regions (CCRs) arise when the observed distance between missense variants in ExAC — a proxy for constraint — is much greater than expected by chance. We demonstrate that our most constrained coding regions are significantly enriched for variants that are pathogenic for autosomal dominant disease, de novo mutations underlying developmental delay, and genes that are predicted to be essential in humans. As a proof of principle, we have also validated on a benign set constructed from the 123,136 exomes in ExAC v2 that are not present in ExAC v1, since ClinVar benign variants are mostly found in ExAC v1. CCRs are also found in many genes known to be associated with severe phenotypes and important cellular function. Moreover, in our studies of 15 infants afflicted with early infantile epileptic encephalopathy, the causal de novo mutation lies within CCRs ranking above the 95th percentile. Therefore, CCRs facilitate the prioritization of genetic variants underlying autosomal dominant disease and, perhaps more importantly, enable the identification of previously unknown coding regions that are likely to have fitness consequences if mutated.

**1428F**

**VIVA: A collaboration tool for processing, storing, exploring, and sharing of next generation sequencing (NGS) data.** *M. Kohram, P.J. Dexheimer, N.A. Felicelli, C.D. Van Horn, P. Komaravolu, S.D. Huitger, J.M. Hendershot, P. Maleki, G. Labilloy, J. Chen, A.M. Rupert, P.S. White.* Cincinnati Children's Hospital, Cincinnati, OH.

Whole exome and genome sequencing projects generate large quantities of data that require organized storage, versioning, filtering and annotating. Genomic research groups often design custom workflows to accommodate particular NGS data analysis needs that lack interoperability standards for data re-use and sharing. We have developed an application suite (VIVA) that has been deployed across a complex academic healthcare environment to provide an institutional variant data commons for NGS data. VIVA seamlessly integrates file storage, metadata, and a variant query tool with a web-based front-end that allows for easy information retrieval. VIVA's backend is designed using a microservice architecture with services communicating through RESTful APIs. A central API integrates all services, exposing a public RESTful API to the outside world. VIVA has been containerized using Docker and a custom deployment utility allows for fast and simple deployment of the application. The web interface of VIVA enables biologists and clinicians without any computer science background to upload FASTQ files and launch an automated workflow for uniform processing of sequence projects. Variant calling in VIVA uses the standard GATK HaplotypeCaller pipeline, and variants are annotated with the Ensembl Variant Effect Predictor tool and dbNSFP annotations. Workflows are automatically launched directly from NGS data outputs at local sequence providers. Results are managed in a variant knowledgebase that provides a facile user interface for variant search and exploration. VIVA allows grouping of samples together by project, phenotype, or any other user specified metadata. A robust permission structure supports assignment of user level permissions to make samples available to a subset of researchers or to a public share so that all users may have access. A primary goal of VIVA is to encourage collaboration among researchers who may benefit from discovering shared interest in a particular gene or variant. To accomplish this, VIVA allows researchers to form collaboration groups to share subsets of their project data or specific queries with others. Each member of the collaboration may contribute all or a portion of their data for the entire collaboration group to see. Future work will enable VIVA to recommend collaborations to users based on query results and variants of interest.

**How low can you go? Recommendations for ultra-low input RNA-seq.** E.A. Tsai<sup>1</sup>, P. Cullen<sup>1</sup>, M. Mingueneau<sup>2</sup>, H. Li<sup>1</sup>, W. Chen<sup>1</sup>, D. Sangurdekar<sup>1</sup>, N. Allaire<sup>1</sup>. 1) Computational Biology and Genomics, Biogen, Cambridge, MA; 2) Neuroimmunology, Acute Neurology and Pain, Biogen, Cambridge, MA.

RNA-seq is a common tool for identifying differentially expressed genes (DEGs) across biological conditions. Due to quantity requirements, RNA is often extracted from whole tissue rather than sorted primary cells. Cell type heterogeneity in tissue-derived RNA could mask underlying gene expression changes, so we turn to low input protocols to enable profiling of specific cell populations. However, amplification bias from increased PCR cycles in these protocols may impair the ability to detect low or moderately expressed DEGs. We designed a standardization experiment to investigate the properties of low input RNA-seq and used the results to set guidelines for library preparation, quality control thresholds, and data analysis. The transcriptomic signature of low input RNA-seq has been reported,<sup>1</sup> but its effects when sequencing primary tissue and on the DEGs identified has yet to be explored. We sequenced 4 replicates of RNA stock standards, Stratagene Universal Human Reference RNA and Ambion Human Brain Reference Total RNA. As a reference, standard input RNA sequencing experiment was prepared using Illumina TruSeq v2 Kit with 500ng of RNA. The ultra-low RNA input experiments were prepared using Clontech SMART-Seq v4 Kit with 10ng, 1ng, 100pg, and 10pg of RNA, spanning the recommended range of detection. We generated ~50 million 150bp PE reads per sample on Illumina HiSeq 2500. We used STAR, RSEM, and DESeq2 to align, quantify, and identify DEGs. We compared the calculated fold changes for each input quantity against those identified by qPCR (n=821).<sup>2</sup> The Spearman correlation coefficient  $\rho$  was 0.82, 0.85, 0.84, 0.79, and 0.65 for 500ng, 10ng, 1ng, 100pg, and 10pg, respectively. With the exception for 10pg, the fold changes correlated well with qPCR validated genes ( $p < 10^{-15}$ ). Applying standard thresholds for DEGs, sensitivity was similar across kits (50-60%), with 10ng having least sensitivity. False positive rates for 10ng (11%), 1ng (11%), and 100pg (14%) were lower than the rate for TruSeq (19%) and at 25% for 10pg. The number of unique splice junctions detected is significantly less ( $p < 0.05$ ) at 100pg and 10pg. While DEGs are detected at similar sensitivity between normal input and low input quantities greater than 100pg, more work is needed to understand the effects of low input sequencing on other properties of the transcriptome including isoform detection. <sup>1</sup>Bhargava et al., *S. Sci. Rep.* 4, 3678 (2014). <sup>2</sup>MAQC-III Consortium, *Nat. Biotech.* 24, 1151 (2006).

**Impact of polygenic risk on changes in biomarkers over time due to lifestyle intervention and aging.** M. Conomos, J.C. Lovejoy, A.T. Magis. Arivale Inc., Seattle, WA.

It is well known that polygenic scores created by aggregating the effects of hundreds or thousands of genetic variants across the entire genome are often correlated with measurements of quantitative traits or disease risk in a cross-sectional population. However, associations of polygenic scores with changes in phenotypes in response to lifestyle intervention or with aging have been less well studied. In order to investigate such longitudinal associations, we utilized a cohort of over 2000 individuals enrolled in a lifestyle intervention program (Arivale, Seattle, WA), for whom WGS data was collected. In addition, clinical biomarkers, including laboratory tests and protein levels, were measured from blood multiple times over the course of at least one year. We identified associations of changes in body mass index (BMI), HDL cholesterol, LDL cholesterol, and triglycerides with corresponding polygenic scores constructed using association data available from previously published meta-analyses of GWAS. The differential changes in these biomarkers implies that individuals with higher polygenic risk may not only be more likely to have unhealthy levels at a specific time point, but may also have more difficulty improving those levels following lifestyle intervention. Additionally, we identified interaction effects indicating different relationships between clinical biomarkers and age at different levels of polygenic disease risk. For example, we identified multiple proteins for which the relationship with age is perturbed among individuals at higher polygenic risk for Alzheimer's disease. These results suggest that increased polygenic disease risk may also disrupt the changes in certain phenotypes that correspond with healthy aging.

**1431F****Small RNA-Seq workflow in Strand NGS: Detection of novel small RNAs.**

H.K. Adil, S. Ramachandrala. Strand Life Sciences Pvt. Ltd, Bangalore, Karnataka, India.

Single cell sequencing techniques are being commonly applied for studying DNA and RNA. A research group designed Small-seq, a method for sequencing small RNAs from single cells and employed it for studying hESCs (naive and prime human embryonic stem cells) and HEK (human embryonic kidney cells). We reanalyzed this data set (GSE81287) using the Small RNA Seq analysis workflow in Strand NGS software. Raw data from GSE81287 was imported into Strand NGS and aligned to human hg19 reference with readily compiled small RNA gene annotations comprising of miRNA annotations from miRBase, tRNA from tRNAscan-SE, and snoRNA, snRNA and piRNA from Ensembl gene model. Adaptors were trimmed and unique small RNA molecules were found by collapsing UMI (Unique Molecular Identifiers) families. Upon quantification, expression profiles of known miRNAs matched with those reported by the authors. Sample correlation indicated that the cells within a cell type group showed consistent expression patterns. We could also distinguish between naive and primed cell types based on expression profiles, indicating the potential of many miRNAs and some snoRNAs as cell type biomarkers. Target genes of active miRNAs were identified. Gene Ontology and Pathway analysis of the target genes indicated a role for miRNAs of naive hESCs in maintenance of pluripotency. In addition, using the novel small RNA detection algorithm in Strand NGS, we identified a large number of novel small RNA regions in hESCs. This algorithm clusters reads and these clusters are categorized as novel and known regions using annotations. These known regions are used to build a decision tree classification model. Each novel region is ascribed a gene type using this classification model. We observed that miRNAs were the most abundant in novel category followed by snoRNAs and tRNAs. In some of the cells, novel small RNAs constituted as high as 70% of the sequenced molecules. This helped us in understanding the complexity of the small RNA transcriptome in hESCs and highlighted how most of this remains uncharacterized. We intend to showcase the bioinformatics utility of novel small RNA detection capability of Strand NGS apart from its ability to handle end-to-end analysis of large scale single cell small RNA sequencing data.

**1432W****Estimating the impact of allele specific expression on detecting genetic associations.** J. Dannemiller. Psychology Dept., Rice University, Houston, TX.

In allele specific expression (ASE), the two coding alleles of a gene are expressed at significantly different rates. ASE is thought to result from a regulatory variant in *cis* with the coding variant that alters the transcription rates of the two coding alleles resulting in a fold factor that can deviate from the expected value of 1. Valle et al. (2008) showed that the fold factors between two differentially expressed coding alleles in the gene *TGFBR1* varied substantially across a sample of 138 patients ranging from approximately 1:2 to 4:1. This variation in the transcription rates of the two *coding* alleles has the potential to alter the apparent strength of the association between the coding genotype and a downstream phenotype by adding unexplained phenotypic variance. This will happen *if the regulatory variant is unknown or is not in strong LD with the coding locus*. To estimate the impact of ASE on the percentage of downstream phenotypic variance explained (PVE) by a simple bi-allelic coding SNP (A/G), we used Gillespie's (1976) method to simulate the transcription/translation of this coding SNP combined with bootstrap sampling of fold factors from the distribution in Valle et al. (2008). A simple downstream phenotype was constructed that depended both on the relative biological activities (G:A, 1.10:1.0) and on the amounts of the two proteins at steady state produced the two alleles. Additional Gaussian *phenotypic* noise was injected to further modulate the strength of the simulated association. 1200 mono-allelic steady-state protein levels (each averaged across 200 isogenic cells) were simulated for each of the four haplotypes: CA, CG, TA, TG. From these 4800 simulated protein levels, the required diplotypes were obtained again using bootstrap sampling, and 1200 phenotypes were computed per experiment. The major results with low LD were: 1) undetected ASE significantly reduced the PVE by the coding genotype, 2) the PVE with ASE seldom rose above approximately 3%-4% even when the coding SNP explained as much as 60% of the phenotypic variance in the absence of ASE. Paradoxically, ASE with strong LD enhanced the coding genotype signal in the phenotypic variance probably because ASE was assumed to operate by *multiplicatively* altering the transcription rates of the two alleles. These results point to the many ways in which *cis*-regulated differential expression of two alleles can either obscure or enhance the genotypic signal in the phenotypic variance.

**Unsupervised pattern discovery in noncoding variants enables identify their potential functional consequences.** *H. Yang<sup>1,2</sup>, R. Chen<sup>1,2</sup>, Q. Wang<sup>1,2</sup>, Q. Wei<sup>1,2</sup>, Y. Ji<sup>1,2</sup>, X. Zhong<sup>2,3</sup>, B. Li<sup>1,2</sup>.* 1) Department of Molecular Physiology & Biophysics, Vanderbilt University, Nashville, Tennessee, United States of America; 2) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, Tennessee, United States of America, Center for Quantitative Sciences, Vanderbilt University, Nashville, Tennessee, United States of America; 3) Department of Medicine, Vanderbilt University Medical Center, Nashville, Tennessee, United States of America.

Comprehensive catalogue of genetics variants which predispose disease risk is key to advancing the understanding disease pathogenesis and drug treatment. Given the complexity of genome non-coding regions, the catalogue of disease causal variants is far from complete yet. Increasing evidence shows that the regulatory function of causal variants is correlated with diverse functional annotations. In this study, we aim to leverage various biochemical and evolutionary evidence to measure the functional impact of non-coding variants through an integrative framework. Specifically, we integrated a total of 887 functional annotations including histone modifications, CTCF marks, DNase, CAGE peaks, super-enhancer regions, transcription start sites (TSS) distance, CpG island marks, chromatin interactions regions and conservation scores and developed a Bayesian framework based on graph model to identify functional variants in an unsupervised fashion. uVAR captures the inherent functional patterns of non-coding variants and constructs the joint distribution to assess the predictive power of functional variants through complex and correlated annotation data. With a purely data-driven perspective, uVAR automatically reveals five distinct patterns which are drastically different from the known functional elements. Leveraging the new insight of the non-coding region revealed in our framework, we developed a new scoring method to assess the functional impact of non-coding variants. We show that uVAR outperforms other state-of-the-art methods on classification of clinically significant SNPs, fine-mapped disease SNPs, eQTLs and experimentally verified SNPs in reporter assays. Note that the joint distribution was learned without distinguish between SNPs and indels, and we also illustrate that uVAR displayed a remarkable ability to handle non-coding indels. In addition, we further integrated other clustering information learned from known functional elements into our approach and achieved further improved performance. Finally, we applied uVAR to all variants in the 1000 Genomes Project data and made the functional prediction publicly available through our website: <https://medschool.vanderbilt.edu/cgg/>.

**Ultra-sensitive profiling of eukaryotic and viral communities residing inside and outside the human body across 300 individuals and 1736 built environments.** *N. LaPierre<sup>1</sup>, S. Mangul<sup>1</sup>, I. Mandric<sup>3</sup>, N. Wu<sup>4</sup>, D. Koslicki<sup>5</sup>, E. Eskin<sup>1,2</sup>.* 1) Computer Science Department, University of California, Los Angeles, Los Angeles, CA; 2) Human Genetics Department, University of California, Los Angeles, Los Angeles, CA; 3) Computer Science Department, Georgia State University, Atlanta, Georgia; 4) The Scripps Research Institute, La Jolla, California; 5) Mathematics Department, Oregon State University, Corvallis, Oregon.

High throughput sequencing has spurred the development of metagenomics, which involves the direct analysis of microbial communities in various environments such as soil, ocean water, and the human body. However, most existing methods use marker genes or k-mers, which do not make use of the maximum possible amount of reads and thus limit sensitivity. Additionally, most work in metagenomics has focused on bacteria and archaea, neglecting to identify other key microbes such as viruses and eukaryotes. Here we present a method, MiCoP, that uses fast-mapping of reads to a comprehensive reference database of full genomes from all types of microbes to achieve maximum read usage and enable the analysis of the virome and eukaryome in each sample. We show that our method is accurate on simulated data and uses a much higher portion of the reads and identifies many more species than previously-reported results on real datasets from the Human Microbiome Project and the MetaSUB consortium.

**1435W****Investigations of unmapped reads from human exome sequencing.** *R. Sood<sup>1</sup>, S. Ennis<sup>2</sup>, J. Gibson<sup>1</sup>.*

1) Faculty of Natural and Environmental Sciences, University of Southampton, Southampton, Hampshire, SO17 1BJ, United Kingdom; 2) Human Genetics & Genomic Medicine, Faculty of Medicine, University of Southampton, Duthie Building (MP 808), Tremona Road, Southampton, SO16 6YD, United Kingdom.

Up to 10% of reads, per sample, in sequencing studies do not map to the intended reference genome. 'Unmapped reads' are usually discarded and not analysed. In this study we analysed unmapped paired-end reads from human exome sequencing of 245 Inflammatory Bowel Disease (IBD) patients and 113 non-IBD 'control' samples. We aimed to determine if these reads originate from regions of the genome which are under-mapped, and if so if they contain clinically important genes. Secondly we aimed to reveal if these reads represent other organisms, which show a different profile of organisms in IBD versus non-IBD samples. Exome data (Agilent Sureselect 51/60Mb V4/5/6) was mapped using BWA (v0.7.12) to the hg38 human reference. Unmapped reads were extracted and filtered by a PHRED score >20 where both reads of the pair were unmapped. Reads were then mapped with BLAST (v2.6.0) against NCBI databases for viruses, plants, fungi, bacteria, mammals and humans, taking the best match per read. Unmapped reads were mapped to the human database only, taking the best match, and annotated with GENCODE v24 genes. Matches were processed using MEGAN6. Classification of reads at kingdom and species levels do not show differences in clustering between case and control samples using PCA analysis. Few fungal or viral reads were found, though sequencing control phiX174 was found in 196 samples, comprising ≥50% unmapped reads. Bacterial reads were detected in 323 samples, top species were commensal, associated with the oral and upper respiratory tract. The greatest percentage of plant matches were in the case group, where plant species were ≥50% of unmapped reads in 42 samples. Most common matches were to *G. hirsutum* and *A. thaliana*. For 61 samples ≥ 50% of unmapped reads matched metazoan, in particular primates such as *P. troglodytes*, likely due to high sequence similarity with *H. sapiens*. Mapping only to the human database matched on average 9% of reads, reflecting 136 genes. 306 samples (total 69,448 reads) matched to the gene *CABIN1*, involved in T-cell receptor signal transduction. Two genes linked with IBD, *TJP1* and *AKT3* had 157 and 96 samples with matches respectively, but few reads per sample. No reads mapped to any gene identified by ACMG as important for clinical reporting. Results show few differences when comparing kingdoms between case and controls, though more plant matches were observed in cases. Matches to human may highlight regions of the genome which are problematic for mapping.

**1436T****High-speed mosaicism detection for agnostic genome-wide detection, using the DGX-1 array processor on an NHGRI website for the genetic community.** *T. Markello<sup>1</sup>, M.G. Gordon<sup>1</sup>, F. Gu<sup>1</sup>, V.L. Arthur<sup>2</sup>, M.J. Ombrello<sup>2</sup>, J. MacDowall<sup>1</sup>, W.A. Gahl<sup>1</sup>, B. Pusey<sup>1</sup>.*

1) Med Gen Branch, NIH Office of the Clinical Director, NHGRI, and NIH Undiagnosed Diseases Network and Program, NIH, Bethesda MD /NHGRI, Bethesda, MD; 2) Translational Genetics and Genomics Unit Institution: National Institute of Arthritis and Musculoskeletal and Skin Diseases.

Mosaicism, in DNA extracted from a sample of multiple cells taken from a single individual, is known to be associated with a variety of human diseases and is expected to contribute to undiagnosed disease complexity. Kolmogorov-Smirnov goodness of fit regression of cumulative distribution functions, and Circulatory Binary Segmentation methods, have both been published for detection and quantification of mosaicism. Here we describe how the first method was re-coded into a vector-graphic method that runs efficiently even at the limit of low quality signal/noise seen in some samples that could be used for genome wide agnostic detection of mosaicism. The code has been optimized to run on 8 high performance GPU processors (NVIDIA's Tesla V100) integrated in a single NVIDIA DGX-1 server. It is capable of analyzing SNP chip data at the rate of ≈500-900 samples per day. Four large sets of SNP data (2 public GWAS and two private) comprising over 5000 samples total, were run in preliminary testing. Those data were manually cross checked for false positive and false negative detections. For three of the data sets, the system detected mosaicism in 1/500 samples. For the UDN data set of 950 samples, it detected a rate of 1/200, suggesting an enrichment for mosaicism in this cohort. To share this resource, an outward facing website was constructed to allow investigators to submit data in the form of b-allele and log R ratio formats and receive a report for the positions, size and degree of mosaicism for their samples. We hope it will aid in the ability of smaller groups to automatically scan for mosaicism in SNP data, and we are working to extend this to sequencing data with sufficient read depths.

**1437F**

**A survey of genetic variant frequency in 220,000 Han Chinese individuals.** Z. Huang<sup>1</sup>, N. Rustagi<sup>1</sup>, F. Tian<sup>2</sup>, J. Li<sup>1</sup>, X. Ge<sup>1</sup>, F. Xia<sup>1</sup>, Y. Zhang<sup>2</sup>, K. Wang<sup>2</sup>, H. Lin<sup>3</sup>, Y. Gao<sup>2</sup>, D. Zhou<sup>2</sup>, F. Yu<sup>1,2</sup>. 1) Molecular and Human Genetics Department, Baylor College of Medicine, Houston, TX 77054; 2) Berry Genomics, Beijing, 100015, China; 3) Aliyun Computing, Hangzhou, 310099, China.

Large scale sequencing projects have been aggregated (such as in ExAC and gnomAD) to provide the frequency of genetic variants in multiple populations, which plays a vital role in the prediction of variant pathogenicity and selection of mutation panel for carrier screening. We explored an alternative approach to survey the frequency of genetic variants in millions of humans interrogated already using Non-Invasive Prenatal Testing (NIPT). As a proof of concept, we accrued 214,277 NIPT samples of Han Chinese population sequenced with 36 base pair single-end short reads. The average sequencing coverage is 0.05x and 97% of covered region is covered by only one read. The ultra-low sequencing coverage and short read length impose serious challenges for the estimation of frequency of high fidelity variants. We addressed the challenge of high fidelity calling with a read-level machine learning based variant caller, significantly reducing sample level false discovery rate from 74% in the raw sequencing data to 3% while maintaining the sample level sensitivity of 67%. Overall we called 25.8 million SNPs (transition-to-transversion ratio of 2.72). In coding region, 4.05% of SNPs discovered in our NIPT data set are novel to ExAC, and 3.89% are novel to gnomAD (all populations). We developed a statistical estimator of allele frequency with error estimated from sequencing coverage variation. The allele frequency estimated using our method is in concordance with the allele frequency of East Asian populations (EAS) in ExAC and gnomAD, and the allele frequency error linearly correlates with the allele frequency difference between our data set and ExAC. Our method unveiled the power of ultra-low coverage sequencing with unprecedented large sample size and high fidelity results. The unique summary data generated using our method provides an independent survey of SNP allele frequencies in Han Chinese population down to  $f \sim 0.01\%$ , offering an important reference resource for population specific carrier allele frequencies.

**1438W**

**PheWeb: Do-it-yourself PheWAS.** P. VandeHaar<sup>1</sup>, S.A. Gagliano<sup>1</sup>, C. Clark<sup>1</sup>, E. Schmidt<sup>1</sup>, M. Flickinger<sup>1</sup>, L.G. Fritsche<sup>2</sup>, G.R. Abecasis<sup>1</sup>. 1) Center for Statistical Genetics, University of Michigan, Ann Arbor, MI; 2) K.G. Jebsen Center for Genetic Epidemiology, Department of Public Health and Nursing, NTNU, Norwegian University of Science and Technology, Trondheim, Norway.

To allow intuitive browsing, comparison and interpretation of continuously growing publicly-available genetic association results across a wide range of complex traits we developed a free online tool, PheWeb. We aggregated GWAS summary statistics across over 100 traits into the first public release of PheWeb. We implemented a wide range of interactive visualizations, including Manhattan, QQ, PheWAS and regional LocusZoom plots. All variants tested for association with a GWAS are visualized in an interactive Manhattan plot, which is accompanied by a QQ plot displaying genomic control inflation factors stratified by allele frequency. Users can dive into particular regions of interest with LocusZoom and explore nearby genes with various genomic annotations. For each variant, we provide a PheWAS plot that displays its association summary statistics across all available traits. For each gene, we provide the traits that show significant associations with variants within the gene, and the region is visualized in a LocusZoom-like view. To confirm known associations or to discover novel signals, an analyst can search PheWeb by gene, variant identifier, or trait. PheWeb is available at [pheweb.sph.umich.edu](http://pheweb.sph.umich.edu). We are continuously expanding the available collection of summary statistics to aid in the discovery of novel findings. Additionally, we provide an easy and well-documented procedure to set up a fully functional PheWeb browser for private in-house datasets.

**A novel method of phenotype similarities of rare-disease patients using gene-pathway-phenotype relationships.** S. Ogishima, S. Nagai. Tohoku Medical Megabank Organization, Tohoku University, Sendai-shi, Miyagi, Japan.

Precision medicine is precisely stratified medicine. Precision medicine aims at provision of the best available medicine for each patient based on stratification into disease subclasses with common genetic and phenotypic factors of disease (Robinson, 2012). The precise stratification of patients into disease subclasses requires precise measures of genetic and phenotypic factors. As for genetic factors, many measurements of sequence similarities have been proposed before, which are supported by the theory of molecular evolution. On the other hand, as for phenotypic factors, Resnik, Jiang and Pesquita have proposed phenotypic similarities with considering semantic relationships in an ontology [Resnik 1995; Jiang and Conrath 1997, Pesquita et al. 2007], which can be applied for calculation of patient similarity. In this study, we proposed a novel method of phenotype similarities of rare-disease patients using gene-pathway-phenotype relationships which take into account the structure of the ontology and the specificity of each term. We then evaluated our methods on simulated phenotype data of rare-disease patients with phenotypic noise and imprecision, and compared our method with 13 measures including the PhenoDigm measure [Smedley et al. 2013] and the simGIC measure [Pesquita et al. 2007].

**1440F**

**PQC: A phenotype checking and tracking tool.** N.W. Rayner<sup>1,2,3</sup>, M.I. McCarthy<sup>1,2,4</sup>. 1) Wellcome Trust Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom; 2) Oxford Centre for Diabetes, Endocrinology and Metabolism, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom; 3) Department of Human Genetics, Wellcome Trust Sanger Institute, Wellcome Genome Campus, Hinxton, United Kingdom; 4) Oxford NIHR Biomedical Research Centre, Oxford University Hospitals Trust, Oxford, United Kingdom.

Genetic studies have traditionally focussed on a single disease and collected only the directly relevant phenotypes, yielding small easily verifiable phenotype data sets. With the rapid growth in the size of genome wide association studies and the use of Electronic Health Records (EHRs) the number of phenotype data points has increased dramatically. The requirement for these to be validated still remains; however the number of data points can now run into the billions, orders of magnitude too large for an individual to check. To address this issue we have developed a Perl program to automatically summarise phenotype files of any size. The program requires only a tab delimited text file. From this it automatically attempts to determine whether the phenotype contains numeric, text, mixed or coded values and a summary is produced based on this determination. If there are <20 unique entries or <0.1% of the total (whichever is the greater) then the field is treated as a coded set of variables and the numbers of each are summarised; otherwise the total number of missing and non-missing entries is reported. For fields identified as a continuous numeric phenotype, e.g. height or weight, the program reports the mean, median, standard deviation (S.D.) and lists the samples greater than 3 S.D.s from the mean. These simple text summaries provide an overview of the data and have allowed us to detect otherwise hard to find errors, such as swapped characters, e.g. O with 0, erroneous values and multiple missing values. The program also produces histograms for all numeric phenotypes, both coded and continuous, providing an additional, visual, verification of the distribution of the data. In addition, the program can track changes between phenotype releases by generating a per-sample and per-phenotype "fingerprint", using the number of missing, numeric, text and coded entries and the total number of entries. These fingerprints are then compared to ascertain whether a sample or a phenotype entry has been changed. The program has been developed to process very large files without requiring extensive compute resources; to date we have used the program on a UK biobank data set consisting of 12,000 phenotype entries and 500,000 individuals. The program is able to summarise and plot all 6 billion entries in <22 hours using a single processor in a workstation. The program is freely available to download and will work on any Unix based system.

**Recombination rate estimation in large-scale genetic data.** *S. Choi, P.F. O'Reilly.* MRC Centre for SGDP, King's College London, London, United Kingdom.

Knowledge of recombination rates across the genome is critical in the study of human genetics, given the impact of recombination in local linkage disequilibrium (LD) structure, its association with genome instability and the potential role of recombination in selection and speciation. Recombination rates can be estimated through sperm typing, pedigree analysis, and can also be inferred based on patterns of LD. LD-based statistical methods, such as LDhat, have the advantage over sperm typing and pedigree analyses that a fine-scale map of recombination rates can be estimated across the entire human genome. With the recent availability of very large-scale genetic data, an improved map of recombination rates may be achieved by applying LD-based methods. However, most of the current methods, including LDhat, are computationally intensive, and thus may be infeasible for estimating recombination rates in biobank scale genetic data, eg. hundreds of thousands of samples. Thus, there is a need for the development of novel methods tailored to the estimation of recombination rates in large-scale genetic data. We investigate the performance of a new algorithm to estimate fine-scale recombination rates via simulations of genetic data with more than 100k individuals. When applied to large sample sizes, the method has sufficient power to provide an accurate fine-scale map of recombination rate of the human genome. An improved map of recombination rate may lead to a better understanding of local LD structure, more accurate inference of structural variants such as inversion polymorphisms, and enable powerful investigation of potential associations between recombination rates and disease susceptibility loci. .

**1442T**

**Automated abstraction of phenotypes from electronic health records facilitates genetic diagnosis.** *K. Wang<sup>1</sup>, J. Son<sup>1</sup>, C. Yuan<sup>1</sup>, N. Stong<sup>1</sup>, L.E. Bier<sup>1</sup>, L. Wang<sup>2</sup>, F. Shen<sup>2</sup>, E.E. Groopman<sup>1</sup>, K. Kiryluk<sup>1</sup>, A.G. Gharavi<sup>1</sup>, H. Liu<sup>2</sup>, D.B. Goldstein<sup>1</sup>, W.K. Chung<sup>1</sup>, C. Weng<sup>1</sup>.* 1) Columbia University, New York, NY; 2) Mayo Clinic, Rochester, MN.

Electronic health records (EHRs) capture rich fine-grained longitudinal phenotypic manifestations of various disorders. Integration of such phenotypic data and knowledge on genotype-phenotype relationships promises to enable high-throughput phenotype-driven diagnosis of genetic diseases. However, how to best extract phenotypes from noisy and heterogeneous EHR data remains a major challenge. Here we developed EHR-Phenolyzer, a novel high-throughput EHR phenotype extraction and analysis pipeline. EHR-Phenolyzer first applies a biomedical concept extraction system called MetaMap followed by heuristic concept filtering to extract relevant phenotype terms from clinical genetic notes and normalize them using Human Phenotype Ontology (HPO) terms. It then feeds these HPO terms into Phenolyzer, a published tool to prioritize candidate genes based on phenotypic manifestations. In the context of clinical exome sequencing, this list of top candidate genes can potentially increase diagnostic yield and decrease analysis time. We assessed EHR-Phenolyzer on 28 pediatric rare disease cases with confirmed genetic diagnoses. First, an experienced physician performed manual chart review on clinicians' notes (written before any genetic test) and summarized relevant phenotype terms. On average, 8 terms were used per patient. Analysis of these expert-compiled terms using Phenolyzer ranked causal genes among the top 50 genes for 12/28 cases, far more than expected by chance ( $p < 2.2e-16$ ), supporting the effectiveness of Phenolyzer for gene prioritization in diagnostic analysis. Next, we applied EHR-Phenolyzer to automate the above process and generated ~20 terms per patient on average. In 16/28 cases, the causal gene was ranked among top 50 genes, supporting that this automated approach is likewise effective. To assess the generalizability of our method, we replicated this finding on several independent EHR datasets from other studies or other institutions. Finally, we propose a disease prediction framework that infers patients with potential genetic syndromes directly from EHR data. This EHR-based method will help clinical geneticists in making key decisions, such as whether to order a genetic test and if so, which modality to use (such as clinical microarrays, clinical exomes, or repeat expansion testing). In summary, EHR-Phenolyzer enables comprehensive utilization of the phenotypic information within EHRs, facilitating the implementation of genomic medicine.

Harrison<sup>2</sup>, R. Patel<sup>3</sup>, P. Pawliczek<sup>3</sup>, E. Rooney Riggs<sup>4</sup>, B. Seifert<sup>4</sup>, N. Strande<sup>5</sup>, R. Ghosh<sup>5</sup>, J. Berg<sup>5</sup>, C. Martin<sup>5</sup>, S. Plon<sup>5</sup>, H. Rehm<sup>5</sup>, C. Bustamante<sup>1</sup>, J.M. Cherry<sup>1</sup>, Clinical Genome Resource (ClinGen).* 1) Stanford University, School of Medicine, Stanford, CA; 2) Laboratory for Molecular Medicine, Partners Healthcare Personalized Medicine, Cambridge, MA; 3) Baylor College of Medicine, Houston, TX; 4) Geisinger Health System, Danville, PA; 5) University of North Carolina at Chapel Hill, NC.

At the core of ClinGen's (clinicalgenome.org) mission is the accurate, consistent curation of the clinical relevance of genes and variants to inform precision medicine and research. Additionally, ClinGen seeks to share its Clinical Validity Classification framework for gene curation and the tools built to support both this and the ACMG/AMP Guidelines for variant interpretation with the broader community, as well as to promote access to shared evidence. Guided by the above objectives, ClinGen's Gene and Variant Curation Interfaces (GCI and VCI) provide access to evidence from a wide variety of genomics resources as well as evidence curated manually from multiple sources. These sources include literature, research labs, clinics, and clinicians. All evidence is accessible to any registered user, allowing all users to view and evaluate the same set of information. In keeping with the principle of shared evidence, the interfaces promote curation by all curators in a guided, standardized manner according to the ClinGen curation frameworks. The VCI programmatically aggregates external data representing multiple evidence types from many existing genomic resources, thereby providing users with efficient, one-stop-shop access to specified, up-to-date data. It achieves this by querying multiple APIs (Application Program Interfaces) as soon as a user enters a unique variant ID and dynamically displaying all returned data for that variant. These external service APIs include those from dedicated data sources such as ClinVar, the ClinGen Allele Registry (CAR), and OMIM, and from aggregating data services such as MyVariant.info, MyGene.info, the Variant Effect Predictor, and the Ontology Lookup Service. The requirement of a unique variant identifier (ClinVar VariationID or CAR ID) representing a canonical allele insures the accurate collection of transcript, population, and *in silico* predictive data for the desired allele. This use of APIs for the aggregation of evidence in the VCI represents a modern approach that eliminates the need for storing and continually updating externally derived evidence in the curation database itself. Combined with shared manually curated evidence, it allows the ClinGen interfaces to provide a vehicle for the consistent, standardized curation of genes and variants with respect to disease for all users. Both interfaces are currently in production (curation.clinicalgenome.org) with continued development focused on new features and data types.

**Effects of filtration on imputation in clusterised variants.** *C.M. Charon<sup>1</sup>, R.S. Allodji<sup>2</sup>, J.F. Deleuze<sup>1</sup>.* 1) CNRGH/CNG, CEA Paris-Saclay Institut Francois Jacob, Evry, Essonne, France; 2) Institut Gustave Roussy, Biostatistics and epidemiology, Unit 1018 INSERM, France.

The standards based on the same principles of filtration are commonly used for genome-wide association studies and imputations. To investigate the effect of imputation with and without pre-filtration of SNP followed by post-filtration on the variants imputed at a conservative and less stringent threshold, we categorised them in different classes. We used 1,031 individuals from diverse ethnicities and compared also their allele frequencies with the 1,089 NCBI recorded individuals, within a 2Mb of chr20 dbSNPB37.p13, after curation of the variants database. Only the markers removed during quality control (QC) and absent from the reference genome were not imputed, with shapeit 2 and impute 2. Hence, to maintain genotyped variants the pre-filtration could be less stringent, but no significant differences in that number was observed between the imputation prior and after pre-filtration of SNP. High correlation between frequencies minor alleles generated after imputation were found between both conditions. We didn't find any significative differences between the frequencies, except within the range of very rare and rare variants. However, the magnitude of those differences were small and became non significative under the hypothesis testing their true mean differences  $m = 1.85E-05$ . There was a slight loss of information after QC. The presence of low quality genotyped variants prior to imputation did not impair neither their imputation quality that showed maximum, nor the imputation of the remaining good quality SNP. When an indel and polymorphism were present at the same locus, there was dual imputation. Variants with no repository names, with position for sole identifier produced unreliable maf. Null allele were detected in NCBI database, by comparison with the imputed variants, and vice et versa, NCBI showed records while many null alleles would be imputed. We also considered as unreliable, SNP with null allele frequencies in both the imputed results and the NCBI dbSNP B37.p13, having very poor quality scores. An addition of 0.5 in the post-filtration imputation score stringency from 0.3 to 0.8 lead to a decrease in the number of SNV  $< 0.01$  maf by 1.8 fold, in both conditions with and without prior QC filtration, and by a 2.5 fold in the number of SNV  $< 0.001$  maf and lowered by half the number of very rare variants ( $< 5E-04$ ). With an average maf  $> 0.01$ , a standard threshold, showed a mean score  $> 0.8$  whether QC was performed or not.

**Modeling and analysis of RNA structures.** Z. Ouyang. The Jackson Laboratory for Genomic Medicine, Farmington, CT.

Determining the structures of RNAs is key to understanding their functions. RNA structure regulates almost all aspects of RNA metabolism. Moreover, structural dysregulation of RNAs contributes to the etiology of various diseases. Ultra high-throughput sequencing technologies are revolutionizing the study of RNA structures of the whole transcriptome (named RNA structure). However, the modeling and analysis of RNA structures remain challenging due to the complexity of such data sets. We have developed a statistical framework for studying RNA structures. It models high-throughput enzymatic and chemical probing data and generates RNA structural information at single-nucleotide resolution. Genome-wide RNA structural information facilitates the understanding of the structure and function of the genome.

**Development and validation of computational approaches for GWAS-informed target gene identification.** S.K. McFarland<sup>1,2</sup>, J.C. Ulirsch<sup>1,2</sup>, S.K. Nandakumar<sup>1,2</sup>, L.M. Mateyka<sup>1,2</sup>, V.G. Sankaran<sup>1,2</sup>. 1) Boston Children's Hospital, Boston, MA; 2) Broad Institute, Cambridge, MA.

In recent years, functional screens using both short hairpin RNAs (shRNAs) and CRISPR/Cas9 genome editing have become increasingly common for gaining insight into a variety of biological phenomena. In particular, such functional perturbation approaches hold considerable promise for uncovering the underlying biology in genome-wide association studies (GWAS), as well as other human genetic studies. Indeed, a major challenge in GWAS follow up has been in the identification and validation of target genes underlying diseases or traits of interest. However, analytic approaches for such functional screens have not been comprehensively evaluated and the results obtained from these approaches can vary considerably. Using a high-throughput shRNA screen in primary human hematopoietic cells focused on the interrogation of loci associated with red blood cell traits as a test set, we benchmark a number of established approaches, including MAGeCK, MAGeCK MLE, and PheLiM. Each of these methods has unique strengths, but also notable limitations, to account for in the analysis of GWAS-based functional screens. Particular to this study, MAGeCK MLE's employment of a design matrix robustly leverages the longitudinal time course information of the screen, and PheLiM's sequence-based approach extends our ability to dissect phenotypic contributions beyond the annotations denoted for each shRNA. However, a number of shortcomings also become apparent, including difficulty accounting for off-target effects, dealing with non-random panel design, and accommodating the integration of a priori controls. Building upon these observations, we have developed and utilized a linear mixed model approach that seeks to incorporate these advantages while minimizing the noted shortcomings, providing a robust framework to optimize the selection of candidate genes that appear enriched for orthogonal metrics of causality. We demonstrate how utilization of this linear mixed model approach allows us to confidently identify candidate gene targets underlying the majority of tested loci in our screen. Our results also demonstrate the broader value of this computational approach for analysis of a variety of large functional genomic datasets.

**OASIS: Omics Analysis, Search and Information System for biological discovery in whole-genome sequence and trans-omics datasets.** *J.A. Perry, K.A. Ryan, B.D. Mitchell, J.R. O'Connell.* Program for Personalized and Genomic Medicine and Division of Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore, MD, 21201, USA.

**Background:** The volume of omics data is virtually exploding. New technologies are providing thousands of whole genomes as well as transcriptomes, methylomes, proteomes and metabolomes. Computers are running nonstop to find associations with hundreds of phenotypes in our quest to understand biology and conquer disease. But how are we to sort through this overwhelming volume of data? How will we quickly translate all this information into knowledge? **Objective:** The key to enabling and accelerating discovery is to effectively deliver new information to biological researchers in a way that directly connects with their thought processes. Effective delivery requires data visualization, a broad spectrum of annotation, and real-time, supplemental analysis for fine-mapping, conditional analysis, and exploring the LD structure. An integrated analysis and search system will enable researchers to quickly follow targeted research questions, generate new hypotheses, and accelerate the discovery process. **Method:** To demonstrate this concept, an Omics Analysis, Search and Information System (OASIS) was populated with annotated GWAS results generated with the MMAP software using phenotypes from 11 studies of the Old Order Amish and 3 genotype platforms including TOPMed WGS, Illumina Exome BeadChip, and 1000 Genomes imputed dosages using the Affymetrix GeneChip 6.0. OASIS was constructed using HTML/JavaScript for form-based user input, a MySQL database, and Perl/CGI scripts all running on a Linux/Apache webserver. Real-time analysis is achieved with system calls to MMAP for conditional, multi-covariate, and SKAT analysis. Visualizations include boxplots & histograms plus LocusZoom & Haploview for LD exploration. Links by variant/gene are provided to NCBI (dbSNP, Gene, Variation Viewer), Broad (HaploReg, GTEx) and WashU (Roadmap) along with annotation from Annovar and WGS. **Result:** 1.4 billion association results with  $p < 0.05$  from 27 million genotypes are searchable in OASIS. Phenotypes include 1200 traits from different Amish research studies (e.g. Calcification, Osteoporosis, Diabetes, Longevity, Wellness), 200 traits from metabolomics datasets and expression levels for 15,000 RNA-Seq transcripts. Researchers can easily search for associations by any combination of trait, gene(s), genomic region(s), rsid(s), p-value, effect size, allele frequency. Boxplots quickly show effect sizes. Real-time supplemental analysis options address follow up questions and new hypotheses.

**1448T**

**Leveraging genomic data for Bayesian analysis of high-throughput regulatory functionalization assays.** *A. Ghazi, C. Shaw.* Baylor College of Medicine, Houston, TX.

The 1000 Genomes project estimates that a typical genome has around 500,000 genetic variants over-lapping known regulatory regions. Moreover, genome-wide association studies continue to identify large numbers of non-coding variants associated with a wide variety of phenotypes and disease states. Because of the prevalence of this type of human variation, functional analysis of variation in the non-coding and regulatory genome is a central challenge. The Massively Parallel Reporter Assay (MPRA) provides a high-throughput experimental method for measuring the transcriptional effects of genetic variants through the use of next generation sequencing. Despite its promise, MPRA exhibits high noise while simultaneously suffering a heavy statistical burden from multiple testing corrections, thus yielding an estimated sensitivity of roughly 20% in recent publications. In order to provide a higher sensitivity to resolve the variant-modulated transcriptional landscape, this research aims to leverage genomic data from projects like ENCODE to formulate a Bayesian statistical framework for MPRA data. Under this approach, the external data sources are used as prior knowledge that define variant similarity metrics that are used to formulate an informative empirical Bayesian prior on variant effects. Preliminary analysis of publicly available MPRA data show substantial agreement with traditional frequentist methods on variants with large effect sizes and an increased detection rate among variants with lower magnitude effects. Large numbers of new candidates are also identified by this new approach. These results are being validated by testing a subset of the putatively functional variants across a spectrum of effect sizes using gold-standard luciferase assay functionalization. Overall the method presents an important contribution to data integration and to improve the power and methodology employed for MPRA studies.

**Integrating functional genomics knowledge to construct comprehensive models for complex traits and translational studies.** *B. Li, A. Frase<sup>2</sup>, M.D. Ritchie.* 1) The Huck Institutes of the Life Sciences, The Pennsylvania State University, University Park, PA; 2) Biomedical and Translational Informatics Institute, Geisinger Health System, Danville, PA.

Rapidly advancing technologies provide the opportunity of using a plethora of omics data to study complex traits, which are likely the outcome of the interplay among biological variations at different regulation levels. However, due to the lack of integrative annotation, mechanistic studies of complex traits remain limited to one single type of omics data at a time. Thus, to help construct a thorough and comprehensive genetic model behind complex traits, we propose a more comprehensive functional unit that more precisely reveals interactions between different levels of biological features. To address this issue, we have developed "omic units" and "omic modules". The omic units are the collection of identifiers to define a single gene. We use two major databases, Ensembl and Entrez Gene, as the core for gene identifiers and expand this to other types of relating identifiers, including exon, transcript, gene symbol, protein, and so on. On the other hand, omic modules describe how each omic unit is regulated by functional elements and how it interacts with other omic units. This is achieved by integrating functional regions and regulatory interactions into the LOKI database developed by our lab. Along the way of building omic units and modules, there are several obstacles to be overcome, such as resolving discrepancy and redundancy between databases of the same and different types of data. For omic units, the discrepancy was found in cross-references provided by Ensembl and Entrez where Ensembl genes link to multiple Entrez genes and vice versa. This is caused by the differences in the way each database records gene information. Currently, by improving the omic unit algorithm, we were able to successfully reduce the number of annotation discrepancies to a few hundred Entrez/Ensembl genes. As for omic modules, we compared annotation coverage on GWAS Catalog variants given by different databases or methods, including VISTA, FANTOM5, TargetFinder, and IDEAS. We found that these databases of similar types of data had little redundancy and annotation achieved the greatest coverage on GWAS Catalog variants when all databases and methods were used. Though in its early stage, we expect omic modules will be of great value to help construct thorough and comprehensive models behind complex disease.

**Custom targeted design workflow for next generation sequencing.** *B. Marosy, D. Mohr, A. Scott, K. Doheny.* Johns Hopkins Genomics, Center for Inherited Disease Research, IGM, Johns Hopkins University - School of Medicine, Baltimore, MD.

Genome Wide Association (GWA) and linkage studies that identify a chromosomal region(s) may require additional follow-up sequencing in order to find a causal variant(s) that contributes to the genetic trait. Targeted sequencing is a powerful tool for querying regions of interest in large sample cohorts at high depth for relatively low cost compared to whole exome or whole genome sequencing. However inefficient design of custom probes across regions of homology and repetitive elements can cause a decrease in the selection metrics which lead to increased sequencing costs, rendering custom capture as an expensive option. By utilizing a rigorous design workflow, these challenges can be addressed prior to manufacturing of a custom product, aiding in reducing unforeseen sequencing costs. Here we have developed a workflow for designing custom targeted panels and present cases where improved sequencing conditions were met. Using the UCSC genome browser, genes and genomic elements of interest are identified for inclusion in the design. GALAXY provides tools to extract exons, add flanks, merge or subtract regions and calculate base coverage. Probes are designed across regions of interest in a tiered fashion, reducing stringency parameters for each subsequent pass of uncovered target regions not covered by a probe in a previous pass. Sequences of the probes from each pass are analyzed using BLAT to identify any potentially problematic probes that will affect selection due to homology. Threshold settings within BLAT can be varied according to the project needs, scaling the stringency of the analysis to either increase coverage or balance sequencing costs. Application of BLAT analysis can improve sequencing selection metrics by >20%. Depending on the capture size, this could prevent as much as 50% of added sequencing costs due to inefficient design.

**1451T**

**RNASeqFPro, a full processing pipeline for RNA-Seq differential gene expression analysis.** *M. Pjanic<sup>1,2</sup>, C. Miller<sup>2</sup>, T. Quertermous<sup>1,2</sup>.* 1) Division of Cardiovascular Medicine, Stanford University, Stanford, California, United States of America; 2) Cardiovascular Institute, Stanford University, Stanford, California, United States of America.

RNA-Seq gene expression analysis comprises multiple steps, including quality control, mapping, read counting and differential expression (DE) analysis. Here we present a pipeline for automated RNA-Seq DE analysis based on top isoform selection. RNASeqFPro is a combined bash/R pipeline that automates the process of RNA-Seq DE analysis. It is designed so that fastq files placed in a working folder are the only prerequisite for running, in addition to installing dependencies and providing a meta information file. RNASeqFPro can perform analysis on paired-end or single-read RNA-Seq data for mouse mm10 and human hg19 genomes. RNASeqFPro sorts and pairs fastq files, then, performs FastQC quality control, and maps fastq files to the reference genomes using STAR second pass mapping. It uses feature-Counts to perform read summarization on the GENCODE mouse or human transcript collection. It calls fileMulti2TableMod1, an awk script we developed to generate the mastertable and writes an R script to select the top transcript and convert GENCODE to RefSeq identifiers using biomaRt. Finally, it writes an R script and performs DESeq analysis of differential gene expression, creates output tables and generates graph outputs using GO term annotations and goseq package. For the human genome it also calls RGSEPD script that will generate multiple graphical outputs using GO annotation. We also created two pipeline versions that use Kallisto for fast pseudo-alignment of the reads to the GENCODE transcripts that dramatically reduced processing time. Both STAR and Kallisto versions of RNASeqFPro are based on the transcription noise model and selection of the top expressed transcript for differential gene expression (DGE) analysis, therefore considering other transcripts rising from the same locus as transcriptional noise not contributing to the effective gene expression level. RNASeqFPro is a DGE pipeline, based on the selection of main transcript isoforms to minimize statistical influences of the transcriptional noise. RNASeqFPro performs all steps in RNA-Seq gene expression analyses in a sequential manner, and thus significantly saving time in script preparation for each individual run. RNASeqFPro should be useful for researchers with less computational experience as it requires a single executing command.

**1452F**

**Drug side effects and adverse events are predicted by genetics of their intended targets.** *P.A. Nguyen, A. Deaton, P. Nioi, L.D. Ward.* Amgen Inc, Cambridge, MA.

Human genetics is a powerful tool to mitigate drug discovery risks. To increase the likelihood of efficacy, it has been proposed that genes associated with the clinical indication should be nominated as drug targets. Historical precedence supports this concept: target-indication pairs with genetic evidence have been shown to be more likely to progress to later phases of development and to get approved (Nelson et al., Nat Genet, 2015). Target safety is another important risk driver, as clinical and non-clinical toxicity are the major reasons for drug failure (Waring et al., Nat Rev Drug Disc, 2015). We propose that genes with causal variants associated with adverse event phenotypes not related to the indication should not be pursued as drug targets, in order to avoid potential toxicities in clinical trials. To test this concept, here we performed a retrospective analysis on historical drug development data to evaluate the power of human genetics of intended targets in predicting drug toxicities. We applied a machine learning approach, using multivariate logistic regression with LASSO regularization, to predict drug side effects and adverse events from the genetics of their intended targets, while controlling for drug indication, modality, and delivery route. For marketed or withdrawn drugs, side effects were obtained from drug labels (SIDER) and physicians' reports (OFFSIDES/FAERS). For drugs that have been in clinical development, adverse events were obtained from clinical trials (Cortellis Clinical and Drug Design APIs). Drug-target and target-genetic phenotype associations were obtained from public and commercial sources. We built two sets of models: (1) predicting side effect profiles of marketed drugs (N=934) and (2) predicting the adverse events seen during clinical development of drugs (N=4639). Both sets of models showed that genetic associations (GWAS and Mendelian) with an organ system predicted side effects and adverse events within that organ system for 9/21 and 13/21 organ systems tested, respectively. Furthermore, absence of genetic phenotypes was predictive of the lack of side effect/adverse event phenotypes for 1/21 and 5/21 organ systems, respectively. The models were most predictive for endocrine system, blood and lymphatic system, and heart disorders. To our knowledge, our study provides the first unbiased and quantitative evidence suggesting that genetics can be used to predict not only efficacy but also safety of drug targets.

**1453W**

**PALMER: A novel pre-masking method for detecting mobile element insertions using long-read sequencing technology.** W. Zhou<sup>1</sup>, S.B. Emery<sup>2</sup>, D.A. Flasch<sup>2</sup>, Y. Wang<sup>2</sup>, K.Y. Kwan<sup>2,3</sup>, J.V. Moran<sup>2,4</sup>, J.M. Kidd<sup>1,2</sup>, R.E. Mills<sup>1,2</sup>. 1) Department of Computational Medicine and Bioinformatics, University of Michigan Medical School, 100 Washtenaw Avenue, Ann Arbor, MI 48109, USA; 2) Department of Human Genetics, University of Michigan Medical School, 1241 East Catherine Street, Ann Arbor, MI 48109, USA; 3) Molecular and Behavioral Neuroscience Institute, University of Michigan Medical School, 109 Zina Pitcher Place, Ann Arbor, MI 48109, USA; 4) Department of Internal Medicine, University of Michigan, 1500 East Medical Center Drive, Ann Arbor, MI 48109, USA.

Mobile genetic elements, including Long Interspersed Element-1 (LINE-1), *Alu*, and SVA retrotransposons, occupy approximately 46% of the human genome and have been shown to play an important role in disease. Several algorithms have been developed to detect mobile element insertions (MEIs) using short-read, next-generation sequencing technologies and have been quite successful at identifying candidate MEIs with a low false discovery rate. However, due to the limitations of aligning short reads to a reference sequence, there is likely an underestimate of MEIs that lie in more complex or repetitive regions of the genome as these sequence reads are typically filtered out using existing computational pipelines. The advent of single-molecule real-time sequencing technology presents an improved long-read sequencing platform to better resolve such difficult regions of the genome and allow for a deeper interrogation for the presence of previously overlooked MEIs. Here, we present a new method naming Pre-mASKing Long reads for Mobile Element insertION (PALMER), which first pre-masks long-read sequences containing known reference MEIs and then searches against a library of MEI sequences to detect non-reference MEIs within the remaining unmasked sequences. Using high coverage (~70x) PacBio whole genome sequencing data of a well-established CEPH pedigree sample, NA12878, we show that PALMER identifies many LINE-1 insertion events, including a number of full-length copies, which have not been reported previously. Comparisons with fosmid paired-end sequencing libraries and other orthogonal data support that the majority of candidates represent *bona fide* MEIs. PALMER is further able to identify characteristic features of MEIs (e.g. short target-site duplications, 3' poly-A homopolymer runs, and 3'-transduction sequences), and can be extended to work with other types of MEIs found in non-human model organisms. This approach should enable a more holistic view of retrotransposon insertions in the human genome and provide additional utility for studies using long-read sequencing technology.

**General validation framework using semi-supervised learning on complex cfDNA clinical assays.** K.R. Haas, K.A. Beauchamp, J. Tratner, K. D'Auria, C. Oyolu, H. Haverly, D. Muzzey. Counsyl Inc., South San Francisco, CA.

**Background** With advancements that enable detection of a greater range and complexity of genetic variation, there are increasing challenges in effectively validating clinical genomic tests and proving their analytical performances. This difficulty is especially conspicuous in the rapidly growing fields of cell-free DNA sequencing, such as noninvasive prenatal screening (NIPS) and circulating-tumor DNA analyses, where one aims to detect miniscule signal from placental or tumor DNA, respectively. In a typical bioinformatics pipeline, a variant is called positive if the confidence score (e.g., z-score, likelihood) exceeds established thresholds, which can vary depending on the type of variant, assay chemistry, and calling algorithm. Tuning this threshold and then evaluating sensitivity and specificity can be difficult (1) when reference samples with consensus genotypes are scarce and (2) when the underlying biology of the assay necessarily causes the signal of positive samples to approach the limits of detection. **Methods** To overcome this challenge, we have developed a Bayesian graphical modeling approach capable of deconvoluting and parameterizing the negative and positive distributions from empirical data of unlabeled samples. One begins by postulating the interrelationship between the latent distributions for variant incidence, allele fraction, and sample classification with the observed confidence score. Inference of the posterior predictive distribution—which assigns probabilistic outcome labels to the previously unlabeled data—is performed using Markov Chain Monte Carlo (MCMC). We then parametrically scan a range of classification thresholds and calculate sensitivity and specificity to construct a ROC curve with confidence intervals given by bootstrap sampling. **Results and Conclusions** We present an illustrative example of how this statistical approach has been leveraged to evaluate major algorithmic enhancements to Counsyl's NIPS using 34,000 random clinical samples, including >500 positives. From the ROC curve, we determined that sensitivity increased significantly, with a ~2x reduction in the false-negative rate, while maintaining 99.9% specificity. Furthermore, we discovered the relationship between sequencing depth, minor allele fraction and confidence score to decipher the limits of detection. This strategy effectively determines analytical performance from a real world collection of test samples for cutting-edge genetic assays.

**Winston: Optimizing parallelized variant calling from large-scale whole genome sequencing data.** *B. Jew, J.H. Sul.* University of California—Los Angeles, Los Angeles, CA.

Recent advancements in sequencing technologies allow the generation of an abundance of genetic information. This data can yield crucial insight into the genetic basis for human diseases and other complex traits through the identification of associated variation. This task is computationally intensive, requiring the use of a multitude of bioinformatics tools that align and process sequencing data before variant calling. Each step can require a significant amount of processing time and resources, introducing issues with scalability and reliability for analyzing large-scale genomic data. Winston, a parallelized variant calling pipeline, utilizes the scalable and efficient approach utilized by Churchill [Kelly et al. *Genome Biology* (2015) 16:6] for fast analysis of sequencing data adhering to GATK best practices. Winston improves upon this regional method by optimizing resource usage, data processing, and robustness for greater efficiency and reliability. While Churchill generates thousands of non-informative and intermediate files and on the order of gigabytes per sample, Winston generates no additional files beyond processed data. The pipeline significantly reduces disk usage and speeds up analysis by avoiding the excessive script and intermediate file generation carried out by Churchill, saving several gigabytes of storage and reducing computational time by roughly five percent per sample. This brings Churchill's analysis of the 1000 genomes dataset on 400 AWS EC2 instances in a week down by nearly half a day while minimizing storage requirements and preventing stalled analysis due to hardware failure. The responsive framework employs a checkpoint and monitor system that detects errors in analysis and availability of resources, rerunning and holding analysis as necessary. This optimized method will allow efficient and accurate discovery of genetic variation in the rapidly growing pool of sequencing data by appropriate utilization of parallel compute resources. The pipeline is currently being used for several large-scale whole genome sequencing projects at UCLA.

**Pipeline for DNA-seq analysis: Streamlining of data processing, quick and accurate variant calling, and annotating variants.** *A. Pal, R. Bet-tadapura, M.W. Saifi, P. Agarwal, S. Ramachandrupa, M. Nagarajan, P. Chitipothu, H.K. Adil, S.C. Cherukuri.* Strand Life Sciences Pvt. Ltd, Bangalore, Karnataka, India.

An ideal DNA-Seq pipeline must (A) identify somatic mutations with high accuracy and reproducibility, eliminating those that are clinically non-relevant and (B) annotate each mutation with its functional consequences. Strand NGS, our flagship NGS tool, contains a best-practices pipeline for somatic whole exome samples. The pipeline comprises alignment, deduplication, local realignment around indels, variant calling and annotation, and structural variant and copy number detection. Each stage in the pipeline has been specifically tuned to detect low frequency point mutations, copy number variations (CNVs), and structural variants (SVs) that occur in a somatic context. Gain of somatic mutations is often the cause for developing drug resistance. Identifying and annotating these mutations are essential in a clinical context, where biological understanding and therapy design are the two major goals. Using our somatic best-practices pipeline, we reanalyzed the whole exome sequencing samples of a drug-resistant basal cell carcinoma (BCC) dataset, GSE58374. As a part of variant calling, low frequency SNPs were detected and annotated with dbSNP. Further, we identified damaging somatic variants, annotating each of them with the COSMIC database and HGVS notation. We also analyzed a 66 sample cohort (GSE58376) of targeted re-sequencing data from untreated and drug-resistant BCC samples. As reported by the authors, we found that *SMO* and/or genes downstream of it in HedgeHog signaling pathway were mutated in all tumor samples. Deletions in *PTCH1* and *TP53* were also found in most tumors. As reported in the re-sequencing study, we found that the resistant tumors had a much higher occurrence of mutations in *PTCH1* and *SMO*. In each of the high coverage samples, the variant support view helped visualize the supporting information at and in the neighborhood of these mutations; the elastic genome browser helped inspect CNVs and SVs spanning thousands of base pairs. Taken together, our visualization tools helped validate the findings in the studies above. The pipelines in Strand NGS while primarily streamlining sequencing data analysis, also aid in easy retrieval, and compact storage. In addition, sequencing data downstream analysis can be performed from multiple omic technologies aided with statistical algorithms, dynamic visualizations, and interpretations, thereby allowing to comprehend the experimental data in a real biological context through pathway analysis.

**A reference haplotype panel for genome-wide imputation of short tandem repeat variants.** S. Saini<sup>1</sup>, M. Gymrek<sup>1,2</sup>. 1) Computer Science and Engineering, University of California, San Diego, San Diego, CA; 2) Department of Medicine, University of California, San Diego, San Diego, CA.

Despite conducting Genome-Wide Association Studies (GWAS) using tens of thousands of individuals, traditional GWAS based on single nucleotide polymorphisms (SNPs) still fail to explain the majority of heritability for many complex traits. One hypothesis for this is that many causal variants are not tagged well by common SNPs. Short Tandem Repeats (STRs) are one of the largest contributors of de novo mutations in humans, are implicated in dozens of Mendelian disorders and are likely to play an important role in complex traits. Next-generation sequencing technologies allow genotyping of complex variant types, including STRs. However, availability of such data is currently limited to at most several thousand samples for a given trait. On the other hand, SNP genotype array data is available for hundreds of thousands of samples. A framework to impute STR genotypes into SNP data would allow testing for STR associations with hundreds of traits across massive sample sizes. However, STR imputation is challenging for several reasons: high STR mutation rates cause lower linkage disequilibrium between STRs and nearby SNPs; and relationships between STR alleles and SNP haplotypes can be complex. Thus, constructing phased reference panels for imputation from unrelated samples has so far remained elusive. Here, we leverage a large sequencing dataset of related individuals along with existing bioinformatics methods to phase STRs onto SNP haplotypes for accurate imputation of STRs into existing SNP datasets. We apply a family based approach to extract SNP-STR haplotypes in 2,000 samples from 500 families sequenced as part of the Simons Simplex Collection. SNPs are jointly genotyped using GATK and phased using Shapelt. STRs are genotyped using HipSTR with phased SNPs as additional input. We tested imputation using our panel at a set of known pathogenic STRs and achieved 70% concordance between true and imputed STRs. These loci are highly polymorphic and thus represent a lower performance bound. Most errors result from rare SNP haplotypes or STR alleles not well represented in the reference panel. Finally, we evaluate genome-wide imputation accuracy using thousands of samples where both SNP haplotypes and STR are available. Overall, this work provides a high quality reference panel of phased STR-SNP haplotypes that will enable imputing STRs into hundreds of thousands of existing SNP datasets.

Rapid development of single cell RNA sequencing techniques have made it easier for researchers to characterize the heterogeneity of cell population and discover new biomarkers for different cell types. Even for those tissues that single cell dissection is not possible, single nucleus RNA sequencing (snRNA-seq) can be applied in a similar way. On the other hand, data analysis of those single cell or nucleus data is extremely challenging, for both technical and biological noisiness, combined with often low amount of RNA expression level. Here, we have developed our computational pipeline that is tailored for single nucleus RNA-seq data. The pipeline will include - Spectral clustering based method for classification of cell population into different sub population, which takes into account of extreme sparseness of expression data, expression biases of nuclei compared to whole cell - Quantitative comparison with publicly available tissue specific gene expression data (Genotype-Tissue Expression = GTEx), to map and compare the identified cell types into known categories - Pseudo temporal path estimation based on tree construction from clusters and investigation of previously known developmental stage-specific marker genes together with standard methods such as Principle Component Analysis (PCA), t-Distributed Stochastic Neighbor Embedding (t-SNE) and differential gene expression analysis. The pipeline will be applied to different in vitro human myotube models, to examine the differentiation efficiency or maturity of each model by characterizing the potentially heterogeneous population of in vitro myotube cell culture. Further, we intend to perform single nucleus RNA-seq and apply this pipeline to human cells with muscle disease (genetically engineered/patients derived) to characterize the transcriptional changes in muscle disease patients in comparison with the cultured myotube models. Combining single nucleus RNA-seq with clustering, differential expression, and pseudo-time reconstruction methods, we aim to deepen our understanding of progression muscle diseases, and ultimately identify novel therapeutic targets.

**Hypertriglyceridemia as a presenting sign of HMG-CoA synthase deficiency.** E. Conboy<sup>1,2</sup>, F. Vairo<sup>2</sup>, K. Agre<sup>1,2</sup>, M. Schultz<sup>2</sup>, R. Ridsdale<sup>3</sup>, D. Deyle<sup>1,2</sup>, D. Oglesbee<sup>2</sup>, E. Klee<sup>2</sup>, B. Lanpher<sup>1,2</sup>. 1) Clinical Genomics, Mayo Clinic, Rochester, MN, USA; 2) Center for Individualized Medicine, Mayo Clinic, Rochester, MN, USA; 3) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN, USA.

We report an 8-month-old patient with decreased consciousness after a febrile episode and reduced oral intake. He was profoundly acidotic but his lactate was normal. Serum triglycerides were markedly elevated and HDL cholesterol was very low. The urine organic acid analysis during the acute episode revealed a complex pattern of relative hypoketotic dicarboxylic aciduria, which was suggestive of a potential fatty acid oxidation disorder, but plasma amino acids and acylcarnitine species were undiagnostic. An MRI showed extensive brain abnormalities concerning for a primary energy deficiency. Whole exome sequencing revealed heterozygotic *HMGCS2* variants, a gene encoding for mitochondrial 3-hydroxy-3-methylglutaryl-CoA (3-hydroxy-3-methylglutaryl-CoA synthase-2 deficiency 3-hydroxy-3-methylglutaryl-CoA 3-hydroxy-3-methylglutaryl-CoA 3-hydroxy-3-methylglutaryl-CoA 3-hydroxy-3-methylglutaryl-CoA HMG-CoA) synthase-2 (*HMGCS2*), which catalyzes the irreversible and rate-limiting reaction of ketogenesis in the mitochondrial matrix. Autosomal recessive *HMGCS2* deficiency is characterized by hypoketotic hypoglycemia, vomiting, lethargy and hepatomegaly after periods of prolonged fasting or illness. *HMGCS2* synthesizes HMG-CoA, a precursor to ketone bodies as well as mevalonate and cholesterol. The biochemical and molecular findings were unexpected as 3-hydroxybutyrate and acetoacetate were present in urine during crisis. A retrospective analysis of the urine organic acid analysis identified putative 4-hydrox-6-methyl-2-pyrone, a recently reported biomarker of *HMGCS2* deficiency. There was also a relative elevation of plasma acetylcarnitine as previously reported in one case. Our patient highlights a unique presentation of *HMGCS2* deficiency caused by novel variants in *HMGCS2*. This is the first report of *HMGCS2* deficiency with a significantly elevated triglyceride level and decreased HDL cholesterol level at presentation. Hence, *HMGCS2* deficiency should be included in the differential diagnosis of individuals with coma induced by fasting or illness, and who present with hypertriglyceridemia, or low HDL cholesterol levels in childhood. Although *HMGCS2* deficiency is a rare disorder with unspecific symptoms, with the advent of next-generation sequencing, and the recognition of novel biochemical biomarkers, the incidence of this condition may become better understood.

**Characterizing NAFLD/NASH drug targets using metabolomics and genetics.** D.M. Waterworth<sup>1</sup>, A. Sahlqvist<sup>2</sup>, J. Freudenberg<sup>1</sup>, D. Rajpal<sup>1</sup>, R.A. Scott<sup>2</sup>, L. Lotta<sup>2</sup>, C. Langenberg<sup>2</sup>, N. Wareham<sup>2</sup>. 1) GlaxoSmithKline, King of Prussia, PA; 2) GlaxoSmithKline, Stevenage, UK; 3) MRC Epidemiology Unit, University of Cambridge, UK.

Non-alcoholic fatty liver disease (NAFLD) is the liver manifestation of the metabolic syndrome and can progress to non-alcoholic steatohepatitis (NASH), a common cause of liver cirrhosis and hepatocellular carcinoma. In order to identify drug targets for NASH we reviewed the literature for genes that have been reported to be associated with NAFLD or NASH. Five genes have been identified by GWAS and an additional six by candidate gene studies where other evidence of disease involvement was available. To date these genes have been characterized mainly using clinical biomarkers (e.g. lipids, glucose, LFTs) and outcomes (diabetes and CVD), but access to metabolomic profiles allows for the opportunity to more deeply understand the role of these proteins in metabolism. We selected 16 NAFLD-associated SNPs from these 11 genes and looked for associated metabolites in up to 7500 subjects from the EPIC-Norfolk study where Metabolon profiles were available, using an FDR threshold of  $\leq 0.1$  to delineate significant associations. Six genes demonstrated significant associations (*TM6SF2*, *MBOAT7*, *PPP1R3B*, *GCKR*, *SOD2* and *TRIB1*). Hierarchical cluster analysis was applied to look for similarities and also variants from 3 genes (*PPP1R3B*, *MBOAT7* and *TM6SF2*) were mapped onto metabolic pathways using MetaCore. *GCKR* variants were highly pleiotropic, *TRIB1* variants were enriched for lipid pathways and the *SOD2* variant was limited to branch chain amino acid pathways. The E167K in *TM6SF2* NAFLD risk allele was associated with higher retinol and lower lysophosphatidylcholine (lysoPC), which has been shown to differentiate between NAFLD with and without insulin resistance. The *MBOAT7* SNPs were associated with lower choline phosphate and phosphoethanolamine (PE). LysoPC and PE are key metabolites in predicting the degree of NASH in NAFLD patients. The NAFLD risk allele for rs4240624 in *PPP1R3B* was associated with higher vitamin A (retinol) and lower sarcosine and glycine. Glycine is known to be correlated with liver fat, and is a rate limiting step in glutathione metabolism, a key detoxifying agent in the liver. It is predicted that higher expression of *PPP1R3B* would result in reduced liver fat, lower circulating lipids and improvements in insulin sensitivity and therefore is a promising target for NAFLD. Thus a targeted analysis of circulating metabolites can provide a window into liver metabolism and help prioritize targets for intervention.

**Elucidation of the complex metabolic profile of cerebrospinal fluid using an untargeted biochemical profiling assay.** L. Hubert<sup>1</sup>, A.D. Kennedy<sup>2</sup>, K.L. Pappan<sup>2</sup>, T.R. Donti<sup>1</sup>, A.M. Evans<sup>2</sup>, J.E. Wulff<sup>2</sup>, L.A.D. Miller<sup>2</sup>, V.R. Sutton<sup>1</sup>, Q. Sun<sup>1</sup>, M.J. Miller<sup>1</sup>, S.H. Elsea<sup>1</sup>. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Metabolon Inc., Durham, NC, USA.

We sought to determine the molecular composition of human cerebrospinal fluid (CSF) and to identify the biochemical pathways represented in CSF to understand the potential for untargeted screening of inborn errors of metabolism (IEMs). Biochemical profiles for each sample were obtained using an integrated metabolomics workflow comprised of four chromatographic techniques followed by mass spectrometry. Secondly, we wanted to compare the biochemical profile of CSF with those of plasma and urine within the integrated mass spectrometric-based metabolomic workflow. Three sample types, CSF (N = 30), urine (N = 40) and EDTA plasma (N = 31), were analyzed from retrospectively collected pediatric cohorts of equivalent age and gender characteristics. We identified 435 biochemicals in CSF representing numerous biological and chemical/structural families. Sixty-three percent (273 of 435) of the biochemicals detected in CSF also were detected in urine and plasma, another 32% (140 of 435) were detected in either plasma or urine, and 5% (22 of 435) were detected only in CSF. Analyses of several metabolites showed agreement between clinically useful assays and the metabolomics approach. An additional set of CSF and plasma samples collected from the same patient revealed correlation between several biochemicals detected in paired samples. Finally, analysis of CSF from several different pediatric cases including gamma-aminobutyrate transaminase, adenylosuccinate lyase (ADSL), dihydropteridine reductase (DHPR) deficiency, and pyridoxine-dependent epilepsy demonstrated the utility of untargeted global metabolic phenotyping as a broad assessment to screen samples from patients with undifferentiated phenotypes. The results indicate a single CSF sample processed with an integrated metabolomics workflow can be used to identify a large breadth of biochemicals that could be useful for identifying disrupted metabolic patterns associated with IEMs.

Gut microbiome composition has been linked to obesity in adults and adolescents, but less is known about its association with rapid weight gain in early childhood – a strong risk factor for obesity later in life. Moreover, connections between oral microbiome and infant weight gain have not, to our knowledge, been explored. Here we studied the relationships among weight gain in early childhood, children's gut and oral microbiomes, and mothers' oral microbiomes, in 226 mother-child dyads. As part of a large study of behavioral interventions on feeding habits, children were followed during the first two years of life -- with weight and length measured at seven time points. We used these data to identify children with rapid weight gain, and to derive growth curves with Functional Data Analysis (FDA) techniques. We also collected oral and gut microbiome samples at the end of the two-year period, and surveyed them with 16S sequencing. Information on diet and other factors was also available for our analysis. We found significant links between weight gain during the first two years of life and the oral microbiome as established by the end of this period. Significantly lower diversity and elevated Firmicutes-to-Bacteroidetes ratio were observed in the oral microbiomes of children with rapid (vs. non-rapid) weight gain, and the abundances of several bacterial taxa showed significant associations with children's growth curves. Also interestingly, the diversities of children's and mothers' oral microbiomes were significantly correlated, suggesting a familial influence. Finally, we found significant associations between diet and children's gut microbiomes but, somewhat surprisingly, not between the latter and weight gain. Our results suggest that, by the age of two years, the oral microbiome may have already established patterns that reflect an association with accelerated weight gain -- in contrast to the gut microbiome, which does not yet harbor the obesity signatures many researchers identified in later life stages.

**Integrative analysis of genome, epigenome and transcriptome data from adipose tissue of obesity in Koreans.** B.-J. Kim, S. Moon, I-U. Koh, N.H. Choi, J.H. Yun, Y.J Kim. Division of Genome Research, Korea National Institute of Health, Cheongju-si, Chungcheongbuk-do, 28159, South Korea.

Obesity is defined as abnormal or excessive fat accumulation, resulting negative effect on health. Interplay of multiple factors such as environmental, behavioral and genetic factors can cause obesity. Nowadays, it is emerging as a major problem in public health. With technological advances of genome-wide association study (GWAS), many risk factors associated with obesity have been identified. However, the vast majority of discovered variants lie in non-coding regions, it is not easy to find the functional relevance between genetic loci and diseases. Recently, owing to recent progress of omics technologies, various analytical approaches to link genome data using epigenome and transcriptome has been studied. Moreover, several integrative studies suggested functional roles of genomic and epigenomic loci. Here, we aimed to find functional relevance between variation and phenotype. To achieve this, we conducted integrative analysis of genome, epigenome and transcriptome data obtained from adipose tissue. Three kinds of omics data were extracted from 65 same individuals (22 case and 43 controls by BMI cutoff point of 25 kgm<sup>2</sup>). We used an Axiome-based customized array named Korea Biobank Array, an Illumina Infinium EPIC 850K, and an Illumina HT-12 V4 for genome, epigenome and transcriptome data, respectively. Regression analysis of case-control samples in genome, epigenome and transcriptome data and integration analysis between these data were performed. From the regression analysis between case-control samples, we confirmed known genetic loci. In addition, we identified 5 differentially methylated regions including on *IL10RA* gene reported in GWAS catalog and 33 differentially expressed gene including obesity related genes such as *LEP*, *AGPAT9*, *APOE* and *CALCRL* genes. Moreover, integrative analysis results showed that gene expressions which are highly correlated with methylated regions were mainly enriched in signal transduction, metabolism, and hemostasis. Our result provides researchers with the comprehensive information to understand genotype and phenotype interactions in obesity.

**RNA sequencing analysis identifies differentially expressed genes in Lymphoblastoid Cell Lines (LCLs) generated from diabetic retinopathy patients.** Y. Cho<sup>1</sup>, H. Choi<sup>1</sup>, K. Lee<sup>2,3</sup>, K. Kang<sup>4</sup>, C. Nho<sup>2,3</sup>. 1) Biomedical Science, Hallym University, Chuncheon, Gangwon-do, South Korea; 2) Convergence Research Center for Smart Farm Solution, Korea Institute of Science and Technology, Gangneung, South Korea; 3) Natural Products Research Center, Korea Institute of Science and Technology, Gangneung, South Korea; 4) Department of Ophthalmology, The Catholic University of Korea Incheon St. Mary's Hospital, Incheon, South Korea.

Diabetic retinopathy (DR) is an ophthalmic complication of diabetes and has a prevalence rate of 14.2% in diabetic patients. Diabetic retinopathy can cause blurred vision and, in severe cases, blindness. The treatment of DR is mainly focused on surgical operations such as laser treatment. However, the development of DR drugs for not only therapeutic but also preventive purposes is necessary in order to reduce medical expenses. In the hope to identify drug targets for DR, we tried to detect differentially expressed genes (DEGs) in DR patients by applying RNA sequencing analysis. In this study, RNA sequencing experiments were performed using 6 samples of lymphoblastoid cell lines (LCLs) (generated from 3 DR patients and 3 normal subjects). After adaptor trimming and removing sequence reads with poor quality (Q < 30) by Trim Galore program (version 0.4.2), TopHat and Bowtie programs were employed to map RNA reads to human reference genome hg38. The number of genes expressed in the cells were counted by HTseq algorithm and DEGs were estimated by DESeq2 program. A total of 43 genes were identified as DEGs that fulfill our selection criteria (adjusted P-value < 0.01 & fold change > 4). To understand the functional role of up- or down-regulated genes in DR cells, we carried out the KEGG pathway analysis and Gene Ontology analysis through DAVID database. In addition, up-regulated or down-regulated genes in the significant KEGG pathways were adopted to generate protein-protein interaction networks using the GeneMANIA module in Cytoscape program. In this presentation, we will discuss and interpret the potential biological roles of these DEGs in the DR development based on the results from these analyses.

**Optimizing simultaneous isolation of biomolecules and cells from cryopreserved adipose tissue for omics applications.** E.C. Lawrence<sup>1</sup>, S.L. Rosenthal<sup>1</sup>, M.A. Schusterman II<sup>2</sup>, L.E. Koka<sup>2</sup>, J.P. Rubin<sup>2</sup>, E.E. Kershaw<sup>3</sup>, Z. Urban<sup>1</sup>. 1) Human Genetics, University of Pittsburgh, Pittsburgh, PA; 2) Plastic Surgery, University of Pittsburgh, Pittsburgh, PA; 3) Medicine, Division of Endocrinology and Metabolism, University of Pittsburgh, PA.

Adipose tissue is notoriously problematic for biomolecule isolation given its high lipid and low protein content. Obesity is a global epidemic and affects an array of comorbidities, thus defining its molecular basis is necessary. Parallel sets of genome, transcriptome and proteome data can provide insight into these mechanisms in an inclusive and targeted fashion. The goal of this study was to compare 11 current simultaneous extraction methods for such comprehensive downstream omics analyses of adipose tissue. We used adipose tissue collected from panniculectomy (n=6) in triplicates with 20-100 mg of input tissue according to the manufacturer's protocol (kits) or established published protocols (Trizol). DNA and RNA concentrations and quality was assessed using UV spectrophotometry. Protein concentration was measured using the Bradford assay. Following these experiments, we determined that the Trizol-based method performed the best, particularly with respect to RNA quality ( $OD_{260/280}=1.6-2.0$ ), although all methods tended to yield variable amounts of DNA, RNA, and protein for extractions from immediate and stored samples. We then sought to identify ideal storage conditions for biomolecules extracted using the Trizol method: whole tissue stored in Qiagen's RNALater solution or homogenized tissue stored in Trizol reagent. We also hoped to improve quality with column purification for DNA and RNA. Preliminary results (n=1) suggest on-column purification improves quality for RNA (RNALater, mean  $OD_{260/280}=2.00$ , Trizol, mean  $OD_{260/280}=2.22$ ), but not for DNA (RNALater,  $OD_{260/280}=4.24$ , Trizol, mean  $OD_{260/280}=14.01$ ). Additionally, we are assessing the viability of cells isolated from cryopreserved lipoaspirates. To this end, we have collected 4 g of tissue in 0.2 M trehalose with 0.5 M DMSO and stored samples at either -80°C or in liquid nitrogen. At present, we have successfully isolated and cultured cells stored in trehalose < 5 days from both storage conditions. Our results corroborate previous studies indicating variability among quality and quantity of biomolecules extracted using existing simultaneous methods. Considerable within-subject variability exists, likely due to difficulty in obtaining precise amounts of tissue and heterogeneity in the tissue composition. While this study is ongoing, we have demonstrated that existing protocols require modification to optimize the consistency, purity and yield of biomolecules and cells from adipose tissue.

**1465W**

**Loss of function variant in *NFKB1* causes autoimmune lymphoproliferative syndrome-like disease.** F. Vairo<sup>1,5</sup>, M.M. Patnaik<sup>2</sup>, N.K. Shenoy<sup>2</sup>, P.N. Pichurin<sup>3</sup>, J.L. Kemppainen<sup>3</sup>, M.J. Smith<sup>4</sup>, W. Ranatunga<sup>4</sup>, R.S. Abraham<sup>4</sup>, E.W. Klee<sup>1,3,5</sup>. 1) Center for Individualized Medicine, Mayo Clinic, Rochester, MN; 2) Department of Hematology, Mayo Clinic, Rochester, MN; 3) Department of Clinical Genomics, Mayo Clinic, Rochester, MN; 4) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 5) Department of Health Sciences Research, Mayo Clinic, Rochester, MN.

Autoimmune lymphoproliferative syndrome (ALPS) is a primary immunodeficiency (PID), characterized by immune dysregulation. Mutations in genes such as *FAS*, *FASLG*, *FADD*, *CASP8*, *CASP10*, *NRAS*, and *KRAS* are usually associated with an ALPS or ALPS-like phenotype. Approximately 30% of patients with an ALPS-like phenotype (lymphadenopathy (LAD) +/- splenomegaly and autoimmune (AI) cytopenias) do not have a confirmed genetic defect. The presence of LAD and AI cytopenias does not necessarily support an underlying diagnosis of ALPS, as other PID conditions could also be associated with this phenotype, including CTLA4 haploinsufficiency, or *STAT3* gain-of-function variants. Whole exome sequencing (WES) is an approach utilized in diagnostic odyssey cases to identify the underlying genetic cause for disease. Here, we report on a male patient who first presented at 20 years of age with idiopathic thrombocytopenic purpura (ITP). Family history was notable for several maternal relatives, including his mother, who had evidence of splenomegaly and ITP. He later developed neutropenia, axillary cellulitis, recurrent sore throat, cervical and mediastinal lymphadenopathy and Coombs positive hemolytic anemia. Flow cytometry for double-negative T cells (DNT; CD3+CD4-CD8-, TCRab+) revealed an expansion in the DNT clone, with these cells expressing B220+. This result suggested a diagnosis of ALPS, and targeted NGS was performed for *CASP8*, *CASP10*, *FADD*, *FAS*, *FASLG*, *ITK*, *KRAS*, *MAGT1*, and *NRAS*, which were negative. Evaluation for other relevant genes associated with AI and LAD, such as *CTLA4*, *PIK3R1* and *LRBA* were also negative. Given the ALPS-like clinical phenotype and negative targeted gene panels, WES was performed on the proband and his parents. An inherited heterozygous loss-of-function novel variant in *NFKB1* (p.Ser237\*) was identified as one of the top candidate variants. *NFKB1* mutations have been reported with an autosomal dominant form of common variable immunodeficiency (CVID) with variable clinical phenotypes. The B cell phenotyping of this patient revealed normal isotype class-switching and memory B cells, but there was a significant increase in transitional (T1) B cells. Protein modeling indicates that heterodimer formation of p50 and p65 subunits of NFκB is affected, which suggests that there may not be normal nuclear translocation or downstream signaling. Additional functional and protein simulation studies are underway to characterize this novel *NFKB1* variant.

**Novel human T cell receptor variable gene alleles revealed by long-amplicon TCR $\beta$  repertoire sequencing with Ion Torrent.** *T. Looney<sup>1</sup>, A. Glavin<sup>1</sup>, S. Pabla<sup>2</sup>, S. Glenn<sup>2</sup>, L. Miller<sup>2</sup>, D. Topacio-Hall<sup>2</sup>, E. Linch<sup>2</sup>, A. Pankov<sup>2</sup>, A. Zheng<sup>1</sup>, J. Conroy<sup>2</sup>, C. Morrison<sup>2</sup>, G. Lowman<sup>2</sup>, M. Andersen<sup>2</sup>, F. Hyland<sup>1</sup>.* 1) Thermo Fisher Scientific, South San Francisco, CA; 2) Thermo Fisher Scientific, Carlsbad, CA; 3) OmniSeq, Inc., Buffalo, NY.

**Background** Human T cell antigen receptors play a critical role in protective adaptive immune responses to infectious disease and cancer but are also implicated in autoimmune disease. The antigen specificity of the T cell receptor is determined in part by the sequence of the CDR and Framework regions encoded by the TCR $\beta$  variable gene. Previous studies of population sequencing data indicate that current antigen receptor allele databases such as IMGT fail to capture a significant portion of human variation, though interpretation of this data is challenging. Here we sought to use long-amplicon multiplex sequencing of rearranged TCR $\beta$  receptors to validate putative novel human variable gene alleles previously recovered from 1000 genomes data. **Methods** TCR $\beta$  rearrangements were amplified from cDNA template from 85 donors using AmpliSeq-based multiplex Framework 1 and Constant gene primers to produce ~330bp amplicons. Samples were sequenced in multiplex using the Ion Torrent S5 530 chip to produce ~1.5M raw reads per sample. Raw data was uploaded to Ion Reporter for clonotyping and identification of rearrangements containing variable gene sequences absent from the IMGT database. Putatively novel sequences were compared with those reported in the Lym1k database of alleles recovered from 1000 genomes sequence data. **Results** We identified 15 variable gene alleles that are absent from the IMGT database but present in the Lym1k database, the majority of which result in amino acid changes to the CDR or Framework regions of the T cell receptor. We also find evidence for novel variable gene alleles that are absent from the Lym1k database, potentially due to challenges in inferring receptor alleles from short-read population sequencing studies. **Conclusion** We find evidence for significant human diversity in TCR $\beta$  variable gene alleles beyond what is currently represented in the IMGT database. TCR $\beta$  sequencing using multiplex Framework 1 and Constant gene targeting primers is ideally suited for the study of the role of T cell antigen receptor diversity in health and disease.

**1467F**

**Transcriptome altered by lytic human cytomegalovirus infection on human foreskin fibroblast cells (HFF) using RNA-seq.** *H. Li, S. Yang, L. Feng, Y. Ran, X. Yang, T. Zhou, Z. Deng.* Dept. Biotechnology, Jinan University, Guangzhou, Guangdong, China.

Human cytomegalovirus (HCMV) is a ubiquitous, highly host-specific herpesvirus that causes severe, sometimes life-threatening disease in congenitally infected newborns as well as in immunocompromised individuals such as bone marrow allograft transplant recipients and AIDS patients. To date, no effective vaccine or antiviral drugs is available to prevent or treat HCMV infection. The most important and effective factor to prevent the development of serious complications after HCMV infection dwells in cellular immunity in humans, which may involved transcriptional alterations. Whereas a virus can potentially modulate the level of cellular mRNA by various mechanisms, identification of the cellular transcription alterations that are repressed or activated after HCMV latent infection could unveil the dynamic virus-host interaction and facilitate the development of antiviral therapy. Here, we profiled the expression of mRNAs in HFF cells using the emerging RNA-seq to investigate the transcriptional changes during HCMV lytic infection. At 18 hours post HCMV infection (MOI:1), a total of 12,124,539 sequence reads was obtained. 12,306 protein-coding genes were observed in Refseq database. Differential gene expression analysis identified 97 differentially expressed genes (DEGs) between HCMV-infected and mock-infected HFF cells, including 91 up-regulated genes and 6 down-regulated genes. These regulated genes were involved in immune response and defense response, all of which may be implicated in viral pathogenesis. These findings have provided a dynamic scenario of differentially expressed candidate genes at the virus-host interface and clearly warrant further experimental investigation associated with HCMV infection.

**1468W****Simultaneous digital measurement of protein and mRNA content by massively parallel single cell sequencing to better identify T cell subsets.**

C. Chang<sup>1</sup>, E.Y. Shum<sup>1</sup>, N. Bansal<sup>1</sup>, J.C. Martin<sup>2</sup>, J. Ghadiali<sup>2</sup>, J.C. Tsai<sup>1</sup>, D. Rosenfeld<sup>1</sup>, H.C. Fan<sup>1</sup>. 1) BD Genomics, Menlo Park, CA; 2) BD Biosciences, San Diego, CA.

High throughput single cell RNA sequencing recently emerged as a powerful tool to profile complex and heterogeneous cell populations and dynamics. However, the lack of information on protein expression can make identifying cell types that have conventionally been defined by cell surface markers challenging, as mRNA and protein expression are often not tightly correlated. T cells in particular, contain relatively low abundance of transcripts, and different T cell subsets often exhibit highly similar transcriptional profiles. Here we demonstrate a novel approach of using oligo-conjugated antibodies to measure protein expression by sequencing, which enables simultaneous detection of protein and mRNA expression in a single cell. The antibody specific oligos are captured, amplified and sequenced alongside mRNA in a single workflow using BD™ Resolve, a massively parallel single cell analysis system. To demonstrate the power of the application, we created an oligo-conjugated antibody panel that includes many common T cell markers and applied the assay to human PBMCs. The detection of protein expression by oligo-conjugated antibodies was highly sensitive and specific. And the addition of protein marker measurement provided more distinct and robust clustering of single cell expression profile, especially in the T cell compartment, such as the separation of naïve CD4 vs CD8 T cells, and naïve vs memory T cells. In particular, we were able to identify a rare and recently described T cell subset, stem memory T cells, which is a long-lasting memory T cell population with stem cell-like properties. The method presented here can transform both single cell transcriptional profiling and high parameter proteomics to further efforts in elucidating complex biological systems, understanding disease states and enabling more effective biomarker discovery.

**1469T****Modulation of Notch pathway in adult mouse airways by antisense oligonucleotides.** T.R. Grossman, M. Carrer, J. Crosby, B.P. Monia, C.H. Hart. Antisense Drug Discovery, Ionis Pharmaceuticals, Carlsbad, CA.

Multiple respiratory disorders, including asthma, cystic fibrosis and chronic obstructive pulmonary disease (COPD), are characterized by aberrant goblet cells metaplasia, which leads to excessive mucus production and insufficient mucus clearance. Previous studies have suggested that Notch signaling is critical for controlling cell fates of the lung epithelium in both healthy and diseased conditions. We designed, screened, and tested chemically modified antisense oligonucleotides (ASOs) that reduce the expression of RNAs produced from genes encoding various Notch-signaling components to further dissect this signaling system. Our goal is to better understand the therapeutic potential of promoting the trans-differentiation of mucus-secreting cells (club and goblet cells) into mucus clearing cells (ciliated cells). Ultimately, we hope to restore the normal mucociliary clearance in diseased airways through therapeutically controlled remodeling of the lung. In wild type mice and in a mouse model for severe asthma, we found that systemic and local administration of ASOs targeting Notch components can result in the significant reduction (ranging from 50 to 80%) of the target mRNAs in the murine lung. Remarkably, we were able to reduce secretory-cell prevalence and induce ciliated-cells within the airway epithelium and in the severe asthma model this robust trans-differentiation led to a significant improvement in lung function. Taken together, These observations extend a foundation for therapeutic modulation of Notch signaling to control cell fate decisions in the adult lung and suggest that ASO targeting of the different Notch components could lead to promising new therapeutic options for the treatment of respiratory disorders including as asthma, cystic fibrosis and COPD.

**1470F****The translational utility of metabolomics in the integrative omics era:**

**A case study in asthma.** J. Lasky-Su<sup>1</sup>, R. Kelly<sup>1</sup>, B. Chawes<sup>1,2</sup>, H. Wolsk<sup>2</sup>, K. Bønnelykke<sup>2</sup>, A. Litonjua<sup>1</sup>, H. Bisgaard<sup>2</sup>, S. Weiss<sup>1</sup>. 1) Network Medicine, Brigham and Women's Hospital, Boston, MA; 2) COPSAC, Copenhagen Prospective Studies on Asthma in Childhood, Herlev and Gentofte Hospital, University of Copenhagen, Copenhagen, Denmark.

Once environmental and genetic variants for complex diseases are identified, it is often difficult to determine the causal mechanisms through which they operate to affect disease. Metabolomic profiling has the distinct advantage of being a marker that reflects the cumulative sum of past and current environmental and genetic exposures leading to the disease. We demonstrate the translational utility of metabolomics through the integration of metabolites with the variants at the well-replicated *ORMDL3* asthma locus and the protective effect of vitamin D supplementation. Using mediation analysis and cox regression in the context of 2 prebirth cohort clinical trials (VDAART & COPSAC) that randomized pregnant mothers to high and low doses of vitamin D, we identified a causal mechanism by which the *ORMDL3* variant (rs12936231) and prenatal vitamin D exposure operate on asthma risk via metabolites in the sphingolipid pathway. Specifically we used cox regression to demonstrate that the effect of vitamin D supplementation is modified by rs12936231 in both VDAART (N=806) and COPSAC (N=581). A meta-analysis of the trial results showed an increasing protective effect of vitamin D by decreasing number of *ORMDL3* C risk alleles: HRs for GG,GC,CC=1.07,0.79,0.50 (individual p<0.05, interaction p=0.062). In order to identify metabolites that may be mediating the observed relationship between vitamin D and asthma incidence, we performed logistic regression and mediation analysis and subsequently identified 11 metabolites associated with both vitamin D and asthma (p<0.05), where sphingomyelin was identified as a significant mediator of the vitamin D induced reduced risk of asthma (p=0.04). Finally, we determined that sphingomyelin levels were inversely correlated to the number of *ORMDL3* risk alleles. Mediation analysis determined that 10% of the effect of the vitamin D intervention was mediated through 4 metabolites, including sphingomyelin and glycosyl-N-palmitoyl-sphingosine, 2 key components of the sphingolipid metabolism pathway. These results suggest a causal pathway, in which prenatal vitamin D supplementation leads to an upregulation of the sphingolipid metabolism pathway in the offspring, which in turn has a protective affect against asthma. Furthermore, we demonstrate that *ORMDL3* modifies this relationship. This approach can be generalized to identify causal mechanisms for genetic and environmental risk factors through the metabolome to enable translational understanding.

**1471W****Global gene expression patterns in X-autosome balanced translocation patients.**

A. Di-Battista<sup>1</sup>, M. Moysés-Oliveira<sup>1</sup>, A. Reymond<sup>2</sup>, M.I. Melaragno<sup>1</sup>. 1) Morphology and Genetics, Universidade Federal de São Paulo, São Paulo, São Paulo SP, Brazil; 2) University of Lausanne, Lausanne, Switzerland.

Balanced structural rearrangements may result in position effects by modifying specific *cis*- and *trans*-acting DNA regulatory element, thus changing the overall chromatin topology and DNA accessibility. These alterations could lead to differential expression patterns, altering the phenotype. Patients with balanced X-autosome translocations with breakpoint in Xq usually show premature ovarian failure, even with no gene disruption related to gonadal function at breakpoints. Expression profile studies in these patients may help in elucidating the repositioning effect of chromosome segments on gene regulation. We performed RNA-seq experiments in three patients with balanced X-autosome and premature ovarian failure and their respective controls in order to identify differential expression patterns between groups. Libraries for RNA-seq were prepared using IlluminaTruSeq RNA sample preparation kit. cDNA libraries were amplified by PCR and samples were sequenced as a pool on an Illumina HiSeq machine (read length 100 bp, single-end). For analysis we used the following pipeline: Tophat2, for reads alignment, and Cufflinks, to assemble transcripts. As reference files, we used iGenomes data. Cuffmerge and Cuffcompare steps were used in order to merge our transcripts assemblies and compare them to annotation files. For transcripts quantification and to perform differential expression analysis we used Kallisto-Sleuth package. As preliminary results, we found at least 23 differentially expressed transcripts, 16 of which were downregulated and 7 upregulated in patients. The different expression patterns observed between groups might be due to derivative chromosomes repositioning within interphasic nucleus, and further analyses may reveal a possible correlation of these transcripts with gonadal function. Financial support: FAPESP 2014/11572-8.

## 1472T

**Tau phosphorylation is impacted by rare AD-associated AKAP9 mutations specific to African Americans.** T. Ikezu<sup>1</sup>, C-D. Chen<sup>1</sup>, E. Zeldich<sup>1</sup>, A. DeLeo<sup>1</sup>, K.L. Lunetta<sup>2</sup>, D. Fallin<sup>1</sup>, C. Abraham<sup>1</sup>, M.W. Logue<sup>1,2</sup>, L.A. Farrer<sup>1</sup>.

1) Boston University School of Medicine, Boston, MA; 2) National Center for PTSD at VA Boston Healthcare System, Boston, MA; 3) Boston University School of Public Health, Boston, MA; 4) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD.

**Background:** We previously identified by whole exome sequencing two rare variants of *AKAP9* (rs144662445 and rs149979685) in African American (AA) cohort. Compared to non-carriers, the odds of late-onset Alzheimer disease (AD) is 2.75-fold greater among individuals having one or both of these variants (*AKAP9*+). This study examined the effect of *AKAP9* mutations on AD-related processes. **Methods:** We examined lymphoblastoid cell lines (LCLs) from AD cases and controls with (*AKAP9*+, n=11) and without (*AKAP9*-, n=17) *AKAP9* variants. The LCLs were infected with the viral vectors expressing human amyloid precursor protein (APP) with Swedish mutation or human 2N4R Tau. Cell lysates were analyzed for total APP and total/phosphor-Tau (pTau) by ELISA, and media was analyzed for amyloid-beta peptide 1-40 (A $\beta$ 40) by ELISA. For measurements of Tau and pTau, cells were treated with or without rolipram, a phosphodiesterase type 4 inhibitor. Tau was also immunoprecipitated for proteomic analysis of its posttranslational modifications and interactomes. A $\beta$ 40/APP and pTau/Tau ratios were analyzed in a random effects model comparing *AKAP9*+ and *AKAP9*- LCLs with covariates for AD status, APOE genotype and a random effect for multiple measures from the same cell line. **Results:** AD was not associated with a difference in the mean A $\beta$ 40/APP ratio, the rolipram-treated pTau/Tau ratio, or the rolipram-untreated pTau/Tau ratio (all p>.3). Similarly, APOE genotype was not associated with a difference in mean A $\beta$ 40/APP or treated or untreated pTau/Tau ratio (all p>.1). *AKAP9*+ was not significantly associated with A $\beta$ 40/APP (p=0.22) or with pTau/Tau in the untreated LCLs (p=0.098), but was significantly associated with pTau/Tau in LCLs treated with rolipram, with higher pTau in *AKAP9*+ lines (p=2.5x10<sup>-6</sup>). Tandem mass spectrometry of Tau-immunoprecipitates revealed different set of posttranslational modifications of Tau and its interactomes between *AKAP9*+ and *AKAP9*- LCLs, suggesting a biological contribution of the *AKAP9* mutation in metabolism and molecular interaction of Tau. **Conclusions:** The association of these *AKAP9* risk variants with tau phosphorylation and interactomes in LCLs suggests that *AKAP9*—and these AD risk variants in particular—impact the posttranslational modification of tau, a central mechanism of AD pathogenesis. However, negative results (e.g. the lack of association with AD status and APOE) are inconclusive until further experiments are performed on neuronal tissue.

## 1473F

**Somatic mutations are abundant in focal cortical dysplasia.** V.S. Almeida<sup>1</sup>, S.H. Avansini<sup>1</sup>, M. Borges<sup>1</sup>, F.R. Torres<sup>1</sup>, F. Rogério<sup>2</sup>, B.S. Carvalho<sup>3</sup>, F. Cendes<sup>1</sup>, J. Lopes-Cendes<sup>1</sup>. 1) Department of Medical Genetics, School of Medical Sciences; 2) Department of Anatomical Pathology, School of Medical Sciences; 3) Department of Statistics, Institute of Mathematics, Statistics and Scientific Computing, IMECC; 4) Department of Neurology, School of Medical Sciences; University of Campinas.

**Introduction:** Malformations of cortical development (MCD), including focal cortical dysplasia (FCD), can cause epilepsy and are often associated with the occurrence of refractory seizures. FCD is characterized by alterations in the cortical cytoarchitecture also observed in other MCDs, such as in Tuberous Sclerosis (TS) and Hemimegalencephaly (HME). Recently, mosaic mutations were detected in TS, HME and in rare cases of FCD; however, it is still unclear if only a single mutation event may lead to FCD or whether somatic mosaicism is a more widespread genetic mechanism. **Materials and Methods:** Deep whole exome sequencing was performed on genomic DNA extracted from brain tissue resected by surgery (BTRS) and blood samples of 12 patients with FCD. We performed capturing and enrichment with Nextera® Expanded Kit (Illumina®). Samples were sequenced following a 200bp paired-end protocol in a HiSeq2500 (Illumina®) to achieve at least 200x of average coverage. We aligned sequences using BWA-MEM and performed realignment around SNPs and indels, quality recalibration and variant calling using the Genome Analysis Toolkit (GATK). We evaluated mosaicism using Mutect2 and Strelka. Variants were classified as mosaic mutations when less than 10% of reads are not aligned to the human genome reference and are present only in BTRS. Variants were filtered prioritizing frameshift, missense, nonsense and splicing site mutations. In addition, we also focused in variants not described previously in the normal population (reference individuals) or variants whose minor allele frequency (MAF) is  $\leq 0.01$ . Effect of variants was evaluated using Variant Effect Predictor (VEP). **Results:** We identified potentially deleterious mosaic mutations in BTRS in all 12 patients analyzed. Mosaic mutations were identified in 28 genes belonging to the mTOR pathway and in 40 genes belonging to the TAU pathway. More interestingly, all 12 patients have somatic mutations in BTRS in at least two genes. **Discussion/Conclusion:** Somatic mutations were identified in genes with functional roles and expression in the central nervous system. Somatic mutations were abundant in FCD tissue, affecting several genes from the mTOR and Tau pathways, and were detected in all samples examined. Therefore, somatic mosaicism seems to be a much more abundant and widespread genetic phenomenon than previously described in FCD. .

**Proteomics analysis of the dentate gyrus isolated from two different animal models of mesial temporal lobe epilepsy.** A. Morato do Canto<sup>1,2</sup>, A.H.B. Matos<sup>1,2</sup>, B.A. Bertelli<sup>1,2</sup>, A.S. Viera<sup>1,2,3</sup>, R. Glioli<sup>4</sup>, B. Henning<sup>2</sup>, B. Carvalho<sup>2</sup>, I. Lopes Cendes<sup>1,2</sup>. 1) Medical Genetics, School of Medical Science - UNICAMP, Campinas, SP, Brazil; 2) Brazilian Institute for Neuroscience and Neurotechnology - BRAINN, Campinas, SP, Brazil; 3) Biology Institute, UNICAMP, Campinas, SP, Brazil; 4) Multidisciplinary Center for Biological Investigation of Laboratory Animals (CEMIB); University of Campinas (UNICAMP), Campinas, SP, BRAZIL.

Mesial temporal lobe epilepsy (MTLE) is the most common form of epilepsy in adults. In most patients with MTLE there is a distinct lesion in the mesial temporal structures, including the hippocampal formation. The dentate gyrus (DG) is a cortical region that is an integral portion of the larger functional structure named hippocampal formation. There are numerous features of the DG that makes it unique in a neuroanatomical and functional way. We studied the DG in its dorsal (dDG) and ventral (vDG) anatomical regions in two MTLE animal models, the perforant pathway stimulation (PPEM - n=5) and the pilocarpine model (PiM - n=5). We performed proteomics analysis using Label-free quantification (LTQ-Orbitrap) and the software MaxQuant, Perseus and R. In the dDG from the PPEM we found that the protein CYS-C was up-regulated suggesting the activation of defense mechanisms against the injury caused in the model. We also identified an extensive process of astrogliosis in both regions (dorsal and ventral) resulting in higher expression of the proteins GFAP and Vimentin. In the vDG of the PPEM we found altered proteins responsible for the structure of Gap junctions suggesting changes in the electrical synapses and in ion homeostasis. By contrast, in the dDG of the PiM we found changes in energy metabolism such as in the Glycolysis and gluconeogenesis pathways as well as in Ca<sup>2+</sup> signaling. Moreover, for the vDG from the PiM we identified changes in signal transduction involving mTORC2, which is related to many processes such as cellular metabolism and cytoskeleton properties. In conclusion, we show that different models of MTLE present remarkable differences in proteomics profiles, indicating that epileptogenesis was induced by different biological pathways in these two models.

**RNA sequencing and proteomics approaches reveal novel multi-cellular deficits in the cortex of Rett syndrome mice.** N.L. Pacheco<sup>1</sup>, M.R. Heaven<sup>2</sup>, L.M. Holt<sup>1,3</sup>, D.K. Crossman<sup>4</sup>, K.J. Boggio<sup>5</sup>, S.A. Shaffer<sup>5</sup>, D.L. Flint<sup>2</sup>, M.L. Olsen<sup>1,3</sup>. 1) Cellular, Developmental, and Integrative Biology, University of Alabama at Birmingham, Birmingham, AL; 2) Vulcan Analytical, LLC, Birmingham, AL; 3) School of Neuroscience, Virginia Polytechnic and State University, Blacksburg, VA; 4) UAB Hefflin Center for Genomic Science, Department of Genetics, University of Alabama at Birmingham, Birmingham, AL; 5) Proteomics and Mass Spectrometry Facility, Department of Biochemistry and Molecular Pharmacology, University of Massachusetts Medical School, Shrewsbury, MA.

Rett syndrome (RTT) is an X-linked neurodevelopmental disorder caused by mutations in the transcriptional regulator MeCP2. RTT is characterized by having apparently normal development until 6-18 months, when a progressive decline in motor and language functions begins and breathing abnormalities and seizures present. Despite intense research, the molecular targets of MeCP2 and their contribution to the disease are unknown. Here we present the first comprehensive transcriptomic and proteomic analysis in a RTT mouse model. Examining whole cortex tissue in symptomatic males (*Mecp2*-null) with wildtype littermates, we have identified 391 genes (FDR < 0.05), and 465 proteins (p < 0.1) considered to be significantly, differentially expressed. These data indicate RNA metabolism, proteostasis, monoamine metabolism, and cholesterol synthesis are disrupted in the RTT proteome. Hits common to both data sets indicate disrupted cellular metabolism, calcium signaling, protein stability, DNA binding, and cytoskeletal cell structure. Finally, in addition to confirming disrupted pathways and identifying novel hits in neuronal function, our data indicate aberrant myelination, inflammation and vascular disruption. Intriguingly, in opposition to what is typically observed in most neurological diseases, there is no evidence of reactive gliosis. Instead, gene, protein, and pathway analyses suggest astrocytic maturation and morphological deficits. To further investigate this finding, we performed transcriptomic analyses on acutely isolated cortical astrocytes throughout postnatal development of *Mecp2*-null and wildtype littermates. Preliminary analysis of transcriptomic data from symptomatic *Mecp2*-null male cortical astrocytes (postnatal day 60+) also indicates disrupted genes and pathways associated with astrocytic maturation. Transcriptomic analyses of the remaining cortical astrocytic developmental time points are ongoing. Collectively, these analyses support previous works indicating widespread CNS dysfunction and may serve as a valuable resource for those interested in cellular dysfunction in RTT.

**Metabolomic studies of a brain-specific mouse model of tuberous sclerosis complex: Major changes in the methylation pathway.** *M.J. Gambello<sup>1</sup>, J.O. McKenna<sup>1</sup>, D.J. Kapfhamer<sup>1</sup>, J. Kinchen<sup>2</sup>, P.L. Hall<sup>1</sup>, B. Wasek<sup>3</sup>, T. Bottiglieri<sup>3</sup>.* 1) Human Genetics, Emory University School of Medicine, Atlanta, GA; 2) Metabolon, Inc Durham, NC; 3) Baylor Institute of Metabolic Disease Dallas, TX.

The tuberous sclerosis complex (TSC) is an autosomal dominant disorder causing substantial neuropathology. TSC is the quintessential mTORopathy as loss of either causative gene, *TSC1* or *TSC2*, leads to unopposed mTORC1 kinase activation and results in cell growth and division. This unrestrained anabolic state requires a major reprogramming of cellular metabolism to support macromolecular biosynthesis including increased NADPH production and de novo purine and pyrimidine generation. Many studies elucidating relevant pathways have focused on cell lines, but little is known about the metabolic reprogramming that occurs in TSC-affected organs in vivo. Using a brain-specific mouse model of TSC, we performed an unbiased metabolic screen of hippocampal lysates to identify *Tsc2*-dependent metabolic changes. We annotated a total of 434 compounds, of which 103 metabolites were upregulated and 68 downregulated in mutant hippocampus compared to control ( $p < 0.05$ ). Rapamycin, an mTORC1 inhibitor, had an effect on 42/103 upregulated metabolites and 29/68 downregulated metabolites. We found that *Tsc2* deficiency caused changes in redox homeostasis and in glucose, purine and neurotransmitter metabolism. Intriguingly, we also observed significant changes in methylation metabolism that were sensitive to rapamycin. Targeted metabolomic analysis of cortical lysates revealed the same changes: decreased methionine, cystathionine, and SAM (S-adenosylmethionine) - the main methyl donor, as well as decreased SAM/SAH ratio. There was also a marked increase in betaine, an alternative methyl donor. We hypothesize that increased methionine utilization is needed to support protein synthesis, which in turn alters the methylation potential in neurons and/or glia. In support of this hypothesis we also found alterations of SAM dependent reactants and products in the mutant brains such as guanidinoacetate (precursor of the energy metabolite creatine), 3-methoxytyramine and O-methyl dopa (neurotransmitter metabolites), and putrescine (polyamine). Alterations in SAM-dependent methylation reactions may be an important aspect of TSC neuropathology, and be amenable to nutritional or pharmacologic therapy.

**Kinome profiling of neural stem cells (NSC): Kinome profiling of NSC derived from induced pluripotent stem cells (iPSC) of Huntington's disease patient.** *A. Baharani<sup>1,2</sup>, E. Scruten<sup>1,2</sup>, S. Napper<sup>1,2</sup>.* 1) Dept of Biochemistry, Univ of Saskatchewan, 107 Wiggins Road, Saskatoon, Saskatchewan SK-S7N5E5, Canada; 2) Vaccine and Infectious Disease Organization (VIDO), 120 Veterinary Road, Saskatoon, Saskatchewan SK-S7N5E3, Canada.

Authors: Akanksha Baharani, Erin Scruten, Scott Napper Primary cell lines derived from patients with Huntington Disease (HD) were used to investigate physiologically relevant molecular aberrations in a cellular context. We used commercially available primary HD neuronal stem cells (NSCs), that were reprogrammed from induced pluripotent stem cells (iPSCs) isolated from an HD patient; as a model; to investigate the signaling aberrations associated with HD pathogenesis. The primary HD cell lines we used were sampled, karyotyped and characterized as having 45 polyglutamine (CAG) repeats. We utilized a custom-designed peptide array comprising 300 unique peptides corresponding to functionally annotated phospho-sites of known signaling intermediates. Lysates from primary HD cells and control human cells were applied on our peptide arrays and phosphorylation intensities corresponding to individual peptides quantified. The intra-array peptide replicate phospho-intensities were normalized and data presented as fold-change difference in peptide-specific phosphorylation between the HD cells and control cells. Our analyses led to the identification of various signaling intermediates that were differentially phosphorylated in HD cells compared to control cells. Using quantitative immunoblotting analyses, we validated a subset of the identified targets that included AKT1 Ser 473, LIMK1 Thr 508 and PTEN Thr 382 in HD cells. We confirmed that, in HD cells, the hypophosphorylation of AKT1 at Ser 473 led to reduced inhibition of the AKT substrate, GSK3b leading to increase phosphorylation at Ser 9. Further, we also validated the hyperphosphorylation of PTEN at Thr 382, a phospho-site associated with promoting PTEN stability. Given that PTEN is a negative-regulator of AKT, our data suggest that the AKT signaling axis is negatively regulated in HD cells, leading to reduced neuronal cell survival. Likewise, we also validated LIMK1 Thr 508 as a hypophosphorylated phospho-site in HD cells. We further found that the hypophosphorylation of LIMK1 at Thr 508 along with reduced phosphatase activity of Slingshot (SSHL1) at S987, led to increased phosphorylation of their substrate, Cofilin at Ser 3. The deregulation of LIMK1, Slingshot and Cofilin represents HD-specific pathway which is linked to disordered cytoskeletal dynamics. Taken together, our data identified key signaling proteins deregulated in HD cells which may be suggestive of a prognostic significance in HD pathogenesis.

## 1478T

**Bridging the therapy gap for rare genetic disorders: Comprehensive high-throughput drug repurposing screening to identify potential new treatment opportunities.** C.M. Maher<sup>1</sup>, B.C. Gay<sup>1</sup>, J. Rader<sup>1</sup>, C.J. Schulz<sup>1</sup>, J.M. Andresen<sup>1</sup>, A.C. Gerlach<sup>2</sup>, B.M. Antonio<sup>2</sup>, S. Santos<sup>2</sup>, K.M. Padilla<sup>2</sup>, O. Devinsky<sup>3</sup>, M. Might<sup>4</sup>, S. Petrou<sup>5</sup>, D.B. Goldstein<sup>6</sup>, G.R. Stewart<sup>1</sup>. 1) Pairnomix LLC, Maple Grove, MN; 2) Icagen Inc, Durham, NC; 3) Neurology Dept, New York University Medical Center, New York, NY; 4) Hugh Kaul Personalized Medicine Institute, University of Alabama at Birmingham, Birmingham, AL; 5) Florey Institute of Neuroscience and Mental Health, University of Melbourne, Parkville, VIC, Australia; 6) Institute for Genomic Medicine, Columbia University, New York, NY.

The power of genetic testing has led to rapid advancements in identifying a growing number of genes directly linked to rare diseases. While genetic testing has provided great insight into the pathoetiology of such disorders, diagnostic discoveries rarely translate into improved therapies. Pairnomix was created to bridge this gap between genetic diagnosis and precision medicine. Starting with a patient's genetic sequencing report, Pairnomix constructs a personalized *in vitro* cellular model that incorporates their specific mutation through site-directed mutagenesis. The functional consequences of the mutated model are characterized in relation to a wild-type model and an assay specific to those consequences is developed and optimized for use in high-throughput drug screening (HTDS). That assay is then used to screen a library of ~1,300 clinically available compounds, mostly taken from the Prestwick library. A panel of targeted inhibitors or potentiators (if available) are also routinely screened. A compound is considered a "lead" if it has activity that is greater than two standard deviations from the mean activity of all compounds. Leads from the HTDS are then re-screened using compound from a second source supplier across a 10-point concentration curve to characterize maximal activity in the assay and to identify an EC<sub>50</sub>. Finally, Pairnomix relays the information from these experiments back to the patient's physician so together they can make better informed healthcare decisions. Here, we describe the use of the Pairnomix approach for a patient with uncontrolled epilepsy who carries an R1872Q mutation in the *SCN8A* gene that encodes the Nav1.6 sodium channel. In a HEK293 cellular model of the mutation, mutated Nav1.6 channels were found to display an increased sensitivity to activation and a delayed inactivation profile that contributed to a gain-of-function phenotype. In an HTDS seeking to identify inhibitors of sodium influx, 90 compounds were identified that provided significant inhibition in the assay. Of these 90 compounds, the majority have not been implicated in ion channel modulation. This approach demonstrates the utility of HTDS to identify and repurpose existing drugs for new therapeutic indications.

**Reproducibility in iPSC omics: An international multicentre study.** V. Volpato<sup>1</sup>, J. Smith<sup>2</sup>, C. Sandor<sup>1</sup>, J. Ried<sup>3</sup>, A. Baud<sup>4</sup>, A. Handel<sup>1</sup>, S. Newey<sup>1</sup>, F. Wessely<sup>1</sup>, M. Attar<sup>1</sup>, E. Whiteley<sup>1</sup>, S. Chintawar<sup>1</sup>, A. Verheyen<sup>5</sup>, A. Artati<sup>6</sup>, E. Sharma<sup>1</sup>, W. Heywood<sup>4</sup>, R. De Filippis<sup>3</sup>, K. Janssen<sup>3</sup>, P. Reinhardt<sup>7</sup>, I. Royaux<sup>8</sup>, P. Peeters<sup>5</sup>, G. Terstappen<sup>3</sup>, M. Graf<sup>6</sup>, R. Livesey<sup>2</sup>, C. Akerman<sup>1</sup>, K. Mills<sup>1</sup>, R. Bowden<sup>1</sup>, G. Nicholson<sup>1</sup>, Z. Cader<sup>1</sup>, V. Lakics<sup>3</sup>, C. Webber<sup>1</sup>, IMI StemBANCC Consortium. 1) University of Oxford, Oxford, United Kingdom; 2) University of Cambridge, Cambridge, United Kingdom; 3) AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany; 4) UCL, London, United Kingdom; 5) Janssen, Antwerp, Belgium; 6) Helmholtz Zentrum München GmbH, Neuherberg, Germany; 7) Max Planck Institute for Molecular Biomedicine, Munster, Germany; 8) Hoffmann-La Roche Ltd, Basel, Switzerland.

Reproducibility is crucial to scientific discovery. Human induced pluripotent stem cells (iPSC) are providing valuable *in vitro* disease models, especially for hitherto inaccessible human tissues. Using agreed protocols across five laboratories within the StemBANCC consortium (three academic and two pharma), we assessed the cross-site reproducibility of a cortical iPSC differentiation protocol in terms of identifying robust differences between the same two iPSC lines, one control and one derived from an Alzheimer's patient carrying a PSEN1 variant. These two cell lines were cultured in triplicate across the five different laboratories with transcriptomic and proteomic data generated at two time points during differentiation, including measurement of the  $\beta$ -amyloid 40/42 ratio. We found that a decreased  $\beta$ -amyloid 40/42 ratio in the PSEN1 line was reliably detected across all five laboratories. However, while the gene expression profiles clustered by cell line within each laboratory's experiment, between laboratories high variation in both omics readouts between the two lines significantly confounded replicating their comparison. Factor analyses (RUVs) demonstrated that the biological variation from the two covariates of interest (cell line and time point) could be revealed after estimating and removing factors of unwanted variation, with "Laboratory" identified as the single largest source of variation. Examining the technical biases, we identified significant confounders in the iPSC-based cell line comparisons such as passage number, feeding patterns, use of frozen neural progenitors among others, that we caution should be explicitly controlled in iPSC study designs. Single-cell analyses further revealed that cell type compositional heterogeneity varied by laboratory as well as cell line, and contributed significantly to the masking of genotypic effects in multi-site analysis, most notably with pathways altered in different directions in different cell populations. Despite significant efforts to replicate the same iPSC experiment across multiple laboratories, omics comparisons were confounded by significant variation. Our study advises caution when comparing different experiments, and identifies many experimental variables that need to be controlled and reported.

**Targeted enrichment without amplification and SMRT Sequencing of repeat-expansion disease causative genomic regions.** *T. Clark, Y. Tsai, D. Greenberg, J. Ekholm.* PacBio, Menlo Park, CA.

Targeted sequencing has proven to be an economical means of obtaining sequence information for one or more defined regions of a larger genome. However, most target enrichment methods are reliant upon some form of amplification. Amplification removes the epigenetic marks present in native DNA, and some genomic regions, such as those with extreme GC content and repetitive sequences, are recalcitrant to faithful amplification. Yet, a large number of genetic disorders are caused by expansions of repeat sequences. Furthermore, for some disorders, methylation status has been shown to be a key factor in the mechanism of disease. We have developed a novel, amplification-free enrichment technique that employs the CRISPR/Cas9 system for specific targeting of individual human genes. This method, in conjunction with SMRT Sequencing's long reads, high consensus accuracy, and uniform coverage, allows the sequencing of complex genomic regions that cannot be investigated with other technologies. Using human genomic DNA samples and this strategy, we have successfully targeted the loci of a number of repeat expansion disorders (*HTT, FMR1, SCA10, C9orf72*) and disease-associated homonucleotide stretches (*TOMM40*). With this data, we demonstrate the ability to isolate hundreds of individual on-target molecules and accurately sequence through long repeat stretches, regardless of the extreme GC-content, followed by accurate sequencing on a single PacBio RS II SMRT Cell or Sequel SMRT Cell 1M. The method is compatible with multiplexing of multiple targets and multiple samples in a single reaction. Furthermore, this technique also preserves native DNA molecules for sequencing, allowing for the possibility of direct detection and characterization of epigenetic signatures. We demonstrate detection of 5-mC in human promoter sequences and CpG islands.

**1481T**

**Novel treatment approaches for autism spectrum disorder: An in vitro model.** *L. Boccuto<sup>1,2</sup>, L. Cascio<sup>1</sup>, K. Champaigne<sup>2</sup>, K. Jones<sup>1</sup>, R. Pauly<sup>1</sup>, S. Srikanth<sup>1</sup>, C.F. Chen<sup>1</sup>, S. Dunn<sup>1</sup>, C. Skinner<sup>1</sup>, C.E. Schwartz<sup>1,2</sup>.* 1) Research, Greenwood Genetic Center, Greenwood, SC; 2) Clemson University, Clemson, SC.

Utilizing the Biolog Phenotype Microarray (PM) panel, our group demonstrated a reduced utilization of the amino acid tryptophan (Trp) as an energy source by lymphoblastoid cell lines (LCLs) from individuals with autism spectrum disorder (ASD), as compared to typically developing (TD) controls. This finding suggested potential targets such as the kynurenine pathway and the mitochondrial respiratory chain. In order to identify potential candidate drugs for novel treatments, 10 ASD and 10 TD LCLs were tested on a customized Trp plate, before and after exposure to several compounds added to the medium: supplemental energy sources (Trp, valine, glucose), intermediates of the kynurenine pathway (kynurenate, 3-OH-kynurenine, quinolinic acid), antipurine (suramin) and anti-oxidant (sulforaphane) drugs. The results confirmed significantly reduced utilization of Trp in untreated ASD LCLs and showed a normal metabolic response when the same ASD LCLs were exposed to an increased amount of Trp (3 mM) and sulforaphane (50  $\mu$ M). Functional tests on mitochondrial metabolism exposing the same cell lines to respiratory chain inhibitors showed that rotenone (1  $\mu$ M) reproduces in TD cells the same metabolic profile observed in untreated ASD LCLs. Additional experiments were conducted on a second, independent cohort of 10 ASD and 10 TD LCLs, utilizing both the customized Trp plate and the PM-Tox1 plate, which focuses on mitochondrial metabolism. The cells were exposed to different concentrations of Nutrifriend, a supplement of omega-3 fatty acids ( $\omega$ -3) and vitamin D3, and a placebo (supplement without  $\omega$ -3). The results replicated the significant differences in Trp utilization between ASD and TD samples and showed reduced utilization by ASD cells of glucose, inosine, galactose, and  $\alpha$ -keto-glutaric acid, confirming a disruption in mitochondrial aerobic metabolism. The supplement proved to be significantly more efficient than the placebo ( $P$  values  $<0.05$ ) in eliminating the metabolic differences between ASD and TD LCLs in both Trp and PM-Tox1 plates. Overall, our studies show how the PM platform can be used to successfully investigate the effect of potential treatments on the function of presumed target pathways involved in the pathogenesis of ASD. The results also suggest novel approaches to normalize metabolic abnormalities detected in ASD cells and indicate a potential beneficial effect of anti-oxidants and supplementation of Trp and  $\omega$ -3 in individuals with this disorder.

**LCM-Seq: Single cell-type whole genome bisulfite sequencing and transcriptomic profiling in post-mortem brain.** *D.M. Almeida<sup>1,2</sup>, G. Chen<sup>2</sup>, M.A. Davoli<sup>2</sup>, N. Mechawar<sup>2,3</sup>, G. Turecki<sup>2,3</sup>.* 1) Integrated Program in Neuroscience, McGill University, Montreal, Quebec, Canada; 2) McGill Group for Suicide Studies, Douglas Hospital Research Center, Verdun, Quebec, Canada; 3) Psychiatry, McGill University, Montreal, Quebec, Canada.

The epigenome and transcriptome of a cell constitutes an essential piece of cellular identity and accounts for the multifaceted complexity and heterogeneity of cell types within the mammalian brain. During neurodevelopment, spatiotemporal control over gene expression through epigenetic regulation of promoters and enhancers leads to precisely defined cellular fates. Each discrete cellular population is also differentially influenced by extrinsic signals from their local environments and neighbouring cells. Thus, while a wealth of studies have investigated epigenomic and transcriptomic alterations underlying the neurobiology of psychiatric or neurological illnesses, the use of bulk-tissue homogenates have masked their ability to determine cell-type specific molecular dysfunctions. Here we describe our progress on a pipeline that employs laser capture microdissection (LCM) of prefrontal layer V pyramidal cells, based on their well defined morphology, followed by downstream whole-genome bisulfite sequencing (WGBS) and transcriptomic profiling. Using this method, we achieve a 59% mapping rate efficiency, bisulfite conversion rates within the expected range and optimal coverage of CpG sites for WGBS. RNA sequencing resulted in a mapping efficiency rate of 98% and captured a wide distribution of transcripts that map back to 13,141 genes. The major utility of this pipeline is its capacity to allow for the investigation of DNA methylation and expression patterns from the exact same dissected population of cells derived from post-mortem human brain tissue. LCM is compatible with immunohistochemistry as well as in-situ hybridization for the visualization and capture of specific cell types. Our goal is to use this pipeline to investigate cell-type specific molecular dysfunction underlying depression and suicide.

**1483W**

**Single-nuclei transcriptomics in the brains of individuals with depression who died by suicide.** *C. Nagy<sup>1,2</sup>, M. Maitra<sup>1,2</sup>, J.F. Theroux<sup>1,2</sup>, H. Djambazian<sup>2</sup>, G. Turecki<sup>1,2</sup>.* 1) Douglas Mental Health University Institute; 2) McGill Group for Suicide Studies; 3) McGill University and Genome Quebec Innovation Centre.

**Purpose:** Molecular changes are typically measured in tissue homogenates or cellular fractions containing millions of cells pooled together. However, most tissue types, particularly the brain, have heterogeneous cellular composition. Multiple neuronal and glial subtypes with specific gene expression patterns are likely to be distinctly modified in a diseased state. As such, the normal variation of gene expression between cell types can mask specific changes when obtaining molecular information from cellular homogenates. The detection of subtle transcriptomic alterations such as those expected in psychiatric, would benefit greatly from single cell resolution. **Methods:** Using post-mortem brain tissue obtained from the Douglas Bell Canada Brain bank we explored the frontal cortex of 16 suicide completers and 16 matched healthy controls. Bulk nuclei were isolated from BA8/9 using an Optiprep™ gradient and single nuclei were captured using 10x Genomics' Chromium technology, a droplet based protocol. Each droplet encapsulates a nucleus, lysis buffer, reverse transcriptase reagents and a hydrogel bead with a DNA oligonucleotide. After encapsulation, the nuclei are lysed and the mRNA in each nucleus is reverse transcribed and tagged with a cell barcode and unique molecular indices (UMIs). The RNA undergoes a linear in vivo transcription base on a T7 priming site to produce amplified RNA (RNAa). The amplified RNA is then fragmented and reverse transcribed, adding the Illumina sequencing primers. A bulk library is made from the uniquely barcoded cells providing adequate material and reducing library prep costs. The tagged cDNA was sequenced using Illumina's HiSeq 4000 platform to approximately 50x coverage per cell. We used a custom Cell Ranger pipeline to de-multiplex the RNA sequencing reads. Cells were separated into clusters based on their transcription profile, and each cluster was further sub-divided into clusters for differential analysis between groups. **Results:** Using this single-nuclei approach, we can identify unique transcriptomic subtleties between groups. The features that cause these differences, need further study. These data are the stepping stone for identifying specific genes and networks of genes whose expression is dysregulated in depression.

## 1484T

**Personalized dosing of dichloroacetate by clinical genotyping assay.** *T. Langaee*<sup>1,3</sup>, *R. Wagner*<sup>2</sup>, *L. Horne*<sup>2</sup>, *P. Starostik*<sup>2</sup>, *L.A. Lawson*<sup>2</sup>, *P. Stacpoole*<sup>2</sup>. 1) College of Pharmacy, University of Florida, Gainesville, FL; 2) College of Medicine, University of Florida, Gainesville, FL; 3) Medosome Biotec LLC, Alachua, Florida.

**Abstract** Dichloroacetate (DCA) represents the first targeted therapy for pyruvate dehydrogenase complex deficiency (PDCD) by stimulating residual pyruvate dehydrogenase complex (PDC) activity. A federally-funded, multi-center Phase 3 Trial of DCA in PDCD is underway. DCA is metabolized to glyoxylate by glutathione transferase zeta1 (GSTZ1). Current data clearly establish variation in GSTZ1 haplotype as the principal variable influencing DCA kinetics and dynamics in humans and occurs independently of subject age. The FDA has stipulated that were DCA to be approved for PDCD, labeling must include the need for genetics-based dosing. We aimed to develop and validate a genetic testing kit at Medosome Biotec clinical laboratory for GSTZ1 genotyping to investigate the plasma pharmacokinetics (PK) of DCA as a function of GSTZ1 haplotype and also determine GSTZ1 haplotype status in individuals who would be treated with DCA. Forty-five healthy volunteer study participants signed consent and completed GSTZ1 genotyping by providing buccal cells and whole blood. DNA samples were genotyped by TaqMan® for 3 functionally important GSTZ1 SNPs (rs7975, rs7972 and rs1046428). There was 100% genotype concordance between DNA samples from blood and buccal swab. Prior studies dichotomized subjects into two classes on the presence of at least one EGT allele, such that EGT carriers metabolized DCA faster than EGT non-carriers. Eight participants were selected to complete a standard pharmacokinetic study based on GSTZ1 genotype: 4 fast metabolizer (EGT carrier) and 4 slow metabolizer participants (EGT non-carrier). Each participant received a singled oral dose of 25 mg/kg of DCA (IND 028625) as a liquid formulation (25 mg/mL) each morning for 5 days, with formal PK evaluation conducted on day 5. Data from 8 subjects shown in the table are consistent with the premise that the EGT haplotype confers relating faster metabolism of DCA.

ID	Haplotype status	Plasma t <sub>1/2</sub> (hr)	AUC (min*mg/mL)	Plasma CL (mL/min/kg)
<b>EGT carrier</b>				
18	EGT/EGT	1.39	4171.42	6.05
22	EGT/KGT	3.32	6128.56	4.08
34	EGT/EGT	2.14	3469.33	7.27
41	EGT/EGT	1.33	3525.55	7.1
<b>EGT non-carrier</b>				
11	EKM/KRT	28.35	83136.05	0.3
26	KGT/KGT	5.68	11341.26	2.21
33	KGT/KGT	2.68	5422.64	4.61
40	KGT/KRT	12.54	19173.44	1.32

We conclude that these preliminary data establish the validity and practicability of our rapid genotyping/haplotyping procedure for genetic-based DCA dosing.

## 1485F

**Sequencing a baby for an optimal outcome: A clinical genomic application of newborn hearing screening.** *A.B.S. Giersch*<sup>1,2,8</sup>, *Y.I. Chekaluk*<sup>1</sup>, *M.S. Cohen*<sup>2,4</sup>, *K. Gregory*<sup>1</sup>, *J. Hochschild*<sup>5</sup>, *M.A. Kenna*<sup>2,3</sup>, *P. Levesque*<sup>4</sup>, *J. Manganello*<sup>3</sup>, *J. Shen*<sup>1,2,8</sup>, *M.R. Toro*<sup>1</sup>, *C.C. Morton*<sup>1,2,6,7,8</sup>. 1) Brigham and Women's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Boston Children's Hospital, Boston, MA; 4) Massachusetts Eye and Ear, Boston, MA; 5) Harvard University, Cambridge, MA; 6) The Broad Institute, Cambridge, MA; 7) The University of Manchester, Manchester, UK; 8) Harvard Medical School Center for Hereditary Deafness, Boston, MA.

**Purpose:** SEQuencing a Baby for an Optimal Outcome (SEQaBOO) is a research project which seeks to integrate high-throughput genomic approaches into routine newborn screening for hearing loss. In this project, we will test the hypothesis that rapid discovery of the exact cause of a newborn's hearing loss will benefit clinical management. **Background:** Today, congenital hearing loss and other subtle birth defects are recognized in newborns through newborn screening, allowing early interventions that limit life-long disabilities. Genetic factors contribute to the majority of congenital hearing loss in the US. The etiologies are highly heterogeneous, and pathogenic variants in hundreds of genes have already been identified. Although not life threatening, hearing loss requires a number of adjustments by the family and patient to optimize quality of life. Cochlear implants can provide hearing in the near normal range, but they do not correct the underlying molecular defect. Development of whole genome sequencing technologies provides a new opportunity as well as challenge for researchers and clinicians dedicated to improving the lives of newborns with birth defects to investigate whether genetic etiologies of congenital defects can be more accurately and efficiently defined and whether improved genetic diagnosis translates into superior clinical care. **Methods:** The project will enroll approximately 500 newborns who do not pass their initial newborn hearing screen along with their biological parent(s) (trios) for whole genome sequence analysis. If parents choose not to enroll in the WGS study arm, they may choose to participate in an annual survey study arm. Genetic information pertinent to the infant's hearing loss will be returned to the child's physicians to guide management. Both study arms includes annual surveys to ascertain general health, including speech and language development, in addition to hearing status, and parental attitudes toward genomic sequencing. **Summary:** SEQaBOO aims to analyze and assemble genomic datasets, perform clinical genomic research of hearing loss identifiable through newborn screening, and explore implications of integration of genomic sequencing into newborn screening. All of this will inform the care and management of newborns with congenital hearing loss and allow us to investigate factors associated with society's acceptance of this new technology for "optimal outcome" of a newborn baby.

**1486W**

**Building and scaling the world's fastest clinical-grade whole genome based pipeline.** Y. Ding, S. Nahas, S. Chowdhury, L. Van Der Kraan, L. Puckett, C. Yamada, S. Batalov, N. Veeraraghavan, R. Hovey, J. Cakici, S. Caylor, L. Salz, D. Oh, P. Mulrooney, W. Benson, P. Laird, D. Dimmock, S. Kingsmore. Clinical Genome Center, Rady Children's Institute for Genomic Medicine, San Diego, CA.

Undiagnosed genetic diseases have a profound impact on the development of infants and young children. They are also the leading cause of death in infants, especially in Neonatal Intensive Care Units (NICU) and Pediatric Intensive Care Units (PICU). Efficacious medical interventions depend critically upon early diagnosis. Next generation sequencing such as the whole exome sequencing (WES) and the whole genome sequencing (WGS) have dramatically increased diagnosis rates. However, the turnaround time (TAT), test cost, data processing and data interpretation/reporting remain major obstacles for clinical facilities trying to perform WES or WGS. In October 2016 Rady Children's Institute for Genomic Medicine (RCIGM) established a clinical genome center at Rady Children's Hospital (RCH) San Diego CA. The laboratory is equipped with Illumina HiSeq2500 and HiSeq4000 instruments which allow performance of 120 rapid 40X WGS (rWGS) per month with an optimized rWGS workflow. From sample acquisition to a provisional diagnosis provided, our average TAT is 6 days and fastest TAT is 37 hours. In order to ensure the accuracy of the rWGS sample identity, Short Tandem Repeat (STR) allele profiling is employed. The laboratory has also optimized protocols to confirm potentially causative variants identified by rWGS using Applied Biosystems Genetic Analyzer. To date, over 300 individuals from more than 100 families have been sequenced and analyzed. To further shorten our current TAT and reduce sequencing cost, we are evaluating a novel library construction method and adopting a novel, rapid Illumina sequencing platform (NovaSeq6000 S2). Early diagnosis in NICU and PICU is further assured by utilizing a hybrid cloud-based ultra-rapid bioinformatics analysis and reporting pipelines, which includes single nucleotide variant (SNV), short insertion or deletion (INDEL) and structural variant detection, as well as the concordance and contamination checking for sample integrity. These which are specifically optimized for the short TAT requirements, yet remain uncompromising of performance. We present protocols and results of validation studies for clinical rWGS with return of results in less than 37 hours.

**1487T**

**Disease relevant structural variation analysis by next-generation mapping.** A. Hastie, A.W. Pang, J. Lee, E.T. Lam, T. Anatharaman, W. Andrews, X.Y. Zhang, M. Saghbini, H. Cao. Bionano Genomics, San Diego, CA.

Next-generation mapping (NGM) using the Saphyr™ System developed by Bionano, offers high-throughput, genome-wide visualization of extremely long DNA molecules in their native form. It allows researchers to interrogate genomic structural variations (SVs) in the range of one kilobase pairs and above. It uses extremely long range information to span interspersed and long tandem repeats making it suitable for elucidating the structure and copy number of complex regions of the human genome, such as loci with complex pseudogene and paralogous gene families. Since NGM is a *de novo* process and with molecules analyzed being longer than almost all genomic repeats, NGM is able to detect a wide range of SVs including insertions of novel sequence, tandem duplications, interspersed duplications, deletions, inversions and translocations. No other single technology can discover the breath and quantity of large SVs. The high throughput, cost-effective, genome wide nature and comprehensiveness of the SV types detected is driving NGM's application to the analysis of human genomes for the detection of SVs potentially involved in disease pathogenesis, including in diagnosing rare disease and cancer. We present several *in silico* and biological validation experiments that demonstrate the sensitivity and specificity of NGM for the detection of insertions, deletions, inversions and translocations compared to benchmark studies using short read and long read sequencing. We also show the application of NGM to study somatic variation in a breast cancer cell line, finding hundreds of somatic structural variations otherwise undetected. Finally, we applied NGM to several leukemia patient samples to find more than 50 cancer related SVs in each patient. NGM is a fast and cost effective method for the detection of a broad range of traditionally refractory SVs across the human genome. .

**A systems biology approach to the understanding of asthma severity through the integration of metabolomic, transcriptomic and epigenetic networks.** R.S. Kelly, W. Qui, B.L. Chawes, Y. Virkud, K. Blighe, J. Celestino, S.T. Weiss, D. De Meo, J. Lasky-Su. 1) Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA; 2) COPSAC, Copenhagen Prospective Studies on Asthma in Childhood, Herlev and Gentofte Hospital, University of Copenhagen, Copenhagen, Denmark; 3) Division of Pulmonary Medicine, Allergy and Immunology, Children's Hospital of Pittsburgh of the University of Pittsburgh Medical Center, University of Pittsburgh, Pittsburgh, PA 15260, USA.

Background: Asthma emerges from a complex interplay between genetics and environmental exposures. Single-omic analyses have provided some insight into asthmatic lung function phenotypes, but the underlying biological pathways are still poorly understood. Integrative omics analysis may provide important insights into the mechanistic basis of this common chronic condition. Methods: 328 children with asthma from the 'Genetic Epidemiology of Asthma in Costa Rica' study underwent metabolomic (8,185 metabolite features), transcriptomic (25,060 gene probes) and epigenetic (118,721 CpG sites) profiling in blood extracted at recruitment (mean: 9.1 years). Weighted gene co-expression network analysis (WGCNA) in each omic dataset was used to independently identify modules of co-regulated metabolites, gene-probes, and gene-associated CpG-sites. Modules significantly associated with metrics of asthma severity; airway obstruction, reversibility, and hyper-responsiveness, were identified and their biology explored. Significantly correlated metabolite-gene and gene-gene module pairs were identified and the constituent variables submitted for integrated pathway analysis using IMPaLA. Results: WGCNA identified eight metabolomic modules, eight transcriptomic modules, and ten epigenetic modules. Of these, six metabolomic, four transcriptomic and three epigenetic modules associated ( $p < 0.05$ ) with asthma severity metrics based on their eigenvalue. The modules were enriched for asthma relevant processes including immune, mitotic and metabolic processes. Between-omic module associations were identified; in particular a 'sphingolipid metabolism' metabolite module associated with a transcriptomic ( $p = 0.05$ ) and epigenetic ( $p = 0.01$ ) module both of which were enriched for immune processes and included *ORMDL3*; a sphingolipid biosynthesis regulator and validated asthma gene. Conclusions: This study demonstrates that integrating multiple omic technologies using a systems biology approach provides a more informative, interpretable and biologically meaningful picture of asthma severity relative to single-omics analyses. Integration of correlated omic modules expanded and refined the single omic findings, linking dysregulated immunity to asthma severity via *ORMDL3* and sphingolipid metabolism. Therefore metabolomics can provide a mechanistic basis for the role of a number of asthma genes.

**1489W**

**An integrative view of genetic and transcriptional regulatory interactions of the human placenta.** F. Delahaye<sup>1</sup>, C. Do<sup>2</sup>, Y. Kong<sup>1</sup>, B. Tycko<sup>3</sup>, F. Hughes Einstein<sup>3</sup>, R. Wapner<sup>4</sup>. 1) Genetics, Albert Einstein College of Medicine, Bronx, NY; 2) Institute for Cancer Genetics, Columbia University, New York, NY; 3) Department of Obstetrics and Gynecology, NYU, New York, NY; 4) Department of Obstetrics and Gynecology, Columbia, New York, NY.

Functional genomics relies on the integration of genomics, epigenomics and transcriptomic information toward the discovery of early biomarkers and insights into disease etiology. The constant improvement in sequencing technologies has resulted in a surge in the number and complexity of multi-omics datasets, providing unprecedented opportunities to map the regulatory landscape, while imposing substantial analytical challenges. From present genomics association studies and quantitative trait loci analysis it became evident that significant efforts are still necessary to accurately depict the regulatory landscape. Yet, they allow the identification of inherent limitations to the current assays and analytical approaches such as the impact of cell subpopulation, genetic background and the need for broader data integration. These limitations have motivated the present study where we provide insight into the regulatory landscape of the human placenta and offer integrative analytical approaches to overcome the limitations of current platform. We intensively characterized the effects of genetic variation on gene expression and DNA methylation, and developed a comprehensive approach to identify methylation-sensitive transcription. We distinguish two profiles of interaction between expression and DNA methylation, revealing linear or bimodal interactions, reflecting differences in genomic context, transcription factor recruitment and cell subpopulation effects. We present here the extensive placenta-specific genome-wide analyses from the largest cohort studied to date. By combining multiple datasets, we overcome the limitations inherent to each individual dataset, improving our understanding of the intricacy of the regulatory mechanism in placenta. We show the complex interactions of genetic and transcriptional regulatory mechanisms, defining expression and methylation quantitative trait loci. We note the limitations of the transcriptional and DNA methylation studies performed, and how they could lead to over-interpretation of findings unless accompanied by stringent analysis. By publicly releasing such a reference dataset, we will considerably improve the interpretability of future (epi)genome-wide association studies.

**1490T****Sequence read length effects on differential gene expression analyses using RNA-sequencing technologies.**

A.C. Shetty<sup>1</sup>, A. Mahurkar<sup>1</sup>, C.M. Fraser<sup>1,2</sup>, D.A. Rasko<sup>1,3</sup>, V. Bruno<sup>1,3</sup>, J.D. Hotopp<sup>1,3,4</sup>. 1) Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, Maryland; 2) Department of Medicine, University of Maryland School of Medicine, Baltimore, Maryland; 3) Department of Microbiology & Immunology, University of Maryland School of Medicine, Baltimore, Maryland; 4) Greenebaum Cancer Center, University of Maryland, Baltimore, Maryland.

**Background:** Since the onset of sequencing, there has been an exponential increase in sequencing throughput with an inconsequential decrease in costs. Sequencing of RNA molecules (RNA-Seq) to measure gene expression and assess differential expression between conditions has become increasingly powerful and an effective analytical approach. The Illumina HiSeq platform is commonly used for RNA-Seq generate 50 – 200 base pair (bp) paired-end reads. **Hypothesis:** Sequencing read lengths, library type and library depths have a significant effect on RNA-sequencing analytical results and need to be adjusted based on factors that are influenced by the variations in genome complexity and study designs. **Methods:** We analyzed 6 different transcriptomic datasets involving 5 reference organisms with varying genome size, gene number, gene length, exons per gene, and intron length. Raw 101 bp sequencing reads for each dataset were aligned to their reference genomes and read counts were computed for their genes as defined by their respective reference annotations. The raw counts were normalized for library size and gene dispersion and compared between conditions to determine differential expression of genes (DEGs). The analytical steps were repeated for read lengths of 72 bp, 54 bp and 36 bp as well as for individual single-end reads or paired-end reads. **Results:** We observed that alignment specificity decreases with increasing read length, except for less complex genomes that have no or a limited number of introns. Principle component analysis (PCA) and hierarchical clustering of samples for each dataset illustrated the factors influential in differentiating between samples from different conditions. We observed read length playing an influential role in multiple datasets further amplified when compared between paired-end and single-end sequencing techniques. When comparing the detected DEGs across the different read lengths, we observed highest correlations between analysis using the 54 bp and 72 bp reads. **Conclusions:** We observed differences in alignment statistics and detected DEGs in varying datasets influenced by the complexity of the genome, read length and sequence read pairing. This implies that longer reads do not necessarily mean better alignment and analytical results when analyzing complex transcriptomic datasets using existing methods.

**1491F****Optimization of CRISPR/Cas9-mediated gene editing in monkey embryos.**

X. Luo<sup>1,2</sup>, B. Su<sup>1</sup>. 1) State Key Laboratory of Genetic Resources and Evolution, Kunming Institute of Zoology, Chinese Academy of Sciences, Kunming 650223, Yunnan, China; 2) Kunming College of Life Science, University of Chinese Academy of Sciences, Kunming 650204, China.

The RNA-guided Cas9 nuclease from the microbial clustered regularly interspaced short palindromic repeats (CRISPR) adaptive immune system have been used to facilitate efficient genome editing in many model and non-model animals. However, its application in non-human primates is still at early stage, and the efficiency of gene modification in primate embryos remains rather low. Here, using zygotic injection of Cas9 mRNA and multiple single-guide RNAs with an optimized protocol, we achieved a high knockout efficiency of 86.67% for *MCPH1*- a human autosomal recessive primary microcephaly gene. Furthermore, through homology directed repair (HDR), we obtained monkey embryos with humanized *MCPH1*, and the efficiency is 21%. The improved gene editing efficiency in monkeys may serve as a useful tool in human disease and human evolution studies.

**1492W**

**Development of a dual platform strategy for targeted DNA sequencing in genetic screening.** C. Schumacher, A. Wood, S. Sandhu, J. Lenhart, L. Kurihara, V. Makarov, T. Harkins. Swift Biosciences, Ann Arbor, MI.

The use of next-generation sequencing (NGS) to assess genetic variation in genes involved in both inherited diseases, as well as cancer, is critical. Traditional NGS assays utilize short-read (SR) chemistry to enable sequencing of biomarkers in accessible parts of the genome, devoid of difficult to sequence motifs and high homology to pseudogenes. Newer long-read (LR) assays offer additional insight into the genetic architecture of known genes including haplotype structure, detection of large insertions/deletions, variants present in regulatory elements, and copy number variations. Both massively parallel screening techniques are economical, and a turn-around time of less than 48 hours makes them ideal for high-throughput use. To assess the utility of both SR and LR platforms, Swift Biosciences has developed single tube, multiplexed amplicon assays for both *CFTR* and *BRCA1/BRCA2 (BRCA)* genes. DNA from MUTCF-2 (Coriell Institute) with known *CFTR* variants was used in both the SR and LR assays. In the SR assay, an 87-amplicon panel comprehensively covered all exons (~10Kb) in *CFTR*. 10ng of DNA was used as input for multiplexed PCR, and the products were adapted and sequenced on an Illumina MiniSeq. The LR assay covered all the same exons, and 6 complete intronic regions, using 21 amplicons (~54Kb). 25ng of DNA was used as input for the multiplexed PCR, barcoded for sample multiplexing, and adapted for Pacific Biosciences (PacBio) sequencing on an RS II. To assess the *BRCA* genes, DNA from BC01 (Coriell Institute) was used as input into the 246-amplicon (~23Kb) SR panel which comprehensively covers all *BRCA* exons. A 35-amplicon panel (~86Kb), was used to cover these same exons and 20 complete intronic regions with the LR assay. Both assays were adapted and sequenced as described for *CFTR*. Libraries from both SR assays were sequenced with >95% on-target and coverage uniformity. Based on the quality of the consensus sequence and the low number of multiplexed amplicons, the LR assays require up to 10x less sequencing reads per amplicon to call the same variants as the SR assays. The same number of variants were detected in both assays, despite the difference in sequencing depth. The LR assay identified indels, such as a 40bp deletion in *BRCA*, that are challenging to detect with short reads, indicating that large insertions/deletions are more robustly detectable with LR technology.

**1493T**

**Enrichment of long reads for Mendelian disease using the Oxford Nanopore MinION.** E. Farrow<sup>1,2,4</sup>, M. Gibson<sup>1</sup>, J. Johnston<sup>1</sup>, B. Yoo<sup>1</sup>, G. Twist<sup>1</sup>, S. Soden<sup>1,2,4</sup>, C. Saunders<sup>1,3,4</sup>, N. Miller<sup>1</sup>, I. Thiffault<sup>1,3,4</sup>. 1) Center for Pediatric Genomic Medicine, Children's Mercy-Hospitals and Clinics, Kansas City, Missouri 64108; 2) Department of Pediatrics, Children's Mercy-Hospitals and Clinics, Kansas City, Missouri 64108; 3) Department of Pathology and Laboratory Medicine, Children's Mercy-Hospitals and Clinics, Kansas City, Missouri 64108; 4) University of Missouri-Kansas City School of Medicine, Kansas City, MO 64108.

The exponential decreases in sequencing costs, combined with the high quality score and accuracy of short read sequencing technology has led to an explosion of genetic testing. This approach has been particularly powerful for point mutations and small insertions and deletions. However, despite widespread utilization, diagnostic rates for Mendelian disorders range from 25-50% in part, due to the limited ability of short read sequencing to detect variation beyond point mutations and small insertions and deletions. Improvement in diagnostic rates will require overcoming challenges in the accurate detection of copy number variants, determination of repetitive sequence lengths, and resolution of pseudogenes. Long read sequencing is a potential tool for improving genetic testing as it addresses many of the current limitations of short read sequencing. However, the cost of long read sequencing combined with lower quality and overall accuracy has limited its utilization. The relatively low cost of the Oxford Nanopore MinION sequencer, both in capital expense and in sequencing costs, offers an attractive option for obtaining long reads. To explore the use of long read sequencing technologies for genetic testing, we have developed a novel enrichment protocol for long reads (average size of ~5Kb) that are sequenced using the MinION. The protocol is amenable to both small panel and whole exome enrichment using kits from Integrated DNA Technologies. Preliminary studies using exome enrichment resulted in 93% of bases on target. Overall output was initially low utilizing a single Mk1 R9 flow cell. Enrichment of a 170 gene panel resulted in approximately 1.19 Gb of raw data, which would enable multiplexing of up to 3 samples. The technology is rapidly improving, and using the newest SpotON Mk1 R9.4 flow cell we obtained more than 2Gb of high-quality reads from a single flow cell. To assist with error correction, samples were also sequenced using Illumina instrumentation (MiSeq or HiSeq 2500/4000). The total time required for sample preparation and sequencing on the MinION is one week. Current studies are ongoing evaluating the resolution of pseudogenes and triplet repeat expansions (*CYP2D6* and *FMR1*, respectively). In sum, we present a robust enrichment strategy for sequencing long reads, which has broad applications.

**1494F**

**NGS pretesting and QC using Illumina Infinium Arrays.** *J. Romm, H. Ling, P. Zhang, I. McMullen, P. Witmer, K. Doheny.* Center for Inherited Disease Research (CIDR), Johns Hopkins University, Baltimore, MD.

The Center for Inherited Disease Research (CIDR) provides high quality next-generation sequencing (NGS), genotyping and statistical genetics consultation to investigators working to discover genes that contribute to disease. To reduce both reagent and sample waste, CIDR routinely performs sample pretesting to evaluate DNA quality, detect contamination/sample mixtures, confirm biological gender assignments, and check for Mendelian inconsistencies and inbreeding prior to initiating laboratory processes. For NGS pretesting, CIDR uses a dense Illumina Infinium array, which permits extended analyses for 1<sup>st</sup> and 2<sup>nd</sup> degree relationships, unexpected relationships, ethnicity and large chromosomal anomalies. In addition, we calculate concordance and sensitivity to call heterozygotes, providing a critical quality control measure for NGS data.

**1495W**

**900 exomes for rare disease research: Outcomes of the 2016 BBMRI-LPC WES call in collaboration with EuroBioBank and RD-Connect.** *S. Beltran<sup>1,2</sup>, M. Bayes<sup>1,2</sup>, J. Dawson<sup>3</sup>, B. Fusté<sup>1,2</sup>, M. Gut<sup>1,2</sup>, S. Laurie<sup>1,2</sup>, H. Lochmüller<sup>3</sup>, E. López-Martín<sup>1,5</sup>, L. Matalonga<sup>1,2</sup>, L. Monaco<sup>6</sup>, G.B. van Ommen<sup>7</sup>, D. Piscià<sup>1,2</sup>, M. Posada<sup>4,5</sup>, S. Sims<sup>8</sup>, R. Thompson<sup>3</sup>, C.M. Wang<sup>6</sup>, E. Zeggini<sup>8</sup>, I. Gut<sup>1,2</sup>, BBMRI-LPC Consortium.* 1) Bioinformatics Analysis Group, Centro Nacional de Análisis Genómico (CNAG), Barcelona, Catalonia, Spain; 2) Universitat Pompeu Fabra (UPF), Barcelona, Spain; 3) Institute of Genetic Medicine, MRC Centre for Neuromuscular Diseases, Newcastle University, UK; 4) Institute of Rare Diseases Research, IIER-ISCIII, Madrid, Spain; 5) Centre for Biomedical Network Research on Rare Diseases, CIBERER, Madrid, Spain; 6) Fondazione Telethon, Milan, Italy; 7) Department of Human Genetics, Leiden University Medical Center, Leiden, The Netherlands; 8) Wellcome Trust Sanger Institute, Hinxton, UK.

The 2016 BBMRI-LPC WES Call offered a unique free-of-charge opportunity to genetically diagnose rare disease patients with biological samples deposited within the EuroBioBank network. The program sequenced and analyzed 900 Whole Exomes from 17 projects, each with 2-3 principal investigators (PIs) from different countries. These projects included rare genetic eye diseases, congenital myasthenic syndromes, ataxia, neuromuscular diseases, CMT, inborn errors of metabolism, mitochondrial diseases, familial gastric neuroendocrine tumors, gastroschisis, disorders of glycosylation and 3-methylglutaconic aciduria, albinism, rett-like syndrome, Pyruvate Kinase Deficiency and Sudden Cardiac Death. The Informed Consent had to allow data sharing for research through controlled access repositories and databases such as the EGA (<https://ega.org.eu/>) and RD-Connect (<https://platform.rd-connect.eu>). Sequencing was conducted at the Centro Nacional de Análisis Genómico (CNAG-CRG, Spain) and at the Wellcome Trust Sanger Institute (WTSI, UK) and was finished in early 2017. Raw data will be submitted to the EGA for long-term storage. Clinical and phenotypic information was collected with RD-Connect's customized PhenoTips instance, using standards such as the Human Phenotype Ontology (HPO), OMIM and Orpha codes. Exomes were processed through the RD-Connect validated analysis pipeline and were made available through the platform once the PIs had fulfilled all the requirements. The RD-Connect platform allows researchers to analyze and interpret their genotype:phenotype data privately for up to 6 months before it is shared with other authorized users. The user-friendly online system includes numerous annotations and filters as well as tools such as Exomiser and Genomiser. It also enables anonymized data sharing through APIs from initiatives such as the GA4GH/IRDiRC MatchMaker Exchange and GA4GH Beacon. The BBMRI-LPC WES Call represents an important move towards developing a best-practice paradigm for secure data and sample sharing for diagnostics and gene discovery in rare disease. We will report on the challenges and lessons learned from conducting such a complex transnational collaborative initiative. We will also present the up-to-date diagnostic yield of the project as a whole while focusing on some success stories.

**1496T**

**Performance comparison of two exome enrichment systems for enhanced coverage of disease-associated regions.** L. Tian<sup>1</sup>, R. Pellegrino Silva<sup>1</sup>, J. Garifallou<sup>1</sup>, M. Hegde<sup>2</sup>, H. Hakonarson<sup>1,3,4</sup>, A. Santani<sup>1,5</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) PerkinElmer, Inc; 3) Department of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 4) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 5) Department of Pathology and Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania.

Exome sequencing is increasingly used as the primary diagnostic test in patients with rare genetic disorders. To ensure the quality of the clinical exome sequencing tests, it is imperative for clinical and research laboratories to be aware of the technical complexities with the commercially available products that can have a critical impact on the sensitivity of mutation detection. We assessed two recently available commercial DNA target enrichment methods, namely SureSelect Clinical Research Exome V2 (Agilent) and SeqCap EZ MedExome (Roche NimbleGen). Both target enrichment systems include enhanced coverage of select disease associated genes. The CRE v2 design was curated by the consortium of the Emory Genetics Laboratory and the Children's Hospital of Philadelphia. Target enrichment libraries from one individual (NA12878) were prepared following each manufacturer's protocol, and pooled libraries were run on an Illumina HiSeq2500 with 2x101 paired end reads. The sequencing data were processed on Edico genome's Dragen BioIT processor. Target enrichment metrics were calculated using Picard and GATK DepthOfCoverage tool. We compared the performance of two enrichment systems based on a comprehensive metrics, including coverage of CCDS, RefSeq, Ensembl, and GENCODE databases, depth of coverage, evenness of coverage, enrichment efficiency, influence of GC content, cumulative distribution of on-target sequence coverage in 1) target bases, 2) coding exons, 3) 5' UTR and 3'UTR, 4) splice junctions, 5) promoters in the following regions 1) ~4600 disease-associated genes, 2) 59 ACMG secondary finding v2.0 genes, 3) 70988 HGMD/ClinVar variants in disease-associated genes. We evaluated the sensitivity and specificity of SNV and small INDEL calls generated from the two enrichment systems by comparing the calls with the high-confidence calls published by the Genome in a Bottle consortium. We concluded that both enrichment systems 1) show high target coverage efficiency (>70%), 2) yield highly sensitive and accurate variants calls in the ~4600 disease associated genes, 3) have a negative correlation between sequencing coverage and extreme GC content. Each system presents its own strength and weakness. CREV2 consistently demonstrated improved performance in coverage over disease associated genes and higher coverage of known pathogenic mutations.

**1497F**

**Improvement in automated NGS sample preparation workflows: Combining the Agilent Bravo Liquid Handling Platform with Covaris Focused-ultrasonicators.** C. Whitman<sup>1</sup>, M. Visitacion<sup>1</sup>, J. Terry<sup>2</sup>, G. Durin<sup>2</sup>. 1) Agilent Technologies, Santa Clara, CA; 2) Covaris Inc, Woburn, MA.

As the field of Next-Generation Sequencing (NGS) continues to expand, more and more genomic researchers are seeking automation as way to increase their sample throughput while maintaining data quality and sample traceability. In addition to have a robust liquid handling platform there is a need to provide a simplified user interface as most new users are not automation experts. Covaris Focused-ultrasonicators employ Adaptive Focused Acoustics™ (AFA) technology for the controlled mechanical shearing of nucleic acids. AFA hydrodynamic shear force-based fragmentation is purely mechanical and designed to be isothermal, ensuring both unbiased fragmentation and high recovery of DNA. It is such recognized as the industry standard for DNA shearing for NGS sample preparation. The Covaris microTUBE is specifically designed and engineered for compatibility AFA technology and small sample volumes. The 96 microTUBE Plate is an automation friendly consumable that is directly compatible with standard automation deck positions. For smaller throughput experiments the 8 microTUBE Strip, with newly developed H Slit septa, provides a versatile solution with a SBS-format plate adaptor that can handle up to 12 tube strips. While most of the available automation workflows have primarily been centered on NGS Library Preparation and Target Enrichment protocols, there have been only a few commercial solutions presented around the initial DNA sample transfer from the Covaris microTUBE consumables. Here we introduce an automated workflow for extracting sheared DNA samples from a 96 microTUBE Plate and 8 microTUBE Strip using the Agilent Bravo NGS liquid handling platform. We show the successful transfer of samples from each microTUBE product and demonstrate that sample and data qualities are comparable between manual and automated handling. Automation is a mandatory requirement for any high-throughput project that reduces variability, improves workflow efficiency and increases walk-away time. Utilizing the Agilent Bravo Liquid Handling Platform for automating extraction of sheared DNA from the Covaris 96 microTUBE Plate and 8 microTUBE Strip offers a reliable and reproducible solution for high-throughput studies. For Research Use Only. Not for use in diagnostic procedures.

**1498W**

**Spike-in controls designed for detecting sample bleeding and misidentification in sequencing workflows.** *J. Kinman, S. Piehl, A. Morris, D. Fox, C. Firmani, M. Toloue.* PerkinElmer, Austin, TX.

Cross contamination in sequencing workflows is a serious issue that has led to inaccurate data interpretation. Verification and elimination of sample ambiguity is critical for the widespread use of NGS. Understanding the extent and source of miscalled reads, even at low levels, is important for accurate variant calling and can affect statistical power in the detection of genetic associations. Traditional library preparation methods lack the ability to effectively screen for procedural, instrumental, and human error in sequencing workflows. A fully validated set of spike-in controls can identify these errors and ensure samples are correctly labeled and identified with minimal impact on sequencing data. These spike-ins offer sequencing service providers and scientists a tool to assess sample purity, cross-contamination, and index carryover; giving them confidence in the integrity of their data and a confirmatory checkpoint for when errors do occur.

**1499T**

**NEBNext Ultra II FS DNA: An enzyme-based, single tube fragmentation system for library construction.** *V. Panchapakesa, L. Apone, K. Duggan, B. Langhorst, T. Shtatland, C. Song, P. Liu, C. Sumner, C. Rozzi, M. Arn, D. Munafa, F. Stewart, E. Dimalanta, T. Davis.* New England Biolabs, 240 County Road, Ipswich, MA 01938.

Success on NGS platforms begins with optimal sample preparation, which has become a bottleneck in NGS workflows. We have developed a robust library preparation method that integrates enzyme-based DNA fragmentation with end repair and dA-tailing in a single tube, resulting in the elimination of expensive equipment to fragment DNA. This streamlined method is compatible with a wide range of DNA samples and input amounts, resulting in reproducible and reliable fragment sizes. Genomic DNA (100pg to 500ng) from various sources was fragmented, end repaired and dA-tailed in a single step, followed by adaptor ligation in the same tube. The sample was then cleaned up and sequenced on an Illumina platform. For low input samples, PCR amplification was performed prior to sequencing. Libraries constructed using intact genomic DNA and this novel library preparation method produced substantially higher yields than those generated using standard methods and mechanically fragmented DNA. The greatest differences were observed with the lowest DNA inputs and most challenging samples, including FFPE where a 2- 4 fold increase in yield was observed with the Ultra II FS DNA kit. Sequencing quality of libraries generated with inputs ranging from 100pg to 500ng DNA show similar coverage uniformity, GC bias and fragment size distribution. Ultra II FS generates high-quality libraries from a broad range of DNA sample amounts and qualities. Sequencing metrics of FS libraries are similar or superior, to those produced with mechanically sheared DNA. This easily automatable, single tube, workflow has a wide range of NGS applications including whole genome, whole exome or targeted sequencing, and single cell RNA-seq.

Rapid advances in sequencing technology promise that genetic information will be increasingly used in mainstream medicine. Established a decade ago, the Personal Genome Project Canada is a foundational research project for ethics protocol development, sample collection, data generation, medical annotation and delivery of findings, all designed for impact in the context of the Canadian health care system. A unique feature of this project is that data are returned to participants by a genetic counsellor. A prime objective was to determine the clinical utility of whole genome sequencing (WGS) when offered to population (healthy) controls. We followed first-come-first-serve enrolment at our website (<http://www.personalgenomes.ca>) and have registered 1107 participants, who undergo an eligibility screening and provide informed consent to publish their data. Using blood DNA, we performed WGS (Illumina HiSeq X) with an average of 38-fold coverage. High-resolution microarray (Affymetrix Cytoscan-HD) and methylation arrays (Illumina EPIC) were also performed, and induced pluripotent stem cell lines are being generated. Here, we report on the analysis of the genomes of the first 56 participants. We assessed all clinically relevant genetic variants. Rare variants (<5%) were emphasized, and those either predicted to result in null alleles or reported to be disease causing, were further assessed according to American College of Medical Genetics recommendations. Of 1587 analyzed variants, 1409 were (likely) benign or of uncertain significance; 169 sequence-level variants and 9 CNVs were classified as (likely) pathogenic, mostly associated with autosomal recessive (162) or semidominant (12) inheritance patterns. Four (likely) pathogenic (semi)dominant sequence variants (in *BRCA1*, *LMNA*, *LZTR1* and *SLC7A9*) and a mosaic (70%) loss of one X chromosome were considered to be of clinical relevance. Several variants with evidence from functional studies remained of uncertain significance but clinically suspicious (in *ANK2*, *CDH1*, *CHMP2B*, *ELN*, *KCNE2*, *TRPM4*). A pathogenic mitochondrial variant in *MT-TV* was found with low level heteroplasmy (7%). We identified an average of 3.2 disease alleles per individual. However, substantial burden of clinically ambiguous alleles and pathogenic variants with insufficient data on disease penetrance hampered individual risk predictions. In 12/56 participants (21%), our research findings may have health planning/management implications.

**1501W**

**Comprehensive discovery of genomic variation from the integration of multiple sequencing and discovering technologies.** X. Zhao<sup>1</sup>, M. Chaisson<sup>2</sup>, Human Genome Structural Variation Consortium. 1) Massachusetts General Hospital, Boston, MA; 2) University of Washington, Department of Genome Sciences, Seattle, WA.

Genomic variants range in size from single nucleotide variants to large structural variants spanning megabases of DNA. Such variation plays an important role in evolutionary selection and can also be a critical driver of human disease spanning the spectrum from neurological disorders to cancers. Comprehensive discovery and sequence resolution of structural genomic variation is a difficult problem that has limited our ability to make disease associations. Here, we applied 7 different genomic technologies and 23 independent algorithms to parent-child trios from diverse ancestries to discover haplotype-resolved SVs at nucleotide resolution. We independently integrated SVs discovered by different platforms, followed by systematic comparison and further integration to achieve a comprehensive SV callset. On average, we identified and validated more than 500,000 indels (1-49 bp) and 30,000 copy number variants ( $\geq 50$ bp) within each child, representing a 10-fold increase over previous 1000 Genomes Project reports derived from standard short read libraries. We also discovered ~235 high confident large inversions and complex SVs per genome, which were often partially misrepresented or omitted by other studies. We further present an analysis of these SVs for their prevalence across the genome as well as their potential impact on gene expression. We show that near complete physical haplotype resolution with 10X Genomics and strand-seq data allows long-read sequences to be accurately partitioned and assembled by haplotype, significantly increasing our yield of structural variation. Application of strand-seq based approaches coupled with optical mapping provides access to large-scale inversions in the human population that were previously underrepresented and where the current human reference genome is likely in error. Our results suggest that haploid resolution of diploid genomes and combinations of orthogonal approaches depending on variant size and class are required to accurately resolve the majority of human genome structural variation. We anticipate that these data will enable a more complete understanding of the evolutionary and functional consequences of these variants in human populations, and serve as the new gold standard for human genetic variation.

**1502T**

**Detection of small exonic CNVs, SNPs and INDELS in a single assay.** S. Melo, K. Jeong, A. Vadapalli, A. Ashutosh, J. Ghosh, G. Amparo, M. Ramaiah, D. Roberts. Agilent Technologies, Santa Clara, CA.

Deletions and duplications in genomic DNA larger than 50 base pairs, collectively known as Copy Number Variations (CNVs), have been recognized as a major source of genetic variation. While many CNVs have no obvious phenotypic effect, many others have been implicated in numerous genetic conditions and cancer, underlying the importance of CNV detection. Next generation sequencing, particularly targeted sequencing of exons, is becoming the predominant approach to identify and characterize genomic variants and mutations. A wide variety of methods and computational solutions that use this type of data to infer CNVs have previously been described. However, measurements along only exonic regions can pose significant limitations to resolution of smaller CNVs spanning one or two exons. To enable higher resolution of CNV calls in and around exons of interest, we have designed custom target enrichment probes flanking exons, described as custom OneSeq probes. These probes were designed to augment Agilent SureSelect exon panels, which enables detection of single nucleotide polymorphisms (SNPs), deletions and insertions smaller than 50 bp (INDELS), and exon level CNVs spanning hundreds to thousands of bp in one single assay. Here, we demonstrate improved detection of small exonic CNVs in several clinically important regions, including DMD, PARK2, and MECP2. Importantly, the addition of custom OneSeq probes refines predicted breakpoints, and reduces the rate of false positives, without sacrificing detection of exonic SNPs/INDELS. Thus, Custom OneSeq probes together with exonic probes allow detection of small exonic CNVs, SNPs and INDELS in a single assay.

**1503F**

**An optimized single tube workflow for robust, low input NGS library preparation.** G. Durin<sup>1</sup>, E. Weiss<sup>1</sup>, J. Terry<sup>1</sup>, J. Donaldson<sup>1</sup>, U. Thomann<sup>1</sup>, E. Daviso<sup>1</sup>, J. Sampson<sup>1</sup>, J. Lenhart<sup>2</sup>, S. Sandhu<sup>2</sup>, L. Kurihara<sup>2</sup>, J. Laugharn<sup>1</sup>. 1) Covaris Inc, Woburn, MA, USA; 2) Swift Biosciences, Ann Arbor, MI, USA.

As Next Generation Sequencing (NGS) moves into the clinical diagnostics space, requiring higher throughput and sensitivity, existing processes need to be improved to ensure accurate, precise data outputs. Mechanical DNA shearing using Covaris Adaptive Focused Acoustic (AFA) technology is recognized as the gold-standard for DNA fragmentation in NGS library preparation. AFA hydrodynamic shear force-based DNA fragmentation is strictly mechanical and isothermal, and thus guarantees a highly controlled process while yielding random, unbiased DNA fragment distributions. We present a new DNA shearing vessel, the Covaris oneTUBE that is optimized for low DNA input and allows single tube DNA shearing and NGS library preparation. This new engineered polymer vessel incorporates features that effectively control acoustic cavitation to enable reproducible and precisely tuned hydrodynamic shear forces. Its low binding surface guarantees high DNA recovery as well as ease of volume handling down to 5  $\mu$ l and picogram DNA inputs. Additionally, this vessel is fully compatible with magnetic separation procedures, thermal cyclers and liquid handling platforms. oneTUBE design is adaptable for scaled-up SBS formats, such as 96, 384, and higher well densities. We present data that demonstrates precise and accurate DNA shearing in the Covaris oneTUBE with optimized truSHEAR buffer, and validation using a wide range of DNA input quantities and %GC. Additionally, processing times are up to two times faster than in traditional vessels. For NGS library construction, DNA shearing in the oneTUBE was paired with Swift Biosciences Accel-NGS 2S Kit. The 2S kit preserves complexity from low input samples due to enhanced end repair chemistry for highly efficient adapter ligation in a single tube workflow. This combination enables for the first time DNA shearing, end repair, and adapter ligation in the same vessel, thereby eliminating cumbersome sample transfers. We present sequencing data from libraries constructed with this workflow and compare them to libraries constructed according to standard "with transfer" protocol. Using genomic DNA from species with varying %GC, no adverse biases in number of PCR duplicates or coverage uniformity were observed at inputs ranging from 10 pg to 100 ng. PCR-free human whole genome sequencing on an Illumina HiSeq X using 200 ng Coriell NA12878 will also be presented, where the oneTUBE workflow produced higher library yields than the standard workflow.

**1504W**

**Microbiome technology comparison: Axiom microbiome array, 16S rRNA sequencing and metagenomics.** *J. Foster<sup>1</sup>, R. Almond<sup>2</sup>, L. Cobb<sup>2</sup>, S. Welsh<sup>2</sup>, G. Tilston<sup>2</sup>, M. Shah<sup>3</sup>, A. Pirani<sup>2</sup>, C. Bloor<sup>1</sup>, G. Scopes<sup>1</sup>.* 1) Thermo Fisher Scientific, Paisley, United Kingdom; 2) UK Biobank, Stockport UK; 3) Thermo Fisher Scientific, Santa Clara, United States.

Historically microbiome research has hinged upon the targeted sequencing of rRNA and whole genome (metagenomic) sequencing for organisms that could not be cultured in the lab. With the release of the Axiom™ Microbiome Array an orthogonal approach to the elucidation of diverse microbiota is possible. As part of a UK Biobank potential sample collection protocol, a pilot study was conducted to determine optimal sample collection, storage and treatment methods. Results for metabolomics, 16S rRNA sequencing, Metagenomics and the Axiom Microbiome Array were generated, allowing the three genomics technologies to be compared. Comparison involved 77 DNA extractions from 7 samples aliquoted in triplicate; one aliquot for each technology. Participants were age-matched samples outside of the UK Biobank cohort. Samples were subjected to one of four treatments (Native, DNA/RNAase-free water, Omnigene, RNA Later) and underwent one of three storage conditions: immediate storage at -80°C and storage at 4°C for 24 or 48 hours then transferred to -80°C prior to extraction. Microarrays were processed in the Thermo Fisher UK Service Lab and sequencing carried out at two independent academic collaborator sites. Microbiota identification was also conducted independently at the microarray/sequencing source site. Cross technology comparison was performed at Thermo Fisher with no re-processing of the reported microbe identifications. Comparison was primarily done at the genera level, that being the lowest common denominator between the three technologies with the 16s rRNA data unable to produce higher resolution species-level identifications. The Axiom Microbiome array compared favourably to 16s rRNA sequencing in respects to within-participant reproducibility of identifications, QC pass rate of samples and resolution of identifications. Metagenomics provided a wealth of high resolution identifications to corroborate those of the Axiom Microbiome array with the trade-off of laborious complex data analysis and high per-sample cost. In addition to bacterial identifications, we also present Axiom Microbiome Array results from the four other super kingdoms of life: Archaea, Fungi, Protozoa and Viruses.

**1505T**

**A spin column and magnetic bead-based approach for the isolation of host and bacterial DNA from human feces.** *D. Wieczorek, S. Lewis, B. Hook, T. Schagat.* Promega Corporation, Madison, WI.

Fecal samples contain an abundance of genetic material and can be collected non-invasively, making them an ideal sample type for human disease and microbiome research. However, the presence of humic acid and other amplification inhibitors in human fecal samples can present significant challenges, as the incomplete removal of these contaminants can affect downstream applications. To effectively purify DNA from these samples, lengthy and hazardous protocols are often necessary. As an alternative, we present two approaches for purification of DNA from feces, one compatible with manual spin columns and another magnetic particle based method adaptable to small, automated instrumentation as well as high throughput platforms. The performance of these methods was compared to another commonly used manual spin column-based technique and DNA quantity, quality, amplifiability, and performance in 16s microbial sequencing were evaluated. In this testing, the methods we describe demonstrated higher DNA yields and equivalent amplification and sequencing performance when compared to the established method. These flexible techniques yield pure, concentrated DNA from fecal samples without the use of organic solvents or cumbersome spin steps for use in rigorous downstream applications.

**1506F****Preparing small RNA libraries from low input and single cell total RNA.**

S. Shore<sup>1</sup>, JM. Henderson<sup>1</sup>, EWT. Tam<sup>2</sup>, JF. Quintana<sup>2</sup>, FWN. Chow<sup>2</sup>, K. Chhatbar<sup>2</sup>, D. Keys<sup>1</sup>, AP. McCaffrey<sup>1</sup>, G. Zon<sup>1</sup>, A. Buck<sup>2</sup>, RI. Hogrefe<sup>1</sup>. 1) Research and Development, TriLink BioTechnologies, San Diego, CA; 2) Centre for Immunity, Infection and Evolution, University of Edinburgh, Edinburgh, UK.

Next-generation sequencing (NGS) has revolutionized nucleic acid analysis, and is revealing new details of diverse RNA functions. Many biological samples contain limited amounts of RNA, thus it is important to use a library preparation method yielding highly specific products from low input amounts. To achieve high sensitivity detection, it is vital to minimize side reactions and contaminants such as adapter dimers that waste flow cell space resulting in unproductive NGS reads. A challenging sample type to prepare for sequencing is small RNA (sRNA), non-coding RNA sequences, such as miRNA. Due to their short sequence lengths, a sRNA library is time-consuming to separate away from adapter dimer prior to NGS. Therefore, we developed a technology using modified adapter chemistries to reduce adapter dimer formation otherwise occurring during sRNA library preparation. By significantly reducing adapter dimer formation in the NGS library, small RNA libraries can be purified by rapid and automatable magnetic bead-based RNA size selection eliminating the need for gel purification. In addition, this reduction of adapter dimer allows for successful NGS library prep when using significantly lower total RNA inputs. For example, using modified CleanTag™ adapters, gel purified libraries generated from the inputting of 10 and 1 nanogram (ng) total human brain RNA resulted in 86% of total reads mapped to miRNA and less than 1% of total reads attributed to adapter dimer. In contrast at 10 ng input RNA the gel purified libraries from a commercially available kit resulted in only 40% of total reads mapped to miRNA while 50% of total reads attributed to adapter dimer. While commercial kits do not produce usable data at 1 ng, by replacing gel purification with magnetic bead purification at 1 ng input, CleanTag™ libraries resulted in sufficient miRNA reads and less than 10% adapter dimer. We have demonstrated broad applicability by successful sequencing low RNA input biological samples such as extracellular vesicles, plasma, urine, FACS sorted and immunoprecipitated samples that have previously proven difficult to sequence. CleanTag™ library sequencing results at 10 picogram total human brain RNA input show the potential to sequence small RNA at the single cell level. These results demonstrate the value of adapter dimer suppression and the utility of CleanTag™ technology for both low input and high throughput library preparation.

**TaqMan Advanced miRNA assays to simultaneously study expression of miRNA and mRNA from serum samples.** H. Veereshlingam<sup>1</sup>, M. Buchholz<sup>2</sup>, K. Varma<sup>1</sup>, S. Brown<sup>1</sup>. 1) ThermoFisher Scientific, South San Francisco, CA; 2) Philipps-Universität Marburg, 35043 Marburg, Germany.

MicroRNAs (miRNA) are a class of small non-coding RNAs (approximately 21 nt long) that bind complementary sequences in target mRNAs to specifically regulate gene expression. miRNAs play important roles in regulation of gene expression during cell development, differentiation, proliferation and apoptosis. Misregulation of miRNAs and their targets has been associated with several diseases including cancer. The interplay between miRNA and mRNA has been found to be important in cancer development and progression. Simultaneous expression studies of miRNA and mRNA can be valuable in understanding molecular mechanisms that may potentially have an underlying role in various diseases. We demonstrate the technical verification of a novel method to reverse transcribe and pre-amplify miRNA and mRNA from sample limiting serum research samples using TaqMan® Advanced miRNA cDNA synthesis Kit. Based on results from previous studies, Dr. Buchholz's research group identified a signature of 55 mRNA and 41 miRNA targets that may help to distinguish between benign and malignant pancreatic tissues in the future. In this study these previously identified miRNA and mRNA targets have been used to study expression pattern differences in serum from Normal and Test samples. These miRNA and mRNA targets were spotted on Custom TaqMan array cards to facilitate investigation of 4 samples on each card. Initial results indicate that miRNA and mRNAs can be reliably quantified from a single reverse transcription reaction.

**1508T****Complete, streamlined, reduced-bias workflow for RNA extraction and small RNA library preparation from serum and plasma samples.** R.Wong<sup>1</sup>, S. Eun<sup>2</sup>, A. Lukasiewicz<sup>2</sup>, K. Allen<sup>2</sup>, D. Simpson<sup>1</sup>, A. Morris<sup>2</sup>, M. Toloue<sup>2</sup>.

1) Queen's University Belfast, Belfast, Northern Ireland; 2) PerkinElmer, Austin, TX.

The profiling of small RNAs, miRNAs in particular, in human plasma and serum samples is a rapidly expanding field, largely due to the great promise of cell-free RNAs as biomarkers. Here we describe a workflow using a phenolic extraction reagent along with magnetic bead-based cleanup for isolation of total RNA from human serum and plasma, followed by reduced bias small RNA NGS library preparation. We have developed a protocol using a phenolic extraction reagent combined with a magnetic bead purification for isolation of total RNA, including small RNA, from up to 600 µL of plasma or serum in a microcentrifuge tube format. The use of magnetic bead-based purification greatly increases throughput, time to complete, and user-friendliness by avoiding time consuming and tedious alcohol precipitation or column-based cleanups. Isolated RNA is then used as input into a reduced-bias library preparation protocol that uses the proven technology of adapters with randomized ends to reduce ligase bias. We also describe a protocol modification that greatly reduces the number of reads mapping to tRNA and YRNA fragments, which can often be a substantial number of reads in libraries created from serum or plasma RNA. This modification results in a greater number of reads mapping to miRNAs which, in combination with bias reduction, allows for detection/discovery of more miRNAs at equal sequencing depth or the ability to sequence samples less deeply than other popular protocols while obtaining comparable data. Here we describe a streamlined, user-friendly workflow for isolation of total RNA and generation of reduced-bias small RNA sequencing libraries from plasma and serum samples. This tool will be valuable to the growing number of researchers exploring extracellular small RNA for various reasons, including biomarker discovery.

**1509F****Study of touch DNA in simulated situations for forensic purposes.** F.T.

Goncalves, D.O. Francisco, J.H. Rios, C. Fridman. Legal Medicine, Ethics and Occupational Health, Medical School, University of São Paulo, Sao Paulo, Sao Paulo, Brazil.

In a crime scene, many types of biological traces can be found, among them, fingerprints are the most commonly. Currently, partial fingerprints can be used to obtaining genetic profiles based on genomic polymorphisms, assisting the elucidation of criminal investigations. However, many variables may interfere with the obtaining of these profiles, for example, the type of the surface on which the biological material was deposited. In Brazil, crimes with cold weapons are very common and happen daily. The most significant are those committed with knives, a tool easily found in any residence. Therefore, trying to assist the forensic work, this study aimed to analyze the feasibility of obtaining STR profiles from three different kind of knife handle: wood, steel and polypropylene. Forty simulated experiments were conducted with three women. Each woman manipulated one of the knives during one hour. The genetic material provided from the fingerprints left on the handle knives were collected with swab and the DNA was extracted by two methodologies in different days. In part of the experiments Chelex 5% was used to extraction and the other part of experiments this step was conducted with Swab Solution and the samples were amplified by multiplex PCR using the kit for Human Identification *PowerPlex® Fusion* System. Results showed that the wood handle knife was the best to recover the biological material deposited by hands, because 20 of the 24 markers were found in the STR profiles. On the other hand, profiles obtained from polypropylene were partials. However, when Chelex was used in the extraction, the quantity of allelic drop-out were higher than when Swab Solution was used. No DNA profile were obtained in the steel knife handle with any methodology used. These results showed that it was possible to obtain DNA profile from fingerprint from two of three types of knife grip materials that may aid in criminal investigations. These data are part of a larger study that evaluate the feasibility of obtaining STR profiles on door handles and steering wheels of cars and computer keyboards, as well as the evaluation of other variables such as gender of participants and different climatic conditions.

**Design of Axiom Asia Precision Medicine Genotyping Array optimized for East and South Asian populations using improved SNP selection algorithms.** A. Mittal, J. Gollub, S. Kaushikkar, T. Webster, J. Schmidt. Thermo Fisher Scientific, Santa Clara, CA.

Most existing pan-population genotyping arrays offer less than ideal high coverage of East and South Asian populations. We have designed Applied Biosystems™ Axiom™ Asia Precision Medicine Array that includes markers ideally suited for imputation in East and South Asian populations. Marker selection was accomplished by extending our previously-described imputation-aware array design algorithm [Hoffmann et al., 2012] using an approach inspired by the multiple-population tag SNP selection algorithm [Carstensen et al., 2014]. The set of markers only occupies 40 % of a typical Axiom array, leaving 60 % for additional content that can be customized, while achieving coverage of up to 93% for variants with minor allele frequency > 0.05 and up to 82% for variants with minor allele frequency > 0.01 in all East and South Asian populations. This compares favorably to the coverage achieved by Axiom™ Precision Medicine Research Array (PMRA). Marker selection was initially achieved in 168 CPU-hours on 180-core Linux cluster with 8GB of RAM/core. We have further demonstrated the ability to execute marker selection using a cloud-based cluster that can reduce development time by up to 6x, permitting flexible customization of the imputation panel if needed. We have extended this population specific approach to coding, LoF, and potentially pathogenic variants, which are also typically biased toward European populations on other arrays. We have identified such variants, taking their alternate allele frequencies for East and South Asian populations into account, from public databases such as ClinVar (May 2017), NHGRI GWAS catalog (May 2017) and PharmGKB, as well as additional recent publications. In summary, we describe a custom genotyping array that efficiently captures genomic variation in East and South Asian populations and offers a powerful approach for precision medicine research initiatives in Asian populations. The approach presented can readily be applied to one or more populations. *For Research Use Only. Not for use in diagnostic procedures.*

**Pathogenic variants that alter protein code often disrupt splicing.** R. Soemedi<sup>1,2</sup>, K. Cygan<sup>1,2</sup>, C. Rhine<sup>2</sup>, J. Wang<sup>2</sup>, C. Bulacan<sup>3</sup>, J. Yang<sup>4</sup>, P. Bayrak-Toydemir<sup>5</sup>, J. McDonald<sup>5</sup>, W. Fairbrother<sup>1,2,6</sup>. 1) Center for Computational Molecular Biology, Brown University, Providence, RI; 2) Department of Molecular Biology, Cell Biology and Biochemistry, Brown University, Providence, RI; 3) Department of Computer Engineering, Brown University, Providence, RI; 4) Department of Computer Science, Brown University, Providence, RI; 5) Department of Pathology, University of Utah, School of Medicine, Salt Lake City, UT; 6) Hassenfeld Child Health Innovation Institute of Brown University, Providence, RI.

The evolution of genome sequencing technology has led to an unprecedented speed and accuracy for the detection human genetic variation. However, the lack of tools to identify causative variants from genome sequencing data has greatly limit the promise of precision medicine. Previous studies suggest that one-third of disease-associated alleles alter splicing. We analyzed 4,964 published disease-causing exonic mutations reported in Human Gene Mutation Database (HGMD) using a novel massively parallel splicing assay (MaPSy) to identify exonic variants that alter pre-mRNA splicing. Our results showed an 81% concordance rate with splicing in patient tissue (Soemedi et al., 2017). Approximately 10% of exonic mutations altered splicing, mostly by disrupting multiple stages of spliceosome assembly. We discovered that alleles causing splicing defects cluster in disease-associated genes (for example, haploinsufficient genes). Interestingly, diseases that are more frequently caused by intronic splice-site mutations also have more exonic splicing mutations (ESM). This likely reflects disease processes that occur through loss-of-function mechanisms. Furthermore, we used the large dataset of ESM generated with MaPSy to build a Random Forest prediction model for exonic splicing mutation. Many exonic properties were found to sensitize an exon to splicing mutations. Finally, we have created a public web-server that enables the visualization of MaPSy results ([http://fairbrother.biomed.brown.edu/ESM\\_browser/](http://fairbrother.biomed.brown.edu/ESM_browser/)). In conclusion, MaPSy facilitates the first large-scale identification and characterization of ESM. The system effectively translates to 5K implementations of basic mutational approaches and can be further adapted to other mutation panels, thus accelerating the efforts to characterize all sequence variation.

**Low-input transcript profiling with enhanced sensitivity using a highly efficient, low-bias and strand-specific RNA-seq library preparation method.** *M. Arn, E. Yigit, K. Krishnan, D. Rodriguez, B. Langhorst, T. Shtatland, C. Sumner, D. Munafo, F. Stewart, E. Dimalanta, T. Davis.* New England Biolabs, 240 County Road, Ipswich, MA.

RNA-seq (RNA sequencing) has undoubtedly become the most popular method for transcriptome analysis. It is widely used, both for gene expression analysis and for other applications, including detection of mutations, gene fusions, alternative splicing, and post-transcriptional modifications. Recent improvements in next generation sequencing technologies (NGS) and sample barcoding strategies have resulted in significant cost reduction. As RNA-seq is increasingly adopted for molecular diagnostics, the quality and reproducibility of library preparation methods become more important. In addition, demand for library preparation methods that produce successful NGS libraries from ultra low input RNA or precious clinical samples is increasing. To overcome these challenges, we have developed a streamlined RNA-seq library preparation method that retains information about which strand of DNA is transcribed, which is now available as NEBNext® Ultra™ II Directional RNA Library Prep Kit for Illumina®. Strand specificity is important for the correct annotation of genes, identification of antisense transcripts with potential regulatory roles, and correct determination of gene expression levels in the presence of antisense transcripts. Our method can be used across a wide range of input RNA (5-1000 ng total RNA) without any modifications to the protocol, making it a convenient method for RNA-seq library preparation. More importantly, GC content analysis, gene body coverage and gene expression correlation show that these important parameters remain consistent across varying inputs, even though input amounts vary by two orders of magnitude. As a result, our method has increased sensitivity and specificity for low-abundance transcripts, and reduced PCR duplicates and sequence bias, delivering high quality strand-specific data. Our method is compatible with poly A-tail enriched and ribosomal RNA depleted samples as well as RNA extracted from FFPE (formaldehyde fixed paraffin embedded) tissue samples, and is amenable to large-scale library construction and automation.

**High-throughput single-cell genomic profiling with droplet microfluidics.** *D. Eastburn, M. Pellegrino, A. Sciambi, S. Treusch, K. Gokhale, J. Jacob, T. Chen, K. Jones, W. Oldham.* Mission Bio, Inc., South San Francisco, CA.

Single cell analysis tools are crucial for studying the role that rare or heterogeneous cells play in disease progression. While there have been recent advances in single-cell RNA-Seq methods, current approaches for genome profiling with single-cell DNA-Seq continue to be limited in throughput and content. The Mission Bio Mosaic Single Cell Platform enables the characterization of genetic variation within cancer cell populations by utilizing a novel approach that barcodes amplified genomic DNA of individual cells confined to microfluidic droplets. The barcodes are used to reassemble the genetic profiles of single-cells from next-generation sequencing data. A key feature of the approach is the "two-step" microfluidic workflow. The workflow first encapsulates individual cells in droplets, then lyses the cells and prepares the genomic DNA for amplification with proteases. Following this lysate preparation step, the proteases are inactivated and droplets containing the genomes of individual cells are paired with molecular barcodes and PCR reagents. We demonstrate that the two-step microfluidic approach is superior to workflows without the two-step process for efficient DNA amplification on up to 5,000 individual cells per run with high coverage uniformity and low allelic dropout of targeted genomic loci. To apply our single-cell sequencing technology to human tumor samples, we developed a targeted panel to simultaneously sequence regions of interest across 19 genes frequently mutated in acute myeloid leukemia (AML) including *TP53*, *DNMT3A*, *FLT3*, *NPM1*, *NRAS*, *IDH1* and *IDH2*. Using this panel, we were able to sensitively assay for changes in clonal architecture within AML samples collected longitudinally at the time of diagnosis, remission and relapse. Our data correlated well with variant allele frequencies (VAFs) obtained from bulk sequencing data; moreover, the single-cell nature of our approach enabled the unambiguous correlation of multiple mutations within subclones not possible with bulk measurements. Collectively, our results show a greater degree of heterogeneity in AML tumor samples than is commonly appreciated with traditional sequencing paradigms. The Mosaic platform enables cost-effective targeted sequencing of SNPs and indels at the single-cell level at unprecedented cell throughput and can be applied to additional disease states with customization of targeted regions of interest.

**1514T**

**Highly efficient transcriptome profiling method for single-cell or low input RNA.** K. Krishnan, Y. Bei, S. Guan, J. Borgaro, T. Shtatland, B. Langhorst, T. Evans, E. Dimalanta, N. Nichols. New England Biolabs, 240 County Road, Ipswich, MA.

RNA sequencing has been widely used to determine gene expression profiles of diverse tissues, cell types, developmental stages and diseases. Most of these studies have been based on population analysis using thousands of cells. Such ensemble studies, however, disguise the potentially significant variations between individual cells. To overcome this limitation, single-cell RNA-seq is emerging as a powerful approach to characterize gene expression heterogeneity within phenotypically identical or complex cell populations and in rare cell types. We have developed a simple and robust single-cell or low input RNA-seq workflow to generate full-length cDNAs that can easily be converted into sequence-ready Illumina libraries with the newly developed NEBNext Ultra II FS DNA Library Preparation Kit (which has an enzyme-based DNA fragmentation method incorporated into the end repair and dA-tailing step). The cDNA can also be used in other workflows to generate libraries for alternate platforms. A variety of single-cell types or low input (2.5 pg-200 ng) Universal Human Reference RNA (UHR) with an RNA spike-in from External RNA Controls Consortium (ERCC) was used to synthesize and amplify full-length cDNAs, in a single tube using a template switching mechanism. The resulting cDNA libraries are converted into Illumina libraries and sequenced on the Illumina Nextseq 500. Paired-end reads are first downsampled, adaptor-trimmed and mapped to the corresponding reference genomes with Hisat 2, and transcriptomes with Salmon. Libraries are assessed across a spectrum of metrics including mapping rate, 5'-3' coverage, %rRNA, transcript level correlation between input amounts, and sensitivity to low abundance transcripts. Using this method, high quality RNA sequencing data was obtained from a variety of single-cell types, and low input RNAs. The data shows strong gene expression correlation (Pearson  $r > 0.9$ ) between inputs that span over five orders of magnitude. In addition, we observe excellent gene body coverage, and high sensitivity as demonstrated by detection of single copy ERCC RNA molecules. We have developed a highly specific and sensitive single-cell/low input RNA-seq method that consistently generates high quality data. It is streamlined and amenable to large-scale library construction as well as high throughput automation. We envision this method facilitating novel discoveries in the area of low-input transcriptome applications.

**Tissue-of-origin identification of forensic material by targeted sequencing of stable regions of RNA using RNase-H2.** L. Parker-Katiraei<sup>1</sup>, R. Fleming<sup>2</sup>, N. Dunn<sup>2</sup>, M. McNeill<sup>1</sup>, Y. Wang<sup>1</sup>, Y. Bao<sup>1</sup>. 1) Product Development, Integrated DNA Technologies, Redwood City, CA; 2) Forensic Research and Development Programme, Institute of Environmental Science and Research Ltd (ESR), Auckland, New Zealand.

Tissue-of-origin identification of forensic material can provide important information regarding the nature of a crime. However, identification is seldom performed due to the amount of material required, the degraded nature of RNA found at crime scenes, and the high cost. Here, we used a highly multiplexed PCR targeting tissue-specific RNAs that are predicted to be more resistant to degradation (StaRs – Stable regions of RNA), followed by next-generation sequencing. RNase-H2 dependent PCR (rhPCR) chemistry was used to circumvent the formation of primer dimers that occur when primers are multiplexed in low inputs of DNA/cDNA. rhPCR uses 3' blocked primers containing one RNA base that is used for primer activation by RNase H2. The RNase H2 cleaves at RNA-DNA heteroduplexes when there is a perfect match, which also removes the 3' blocking modification. Initial workflow and assay performance were evaluated on synthetic templates and universal RNA samples using a multiplexed pool of 71 primer pairs designed to identify the expression of tissue-specific transcripts in circulatory blood, menstrual blood, semen, saliva, vaginal material, or skin. Additional primer pairs were included to identify reference transcripts and spike-in controls. We observed on-target rates as high as 85% in universal RNA samples. Using titrated amounts of cDNA from body fluids, including blood, menstrual fluid, and semen, we tested the sensitivity of the assay and the exclusive expression of the stable markers. Our data suggest that StaRs amplified by rhPCR can successfully predict tissue of origin in representative forensic samples.

**Quality deep-sequencing miRNA data from matched fresh and FFPE cells for expression analysis profiling.** K. Tokarz, T. Vilboux, R. Iyer, D. Thach, M. Ahmad. Inova Translational Medicine Institute, Falls Church, VA.

Micro-RNAs (miRNA) are small noncoding RNAs that posttranscriptionally regulate gene expression and are currently used as biomarkers in many diseases, including cancer. Formalin is the most widely used fixative and is the standard preservation method for diagnostic pathology. Many molecular analyses including Next Generation Sequencing can show discrepancies in the data depending on the sample processing and storage. In this study, we investigated the variability of the miRNA repertoire from 10 pairs of formalin-fixed paraffin-embedded (FFPE), and their freshly collected counterparts. The samples were prepared on a liquid handler using the HTG EdgeSeq miRNA Whole Transcription Assay. Processed samples underwent library preparation and were sequenced on a MiSeq instrument. The libraries gave quality deep sequencing data for both fresh and FFPE embedded cells. Our laboratory implemented a filtering procedure, removing any probes where the sum of counts for the given probe was less than ten across the samples. This gave us 1498 unique miRNA for the samples after filtering. In order to evaluate the expression of each miRNA probe in proportion to the total counts per million of the run, a  $\log_2(\text{CPM})$  was applied. Statistical analysis gave Pearson correlation data between the sample types across all cell lines. This study shows that our process produces a high quality data from FFPE samples, which are typically a challenging sample type for next generation sequencing. Because of the volume of collections of surgical specimens and archived tissues from retrospective studies of human diseases, the ability to isolate and sequence miRNA from FFPE samples with high confidence will provide a powerful tool to identify new biomarkers and understand the mechanism of many diseases. We will now begin to look for specific miRNA expression profiles that can be correlated to the clinical information for these known Coriell cell lines in order to explore various genetic disorders.

**Evaluation of NXType™ NGS high-resolution HLA typing kit.** S. Khor<sup>1</sup>, Y. Hitomi<sup>1</sup>, Y. Okudaira<sup>2</sup>, A. Masuya<sup>2</sup>, Y. Ozaki<sup>3</sup>, M. Ueta<sup>4</sup>, K. Nakatani<sup>1</sup>, M. Nagato<sup>5</sup>, T. Ogawa<sup>5</sup>, C. Sotozono<sup>4</sup>, S. Kinoshita<sup>4</sup>, H. Inoko<sup>2</sup>, K. Tokunaga<sup>1</sup>. 1) Department of Human Genetics, Graduate School of Medicine, University of Tokyo, Tokyo, Tokyo, Japan; 2) GenoDive Pharma Inc., Honatsugi, Kanagawa, Japan; 3) The Center of Medical Innovation and Translational Research, Graduate School of Medicine, Osaka University, Osaka, Japan; 4) Department of Frontier Medical Science and Technology for Ophthalmology, Kyoto Prefectural University of Medicine, Kyoto, Japan; 5) Research and Development Section, Wakunaga Pharmaceutical Co., Takata, Hiroshima, Japan.

The human MHC region has been shown to be associated with a wide range of diseases. The recent advancement in the next generation sequencing (NGS) technology has definitely helped in increasing the resolution (up to 4-field) of HLA genotyping. However, it remains a challenge in interpreting the results from NGS platform due to biases including systematic sequencing error by sequencing platform, difference in the sensitivity and specificity of HLA calling algorithm, ability to resolve HLA alleles ambiguity by incorporating phasing information, and more importantly incompleteness of the current IMGT database. In order to access the sensitivity and specificity of the NXType™ NGS HLA typing kit (One Lambda), a total of 105 Japanese samples were sequenced for HLA class I genes using the Ion Torrent Personal Genome Machine (PGM) following the NXType protocol. HLA calling was performed using the HLAStream v1.1.0.11 with IMGT/HLA databases of 3.27.0.3. Concordance rates were evaluated by comparing HLAStream results with Luminex-based HLA typing result for up to 2-field result. With the default setting of HLAStream and without manual interpretation of the results, the allelic concordance is more than 99% for HLA-A, HLA-B and HLA-C. Other commercially available HLA calling software and open-access software were also evaluated. Careful inspection of the final results and occasionally manual interpretations of results are necessary especially for rare or novel HLA alleles.

**European Genome-phenome Archive: Finding, applying for, and accessing controlled-access data.** J. Spalding<sup>1</sup>, J. Almeida-King<sup>1</sup>, A. Carreño-Torres<sup>2</sup>, M. Ding<sup>1</sup>, P.A. Garcia<sup>1</sup>, A. Gil<sup>2</sup>, J. Kandasamy<sup>1</sup>, G. Kerry<sup>1</sup>, O.M. Llobet<sup>2</sup>, A. Lloret-Villas<sup>2</sup>, M. Moldes<sup>2</sup>, A. Semf<sup>1</sup>, N. Spataro<sup>2</sup>, S. de la Torre<sup>2</sup>, S. Ur-Rehman<sup>1</sup>, A. Navarro<sup>2,3,4</sup>, R. Guigó<sup>2</sup>, P. Flicek<sup>1</sup>, H. Parkinson<sup>1</sup>, J. Rambla<sup>2</sup>, T. Keane<sup>1</sup>. 1) European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Wellcome Trust Genome Campus, Hinxton, Cambridge, CB10 1SD, United Kingdom; 2) Centre for Genomic Regulation (CRG), Dr. Aiguader 88, Barcelona 08003, Spain and Universitat Pompeu Fabra (UPF), Barcelona, Spain; 3) Institute of Evolutionary Biology, Barcelona, Spain; 4) Institutió Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.

The European Genome-phenome Archive (EGA) is a controlled-access archive, which provides secure long-term storage and distribution of human genetic and phenotypic data for biomedical research. Access to datasets is made by application to data access committees in accordance with donor consent agreements. As of May 2017, the EGA stores over 4.2 petabytes of data available for download from over 965,000 unique samples in over 1100 studies. EGA hosts reference data collections and supports data re-use, such as data derived from the UK10K project, WTCCC, Human Induced Pluripotent Stem Cells Initiative (HipSci), RD-Connect and the International Cancer Genome Consortium (ICGC). The EGA is working closely with the Global Alliance for Genomics and Health (GA4GH) to improve the way controlled access data can be found, applied for, and accessed. In collaboration with GA4GH we have been mapping consent codes to the Data Use Ontology (DUO) that classifies data use restrictions to 5 main classes, which can be further refined by referencing secondary classes and other ontologies. The use of DUO aids data discoverability by allowing researchers to determine which data can be used for specific research projects. Ontologies are machine-readable, allowing fully automated data access and providing a basis for supporting interoperability with other relevant GA4GH access projects. To access data at EGA, the EGA downloader enables any file in EGA to be delivered to a destination in an encrypted format and accessed via a FUSE layer. This allows applications to access these files without decryption irrespective of file format, which leads to the possibility of data being hosted in cloud environments securely. EGA is working with the GA4GH to develop a standardised encryption container format allowing random access to common NGS formats while the data remains encrypted at rest. Combining these GA4GH projects with a Beacon allows a researcher to find a dataset by variant, immediately determine the DUO code for the dataset, electronically apply for and be granted access, and visualise the region of interest with the bam file remotely as if the data was open access and hosted on their own computer.

**1519W**

**Machine learning applied to single-molecule electronic DNA mapping for structural variant verification in human genomes.** B. Bready, J.R. Davis, B.S. Grinberg, M.D. Kaiser, J.S. Oliver, J.M. Sage, L. Seward. Nabsys, Providence, RI.

The importance of structural variation in human disease and the difficulty of detecting structural variants larger than 50 base pairs has led to the development of several long-read sequencing technologies and optical mapping platforms. Frequently, multiple technologies and *ad hoc* methods are required to obtain a consensus regarding the location, size and nature of a structural variant, with no single approach able to reliably bridge the gap of variant sizes between those readily detected using NGS technologies and the largest rearrangements observed with optical mapping. Often, structural variants larger than 10 kilobases are not detected. To address this unmet need, we have developed a new software package, *SV-Verify*<sup>TM</sup>, which utilizes data collected with the Nabsys High Definition Mapping (*HD-Mapping*<sup>TM</sup>) system, to perform hypothesis-based verification of putative deletions. We demonstrate that whole genome maps, constructed from data generated by electronic detection of tagged DNA, hundreds of kilobases in length, can be used effectively to facilitate calling of structural variants ranging in size from 300 base pairs to hundreds of kilobase pairs. *SV-Verify* implements hypothesis-based verification of putative structural variants using supervised machine learning. Machine learning is realized using a set of support vector machines, capable of concurrently testing several thousand independent hypotheses. We describe support vector machine training, utilizing 1089 deletions and 4637 negative controls from a well-characterized human genome. Plots delineating the specificity versus sensitivity of each of the support vector machines will be presented. We subsequently applied the trained classifiers to another human genome, evaluating > 5000 putative deletions, demonstrating high sensitivity and specificity for deletions from 300 base pairs to hundreds of kilobases. Over 78% of deletions called by three or more technologies were confirmed by *SV-Verify*.

**1520T**

**Automation of ultra-high molecular weight DNA isolation and labeling for genome mapping.** P. Lynch, A. Lee, W. Stedman, C. Gadd, D. Bollish, M. Saghbini, M. Borodkin. Bionano Genomics, San Diego, CA.

Structural variations (SVs) are known to play an important role in human genetic disease. Those SVs include deletions, insertions, and other complex rearrangements of genomic material. They are frequently disrupting or altering genes and regulatory elements. SVs are used as markers in the clinical diagnosis of diseases such as childhood syndromic disorders (Ex.: DiGeorge syndrome) as well as in cancers. Next Generation Mapping (NGM) using the Saphyr™ system from Bionano Genomics provides high-speed, high-throughput genome mapping with unparalleled structural variation detection. These variants are able to be detected by utilizing ultra-high molecular weight DNA. Molecules that range from hundreds of kilobases to over a megabase are linearized and imaged using NanoChannel array technology. These images are then used as input to the Bionano Solve *de novo* genome map assembly and SV calling pipeline. High quality, ultra-high molecular weight DNA is essential to enable the Saphyr system to identify structural variants. The current Bionano Prep™ protocol is a three day process of harvesting cells, embedding in agarose gel plugs, isolation and purification of DNA, and sequence-specific labeling. As the size of studies focusing on SVs increases, there is a need to develop automated ultra-high molecular weight protocols to enable processing large numbers of samples. Here we present a novel, automated protocol for preparation of ultra-high molecular weight DNA from cell lines and blood. This protocol consists of using a standard liquid handling instrument with custom hardware developed specifically for ultra-high molecular weight DNA isolation and labeling. This method significantly decreases the hands-on time needed while improving genome map contiguity and SV sensitivity. We present data from multiple replicates of DNA isolation from the same donor's cells prepared using this automated method. Each of the replicates was run on a Saphyr chip to sufficient coverage for haplotype-aware SV detection using the hands-off, adaptive loading protocol that significantly reduces instrument hands-on time and improves throughput. SVs were detected using the latest automated Bionano Solve assembly and SV detection pipeline and were compared between the replicates. We observed very high rates of concordance between replicates, as well as a greater number of SVs detected compared to the current commercially available protocol.

**1521F**

**Application of electronic mapping to metagenomic characterization of a complex microbial sample.** J.M. Sage, B. Bready, A.P. Catalano, J.R. Davis, M.D. Kaiser, J.S. Oliver, L. Seward. Nabsys, Providence, RI.

The microbiome is a complex and dynamic mixture of microbes inhabiting many surfaces on and within the human body. While increasing lines of evidence point to the crucial role that these microbes play in maintaining health, disruptions in population compositions also correlate with a variety of diseases. The characterization of microbe populations has historically been limited to known genetic markers of strains such as 16S rRNA genes. More recently, shotgun sequencing has been employed in an attempt to provide a more accurate measure of biodiversity. While whole metagenome sequencing is more comprehensive than single marker typing, short read lengths prevent accurate quantitation of related strains within a mixture as well as consistent characterization of large-scale structural variation that can significantly impact pathogenicity. To address these issues, Nabsys has applied the *HD-Mapping*™ platform to the identification and quantitation of microbial strains in the context of a single defined complex sample. *HD-Mapping* employs fully electronic detection of tagged single DNA molecules, hundreds of kilobases in length, at a resolution superior to existing optical mapping approaches. The preservation of long-range information coupled with superior resolution allows for highly sensitive and specific genome detection and structural characterization. Nabsys single-molecule reads derived from this complex mixture were mapped to a database of microbial references resulting in identification of strains within the sample. Titrating the relative abundance of a single bacterial genome in a complex sample resulted in quantitation that was linear over 3 orders of magnitude. In addition, assembly of the mixed reads into independent, map-level contigs allowed for the identification and structural comparison of distinct but related strains contained within the same sample.

**1522W**

**A comprehensive workflow for copy number variation identification from whole-genome sequencing data.** B. Trost<sup>1</sup>, Z. Wang<sup>1</sup>, S. Walker<sup>1</sup>, B. Thiruvahindrapuram<sup>1</sup>, J.R. MacDonald<sup>1</sup>, W.W.L. Sung<sup>1</sup>, S. Pereira<sup>1</sup>, J. Whitney<sup>1</sup>, A.J.S. Chan<sup>1,2</sup>, G. Pellecchia<sup>1</sup>, M.S. Reuter<sup>1</sup>, S. Lok<sup>1</sup>, R.K.C. Yuen<sup>1</sup>, C.R. Marshall<sup>1,3</sup>, D. Merico<sup>1,4</sup>, S.W. Scherer<sup>1,2,5</sup>. 1) The Centre for Applied Genomics, Genetics and Genome Biology, The Hospital for Sick Children, Toronto, Canada; 2) Department of Molecular Genetics, University of Toronto, Toronto, Canada; 3) Genome Diagnostics, Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, Canada; 4) Deep Genomics Inc., Toronto, Canada; 5) McLaughlin Centre, University of Toronto, Toronto, Canada.

Whole-genome sequencing (WGS) is poised to become a first-tier genetic test, replacing less comprehensive technologies such as karyotyping, microarrays, and exome sequencing. A remaining hurdle to broad uptake has been to demonstrate accurate detection of copy number variations (CNVs) from WGS data. Here, we describe a comprehensive workflow for identifying germline CNVs from short-read WGS data using read depth-based computational algorithms. Using multiple datasets to evaluate sensitivity, false discovery rate (FDR), and reproducibility, we empirically determined best practices for several stages of the CNV-detection workflow, including DNA library preparation, sequencing, quality control and assurance, reference mapping, computational CNV identification, and filtering based on technically-difficult genomic regions. Based on our findings, we make several recommendations, including the use of PCR-free DNA library preparation methods, sequencing to an average depth of ~30x, maintaining minimum standards for uniformity of sequencing depth, and using consensus predictions from the CNV detection algorithms ERDS and CNVnator. We compared CNVs detected using our workflow with a comprehensive, multi-technology benchmark of CNVs in the HuRef genome. For the highest-confidence CNVs in this benchmark (those detected by two or more different technologies), deletions >10 kb (the size range typically detectable by high-resolution microarrays) could be identified with 100% sensitivity and 0% FDR (71% and 25%, respectively, for all deletions >1 kb). Unsurprisingly, detecting duplications was less accurate than detecting deletions. We used our workflow to detect rare, genic CNVs in individuals with autism spectrum disorder (ASD), and both deletions and duplications in this subset of CNVs could be detected highly accurately, with 100% of CNVs chosen for validation using orthogonal methods (ranging in size from 3 kb to 33 Mb) successfully confirmed. In the subset of individuals with ASD in which both clinical microarray experiments and WGS were performed, WGS detected all clinically-relevant CNVs that were detected by microarray, as well as additional pathogenic CNVs smaller than 10 kb. Thus, CNVs of clinical relevance can be found from WGS with a detection rate exceeding microarrays, positioning WGS as a single assay for variant detection in clinical genomics.

**1523T**

**Implementation of an automated sample quality control tool in a whole exome sequencing workflow.** A. Regala<sup>1</sup>, M. Liu<sup>2</sup>, E. Viering<sup>3</sup>, J. Petersen<sup>4</sup>, M. Beckhaus<sup>4</sup>, S. Wolf<sup>4</sup>. 1) Agilent Technologies, Santa Clara, CA; 2) Agilent Technologies, La Jolla, CA; 3) Agilent Technologies, Waldbronn, Germany; 4) DKFZ Genomics and Proteomics Core Facility, High Throughput Sequencing Unit, Heidelberg, Germany.

Sample quality control is of major importance in the Next Generation Sequencing (NGS) workflow as it avoids time- and cost-intensive repetition of experiments. Here the German Cancer Research Center (DKFZ) demonstrates how an automated electrophoresis system can be used to control an exome sequencing workflow to assure the generation of high quality sequencing data. 88 genomic DNA samples from formalin-fixed paraffin-embedded (FFPE) tumor tissues were analyzed. Samples that passed the initial quality assessment, with respect to sample quantity and integrity, were submitted to the library preparation workflow. Depending on the DNA integrity, a suitable DNA fragmentation protocol was used to enable library preparation from degraded DNA. Implementation of quality control steps at various steps throughout the protocol allowed the monitoring of the workflow by checking for library preparation artifacts, as well as controlling sample concentrations and average fragment sizes to increase read number during sequencing. The stringent quality control criteria used by the DKFZ allow for an increase in efficiency during library preparation and ensure reliable sequencing results in high throughput sample analysis.

**Capillary electrophoresis using the SeqStudio™ Genetic Analyzer as part of genome editing workflows.** *S. Jackson<sup>1</sup>, S. Kumar<sup>2</sup>, N. Ravinder<sup>2</sup>, K. Varma<sup>2</sup>.* 1) Genetic Analysis, Thermo Fisher Scientific, South San Francisco, CA; 2) Synthetic Biology, Thermo Fisher Scientific, Carlsbad, CA.

Genome editing is poised to revolutionize our understanding and control of diverse biological systems. Critical to any genome editing workflow is monitoring the efficiency and accuracy of the steps leading to a designed edit. Thermo Fisher Scientific offers complete toolkits for designing, verifying and analyzing the effects of a genome editing experiment. To illustrate this workflow, we used the Thermo Fisher Scientific Cloud-based CRISPR Search and Design tool to identify guide RNAs against human HPRT and RELA loci. Guide RNAs and mRNA encoding Cas9 enzyme (Invitrogen) were introduced into HEK293 cells and incubated for 78 hours. Primers were designed that flanked the targeted sequence. Amplified products from primary pools of edited cells were analyzed for efficiency of editing on SeqStudio Genetic Analyzer by three methods: 1) by fragment analysis using GeneArt™ Genomic Cleavage Detection Kit, 2) by Sanger sequencing of the mixed pool of transformants, and 3) by subcloning into a plasmid (Invitrogen) and Sanger sequencing individual clones. The efficiency measured by these three methods correlated extremely well. Cells from the primary pool were diluted and plated to single cell density; these cultures were then sequenced to confirm that they were monoclonal and to establish sequence of the edit that was introduced. Together, these results demonstrate that the portfolio of tools available from Thermo Fisher Scientific can provide an integrated solution that facilitates genome editing experimentation.

**Chromosomal integration of libraries of full-length mutant genes with associated barcode tags.** *X. Jia, V. Chen, M. Maksutova, S. Jayakody, R. Lemons, J. Kitzman.* Department of Human Genetics, University of Michigan, Ann Arbor, MI.

Genome editing provides a powerful toolset to interrogate sequence variants' functional impacts via targeted genomic integration in living cells. Recently, these techniques have been multiplexed to tile short genomic targets, such as single exons, for replacement with pools of mutations. However, current approaches have been limited by the inefficiency of homology-directed repair as well as the necessity of individually targeting disperse sequences such as the multiple exons comprising typical mammalian genes. To overcome this technical bottleneck, we have devised Blunt Library Integration of Tagged Sequences (BLITS), which leverages Cas9-mediated homology-independent targeted integration (HITI) to knock-in complex libraries of full-length sequences into a genomic "safe harbor" locus. A key aspect of BLITS is that each integrated gene variant is pre-tagged with a unique molecular identifier (UMI), with the variant-to-UMI pairing established by sequencing prior to genomic integration. Consequently, during downstream pooled functional selections, it is only necessary to track the identity and abundances of these short UMIs rather than the full sequence of each mutant gene. As a proof of principle, we integrated an allelic series of human cDNAs into the AAVS1 genomic safe-harbor locus. We demonstrate that BLITS can achieve site-specific knock-in of ~3 kbp fragments at an efficiency of ~10% in cultured human cells, compared to ~1% for homology dependent repair of typically much shorter regions. In pilot functional selection experiments, we show that tracking integrated UMI counts reduces sequencing costs, and we model the corresponding improvements in accuracy and reproducibility in functional effect measurements. We believe BLITS will be a useful tool for high-throughput structure-function studies of complex libraries of gene variants.

**Monitoring guide RNA synthesis for CRISPR/Cas9 genome editing workflow.** *M. Liu<sup>1</sup>, A. Padmanaban<sup>2</sup>*. 1) Agilent Technologies, Inc., La Jolla, CA; 2) Agilent Technologies, Bangalore India.

Bacterial clustered regularly interspaced short palindromic repeats (CRISPR) - associated protein 9 (Cas9) system has increased in popularity as a genome editing tool for targeted mutations, insertions, deletions and gene knock-out studies. CRISPR genome editing has also proved superior to Zinc-finger nucleases (ZFN) and transcription activator-like effector nucleases (TALENs) due to its simplicity and easy programmability. In CRISPR, a guide RNA (gRNA) is used to recognize and introduce a double strand break (DSB) in a target DNA. The DNA repair mechanism triggered after the break is then exploited to introduce an insertion/deletion (indel) in the case of non-homologous end joining (NHEJ), or precise genetic modification if a homology-directed repair (HDR) pathway is triggered. A critical part of the CRISPR-Cas9 tool is the design and synthesis of the gRNA that comprises T7 promoter sequence, target sequence, and protospacer adjacent motifs (PAM). Monitoring the transcription of the gRNA is critical to the workflow to ensure successful gene editing. Here we present an automated electrophoresis approach for monitoring the synthesis, integrity, and functional activity of gRNAs created for a CRISPR/Cas workflow.

**Copy number variants can be detected using next generation sequencing.** *R. Drouin<sup>1</sup>, J. Morin-Leisk<sup>2</sup>, B. Lacey<sup>1</sup>, C. Bouffard<sup>2</sup>, H. Gao<sup>2</sup>*. 1) Div Med Genetics, Dept Pediatrics, Laval University, Quebec City, Quebec, Canada; 2) Fulgent Genetics, Temple City, CA; 3) Div Genetics, Dept Pediatrics, University of Sherbrooke, Sherbrooke, Quebec, Canada.

**Background.** Next generation sequencing (NGS) is frequently used to quickly make a diagnosis. NGS data is primarily used for detection of SNPs and small indels. But diagnostic findings commonly include copy number variants (CNVs), which can also be detected by NGS, which broadens the scope of NGS as a method for identifying diagnostic genetic changes. **Objectives.** The case studies described here aim to demonstrate the clinical utility of CNV analysis using NGS data. Specifically, the presentation of cases with a multi-exon deletion or duplication, detected by NGS, that appear to explain the clinical phenotype of the individuals tested. **Methods.** Genomic DNA, extracted from peripheral leukocytes, barcoded and enriched for coding exons, was sequenced using an Illumina HiSeq. Sequencing results were aligned to the GRCh37.p13 (hg19) human reference sequence. Single nucleotide variants and short insertions and deletions were detected by VarScan. CNV analysis was performed using Fulgent-developed computational tools and verified by qPCR. **Cases.** Here we describe six children in whom a CNV, detected by NGS, was identified and is likely diagnostic. We found: (1) a paternally inherited duplication of all coding exons of the *UBE3A* gene; (2) a *de novo* deletion of all coding exons of the *PRRT2* gene; (3) a maternally inherited 2-exon duplication of the *GRIA3* gene, located on the X-chromosome; (4) a *de novo* whole-gene deletion of the *RBCK1* gene; (5) a *de novo* whole-gene duplication of the *TUSC3* gene; and (6) a paternally inherited deletion of all coding exons of the *TANGO2* gene with a maternally inherited c.218G>C (p.Arg73Pro) variant on the other allele. These CNVs were confirmed by microarrays to be part microdeletion/microduplication that included several genes. **Conclusions.** These findings support the clinical utility of using NGS data to detect CNVs, since they provide faster and optimal diagnosis and healthcare management. From a clinical, ethical and social perspective, it is beneficial for the treating physicians, their patients, and their patients' families.

**HiSeq X and NovaSeq optimization for clinical applications.** *K. Walker<sup>1</sup>, Q. Wang<sup>1</sup>, D. Kalra<sup>1</sup>, H. Doddapaneni<sup>1</sup>, J. Hu<sup>1</sup>, Z. Momin<sup>1</sup>, J. Santibanez<sup>1</sup>, N. Osuji<sup>1</sup>, C. Nessner<sup>1</sup>, G. Metcalf<sup>1</sup>, Z. Khan<sup>1</sup>, J. Farek<sup>1</sup>, W. Salerno<sup>1</sup>, Y. Han<sup>1</sup>, H. Dinh<sup>1</sup>, E. Boerwinkle<sup>1,2</sup>, R. Gibbs<sup>1</sup>, D.M. Muzny<sup>1</sup>.* 1) Baylor College of Medicine HGSC, Houston, TX; 2) Human Genetics Center, University of Texas Health Science Center at Houston, Houston, TX.

High-throughput parallel nucleotide sequencing has revolutionized genomic research and reshaped applications in clinical diagnostics. The HiSeq X Ten and NovaSeq platforms further expand these opportunities by providing unprecedented capacity and the opportunity for routine clinical whole genome sequencing (WGS). The Human Genome Sequencing Center (HGSC) at Baylor College of Medicine has more than three years' experience with the HiSeq X Ten platform and recently acquired a NovaSeq 6000. These platforms have now been benchmarked for WGS, relative to our extensive experience with whole exome sequencing (WES), and are now optimized for validation in the HGSC's clinical diagnostic laboratory environment (HGSC-CL). To date, we have analyzed more than 37,000 30X human WGS on the HiSeq X platform in the research environment. These studies have included cohorts for studying common diseases, samples of inherited cancers and families with Mendelian disease. PCR-Free library methods were evaluated and implemented for optimized coverage in GC-rich regions. Metrics for coverage, sample integrity and variant representation were established to ensure consistently high quality WGS. Genome coverage metrics include 90% of genome covered at 20x and 95% at 10x with a minimum of 86x10<sup>9</sup> mapped and aligned bases with ≥Q20. Platform sensitivity and precision at 30X coverage was determined to be 97.8% and 99.6% respectively. Our primary finding is that effective clinical WGS will require ≥40X coverage to provide high consistent exonic coverage of clinically relevant genes similar to that generated in clinical WES. The NovaSeq platform offers to both improve WGS and lower the cost of WES. We acquired a NovaSeq 6000 in March 2017 and preliminary data shows similar performance to HiSeq X in read alignment rates and %coverage at 10X and 20X. Additionally, %read error rates and %duplicate reads are lower for the NovaSeq and suggest the instrument could ultimately produce a higher yield at greater quality. A direct comparison of SNP calls from these two platforms were found to be highly concordant (98.11%) and both have >96% overlap to NIST standards.

**1529T**

**An optimal long-read workflow for human genome sequencing.** *J. Lenhart, S. Sandhu, L. Kurihara, V. Makarov, T. Harkins.* Swift Biosciences, Ann Arbor, MI.

The goal of precision medicine is to treat disease with targeted therapies predicated on highly accurate diagnostic sequencing. Short-read sequencing technology offers low error-rates, high throughput capabilities, and low sequencing costs; however, short-read sequencing has a limited ability to map reads in regions beset by low complexity (i.e. repetitive elements) or high polymorphic density while having minimal ability in identifying large insertions or deletions. An alternate long-read sequencing technology, Single Molecule Real-Time (SMRT®) offered by Pacific Biosciences® (PacBio®) provide continuous, low bias DNA reads upwards of 60 kb in length. SMRT technology is ideally suited to produce readily mapped reads in regions that would typically be undetected with short-read technologies. These capabilities ideally position the long-range sequencing PacBio platform to provide enhanced coverage and assembly metrics for whole-genome sequencing and potentially *de novo* assembly of human genomes, bringing the goal of precision medicine within reach. However, standard workflows are laborious and time consuming. Here, we provide a complete workflow with the Swift Accel-NGS® XL Library Kit for the acquisition of ultra-long (> 30 kb) subreads for the PacBio sequencing platforms. The Accel-NGS XL Library Kit for PacBio combines Swift's proprietary repair and ligation chemistry to offer a significant improvement in library conversion efficiency. Furthermore, we highlight several strategies to further optimize average human library subread read length (> 10 kb), from producing a high quality initial shear using the Diagenode Megaruptor2 and selection of ultra-long library molecules with the Sage BluePippin™, to improving integrity of the final library with the provided Swift terminal repair module. These long-read libraries can result in increased coverage of hard-to-sequence regions of the human genome, facilitating detection of both small and large structural variants, improved phasing of distant SNPs, along with precise elucidation of repetitive repeat number. Ultimately, by enabling an improved, complete genomic landscape for precision medicine, better understanding of variants can be realized.

**Digital gene expression of up to 96 targets in 96 samples for cell line screening with nCounter<sup>®</sup> PlexSet<sup>™</sup>.** *G.T. Ong, C. Merritt, P. Webster.* Nanostring Technologies, Seattle, WA.

Cell line screening studies require highly efficient protocols for studying many samples in parallel. We have developed a lyse-and-go protocol for digital gene expression profiling of 96-samples by 96-genes in parallel. This protocol is based on nCounter PlexSet Reagents which enable multiplexing of samples and gene targets. The NanoString nCounter Analysis platform uses a novel molecular barcoding technology to measure multiplexed gene expression. The assay counts fluorescent barcodes hybridized to targets to provide precise digital data. This platform is used in a wide variety of research applications. The standard nCounter gene expression assay can be used to process 12 samples per run. We recognize an additional need for a higher sample-throughput assay which would enable researchers to quickly evaluate up to 96 multiplexed targets in samples processed in a 96-well plate-based format. The PlexSet protocol is simple and fast and can be divided into 3 steps: 1) lyse cells, 2) set-up hybridization with crude lysate; 3) initiate automated post-hybridization processing and digital counting. We will present data showing that up to 96 high-quality, digital data points for gene expression in each of 96 samples can be generated from crude cell lysates in an efficient, high-throughput protocol.

**1531W**

**NCBI resources for visualization and analysis of genome assemblies.** *V.A. Schneider, P. Meric, N. Bouk, E. Weitz, V. Ananiev, W.R. Anderson, A. Kuznetsov, P.A. Kitts, F. Thibaud-Nissen, T. Murphy, K.D. Pruitt.* IEB, NIH/NCBI, Bethesda, MD.

Ongoing technological developments in sequencing, coupled with a decrease in cost, are contributing to growth in the number of human genome assemblies in public databases. Meanwhile, improvements in assembly algorithms are making the production of de novo diploid assemblies a reality. The availability of these data present exciting new opportunities for analysis and discovery in many areas of basic and clinical genomic research. However, effective and efficient interpretation of these data requires compatible tools and resources that can be used as part of analysis workflows. Genome Data Viewer (GDV), NCBI's new genome browser, provides graphical displays for all RefSeq annotated eukaryotic genome assemblies and is replacing Map Viewer. Built on NCBI's existing browser technology used for the Variation Viewer and 1000 Genomes Browser, GDV makes use of the wealth of sequence-associated data stored at NCBI, including gene annotation, variation, transcript expression, alignments, and GWAS results, to offer users a rich and diverse set of tracks for display and analysis. We will present several recent feature additions to GDV that support improved navigation and analysis of supported genomic assemblies and their annotation, as well as its integration with other NCBI resources such as Assembly, Gene, dbGaP, GEO and BLAST. We will also discuss recent updates that improve the management and display of user-supplied data in GDV. In addition, we will present new features and datasets available in the NCBI Remapping Service, which allows users to move feature annotations between different versions of the same assembly or different assemblies. These include a new stand-alone software package and improvements specifically targeted for remapping of data to diploid assemblies. We will also highlight other NCBI resources, such as the Genome Decoration Page, Bulk Conversion Service, and Clone DB that further support the analysis and communication of genome scale datasets. Together, this collection of public resources will help users take full advantage of the growing collection of genome assemblies.

**1532T**

**Genomic DNA analysis using automated pulsed-field capillary electrophoresis.** *J. Uthe, K. Wong, S. Siembieda.* Advanced Analytical Technologies, Inc. 2450 SE Oak Tree Ct, Ankeny, IA, USA, 50021.

Advances in the third-generation sequencing platforms from small genomes analysis to de-novo assembly of complex genomes impose high quality standards for large genomic DNA samples. Preparation and qualification of genomic DNA (gDNA) samples remains a bottleneck in the workflow involving long read sequencing platforms. Pulsed field gel electrophoresis (PFGE), a classical method for assessment of size and integrity of gDNA preparations, takes hours to days to complete. Thereby an automated pulsed field capillary electrophoresis system (FEMTO *Pulse*<sup>™</sup>) that can assess the size and integrity of high molecular weight gDNA samples in a fraction of a time compared to PFGE gels was developed. In the FEMTO *Pulse* system, superior resolution, qualitative and quantitative gDNA analysis and automated gDNA quality scoring can be obtained in 70 minutes to 3 hours as compared to the 14 - 20 hours PFGE analysis. In addition, the FEMTO *Pulse* system requires only picograms to femtograms of gDNA for analysis thus conserving precious gDNA samples for downstream applications. With an enhanced sensitivity protocol, as little as 5 pg of gDNA (comparable to gDNA yield from a single cell) can be analyzed on FEMTO *Pulse*. Key features of the FEMTO *Pulse* system will be presented including sizing, resolution, sensitivity and reproducibility of gDNA analysis along with comparison of the system to classical PFGE gels. The FEMTO *Pulse* system streamlines the quality assessment of gDNA samples and offers innovation to the third generation sequencing workflow by eliminating the long wait times associated with the agarose-based PFGE gels, reducing labor and decreasing costs by quickly excluding unqualified samples.

**1533F**

**Targeted sequencing using a long-read sequencing technology.** *I. McLaughlin, P. Baybayan, R. Hall, J. Harting.* Pacific Biosciences of California, Inc., Menlo Park, CA.

Target enrichment by PCR in massively parallel sequencing is a common approach to studying variation in the human genome and its relation to genetic diseases whether somatic or germline in origin. Complications in genotype calling in clinically relevant genes with nearby homologous pseudogenes, such as *CYP2D6* and *CYP2D7*, or typing assignments due to incomplete haplotype phasing, such as in HLA typing, can arise in methods using short amplicon sequencing. Pacific Biosciences' ability to generate highly accurate, long sequencing reads makes it well suited for studying genomic variation in a wide range of amplicon sizes from 250 bp to > 10 kb. With the recent introduction of the Sequel System, high-throughput analysis of multiplexed samples opens the door to cost-effective sample processing in the diagnostic setting. Circular Consensus Sequencing (CCS) for amplicons ranging in length from 250 bp to 3 kb and Long Amplicon Analysis (LAA) for amplicons greater than 3 kb in length represent two workflows that can generate the high-quality data (> QV50) required to study a range of genetic variation from minor variants and insertion/deletion polymorphisms to SNP phasing on the Sequel System. CCS generates high intra-molecule consensus accuracy by enabling the polymerase to sequence the same molecule multiple times. This approach allows for reliable identification of minor variants with allelic frequencies as low as 1% with 6,000 CCS reads. Unlike single molecule CCS, LAA generates a highly accurate consensus from multiple molecules using clustering. LAA can be used to generate phased, full-length consensus sequences for multiple genes in a single sequencing run. A benefit of LAA in HLA typing, as an example, is imputation-free analysis due to long haplotype phasing of 3-5 kb amplicons. Barcoding options to enable sample multiplexing are available for both CCS and LAA workflows. A PCR primer-based approach is available with the flexibility to redesign primers with up to 384 barcodes. A second approach using up to 96 barcoded adapters is available for customers not able to update existing PCR primer designs. Data analysis for either approach is straightforward and simple through SMRT Analysis software consisting of demultiplexing, reference alignment, and consensus sequence generation. Here we present workflows for single-molecule sequencing of amplicons ranging from 250 bp to > 10 kb in length for human genetic analysis.

**Irreversible inactivation of ribonuclease A on a surface by UV LED.** T.L. Thompson, J. Pasquantonio, G. Eliason. Phoseon Technology, Hillsboro, OR.

RNases are pervasive and when contaminating critical surfaces can present problems for laboratories engaged in RNA sequencing and analysis. RNases, specifically RNase A, are difficult to irreversibly inactivate in the absence of long-term heat treatment (1) or harsh chemicals. Such methods may be incompatible with common laboratory materials or complicate subsequent biochemical reactions. UV light at 254 nm is known to act on RNase A via the effect of the aromatic amino acids proximal to disulfide bonds (2). While UV methods for inactivation of RNase A are well known for mercury arc lamp sources, fast, complete, irreversible inactivation has been difficult to achieve. We report here the first use of high irradiance UV LED sources for enzyme inactivation. In this study, an RNase A solution (0.02 U/ml) was used to contaminate glass slides and allowed to dry. The samples were then exposed to 275 nm UV LED light at irradiances of 316 mW/cm<sup>2</sup> or 635.4 mW/cm<sup>2</sup>. UV LED exposure times of the dried samples ranged from 0 to 30 minutes. Samples were resuspended from the slides in nuclease free water. RNase A activity of the resuspended samples was assayed using RNaseAlert Kit (IDT) for each illumination condition. Reactions were monitored for 2 hours at 1 minute intervals. Exposure to 316 mW/cm<sup>2</sup> 275 nm source decreased V<sub>max</sub> from 163 RFU/min at a 3 minute exposure and 9 RFU/min for a 15 minute exposure to reach RNase A negative control levels at a 30 minute exposure. Illumination with the 635.4 mW/cm<sup>2</sup> 275 nm source reduced V<sub>max</sub> to match the RNase A negative control at an exposure time of less than 5 minutes. Total radiant exposure to reach RNase A activity equivalent to the negative controls was 190 J/cm<sup>2</sup> for the 635.4 mW/cm<sup>2</sup> source and 568.8 J/cm<sup>2</sup> for the 316 mW/cm<sup>2</sup> source. These results show that both radiant flux (power) and radiant fluence (dose) contribute to rapid inactivation of the enzyme. We conclude that high power 275 nm UV LED irradiation represents a novel, fast and convenient irreversible inactivation method for RNases on surfaces. 1) Zale and Klibanov, Why does Ribonuclease Irreversibly Inactivate at High Temperatures. *Biochem* **25**:5432-5444 (1986). 2) T.K. **iMETHYL: An integrative database of whole genome DNA methylation analysis combined with whole genome and whole transcriptome analyses of over 100 Japanese individuals.** S. Komaki<sup>1</sup>, Y. Shiwa<sup>1</sup>, R. Furukawa<sup>1</sup>, T. Hachiya<sup>1</sup>, H. Ohmomo<sup>1</sup>, R. Otomo<sup>1</sup>, M. Satoh<sup>1</sup>, J. Hitomi<sup>2</sup>, K. Sobue<sup>2</sup>, M. Sasaki<sup>2</sup>, A. Shimizu<sup>1</sup>. 1) Division of Biomedical Information Analysis, Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Iwate, Japan; 2) Iwate Tohoku Medical Megabank Organization, Iwate Medical University, Iwate, Japan.

Purpose DNA methylation (DNAm), a key regulator of transcription, is being explored in epigenetic studies. Particularly, epigenome-wide association studies have identified numerous associations of DNAm signatures with phenotypes in humans. However, public databases of DNAm in humans that can be used as references for epigenetic studies are limited. Here, we introduce a DNAm database, iMETHYL, which integrates whole DNA methylation analysis, whole genome analysis, and whole transcriptome analysis. Methods Blood samples were collected from 209 apparently healthy participants (mean age ± SD, 56.9 ± 13.4; %Female, 51.7) of the Tohoku Medical Megabank Project, Japan. From the whole blood samples, CD4+ T-lymphocytes (CD4T, N = 102), CD14+/CD16- monocytes (N = 102), and CD16+ neutrophils (N = 106) were isolated. DNA and RNA extracted from each cell type were subjected to whole genome bisulfite sequencing and whole transcriptome sequencing, respectively. Simultaneously, whole genome sequencing was performed using DNA extracted from the whole blood samples. Based on the DNAm status, gene expression levels, and genotypes obtained in this study, expression Quantitative Trait Locus (eQTL), DNA methylation Quantitative Trait Locus (mQTL), and expression Quantitative Trait Methylation (eQTM) analyses were performed. Results We obtained a comprehensive dataset of DNAm (~24,000,000 autosomal CpG sites) and gene expression (~16,000 genes) profiles of CD4T, monocytes, and neutrophils and single nucleotide variants (~4,000,000 SNVs). We summarized these genetic data and developed a public database named iMETHYL (available at: <http://imethyl.iwate-megabank.org>). On the iMETHYL browser, regions of interest can be specified using gene symbols, dbSNP rsIDs, and genomic positions; the mean, variation, and distribution of DNAm and gene expression levels and frequency of genotypes of the regions can be referred to with respect to cell-type specificity. Association analyses of eQTL, mQTL, and eQTM are still ongoing. Conclusion We established a public DNAm database, iMETHYL, based on specific cell types with wide genome coverage. Although improvement of iMETHYL is still under progress, this integrative database should be a useful reference for multi-omics analyses. Associations between DNAm signatures, gene expression profiles, and genotypes will appear on iMETHYL when the analyses are finished, which will make iMETHYL a more powerful database.

**CNVs from whole exome sequencing and array: First comparative study in a Brazilian clinical cohort.** E.A. Zanardo<sup>1</sup>, G.M. Novo-Filho<sup>1</sup>, M.M. Montenegro<sup>1</sup>, A.S. Brasil<sup>1</sup>, S.N. Chehimi<sup>1</sup>, F.A.R. Madia<sup>1</sup>, F. Montenegro<sup>2</sup>, A.M. Nascimento<sup>1</sup>, L.S.A. Costa<sup>2</sup>, F.B. Piazzon<sup>2</sup>, Y.G. Oliveira<sup>1</sup>, A.T. Dias<sup>1</sup>, T.V.M.M. Costa<sup>1</sup>, J.G. Damasceno<sup>1</sup>, F. Kok<sup>2</sup>, C.A. Kim<sup>3</sup>, L.D. Kulikowski<sup>1</sup>. 1) Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil; 2) Mendelics Análises Genômica, São Paulo, Brazil; 3) Unidade de Genética, Departamento de Pediatria, Instituto da Criança do Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil.

Over the last years, the identification of CNVs from arrays and whole-exome sequencing (WES) data has become a common practice for research. Consequently, the demand for more efficient clinical methods has increased. In this study, we evaluated 32 Brazilian patients with multiple congenital malformations and developmental delay by WES technique for CNVs assessment using the software CoNIFER (Copy Number Inference From Exome Reads). We used the array for comparison and confirmation of the results and verification of possibility of the other CNVs. We identified several different genomic alterations in all patients by the array and/or WES analysis. The array identified 466 CNVs, among them 190 alterations were deletions, 244 duplications and 32 loss of heterozygosity. The exome identified 1322 CNVs, wherein 890 were deletions and 432 were duplications. We were able to verify that this technique identified a greater amount (839/1322) of small CNVs with a maximum size of 50 kb. To measure the consistency of exome with array, we determined the overlap of CNVs identified between them. Among all alterations we found 60 CNVs consistent in both techniques evaluated, corresponding to 35 deletions and 25 duplications. So the rates of proportion of consistent changes regarding to inconsistent changes in the same technique were 12.9% for array and 6.5% for exome. The CNV identification through WES data has some shortcomings and still needs better standardization. However, a high amount of changes detected by exome were small changes and often impossible to be identified in array coverage. So there is value in identifying CNVs using WES data but extra caution needs to be taken into consideration due to the high false positive rate and additional confirmation is highly recommended in this analysis.

**Hitting the target: An analysis of noncoding alterations as captured by panels and diagnostic exome sequencing at a commercial lab.** B. Schoenfeld, M. Towne, H. Laduca, P. Reineke, H. Vuong, S. Tang. Ambray Genetics, Aliso Viejo, CA.

Multigene panels offer comprehensive targeted analysis of genes of interest and can be useful for diagnosis in clinically-variable or genetically-heterogeneous disorders. Overtime, diagnostic exome sequencing (DES) is more frequently ordered as a 1<sup>st</sup> or 2<sup>nd</sup> tier test. We assessed the technical sensitivity of DES for variants in noncoding regions to test the belief that panels offer far better intronic and promoter coverage than DES can. Using *in silico* analysis, we explored the coverage and sensitivity of DES for detecting VUS, VLP or MUT located in promoter or intronic regions that were reported on cancer and cardiac panels offered by Ambray Genetics. Corresponding nucleotide positions were interrogated in data from 100 randomly-selected DES samples to determine the mean sequence coverage at each position. In total, 1675 noncoding alterations in 108 genes were reported. Most alterations were classified as VUS (1172; 70.0%), and the remaining were split between MUT (217; 13.0%) and VLP (286; 17.0%). In sum, 1207 (72.1%) had mean coverage  $\geq 20X$  on DES, with only 4.0% (20/503) of VLP/MUT alterations with mean coverage  $< 20X$ . Most noncoding variants with insufficient coverage on DES (428/468; 91.5%) were located in the promoter regions of 3 genes. The remaining 40 alterations without sufficient coverage on DES were located in intronic regions and had a median coverage of 16.6X. Reported alterations in canonical splice sites (+/-1 or +/-2) were more often reported as VLP or MUT than those located 3, 4 or 5 nucleotides from the intron-exon junction; however the percent of loci with  $\geq 20X$  coverage was high (96.9%) for all positions +/-5 of the intron-exon junction. Among 14 variants (13 MUT/ VLP and 1 VUS) reported beyond the 5<sup>th</sup> intronic nucleotide in panels, 10 had coverage  $\geq 20X$  on DES (71.4%). In summary, DES has adequate coverage of variants within +/-5, but less sufficient coverage of deep-intronic and promoter region alterations. The vast majority (96.0%) of noncoding MUT/VLP by panels are technically detectable by DES. The number of reported noncoding VUSs on panels greatly outweighs those reported on DES, likely causing the belief that DES has inferior coverage. Intronic alterations beyond +/-2 are mainly uninformative. DES reporting filters to focus on variants at canonical splice sites and established VLP/MUT in deep-intronic regions provide the most informative results while reducing VUSs and lessening the burden of uncertain results for clinicians.

**Evaluation of PCR followed by high-resolution melting analysis and synthetic constructs on four commercial thermocyclers.** K. Dawkins<sup>1</sup>, L. Chambers<sup>1</sup>, Z. Kabir<sup>1</sup>, V. Mukherjee<sup>1</sup>, K. Nunnally-Rivera<sup>1</sup>, J. Moll<sup>1</sup>, E. Sagini<sup>1</sup>, L. Papazisi<sup>1</sup>, L. Jiang<sup>1</sup>, J. Huuskonen<sup>1</sup>, I. Knight<sup>1,2</sup>. 1) Canon U.S. Life Sciences, Inc., Rockville, MD; 2) Canon BioMedical, Rockville, MD.

Introduction PCR followed by high-resolution melting (HRM) analysis is an accurate and effective method for genotyping, and many manufacturers have incorporated HRM technology into their thermocyclers. The Novallele™ genotyping assays were designed and optimized using one thermocycler and the accompanying software. The purpose of this study was to demonstrate that the Novallele genotyping assays are robust and are easily transferred between different thermocyclers without compromising assay reliability. Methods Four HRM-capable thermocyclers were used to compare the performance of six unlabeled-probe assays and six small-amplicon assays. PCR robustness and assay reliability were tested using the software provided with each thermocycler. Synthetic double-stranded DNA constructs were designed for each assay to provide materials to genotype each mutation, and this approach facilitated genotyping target and non-target mutations when genomic DNA was not available. Results All twelve assays accurately identified their target genetic variation on each of the four thermocyclers. PCR amplification and melting temperature difference between the wild-type and variant samples was consistent from instrument to instrument. In addition, reliable genotyping was achieved for these assays using a wide concentration range of approximately 6–60ng. The synthetic genotyping controls showed similar wild-type to homozygous variant melting temperature difference, validating the concept of using these as a relevant control. For two thermocyclers, four assays required minor optimization of either a change to the annealing temperature by  $\leq 1.5^{\circ}\text{C}$  or an extra five amplification cycles. On another instrument, five assays required minor optimization of increasing the annealing, denaturing, and extension hold times in order to maintain an equivalent degree of performance. Conclusion Our study indicates that carefully designed and optimized genotyping assays can perform robustly on different HRM-enabled thermocyclers with modest, if any, adjustment to the cycling conditions. In addition, the use of controls resulted in comparable genotyping results to genomic DNA, validating their use if genomic DNA is not available. The Novallele genotyping assays are for Research Use Only. Not for use in diagnostic procedures.

**Merck-custom Affymetrix Axiom™ genotyping array performance evaluation.** J. Xu<sup>1</sup>, B. Scherer<sup>2</sup>, W. Hussain<sup>2</sup>, P. Shaw<sup>2</sup>. 1) Department of Clinical Biostatistics, Merck & Co., Inc., North Wales, PA; 2) Nelson Biological Laboratories, Piscataway, NJ, USA; 3) Department of Clinical Pharmacogenomics, Merck & Co., Inc. West Point, PA.

The Merck-custom Affymetrix Axiom™ Genotyping Array was designed based on the back bone of the Axiom™ UK Biobank Genotyping Array and modified to improve imputation of common variants to over 10 million genetic variants in broader ethnic populations often found in global clinical (clin. PGx) studies. There were four experiments conducted to evaluate the array performance: 1) 96 genetic samples genotyped in two facilities to evaluate the within plate and between plate reproducibility; 2) 270 genetic samples called by different genotype calling algorithms (SNP specific prior against generic prior) to evaluate algorithm performance, the concordance rate against 1000 Genome Project were higher in at least 90K assayed SNPs using SNP specific prior compared to generic prior; 3) 7,090 samples called in single batch and multiple batches to evaluate batch effect, the average per SNP concordance rate is 99.98% between single and multiple batches, which translates into only 1.2 / 7,090 discordant genotype calls per SNP on average; and 4) 2 positive control samples were compared with 1000 Genome Project in each plate to assess the plate by plate variability over time. Call rate and concordance rate within the same sample data were compared. The concordance rates against 1000 Genome Project are on average 98.7% and 98.1% for the two samples, respectively, and consistent across two year period.

**Streamlined, efficient, and uniform molecular inversion probe capture for targeted sequencing.** *E. Boyden, E. Tsung, D. Maganzini, G. Porreca, M. Umbarger.* Good Start Genetics Inc, Cambridge, MA.

Molecular inversion probe (MIP) capture represents an attractive targeted sequencing sample preparation technology as it enables simultaneous library construction and highly specific target enrichment. However, the adoption of MIP technology for targeted sequencing applications has been relatively limited in part due to probe design challenges and the perceived complexity of the MIP capture workflow. We have optimized MIP sequence design and the associated experimental workflow to minimize these barriers to adoption. More specifically, we implemented a new algorithm to design probes that tile along both strands of the genome in a strand-alternating fashion. The resulting design mitigates the risk of allele dropout, a common pitfall of other amplicon-based targeting strategies, while simultaneously improving capture/sequencing depth uniformity and per-locus capture efficiency, and reducing sequencing costs and sample input requirements. Across 5 MIP panels targeting a collection of polymorphic loci and coding regions of genes throughout the human genome, we observed that greater than 98% of the target bases were within 20% of the mean coverage, and the fold-80 base penalties (the amount of additional sequencing required to raise the 20th percentile coverage to the mean) ranged from 1.3 to 2. Achieving this level of sequence coverage uniformity generally did not require empirical probe concentration optimization or 'rebalancing', a strategy often used with other target capture technologies to improve uniformity. We also employed unique molecular identifiers (UMIs) to enable PCR duplicate removal and low frequency somatic variant detection. Using UMI-barcoded MIPs, we derived median per-locus capture efficiency estimates of ~12% and observed that allele fractions of 5% can be detected reliably with 10 ng of DNA input. Finally, we have developed a streamlined MIP capture protocol that can be completed in less than 12 hours. This single-tube protocol is easily automated, utilizes dual indexed barcode primers to minimize the risk of index swapping, and can be scaled to run hundreds to thousands of samples simultaneously. Collectively, our highly optimized target capture technology represents an attractive option for highly efficient and uniform, streamlined, and scalable targeted sequencing.

**Use of a molecular inversion probe (MIP) system for the detection of copy number variants.** *K. Jefferson, R. Bannen, M. Brockman, S. Suresh, T. Richmond, D. Burgess.* Roche Sequencing Solutions, Madison, WI.

Copy number variants (CNVs) are large (>50bp) indels which often have been associated with inherited disease, disease susceptibility, neurological disorders, and cancer. We evaluated the MIP-based HEAT-Seq target enrichment method for use in rapid and sensitive SNV detection. Here, we report the validation and application of the HEAT-Seq target enrichment assay for the efficient detection of CNVs at known disease loci. The HEAT-Seq target enrichment system is a targeted NGS method based on optimized, multiplexed molecular inversion probes (MIPs). It utilizes an advanced version of MIPs, with unique molecular identifiers (UID or UMI) incorporated into probes in order to identify PCR duplicates, improve sensitivity, and reduce false positive calls. The probes in the HEAT-Seq Choice panel used in this study were selected from an empirically tested database containing the entire protein-coding exome plus non-coding medically relevant regions of the human genome. This panel targets CNVs in Charcot-Marie-Tooth type 1A, Smith-Magenis Syndrome, and Burkitt's Lymphoma, including the protein-coding regions of the disease genes and nearby non-disease genes. The targets were chosen to overlap affected regions in which CNVs previously have been characterized in known samples. The HEAT-Seq target enrichment system was originally developed as a rapid single-nucleotide variant detection discovery and validation platform with a simple workflow. Using CNVkit software for genome wide copy number detection and visualization, we were able to detect CNVs with multiple duplications and deletions. The results of this study show the HEAT-Seq target enrichment system can also be used for CNV detection, broadening the applications for this technology in the study of inherited disease, neurology, and cancer.

**ELOVL5, an epigenetic biomarker, predisposes for the risk of type 2 diabetes mellitus with inflammation.** *H. Lee, J. Hwang, M. Go, H. Jang, B. Kim.* NIH Korea, Cheongju, South Korea.

Genome-wide DNA methylation has been implicated in human complex diseases. Here, we aimed to unravel epigenetic biomarkers for type 2 diabetes (T2D) underlying obesogenic environments. In a blood-based DNA methylation analysis of 11 monozygotic twins (MZTW) discordant for T2D, we discovered genetically independent candidate methylation sites. We replicate the T2D-association at a novel CpG-signal in the ELOVL5 gene specific to T2D-discordant MZTW. ELOVL5 gene is significantly associated with differential expression in adipose tissues from unrelated T2D patients and in human pancreatic islets. Further functional studies in cellular models demonstrated that ELOVL5 is increased in compliance with the gene expression of increased endoplasmic reticulum (ER) stress and hepatic gluconeogenesis. Also, ELOVL5 expression is increased with IL6, ELOVL6, SCD, and plkB $\alpha$  in arachidonic acid treated SK-Hep I human liver cell line. These data suggest that increase of ELOVL5 methylation is associated with increased ER stress mediated diabetic risk. An integrative multi-target tissue analysis might reveal new functional and clinical implications related to epigenetic control in human T2D.

**Star strand miR-192 (miR-192\*) as an overlooked metabolic regulator in pre-diabetic liver.** *K.K. Miu, X. Zhang, TY. Ha, HH. Cheung, B. Feng, WY. Chan.* School of Biomedical Sciences, Faculty of Medicine, The Chinese University of Hong Kong, Hong Kong.

Circulating levels of miR-192 in serum was reported to rise in both the plasma of glucose-intolerant mice and in patients under pre-diabetic state. Nonetheless, its presence in the serum had been suggested as a sensitive marker of liver damage. Interestingly, the star strand miR-192 (miR-192\*) was predicted to target multiple genes related to fatty acid (FA) metabolism and inflammation. In fact, a recent study demonstrated that miR-192\* expression in human visceral adipose tissue negatively-correlates with serum fat content. We discovered that miR-192\* rather than miR-192 was lower in the liver of *db/db* mice when compared to heterozygous lean control. In addition, we confirmed expression changes in some of the predicted targets of miR-192\* in their liver. Furthermore, key genes related to hepatic anabolism of FA or for its transport were upregulated correspondingly, potentially resulted from loss of the miRNA, hence aggravating diabetic conditions. Indeed, we noted expression changes of those genes upon transfection of miR-192\* mimics to isolated primary mouse hepatocytes. Likewise, miRNA mimics reduced pro-inflammatory interleukin-6 (IL6) signalling in the hepatic cell line HepG2, with IL6R, IL6ST, STAT3 predicted as common target genes for both mature miRNAs. To demonstrate the unique activity of miR-192\* in regulating liver metabolism, we constructed an artificial shRNA stem-loop construct for its overexpression. Active uptake of saturated FA palmitic acid-BSA complexes was prevented in LO2 human liver cell clones stably transfected with the construct. Its physiological action was checked by replenishment via hydrodynamic injection of the construct *in vivo*. Finally, liver cell lines with altered expression of miR-192\* were constructed for subsequent transcriptomic analysis to confirm its target gene ontology. In retrospect, our investigation suggested that the regulatory role of miR-192\* in liver metabolism might be overlooked. Therefore, we forecast that the loss of miR-192\* in liver aggravated diabetic conditions with dysregulated FA metabolism.

**Physical interaction in human beta-cells between islet eQTL sites and target gene promoters at loci associated with type 2 diabetes risk and glycaemic traits.** J. Torres<sup>1,2</sup>, V. Nylander<sup>2</sup>, D. Downes<sup>3</sup>, M. Thurner<sup>1,2</sup>, C. Burrows<sup>2</sup>, J. Hughes<sup>3</sup>, M. McCarthy<sup>1,2,4</sup>, A. Gloyn<sup>1,2,4</sup>, WIGWAM Consortium. 1) Wellcome Trust Centre for Human Genetics, The University of Oxford, Oxford, United Kingdom; 2) Oxford Centre for Diabetes Endocrinology & Metabolism, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom; 3) Weatherall Institute of Molecular Medicine, Radcliffe Department of Medicine, University of Oxford, Oxford, United Kingdom; 4) NIHR Oxford Biomedical Research Centre, Churchill Hospital, Oxford, United Kingdom.

Determining the effector transcripts at loci associated with type 2 diabetes (T2D) risk and glycaemic traits remains a challenge as the majority of GWAS signals map to non-coding regions. Given that pancreatic islet enhancers are strongly enriched for GWAS variants, we previously mapped expression quantitative trait loci (eQTLs) in primary human islets and identified eQTLs co-localizing with T2D-associated variants. To determine if islet eQTLs physically interact with the promoters of their target genes, we used next-generation (NG) Capture-C to generate high-resolution interaction maps in EndoC-βH1 cells - a glucose-responsive, human β-cell line. Capture probes were designed to target promoters of effector genes corresponding to 9 cis eQTLs that co-localize with variants associated with either T2D or glycaemic traits (linkage disequilibrium  $r^2 > 0.8$ ). Significantly interacting restriction fragments were determined based on a rank-product test implemented in peakC. We found that all 9 islet cis eQTLs co-localizing with T2D and glycaemic trait-associated SNPs map to the interaction domains of their target gene promoters in EndoC-βH1 cells. These include variants at the *GCK*, *ADCY5*, *AP3S2*, and *WARS* loci and two independently mapped eQTLs at the *DGKB* locus. At the *CAMK1D* and *STARD10* loci, eQTLs map to significantly interacting contact sites that indicate stable enhancer-promoter looping events. Moreover, these contact sites map to open chromatin regions in both islets and EndoC-βH1 cells and correspond to signatures of active gene regulation in human islets. These maps support gene regulatory mechanisms involving T2D and glycaemic trait-associated variants facilitated by enhancer-promoter interactions and show how integrating eQTL and epigenomic annotations with 3D interaction maps can advance resolution of causal genes at loci associated with human disease.

**The molecular basis of increased diabetes susceptibility in carriers of the PGC1α (Ser482) risk allele.** R. Vandnebeek<sup>1,2</sup>, N. Perwaiz-Khan<sup>1,2</sup>, A. Besse-Patin<sup>1,3</sup>, M. Leveille<sup>1,3</sup>, J.L. Estall<sup>1,2,3</sup>. 1) Experimental Medicine, McGill University, Montreal, Quebec, Canada; 2) Institut de recherches cliniques de Montreal, Montreal, Quebec, Canada; 3) Cellular and Molecular Medicine, University of Montreal, Montreal, Quebec, Canada.

A Gly482Ser SNP within the coding region of human peroxisome proliferator activated receptor (PPAR)-γ coactivator 1 (PGC-1α) is associated with type 2 diabetes susceptibility (T2D) and other metabolic diseases. It has been shown that the Serine expressing variant increases the relative risk of T2D; however, the functional significance of this single nucleotide polymorphism (SNP) has not yet been characterized. By cycloheximide chase, we determined that a serine residue at amino acid position 482 decreases protein stability, compared to the 482Gly counterpart. Replacing this residue with either an alanine residue (phosphorylation-null) or an aspartate residue (phosphomimetic) led to protein stabilization and destabilization, respectively, when expressed in INS-1 pancreatic β-cells. Upon addition of a proteasomal/lysosomal inhibitor (MG132), we observed equal PGC-1α protein levels, suggesting that this modification leads to proteasomal degradation. These data provide evidence that there is a phosphorylation event at the 482Ser site and that this post-translational modification regulates stability of the protein. This regulation was also observed when constructs were expressed in HepG2 human hepatocytes, suggesting this mechanism is not beta cell specific. Furthermore, the 482Gly variant had enhanced expression of target genes involved in metabolic pathways compared to the Serine containing variant. Using mice that are homozygous for the glycine variant (generated using CRISPR/Cas9) offers us many benefits: it allows us to study the effect of endogenous Gly and Ser variants on gene/protein stability and, consequently, on co-activator activity. Taken together, our data suggests that links between the Gly482Ser SNP variants and metabolic disease may be due to reduced protein stability, and thus, coactivator function. Understanding how the variant affects PGC-1α gene and protein stability, as well as function, may help to design novel therapeutics to treat those who possess this SNP and are at heightened risk of diabetes complications.

**1546W****Cytosine methylation predicts renal function decline in American**

**Indians.** *R. Hanson<sup>1</sup>, C. Qiu<sup>2</sup>, G. Fufaa<sup>1</sup>, S. Kobes<sup>1</sup>, C. Gluck<sup>2</sup>, J. Huang<sup>3</sup>, Y. Chen<sup>3</sup>, R. Nelson<sup>1</sup>, W. Knowler<sup>1</sup>, K. Susztak<sup>2</sup>. 1) Diabetes Epidemiology Clin Res, NIDDK, Phoenix, AZ; 2) Dept of Medicine, Dept Genetics, University of Pennsylvania Perelman School of Med, Philadelphia, PA; 3) Dept of Biostatistics and Epidemiology, University of Pennsylvania Perelman School of Med, Philadelphia, PA.*

Diabetic nephropathy accounts for most of the excess mortality experienced by individuals with diabetes, but understanding of the molecular mechanisms by which nephropathy develops is limited. In the present study, we analyzed the association of cytosine methylation levels with decline in estimated glomerular filtration rate (eGFR) in 181 diabetic Pima Indians who participated in a longitudinal study. Methylation levels at 397,063 CpG sites were measured with the Infinium HumanMethylation450 Beadchip in peripheral blood specimens. Rate of decline in eGFR (over an average of 6 years) was assessed using a mixed model and analyzed for association with methylation levels. Methylation levels at 77 sites showed significant association with eGFR decline after correction for multiple comparisons (false discovery rate < 0.05). Using a split-sample validation procedure we found that a model including methylation level at two probes (cg25799291 and cg22253401) improved prediction of eGFR decline in addition to currently used predictors (baseline eGFR, albumin:creatinine ratio [ACR]) with percent of variance explained improving from 23.1% to 35.9% ( $P=3.6 \times 10^{-6}$ ). A risk score based on these two sites significantly predicted development of end-stage renal disease (80 cases, hazard ratio=1.46 per SD,  $P=0.01$ ). The 3490 probes at which methylation significantly associated with eGFR decline ( $P<0.05$  and effect size in the top 1%) were significantly more likely than non-significant probes to localize to gene promoter regions (31% versus 23%) and to localize to validated transcription binding sites in ENCODE kidney cell lines (81% versus 73%). This indicates that many of the associations are likely functional in the human kidney, as the associated sites localize to regulatory regions of the genome. Weighted gene co-network regulatory analysis showed that these sites were enriched for genes with metabolic functions and apoptosis ( $r=-0.15$ ,  $P=0.04$ ). Four of the probes that associated with eGFR decline in blood samples also showed significant association with fibrosis in microdissected human kidney tissue in a separate cohort ( $n=94$ ). These analyses suggest that cytosine methylation levels may be useful biomarkers of disease progression in diabetic nephropathy, and they strongly suggest that epigenetic factors contribute to development of diabetic kidney disease.

**1547T****Dissecting features of epigenetic variants underlying cardiometabolic risk using full-resolution epigenome maps.**

*F. Allum<sup>1,2</sup>, X. Shao<sup>1,2</sup>, A. Hedman<sup>3</sup>, J. Vijay<sup>1,2</sup>, T. Kwan<sup>1,2</sup>, F. Guénard<sup>4</sup>, M.M. Simon<sup>1,2</sup>, M. Lathrop<sup>1,2</sup>, A. Tchernof<sup>5</sup>, M. McCarthy<sup>6,7,8</sup>, P. Deloukas<sup>9,10</sup>, T. Pastinen<sup>1,2</sup>, M.C. Vohr<sup>4</sup>, E. Grundberg<sup>1,2</sup>.* 1) Department of Human Genetics, McGill University, Montreal, Canada; 2) McGill University and Genome Quebec Innovation Centre, Montreal, Canada; 3) Cardiovascular Medicine Unit, Department of Medicine Solna, Karolinska Institute, Stockholm, Sweden; 4) Institute of Nutrition and Functional Foods (INAF), Université Laval, Québec, Canada; 5) Québec Heart and Lung Institute, Université Laval, Québec, Canada; 6) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; 7) Oxford Centre for Diabetes, University of Oxford, Churchill Hospital, Oxford, United Kingdom; 8) Oxford National Institute for Health Research Biomedical Research Centre, Churchill Hospital, Oxford, United Kingdom; 9) Wellcome Trust Sanger Institute, Wellcome Trust Genome Campus, Hinxton, United Kingdom; 10) William Harvey Research Institute, Queen Mary University of London, London, United Kingdom.

Complex diseases such as obesity are caused by joint action of predisposing genetic and environmental factors. Genome-wide studies (GWAS) have mined multiple metabolic disease-linked variants enriched in non-coding regions, making translation into biological knowledge challenging. Linking variants to function by cellular traits such as CpG methylation in disease-relevant tissues can aid interpretation. Most large-scale epigenome-wide studies (EWAS) use targeted arrays (e.g. 450K array) biased to static promoters, preventing full-resolution mapping of functional CpG methylation. As such, we implemented MCC-Seq to simultaneously profile methylomes and genotypes in active regulatory regions at single-base resolution. Using an adipose MCC-Seq panel, we linked adipose methylation (1.3M CpGs;  $N=199$ ; ULaval) to cardiometabolic risk through an EWAS of circulating lipid levels, identifying 12,987 TG-CpGs and 6,015 HDL-CpGs (5% FDR) enriched in adipose enhancers but depleted in promoters, validating the targeting of dynamic regions. Further specific mapping of lipid-CpGs revealed key positional differences at these elements with variant "hotspots" enriched for adipogenesis transcription factor binding motifs. Using heritability values ( $h^2$ ) from the MuTHER cohort ( $N \sim 650$ ; 450K array), genetic vs. environmental contribution dissection at our lipid-CpGs showed enrichment among heritable sites ( $h^2 > 0.7$ ;  $> 1.6$ -fold;  $p < 2.2 \times 10^{-16}$ ). The genomic density of nearby lipid-CpGs ( $\pm 250$ bp) found heritable sites clustering in regions ( $> 49\%$ ) and environmentally driven sites occurring more as singletons ( $> 72\%$ ). Of note, clustered heritable lipid-CpGs showed marked enrichment within adipose-unique promoters that themselves are enriched near genes with adipose-specific expression ( $\log_2$ -fold $>2$ ;  $p < 0.05$ ). By linking genetic variation to adipose methylation (metQTL) we highlight key examples of heritable genetically driven lipid-CpGs (metQTL  $p < 1.0 \times 10^{-8}$ ) where driving SNPs overlap Global Lipids Consortium GWAS findings. Finally, we validated lipid-CpGs in the MuTHER cohort (450K array), replicating 1,283/4,192 (31%) TG-CpGs and 99/254 (39%) HDL-CpGs within  $\pm 250$ bp. We show the fine-mapping potential of MCC-Seq by noting that  $> 80\%$  of replicated MuTHER lipid-CpGs exhibit stronger lipid associations at nearby non-overlapping sites. We demonstrate the value of full-resolution epigenetic profiling in functional regions to dissect and map variants to better understand the etiology of complex traits.

**Background:** Epigenome-wide association studies (EWAS) have identified DNA methylation loci involved in adiposity. However, EWAS on adiposity in sub-Saharan Africans are lacking despite the high burden of adiposity among African populations. We undertook an EWAS for anthropometric measures of adiposity among Ghanaians aiming to identify DNA methylation loci that are significantly associated. **Methods:** The Illumina 450k DNA methylation array was used to profile DNA methylation in whole blood samples of 547 Ghanaians from the Research on Obesity and Diabetes among African Migrants (RODAM) study. Differentially Methylated Positions (DMPs) and Differentially Methylated Regions (DMRs) were identified for BMI and obesity (BMI  $\geq 30$  kg/m<sup>2</sup>), as well as for waist circumference (WC) and abdominal obesity (WC  $\geq 102$ cm in men,  $\geq 88$ cm in women). All analyses were adjusted for age, sex, blood cell distribution estimates, technical covariates, site of data collection and population stratification. We also did a replication study of previously reported EWAS loci for anthropometric measures in other populations. **Results:** We identified 18 DMPs for BMI and 23 for WC. For obesity and abdominal obesity, we identified three and one DMP, respectively. Fourteen DMPs overlapped between BMI and WC. DMP *cg00574958* annotated to gene *CPT1A* was the only DMP associated with all outcomes analysed, attributing to 6.1% and 5.6% of variance in obesity and abdominal obesity, respectively. DMPs *cg07839457* (*NLR5*) and *cg20399616* (*BCAT1*) were significantly associated with BMI, obesity and with WC and had not been reported by previous EWAS on adiposity. **Conclusions:** This first EWAS for adiposity in Africans, identified three epigenome-wide significant loci (*CPT1A*, *NLR5* and *BCAT1*) for both general adiposity and abdominal adiposity. The findings are a first step in understanding the role of DNA methylation in adiposity among sub-Saharan Africans. Studies on other sub-Saharan African populations as well as translational studies are needed to determine the role of these DNA methylation variants in the high burden of adiposity among sub-Saharan Africans.

**1549W**

**Serum bilirubin levels, UGT1A1 gene expression, and risk for ulcerative colitis.** C.J. Gallagher<sup>1</sup>, K. Schieffer<sup>2</sup>, S. Bruffy<sup>3</sup>, R. Rauscher<sup>2</sup>, L. Harris<sup>2</sup>, S. Deiling<sup>2</sup>, G. Yochum<sup>2</sup>, W. Koltun<sup>2</sup>. 1) Biochemistry, Lincoln University, Lincoln University, PA; 2) Department of Surgery, The Pennsylvania State University, College of Medicine, Hershey, PA, USA; 3) Center for Clinical and Translational Research, Virginia Commonwealth University, Richmond, VA, USA.

Chronic inflammation associated with inflammatory bowel disease (IBD) results in increased oxidative stress that damages the colonic microenvironment. A low level of serum bilirubin, an endogenous antioxidant, has been associated with increased risk for Crohn's disease (CD), but no study has tested another common IBD ulcerative colitis (UC). Bilirubin is metabolized in the liver by uridine glucuronosyltransferase 1A1 (UGT1A1) exclusively. Genetic variants cause functional changes in UGT1A1 which result in hyperbilirubinemia, which can be toxic to tissues if untreated and results in a characteristic jaundiced appearance. Approximately 10% of the Caucasian population is homozygous for the microsatellite polymorphism *UGT1A1\*28*, which results in increased total serum bilirubin levels due to reduced transcriptional efficiency of *UGT1A1* and an overall 70% reduction in UGT1A1 enzymatic activity. The aim of this study was to examine whether bilirubin levels are associated with the risk for ulcerative colitis (UC). Using the Informatics for Integrating Biology and the Bedside (i2b2), a large case-control population was identified from a single tertiary care center, Penn State Hershey Medical Center (PSU). Similarly, a validation cohort was identified at Virginia Commonwealth University Medical Center. Logistic regression analysis was performed to determine the risk of developing UC with lower concentrations of serum bilirubin. From the PSU cohort, a subset of terminal ileum tissue was obtained at the time of surgical resection to analyze *UGT1A1* gene expression (which encodes the enzyme responsible for bilirubin metabolism). Similar to CD patients, UC patients also demonstrated reduced levels of total serum bilirubin. Upon segregating serum bilirubin levels into quartiles, risk of UC increased with reduced concentrations of serum bilirubin. These results were confirmed in our validation cohort. *UGT1A1* gene expression was up-regulated in the terminal ileum of a subset of UC patients. Lower levels of the antioxidant bilirubin may reduce the capability of UC patients to remove reactive oxygen species leading to an increase in intestinal injury. One potential explanation for these lower bilirubin levels may be up-regulation of *UGT1A1* gene expression, which encodes the only enzyme involved in conjugating bilirubin. Therapeutics that reduce oxidative stress may be beneficial for these patients.

Stark differences exist across sexes in central adiposity and its genetic predisposition. DNA methylation is a key epigenetic mechanism that links genotypes and the environment to central adiposity. While there is clear evidence of sex-specific global and regional methylation patterns, these patterns have yet to be examined within the context of adiposity. Given the sex-specific genetic architecture of central adiposity traits, such studies are of great interest. Thus, our primary aim was to conduct a methylation-wide association study (MWAS) to identify CpGs associated with waist circumference (WC), while accounting for sex as a possible effect moderator. We included 1,669 female and 954 male African Americans of the Atherosclerosis Risk in Communities study with whole blood Illumina 450K methylation array data. CpG beta values were adjusted for batch effects and blood cell type proportions. We used linear regression for CpG association analyses with WC, stratified by sex and adjusted for age, education, body mass index, smoking, center, and 10 principal components calculated from genotype data. The stratified results were used to estimate differences in sex-specific methylation effects (CpG<sub>Sex</sub> interaction [INT]) and joint main+interaction effects (JOINT). CpGs that reached suggestive significance ( $P_{\text{JOINT}}$  or  $P_{\text{INT}} < 1 \times 10^{-6}$ ) were brought forward for validation of INT in an independent sample, the Framingham Heart Study (2,140 females and 1,847 males, European descent). We identified 8 CpGs in our discovery analyses. In the validation study, cg06500161 in *ABCG1* was nominally significant for INT, but did not meet the significance criteria after multiple test correction. Cg19693031 in *TXNIP* reached Bonferroni corrected significance for INT on WC ( $P < 0.006$  [0.05/8 CpGs]). Increased methylation at this site is associated with a decrease in WC and exhibits a two-fold greater effect on WC in females compared to males. Methylation at cg19693031 has been associated with expression of *TXNIP* and several cardiometabolic traits (i.e. type 2 diabetes [T2D], insulin, glucose, and triglycerides) for which central obesity is a known risk factor. *TXNIP* displays the highest expression in subcutaneous adipose tissue, and is involved in glucose homeostasis. Differences in fat distribution between sexes and *TXNIP* methylation effects may help to explain sex differences in downstream diseases, like T2D. These findings underscore the importance of accounting for sex in MWAS studies.

**Body mass index variant protects Mexicans from obesity through long intergenic non-coding RNA on chromosome 20q13.33.** Y.V. Bhagat<sup>1</sup>, A. Ko<sup>2</sup>, K.M. Garske<sup>1</sup>, D.Z. Pan<sup>1,3</sup>, M. Alvarez<sup>1</sup>, Z. Miao<sup>1,3</sup>, K.L. Mohlke<sup>1</sup>, M. Laakso<sup>5</sup>, T. Tusie-Luna<sup>6,7</sup>, C.A. Aguilar-Salinas<sup>1</sup>, P. Pajukanta<sup>1,2,3</sup>. 1) Department of Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, USA; 2) Molecular Biology Institute at UCLA, Los Angeles, USA; 3) Bioinformatics Interdepartmental Program, UCLA, Los Angeles, USA; 4) Department of Genetics, University of North Carolina, Chapel Hill, North Carolina, USA; 5) Department of Medicine, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland; 6) Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubiran, Mexico City, Mexico; 7) Instituto de Investigaciones Biomédicas de la UNAM, Mexico City, Mexico.

The Mexican population has a high susceptibility to obesity-related complex cardio-metabolic disorders. Genome-wide association studies (GWASs) have identified many noncoding variants associated with measures of obesity, such as body mass index (BMI), but the underlying mechanisms through which these variants influence an individual's BMI remain elusive. A previous cross-population GWAS performed in our laboratory showed that variant rs6027281 at locus 20q13.33 is associated with lower BMI in Mexicans. We hypothesized that the protective allele of this lead GWAS variant, or its linkage disequilibrium (LD) proxies, differentially regulates *cis* genes to drive the lean phenotype in Mexicans. Our data-mining for LD proxies and overlap with known epigenetic histone mark ChIP-seq data found that variant rs11086694, in LD ( $r^2 = 0.87$ ) with the lead GWAS SNP, resides in a transcription start site (TSS), known to be active in monocytes. Our *cis* expression quantitative trait locus (eQTL) analysis on RNA-sequence (RNA-seq) data from subcutaneous adipose biopsies of 335 Finnish men of the Metabolic syndrome in men (MET-SIM) cohort found that the protective allele G increases expression of long intergenic non-coding RNA (lincRNA) *MIR646HG* ( $p = 1.4 \times 10^{-6}$ ), indicating a connection with obesity in a directly relevant tissue type. The *cis*-eQTL finding was also strongly replicated in a previously reported independent whole blood microarray study ( $n = 5,311$ ,  $p = 7.7 \times 10^{-11}$ ), supporting a connection of variant rs11086694 to inflammatory response in obese adipose tissue. To assess its function, we performed electrophoretic mobility shift assays (EMSA) with monocyte and pre-adipocyte extracts to find that the protective allele G of variant rs11086694 reduces binding of *HOXA9* when compared to the reference allele A. We compared the consequence of this allelic effect on local gene expression by conducting dual luciferase reporter assays in liver cells (HepG2) to show that allele G increases transcription ( $p = 5.6 \times 10^{-4}$ ). Overall, our analysis suggests that protective allele G of variant rs11086694 prevents obesity in Mexicans through disrupting *HOXA9* binding and consequent increased expression of lincRNA *MIR646HG* in *cis*, which may in turn upregulate production of miR-646 that ultimately regulates obesity-related genes in *trans*.

**1552W****Transcriptome study of metabolic healthy obesity in African Americans.**

A. Gaye<sup>1</sup>, A. Doumatey<sup>1</sup>, S. Davis<sup>1</sup>, C. Rotimi<sup>1</sup>, G. Gibbons<sup>1,2</sup>. 1) National Human Genome Research Institute, Bethesda, MD 20892, USA; 2) National Human Genome Research Institute and National Heart, Lung, and Blood Institute, Bethesda, MD 20892, USA.

**Background** Several clinical guidelines have been proposed to distinguish metabolically healthy obesity (MHO) from other subgroups of obesity but the molecular mechanisms that underlie this phenotype remains elusive. In this study of whole blood transcriptome, we searched for specific sets of genes that might play a role in protecting obese subjects from developing metabolic disorders or in delaying their onset. **Methods** MHO was defined as the absence of hypertension, insulin resistance, type 2 diabetes, inflammation and dyslipidemia in obese state. Total RNA samples from 8 MHO and 21 metabolically abnormal obese (MAO) subjects were sequenced. Unbiased transcriptome-wide network analysis was carried out to identify co-expressed genes whose collective expression is associated with MHO status. Machine learning technique (Random Forest) and differential expression analysis were used to respectively predict MHO status and identify differentially expressed genes. **Results** Network analysis identified a group of 23 co-expressed genes (network module), including 17 ribosomal protein genes (RPs), significantly downregulated in MHO compared to MAO individuals. Three pathways were enriched in the network module: EIF2 signaling, regulation of eIF4 and p70S6K Signaling and mTOR Signaling. The expression of 10 of the RPs collectively predicts MHO with an area under the curve of 0.81. Triglycerides/HDL-C ratio (TRIG/HDL) is the best predictor of expression of genes in the network module. **Conclusion** The results revealed a whole-blood transcriptomic signature of MHO that points to the role of endoplasmic reticulum (ER) and ribosomal stresses, via RPs, in the onset of inflammation in obesity state. The higher TRIG/HDL (an indicator of insulin resistance) observed in the MAO subjects appears to activate ER and related-stress pathways that lead to the inflammatory state. These findings suggest that alleviating ER stress and/or ribosomal stress by downregulating RPs or controlling TRIG/HDL ratio may be effective in maintaining normal metabolic profile in obese individuals.

**1553T****A multi-tissue transcriptome association analysis of BMI provides a whole-body view into the impacts of adiposity.**

T. Tukiainen<sup>1,2</sup>, T. Pers<sup>3</sup>, F. Aguet<sup>4</sup>, K. Pietiläinen<sup>3</sup>, S. Ripatti<sup>4,5</sup>. 1) Institute for Molecular Medicine Finland, Helsinki, Helsinki, Finland; 2) Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA; 3) Obesity Research Unit, Research Programs Unit, University of Helsinki, Helsinki, Finland; 4) Public Health, Faculty of Medicine, University of Helsinki, Finland; 5) Wellcome Trust Sanger Institute, Hinxton, UK.

Obesity is a world-wide epidemic with severe health consequences ranging from increased cardiometabolic risk to higher susceptibility to certain cancers. The mechanisms that link adiposity to these sequelae remain incompletely understood. GWAS findings point to the role central nervous system (CNS) in obesity susceptibility, yet recent work shows adiposity associates with epigenetic changes in tissues from other organ systems. To further elaborate the underlying biology, we investigated the association of body mass index (BMI), a common proxy for adiposity, with gene expression (GE) in 44 tissue types in 449 individuals from GTEx (v6p). We identify significant (5% FDR) BMI-GE-associations in 40% of the studied tissues with up to 2400 BMI-associated genes per tissue (in subcutaneous fat) including, e.g. the upregulation of leptin with increasing BMI in three tissue types. The GE changes are expectedly enriched insulin responsive tissues yet not limited to these. For instance, skin ranks among tissues with most BMI-associated genes. Gene set enrichment analyses implicate diverse underlying processes, many with established connection to adiposity (e.g. inflammation and mitochondrial dysfunction), yet some more debated (e.g. reduced sensory perception in skin and circadian clock in colon) and several that are tissue-dependent (e.g. infertility in testes). While BMI-GWAS discoveries point to CNS, in our analyses the brain shows only a weak signal, suggesting the BMI-associations discovered here are likely primarily consequences of adiposity. In line with recent methylation-based findings in whole blood, our Mendelian randomization analyses demonstrate that a majority of the GE-changes in several tissues are indeed driven by changes in BMI. This observation is further supported by the lack of enrichment of BMI-GWAS genes among the top associations in any of the studied tissues. GWAS genes from other conditions, in particular autoimmune disorders, however, show significant overlap with the BMI-associated GE changes. E.g. genes conferring risk to multiple sclerosis are enriched among genes upregulated with increased BMI in adipose tissue. Analysis of BMI-associated expression changes in dozens of human tissues provides an unprecedentedly extensive view into the impacts of adiposity. By pinpointing the disturbed biologic processes this work provides potential avenues for the treatment of the complications of obesity.

**CLEC16A dysfunction compromises lipophagy and mitophagy and facilitates risk to autoimmunity.** R. Pandey<sup>1</sup>, H. Hain<sup>1</sup>, M. Bakay<sup>1</sup>, B. Strenkowski<sup>1</sup>, H. Hakonarson<sup>1,2</sup>. 1) The Center for Applied Genomics, Children's Hospital Of Philadelphia, Philadelphia, PA; 2) Department of Pediatrics, the Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Genetic variants in the 16p13 locus harboring the C-type lectin-like domain family 16A (*CLEC16A*) gene are associated with the susceptibility to multiple autoimmune disorders. *CLEC16A*'s genomic location next to the suppressor of cytokine signaling 1 (SOCS1) gene and the altered cytokine /chemokine profile in *Clec16a* knockdown mice led us to hypothesize that CLEC16A exerts its effect on a wide variety of immune cells via modulating SOCS expression and regulating cytokine signaling. We hypothesize that the molecular link between CLEC16A, mitophagy, lipophagy, and SOCS1 is abnormal and leads to autoimmune disorders. **Results:** We generated *Clec16a* inducible knockdown mice to examine the mechanism underlying the link between CLEC16A expression alteration and autoimmune susceptibility. Our ubiquitous *Clec16a* KD mice display a complex phenotype similar to that observed in lipodystrophy. CLEC16A Knockdown mice exhibit severe weight loss (loss of visceral and subcutaneous fat) despite eating normal in comparison to control. Adipose tissue is a complex organ, and plays major role in the control of energy, metabolic homeostasis and insulin sensitivity. Weight loss is attributed to increased lipolysis, confirmed by immunoblot analysis of phosphorylated hormone sensitive lipase (HSL). Adipose tissue lysates of CLEC16A knockdown mice also exhibit upregulated HIF-1 $\alpha$  in response to stress. In addition, knockdown mice exhibit altered cytokine/chemokine profile, suggesting *Clec16a* exerts its effect on wide variety of immune cells by modulating SOCS1 expression in response to increased lipolysis and hypoxia and dysregulated mitophagy.

**Conclusions:** The derailed functional link exhibited in our ubiquitous *Clec16a* knockdown (KD) mice with dysregulated mitophagy and lipophagy (increased lipolysis) and altered cytokine /chemokine profile may explain the immune dysregulation and the risk of autoimmunity associated with specific *CLEC16A* variants. Our results establish a functional link between *CLEC16A*, mitophagy, and lipophagy in the context of autoimmunity which explains the immune dysregulation in *Clec16a* KD mice and may explain the risk of autoimmunity in humans with specific *CLEC16A* risk variants.

**Promoter capture Hi-C in primary human white adipocytes identifies an interaction hub at a Mexican lipid locus.** K.M. Garske<sup>1</sup>, A. Ko<sup>2</sup>, D.Z. Pan<sup>1,2</sup>, J. Boocock<sup>1</sup>, T. Tusie-Luna<sup>4,5</sup>, C. Aguilar-Salinas<sup>4</sup>, P. Pajukanta<sup>1,2,3</sup>. 1) Department of Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA; 2) Bioinformatics Interdepartmental Program, UCLA, Los Angeles, USA; 3) Molecular Biology Institute at UCLA, Los Angeles, USA; 4) Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubiran, Mexico City, Mexico; 5) Instituto de Investigaciones Biomédicas de la UNAM, Mexico City, Mexico.

The Mexican population is highly predisposed to hypertriglyceridemia (HTG), which is an independent risk factor for coronary artery disease (CAD) and fatty liver. We previously identified a Mexican-specific triglyceride (TG) GWAS signal on chromosome 11, with the associated SNP rs139961185 exhibiting a minor allele frequency of <1% in Europeans, 20% in Mexican cases and 15% in Mexican controls. Here we evaluated the region using promoter capture Hi-C (pChi-C) in primary human white adipocytes (HWA), a highly metabolically relevant cell type. We determined the linkage disequilibrium (LD) of the region in both the Mexican control GWAS subjects and the 1000 Genomes Mexican Ancestry subjects (MXL) subjects, which revealed 5 SNPs in LD ( $r^2 > 0.8$ ) with the Mexican lead TG GWAS SNP rs139961185. A highly replicated European cardiometabolic GWAS signal at this locus that was also replicated in our Mexican TG GWAS contains the SNP rs964184, which, along with rs139961185, tags a Mexican-specific, TG-associated haplotype. We performed pChi-C in the primary HWA, and used the CHiCAGO software to call significant chromatin interactions. We found that the most significant interactions at the locus are with the salt-inducible kinase 3 (*SIK3*) promoter and the lead TG GWAS SNP rs139961185. Furthermore, rs964184 also exhibits a highly significant interaction with the *SIK3* promoter. We analyzed all of the interactions within the Mexican-specific risk haplotype, and found that the *SIK3* promoter interacts with numerous *HindIII* fragments along the haplotype, and is in the top 0.1% of interacting captured baits genome-wide. These data indicate that the *SIK3* promoter embodies an interaction hub, which have been shown to be enriched for trait-associated SNPs, as well as play an important role in cell-type-specific gene regulatory programs. *SIK3* has previously been implicated in energy homeostasis as a fasting-feeding regulator. Notably, this TG GWAS locus also contains the apolipoprotein gene cluster *APOA1/C3/A4/A5* known to affect serum TG levels. The identification of this chromosomal interaction hub contained within a Mexican-specific TG-associated haplotype on chromosome 11 suggests that the Mexican-specific genetic variation contributes to the HTG in the Mexicans via this regulatory interaction hotspot.

**Transcriptomic profiles of duodenal biopsies in cholesterol gallstone diseases.** *E. Riveras<sup>1</sup>, L. Azocar<sup>1</sup>, TC. Moyano<sup>2</sup>, M. Ocares<sup>1</sup>, H. Molina<sup>1</sup>, D. Romero<sup>2</sup>, JC. Roa<sup>2</sup>, RA. Gutierrez<sup>2</sup>, JF. Miquel<sup>1</sup>.* 1) Departamento Gastroenterología, Facultad de Medicina, Pontificia Universidad Católica de Chile, Santiago, Chile; 2) Departamento de Anatomía Patológica, Facultad de Medicina, Pontificia Universidad Católica de Chile, Santiago, Chile; 3) Departamento de Genética Molecular y Microbiología, Facultad de Ciencias Biológicas, Pontificia Universidad Católica de Chile, Santiago, Chile.

Cholesterol Gallstone (GSD) is a common multifactorial disease characterized by an aggregation and growth of cholesterol crystals in the gallbladder. 10-20% of the global adult population has GSD. Indeed, the Chilean population has the highest prevalence of GSD in the world, being 17% in men and 30% in women. The pathogenesis and molecular mechanisms involved in GSD are still poorly understood, however, environmental and genetic factors are implicated. Although, a handful of lithogenic genes have been identified in humans, only a few of these have been validated/replicated. Additionally, emerging evidence suggests that the small intestine plays an important role in GSD pathogenesis. To understand the role of the upper small intestine in the molecular mechanism involved in GSD pathogenesis, we performed transcriptomic approach using RNA sequencing to evaluate changes in gene expression profile in GSD. Whole transcriptome data were generated on 6 control and 6 GSD duodenal biopsy samples. Presence or absence GSD was defined by abdominal ultrasonography. Sequencing was performed using the Illumina HiSeq 2500. We used HISAT2 to align to the human genome and Rsubread for the read count per transcript. To capture the genes that are differentially expressed, we used DESeq2 package with a false discovery rate adjusted P-value of 0.05. Interestingly, the differential expression analysis between control and GSD patients revealed genes involved in lipid and cholesterol metabolism, immune response and metabolic pathways. Then, we used real time PCR to validate the changes identified in the sequencing analysis in 15 control and 15 GSD patients. Among the differentially expressed genes in GSD, we found that Zone Occludens 1 (ZO-1) and Occludin (OCLN) were repressed in GSD. These genes are key in the formation and regulation of the tight junction in the intestinal barrier. Therefore, these results suggest that GSD subjects may have an increase in intestinal permeability. Furthermore, these data suggest that the upper small intestine may be an important organ in GSD pathogenesis. Further studies are needed to confirm and expand these findings. **Acknowledgment:** Funded by FONDECYT 3160400. FONDAF Center for Genome Regulation 15090007.

**Allele specific chromatin signals uncover regulatory mechanisms in autoimmune and B cell related diseases.** *M. Cavalli<sup>1</sup>, N. Baltzer<sup>2</sup>, H. Umer<sup>2</sup>, J. Grau<sup>2</sup>, I. Lemnian<sup>2</sup>, G. Pan<sup>1</sup>, O. Wallerman<sup>1</sup>, R. Spalinskas<sup>1</sup>, P. Sahlen<sup>1</sup>, I. Grosse<sup>2,3</sup>, J. Komorowski<sup>4</sup>, C. Wadelius<sup>1</sup>.* 1) Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; 2) Institute of Computer Science, Martin Luther University Halle-Wittenberg, Halle, Germany; 3) German Centre for Integrative Biodiversity Research (iDiv) Hall-Jena-Leipzig, Leipzig, Germany; 4) Science for Life Laboratory, Division of Gene Technology, KTH Royal Institute of Technology, Stockholm, Sweden; 5) Department of Cell and Molecular Biology, Computational Biology and Bioinformatics, Uppsala University, Uppsala, Sweden.

Many signals for predisposition to disease and contribution to common traits are mediated by sequence variation in gene regulatory elements. Identifying such variations is a challenging task that involves three major steps: (i) identify the true, causal variant(s), (ii) identify the transcription factors (TFs) mediating the effect, (iii) identify the target gene(s) whose deregulation lead to the phenotypic effect. CHIP-seq data for TFs and histone modifications provide snapshots of chromatin landscapes that allow the identification of heterozygous SNPs with significant allele specific binding (AS-SNPs) and thus might be indicative of a putative functional role. (i) We searched for AS-SNPs in 7 B cell lines and identified 17293 unique AS-SNPs across the different B cell lines. We found 1199 (7%) variants with minor allele frequencies below 1%, indicating that rare variants may significantly affect B cells phenotypes. In order to add a layer of biological relevance to the allele-specific binding behavior, we searched for AS-SNPs in high linkage disequilibrium to GWAS and eQTL SNPs and found 237 AS-SNPs that were associated to B cells related traits and autoimmune diseases and 714 AS-SNPs to gene expression in B cells. (ii) We identified TF binding sites affected by AS-SNPs as a way to prioritize candidate functional variants using Parsimonious Markov Models that take into account intra-motif dependencies. Using stringent models and cutoffs in scanning the genome we found candidate TFs that bound to AS-SNPs associated to 98 B cells traits and 325 eQTLs. (iii) Identifying the gene(s) regulated by a distant enhancer can be difficult since they can act at distances up to hundreds of kb. Hence, we used targeted chromosome conformation capture (HiCap) to identify high-resolution promoters-enhancers interactions affected by AS-SNPs and putative target genes. We found 60 genes as candidates to mediate GWAS signals and 173 AS-SNPs likely mediating eQTLs. This combined approach led to a collection of putative AS-SNPs supported by multiple pieces of evidence that might be putative drivers of gene regulatory processes in B cells and promising candidates for experimental validation of their functional molecular mechanisms.

**Comprehensive identification of differentially methylated regions associated with systemic sclerosis in dermal fibroblasts from African-American patients.** *W.A. da Silveira<sup>1</sup>, I. Atanelishvili<sup>2</sup>, R.C Wilson<sup>1</sup>, E.S Hazard<sup>1</sup>, J.C Oates<sup>2</sup>, G.S Bogatkevich<sup>2</sup>, G. Hardiman<sup>1,2,3</sup>, P.S Ramos<sup>2,3</sup>.* 1) Center for Genomic Medicine, Medical University of South Carolina, Charleston, SC; 2) Department of Medicine, Medical University of South Carolina, Charleston SC 29425; 3) Department of Public Health Sciences, Medical University of South Carolina, Charleston SC 29425.

Systemic sclerosis (SSc) is a fibrotic autoimmune disorder characterized by cutaneous and visceral fibrosis, immune dysregulation, and vasculopathy. It disproportionately affects African-Americans (AA) who, despite the higher disease severity, are dramatically underrepresented in research. The role of DNA methylation in disease risk remains unclear. This analysis was conducted to comprehensively identify differentially methylated loci associated with SSc in AA. We profiled DNA methylation patterns on cultured dermal fibroblasts isolated from 15 AA SSc cases and 15 AA controls through reduced representation bisulfite sequencing (RRBS). Alignment and methylation calling were performed using Bismarck v0.16.3 and the GRCh37/hg19 reference genome. Data was filtered, normalized, and analyzed with RnBeads v1.6.1. Differential methylation analysis was conducted on CpG, promoter, gene and system level. We generated DNA methylation data for over 5 million CpGs in each sample with at least 40x coverage in promoter and CpG islands. A total of 97 CpG islands and 197 genes and 112 promoters showed significant differential enrichment (using the Combined Score – RnBeads best practices approach) in methylation levels between cases and controls including, among others, the promoter of *SERPINA1* - a protease inhibitor of elastase, plasmin, thrombin and trypsin – and *SERPINA3*, *SERPINA4*, *SERPINA5*, *SERPINA11* and *SERPINA13P*. The SERPIN superfamily is characterized by its function as chaperone proteins and its roles in inflammation and immune function. Enrichment analysis revealed that both hypo and hypermethylated genes and their promoter regions were enriched for immune-related and differentiation gene ontology terms (hypomethylated regions: interleukin-2-mediated signaling pathway,  $P=0.005$  and mesenchymal cell differentiation,  $P = 3 \times 10^{-4}$ ; hypermethylated regions: type I interferon signaling pathway,  $P=8 \times 10^{-4}$  and positive regulation of cell differentiation,  $P= 1 \times 10^{-3}$ ). In summary, we observed dramatic DNA methylation differences between cases and controls. Interestingly, most of the dysregulated genes can be placed in immune pathways, supporting the role of immune dysregulation in triggering the fibrosis characteristic of SSc. These data support a role for DNA methylation differences in mediating susceptibility to SSc in AA.

**Identification of hypermethylated T- and B-cell receptor signaling molecule clusters in systemic lupus erythematosus (SLE) patients by integrative analysis.** *M.B. Guo, T.Y Wang, Y.F. Wang, J.J. Shen, J. Yang, Y.L. Lau, W.L. Yang.* Department of Paediatrics and Adolescent Medicine, The University of Hong Kong, Hong Kong, China.

Molecular mechanism underlying the pathogenesis of systemic lupus erythematosus (SLE) has yet to be found. Epigenetics, as an intermediate mediator between genetics/environmental factors and disease phenotypes, has been investigated frequently for a possible answer. Here we used a dataset of DNA methylation to identify genes with differentially methylated regions (DMR) in patient immune cells, and validated the results in an independent dataset. Many of these DMRs are *in vivo* targets of DNA methyltransferases (DNMTs), and the methylation level of a DMR gene DNMT3B was found negatively correlated with methylation of a number of DMR genes. We also found that many T- and B-cell receptor (TCR, BCR) signaling molecules were hypermethylated in SLE patients. Both important stimulatory and inhibitory genes such as CTLA-4, PD-1, BTLA, CD28, LCK and ZAP70 in T cells, BLK, CD19 and LCK in B cells were found hypermethylated. By integrating ENCODE data from transcription factor (TF) binding experiments, we found a group of TFs having enriched binding peaks in these DMR genes. STATs, IKZFs, IRFs, NF- $\kappa$ B, AP-1, ESR1 and several other immune-related TFs were among those enriched. We also observed a list of TF clusters possibly bound to a subset of DMR genes and regulate their expression synergistically. Lastly, we integrated DNA methylation, TFs, histone modifications and SLE differential gene expression data to investigate the important factors influencing gene expression in SLE, using the machine learning algorithm LASSO. And methylation status was found to be the most important factor driving abnormal gene expression in SLE patients. By regulating the chromatin openness and TF binding, DNA methylation played a pivotal role in the pathogenesis of SLE.

**A functional SNP in 2p14 associated with rheumatoid arthritis by modulating *ACTR2* gene expression via long-range interaction.** B. Lu, M. Yang, X. Chen, H. Chen, S. Yao, Y. Guo. School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, Shaanxi, China.

Rheumatoid arthritis (RA) is a common autoimmune disease, characterized by chronic, multi arthritis synovial inflammation and the destruction of cartilage and bone, resulting in progressive disability. Genome-wide association studies (GWASs) have revealed the association between variants within the noncoding regions of chromosome 2p14 and RA, but the molecular mechanisms of these variants are unclear. Therefore, we aimed to interpret the functions and mechanisms of noncoding variants in 2p14 by integrating a series of bioinformatics analyses and functional assays. Firstly, RA-associated SNPs (rs1858037, rs934734, rs1876518) residing in the noncoding regions in 2p14 were obtained from GWASs catalog database. By using epigenetic annotation in GM12878 and osteoblasts cell lines from Roadmap Epigenomics Project and ENCODE project, we found that all of the SNPs were enriched in active histone modifications (H3K4me1, H3K4me3 and H3K27ac), and SNP rs1858037 specifically occupied for DNaseI hypersensitive site. We further performed the eQTLs analysis in 3 different kinds of samples including whole blood (Genotype-Tissue Expression project, GTEX), lymphoblastoid cell lines (1000 genome project) and peripheral whole blood of RA patients. Consistent eQTL results were observed for rs1858037 ( $p = 3.20 \times 10^{-3}$ /GTEx,  $p = 7.57 \times 10^{-3}$ /1000 genome project,  $p = 1.10 \times 10^{-9}$ /RA patients) which affects expression of a distal gene *ACTR2* (about 143kb). Moreover, the SNP rs1858037 physically interacted with *ACTR2* in GM12878 cell line as demonstrated by Hi-C analysis. We further conducted dual-luciferase reporter assay and demonstrated that rs1858037-A allele significantly inhibited *ACTR2* gene expression comparing to the rs1858037-T allele in both human embryonic kidney 293T cells (HEK 293T) and human rheumatoid synoviocyte MH7A cell line (MH7A). In conclusion, our study indicates that noncoding SNP rs1858037 affects RA by modulating *ACTR2* gene expression via long-range chromosome interaction. Our finding may illuminate the dark road of regulatory mechanisms of noncoding variants leading to underlying the development and progression of RA.

**Whole blood DNA methylation signatures of Crohn's disease susceptibility and progression.** H.K. Sominen<sup>1,2</sup>, V. Kilaru<sup>3</sup>, S. Venkateswaran<sup>1,2</sup>, P. Chopra<sup>2</sup>, D. Okou<sup>1</sup>, G. Gibson<sup>4,5</sup>, K.N. Conneely<sup>2</sup>, A.K. Smith<sup>3</sup>, S. Kugathasan<sup>1,2</sup>. 1) Department of Pediatrics, Emory University, Atlanta, GA; 2) Department of Human Genetics, Emory University, Atlanta, GA; 3) Department of Gynecology & Obstetrics, Emory University, Atlanta, GA; 4) Department of Biological Sciences, Georgia Institute of Technology, Atlanta, GA; 5) Center for Integrative Genomics, Georgia Institute of Technology, Atlanta, GA.

**Background:** Crohn's Disease (CD) is a life-long condition characterized by ulceration, pain, rectal bleeding, loss of quality of life and a need for bowel surgery. Most CD patients present with an inflammatory phenotype (B1), however, a subgroup rapidly progress to complicated disease behaviours such as stricturing (B2). Recent evidence suggests the involvement of gene-environmental interactions in CD. Epigenetic processes play an important role in mediating environmental influences. Therefore, we set out to examine genome-wide DNA methylation differences associated with CD susceptibility and progression. **Methods:** We utilized a subset of pediatric subjects recruited under the RISK multicenter inception cohort study to elucidate the epigenetic basis of CD. We generated genome-wide DNA methylation data using the Illumina HumanMethylationEPIC 850K array in whole blood DNA samples of 59 controls and 139 newly diagnosed CD cases (B1), of which 71 progressed to B2 at a later time point within 36 months from the day of diagnosis.  $\beta$ -values for each CpG site were modeled as a linear function of disease status with age, gender, and cell-type proportions as covariates to profile disease-related methylation changes. **Results:** 463 differentially methylated positions (DMPs) exhibited significant association with CD susceptibility (FDR<.05). Of these, 349 DMPs were hypermethylated and 114 were hypomethylated in cases compared to controls. We observed strong CD-associated signals on chromosomes 17 and 19. CpGs in a long non-coding RNA, *LOC100996291*, showed the strongest association with CD. In addition to detecting several novel DMPs, some of the previous 450K array findings from whole blood (*TMEM49/VMP1*, *SBNO2*, *RPS6KA2*, *ITGB2*, and *TXK* genes) were replicated in our study. Furthermore, many of the DMPs exhibited strong correlation with disease-related plasma C-reactive protein, albumin, and hemoglobin levels. The 463 DMPs mapped to 299 unique genes, which were enriched for immune function-related TNF-alpha, IL-10, and IL-9 signaling pathways. 154 of the 463 CD-susceptibility DMPs also exhibited association with disease progression (B1 vs B2), suggesting common epigenetic processes underlying both susceptibility and progression of CD. **Conclusion:** Our findings suggest that dysregulated DNA methylation is associated with CD susceptibility and progression, and may offer new pathophysiological insights and therapeutic targets to prevent the onset of CD and delay its progression.

**An epigenome-guided approach to causal variant discovery in autoimmune disease.** R.C. Pelikan<sup>1</sup>, J.A. Kelly<sup>1</sup>, Y. Fu<sup>1</sup>, C.A. Lareau<sup>2,3</sup>, G.B. Wiley<sup>1</sup>, S.B. Glenn<sup>1</sup>, M.J. Aryee<sup>2,3</sup>, C.G. Montgomery<sup>1</sup>, P.M. Gaffney<sup>1</sup>. 1) Arthritis & Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, OK; 2) Department of Biostatistics, Harvard T.H. Chan School of Public Health, Charlestown, MA; 3) Department of Pathology, Harvard Medical School, Boston, MA.

Translating genetic findings into functional mechanisms is an inefficient, resource-intensive task. Here, we expedite causal variant discovery for autoimmune diseases by identifying genetic variants (epiQTLs) that leave an epigenomic footprint of allelic imbalance in sequencing reads recovered by chromatin immunoprecipitation of enhancer marks (H3K4me1 and H3K27ac). Using the WASP pipeline to control for reference genome bias and the combined haplotype test to determine statistically robust allelic imbalance, we discovered a total of 6261 epiQTLs across 25 patient-derived EBV-transformed B-cell lines. We overlaid these epiQTLs onto risk haplotypes from 21 autoimmune (AI) diseases and found that 145 reported AI risk haplotypes contained one or more of our epiQTLs. A total of 14 epiQTL SNPs were the same as the AI risk SNP reported in the GWAS catalog, while 180 epiQTLs were proxies of the reported SNP. We demonstrate that epiQTLs located on disease risk haplotypes disproportionately influence gene expression variance over non-epiQTL variants in tight linkage disequilibrium. Following this, we characterized the three-dimensional chromatin interaction topography of our cell lines by HiChIP for H3K27ac-marked active enhancers, locating a majority (78%) of epiQTLs in chromatin loop anchors. Using a generalized linear model, we identified 571 epiQTLs – not associated with autoimmune disease – that modify gene expression from 68 previously established autoimmune disease risk haplotypes through chromatin looping at an FDR  $\leq$  5%. Expanding this analysis to include both risk haplotypes and independent eQTLs increased the number of epiQTLs with significant (FDR  $\leq$  5%) modifier effects on gene expression to 1062. Of these gene expression modifying interactions, 717 (68%) increased eQTL-driven gene expression by the epiQTL, while 345 (32%) suppressed eQTL-driven gene expression. Taken together, our data suggest that the epiQTL approach can facilitate the decomposition of risk haplotypes into specific regions that are highly likely to contain functional causal variants. Moreover, epiQTLs not associated with disease haplotypes function to modify gene expression from risk haplotypes and eQTLs through long-range allele-dependent epigenetic mechanisms.

Multiple sclerosis (MS [MIM 126200]) is an immune-mediated disease in which T cells damage the myelin sheath surrounding nerves in the brain and spinal cord, leaving lesions. CD4+ helper T cells predominate in new, active lesions, while CD8+ cytotoxic T cells predominate in chronic lesions. Several genetic and environmental risk factors have been identified for MS, but their mechanisms are not fully understood. DNA methylation is an epigenetic modification that can alter gene expression, and it is influenced by genetic and environmental factors. Methylation is a potential mechanism by which exposures affect disease and may play a role in MS pathogenesis. To test methylation differences between MS cases and controls, we performed an epigenome-wide association study with 96 cases and 102 controls. We generated methylation profiles in both CD4+ and CD8+ sorted T cells for all participants using Infinium BeadChips (396 profiles total). All participants were female and recruited from Norway or Australia. All cases had relapsing-remitting MS and available treatment information. Analyses for CD4+ and CD8+ cells were performed separately. Data were processed using *Minfi*, and *SVA* was used to estimate latent variables that might confound results. Regions of differential methylation were identified with *Bumphunter*, using regression models adjusted for age, recruitment site, and latent variables. Preliminary results showed several regions of differential methylation. Cases were hypomethylated in CD4+ cells in a 22-CpG regulatory region 8 kb downstream of the myelin oligodendrocyte glycoprotein (*MOG*) gene, a primary target antigen in immune-mediated demyelination. Cases were also hypomethylated in both CD4+ and CD8+ cells in a 5-CpG region in a transcription factor binding site (TFBS) ~400 bp upstream of *LCLAT1*, an acetyltransferase involved in lipid synthesis that is upregulated in diet-induced obesity. Cases were hypermethylated in CD8+ cells in an 11-CpG region in a TFBS in the 5' UTR of *SLFN12* and 2 kb downstream of *SLFN13*. Genes in this family are regulated by interferons and inhibit retrovirus protein synthesis. Since obesity and Epstein-Barr virus infection, which can activate human endogenous retrovirus expression, are known risk factors for MS, these results suggest that environmental factors can exert their influence on MS risk through methylation changes.

**1564W****Functional annotation of chronic lymphocytic leukemia (CLL) risk loci.**

*H. Yan, S. Tian, G. Kleinstern, S. Slager.* Division of Biomedical Statistics and Informatics, Department of Health Sciences Research, Mayo Clinic, Rochester, MN 55902.

Genome-wide association studies (GWAS) have been extensively used to identify disease-associated single nucleotide polymorphisms (SNPs). Over 90% of the GWAS SNPs were found to reside in the noncoding regions, often distal to the transcription start sites. They are particularly enriched in regulatory regions, such as enhancers, promoters, and insulators, that can be defined epigenetically using chromatin accessibility, histone modification and transcription factor (TF) ChIP-seq data. It is widely accepted that disease risk SNPs exert their regulatory roles, individually or in a combinatorial fashion, by altering local chromatin states, TF binding, and enhancer-promoter looping interactions, ultimately leading to the expression changes of the target genes. Nevertheless, functional interpretation of GWAS SNPs is often limited by multiple correlated SNPs in linkage disequilibrium (LD) with the index SNP, a lack of comprehensive epigenetic data in the pathogenically relevant cell type, or the difficulty to link enhancer-SNPs to the target genes. We and others have identified 41 CLL risk SNPs through GWAS. To gain a deeper understanding of the underlying mechanisms of these SNPs in the CLL etiology, we performed a systematic annotation of the risk loci. We analyzed 215 publicly available epigenetic data sets generated in CLL, B cells from healthy individuals, and lymphoblastoid cell line GM12878, which include chromatin accessibility, Hi-C chromatin interaction data, and ChIP-seq for H3K4me1, H3K4me3, H3K27ac, chromatin regulators and TFs. We extracted an additional 4,376 SNPs from the 1000 Genomes Project that were in LD ( $R^2 \geq 0.5$  in the EUR ethnic group) with the 41 index SNPs. Intersection with internal H3K4me1, H3K4me3 and H3K27ac ChIP-seq data in CLL and the public epigenetic data revealed that 47% of the SNPs overlapped at least 1 epigenetic mark and 16.6% overlapped marks from over 10 samples. To pinpoint the potential causal SNPs, we identified cases of allele imbalance from chromatin accessibility and ChIP-seq data. We also scanned the SNP regions for matches to five TF motif databases. Our analyses revealed 485 SNPs from 36 risk loci that provide evidence of allele imbalance or altered TF binding motifs, suggesting a role for epigenetic mechanism in CLL pathogenesis. Further analysis with HiC data in GM12878 and RNA-seq data in CLL will illustrate how the causal SNPs contribute to the alteration of transcription program.

**Integrative analysis identified pervasive long-range regulation mediated by super-enhancers shared in multiple autoimmune diseases.** *X.F. Chen, B.J. Lu, M. Yang, Y.Y. Duan, Y. Guo.* School of Life Science and Technology, Xi'an Jiaotong University, Xi'an 710049, P. R. China, China.

Genome-wide association studies (GWASs) have identified over one thousand susceptibility SNPs for autoimmune diseases, and most of them are located in noncoding regions. Currently, the greatest challenge is to decipher the functional roles of these flourishing noncoding autoimmune SNPs, and discover the shared genetic mechanisms underlying multiple autoimmune diseases. Therefore, in this study, we aimed to identify the regulatory noncoding SNPs and potential shared pleiotropic immune genes for 20 autoimmune diseases, through an integrative analysis combining score-based epigenetic annotation, expression quantitative trait loci (eQTLs) and genomic chromatin interaction (Hi-C). We firstly extracted 1350 autoimmune GWAS SNPs from GWAS Catalog and ImmunoBase. To evaluate functionality for 25,483 noncoding primary and LD ( $r^2 > 0.8$ ) autoimmune SNPs, we devised a cell-specific and score-based epigenetic annotation approach, which adopted an accumulative quantitative score system using fold change as weight of particular functional element in 27 blood cells from Roadmap or ENCODE project by comparing 25,483 autoimmune SNPs and 388,210 GWAS SNPs. We further scored for 1,784,477 negative control SNPs ( $r^2 < 0.1$ ) to build null distribution with score value ranked in 5% chosen as criteria to define functionality. There are totally 1,364 potential functional SNPs as determined by the custom score system. We further identified 330 potential regulatory SNPs regulating expression of 106 target genes through combining Hi-C and eQTLs analysis. 243/330 SNPs are located in super-enhancers in blood cells, with 80 SNPs annotated in over 10 blood cells. We detected a core regulatory network involving 39 SNPs and 3 immune-related target genes (*ERAP1*, *ERAP2*, *LNPEP*). All the 39 SNPs are located in super-enhancers. Our results suggest that super-enhancers play important roles in autoimmune diseases. Moreover, most of regulatory SNPs (80.3 %) affect distal target genes, suggesting pervasive long-range regulation in autoimmune diseases. We found that many target genes (59/106) were associated with two or more autoimmune diseases. Of which, 8 genes were associated with over 5 diseases, indicating prevailing shared genetic variants on different autoimmune diseases. In a summary, our study deciphered functional basis for noncoding variants for autoimmune diseases, which is characterized by pervasive long-range regulation mediated by super-enhancers shared in multiple autoimmune diseases.

**Cis regulatory variation determines dynamic HLA-DQB1 allelic expression in response to T cell activation.** M. Gutierrez-Arcelus<sup>123</sup>, S. Hannes<sup>123</sup>, N. Teslovich<sup>123</sup>, Y. Luo<sup>123</sup>, H.J. Westra<sup>123</sup>, K. Slowikowski<sup>123</sup>, D.A. Rao<sup>3</sup>, J. Ermann<sup>3</sup>, M.B. Brenner<sup>3</sup>, S. Raychaudhuri<sup>1234</sup>. 1) Divisions of Genetics, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; 2) Program in Medical and Population Genetics, Broad Institute of Harvard and MIT, Cambridge, MA, USA; 3) Division of Rheumatology, Immunology, and Allergy, Brigham and Women's Hospital, BTM, 60 Fenwood Road, Boston, MA 02115, USA; 4) Faculty of Medical and Human Sciences, University of Manchester, Manchester, UK.

The HLA class II genes, such as DQB1, play a major role in autoimmune disease. While the prevalent view is that coding variation and antigen presentation is driving disease risk in this locus, there is also the possibility that *cis* regulatory HLA effects might play a role. Most of the non-MHC causal variants for autoimmune diseases are in non-coding genomic regions in CD4+ T cells (Trynka *et al.* 2013). Hence, it is essential to define the genetic regulatory effects acting at the specific cell-types and physiological states most relevant for each disease within and outside of the MHC region. Since allelic expression is largely driven by genetic regulatory variation in *cis* (Buil *et al.* 2015), it is a powerful approach to study regulatory effects in multiple cell states without the need of a large sample size. This study brings **two main contributions**: 1) we developed a **robust way for studying allele specific expression in the HLA locus**, leveraging its high polymorphic and LD nature. 2) We identified **dynamic condition-specific cis regulatory effects harboring dramatic changes in DQB1 expression**. We isolated CD4+ memory T cells from the peripheral blood of 24 healthy genotyped individuals. We then queried the transcriptome with RNA-seq after non-antigenic stimulation at 0, 2, 4, 8, 12, 24, 48 and 72 hours. Genome-wide analysis to identify heterozygous SNPs where the **relative contribution of each allele changes across activation states**, revealed most significant signals at the DQB1 gene. Targeted sequencing revealed 14 unique DQB1 alleles across the 24 heterozygous individuals. Strikingly, by mapping RNA-seq reads to the exonic sequences of DQB1, 16 out of 24 individuals had **strong and significant time-dependent allelic expression** ( $P < 1e-18$ ,  $\beta > 1$ ). For example, in an individual carrying the alleles 0503 and 0301, the transcript coded by the 0503 allele represented 61% of overall DQB1 counts at 0 hours, and gradually increased to 96% of counts at 72 hours. Furthermore, we observed that the same DQB1 alleles in different individuals had similar expression patterns ( $P < 1e-04$ ). Unsupervised clustering indicates there are **3 main genetic regulatory programs influencing DQB1's dynamic expression in response to T cell activation**. Notably, we did not observe regulatory activity to this extent anywhere else in the genome. This study illustrates the dramatic gene regulatory variation, mirroring the dramatic coding variation, in DQB1.

**Investigation of the effect of an autoimmunity associated SNP in the 6q23 locus on enhancer function using CRISPR/Cas9.** S. Singh<sup>1</sup>, T. Katopodis<sup>1</sup>, K. Duffus<sup>1</sup>, P. Martin<sup>1</sup>, G. Orozco<sup>1,2</sup>. 1) Arthritis Research UK Centre for Genetics and Genomics, School of Biological Sciences, Faculty of Biology, Medicine and Health, The University of Manchester, Stopford Building, Oxford Road, Manchester M13 9PT, UK; 2) NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Sciences Centre, Central Manchester Foundation Trust, Grafton Street, Manchester M13 9NT, UK.

It is estimated that 90% of disease-associated genetic variants identified by GWAS lie in noncoding regions of the genome and, although their role in disease is not well understood, they accumulate in enhancers. This suggests that disease may be the consequence of an impaired regulatory circuitry between enhancers and their target genes. A previous study characterizing chromatin interactions between all associated genetic regions for four autoimmune diseases and their potential target genes revealed that non-coding variants on 6q23 show significant interactions with the genes *IL20RA*, *IL22RA2*, *IFNGR1* and *TNFAIP3* in T and B cell lines. Further assays suggested that one of the SNPs mapping to a predicted enhancer, rs6927172, was correlated with increased expression of *IL20RA* and increased binding of regulatory proteins. The aim of this work is to functionally validate the ability of this predicted enhancer, containing the autoimmunity associated variant rs6927172, to modulate the expression of its putative target genes using CRISPR/Cas9-based epigenome editing. We used tiled dCas9-KRAB repression constructs to target this enhancer, using seven guide RNAs (gRNAs) spanning 250bp around rs6927172. They were each cloned into the pLV hU6-sgRNA hUbc-dCas9-KRAB-T2a-GFP plasmid. Lentivirus was produced by using third generation packaging system and gRNA cloned plasmid into Lenti-X HEK293-T cells. Concentrated virus was used to perform transduction into HEK293-T and Jurkat cells. Transduced cells expressing GFP were sorted by FACS. The effect of repressing the enhancer of interest on the expression of its putative target genes (*IL20RA*, *IL22RA2*, *IFNGR1* and *TNFAIP3*) was measured by using Taqman Gene Expression assays. *TNFAIP3* expression was significantly downregulated in engineered Jurkat cells ( $P = 0.0003$ ). *IL22RA2* and *IFNGR1* gene expression was also reduced but it was not statistically significant in these cells. *IFNGR1* expression was reduced in engineered HEK293-T cells ( $P = 0.0004$ ). *IL20RA* gene expression was also reduced in these cells but it was not statistically significant. Our results further support that genetic variation at 6q23 may be involved in autoimmunity through impaired ability to regulate expression of immune genes such as *IL20RA*, *IL22RA2*, *IFNGR1* and *TNFAIP3*. These results demonstrate that functional evaluation of GWAS loci, using CRISPR, can aid the translation of descriptive genetic association results into molecular mechanisms underlying disease.

From GWAS we know of nearly three thousand genetic variants associated with human phenotypes, a third of which are related to autoimmune diseases. Most of these variants fall within noncoding regions expected to regulate chromatin or gene expression, however, in many cases the relevant cell type and condition-specific mechanisms connecting genotype and phenotype remain unknown. Therefore, we developed the first comprehensive immune cell type atlas consisting of ATAC and RNA-seq data from 25 differentiated cell types under resting state and stimulated conditions from peripheral blood of four healthy individuals. On average we identified 85 thousand chromatin accessible regions per cell type, additionally, stimulated cells had 43% more accessible peaks compared to their resting state counterpart (MACS2 identified peaks,  $q < 1\%$ ). Furthermore, identified chromatin regions were significantly enriched for corresponding cell type and stimulation-specific transcription factor motifs. Comparing stimulation to resting state-specific open chromatin regions, we observed a 1.5-fold enrichment increase of genome-wide GWAS summary statistic values for rheumatoid arthritis and found a similar trend for significant fine-mapped GWAS variants from 18 other autoimmune disorders. Finally, as an example of the utility of such a data set, we leverage cell type-specific functional information to fine map the likely causal variant linking the expression of *POLB* to systemic lupus erythematosus. Overall, our atlas of chromatin accessibility and gene expression is a powerful resource for linking genetic variants to autoimmune diseases and understanding mechanisms of gene expression regulation.

**Integrative fine-mapping of genetic loci affecting risk for multiple sclerosis using stimulated primary immune cells.** *R. Hinch*<sup>1</sup>, *J. Davies*<sup>2</sup>, *C. Dendrou*<sup>2,3</sup>, *L. Fugger*<sup>2</sup>, *G. McVean*<sup>1</sup>. 1) Big Data Institute, Oxford University, Oxford, UK; 2) MRC Weatherall Institute of Molecular Medicine, Oxford University, Oxford, UK; 3) Wellcome Trust Centre for Human Genetics, Oxford University, Oxford, UK.

Genetic variation tells us about common disease susceptibility, however, rarely identifies casual biological pathways. This is because the casual variant is often unknown due to linkage disequilibrium and/or the variant affects gene regulation which is not localised in the gene of interest. Gene regulation is also highly cell-type dependent and varies with environmental changes. An example of an environmental stimulus is when immune cells are presented with pathogens which trigger key pathways to attack the pathogen. We analyse the response of primary immune cells to stimuli (e.g. LPS) to identify the genetic mechanism of the response pathways. Using this approach, we gain power by focussing on a subset of genes involved in immunological response. Taking an integrative approach, we simultaneously analyse changes in RNA expression (RNA-seq), DNA accessibility (ATAC-seq) and histone modifications (ChIP-seq), along with structural data (Hi-C and capture-C) and genetic variation (GWAS and eQTLs) to identify pathways of genetic regulation. Further, using machine-learning techniques, we analyse transcription factor binding sequences to demonstrate how individual SNPs alter gene regulation. We apply our approach to 103 loci associated with multiple sclerosis.

**The role of T cell stimulation intensity in the expression of immune disease genes.** D.A. Glinos<sup>1</sup>, B. Soskic<sup>1,2,3</sup>, D.M. Sansom<sup>2</sup>, G. Trynka<sup>1,3</sup>. 1) Wellcome Trust Sanger Institute, Wellcome Genome Campus, Cambridge, UK; 2) Royal Free Campus, Institute of Immunity and Transplantation, University College London, UK; 3) Open Targets, Wellcome Genome Campus, Cambridge, UK.

Recent studies have recognised the importance of mapping the effects of genetic variants on gene regulation in specific cell types, environmental contexts and stimulation time points. Here, we demonstrate that the titration of the stimulatory signal is a variable that can influence gene expression profiling. Genome wide association studies (GWAS) for common autoimmune diseases have identified a large number of genetic variants located near genes involved in T cell stimulation. T cells need two signals to become activated, one generated by the T cell receptor (TCR) and the second from the CD28 costimulatory molecule. However, there is limited information on the exact pathways underlying these two signals in human CD4+ T cells. Since T cell stimulation is critical for the development of autoimmunity, we tested if GWAS variants play a role in specific TCR and CD28 stimulatory conditions. We stimulated CD4+ T cells *in vitro* with varying intensities of TCR and CD28 signals across seven conditions. Following stimulation, we performed RNA-seq and ATAC-seq on sorted activated cells from four healthy individuals. We observed a distinct gene expression and chromatin accessibility profile for each cell-type stimulation combination. Clusters of genes that were co-regulated through different stimulations were controlled by costimulation in memory cells, while dominated by the TCR in naïve cells. Surprisingly, genes in the DNA replication pathway were regulated by the different stimulatory signals in the two cell types, under CD28 control in memory cells ( $p\text{-value} < 10^{-7}$ ) and TCR in naïve cells ( $p\text{-value} < 10^{-3}$ ). We confirmed this result by cell proliferation assays. Finally, we used our dataset to test if GWAS variants play a role in specific TCR and CD28 stimulation contexts. We identified that immune disease variants were enriched nearby highly expressed genes specific to cell stimulated conditions. Crohn's disease variants were only enriched in conditions with strong TCR stimulation in the presence of costimulation in memory but not naïve T cells, while celiac disease variants were specifically enriched in memory T cells under low TCR and low CD28. This study provides a primer to prioritise TCR and CD28 stimulation states for the study of disease variants in specific cellular contexts.

**Blood cell type-specific genome-wide DNA methylation analysis of Chinese patients with early-onset systemic lupus erythematosus identifies loss of DNA methylation in genes related to the Type I Interferon pathway.** H.Y.B. Chung<sup>1</sup>, K.S. Yeung<sup>1</sup>, T. Mok<sup>2</sup>, S. Choufani<sup>2</sup>, Y.L. Lau<sup>1</sup>, R. Weksberg<sup>3</sup>. 1) Pediatrics and Adolescent Medicine, Queen Mary Hospital, Hong Kong, Hong Kong; 2) Department of Biomedical Sciences, The City University of Hong Kong, Hong Kong; 3) Genetics and Genome Biology Program, The Hospital for Sick Children Research Institute, Toronto, Canada.

Background: About 20% of Systemic Lupus Erythematosus (SLE) is diagnosed in children under 18. These children often present with more active and severe disease than adult-onset patients. Since whole blood is comprised of different immune cells, we aimed to identify the cell type-specific DNA methylation signatures of CD4+ T cells, CD8+ T cells, B cells, neutrophils and whole blood in individuals with SLE patients who presented before 18-years of age. Method: Specific immune cells were isolated by positive selection using MACS MicroBeads (Miltenyi Biotec). We compared the DNA methylation profiles of different blood cells for 16 Chinese SLE patients to that of 13 healthy controls using the Illumina HumanMethylationEPIC BeadChip. Data pre-processing was performed to remove cross-reactive probes, probes with SNPs at the target site, and probes from sex chromosomes. For each specific region, Wilcoxon rank-sum test was used for group comparisons, and false discovery rate was used for multiple testing corrections. CpG sites with an adjusted  $p\text{-value} < 0.05$  and a mean methylation change  $> 0.1$  were considered to be differentially methylated. Results: After data pre-processing, 775280 probes remained and principal component analysis showed that samples clustered according to specific cell types rather than disease manifestation. Global changes of DNA methylation were not observed among different cell types. The number of differentially methylated CpG sites ranged from 46 to 160 in comparisons of different cell types, with more CpG sites showing hypomethylation than hypermethylation. Principal component analysis showed that samples could be separated according to disease manifestation. Gene ontology analysis was performed for each cell type and revealed that in all the cell types examined, hypomethylated genes identified were overrepresented in the type I interferon pathway. This suggests that the DNA methylation changes in different immune cells of SLE patients target the same biological pathway. As type I interferon has long been believed to be involved in the pathogenesis of SLE, our findings support the importance of an epigenetic mechanism in the dysregulation of type I interferon in SLE pathogenesis. Acknowledge: This work was supported by the General Research Fund (Ref: HKU 765513).

**Integrative methylation/mRNA analyses identified an interferon-inducible-gene interaction network with a key gene PARP9 in rheumatoid arthritis.** S. Lei<sup>1,2</sup>, H. Zhu<sup>1,2</sup>, F. Deng<sup>1,2</sup>, L. Wu<sup>1,2</sup>. 1) Center for Genetic Epidemiology and Genomics, Soochow University, Suzhou, Jiangsu, China; 2) Jiangsu Key Laboratory of Preventive and Translational Medicine for Geriatric Diseases, School of Public Health, Soochow University, Suzhou, Jiangsu 215123, P.R. China.

To detect the comprehensive genome-wide rheumatoid arthritis (RA) associated methylation sites, and build their downstream regulatory networks, the peripheral blood mononuclear cells of 25 RA patients and 18 healthy controls were used to detect genome-wide methylation status and gene expression by 450K Infinium Methylation arrays and lncRNA/mRNA expression Bead Chip, respectively. The regulatory networks were constructed by applying STRING, CYTOSCAPE and the Causal Inference Test. The differential DNA methylation sites and differential mRNA levels of ten candidate genes were validated in two independent samples. We also generated *PARP9* over-expressed (OE) and knockdown (shRNA) Jurkat cell strains to explore the influence of *PARP9* on cell cycle, cell proliferation and the expression of RA-related inflammatory cytokines. About 1046 differential methylation loci (DML) were identified. The methylation level of 107 DML was significantly correlated with their corresponding gene expression ( $P < 0.05$ ). An interferon inducible gene interaction network was constructed in which *MX1*, *IFI44L*, *DTX3L*, *PARP9* were the 4 key differential methylated genes. The differential methylation locus/loci of three genes (*BLK*, *MX1*, *PARP9*), especially for three loci of *PARP9*, were verified in independent sample. The differential gene expression level and the up-regulation or down-regulation of four genes, *BLK*, *IFI44L*, *MX1*, *PARP9*, in RA patients were validated in independent samples. In Jurkat cells, the methylation level of two loci of *PARP9* showed significantly negative correlation with gene expression. The proliferation of OE Jurkat cell was significantly faster than that of OE-negative controls ( $P < 0.05$ ), the proliferation of shRNA Jurkat cell was significantly slower than that of shRNA-negative controls ( $P < 0.05$ ). Compared with negative control, the percentage of G0/G1 and S cells was lower than that of G2/M cell in OE Jurkat cells, but higher in shRNA Jurkat cells. The expression level of *IL-2* was positively regulated while *IL-4* and IFN $\gamma$  was negatively regulated by *PARP9*. This study has identified a genome-wide rheumatoid arthritis (RA) associated methylation profiles and constructed their downstream regulatory networks. The interferon-inducible-gene interaction network with *PARP9*, *MX1*, *IFI44L* and *DTX3L* as the key genes might play an important role in RA pathology. The abnormal methylation status of specific sites in *PARP9* may mediate pathogenic effects in RA.

Thyroid peroxidase antibody (TPOAb) positivity is strongly associated with two major autoimmune thyroid diseases (Graves' and Hashimoto's diseases). Although the heritability of serum TPOAb levels is estimated at 66%, studies have shown that environmental factors such as stress, smoking and infection also contribute and can have opposing effects in different disease subtypes. Epigenetics, particularly DNA methylation, is seen as the link connecting environment and genetics to phenotype and thus could play a major role in thyroid diseases. In this study, we performed epigenome-wide association study (EWAS) to 98 TPOAb-positivity discordant MZ twin pairs (only female Caucasians) using the state-of-art MethylC-Capture Sequencing (MCC-Seq) approach. TPOAb levels were measured by immunoassay. MCC-Seq used a custom autoimmune panel designed for whole-blood interrogation and covering 4.9M CpGs and 1.3M SNPs. CpGs were selected in dynamic regions of the epigenome including DNaseI hypersensitive sites from the ENCODE project and blood-methylome footprints (unmethylated and low methylated regions from different blood cell-types). Analyses employed a likelihood ratio test in a generalised linear mixed model with a beta-binomial distribution for differentially methylated positions (DMPs) and a Bonnett-Seire test for differential variability in DNA methylation (DVMPs); smoking, blood cell composition, age, family and analytical batch were included as covariates. We obtained on average 63% on-target rate per sample corresponding to 14x mean genome coverage. After quality control, downstream analyses comparing the level and variance of DNA methylation in the TPOAb discordant MZ pairs highlight 72 DVMPs associated with TPOAb positivity and a single DMP that was contingent on adjustment for smoking. As expected, a considerable reduction in a number of CpG sites significantly associated with TPOAb-positivity was observed when we corrected for blood cell composition and smoking. In summary, this cutting-edge EWAS of TPOAb in a discordant MZ twin study design using MCC-Seq technology identified a large number of DVMPs driven by biological and environmental factors and suggests methylation variability is a key factor in disease susceptibility in autoimmune thyroid disease.

**Using clustering analysis and meQTLs to probe differential methylation in females with multiple sclerosis.** *B. Reinstadler*<sup>1,2</sup>, *B. Rhead*<sup>2</sup>, *H. Quach*<sup>2</sup>, *D. Quach*<sup>2</sup>, *C. Schaefer*<sup>3</sup>, *L.F. Barcellos*<sup>2</sup>. 1) Department of Applied Mathematics and Theoretical Physics, Cambridge Computational Biology Institute, University of Cambridge, Cambridge, United Kingdom; 2) Genetic Epidemiology and Genomics Laboratory, Division of Epidemiology, School of Public Health, University of California, Berkeley, Berkeley, California; 3) Kaiser Permanente Division of Research, Oakland, CA.

Multiple sclerosis (MS [MIM 126200]) is an immune-mediated demyelinating disease that exhibits substantial heterogeneity in disease type and severity. Several genetic and environmental risk factors are associated with MS, but their mechanisms are not fully understood. DNA methylation is an epigenetic modification that is influenced by genetic variants and environmental exposures and can alter gene expression; thus it may play a role in MS pathogenesis and in determining disease course. We generated genome-wide DNA methylation profiles of whole blood from 250 MS cases using Infinium MethylationEPIC BeadChips. Cases were non-Hispanic black and non-Hispanic white female never-smokers drawn from Kaiser Permanente Northern California. We used unsupervised clustering and supervised classification methods to identify MS case groups characterized by methylation differences. When we assessed cases using the most variable CpG sites, they clustered into groups based on self-reported race. Clinical differences between black and white MS cases have been observed and support a complex disease etiology; black cases are more likely to experience relapses and greater disability, have greater risk of faster progression, later age of symptom onset and are more likely to have optic nerve and spinal cord involvement (Khan, 2015). We aimed to identify methylation differences between the two patient groups that are biologically relevant to underlying MS etiology and are not due to differences in ancestry. We estimated measures of genetic ancestry and cellular heterogeneity using GLINT (Rahmani, 2017). We then evaluated ~33,000 CpG sites known to be affected by methylation quantitative trait loci (meQTLs; Moen, 2013) and tested for differential methylation in the two groups after adjusting for genetic ancestry, cellular heterogeneity, age at sampling, and batch. We prioritized CpGs with meQTLs that are also known MS risk SNPs. Preliminary results showed that cg20485607 was hypomethylated in black MS cases compared to white cases ( $p=0.0003$ ). The CpG lies in a transcription factor binding site 50 kb upstream of the MS risk SNP rs483180, in an intron of *PHGDH*, a protein-coding gene expressed in most brain tissues. This finding suggests that differential methylation may contribute to disease differences in black and white MS cases. Full characterization of disease differences in MS cases will have implications for both more effective treatment through precision medicine and prevention.

**A proteomic approach to identify transcription factors that selectively bind to causal polymorphisms in inflammatory bowel disease (IBD).** *C.J. Cardinale*, *H. Fazelinia*, *L.A. Spruce*, *S.H. Seeholzer*, *H. Hakonarson*. Children's Hospital of Philadelphia, Philadelphia, PA.

Genome-wide association studies have identified thousands of trait-associated SNPs, but the causal variant responsible for the association signal as well as the mechanism by which the SNP modifies gene expression is generally unknown. Recently, in inflammatory bowel disease, high density genotyping on the Immunochip with imputation made it possible to fine-map association signals to single variants. Ten of the single variants are non-coding SNPs located in introns and intergenic regions. We used causal variant rs1887428 in the promoter of *JAK2* as a model system for developing a method to identify the mechanism of action of GWAS SNPs by affinity purification-mass spectrometry (AP-MS). Nuclear extracts were prepared from a relevant cell line, in this instance, Jurkat T cells, and an affinity purification was performed using desthiobiotinylated 35-mer dsDNA probes bearing either allele as baits. After competitive elution with biotin, the proteins were pixelated on an SDS-PAGE gel followed by trypsinization and label-free relative quantification on the Q-Exactive HF mass spectrometer. Spectral counts for peptides were determined in MaxQuant and analyzed in the CRAPome resource using fold-change scores and Significance Analysis of INteractome (SAINTexpress) probabilistic scoring to identify a transcriptional repressor which binds selectively to the protective allele of this SNP. AP-MS is an effective means to identify regulatory factors for causal SNPs and can find mechanisms undetected by other genomic methods.

**Functional characterization of *TNIP1* causal variants associated with Systemic Lupus Erythematosus.** S. Pasula<sup>1</sup>, M. Wiley<sup>1</sup>, A. Nair<sup>1</sup>, Y. Fu<sup>1</sup>, J. Gopalakrishnan<sup>1,2</sup>, Y.Y. Wu<sup>1</sup>, P.M. Gaffney<sup>1,2</sup>. 1) Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, OK, USA; 2) Department of Pathology, University of Oklahoma Health Science Center, Oklahoma City, OK, USA.

**Background:** GWAS have identified more than 80 susceptibility loci associated with systemic lupus erythematosus (SLE) and other autoimmune diseases. Fine mapping of the TNFAIP3 interacting protein 1 (*TNIP1*) locus identified two independent *TNIP1* SLE risk haplotypes that reduced the expression of *TNIP1* mRNA and ABIN1 protein. In this work, we characterized SLE-associated candidate causal SNPs that influence hypomorphic expression of *TNIP1*. **Methods:** We selected eleven SLE-associated *TNIP1* SNPs with low binding scores (RegulomeDB) for EMSAs to evaluate whether SLE risk alleles affect binding of nuclear protein complexes extracted from different immune cells treated with and without PMA/Ionomycin (P/I). Affinity DNA pull-down assays and Western blotting (WB) were performed to identify proteins bound to the rs10036748 probe. Enhancer activity of rs10036748 was measured by luciferase assay. **Results:** Three of the eleven *TNIP1* risk variants exhibited reduced binding of nuclear proteins from Jurkat T cells, EBV transformed B cells and THP-1 monocytoid cells. Five risk variants demonstrated P/I stimulation dependency. Furthermore, three risk variants showed increased binding under resting conditions; one showed increased binding after P/I stimulus. Overall, the SNPs carried on both *TNIP1* SLE risk haplotypes demonstrated complex binding activity; Jurkat T cells exhibited the most activity with 8 of 11 SNPs showing differential binding. The rs10036748 variant demonstrated reduced binding of nuclear proteins to the risk allele in all cell types. Affinity pull-down followed by WB confirmed ENCODE-defined transcription factor binding predictions that the rs10036748 non-risk allele bound early growth response protein 1 (EGR-1), cyclic AMP-responsive element binding protein 1 (CREB-1), and class E basic helix-loop-helix protein 40 (bHLHe40) with relative higher affinity than the risk allele. Interestingly, the risk allele showed increased enhancer activity in HEK293T, Jurkat and EBV transformed B cells. **Conclusion:** Functional analyses of SNPs in *TNIP1* SLE risk haplotypes suggest a complex regulation at *TNIP1* locus. Further, these SNPs exhibit cell type specific, stimulation dependent and allele specific binding of transcriptional protein complexes. Regulatory insights gained will better direct future characterization of individual SLE-associated *TNIP1* variants *in-vivo* to decipher molecular mechanisms and cell states that contribute to SLE pathogenesis.

## 1577T

**Long-range regulation of *IRF5* expression mediated by a functional SNP associated with systemic lupus erythematosus and systemic sclerosis.** H.N. Thynn, X.F. Chen, D.L. Zhu, B.J. Lu, M. Yang, Y. Rong, W.X. Hu, S.S. Dong, T.L. Yang. School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, Shaanxi, China.

Systemic Lupus Erythematosus (SLE) and Systemic Sclerosis (SSc) are autoimmune diseases, which have been shown to share similar genetic backgrounds. Genome-wide association studies (GWASs) have successfully identified numerous genetic variants conferring SLE and SSc disease risk, but the functional mechanisms underlying them are still unknown. In this study, we aimed to decipher the functional mechanisms underlying rs13239597 located in the noncoding region in 7q32.1, which is the most significant SNP ( $p = 1 \times 10^{-29}$ ) associated with both SLE and SSc, through the assimilation of various bioinformatics analyses and functional assays. We found that rs13239597 was located in a putative regulatory element (PRE) with extremely enriched enhancer-related epigenetics markers (H3K27ac, H3K4me3, H3K4me1, Pol II, P300, DNase hypersensitivity) in GM12878 cell line from Roadmap and ENCODE project. The expression quantitative trait locus (eQTL) analysis indicated that different alleles of rs13239597 significantly generated different expression levels of the distal gene *IRF5* (~118kb), which is a key regulator of immune complex formation leading to the risk of SLE and SSc, with the consistent eQTL results in three independent samples including lymphoblastoid cell lines ( $p = 1.84 \times 10^{-27}$ ) from 1000 genome project, whole blood ( $p = 9 \times 10^{-24}$ ) and cell-transformed fibroblasts ( $p = 4.3 \times 10^{-23}$ ) from Genotype-Tissue Expression (GTEx) project and meta-analysis in peripheral blood samples ( $p = 6.97 \times 10^{-27}$ ) from 5,311 individuals. We further revealed that rs13239597 physically interacted with *IRF5* promoter in K562, MCF7, IMR90, CD34 and GM12878 cell lines through Hi-C analysis. Besides, we conducted motif analysis by using multiple databases and found that EVI1, BCL6B, TAL1, FOXD2 and FOXD3 transcription factors specifically bind to rs13239597-A allele. Moreover, we also demonstrated that rs13239597-A allele significantly enhanced *IRF5* gene expression than rs13239597-C allele through the dual-luciferase reporter assay. Therefore, our effort deciphered the functional basis of rs13239597 in noncoding region which affects the risk gene *IRF5* via a long-range chromatin loop formation. Our finding might fulfill the current challenges for complete ascertainment of causal variants towards the understanding in complex genetic architecture of SLE and SSc autoimmune diseases.

**Annotating the regulatory genome of CD4+ T cells: Predicting active in vivo transcription factor binding sites.** *T. Amariuta*<sup>1,2,3,4</sup>, *E. Davenport*<sup>2,3,4</sup>, *H.J. Westra*<sup>2,3,4</sup>, *N. Teslovich*<sup>2,3</sup>, *S. Raychaudhuri*<sup>2,3,4</sup>. 1) Department of Biomedical Informatics, Harvard Medical School, Boston, MA, 02115, USA; 2) Divisions of Genetics and Rheumatology, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, 02115, USA; 3) Partners Center for Personalized Genetic Medicine, Boston, MA, 02115, USA; 4) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA, 02142, USA.

CD4+ T cells regulate the adaptive immune response by mediating inflammation via cytokine signaling. Understanding CD4+ T cell gene regulation may help us better interpret non-coding autoimmune disease risk alleles and the wide range of differentiated CD4+ T cell and memory states. Transcription factor (TF) binding is the hallmark of regulatory elements. However, TF binding cannot be determined by sequence alone. We therefore propose constructing a map of the human CD4+ T cell regulome that defines a per base pair probabilistic score, from 0 to 1, quantifying regulatory binding potential using multiple regulatory markers. We build our regulatory map by training a probabilistic binary classifier on lineage-specific TF binding sites (TFBS) using elastic net logistic regression. To stratify cell-type specific regulation, we utilized data on 9 lineage-associated CD4+ T cell regulators, including TBET (Th1), GATA3 (Th2), STAT3 (Th17), and FOXP3 (Treg). We acquired publicly available ChIP-seq data from isolated CD4+ naïve Treg, Th1, Th2, and Th17 cells of healthy donors, identified TF binding motifs genome-wide and annotated their TF binding state (active/inactive). Finally, we used a total of 65 publicly available datasets of DNase-, ATAC-, FAIRE-, TF and histone modification ChIP-seq, and Capture Hi-C from ENCODE, Roadmap, Blueprint, and NCBI as well as Phastcons conservation. Our classifier predicts TFBS with a mean AUC of 0.73 (95% CI=[0.69, 0.77];  $n=50$  repeated 10-fold cross validation). However, individual TF performance varied: active TFBS in Th1, Th2, and Th17 cells are more accurately predicted (mean AUC=0.86) than those in Tregs (mean AUC=0.59) ( $p<5.8e-4$ ). This may be due to a more specific chromatin landscape in Th1, Th2, and Th17 cells, greater heterogeneity within Tregs, or differences in data quality. We show that our classifier also predicts the presence of active regulatory sites, independent of TF binding. With FANTOM5 data, the classifier predicts that T cell enhancers have significantly more regulatory potential than random genomic sites (mean  $p(\text{bound})$  for enhancers: 0.56, for random: 0.14;  $p<6.4e-207$ ). The classifier more accurately predicts active enhancers (AUC=0.74) than H3K4me1 and H3K4me3 annotations (AUC=0.68). Our classifier may be used to annotate the noncoding CD4+ T cell regulome for active regulatory elements. Our method already out-performs standard annotations and may be applied to any cell-type where TF ChIP-seq is available.

## 1579W

**Annotations that capture tissue-specific transcription factor binding explain a large fraction of disease heritability.** *B. van de Geijn*<sup>1</sup>, *H. Finucane*<sup>1,2,4</sup>, *S. Gazal*<sup>1</sup>, *A. Gusev*<sup>1,3</sup>, *F. Hormozdiani*<sup>1</sup>, *X. Liu*<sup>1</sup>, *P. Loh*<sup>1</sup>, *Y. Reshef*<sup>1</sup>, *A. Price*<sup>1,2,5</sup>. 1) Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA; 2) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; 3) Dana Farber Cancer Institute, Harvard Medical School, Boston, MA; 4) Department of Mathematics, Massachusetts Institute of Technology, Cambridge, MA; 5) Department of Biostatistics, Harvard T.H. Chan School of Public Health, Boston, MA; 6) Department of Computer Science, Harvard University, Cambridge, Massachusetts.

It is widely known that regulatory variation plays a major role in complex diseases and that tissue-specific binding of transcription factors (TF) is critical to gene regulation, but TF binding information is not currently available for most (tissue,TF) pairs. Here, we construct tissue-specific TF binding annotations by intersecting sequence-based TF predictions with tissue-specific chromatin data; this addresses both the limitation that identical sequences may be bound or unbound depending on surrounding chromatin context, and the limitation that sequence-based predictions are not tissue-specific. We evaluated different combinations of sequence-based TF predictions and chromatin data from T cells by partitioning the heritability of 5 autoimmune diseases (celiac, Crohn's, lupus, rheumatoid arthritis, and ulcerative colitis; average  $N = 30,789$ ) using stratified LD score regression (Finucane et al. 2015 Nat Genet) with the baselineLD model (Gazal et al. biorxiv). We determined that 100bp windows around MotifMap sequenced-based TF predictions (Daily et al. BMC Bioinformatics 2011) intersected with a union of promoter and enhancer related chromatin marks (H3K4me1, H3K4me3, H3K27ac, and DHS) performed best, with 0.9% of SNPs explaining 27% of SNP-heritability (29x enrichment;  $P = 7 \times 10^{-12}$ ). This is significant conditional on the baselineLD model, which includes many non-tissue-specific functional and genomic annotations ( $\tau^* = 2.20 \pm 0.38$ ;  $\tau^*$  = proportionate change in per-SNP heritability associated to a 1 s.d. change in the annotation value conditional on other annotations in the model). This represents a large improvement over results obtained using either MotifMap+100bp (2.3x enrichment,  $\tau^* = 0.17 \pm 0.35$ ) or chromatin (9x,  $\tau^* = 0.83 \pm 0.23$ ) alone. We thus focused on MotifMap+100bp intersected with tissue-specific chromatin in our remaining analyses. We applied this approach to 32 diseases and complex traits (average  $N=74,562$ ), using Roadmap chromatin data from 127 tissues. We observed stronger enrichments using our approach vs. chromatin data alone, including 31x enrichment for HDL cholesterol in the liver (vs. 11x for chromatin alone) and 11x enrichment for schizophrenia in fetal brain (vs. 4x for chromatin). Overall, our results show that intersecting sequence-based TF predictions with chromatin information is a promising approach to pinpointing disease-relevant regulatory regions, which will aid interpretation and fine-mapping of GWAS signals.

**1580T**

**Integrative analysis of transcriptional regulation unveils regulatory modules that stratify SLE transcriptome.** *T. Wang<sup>1</sup>, Y.F. Wang<sup>1</sup>, Y. Zhang<sup>1</sup>, J.J. Shen<sup>1</sup>, M. Guo<sup>1</sup>, J. Yang<sup>1</sup>, Y. Lau<sup>1,2</sup>, W. Yang<sup>1</sup>.* 1) Department of Paediatrics and Adolescent Medicine, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong; 2) The University of Hong Kong-Shenzhen Hospital, Shenzhen, China.

Systemic lupus erythematosus (SLE) is a prototype autoimmune disease with a poorly understood pathogenesis, despite recent advances in unraveling the genetic contributions to SLE. Integrative analysis of multi-omics data is demanded to uncover its detailed mechanisms. In this study, making use of transcriptomic data on SLE, we identified 750 differentially expressed genes (DEGs) in T, B and peripheral blood cells. Using transcription factor (TF) ChIP-seq data from ENCODE project, we have analyzed TFs bound to the regulatory regions of the upregulated DEGs in SLE and identified enriched TFs that may play vital roles in SLE pathogenesis. Intriguingly, further clustering analysis of binding patterns of these enriched TFs unveiled multiple co-regulatory modules among the DEGs. The modular regulatory repertoire not only stratifies the IFN signature genes, but reveals a number of SLE-relevant pathways, including inflammation process, cell cycle regulation, NETosis, and immunoproteasome activity. By integrative analyses of the disease-associated genes (DAGs), the DEGs and relevant TFs, we also identified a hierarchical regulatory system with TFs generally regulated by DAGs and in turn modulating gene expression. Overall, the analytical strategy we used in multi-omics data analysis provided an efficient method for interpretation of large-scale datasets and facilitation of the mechanistic understanding of SLE.

**1581F**

**Altered methylation marks and compromised spermatogenesis in human male infertility.** *S.Kumar. Mohanty, Saumya Sarkar, Rajender Singh.* Endocrinology, Central Drug Research Institute, Lucknow, India.

Male Infertility or subfertility is a highly complex and multifactorial disorder that affects 15% of the couples worldwide. Aberrant methylation patterns are frequently associated with germ cell dysfunctions in subfertile and infertile men. We hypothesized that altered epigenetic mechanisms may contribute significantly towards the development of male infertility. To test this, we utilized an epigenome-wide association approach to analyzing DNA methylation levels in subfertile (n=6, Oligozoospermia) and fertile controls (n=6) using Illumina Human 450K Bead array. We identified 1640 significant and differentially methylated CpG sites in infertile individuals. The differentially methylated regions (DMRs) were specifically over-represented in gene regions such as gene body, intergenic and 3'UTR, while under-represented in the promoter region. Gene ontology and pathway analysis revealed different biological processes (reproduction, development, immune system) and pathways pertinent to modulation of male reproductive capacity. The prospective DMRs were validated using independent sequencing approach in a larger cohort of samples. These results strongly suggest that spermatogenesis specific aberrant DNA methylation patterns are involved in the pathogenesis of infertility. In depth investigation of the candidate genes would identify the signaling and developmental pathways that are critical to spermatogenesis. The study clearly suggests that the pathology of male infertility is associated with impairment of various biological pathways and advances our understanding of epigenetic regulation in the etiology of male infertility.

**1582W****Comparison of X chromosome inactivation in peripheral tissues and visceral organs in females with X-linked diseases.**

*M. Reboun<sup>1</sup>, D. Musalkova<sup>1</sup>, M. Hrebicek<sup>1</sup>, J. Sikora<sup>2</sup>, J. Kulhanek<sup>2</sup>, J. Vcelak<sup>3</sup>, G. Storkanova<sup>1</sup>, H. Vlaskova<sup>1</sup>, L. Dvorakova<sup>1</sup>.* 1) Institute of Inherited Metabolic Disorders, Charles University-First Faculty of Medicine and General University Hospital in Prague, Prague, Czech Republic; 2) Department of Pediatrics and Adolescent Medicine, Charles University-First Faculty of Medicine and General University Hospital in Prague, Prague, Czech Republic; 3) Department of Molecular Endocrinology, Institute of Endocrinology, Prague, Czech Republic.

X chromosome inactivation (XCI) is considered to be one of the factors determining the phenotypic severity of X-linked diseases in heterozygous female patients. XCI analysis in peripheral tissues (e.g. circulating white blood cells (WBC), buccal or urine epithelia) is commonly used to infer the XCI ratios in the visceral organs that are affected by the diseases but cannot be sampled for testing. Herein, we present the results of XCI analyses performed by DNA-based methylsensitive and/or transcript analyses in heterozygous female patients with Danon disease (DD, OMIM 300257), ornithine transcarbamylase deficiency (OTCdef, OMIM 311250), and apoptosis-inducing factor deficiency associated with the *AIFM1* gene (OMIM 300169). XCI ratios (46:54, 33:67, 34:66, 42:68, and 27:73) in WBCs of 5 female patients with DD were random. In a single DD patient (XCI 27:73 in WBCs), the total of 28 myocardial samples were available for further testing. Interestingly, the myocardial values ranged from 19:81 to 56:44 (average 42:58, median 42:58). Similarly, a single OTCdef female patient was tested both in peripheral tissues and 37 liver samples. The values of XCI in WBCs, buccal and urine epithelium were 44:56, 60:40 and 55:45 respectively. In the liver tissue the XCI ranged from 46:54 to 87:13 (average 71:29, median 75:25) with the mutated allele being preferentially active. Last, XCI was assessed in one symptomatic and two asymptomatic *AIFM1* female patients. In all three, XCI was extremely skewed in WBCs with the mutant allele almost completely inactivated (93:7) regardless of the patients phenotype. XCI skewing in buccal swabs was less pronounced (85:15). As the *AIFM1* protein contributes to apoptosis regulation, our results imply secondary skewing as a result of clonal disadvantage of the cells expressing the mutant *AIFM1* allele. To summarize – (i) XCI ratios in individual samples from the visceral organs are very variable, which suggests that small-sized biopsic sampling to establish the XCI ratios could be biased, (ii) provided there is no additional clonal selection, peripheral tissues can be used as an approximation of XCI in the visceral organs, (iii) skewed XCI is not required for the manifestation of either DD or OTC deficiency in heterozygote females. Support: GAUK No.580716, MZ CR – RVO VFN 64165, MZ CR – RVO EU 00023761, SVV No.260367, AZV CR - 15-27682A and 15-33297A,.

**1583T****Transcriptome analysis of cystic fibrosis molecular signatures.**

*J.E. Ideozu<sup>1,2</sup>, X. Zhang<sup>1,2</sup>, Z. Ashrafi<sup>1</sup>, M. Kaldunski<sup>3</sup>, A. Pan<sup>3</sup>, M. Kandpal<sup>4</sup>, R.V. Davuluri<sup>4</sup>, P. Simpson<sup>3</sup>, M. Hessner<sup>2</sup>, H. Levy<sup>1,2,4</sup>.* 1) Ann & Robert H. Lurie Children's Hospital of Chicago, IL; 2) Stanley Manne Children's Research Institute, Chicago, IL; 3) Children's Hospital of Wisconsin, Medical College of Wisconsin, Milwaukee, WI; 4) Feinberg School of Medicine at Northwestern University Chicago, IL.

**Introduction:** Cystic fibrosis (CF) is an autosomal recessive disease due to mutations in the cystic fibrosis transmembrane conductance regulator (*CFTR*) gene. Airway inflammation leading to chronic lung disease due to colonization of *Pseudomonas aeruginosa* (*Pa*), is the major cause of morbidity and mortality with median predicted age of survival in CF now 40 (Cystic Fibrosis Foundation). Clinical heterogeneity, even in patients with the same *CFTR* genotype, suggests modifier genes and their regulatory molecules including microRNAs (miRNAs) are involved in underlying pathogenesis. **Objective:** Characterize molecular signatures of CF airway inflammation underlying the lung disease via simultaneous total RNA and miRNA transcriptome sequencing of peripheral blood mononuclear cells (PBMCs). **Methods:** Molecular signatures were captured via whole transcriptome sequencing, and comparison made between CF subjects infected with mucoid *Pa* (n=4) and non-infected (n=5). Simultaneous total RNA and small RNA single-ended sequencing libraries were prepared from one RNA source and sequenced using Illumina Next-Seq and MiSeq sequencer respectively. We performed miRNA target prediction using the Targetscan algorithm in Integrated Pathway Analyses and correlated with the predicted miRNA-mRNA pairs to validate the target pairs. Biological pathway and gene ontology enrichment were performed for top differentially expressed genes with at least 2-fold difference (p<0.05) or more. **Results:** We generated average of ~37.2 million (total RNA-Seq) and ~10.1 million (miRNA-Seq) single-ended reads. Preliminary analyses indicate five hundred and seventy-two genes were differentially expressed by 2-fold or greater between CF subjects infected with mucoid *Pa* compared to non-infected (p<0.05). A total of 76 miRNAs targeting 36 mRNAs in our miRNA-mRNA pairs were inversely expressed and a cluster of miRNAs interacting with inflammatory mediators- CXCL8 and IL10. Ontological analysis of differential expressed genes revealed biological processes altered including regulation of immune response, cytokine activity and response to bacterial origin (p<0.05). Upstream regulator analysis showed downregulation of NFkB proteins and cytokines including CCL5 and IL17A. **Conclusion:** Transcriptional signatures generated suggest miRNAs are key regulatory molecules likely modulating host immune response to *Pa* infection in CF.

**DNA hypermethylation and other epigenetic regulatory signaling pathway genes associated with hidradenitis suppurativa (acne inversa).** D. Jhala<sup>1</sup>, U. Ratnamala<sup>2,3</sup>, N.K. Jain<sup>2</sup>, F.M. Al-Ali<sup>4</sup>, M. Naveed<sup>4</sup>, B.C. Gorijala<sup>5</sup>, U. Radhakrishna<sup>6</sup>. 1) Department of Zoology, School of Sciences, Gujarat University, Ahmedabad, Gujarat, India; 2) Department of Life Sciences, School of Sciences, Gujarat University, Ahmedabad, India; 3) Department of Pharmacology, Creighton University, Omaha, NE, USA; 4) Dermatology Centre, Rashid Hospital, Dubai Health Authority (DHA), Dubai, United Arab Emirates; 5) Oncology Department, Krishna Institute of Medical Sciences, Secunderabad, Andhra Pradesh, India; 6) Department of Obstetrics and Gynecology, Oakland University William Beaumont School of Medicine, Royal Oak, MI, USA.

Hidradenitis Suppurativa (HS), also known as Acne Inversa (AI), is a chronic skin condition characterized by swollen, painful lesions occurring in the armpit (axillae), groin, and breast regions. Mutations in  $\gamma$ -secretase genes have been found to cause HS in some individuals and familial cases. Genetic heterogeneity has long been suspected and a role for other molecular mechanisms such as epigenetic modifications anticipated. To identify DNA methylation biomarkers for the detection of HS, a genome-wide DNA methylation scan using the Infinium HumanMethylation450 BeadChip array (Illumina) was performed in a cohort of 24 HS subjects previously excluded from  $\gamma$ -secretase mutations and 24 controls matched for age, gender, and ethnic origin. We identified significant CpG hypermethylation (at least 2.0-fold) at 304 sites in 304 genes in HS subjects (false discovery rate (FDR)  $\leq 0.00001$ ). No hypomethylation was detected. These 304 CpG sites have a receiver operating curve area under the curve (ROC AUC)  $\geq 0.75$  and for HS detection and were spread throughout the whole-genome. A total of 23 cytosine loci had excellent accuracy (AUC  $\geq 0.90$ ) for the detection of HS. The top 10 hypermethylated genes were *CUL2* (cg15475055), *KIAA1539* (cg10455757), *ZFYVE28* (cg11332822), *SEC24B* (cg05861071), *TMEM191A* (cg08235057), *CHD1L* (cg27261837), *DCPS* (cg20032723), *LRR8B* (cg22081084), *LYST* (cg12875892) and *PHTF1* (cg00419759). Pathway analysis of the differentially-methylated genes in HS revealed the involvement of multiple signaling pathways. CpG methylation sites that reside in promoter regions or within the genes of the Notch pathway are implicated in the development of skin and other cancers, wound healing, immunological processes, cell cycle regulation and apoptosis, and the formation of channel proteins that are required for skin development and growth.

Skin pigmentation varies considerably across human populations and is correlated with latitude and levels of ultraviolet radiation (UVR), suggesting it is an adaptive trait. To gain a more complete understanding of the genetic and biological basis of skin pigmentation variation we conducted a genome-wide association study (GWAS) in ethnically diverse African individuals, revealing novel variants associated with pigmentation in or near the genes *SLC24A5*, *MFS12*, *TMEM138[DDB1]*, *OCA2* and *HERC2*. To make finer resolution predictions we performed fine mapping and predicted causal variants using *CAVIAR*. A number of candidate causal loci are located in non-coding regions. We integrated RNA-seq data from primary human melanocytes with publicly available functional genomic datasets and performed luciferase expression reporter assays to identify potential regulatory variants. At the *MFS12* locus we identify variants overlapping CTCF and a melanocyte-specific enhancer element bound by MITF, a key regulator of the melanocyte lineage. Genetic variation at this locus is significantly correlated with expression of nearby genes and luciferase reporter assays confirm their regulatory potential. At the *DDB1* locus we identify variants intersecting predicted melanocyte enhancer elements. For example, we identify an insertion/deletion polymorphism intersecting a melanocyte-specific enhancer bound by MITF. Genetic variation in this region is significantly correlated with expression of genes important for DNA mismatch repair, vesicle trafficking, and protein sorting in vacuoles (including melanosomes) and luciferase reporter assays confirm their regulatory potential. Finally, at the *OCA2/HERC2* locus, we identify a variant disrupting an antioxidant response element (ARE), elements which, in conjunction with Nrf2, regulate genes important for cellular response to oxidative damage, a pathway known to be disrupted in individuals with vitiligo. This work identifies novel variants related to human pigmentation variation and identifies functionally important variants, genes, and molecular mechanisms for future study.

**Hippocampus and blood APOE locus DNA methylation in Alzheimer's disease.** L. Bekris<sup>1</sup>, M. Krestian<sup>1</sup>, G. DAleo<sup>1</sup>, J. Zahratka<sup>1</sup>, J. Leverenz<sup>2</sup>, Y. Shao<sup>1</sup>. 1) Genomics Medicine Institute, Cleveland Clinic Lerner Research Institute, Cleveland, OH; 2) Lou Ruvo Center for Brain Health, Cleveland Clinic Neurological Institute, Cleveland, OH.

In humans and in mouse models, APOE  $\epsilon 2$  carriers have higher apoE levels, compared to  $\epsilon 3$  and  $\epsilon 4$  ( $\epsilon 2 > \epsilon 3 > \epsilon 4$ ) and are protected against Alzheimer's disease (AD) pathology, such as the toxic A $\beta$  protein. It has been suggested that if apoE2 or apoE3 protein levels are therapeutically increased, without increasing apoE4, this will allow for better clearance and less deposition of the toxic A $\beta$  protein in AD. Many questions still remain on how APOE expression is regulated by distant regulatory elements at this locus and how they might be exploited to modulate apoE levels in AD. For example, our groups and others have proposed that the activity of a APOE exon 4 regulatory element is influenced by epigenetic factors, such as methylation, that either enhance transcription or decrease expression depending on the APOE  $\epsilon 2/\epsilon 3/\epsilon 4$  haplotype and regional promoter. However, it is still unclear if other regulatory elements at this complex extended locus are influenced by epigenetic factors in human tissue. Therefore, the aim of this exploratory investigation is to characterize the DNA methylation status of TOMM40-APOE-APOC2 gene region in both hippocampus and blood in AD compared to cognitively normal controls. The central hypothesis of this exploratory investigation is that the complex regulatory structure surrounding the APOE gene is differentially methylated depending on tissue type and disease status. DNA was extracted from human brain (n=12) and lymphocytes (n=85) and percent methylation was measured using the bisulfite conversion EZ DNA Methylation™ Kit (Zymo Research) and Infinium HumanMethylation450 BeadChip Kit (Illumina). Extended methylation analysis of the APOE locus suggests that methylation at TOMM40 and APOC1, but not the APOE exon 4-3'UTR CpG, are different between AD and controls in hippocampus DNA. Methylation at the TOMM40, APOE exon 4-3'UTR CpG island, APOC1, APOC1P1 and APOC4-APOC2 is different primarily in MCI compared to controls in blood DNA. This exploratory DNA methylation analysis of an extended region of the APOE locus identified regions outside of the APOE gene that may be differentially regulated according to tissue type and disease status. These results suggest that other regulatory regions at this locus, in addition to APOE, are differentially methylated implicating tissue and disease specific regulatory mechanisms that may play an important role in neurodegenerative diseases, such as AD. .

**Transcriptomic analysis of whole blood reveals potential biomarkers in African American Alzheimer disease.** S.K. Sivasankaran<sup>1</sup>, A.J. Griswold<sup>1</sup>, F. Rajabli<sup>1</sup>, B. Kunkle<sup>1</sup>, K. Hamilton<sup>1</sup>, J. Jaworski<sup>1</sup>, W.S. Bush<sup>1,2</sup>, E.R. Martin<sup>1,3</sup>, G.W. Beecham<sup>1,3</sup>, G.S. Byrd<sup>4</sup>, J.L. Haines<sup>2</sup>, M.A. Paricak-Vance<sup>1,3</sup>. 1) John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL; 2) Department of Epidemiology & Biostatistics, Case Western Reserve University, Cleveland, OH; 3) Dr. John T. Macdonald Foundation Department of Human Genetics, University of Miami, Miami, FL; 4) Department of Biology, North Carolina A&T State University, Greensboro, NC.

Alzheimer disease (AD) is the leading cause of dementia in the elderly and occurs in all ethnic and racial groups. African Americans (AA) are substantially underrepresented in efforts to identify genetic variation that enhance or protect against AD, despite having a higher prevalence than non-Hispanic Whites (NHW). To address this important disparity, we are performing RNA-sequencing of peripheral blood samples on 250 AA and 250 NHW (125 cases, 125 controls in each ethnic group) all with genome-wide association study (GWAS) data as an extension to The Alzheimer's Disease Sequencing Project (ADSP). Because the majority of variants identified from WGS will be regulatory in nature, direct measurement of blood gene expression will help translate variant associations to functional outcomes. Here we present the results from the first pilot set of 35 samples (AA: 7 cases and 13 controls, NHW: 7 cases and 8 controls). Total RNA was extracted, enriched by poly-A selection, and globin and ribosomal RNA depleted. Libraries were sequenced for minimum of 40 million paired end 100bp reads on the Illumina HiSeq3000. Alignment to hg19 and gene quantification to GENCODE v.19 were performed with the STAR algorithm. Differential expression of genes was calculated using baySeq. Alignment was robust with 89% overall unique alignment of which 70% of reads map to known protein coding genes. Case-control comparison in the NHW samples did not reveal any significant genes by false discovery rate (FDR) correction. In the AA, there were eight genes FDR significant by baySeq. These genes include an increase in AD cases of MTRNR2L12 (FDR = 0.0002, fold change (FC) = 3.5) which has been identified as a potential biomarker in blood expression studies of Down syndrome patients with dementia. Furthermore, significant increases were noted in a cell adhesion molecule NCAM1 (FDR = 0.0003, FC = 1.9) and synaptic exocytosis regulator SCAMP5 (FDR = 0.0447 FC = 1.5). Notably, these genes have high expression in brain tissue according to the Genotype-Tissue Expression (GTEx) project, suggesting blood may be a useful material to understand a neurodegenerative disease. While this represents preliminary data from an ongoing larger study, identification of disease biomarkers, correlation of expression to DNA sequence changes, and creation of ethnically diverse expression reference sets is a critical component of understanding the etiology of AD.

**1588W****Understanding the endogenous regulation of Ataxin-1 in SCA-1. R.**

*Manek<sup>1,2</sup>, T. Nelson<sup>1,2</sup>, E. Rodríguez-Lebrón<sup>1,2</sup>.* 1) University of Florida, Department of Pharmacology and Therapeutics Gainesville, FL; 2) University of Florida, Center for Translational Research in Neurodegenerative Diseases, Gainesville, FL.

Spinocerebellar ataxia type-1 (SCA-1) is an autosomal dominantly inherited, progressive neurodegenerative disease caused by the abnormal expansion of a 'CAG' tri-nucleotide repeat within the coding region of the *ATXN1* gene. The CAG expansion is translated into a polyglutamine (PolyQ) tract in the N-terminus of the Ataxin-1 protein. Mutant Ataxin-1 expression is necessary for both the onset and progression of this currently untreatable disease. Novel therapeutic strategies such as RNAi that down regulate overall Ataxin-1 protein levels mitigate SCA-1 phenotype in mouse models of the disease. Thus, understanding the endogenous cellular mechanisms that regulate Ataxin-1 expression, and how this regulation may be disrupted in SCA-1, is key to the development of novel, clinically relevant therapeutics. Here we seek to better define the post-transcriptional regulation of *ATXN1* by evaluating the role that the 5'UTR of *ATXN1* plays on the expression of Ataxin-1, in the context of both the WT and the CAG-expanded transcript. In order to determine if the 5'UTR *ATXN1* can independently regulate Ataxin-1, we have designed highly versatile reporter-based assays. In preliminary studies, we find that the 5'UTR *ATXN1* sequence exerts a strong regulation of protein levels ( GFP reporter gene). Analysis of steady-state RNA levels by quantitative PCR appear to indicate decrease in RNA levels. Since cellular post-transcriptional gene regulation is mainly exerted by altering mRNA stability and/or translational efficiency, we have designed studies to investigate the role the 5'UTR of *ATXN1* plays in regulating *ATXN1* mRNA stability and translational efficiency.

**1589T****Haploinsufficiency models of *CHD8* in neuronal cells display alterations in chromatin landscape and regulatory consequences in Wnt signaling.**

*E. Kerschbamer<sup>1</sup>, T. Tripathi<sup>1</sup>, S. Erdin<sup>2,3</sup>, F. Di Leva<sup>1</sup>, J.F. Gusella<sup>2,3</sup>, S. Piazza<sup>1</sup>, M.E. Talkowski<sup>2,3</sup>, M. Biagioli<sup>1</sup>.* 1) Center for Integrative Biology, University of Trento, Trento, Italy; 2) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, United States; 3) Department of Neurology, Harvard Medical School, Boston, MA, United States.

Autism Spectrum Disorders (ASD) is a collection of heterogeneous neurodevelopmental disorders defined by social impairment and repetitive behaviors with significant genotypic and phenotypic complexity. Mutations in several hundred loci have been associated with the disease, but the chromodomain helicase DNA binding protein 8 (*CHD8*) represents a recurrent and independently validated ASD-risk gene. All ASD mutations in *CHD8* gene have been reported to be disruptive, leading to haploinsufficiency. In physiological conditions, *CHD8* binds to the DNA at promoter and enhancers regions where it regulates transcriptional initiation. Here we investigate how chromatin landscape reacts to *CHD8* suppression by analyzing different histone modifications through Chromatin Immunoprecipitation and Sequencing (ChIP-seq) in iPS-derived neural progenitors after *CHD8* knock-down. We interrogated transcriptionally active and repressed regions as well as active and poised enhancers to explore the potential impact of loss-of-function mutations in *CHD8* on regulatory networks and pathways. *CHD8* suppression alters the overall chromatin landscape and ~4000 poised enhancers (enriched for H3K4me1) targeting genes implicated in 'cell cycle' and 'Wnt signaling' pathways. *CHD8* suppression also affected ~5000 actively transcribed gene bodies (enriched for H3K36me3) that were again associated with 'Wnt signaling' and 'RNA pol II transcription activity', as well as 2130 silent promoters (-5Kb/+2Kb of the transcription start site; enriched for H3K27me3) involved in biological processes such as 'axon guidance' and 'synaptic transmission'. The majority of loci that undergo chromatin changes are unique to one specific histone mark, while other genomic regions (enriched for H3K4me2, H3K4me3 and H3K27ac) seem to be less sensitive to *CHD8* suppression. Our results point toward both broad regulatory consequence of *CHD8* suppression as well as association with specific biological pathways of relevance to ASD pathogenesis.

**Correlation of methylomic profiles between blood and cerebral spinal fluid in aneurysmal subarachnoid hemorrhage patients.** A. Arockiaraj<sup>1</sup>, J.R. Shaffer<sup>1</sup>, P.R. Sherwood<sup>2</sup>, E.A. Crago<sup>2</sup>, S.M. Poloyac<sup>3</sup>, D.E. Weeks<sup>3</sup>, Y.P. Conley<sup>4</sup>.

1) Department of Human Genetics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA; 2) Department of Health Promotion and Development, School of Nursing, University of Pittsburgh, PA; 3) Department of Acute and Tertiary Care, School of Nursing, University of Pittsburgh, Pittsburgh, PA; 4) Department of Pharmaceutical Sciences, School of Pharmacy, University of Pittsburgh, Pittsburgh, PA.

Aneurysmal subarachnoid hemorrhage (aSAH) is a form of stroke leading to severe patient outcomes including mortality, cognitive impairment, functional disability, and emotional dysfunction. Methylomic changes in neurological tissue are hypothesized to occur in patients after aSAH, and these changes may influence the development of adverse outcomes. Consequently, the methylomic profiles of brain tissue in aSAH patients are of particular interest, both for understanding the pathophysiology of aSAH, and for identifying predictive biomarkers of adverse outcomes and/or recovery. However, assessment of methylomic profiles in relevant neurological tissue requires prohibitively invasive biopsy. Therefore, we investigated to degree to which methylomic profiles in peripheral blood, a readily available tissue, were correlated with those in cells derived from cerebral spinal fluid (CSF), a feasibly accessible neurological tissue surrogate. Blood and CSF samples were obtained from 68 patients within two days after aSAH. Whole-genome methylation data were collected using the Illumina HumanMethylation450K BeadChip. Batch effects were removed by functional normalization. CpG sites assayed by probes containing SNPs, cross reactive probes, and sex-chromosome probes, as well as CpG sites showing multimodal methylation distributions or identified via data quality diagnostics were removed from analysis. Duplicate samples were used to identify noisy CpG sites showing greater technical variation than experimental variation, separately in blood and CSF. After filtering, we retained 249,821 and 255,280 CpG sites in blood and CSF samples, respectively, with 172,278 CpG sites common to both tissues. For each of these CpG sites we calculated the correlation in methylation M values between blood and CSF. CpG sites showed a range of correlation coefficients (mean=26%, min=-69%, max=95%), with CpG islands and shores showing greater correlation than shelves. Moreover, the correlation differed with respect to the position of the CpG sites within genes, with CpG sites generally nearer the transcription start site and first exon showing stronger positive correlations than CpG sites in the 3' UTR. These results suggest that, while some CpGs are correlated between blood and CSF, globally, blood is not a suitable surrogate for inferring methylomic profiles in neurological tissue post-aSAH. More work is needed to identify the methylomic profiles relevant to aSAH recovery outcomes. R01NR013610.

**Epigenomic signature of adrenoleukodystrophy predicts compromised oligodendrocyte differentiation.** A. Pujol<sup>1</sup>, A. Schluter<sup>1</sup>, M. Ruiz<sup>1</sup>, S. Fourcade<sup>1</sup>, J. Sandoval<sup>2</sup>, A. Diaz-Lagares<sup>2</sup>, M. Esteller<sup>2</sup>. 1) Neurometabolic Diseases, IDIBELL, Barcelona, Barcelona, Spain; 2) Program of Epigenetics and Biology of Cancer, IDIBELL, Barcelona, Spain.

Epigenomic changes occur in cancer, aging and neurodegenerative disorders, and may either cause disease or modulate its expressivity, adding a layer of complexity to mendelian conditions. X-linked adrenoleukodystrophy (X-ALD) is a rare neurometabolic condition exhibiting discordant phenotypes, ranging from a childhood cerebral inflammatory demyelination (cALD) to an adult-onset mild axonopathy in spinal cords (AMN). The AMN form may occur with superimposed inflammatory brain demyelination (cAMN). All patients harbor loss of function mutations in the ABCD1 peroxisomal transporter of very-long chain fatty acids. The factors that account for the lack of genotype-phenotype correlation, even within the same family, remain largely unknown. To gain insight into this matter, here we compared the genome-wide DNA methylation profiles of morphologically intact frontal white matter areas of children affected by cALD with adult cAMN patients, including age-matched male controls. We identified a common methylomic signature between the two phenotypes, comprising i) hypermethylation of genes harboring the H3K27me3 mark at promoter regions, ii) hypermethylation of genes with major roles in oligodendrocyte differentiation such as *MBP*, *CNP*, *MOG* and *PLP1*, and iii) hypomethylation of immune-associated genes such as *IFITM1* and *CD59*. Moreover, we found higher hypermethylation in CpGs of genes involved in oligodendrocyte differentiation such as *MBP*, *CNP*, *SOX10* and *NINJ2*, and also in genes with H3K27me3 marks in their promoter regions such as *HOXA3* and *AGAP2*, in cALD compared with cAMN. We also uncovered differentially methylated and expressed genes related to immune response, such as *UNC45A*, which may be of use in discriminating between these phenotypes. The differences of methylation correlated with transcriptional and translational changes, as supported by Affymetrix expression arrays, quantitative PCR and protein expression. Further, using a penalized logistic regression model, we identified the hypermethylation of *SPG20*, *UNC45A* and *COL9A3* to be good markers capable of discriminating childhood from adult inflammatory phenotypes. We thus propose that an epigenetically controlled, altered transcriptional program drives an impaired oligodendrocyte differentiation and aberrant immune activation in X-ALD patients. These results shed light into disease pathomechanisms and uncover biomarkers for prognosis and phenotypic stratification.

**1592T**

**Epigenetic silencing in Friedreich ataxia is caused by hypermethylation of the *FXN* promoter CpG island shore.** L.N. Rodden<sup>1</sup>, Y.K. Chutake<sup>2</sup>, S.I. Bidichandan<sup>1,2</sup>. 1) Graduate Program in Neuroscience, University of Oklahoma Health Sciences Center, Oklahoma City, OK; 2) Department of Pediatrics, University of Oklahoma Health Sciences Center, Oklahoma City, OK.

Friedreich ataxia (FRDA) is caused by an expanded GAA triplet-repeat (GAA-TR) mutation in intron 1 of the *FXN* gene that results in epigenetic silencing of the *FXN* promoter. DNA methylation of CpG island shores, regions flanking human gene promoters that are embedded in CpG islands, is a known mechanism of epigenetic silencing. Deep sequencing revealed that DNA hypermethylation spreads from the expanded GAA-TR mutation to the *FXN* CpG island shore. The CpG island shore is hypermethylated in FRDA, but it remains unmethylated in the non-disease state, and becomes unmethylated when the expanded GAA-TR is reverted to the normal size in isogenic cell lines, thus functioning as a FRDA-specific differentially methylated region (FRDA-DMR). The hypermethylated FRDA-DMR was detected in various patient-derived cell types, and also in tissues from the humanized mouse model of FRDA that carries an expanded GAA-TR. Analysis of individual DNA molecules revealed a variegated pattern of DNA methylation within the FRDA-DMR, the magnitude and extent of which was dependent on the length of the expanded GAA-TR mutation. Knockdown of DNMT3A in patient-derived cells reduced methylation of the FRDA-DMR, and a CRISPR-deactivated Cas9 strategy to target DNMT3A to the *FXN* CGI shore increased methylation of the FRDA-DMR. Treatment with 5-aza-2'-deoxycytidine enhanced the ability of a class I histone deacetylase inhibitor, known to ameliorate epigenetic promoter silencing in FRDA, to further increase *FXN* transcript levels in patient-derived cells. We conclude that hypermethylation of the *FXN* promoter CpG island shore, which is mediated by DNMT3A, plays a key role in epigenetic silencing in FRDA, and is a novel therapeutic target for reactivation of the epigenetically silenced *FXN* gene.

**The study of Vitamin D effect on *VDR* gene expression in multiple sclerosis patients.** Z. Shirvani-Farsani<sup>1</sup>, M. Behmanesh<sup>2</sup>, M.A. Sahraian<sup>3</sup>. 1) Department of Cellular and Molecular Biology, Faculty of Biological Sciences and Technology, Shahid Beheshti University G.C., Tehran, IR Iran; 2) Department of Basic Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 3) MS Research Center, Neuroscience Institute, Tehran University of Medical Science, Tehran, Iran.

**Background:** Multiple sclerosis (MS) is an autoimmune disease. Inflammatory immune responses in MS patients could be inhibited by vitamin D. Vitamin D effects are occurred via the vitamin D receptor (VDR). VDR is a transcription factor and expresses in different immune cells. It plays an important role in the stating of MS risk and disease activity. **Objective:** The aim of this study was to investigate the expression of VDR gene in MS patients before and after treatment with Vitamin D. **Methods:** Blood samples were obtained from 20 MS patients before and after Vitamin D treatment. RRMS patients received 50,000 IU vitamin D3 per week as intra-muscular injection for 8 weeks. *VDR* mRNA levels were measured by real time polymerase chain reaction and analyzed with paired t-test. Moreover, correlation analysis was performed between the expression level of gene and some clinical features. **Results:** Beside significant increase of serum 25(OH) D levels after supplementation, the expression level of *VDR* gene significantly decreased after 8 weeks Vitamin D treatment. **Conclusion:** We found some new evidences about the molecular mechanism of vitamin D effectiveness in MS treatment.

**1594W**

**Supplemental treatment for Huntington disease (HD) with miR-132 that is deficient in HD brain.** M. Fukuoka<sup>a</sup>, M. Takahashi<sup>b,c</sup>, H. Fujita<sup>a</sup>, T. Chiyo<sup>d</sup>, A. Popiel<sup>e</sup>, S. Watanabe<sup>e</sup>, H. Furuya<sup>e</sup>, M. Murata<sup>e</sup>, K. Wada<sup>a</sup>, T. Okada<sup>a</sup>, Y. Nagai<sup>b</sup>, H. Hohjoh<sup>f</sup>. 1) Department of Molecular Pharmacology, National Institute of Neuroscience, National Center of Neurology and Psychiatry, Tokyo, Japan; 2) Department of RNA medical Science, The Institute of Medical School, The University of Tokyo, Tokyo, Japan; 3) Department of Degenerative Neurological Diseases, National Institute of Neuroscience, NCNP, Tokyo, Japan; 4) Department of Molecular Therapy, National Institute of Neuroscience, NCNP, Tokyo, Japan; 5) National Center Hospital, NCNP, Tokyo, Japan; 6) Oomuta Hospital, Fukuoka, Japan.

Huntington disease (HD) is a dominantly-inherited neurodegenerative disorder characterized by chorea movement, muscular incoordination, cognitive decline and psychiatric problems. The responsible gene for HD is the *Huntingtin (HTT)* gene, and aberrantly expanded CAG repeats (translated into polyglutamine tracts) in exon 1 are closely related to the onset and severity of HD. Currently, there is no definitive treatment of HD; and many efforts have been made for searching for clues that would provide better treatments for HD. MicroRNAs (miRNAs) are 21~23-nucleotide-long small noncoding RNAs and function as mediators in gene silencing by inhibiting translation of messenger RNAs (mRNAs), and by digestion of mRNAs, or by RNA interference (RNAi). MiRNAs might provide us with clues helpful for better treatments of diseases because their disease-associated expression has been detected. A major change in the expression of miRNAs occurs in the brain during the first one month of mouse life, which corresponds to the stage of a rapid brain growth. Abnormal changes in the expression of miRNAs during the stage may cause deleterious effects on the brain formation. In this study, we investigated *miR-132* that markedly decreased in the brain of R6/2 (HD-model) mice and conducted a challenging experiment to see what would happen to HD mice if *miR-132* were supplied into the brain. To reduce the shortage of *miR-132* in the brain, we constructed a viral *miR-132*-expression system with a recombinant adeno-associated virus (rAAV) and introduced the rAAV into the striatum of HD and wild-type mice, at the age of 3weeks when a marked difference in the *miR-132* level started appearing between the mice. The results demonstrated that *miR-132* supplement into the brain of HD mice produced symptomatic improvement of the motor function and lifespan of the mice without altering the expression level of mutant *HTT*. In addition, the post synaptic density 95 kDa (Psd95) protein decreased in the striatum of HD mice recovered to a normal level as in wild-type mice after supplementation of *miR-132*. Our study shed light on a new HD pathophysiological condition involving *miR-132* deficiency, and also on a novel therapeutic approach to HD.

**1595T**

**Decreased expression of *Beclin2* and *LC3* genes in PGRN deficiency: A CRISPR-Cas9 neuronal cell model.** S. Napolitano<sup>1</sup>, H. Kukreja<sup>2</sup>, A. Rendina<sup>1</sup>, A. Riccio<sup>2</sup>, E. Vitale<sup>1</sup>. 1) Institute of Protein Biochemistry (IBP), National Research Council of Italy (CNR), Naples, Italy; 2) Institute of Genetic and Biophysics, (IGB), National Research Council of Italy (CNR), Naples, Italy.

Progranulin (*GRN*) is genetically associated with frontotemporal dementia (FTD), with mutations present in 23% of patients with familial FTD. The neurobiology of progranulin (PGRN) is still unclear, although the proposed disease mechanism is linked to a deficiency of the protein. Furthermore, patients with PGRN deficiency express primarily ubiquitin-positive TAR DNA-binding protein 43 (TDP-43) aggregates in the brain. It is possible that misfolded proteins may aggregate similarly to prions, converting a native protein into a pathologic misfolded replicate able to initiate template-directed protein misfolding. We enrolled 256 FTD patients and 300 healthy age-, sex- and geographic region-matched controls and sequenced all the coding exons of *GRN* and *MAPT* genes in patients with a familial history for dementia. We identified a rare *GRN* gene exon six deletion, g10325\_10331delCTGCTGT (relative to nt 1 in NG\_007886.1), alias Cys157LysfsX97, in three autosomal dominant pedigrees in Southern Italy segregating FTD in three generations. Transcriptional and translational analysis of mRNA from WBC and plasma proteins from FTD patients carrying the mutation exhibited deficiency of the protein. We used mouse embryonic stem cells (E14) with the goal of generating a cell model using CRISPR-Cas9, to test regulatory functions and pathological mechanisms of PGRN in vitro. We designed single guide RNA for the *GRN* gene with high specific, on-target activity and derived pure cellular clones carrying homozygote *GRN* gene mutations causing protein deficiency. We subjected wild-type and knock-out E14 cells to neuronal differentiation, generating an efficient model system to dissect the molecular mechanisms of PGRN in pathways potentially involved in FTD-TDP43 proteinopathy. To test the hypothesis that PGRN deficiency results in an impairment of the autophagic-lysosomal pathway, we performed mRNA gene expression analysis of autophagy-related genes using quantitative RT-PCR. Preliminary results demonstrated a decrease of *Beclin2* and *LC3* genes in PGRN-deficient cells compared to wild-type E14. Our findings support the role of the *GRN* gene in the etiology of FTD and the hypothesis that PGRN insufficiency can be a predisposing factor in neuronal degeneration. We can also speculate that PGRN plays a role in the regulation of the autophagic-lysosomal pathway. Further analyses are in progress to confirm this hypothesis and to identify the connection with the onset of FTD.

**An integrated genetic-epigenetic approach for assessing risk for stroke in the Framingham Heart Study.** R. Philibert<sup>1,2</sup>, M. Dogan<sup>2,3</sup>. 1) Behavioral Diagnostics, Coralville, IA. 52241; 2) University of Iowa, Iowa City, IA 52242; 3) Cardio Diagnostics, Coralville IA 52241.

Stroke is the fifth leading cause of death in the United States with one in every 17 Americans dying as a result of a stroke. Uncommon genetic variants contribute to a small proportion of total risk variance. But the majority of total risk is not well explained through conventional molecular approaches but can be partially attributed to known clinical risk factors such as high blood pressure, smoking and atrial fibrillation. Unfortunately, efforts to combine the genetic and clinical assessments of these risk factors into effective screening tools for the prevention of stroke have not been fully effective. In prior work, we have demonstrated that the methylation effects of smoking, which is a major risk factor for stroke, map to gene networks associated with embolic stroke. When taken together with other evidence, this suggests the possibility that a method that incorporates other epigenetic signatures of risk variables, such as hypertension, together with genetic risk factors, may be able to predict risk for stroke. Using the Random Forest analytic approach and integrated genome wide methylation and genetic variation data sets from Framingham Heart Study subjects, we herein test whether machine learning algorithms that use a combination of SNP, methylationxSNP interaction (MethxSNP) and methylation effects can predict stroke. As a first step, using the training set of 1562 individuals (38 with stroke), genome wide methylation and SNP data was regressed against stroke status to identify the CpG residues and SNPs most associated with stroke. Then, using stratified sampling to account for class imbalance, the Gini index was used to identify important loci. 10 CpG sites and 5 SNPs were retained for prediction. The trained model had an area under the curve (AUC) of 0.89, and an accuracy of 85%. However, in a very limited test set of 18 cases and 18 controls, the model performed only modestly with an AUC of 0.60 and accuracy of 56%. In light of prior results, these results suggest the possibility that Precision Medicine tools utilizing machine learning algorithms and both genetic and epigenetic data may be able to accurately predict the occurrence of stroke. However, in order to effectively construct those tools, larger data sets from longitudinally informative cohorts for stroke will be necessary.

**Isogenic iPSC-derived neurons for modeling the differential regulation of SNCA expression: Implication to the heterogeneity of synucleinopathies.** O. Chiba-Falek<sup>1,2</sup>, L. Tagliaferro<sup>1,2</sup>, M.E. Zamora<sup>1,2</sup>, O. Glenn<sup>1,2</sup>, H. Bergstrom<sup>1,2</sup>, D. Lukatsky<sup>3</sup>, R. Gordan<sup>3</sup>. 1) Neurology, Duke University, Durham, NC 27710, USA; 2) Center for Genomic and Computational Biology, Duke University, Durham, NC 27710, USA; 3) cDepartment of chemistry, Ben-Gurion University of the Negev, Beer Sheva, Israel.

Synucleinopathies share a common pathological hallmark of intracellular a-syn inclusion bodies, however each disease presents distinct pathological and clinical characteristics. While *SNCA* expression levels are crucial to the development of synucleinopathies, the molecular mechanisms regulating *SNCA* expression and their contribution to the phenotypic heterogeneity of synucleinopathies are largely unknown. To study the differential regulation of *SNCA* expression in the context of Parkinson's Disease (PD) compared to Dementia with Lewy Bodies (DLB), we have developed *isogenic* induced Pluripotent Stem Cells (iPSCs)-derived dopaminergic and cholinergic neurons to model PD and DLB, respectively. We established two *isogenic* systems using iPSC-lines derived from a healthy subject and a patient with *SNCA*-triplication. *SNCA*-mRNA and protein expression in the *SNCA*-triplication derived neurons exhibited two-fold increase compared to the healthy neurons, recapitulating the observations in human tissues. The *SNCA*-triplication neurons exhibited increased susceptibility to disease related phenotypes and progressive aging compared to the healthy lines, indicating the system's suitability for studying the downstream effects of *SNCA* upregulation. The *isogenic* dopaminergic vs. cholinergic neurons revealed differential vulnerability to cellular phenotypes of disease related pathways and aging. Next, we assessed *cis* and *trans* factors involved in *SNCA* regulation. Expression profiles of conserved miRNAs targeting the *SNCA*-3'UTR (TargetScan) were different in cholinergic compared to dopaminergic neurons. We then sequenced the *SNCA*-3'UTR from PD and DLB cases. While we did not detect variants that overlap with the conserved miRNAs binding sites, common variants, most significantly associated with PD (but not with DLB), were identified within the binding sites of 3 poorly conserved miRNA families. Interestingly, one of these miRNAs was expressed significantly higher (~70%) in dopaminergic neurons compared to cholinergic. Similarly, transcription factors (TF) that bind to *SNCA* locus (ChIP-seq, ENCODE) were differentially expressed in dopaminergic compared to cholinergic neurons. We evaluated the effect of proximate repeat variants on the TFs binding affinity and found considerable variation among different allele lengths. These findings suggested that neuronal-type specific mechanisms regulating *SNCA* expression contribute, at least in part, to the heterogeneity of synucleinopathies.

**Interpreting regulatory effects of disease-associated variants: A lesson from SNCA rs356168.** O. Glenn<sup>1,2</sup>, L. Tagliafierro<sup>1,2</sup>, O. Chiba-Falek<sup>1,2</sup>. 1) Neurology, Duke University Medical Center, Durham, NC; 2) Center for Genomic and Computational Biology, Duke University Medical Center, Durham, NC.

In the post genome wide association (GWA) era the fundamental question is, which are the actual causal variants within disease-associated genomic regions and what are their mechanisms of action. The *SNCA* locus has been implicated in the genetic etiology of Parkinson's disease (PD), and the *SNCA* intronic single nucleotide polymorphism (SNP), rs356168, is among the top ranked PD-associated SNPs in large genome wide association studies (GWAS). Recently, the PD-risk allele, rs356168-G was shown to increase *SNCA*-mRNA expression using genome edited human induced pluripotent stem cells (iPSC)-derived neurons. In this study, as means of validation, we tested the effect of rs356168 on total *SNCA*-mRNA levels using brain tissues, temporal and frontal cortex, from healthy control donors. Carriers of the rs356168-G allele demonstrated significantly decreased *SNCA*-mRNA levels in temporal brain tissues ( $p=0.02$ ) compared to individuals homozygous for the 'A' allele. Similar trend was observed in the analysis of frontal cortex samples, however, this analysis did not reach statistical significance. Furthermore, eQTL analysis using the available GTEx datasets suggested a similar trend (AA>GG) for several human brain regions. These results conflict with effect of *SNCA* SNP rs356168 reported previous by Soldner *et al.* Our study conveys the need to carefully interpret the precise molecular mechanism by which rs356168, or another tightly linked variant, affects the regulation of *SNCA* expression. We postulate that non-transcriptional mechanisms, such as splicing, selection of polyadenylation site, and/or message stability, may also contribute to the observed associations between PD and the *SNCA*-3' linkage disequilibrium (LD) region. .

**Translation regulation in Alzheimer's disease.** A. Shieh, C. Liu. Psychiatry, University of Illinois - Chicago, Chicago, IL.

Alzheimer's Disease (AD) is the most common cause of dementia with molecular hallmarks of abnormal proteins in the brain. Studies in human and model organisms have observed that abnormalities in protein translation frequently accompany neurodegenerative phenotypes, highlighting the importance of studying translation regulation in the brain. In this study, we used Ribosome Profiling to measure translation in postmortem brains of 16 age-matched individuals (8 AD cases and 8 controls). We found 250 differentially translated genes at 10% FDR. These genes are enriched for pathways in concordance with neuroinflammation and neuronal and metabolic dysfunctions in the pathogenesis of AD. Ribosome Profiling measures the footprints of translating ribosomes. The resulting sequencing reads exhibit a signature 3-nucleotide codon periodicity that captures the mechanism of translation, and demarks coding regions. Using this signature, we identified more than 30,000 Open Reading Frames (ORFs) that show strong evidence of translation. Among these, we recovered ORFs from 25,971 transcripts, which covers more than 80% of the annotated CCDS genes. In addition, we found 1,971 ORFs originating from transcripts that are either antisense or classified as non-protein coding RNAs (lincRNA and pseudogenes). Finally, We found evidence of active translation at the UTR of nearly 2,000 genes. Translation at the 5' UTR (upstream ORF) has been shown to regulate the expression of their associated genes (main ORF). When compared to the 5'UTR ORFs found in HEK cells, we found only 20% overlap. Importantly, while the genes with translated 5'UTR in our samples are enriched for pathways important for the brain (ion transport and neurotransmitter signaling), those found in HEK cells are involved in cell cycle and growth, as expected for a transformed embryonic cell-type. Our results demonstrate that 5'UTR ORFs and their potential regulatory roles are tissue specific. In addition to potential regulatory functions, many of the newly discovered ORFs are small and predicted to encode short peptides. These peptides are likely secreted into the bloodstream and could be potential biomarkers for AD. Further analysis of the data produced in this study would provide important understanding of brain biology and the etiology of AD.

**5-hydroxymethylcytosine alterations in the human postmortem brains of autism spectrum disorder.** Y. Cheng<sup>1</sup>, Z. Li<sup>2</sup>, L. Lin<sup>1</sup>, S. Manupatpong<sup>1</sup>, T. Xu<sup>2</sup>, H. Wu<sup>2</sup>, Y. Jiang<sup>2</sup>, P. Jin<sup>1</sup>. 1) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA 30322, USA; 2) Department of Biostatistics and Bioinformatics, Rollins School of Public Health, Emory University, Atlanta, GA 30322, USA; 3) Department of Pediatrics, Duke University School of Medicine, Durham, NC 27710, USA.

Autism spectrum disorders (ASDs) comprise a group of disorders characterized by impaired language, social, and communication skills, in addition to restrictive behaviors or stereotypes. Symptoms begin to manifest in early development and persist throughout the affected individual's life. However, with a prevalence of 1.5% in developed countries and relatively high comorbidity rates, no clear underlying mechanism that unifies the heterogeneous phenotypes of ASD is known. Cytosine methylation has been shown to serve as a critical epigenetic mark in gene regulation and 5-methylcytosine (5mC) was viewed as a stable and long-lasting covalent modification to DNA. However, it has been shown that 5mC could be enzymatically modified to 5-hydroxymethylcytosine (5hmC) by Tet family proteins through Fe(II)  $\alpha$ -ketoglutarate-dependent hydroxylation, resulting in a new perspective on the previously observed plasticity in 5mC-dependent regulatory processes. 5hmC has been reported highly enriched in the central nervous system, and is now recognized as an important epigenetic mark in developmental and neurological disorders. To explore the role of 5hmC in ASD, we utilized the genomic DNA isolated from the postmortem cerebellum of both ASD patients and age-matched controls to profile genome-wide distribution of 5hmC. Compared to adult samples, we identified many more differential hydroxymethylated regions (DhMRs) (232 vs 58;  $q$ -value < 0.05, FDR adjusted) in young group (age < 18). No significant DhMR was identified in the group over 18-year-old, suggesting the dynamic change of 5hmC could play important roles in neurodevelopment and ASD pathogenesis. Pathway and disease association analyses indicated that the DhMRs identified in young group were located in the genes that involved in axon guidance ( $q$ -value = 0.0030) and Williams Syndrome ( $q$ -value = 0.0279). These results together suggest that 5hmC dynamic alteration is associated with ASD, particularly in the early development stage, and could contribute to the pathogenesis of ASD.

**Genome-wide analyses of DNA methylation in autism brains suggest epigenetic-mediated dysfunction in GABA signaling.** J.I. Young<sup>1</sup>, A. Siladi<sup>1</sup>, C. Brandenburg<sup>2</sup>, J.M. Vance<sup>1</sup>, M.A. Pericak-Vance<sup>1</sup>, G.J. Blatt<sup>2</sup>. 1) Hussman Inst Human Genomics, Univ Miami, Miami, FL; 2) Hussman Institute for Autism, Baltimore MD, USA.

Autism is characterized by social deficits, impaired communication and repetitive behaviors. Ample evidence supports involvement of the striatum and cerebellum in autism pathophysiology. Emerging evidence implicates altered DNA methylation as a likely factor contributing to autism etiology. To gain understanding on the role of DNA methylation and transcriptional regulation in autism, we profiled the methylome and transcriptome of striatal and cerebellar tissue from autistic and control individuals. DNA methylation patterns were interrogated by use of the EPIC array. This analysis identified isolated CpGs with significant methylation differences between postmortem autism cases compared to age- and post mortem interval matched controls. Further, we identified significant differentially methylated regions (DMRs) in both tissues in genes previously implicated in autism through genetic studies. Pathway analysis of genes with DMRs in the striatum shows significant enrichment in the pathway "GABAergic synapse", whereas the pathway "endocytosis" is enriched in the cerebellum. Both pathways have been postulated to contribute to autism pathophysiology. RNA-seq based analysis identified differentially expressed genes (DEG) in both brain regions, including several that have been implicated in autism. Pathway analysis found that striatal DEG genes were enriched for the pathway "Neuroactive ligand-receptor interaction" and the category "GABA-A receptor activity". Thus, analysis of the methylome and transcriptome suggested that autism is associated with transcriptional de-regulation of GABAergic neurotransmission in the striatum leading to altered inhibitory signaling to cortical and cerebellar areas likely affecting autism-related behaviors. Comparison of the genes containing DMRs and DEG in the striatum suggests direct epigenetic regulation of transcription through DNA methylation in autism. In addition, transcription factor binding site enrichment analysis revealed enrichment of PAX6 binding to striatal DEG genes. Our data showing that PAX6 contains a DMR in the striatum in autism individuals suggest epigenetic indirect transcriptional regulation mediated by PAX6. Thus, in spite of genetic and phenotypic heterogeneity in autism, shared molecular alterations could be uncovered by smaller sample sets than those required for genetic studies. We identified tissue-specific epigenomic alterations in autism brains, including alterations in known autism-associated genes. .

**A massively parallel reporter assay for variants associated with schizophrenia and Alzheimer's disease.** D. Avramopoulos, L. Myint, R. Wang, L. Boukas, K. Hansen, L. Goff. Johns Hopkins University, Baltimore, MD.

Genome wide association studies (GWAS) have reported on numerous loci for complex disorders including schizophrenia (SZ) and Alzheimer's disease (AD), most located outside protein coding regions. We hypothesize that some of these loci act through differential enhancer activity and we test this hypothesis by systematically assaying each locus using a Massively Parallel Reporter Assay (MPRA). Specifically, we investigate all variants in high LD with 71 SZ and 8 AD loci, for a total of 1083 variants. For each variant we designed a 95 bp sequence centered on the variant and linked it to 5 distinct barcodes, including positive and negative controls. We generated a plasmid library using standard protocols, with final oligo representation of 80% (85% of alleles represented by  $\geq 3$  oligos) and transfected it 3 independent times into K562 and SHSY5Y cells. Following transfection we extracted RNA and DNA and assayed the transfection efficiency and technical reproducibility. Specifically we found that on average, 80% of barcodes were represented in DNA and 72% in RNA. After summing counts over barcodes, we compute the correlation of counts and activity measures (log ratio of RNA over DNA) across replicates and find high mean correlations: 0.94 - 0.99 for both DNA and RNA. Significant overlaps with open chromatin marks validate our results. We find 116 SNPs with significant differences in driving expression between the two alleles including 5 observed in both cell lines. More specific results of our assay for SZ and AD will be presented.

**Gene body methylation of tyrosine hydroxylase (TH) in the striatum is associated with cocaine dependence in humans.** K. Vaillancourt<sup>1,2</sup>, C. Ernst<sup>1,3</sup>, G. Chen<sup>1</sup>, A. Bramoullé<sup>1</sup>, J-F. Thérault<sup>1</sup>, L. Fiori<sup>1</sup>, G. Maussion<sup>1</sup>, E. Calipari<sup>4</sup>, B. Labonté<sup>4</sup>, E. Nestler<sup>5</sup>, D.C. Mash<sup>5</sup>, G. Turecki<sup>1,2,3</sup>. 1) McGill Group for Suicide Studies, Douglas Hospital Research Center, Verdun, Quebec, Canada; 2) Integrated Program in Neuroscience, McGill University, Montreal, QC, Canada; 3) Department of Psychiatry, McGill University, Montreal, QC, Canada; 4) Icahn School of Medicine, Mount Sinai Hospital, New York, NY, USA; 5) Department of Neurology, University of Miami Miller School of Medicine, Miami, FL, USA.

**Background:** Cocaine dependence is a chronic relapsing disorder with widespread biological consequences, including epigenetic alterations, in numerous brain areas. In particular, the striatum is a highly addiction-relevant structure that has been investigated in animal models of cocaine seeking behaviors and epigenetics. Of particular interest is DNA methylation as it may mediate the long-term effects of chronic cocaine abuse on brain cell functioning. While research has begun to identify diverse sites of hyper- and hypo-methylation in rodents, little is known about the relationship between cocaine dependence and DNA methylation in the context of the human disorder. **Methods:** We used Reduced Representation Bisulfite Sequencing (RRBS) to identify clusters of differentially methylated CpGs (DMRs), in post mortem tissue from 25 individuals with cocaine dependence and 25 drug-naïve controls. We focused on two striatal sub-regions, the nucleus accumbens (NAc) and caudate nucleus (CD), and validated a DMR within the tyrosine hydroxylase (TH) gene using targeted amplicon bisulfite sequencing. This method was also used on an independent cohort of human samples (n=18 per group) and on neuronal and non-neuronal nuclei separated by fluorescence activated cell sorting (FACS). In addition, we used cocaine self-administering mice, transcriptome sequencing, and *in vitro* experiments to investigate the relationship between methylation, expression and behavior at this locus. **Results:** We found numerous DMRs in both brain regions, including within exon 8/9 of TH that are more methylated in the cocaine group. Methylation negatively correlates with TH expression in the CD of the cocaine group only. We replicated this effect in the striatum of an independent cohort (N=18 per group), and of chronically self-administering mice (N=8-10 per group). This hypermethylation appears to be neuron-specific and impedes enhancer activity at this locus. **Conclusions:** Hypermethylation of TH is associated with chronic drug seeking behavior and may have regulatory potential. Our ongoing research uses epigenome editing techniques to understand the mechanisms through which methylation regulates TH transcription. Ultimately, work on this system will uncover the importance of epigenetic dysregulation of TH to the time course and trajectory of chronic cocaine dependence. Funded by NIDA (DA033684).

**1604T****DNA methylation profiles in a cohort of Brazilian children with ADHD.**

Attention deficit hyperactivity disorder (ADHD) is a heterogeneous behavioral syndrome characterized by inadequate levels of hyperactivity/impulsivity and/or inattention. ADHD begins in childhood and affects around 5% of school children worldwide and, in most cases (50-80%), the disorder persists during adolescence and adulthood. High heritability (estimated at 76%) suggests that genetic factors strongly influence the etiology of ADHD. However, the genetic architecture of ADHD is not clear. In addition, some environmental factors are epidemiologically associated with ADHD. Therefore, it is possible that the actions of the environmental factors associated with ADHD are mediated by epigenetic mechanisms. In this sense, we studied the DNA methylation profiles in a cohort of Brazilian children with ADHD. Diagnosis was performed according to Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR). DNA was extracted from blood lymphocytes of ADHD children (n=29) and children with neurotypical development (n=11). After, DNA methylation profiles of all children were performed using Infinium HumanMethylation450 BeadChip (Illumina). Arrays data were treated and analyzed using specific packages in the R environment. The probes were annotated according to the data provided by Illumina using the genome hg19 reference. Considering  $p \leq 0.05$ , we obtained 121 differentially methylated probes between the children groups (with and without ADHD). Also, when we compared the samples by gender, we obtained two lists of differentially methylated probes: a list with 50 hypomethylated probes and a list with 50 hypermethylated probes. The classification of the probes, in both lists, was performed according to the  $p$ -values. Our results highlight the importance to perform epigenetic studies in ADHD, provide novel insights to genetic architecture in this disorder and also allows to envision how these can be transformed into future effective treatments. Grants: FAPESP: 2015/05350-5, 2014/02565-8 and FINEP-CT INFRA 0160/12 SP8.

**A reference map for open chromatin-associated histone methylation and acetylation landscapes in the human frontal lobe.** *K.G. Girdhar<sup>1</sup>, G.H. Hoffman<sup>1</sup>, YG. Jiang<sup>1</sup>, MK. Kundakovic<sup>1</sup>, LB. Brown<sup>1</sup>, LZ. Zharovsky<sup>1</sup>, RJ. Jacobov<sup>1</sup>, JW. Wiseman<sup>1</sup>, RP. Park<sup>1</sup>, SKS. Sieberts<sup>3</sup>, MP. Peters<sup>3</sup>, BH. Harris<sup>1</sup>, BL. Lipska<sup>4</sup>, PS. Sklar<sup>1</sup>, PR. Roussos<sup>1,2</sup>, SA. Akbarian<sup>1,2</sup>.* 1) Division of Psychiatric Genomic, Icahn School of Medicine at Mount Sinai, NYC, NY; 2) Department of Psychiatry and Friedman Brain Institute, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Systems Biology, Sage Bionetworks, Seattle, WA; 4) NIMH Neuroscience Center at St. Elizabeth's Hospital, Washington DC, Maryland.

We present for the dorsolateral prefrontal and anterior cingulate cortex, two frontal lobe areas broadly implicated in cognition and neuropsychiatric disease, cell-, subject- and region-specific reference maps for two histone marks associated with transcription and open chromatin, H3-trimethyl-lysine 4 (H3K4me3) and H3-acetyl-lysine 27 (H3K27ac). Exploration of this to date largest histone ChIP-seq resource for the human brain, with 128 datasets collected from 17 individuals, revealed cell type and subject as the two key variables shaping histone modification landscapes in the human frontal lobe, but only minimal contributions by region- and sex-specific factors. We highlight regulatory mechanisms unique to neurons, including much higher (20% vs. 15%) genome-wide coverage for H3K27ac and broader histone methylation and acetylation peaks at proximal promoters and transcription start sites, and strong overlap with the genetic risk architectures of schizophrenia, depression and neuroticism. These findings highlight the utility of this PsychENCODE NIMH-sponsored resource to explore epigenomic architectures of regulatory and disease-associated non-coding DNA in the human brain.

**Convergence analysis on risks for schizophrenia by integrating genomics, DNA methylation and gene expression.** D. Lin<sup>1</sup>, J. Chen<sup>1</sup>, J. Bustillo<sup>2,4</sup>, N. Perrone-Bizzozero<sup>2,4</sup>, J. Sui<sup>1</sup>, Y. Du<sup>1</sup>, V. Calhoun<sup>1,2,3</sup>, J. Liu<sup>1,3</sup>. 1) The Mind Research Network, Albuquerque, NM; 2) Dept. of Neurosciences, University of New Mexico, Albuquerque, NM; 3) Dept. of Electronic and Computer Engineering, University of New Mexico, Albuquerque, NM; 4) Dept. of Psychiatry, University of New Mexico, Albuquerque, NM.

Schizophrenia (SZ) is a complex mental disorder with estimated heritability of ~80% and lifetime prevalence of 1%. Substantial success has been made to explore genetic risk loci of SZ by international consortium. Yet the precise causal relations and exact mechanisms remain to be elucidated. By integrating cellular level variation such as DNA methylation and gene expression with sequence risks we are able to tap into pathologic mechanism of identified risk loci, and thus shed light on the true causal relation. DNA methylation and gene expression are known to be tissue specific. To increase the confidence on risk SNPs effect, and test the surrogate ability of peripheral tissues for the hardly accessible brain tissues, we focused on tissue independent genetic effect on DNA methylation and gene expression across brain, blood and/or saliva. First we investigated genomic methylation quantitative trait loci (meQTLs), and characterized consistent cis-acting effects (<20k base pairs) cross brain, blood and saliva. Then we identified cross-tissue cis-acting (within 1M bp) expression QTLs (eQTL) from brain and blood GTEx project. Enrichment test was applied to cis-meQTLs on cis-eQTLs with consideration of minor allele frequency and Linkage disequilibrium. Finally, we matched QTLs regulating both methylation and expression with the reported SZ risk loci to identify potential pathways from risk SNPs to SZ through epigenetics and gene expression. We identified tissue independent 116,005 meQTLs, 10879 target CpGs, and 39,653 eQTLs. 7372 SNPs were both eQTLs(18.59%) and meQTLs(6.35%), showing significant enrichment of meQTLs in eQTLs (odds ratio = 16.21, P<sub>permutation</sub> < 1e-5, P<sub>Fisher exact</sub> < 1e-200) compared to non-meQTLs. Interestingly, the overlapped eQTLs and meQTLs, mainly located on chromosome 6p21.1 – 6p24.3 regions, showed significant SZ risk with p-value < 1e-5. In particular, SNPs in genes BTN3A2, ITIH4 and HLA-DQA strongly regulate both methylation of their promoter and gene expression, suggesting potential functional pathways.

**The role of DNA methylation and the 5-HTTLPR long/short variant of the serotonin transporter gene (SLC6A4) in antidepressant treatment response.** A.J. Lisoway<sup>1,2</sup>, C.C. Zai<sup>1,3,4</sup>, A.K. Tiwari<sup>1,3</sup>, R. Harripaul<sup>1,2</sup>, N. Freeman<sup>1</sup>, L. French<sup>2,3,5</sup>, Z.A. Kaminsky<sup>6</sup>, J.L. Kennedy<sup>1,2,3</sup>. 1) Neurogenetics Section, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON; 2) Institute of Medical Science, University of Toronto; 3) Department of Psychiatry, University of Toronto; 4) Department of Laboratory Medicine and Pathobiology, University of Toronto; 5) Computational Neurobiology Lab, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON; 6) Department of Psychiatry and Behavioral Sciences, Johns Hopkins University, Baltimore, MD.

**Background:** The current process used to prescribe antidepressant medication is markedly inefficient, as more than 50% of treated patients fail to reach remission. Antidepressant treatment success has been associated with genetic variation, but studies are not well replicated and epigenetic mechanisms remain under investigated. DNA methylation may provide more information regarding antidepressant response and guide physicians in choosing the most effective medication for each patient. We investigated the influence of *SLC6A4* methylation and 5-HTTLPR genotypes on antidepressant response in our sample. **Methods:** A subset of depression patients with complete clinical data (European Caucasian, n=166), were selected from our discovery sample (IMPACT; N=8,000). Saliva samples were collected at enrollment and genetic testing was done of cytochrome P450 liver enzyme, 5-HTTLPR and *5HT2A* variants to guide clinical choice and dosage of psychotropic medications. DNA was bisulfite converted and methylation profiles were interrogated using the Infinium HumanMethylation450 Beadchip array. Nine CpG probes located across the *SLC6A4* promoter region were selected, based on previous studies, to quantify methylation levels. Change in Beck Depression Inventory II (BDI-II) score was used to measure antidepressant response over eight weeks. The relationship among genotype, methylation levels, and antidepressant response was analysed using linear regression modeling. **Results:** Increased methylation in the promoter region of the *SLC6A4* gene was nominally associated with impaired response to antidepressants in our sample. The effect was driven by methylation site cg05016953, located in exon 1A. Increased methylation level as measured by CpG cg05016953 was associated with less improvement in BDI-II score over eight weeks of antidepressant treatment (F(3,163)=6.14, p<sub>uncorr</sub>=0.012). 5-HTTLPR genotype was not associated with *SLC6A4* DNA methylation or antidepressant treatment response. **Conclusions:** *SLC6A4* DNA methylation at cg05016953 may be associated impaired response to antidepressant medications in our sample. The *SLC6A4* transcriptional control region contains a CpG island, previously shown to functionally influence mRNA levels depending on 5-HTTLPR genotypes. Typically, hypermethylation in promoter regions is associated with decreased gene expression. Further pharmaco-epigenetic studies are required to elucidate the effect of DNA methylation changes on antidepressant response.

**Dynamic DNA N6-methyladenine modification in mammalian brain and implications in neuropsychiatric disorders.** B. Yao<sup>1</sup>, Y. Cheng<sup>1</sup>, Z. Wang<sup>1,2</sup>, Y. Li<sup>1</sup>, L. Chen<sup>1</sup>, L. Huang<sup>1</sup>, W. Zhang<sup>3</sup>, D. Chen<sup>3</sup>, H. Wu<sup>4</sup>, B. Tang<sup>2</sup>, P. Jin<sup>1</sup>. 1) Department of Human Genetics, Emory University, Atlanta, GA, USA; 2) Department of Neurology, Xiangya Hospital, Central South University, Changsha, Hunan, P.R. China; 3) Institute of Zoology, Chinese Academy of Sciences, Beijing, P.R. China; 4) Department of Biostatistics and Bioinformatics, Emory University School of Public Health, Atlanta, GA, USA.

Chemical modifications on DNA molecules, such as 5-methylcytosine and 5-hydroxymethylcytosine, play important roles in mammalian brain. A novel DNA adenine modification, N6-methyladenine (N6mA), has been recently found present in mammalian cells. However, the presence and function(s) of N6mA in mammalian brain remain unclear. Here we demonstrate the dynamics of N6mA in mouse brain in response to environmental stress. We found that overall N6mA level was significantly elevated upon stress. Genome-wide N6mA and transcriptome profiling revealed an inverse association of N6mA dynamic changes with a set of upregulated neuronal genes or downregulated LINE transposon expression. Genes bearing stress-induced N6mA changes significantly overlap with loci associated with neuropsychiatric disorders. These results together suggest the epigenetic role of N6mA in mammalian brain as well as its potential involvement in neuropsychiatric disorders.

**A multi-dimensional characterization of anxiety in monozygotic twin pairs reveals susceptibility loci in humans.** R.S. Alisch<sup>1</sup>, C. Van Hulle<sup>2</sup>, P. Chopra<sup>3</sup>, R.J. Davidson<sup>2,4</sup>, N.H. Kalin<sup>1</sup>, H.H. Goldsmith<sup>2,4</sup>. 1) Department of Psychiatry, University of Wisconsin, Madison, Madison, WI; 2) Waisman Center, University of Wisconsin, Madison, WI; 3) Department of Human Genetics, Emory University, Atlanta, GA; 4) Department of Psychology, University of Wisconsin, Madison, WI.

The etiology of individual differences in human anxiousness is complex and includes contributions from genetic, epigenetic (i.e., DNA methylation) and environmental factors. Past genomic approaches have been limited in their ability to detect human anxiety-related differences in these factors. To overcome these limitations, we employed both a multi-dimensional characterization method to select monozygotic twin pairs discordant for anxiety, and whole genome DNA methylation sequencing. This approach revealed 230 anxiety-related differentially methylated loci that were annotated to 183 genes, including several known stress-related genes such as *NAV1*, *IGF2*, *GNAS*, and *CRTC1*. As an initial validation of these findings, we tested the significance of an overlap of these data with anxiety-related differentially methylated loci that we previously reported from a key neural circuit of anxiety (i.e., the central nucleus of the amygdala) in young monkeys and found a significant overlap ( $P$ -value  $< 0.05$ ) of anxiety-related differentially methylated genes, including *GNAS*, *SYN3*, and *JAG2*. Annotation of the 183 anxiety-associated human loci to gene ontologies found several biologically relevant ontological terms that were among the differentially methylated genes, including regulation of dendrite development and neuron differentiation. Finally, sequence motif predictions of all the human differentially methylated regions indicated an enrichment of five transcription factor binding motifs, suggesting that DNA methylation may regulate gene expression by mediating transcription factor binding of these transcripts. Together, these data demonstrate environmentally sensitive factors that underlie the development of human anxiety.

**1610T****Methylomic profiling and replication implicates deregulation of PCSK9**

**in alcohol use disorder.** F.W. Lohoff<sup>1</sup>, J. Sorcher<sup>1</sup>, A. Rosen<sup>1</sup>, K. Mauro<sup>1</sup>, R. Fanelli<sup>1</sup>, R. Momenan<sup>1</sup>, C. Hodgkinson<sup>1</sup>, L. Vendruscolo<sup>2</sup>, G. Koob<sup>2</sup>, M. Schwandt<sup>1</sup>, D. George<sup>1</sup>, I. Jones<sup>3</sup>, A. Holmes<sup>1</sup>, Z. Zhou<sup>1</sup>, M. Xu<sup>1</sup>, B. Gao<sup>1</sup>, H. Sun<sup>1</sup>, M. Phillips<sup>1</sup>, C. Muench<sup>1</sup>, Z. Kaminsky<sup>3</sup>. 1) National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, MD; 2) National Institute on Drug Abuse, National Institutes of Health, Baltimore, MD; 3) Department of Psychiatry and Behavioral Sciences, Johns Hopkins University School of Medicine, Baltimore, MD.

Alcohol Use Disorder (AUD) is a common and chronic disorder with substantial effects on personal and public health. The underlying pathophysiology is poorly understood but strong evidence suggests significant roles of both genetic and epigenetic components. Given that alcohol affects many organ systems, we performed a cross-tissue and cross-phenotypic analysis of genome-wide methylomic variation using Illumina HM450 and EPIC chip arrays in AUD samples from 3 discovery, 4 replication, and 2 translational cohorts. The discovery samples consisted of postmortem brain tissues (n=46), bloods from a resting-state functional connectivity imaging endophenotypes (n=68) and postmortem brain tissues sorted into neuronal and non-neuronal cells (n=58). Overrepresentation analyses identified 68 significant CpG probes of which the most significantly associated probe cg01444643 was in the promoter of the proprotein convertase subtilisin/kexin 9 (*PCSK9*) gene (p=0.002). Biological validation showed that *PCSK9* promoter methylation is conserved across tissues (brain-blood-liver) and positively correlated with expression. Replication in AUD datasets confirmed *PCSK9* hypomethylation (n=392, p<0.05) and a translational mouse model of AUD showed that alcohol exposure leads to *PCSK9* mRNA and protein downregulation (p<0.0001). Postmortem human liver tissue analyses in control (n=47) and liver transplant cases due to alcohol cirrhosis (n=50) showed marked increase of methylation at cg01444643 (P<0.0001) and significantly decreased *PCSK9* expression (p<0.01). *PCSK9* is primarily expressed in the liver and regulates low density lipoprotein cholesterol (LDL-C). Our finding of alcohol-induced epigenetic regulation of *PCSK9* represents one of the underlying mechanisms between the well-known effects of alcohol on lipid metabolism and cardiovascular risk, with light alcohol use generally being protective while chronic heavy use has detrimental health outcomes.

**1611F****Epigenome-wide association study of opioid dependence in European**

**American women.** J.L. Montalvo-Ortiz<sup>1</sup>, H.R. Kranzler<sup>2,3</sup>, H. Zhao<sup>1</sup>, H. Zhang<sup>4</sup>, J. Gelemtier<sup>1,6</sup>. 1) Division of Human Genetics, Department of Psychiatry, Yale School of Medicine, West Haven, CT; 2) Department of Psychiatry, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 3) Center for Studies of Addiction and Crescenz Veterans Affairs Medical Center; 4) Department of Biostatistics, Yale School of Public Health, New Haven, CT; 5) Departments of Psychiatry and Medicine (Biomedical Genetics) Boston University School of Medicine, Boston, MA; 6) Veterans Affairs Connecticut Healthcare Center, West Haven, CT.

Opioid dependence (OD) is currently epidemic in the US. Although OD has a higher prevalence in men, fatal opioid overdoses have increased at a higher rate among women. Epigenetic mechanisms have been implicated in the increased risk for OD, however, most studies to date have used candidate gene approaches, mainly focusing on the opioid receptor mu 1 (*OPRM1*) gene. In this study, we conducted the first epigenome-wide association study (EWAS) of OD in women. DNA was derived from whole blood samples and EWAS was assessed using the Illumina Infinium HumanMethylationEPIC array. Our sample included 111 European American women who were administered the Semi-Structured Assessment for Drug Dependence and Alcoholism (SSADDA), which yields a DSM-IV diagnosis of OD. To identify differentially methylated CpG sites, we performed an association analysis using the 'cpg.assoc' function from the minfi Bioconductor R package, adjusting for age, estimates of cell proportions, and the first 3 principal components estimated using the Barfield et al. method to correct for population stratification. Association analysis identified a significant differentially methylated CpG at cg19642402 (p = 4.6 x 10<sup>-8</sup>, FDR = 0.03) located within the proline-serine-threonine phosphatase interacting protein 1 (*PSTPIP1*) gene. *PSTPIP1* is involved in inflammatory responses. When the top 10 ranked differentially methylated CpGs were used in a gene-based functional enrichment analysis, "response to stress" emerged as the top significant GO biological process (p = 7.35 x 10<sup>-6</sup>, FDR = 0.005). If replicated, our results would suggest that changes in DNA methylation at *PSTPIP1* may play a role in OD in women and implicates stress response as a potential mechanism of that effect. Two limitations of this study are the modest sample size and the use of blood for DNA extraction given the tissue-specific DNA methylation changes.

**1612W**

**EGR family genes; new potential markers for etiology and symptoms' severity of schizophrenia.** *M. Amini faskhodi<sup>1</sup>, R. Mahdian<sup>2</sup>, A. Haghghatfard<sup>3</sup>, M. Hashemi<sup>1</sup>.* 1) Department of Biology, Tehran Medical Branch, Islamic Azad University, Tehran, Iran, Tehran, Iran; 2) Department of Medical Biotechnology, Pasture Institute, Tehran, Iran; 3) Department of Biology, Tehran North Branch, Islamic Azad University, Tehran, Iran.

Schizophrenia (SCZ) is a major psychiatric disorder with 1 percent prevalence and unknown etiology with acute and chronic positive, negative and cognitive symptoms. Early growth response (EGR) family genes including EGR1 to EGR4 are transcription factors that are essential for development and function of central and peripheral nervous system. Previous studies were reported involvement of EGR1 and EGR3 with etiology of schizophrenia and addiction. mRNA level of EGR1, EGR2, EGR3 and EGR4 were studied in blood samples of 150 Iranian schizophrenic patients and 50 non-psychiatric subjects using quantitative Real time PCR. Also positive and negative symptom scale (PANSS) from patients and Wechsler Adult Intelligence Scale (WAISE) and NEO-FFI personality test from all subjects were obtained. Significant down regulation of EGR1, EGR2 and EGR3 were detected in SCZ vs. non-psychiatrics. No significant expression alteration was revealed in EGR4 between SCZ vs. non-psychiatrics. Correlations were found between EGR1 and EGR2 down expression and higher scores of negative symptoms in PANSS and memory deficit in digit span memory subscale of WAISE. In addition significant correlation was found between neuroticism personality factor and EGR1 down regulation. Results were suggested EGR family role in etiology of schizophrenia. In addition findings indicate down regulation of transcription factors may lead to negative symptoms, memory deficiency and higher neuroticism in patients. EGR family genes may present as biomarker for schizophrenia.

**1613T**

**Transcriptional profiling of long noncoding RNA in PTSD patients reveals a potential early biomarker of trauma-induced alterations in the acute phase after exposure.** *G. Guffanti<sup>1</sup>, A. Wingo<sup>2</sup>, T. Jovanovic<sup>2</sup>, S. Maddox<sup>1</sup>, S. Sharma<sup>1</sup>, C. Nemeroff<sup>1</sup>, A. Myers<sup>3</sup>, K. Ressler<sup>1</sup>.* 1) Harvard Medical School, Belmont, MA; 2) Emory University, Atlanta, GA; 3) University of Miami, Miami, FL.

Though relatively few long noncoding RNAs (lncRNAs) have been fully functionally characterized yet, there is growing evidence on their well-adapted and highly specialized biological role. Transcriptome analyses have demonstrated that lncRNAs are actively transcribed in a much more condition-specific manner than protein coding genes, underlying their potential as biomarkers of early detection. Finding lncRNAs that are associated with development of PTSD in the aftermath of a traumatic event is a key step toward identifying biomarkers of early diagnosis of stress- and trauma-related outcomes. We set up to test the hypothesis that lncRNA regulation might be perturbed in PTSD in a longitudinal cohort of individuals highly traumatized. The study sample derives from the larger ongoing collaboration between the University of Emory (Atlanta, GA) and Miami (FL) for the analysis of transcriptome of peripheral blood of individuals highly traumatized admitted at the Emergency Department. We decided to arbitrarily divide the overall sample in two subsamples, called discovery (n = 228) and replication (n = 85), respectively, based on the timing of the analysis of their RNA. Only ~7% of the participants developed PTSD in the aftermath of traumatic events. Raw paired end RNAseq data were processed using ad hoc pipeline PLAR to identify and annotate novel and already established lncRNAs. We tested for statistical significance of observed changes in lncRNA expression between PTSD patients and trauma-exposed controls using FPKM, correcting for demographic and batch effect variables. We used the individual level of expression of a set of genes that were significantly perturbed both in discovery and replication samples to generate lncRNA-based profile to classify cases and controls in discovery sample. We found 67 lncRNAs and other noncoding RNAs significant in both the discovery and replication samples at the significance threshold of  $p < 0.05$ . The profile generated based on the individual level of expression of these signature lncRNAs classifies cases and controls with ~98% accuracy. Our analysis shows that lncRNA-based profile provides a potential biomarker for individual "personalized" perturbation. These findings support the original hypothesis that lncRNAs play a role in PTSD and are regulated by trauma exposure. The mechanism by which signature lncRNAs perform regulatory function remains to be elucidated and is currently investigated in PTSD-related animal models.

**1614F**

**DNA methylation as a candidate biomarker for predicting antidepressant response.** C. Ju<sup>1</sup>, R. Belzeaux<sup>1</sup>, L.M. Fiori<sup>1</sup>, J.F. Theroux<sup>1</sup>, J. Foster<sup>2</sup>, S. Kennedy<sup>2</sup>, CANBIND Working group<sup>3</sup>, G. Turecki<sup>1,2</sup>. 1) McGill Group for Suicide Studies, Douglas Mental Health University Institute, McGill University, Montreal, Quebec, Canada; 2) Department of Psychiatry, University Health Network, University of Toronto, Toronto, Ontario, Canada; 3) Canadian Biomarker Integration Network In Depression.

**Purpose:** Major depressive disorder (MDD) is a severe diagnosis and recognized as the leading cause of global disability. Antidepressant therapy (ADT) is the standardized first-line treatment, but an estimated 40% of patients fail to respond initially, and 20-30% do not respond after multiple interventions. Identifying a biomarker for ADT response is enticing, as it would promote evidence-based clinical guidelines. MDD has a heterogeneous phenotype, and our lab has shown the importance of epigenetic considerations when pursuing candidate biomarkers. DNA methylation, particularly at CpG dinucleotide sites, is an epigenetic mark that serves as a suitable candidate for biomarker studies given its stability and accuracy, even when retrieved from indirect tissue, such as peripheral blood. Within a well-characterized, clinical cohort, I will investigate differentially methylated positions (DMPs) between responders and non-responders of ADT, and assess if they are suitable biomarkers for predicting response. **Methods:** Peripheral blood samples were obtained from 206 MDD patients and 101 healthy controls (HCs) recruited under the CAN-BIND-1 clinical trial. MDD patients were subjected to 8 weeks of escitalopram ADT. At week 0 (pre-ADT), and week 8 (post-ADT), MDD patients received Montgomery-Asberg Depression Rating Scale (MADRS) scores for symptom severity. A patient was considered a responder (RES) if they had a  $\geq 50\%$  MADRS score decrease, and a non-responder (NRES) otherwise. Genome-wide methylation analysis was conducted using Illumina's EPIC microarray platform. Array data was pre-processed, and analyzed with the *ChAMP* Bioconductor package in R. Differential methylation analysis was performed between (i) HCs and MDD patients and (ii) ADT RES and NRES. Furthermore, week 0 genome wide expression data was acquired from the same cohort using Illumina's HT-12 Beadchip platform. DMPs found between RES and NRES that overlap with differential gene expression data will be subject to targeted validation using bisulfite amplicon sequencing. **Results:** 39,727 DMPs were identified between MDD patients and HCs, and 9,551 DMPs were identified between RES and NRES ( $p < 0.05$ , FDR=0.05). 817 genes were found to be differentially expressed between RES and NRES ( $p < 0.05$ ). After overlap analysis, 3 genes (*CHN2*, *FAM24B*, and *JAK2*) were found to have both differential expression, and DMPs within their promoter regions. These findings are specific to ADT response.

**1615W**

**DNA methylation markers associated with injection drug use status and HIV infection among chronic injection drug users in the ALIVE study.** C. Shu<sup>1</sup>, K.M. Bakulski<sup>2</sup>, K.S. Benke<sup>3</sup>, A.E. Jaffe<sup>3</sup>, S. Wang<sup>1</sup>, S.H. Sabuncuyan<sup>1</sup>, S.H. Mehta<sup>1</sup>, G.D. Kirk<sup>1</sup>, B.S. Maher<sup>1</sup>. 1) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA; 2) University of Michigan, Ann Arbor, MI, USA; 3) Lieber Institute for Brain Development, Baltimore, MD, USA.

**Background:** Injection drug use (IDU) is associated with biological modification of the genome, i.e., epigenetics marks such as DNA methylation and histone modification. However, the biological mechanisms of how substance use and cessation affects epigenetic outcomes remain largely unknown.

**Objective:** To conduct the epigenome-wide association analyses among injection drug users to identify whether injection drug use and HIV status during the past six months is associated with genome-wide blood epigenetic changes. **Methods:** In the AIDS Linked to the Intravenous Experience (ALIVE) study, blood was obtained from 288 current IDUs, resampled after cessation and then again after relapse (total samples = 774). Blood DNA methylation marks were measured using the Illumina Infinium MethylationEPIC BeadChip. Standard procedures in the minfi R package were used to preprocess raw Illumina image files into noob processed methylation beta values. Differences in DNA methylation at individual probes by current injection status were tested using generalized linear regression including age, gender, race and cell heterogeneity as covariates. DNA methylation age was estimated for study subjects using the epigenetic clock method developed by Horvath et al. 2013. **Results:** DNA methylation at individual loci (cg10801015,  $p=2.47 \times 10^{-11}$ ; cg11415166,  $p=5.15 \times 10^{-10}$ ; cg03426703,  $p=2.62 \times 10^{-9}$ ; cg14977491,  $p=9.94 \times 10^{-8}$ ) is significantly associated with current injection drug use status after correction for multiple testing. Those CpG sites were near the PDP1, NARFL, DVL2 and PFN2 genes correspondingly. Single-site epigenetic analysis of HIV status was also performed. HIV positive individual's average biological age is about 3 years older than their chronological age, but the biological age among HIV negative individuals, injection drug users and non-users is no different from their chronological age. **Conclusion:** In a preliminary study, we performed a genome-wide scan of methylation changes in a longitudinal study of injection drug use and identified genomic locations exhibiting significant changes in peripheral DNA methylation associated with injection drug use status. Individuals with HIV infection's biological age is older than their chronological age, which is consistent with the literature.

**1616T****Small non-coding RNAs in major depression and antidepressant**

**response.** R. Lin<sup>1</sup>, J.P. Lopez<sup>1</sup>, L. Fiori<sup>1</sup>, R. Belzeaux<sup>1</sup>, C. Cruceanu<sup>1</sup>, J.F. Theroux<sup>1</sup>, CANBIND Working group<sup>3</sup>, J. Foster<sup>2</sup>, S. Kennedy<sup>2</sup>, G. Turecki<sup>1</sup>. 1) Department of Psychiatry, McGill Group for Suicide Studies, Douglas Mental Health University Institute, McGill University, Montreal, Quebec, Canada; 2) Department of Psychiatry, University Health Network, University of Toronto, Toronto, Ontario, Canada; 3) Canadian Biomarker Integration Network in Depression.

**Statement of Purpose:** Major depressive disorder (MDD) is a prevalent disorder treated primarily by antidepressants (ADT). Although effective, on average 30%-40% of subjects experience an inadequate response to treatment after several attempts. Thus, there is a great need to identify biomarkers associated with MDD and ADT response. Recent discoveries have pointed towards small non-coding RNAs (sncRNAs) as feasible biomarkers, as they have shown to be stably circulated in peripheral blood and may be associated with a disease state. Here, I profile sncRNAs in MDD pathology, and evaluate their ability to act as candidate biomarkers for diagnosis and/or ADT treatment response. This project addresses these questions with a unique combinatorial approach of using both post-mortem human brain tissue samples and living patient blood samples. **Methods:** Human post-mortem brain samples were obtained from the Douglas-Bell Canada Brain Bank. Brain tissue will be collected from individuals who died by suicide during an episode of MDD, and psychiatrically normal individuals who died suddenly. Human peripheral blood samples were collected from a clinical trial using duloxetine (samples provided by Lundbeck). This cohort consisted of depressed subjects treated with duloxetine for 8 weeks. All subjects were assessed for depression severity based on the Montgomery-Asberg Depression Rating Scale (MADRS) at week 0 (pre-ADT treatment) and week 8 (post-ADT treatment). After concluding 8-weeks of ADT therapy, subjects were separated into responders (>50% decrease in MADRS score) or non-responders (<50% decrease in MADRS score) of ADT treatment. Small RNA-sequencing was used to generate expression data on whole sncRNA-transcriptome in post-mortem brain and peripheral blood of MDD subjects. **Results:** 37 snoRNAs and 6 piRNAs showed significant up-regulation in MDD brains compared to healthy controls. From this study snoRNAs and piRNAs do not show predictive value for ADT response. snoRNAs and piRNAs only showed differential expression across time-points (i.e. week 0 vs week 8) in responders of duloxetine treatment. 31 snoRNAs showed significant up-regulation in responders of duloxetine. 3 piRNA showed significant up-regulation and 4 piRNAs showed significant down-regulation in responders of duloxetine after treatment. Significant results were specific to responders for both snoRNAs and piRNAs.

**Transcriptional and genetic changes underlying psychiatric disorders converge on a network of transcription factors and their target genes in the human brain.** S.A. Ament<sup>1</sup>, J.R. Pearl<sup>2,3</sup>, D. Bergey<sup>2</sup>, C. Funk<sup>2</sup>, L. Hood<sup>2</sup>, C. Colantuoni<sup>1,4</sup>, N.D. Price<sup>2</sup>. 1) Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD; 2) Institute for Systems Biology, Seattle, WA; 3) Molecular and Cellular Biology Graduate Program, University of Washington, Seattle, WA; 4) Departments of Neurology and Neuroscience, Johns Hopkins University School of Medicine.

Genetic and genomic studies suggest that psychiatric disorders involve changes in brain gene regulation, but roles for specific transcription factors remain largely uncharacterized. We reconstructed a transcriptional regulatory network (TRN) model for the human brain by integrating human brain-specific DNase-seq and TF-gene co-expression, predicting the genome-wide binding sites and target genes for 741 TFs. We used our TRN model to predict TFs that regulate prefrontal cortex gene expression changes in psychiatric and neurodegenerative diseases, as well as functional, disease-associated SNPs that disrupt transcription factor binding sites. Our model predicted that 69 TFs are key regulators of prefrontal cortex gene expression changes in schizophrenia (SCZ), 13 of which were also predicted to be key regulators of gene expression changes in bipolar disorder (BD). Notably, several of these predicted key regulator TFs are located at genetic risk loci for SCZ or BD, including *POU3F2*. We over-expressed *POU3F2* in primary human neural stem cells to validate our network predictions and characterize its biological functions. We show that *POU3F2* has anti-proliferative effects, involving transcriptional repression of a cluster of cell cycle genes that is highly expressed in proliferative neural stem cells and in adult astrocytes, and which is up-regulated in the prefrontal cortex of individuals with SCZ and BD. In addition, we found that a BD- and SCZ-associated SNP in the promoter of *VRK2* disrupts a putative *POU3F2* binding site and alters the activity of the *VRK2* promoter. Our results suggest that genetic and transcriptional changes underlying psychiatric diseases converge on a shared transcriptional regulatory network in the brain, with key regulators linked to disease through both cis- and trans-acting mechanisms.

**1618W**

**A direct regulatory link between microRNA miR-137 and SHANK2 with implications for neurodevelopmental disorders.** S. Berkel<sup>1</sup>, A. de Sena Cortabitarte<sup>1</sup>, C. Fischer<sup>1</sup>, G.A. Rappold<sup>1,2</sup>. 1) Institute of Human Genetics Heidelberg, University of Heidelberg, Heidelberg, Germany; 2) Interdisciplinary Center for Neuroscience (IZN), University of Heidelberg, Heidelberg, Germany.

Mutations in the genes coding for the postsynaptic scaffolding proteins SHANK2 and SHANK3 have been linked to a spectrum of neurodevelopmental disorders including intellectual disability, autism spectrum disorders and schizophrenia. We have carried out an *in silico* analysis of the SHANK gene family for microRNA binding sites which revealed a putative binding site for the schizophrenia GWAS top hit miR-137 in the SHANK2-3' UTR. Using human neuroblastoma cells (SH-SY5Y) and mouse primary hippocampal neurons, we now show that miR-137 targets the 3' UTR of SHANK2 in a site-specific manner. Overexpression of miR-137 significantly lowered endogenous Shank2 protein levels without detectable influence on mRNA level; conversely, the inhibition of miR-137 resulted in the increase of Shank2 protein. We conclude that miR-137 regulates SHANK2 expression and that this takes place by repression of protein translation rather than mRNA degradation. To further support the link between miR-137 and schizophrenia, we compared the expression of miR-137 precursor and miR-137 target genes (including SHANK2) in the dorsolateral prefrontal cortex (DLPFC) of schizophrenia and control individuals using RNA-Seq data from the CommonMind Consortium. Almost a third (18/63; 29%) of the validated miR-137 target genes showed significant expression differences in the DLPFC of schizophrenia individuals compared to controls and we propose that further targets (like SHANK2) may be regulated on protein level. Our study provides first evidence of a direct regulatory link between miR-137 and SHANK2 and supports the finding that miR-137 signaling is altered in schizophrenia.

**G-quadruplex binding chemicals may ameliorate the cognitive function of ATR-X syndrome.** T. Wada<sup>1</sup>, N. Shioda<sup>2</sup>, H. Sugiyama<sup>3</sup>, H. Tanabe<sup>4</sup>, K. Kurosawa<sup>5</sup>, N. Okamoto<sup>6</sup>, K. Fukunaga<sup>7</sup>. 1) Medical Ethics and Medical Genetics, Kyoto Univ. Grad. Sch. Medicine, Kyoto, Kyoto, Japan; 2) Department of Biofunctional Analysis Laboratory of Molecular Biology, Gifu Pharmaceutical University, Gifu, Japan; 3) Department of Chemistry, Graduate School of Science, Kyoto University, Kyoto, Japan; 4) Biosystems Science, School of Advanced Sciences, The Graduate University for Advanced Studies, Hayama, Japan; 5) Division of Genetics, Kanagawa Children's Medical Center, Yokohama, Japan; 6) Department of Medical Genetics, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan; 7) Department of Pharmacology, Graduate School of Pharmaceutical Sciences, Tohoku University, Sendai, Japan.

Background; Disorchestration of epigenetic regulation of genes can cause many mendelian diseases, one of which is ATR-X syndrome due to mutations of ATRX gene, encoding a chromatin remodeling protein, ATRX. One of the strategies of treatment for this syndrome is to hunt for the genes which are regulated by ATRX, and to ameliorate the abnormally expressed genes. Recently, it has been reported that ATRX protein targets tandem repeats, forming G-quadruplex (G4) structures, and regulates genes nearby. This suggests that the expression of many target genes of ATRX protein with G4 structure should be perturbed in ATR-X patients. In this presentation, we show that a porphyrin analogue, TMPyP4, with G4 binding ability, could improve the cognitive function of Atrx mouse. Method and Results; Atrx mice, lacking Atrx exon 2, shows cognitive dysfunction as well as other several phenotypes in ATR-X syndrome, with abnormal dendritic spine morphology leading to aberrant CaMKII activity. [Nogami T. Hippocampus, 2011, and Shioda N. J Neuroscience, 2011]. After TMPyP4 treatment, the mice showed ameliorated cognitive function based on memory-related behavioral tests, including Novel-object recognition test, Latency time in retention trials in a passive avoidance test, Alternations in a Y-maze test. DNA microarray analysis in fore brain of wild-type and Atrx mice showed 260 out of 23474 genes were abnormally expressed in Atrx mice, and TMPyP4 normalized their expression in 92 out of 140 genes. Discussion; Recently the connections between G-quadruplexes (G4) and mendelian diseases have been established. Our findings suggest a potential therapeutic strategy targeting G-quadruplexes could be treatment for ATR-X syndrome, as well as for other G4-related diseases. We should find other safe agents with G4 binding ability other than TMPyP4, because of its toxicity. We are now studying the effectiveness of these compounds for neurons developed from ATR-X patients-derived iPS cells. We are searching a key gene for cognitive function with ATRX-regulated G4-structure.

**An epigenome-wide association study of Williams syndrome.** *R. Kimura<sup>1</sup>, T. Awaya<sup>1</sup>, M. Nakata<sup>1</sup>, T. Kato<sup>2</sup>, Y. Funabiki<sup>3</sup>, K. Tomiwa<sup>4</sup>, T. Heike<sup>2</sup>, M. Hagiwara<sup>1</sup>.* 1) Department of Anatomy and Developmental Biology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 2) Department of Pediatrics, Graduate School of Medicine, Kyoto University, Kyoto, Japan; 3) Department of Cognitive and Behavioral Science, Graduate School of Human and Environmental Studies, Kyoto University, Kyoto, Japan; 4) Todaiji Ryoiku Hospital for Children, Nara, Japan.

Epigenetic alterations, including DNA methylation, have been implicated in many psychiatric and neurodevelopmental disorders. Williams Syndrome (WS) is rare genetic neurodevelopmental disorder and characterized by multiple symptoms including hypersociability. WS is caused by a 7q11.23 heterozygous deletion containing 26-28 genes, which include genes associated with epigenetic regulation. In this study, we performed epigenome-wide association study (EWAS) to determine the contribution of DNA methylation to WS. We examined a total of 171 subjects, including a discovery set (34 WS and 34 controls) and an independent confirmation set (56 WS and 47 controls). We used the Social Responsiveness Scale-2 (SRS-2), the Hyperacusis Questionnaire (HQ), the revised Fear Survey Schedule for Children (FSSC-R) and the sensory profile (SP) to evaluate behavioral and neuropsychiatric symptoms in WS. DNA methylation profiles were obtained from whole blood samples from a discovery set using the Illumina HumanMethylation 450 K BeadChip. Validation analyses of the epigenome-wide findings performed in a confirmation set using site-specific methylation with pyrosequencing. After accounting for batch effects, the effects of leukocyte subsets and multiple testing, we have identified multiple differentially methylated positions (DMPs) and regions (DMRs) consistently associated with WS in a discovery set. Some of the identified genes with differential methylation (ANKRD30B) have previously been associated with WS and we replicate those findings in a confirmation set. GO and Pathway analysis revealed significant enrichment of our DMPs in Synapse organization, Glutamatergic synapse and Calcium signaling pathway. To our knowledge, this study is the largest EWAS performed in WS. Our findings provide insights into the molecular basis and pathophysiology of the various phenotypes of WS.

**Epigenetic suppression of VEGF in retinal pigment epithelial cells by ascorbate.** *D. Sant<sup>1</sup>, V. Camarena<sup>1</sup>, S. Mustafi<sup>1</sup>, C. Gustafson<sup>1</sup>, Y. Li<sup>2</sup>, L. Denison<sup>1</sup>, B. Hampton<sup>1</sup>, Z. Wilkes<sup>1</sup>, D. Van Booven<sup>1</sup>, R. Wen<sup>2</sup>, G. Wang<sup>1,2,3</sup>.* 1) John P. Hussman Institute for Human Genomics, University of Miami - Miller School of Medicine, Miami, FL; 2) Dr. John T. MacDonald Foundation Department of Human Genetics, University of Miami - Miller School of Medicine, Miami, FL; 3) Dr. Nasser Ibrahim Al-Rashid Orbital Vision Research Center, University of Miami - Miller School of Medicine, Miami, FL.

Age-related macular degeneration (AMD) is the leading cause of blindness in individuals over 50 years of age in the industrialized world. Intraocular anti-VEGF therapies are effective for many but not all cases of wet AMD, (advanced AMD, characterized by choroidal neovascularization.) The anti-VEGF therapies target VEGF protein, but do not influence the expression of VEGF. Ascorbate is known to influence DNA demethylation, through which it regulates gene expression. We examined the impact of ascorbate on RPE cells. In cultured ARPE-19 cells, treatment with ascorbate (50 mM) induced 5hmC generation and differential expression of 1,915 genes, as revealed by RNA-seq. Among which, *VEGFA*, a gene encoding VEGF protein, is one of the most downregulated genes. Consequently, the translation and secretion of VEGF are decreased by ascorbate treatment. The downregulation of VEGF expression by ascorbate was validated in RPE-J cells. Furthermore, we found that supplementation of ascorbate in *Gulo*<sup>-/-</sup> mice, which are dependent on exogenous ascorbate, also downregulated VEGF levels in the vitreous humor. The suppression of *VEGFA* is independent of HIF-1a but corroborates with increased 5hmC at promoter of the gene. These results are consistent with the notion that ascorbate suppresses VEGF expression through 5hmC-mediated epigenetic pathway. Our findings provide experimental basis for using ascorbate to treat retinal angiogenesis diseases, such as wet AMD and diabetic retinopathy.

**C-to-U RNA editing of osteopontin in mouse retina with laser-induced choroidal neovascularization.** *J. Chen<sup>1</sup>, Z. Xu<sup>1</sup>, Z. Wei<sup>1</sup>, R. Sun<sup>1</sup>, X. Pan<sup>2</sup>, D. Zhou<sup>2</sup>.* 1) Laboratory of Genomic and Precision Medicine, Wuxi School of Medicine, Jiangnan University, Wuxi, Jiangsu, China; 2) Department of Ophthalmology, Affiliated Hospital of Jiangnan University, Wuxi, Jiangsu, China.

**Purpose:** Laser-induced choroidal neovascularization (CNV) in mice is an important animal model to study exudative age-related macular degeneration, but the role of RNA editing in the retina in CNV mice remain largely unclear. In this study we reported that C-to-U RNA editing of osteopontin, a key cytokine in cell-mediated inflammation, was found in the retina of a mouse CNV model.

**Methods:** Laser photocoagulation of Bruch's membrane was used to induce CNV in the right eyes (OD) of three adult C57B/L6 mice. Total RNA was extracted from the whole retina of CNV (OD) and untreated contralateral (OS) eyes on Day 3. RNA-Seq was performed on the Illumina HiSeq 2000 platform with configuration of 20 million 100 bp pair-end reads per sample. Reads were aligned to the mouse full genome (UCSC version mm10) using Bowtie and splice junctions were identified by using TopHat2. Quantification of expression level and analysis of differential expression of RNA-Seq data were done using R language package EdgeR. Candidate RNA editing sites with editing level  $\geq 1\%$  were identified using Samtools and VarScan, and verified using Sanger sequencing. Expression level of mRNA was confirmed using quantitative real-time PCR (qPCR). **Results:** We focused on C-to-U RNA editing in protein-coding genes. The highest C-to-U RNA editing was found at the 3'-UTR of osteopontin mRNA, and was only in the retina with CNV (average editing level 6.69%) but not in the contralateral untreated retina. Sanger Sequencing of the osteopontin 3'-UTR confirmed that the editing was specific to CNV induction. RNA-Seq and qPCR results showed that expression of osteopontin dramatically increased in the retina with CNV, and intriguingly correlated with a higher expression level of C-to-U-editing enzyme *APOBEC1*. **Conclusions:** In the current study, RNA-Seq analysis revealed a novel target of C-to-U RNA editing in osteopontin in the retina of CNV mouse model. These findings thus warrant further investigation of the role played by RNA editing in retina inflammation during CNV.

**DNA hypermethylation is associated nonsyndromic cleft lip and palate.** *B. Gorijala<sup>1</sup>, U. Ratnamala<sup>2</sup>, D.D. Jhala<sup>3</sup>, N.K. Jain<sup>2,4</sup>, S.S. Chettiar<sup>5</sup>, A.K. Maiti<sup>6</sup>, S.K. Nath<sup>7</sup>, U. Radhakrishna<sup>7</sup>.* 1) Oncology Department, Krishna Institute of Medical Sciences, Secunderabad, Andhra Pradesh, India; 2) Department of Life Sciences, School of Sciences, Gujarat University, Ahmedabad, India; 3) Department of Zoology, School of Sciences, Gujarat University, Ahmedabad, Gujarat, India; 4) Department of Pharmacology, Creighton University, Omaha, NE, USA; 5) Green Cross Pathology & Molecular Laboratory, Ahmedabad, India; 6) Arthritis and Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, US; 7) Department of Obstetrics and Gynaecology, Oakland University William Beaumont School of Medicine, Royal Oak, MI, USA.

Non-syndromic cleft lip with or without cleft palate (NSCL/P) is considered the most common, severe craniofacial disorder worldwide. While most studies point to genetic factors as the major cause, NSCL/P has a multifactorial complex etiology and arises through the interaction of genetic and environmental factors. However, the exact mechanisms by which these environmental factors induce NSCL/P remain unknown. Epigenetics is among the most rapidly-expanding areas of study in molecular biology. Epigenetic studies that pertain to NSCL/P development are still relatively new but represent an important area for future study. To identify epigenetic risk variants for NSCL/P, we have conducted genome-wide DNA methylation profiles using the Infinium Methylation EPIC BeadChip (Illumina) in 24 NSCL/P cases and an equal number of age, ethnic and sex-matched controls from India. The samples included were children aged between 2 to 5 years. We identified significant CpG hypermethylation ( $> 2.0$ -fold) at 3500 sites in 3500 genes (false discovery rate (FDR)  $\leq 0.000001$ ) with a receiver operating curve area under the curve (ROC AUC)  $\geq 0.75$  for NSCL/P detection. The methylation difference between NSCL/P and controls  $\geq 20\%$ , in the majority of the genes. A total of 183 CpG loci had an excellent accuracy (AUC  $\geq 1.00$ ) for the detection of NSCL/P. We identified significantly altered CpG sites that are not only located within the CpG islands in the promoter region of genes but were also distributed throughout the gene bodies. Pathway analysis identified genes with significant methylation changes are involved in several important pathways including cancer, calcium signaling, MAPK signaling, signaling pathways regulating pluripotency of stem cells, and HIF-1 signaling pathway. These epigenetic studies may give us clues towards the elucidation of the disease mechanisms and pathogenesis of NSCL/P.

**Developmental *cis*-regulatory elements revealed by open chromatin landscapes in mouse fetal tissues.** Y. Zhao<sup>1,2</sup>, H. Huang<sup>1,2</sup>, D. Gorkin<sup>3</sup>, S. Preissl<sup>4</sup>, Y. Zhang<sup>5</sup>, R. Fang<sup>1,2</sup>, V. Afzal<sup>3</sup>, D. Dickel<sup>3</sup>, A. Visel<sup>3,4,5</sup>, L. Pennacchio<sup>3,4</sup>, B. Ren<sup>1,2</sup>. 1) UC San Diego, La Jolla, CA; 2) Ludwig Institute for Cancer Research, La Jolla, CA; 3) Lawrence Berkeley National Laboratory, Berkeley, CA; 4) US DOE Joint Genome Institute, Walnut Creek, CA; 5) UC Merced, Merced, CA.

Mammalian development depends on coordinated regulation of gene expression in each cell type and tissue. In order to identify and characterize the *cis*-regulatory sequences and their dynamics during development, we carried out assays of transposase-accessible chromatin followed by sequencing (ATAC-seq) to delineate the open chromatin regions during mouse fetal development. We examined 12 distinct tissue types across up to 7 developmental stages, identified over 740,000 candidate developmental *cis*-regulatory sequences. We characterized their dynamic chromatin states among different tissues and developmental stages. We showed that promoter-distal elements exhibit highly tissue-specific and stage-specific dynamics in transposase accessibility relative to promoter-proximal regions. Integrating our catalog of *cis*-regulatory elements with matched gene expression data, we predict key regulators for lineage specification. Finally, we map 70.2% of our catalog to orthologous human loci, and find that disease-associated variants are enriched in a tissue-dependent manner. Together, our results provide a general resource for understanding mammalian development and human disease.

**1625T**

**Disruption of a remote putative novel enhancer in the *cis*-regulatory domain of *FOXL2* in a multigenerational Polynesian family with BPES.** H. Verdin<sup>1</sup>, A. Shelling<sup>2</sup>, D. Markie<sup>3</sup>, A.L. Vincent<sup>4,5</sup>, E. De Baere<sup>1</sup>. 1) Center for Medical Genetics, Ghent University Hospital and Ghent University, Ghent, Belgium; 2) Department of Obstetrics and Gynecology, Faculty of Medical and Health Sciences, University of Auckland, Auckland, New Zealand; 3) Pathology Department, Dunedin School of Medicine, Otago University, Dunedin, New Zealand; 4) Department of Ophthalmology, New Zealand National Eye Centre, Faculty of Medical and Health Sciences, The University of Auckland, Auckland, New Zealand; 5) Eye Department, Greenlane Clinical Centre, Auckland District Health Board, Auckland, New Zealand.

Both loss-of-function mutations in *FOXL2* and *cis*-regulatory deletions lead to the rare, autosomal dominant, developmental disorder blepharophimosis syndrome (BPES), associating an eyelid malformation with premature ovarian insufficiency. Despite extensive genetic studies, the molecular causes remain unexplained in 12% of typical BPES patients. The goal of this study was to unravel the molecular cause in a multigenerational Polynesian family in which linkage to a 34.4 Mb genomic region on 3q23 containing *FOXL2* was shown (LOD of 3.8). First, we delineated the *cis*-regulatory domain of *FOXL2* to a 414 kb region (chr3:138,652,808-139,067,278;GRCh37) using a combination of whole-genome human-mouse-chicken multiple alignments and publically available high-resolution interaction maps enabling us to visualize the topologically associated domain (TAD) containing *FOXL2*. Next, we resequenced this putative *cis*-regulatory domain using HaloPlex enrichment followed by massive parallel sequencing on the MiSeq next-generation sequencing in seven affected and 4 unaffected family members. Data-analysis was performed using CLC bio Genomics Workbench. After mapping, variants were called, annotated and filtered using several online resources including VEP, RegulomeDB, CADD, Roadmap Epigenomics, goNL and Kaviar. Using this approach, we identified a heterozygous non-coding variant, Chr3(GRCh37):g.138954755G>A, located in a genomic fragment predicted by the Roadmap Epigenomics to function as an enhancer in the ovary. In addition, this predicted enhancer is located in the shortest region of overlap of previously delineated *cis*-regulatory deletions and an interaction of this fragment with the *FOXL2* promoter has been demonstrated using chromosome conformation capture in human granulosa-like tumor KGN cells (D'haene et al. PLoS Genetics 2009). We are currently performing *in vitro* reporter assays in KGN cells to validate the regulatory potential of this predicted enhancer. In conclusion, this is the first report of a non-coding variant in a putative novel enhancer of *FOXL2* leading to BPES. Our study adds to increasing number of Mendelian developmental disorders caused by subtle genetic defects of *cis*-regulatory elements, such as the ZRS and SIMO elements in the *SHH* and *PAX6* regions respectively.

**1626F****Differential expression of immunoglobulin genes in blood and lesion burden in familial cavernous malformation type 1 (CCM1) patients.**

H. Kim<sup>1,2,3</sup>, J. Nelson<sup>1</sup>, H. Choquet<sup>4</sup>, D. Guo<sup>1</sup>, C.E. McCulloch<sup>2</sup>, M. Bartlett<sup>5</sup>, B. Hart<sup>6</sup>, L. Morrison<sup>5,7</sup>, L. Pawlikowska<sup>1,3</sup>. 1) Center for Cerebrovascular Research, Department of Anesthesia and Perioperative Care, University of California San Francisco, San Francisco, CA; 2) Department of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA; 3) Institute for Human Genetics, University of California San Francisco, San Francisco, CA; 4) Kaiser Permanente of Northern California, Division of Research, Oakland, CA; 5) Department of Neurology, University of New Mexico, Albuquerque, NM; 6) Department of Radiology, University of New Mexico, Albuquerque, NM; 7) Department of Pediatrics, University of New Mexico, Albuquerque, NM.

**Background:** Inflammation may contribute to the pathogenesis of cerebral cavernous malformations (CCM); increased mRNA expression of immunoglobulins has been found in CCM lesions. We previously reported common genetic variants in inflammatory and immune response genes associated with CCM1 disease severity phenotypes, including total and large (>5mm) lesion burden. We investigated whether blood mRNA expression levels of these genes were associated with total and large lesion burden in familial CCM1 cases with the Common Hispanic Mutation (CCM1-CHM). **Methods:** RNA was extracted from whole blood (PAXgene) collected from 95 Hispanic CCM1-CHM patients enrolled in the Brain Vascular Malformation Consortium CCM study RNA expression was measured using the Affymetrix HuGene ST 2.1 array, containing probes for 48,226 transcripts. We compared whole-transcript RNA expression levels between subjects with higher than expected vs. lower than expected log-lesion or log-large lesion counts given age and sex using ANOVA. Transcripts with absolute fold-change (FC) >1.2 and ANOVA  $p < 0.05$  were considered differentially expressed between the two groups. We evaluated the expression of 13 individual genes and of transcripts mapping to the IGH (chr14, 58 transcripts) and IGL (chr22, 46 transcripts) immunoglobulin clusters. **Results:** There was no difference in blood expression levels of 13 individual inflammatory and immune response genes between the high lesion vs. low lesion group for either lesion phenotype. However, there was evidence for differential expression of immunoglobulin cluster transcripts. For total lesion burden, transcript levels of 1 IGL and 4 IGH genes were up-regulated in the high lesion group (3 IGH transcripts had FC >1.5). For large lesion burden, 8 IGL transcripts and 4 IGH transcripts were down-regulated (one IGH transcript had FC >1.5). One IGH transcript (IGHM;IGHV4-31) and one IGL transcript (IGLV3-12) were consistently up-regulated or down-regulated, respectively, in both total and large lesion analysis. In transcriptome-wide analysis, IGH transcripts were amongst the top differentially expressed genes for total lesion burden (FC >1.5 and  $p < 0.05$ ). **Conclusions:** Blood RNA expression levels of IGH and IGL genes are associated with total and large lesion burden in CCM1-CHM patients. Specific immunoglobulin levels may serve as a potential biomarker of CCM disease severity.

**1627W****NSD1 haploinsufficiency evokes DNA hypomethylation at imprinted DMRs and the increased expression of imprinted genes.**

H. Watanabe<sup>1</sup>, K. Higashimoto<sup>1</sup>, N. Miyake<sup>2</sup>, T. Maeda<sup>1</sup>, H. Hidaka<sup>1</sup>, S. Aoki<sup>1</sup>, N. Matsumoto<sup>2</sup>, H. Soejima<sup>1</sup>. 1) Division of Molecular Genetics & Epigenetics, Department of Biomolecular Science, Faculty of Medicine, Saga University, Saga, Japan; 2) Department of human genetics, Yokohama City University Graduate School of Medicine.

Purpose SS is caused by haploinsufficiency of *NSD1*, which catalyzes mono- and di-methylation of histone H3K36. In addition, mutations of the *DNMT3A* (*de novo* DNA methylase) and *SETD2* (H3K36 trimethylase) have been identified in Sotos-like over growth syndrome, which exhibits only some SS features. Because DNMT3A recognizes H3K36me3 and plays a pivotal role in the DNA methylation of imprinted loci, we hypothesized that the mutations of *NSD1* cause aberrant methylation at imprinting associated differentially methylated regions (DMRs). The purpose of this study is elucidation of relationship between *NSD1* mutation and aberrant methylation of DMRs, and expression of imprinted genes. **Materials and Methods** Genomic DNAs were extracted from peripheral blood of 31 SS patients with the *NSD1* mutation. We screened DNA methylation status of 32 DMRs by the MALDI-TOF MS and confirmed aberrant methylation by bisulfite-pyrosequencing. TCL-1 and HTR8 cells were treated with DNA demethylating agent 5-Aza-2-deoxycytidine (5-Aza-CdR). After the treatment, we analyzed methylation status of DMRs and the expression level of imprinted genes by quantitative RT-PCR. **Results** *IGF2*-DMR0 and *IG*-DMR-CG6 showed hypomethylation in approximately half of SS patients. 5-Aza-CdR treatment induced hypomethylation of the two DMRs in the cell lines. Expression of *IGF2* in the 5-Aza-CdR treated cells increased approximately 5 times compared to that in the untreated cells. Expression of *MEG3* and *MEG8* also increased in the cell lines with 5-Aza-CdR treatment. **Discussion and Conclusions** Our results suggested that the *NSD1* mutation induced hypomethylation of DMRs, leading to overexpression of the imprinted genes. Especially, since *IGF2* encodes a growth factor and its overexpression causes Beckwith-Wiedemann syndrome, which is a representative overgrowth syndrome, it is plausible that overgrowth of SS is attributed to *IGF2* overexpression. In addition, overexpression of *MEG3* and *MEG8* also may involve in the features of SS.

**1628T**

**Genome-wide miRNA profiling in plasma of pregnant women with Down syndrome fetuses.** *I. Svobodova<sup>1</sup>, S. Pospisilova<sup>1</sup>, B. Chylikova<sup>1</sup>, M. Korabecna<sup>1</sup>, P. Calda<sup>2</sup>, M. Brestak<sup>2,3</sup>, M. Krkavcova<sup>4</sup>, O. Seda<sup>1</sup>, A. Horinek<sup>1</sup>.* 1) Institute of Biology and Medical Genetics, General University Hospital in Prague, Prague, Czech Republic; 2) Department of Obstetrics and Gynecology of the First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; 3) Screening center, Prague, Czech Republic; 4) GENVIA genetic laboratories, Prague, Czech Republic.

**Introduction:** Down syndrome (DS) is the most common aneuploidy (1:700 live births). Molecular pathogenesis of the DS is still incompletely understood. Impact of epigenetic mechanisms is currently often discussed in the context of DS. We follow up on a previous study comparing miRNA expressions in normal and trisomic placentas<sup>1</sup>, where seven miRNAs were found as being significantly upregulated in DS placentas. In the present study, we focused on plasma samples to further investigate biological functions of miRNAs. **Methods:** Total RNA enriched for small RNAs was extracted from 900ul of plasma using NucleoSpin miRNA Plasma kit (Mecherey-Nagel) and eluted with 20ul of elution buffer. A total of 26 plasma samples from pregnant women - 13 bearing DS fetuses and 13 normal karyotype fetuses, were included to our study. Genome-wide miRNA profiling was performed using Affymetrix miRNA 4.1 array strips. This pilot study serve to rough selection of miRNAs discriminating compared groups of pregnant women. Results were evaluated using Partech Genomics Suite software. The one-way ANOVA with a cut-off p-value  $\leq 0.05$  and fold change  $\geq 1.8$  was used for detection of differentially expressed miRNAs. Association with potentially affected biological pathways was performed using Ingenuity pathway analysis (IPA) software. **Results:** A total of 23 miRNAs were selected for a following validation study. The set of miRNAs consisted of three groups: 1) 12 human miRNAs which were identified as being significantly dysregulated between euploid and DS plasma samples of pregnant women according to the results of the pilot study; 2) 7 miRNAs which were verified as being overexpressed in DS placentas in our previous study; 3) 4 miRNAs which were in a wider group of differentially expressed miRNA in case of setting milder criteria (p-value  $\leq 0.05$ ; fold change  $\geq 1.5$ ) and simultaneously are mentioned in the literature as being possibly associated with Down syndrome. **Conclusion:** Our pilot study suggested that differences of miRNA profiles between normal and DS fetuses are detectable even on the level of maternal plasma. Many biological pathways might be potentially influenced based on pilot study results; cell communication and signalling pathways are between the most enriched ones. More accurate data will be available after the validation study. Supported by the Ministry of Health of the Czech Republic RVO VFN64165.

**The NIA Aging Cell Repository: Facilitating aging research on cells in culture.** *D. Requesens, A. Green.* Coriell Institute for Medical Research, Camden, NJ.

The NIA Aging Cell Repository was established at the Coriell Institute for Medical Research, an independent non-profit research institution, in 1974. This invaluable resource supports cellular and molecular research studies on the mechanisms of aging and associated degenerative processes. The NIA Repository aims to provide well-characterized, viable cultured cell lines requested by researchers in the field of aging, and to publicize the availability of these cell lines and in some cases cell-line derived DNA to the research community. The cells stored and distributed by the repository have been collected over three decades using strict diagnostic criteria and banked under the highest quality standards. Scientists use the highly-characterized, viable, and contaminant-free cell cultures from this collection for research on aging-related diseases. These samples have been used in the identification of many disease genes including the gene for Hutchinson Gilford Progeria Syndrome. Included in the repository are skin fibroblast cultures from individuals with premature aging syndromes, including Werner and Hutchinson-Guilford (progeria), cultures from clinically documented and at-risk individuals from families exhibiting familial Alzheimer's disease, differentiated cell lines, cell lines from animals, mouse embryonic stem cells (ESC) and human induced pluripotent stem cells (iPSC). The repository also contains DNA from many cell lines, available individually or in panels such as the Primate DNA panel, Aging Syndrome DNA panel, Characterized Alzheimer's disease mutation DNA panel, Early and Late Onset Alzheimer's disease DNA panels, and Aged Sib Pairs DNA panel. Scientists from over 40 countries have used samples from this collection for research. More than 1,000 papers have been generated used samples from the NIA Repository. The full online catalog can be accessed at <https://catalog.coriell.org/NIA>.

**1630W****Transcriptional profiling of aging effects in human trabecular meshwork.**

S. Ramdas<sup>1</sup>, G. Li<sup>1</sup>, Q. Ma<sup>2</sup>, F. Rozsa<sup>3</sup>, J. Richards<sup>3</sup>, J.Z. Li<sup>1,2</sup>. 1) Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 2) Department of Human Genetics, University of Michigan, Ann Arbor MI; 3) Department of Ophthalmology and Visual Sciences, University of Michigan, Ann Arbor, MI.

The trabecular meshwork (TM) is an area of tissue in the outer eye, consisting of a network of fibers involved in the outflow of aqueous humor from the cornea. Increasing stiffness of this tissue with age is a risk factor for glaucoma, one of the leading causes of blindness in the world. In this study, we use microarray-based gene expression profiling of post-mortem samples from 93 subjects (age: 13-88 yrs) to analyze age-related gene expression changes in the TM. We identify a transcriptional signature of age in this tissue, involving genes such as *SPOPL*, *CASC15* and *TGM2*. The *TGM2* protein is responsible for cross-linking of extracellular proteins, making them resistant to degradation. Previous studies have reported higher levels of *TGM2* (transglutaminase 2) in glaucoma samples than in controls. The age-related increase of *TGM2* therefore could be related to the increasing stiffness of the TM with age and a risk factor for glaucoma. Comparisons with published aging signatures in the rat reveal convergence at the level of biological pathways, including those related to the immune system, the extracellular space and the ribosome. Genes in these pathways tend to have higher expression in older subjects. While aging studies of other tissues show a decreased expression of genes for ribosomal function, TM appears to be one of the few tissues showing an increase with age. Further, more genes show a higher variance among older samples than those showing higher variance in the young. This greater inter-individual variation in older samples is consistent with a decreased stringency of gene regulation with advancing age, as proposed by previous studies. Lastly, we were able to develop gene expression predictors of age using subsets of our samples as training sets, achieving a performance of correlation coefficient  $r$  of 0.68 between the predicted and actual age in the test set.

**1631T****Aging and subregion specific transcriptional changes in the rat hippocampus.**

I.S. Piras<sup>1</sup>, M.D. De Both<sup>1</sup>, A.L. Siniard<sup>1</sup>, L. Ianov<sup>2</sup>, M.K. Chawla<sup>3</sup>, A. Rani<sup>4</sup>, A.J. Kennedy<sup>4</sup>, J.J. Day<sup>4</sup>, A. Kumar<sup>2</sup>, J.D. Sweatt<sup>5</sup>, T.C. Foster<sup>2</sup>, C.A. Barnes<sup>4</sup>, M.J. Huentelman<sup>1</sup>. 1) Evelyn F. McKnight Brain Institute, & Translational Genomic Research Institute, Phoenix, 85004 AZ; 2) Evelyn F. McKnight Brain Institute, & University of Florida, Gainesville, 32611 FL; 3) Evelyn F. McKnight Brain Institute, & University of Alabama, Birmingham, 35294 AL; 4) Evelyn F. McKnight Brain Institute & University of Arizona, Tucson, 85724 AZ; 5) Evelyn F. McKnight Brain Institute & Vanderbilt University School of Medicine, Nashville, 37232 TN.

Here we used next generation RNA sequencing to investigate differential changes in the rat whole transcriptome within each of three hippocampal subfields CA1, CA3 and Dentate Gyrus (DG). We investigated the genes associated with normal aging and the sub-regional specific transcriptome differences regardless of age. The Morris Water Maze was conducted in male Fisher 344 rats ( $n=34$ ) of two different age groups: *young* (5-6 mos;  $n=10$ ) and *aged* (17-22 mos;  $n=24$ ). The experiments were conducted at University of AZ ( $n=16$ ) and University of FL ( $n=18$ ). The whole RNA isolated from the three subfields was library prepped with TruSeq Stranded Total RNA with Ribo-Zero Gold Kit (Illumina) and sequenced using the Illumina HiSeq2500; differentially expressed genes (DEGs) between groups and subregions were determined using DESeq2. We sequenced an average of  $58.6 \pm 19.5$  millions of reads for sample, detecting DEGs associated with aging ranging from 6 (CA3) to 23 (CA1). When considering all of the three subfields as one group, we detected a total of 135 DEGs. Among all of the genes observed, most of them were region specific: CA1 ( $n=4$ ), CA3 ( $n=22$ ), and DG ( $n=6$ ). Pathway analysis suggested the enrichment of immune related pathways as "*Innate Immune System*" (adj  $p=5.6E-10$ ;  $n=36$ ). The subregion specific transcriptome analysis regardless of age enabled us to detect expression patterns including genes specifically over or under expressed in each subregion: CA1 ( $n=406$ ), CA3 ( $n=540$ ), and DG ( $n=963$ ). In particular, the DG was enriched with specific pathways for high expressed genes as "*Axon guidance*" (adj  $p=7.4E-04$ ) and "*cAMP signaling*" (adj  $p=3.2E-03$ ). Our results highlight the association of immune response genes with aging. The subfield with most relevant changes was CA1. In this region we identified: overexpression of *Laptm5*, associated with Systemic Lupus Erythematosus and lysosomal degradation; *Trem2*, associated with Alzheimer's Disease and *Npc2*, associated with the neurodegenerative *Niemann-Pick disease*. In DG we found *Adgre1*, and the lncRNA *AABR07001734.1*. Finally, we detected specific expression signatures for each hippocampus subfield regardless of age, with enrichment for neurogenesis processes in the DG. These data may be useful in identifying transcriptional changes associated with the normal aging process in the mammalian hippocampus as well as identifying molecular approaches to limit or target gene expression to specific subregions of the hippocampal formation.

**Background:** Age is the main risk factor for many chronic diseases in humans. Age-related cardiovascular diseases, cancers, and neurodegenerative disorders are among the dominant health problems faced by the population. Aging is marked by widespread, reproducible changes in biological processes and the epigenome. The most studied epigenetic mechanism, DNA methylation (DNAm), has been found to show robust and widespread age-related changes across the genome. DNAm profiles from whole blood can be used to predict human aging rates with great accuracy, suggesting that DNAm can act as a biomarker of aging. We sought to test whether DNAm-based predictions of age are related to risk factors for diabetes, with the goal of identifying risk factors potentially mediated by DNAm. **Methods:** Our participants were 43 post-menopausal women, between 50 and 76 years of age, enrolled in the Women's Health Initiative (WHI). We obtained methylation data via the Illumina 450K Methylation array on whole blood samples from participants at three timepoints (covering on average 16 years per participant). We employed the method and software of Horvath, which uses DNAm at 353 CpGs to form a DNAm-based estimate of chronological age (DNAm age). We then calculated the epigenetic age acceleration, or  $\Delta_{\text{age}}$  (DNAm age minus chronological age), of participants at each timepoint. This allowed us to observe longitudinal changes in participants'  $\Delta_{\text{age}}$  and DNAm age. We fit linear mixed models to characterize how  $\Delta_{\text{age}}$  contributed to a longitudinal model of aging and diabetes-related phenotypes. **Results:** For most participants,  $\Delta_{\text{age}}$  remained constant over the course of the follow-up period, indicating that age acceleration is generally stable over time. We found that  $\Delta_{\text{age}}$  contributed significantly to models of body mass index (BMI) ( $p=0.0012$ ), waist circumference ( $p=0.033$ ), and fasting glucose ( $p=0.0073$ ), with the relationship with BMI maintaining significance after correction for multiple testing. Replication in a larger cohort of 157 WHI participants spanning three years was unsuccessful, possibly due to the shorter time frame covered. **Conclusions:** Our results suggest that DNAm has the potential to act as a mediator between aging and risk of having a high BMI, waist circumference, and fasting glucose, or alternatively, it may serve as a biomarker of these phenotypes. Further studies of the role of DNAm in mediating age-related outcomes are warranted, as is follow-up in other longitudinal cohorts.

## 1633W

**An evolutionary perspective of DNA methylation associated with age within the primate lineage.**

G. Housman<sup>1,2</sup>, E. Quillen<sup>3</sup>, A.C. Stone<sup>1,2</sup>. 1) School of Human Evolution and Social Change, Arizona State University, Tempe, AZ, USA; 2) Center for Evolution and Medicine, Arizona State University, Tempe, AZ, USA; 3) Department of Genetics, Texas Biomedical Research Institute, San Antonio, TX, USA.

**Background:** Aging is thought to be a developmentally regulated process that is controlled by epigenetic mechanisms, such as DNA methylation. Methylation patterns throughout the genome show distinct changes with age in humans. However, the evolution of age epigenetics and the degree to which epigenetic signatures of aging are conserved between species has not readily been explored. **Objective:** This project examines the evolution of aging epigenetics specifically within the primate lineage by identifying age-related DNA methylation patterns in baboons (*Papio spp.*) and by comparing these findings to what is known in humans. **Methods:** Genome-wide DNA methylation patterns were identified in femoral trabecular bone from 46 pedigreed baboons, 28 that were adults and 18 that were juveniles using the Illumina Infinium MethylationEPIC BeadChip. **Results:** Several significantly differentially methylated positions (DMPs) were found between these age cohorts. Specifically, out of the 191,631 sites examined, 17% (33,057 sites) were differentially methylated between age cohorts, and similar to other animals, adult baboons display global hypomethylation as compared to juvenile baboons. The significant age-related DMPs identified are associated with genes involved in developmental processes and pathways related to the progression of diseases of aging. Additionally, while some of these age-related DMPs overlap with and display methylation patterns similar to those previously identified in human aging studies ( $n=11$ ), the majority of previously identified age-related methylation loci in humans that were also tested in baboons ( $n=137$ ) either showed opposite methylation patterns in baboons ( $n=3$ ) or were not significantly differentially methylated in baboons ( $n=123$ ). Nevertheless, methylation levels at these human loci are still able to differentiate baboon age cohorts. **Discussion:** Overall, these results begin to clarify the evolutionary conservation of epigenetic aging processes within the primate lineage. This is the first study to specifically assess aging effects on the DNA methylation profiles of skeletal tissues from a nonhuman primate, and the findings of this research inform our understanding of DNA methylation variation in one skeletal tissue from a nonhuman primate, as well as the degree to which chronological age affects this variation.

Robust DNA methylation changes are known to occur with age at sites across the human genome. These age-related changes, collectively termed epigenetic drift, are suggested to be caused by environmental factors and dysfunctional epigenetic maintenance and repair mechanisms. The drift process is hypothesized to be stochastic with the gains and losses of methyl groups directly resulting from random unrepaired environmental insults and methylation maintenance failures. Here we test the stochastic process hypothesis of epigenetic drift using a stochastic Ornstein-Uhlenbeck (OU) model and longitudinal DNA methylation data. DNA methylation was measured at >480K CpG sites in blood sampled at 3 time points (timespan avg=16 y) from 43 women participating in the Women's Health Initiative Long Life Study (age range=50-76). After exclusion of probes containing SNPs, multi-modal probes, probes that bind to multiple chromosomes, and probes without a CpG site, 382K sites remained for analysis. We hypothesize age-related methylation changes to be the result of gains and losses of methyl groups that occur at random throughout the genome rather than at targeted genes or CpG sites. If these changes are truly stochastic, we expect constant rates of methyl group gain/loss across all CpG sites. To test this hypothesis we estimated the rates of methyl group gain/loss via maximum likelihood estimation for nested OU models: 1) a null model where all CpG sites have the same rate methyl group gain/loss, and 2) an alternative model where CpG sites included in a functional group (e.g. sites in a promoter) have different rates of methyl group gain/loss. Five functional groups were investigated: promoters, enhancers, insulators, CpG islands, CpG island shores, and CpG island shelves. We compared the models via likelihood ratio tests and rejected the null model for all functional groups tested ( $p < 10^{-27}$ ). This result is consistent with a scenario where age-related methylation changes resulting from epigenetic drift are not purely stochastic at the genome-wide scale. This may suggest the presence of targeted rather than stochastic changes, or that methylation maintenance and repair mechanisms may be better maintained at select sites or in select regions based on location or function. Future analyses will include cell type proportions as covariates to remove potential confounding due to the heterogeneous and changing composition of whole blood, and to assess the robustness of our results. .

**Identification, replication and characterization of epigenetic remodelling in the aging genome.** S. Li<sup>1</sup>, L. Christiansen<sup>2</sup>, K. Christensen<sup>2</sup>, T.A. Kruse<sup>1</sup>, P. Redmond<sup>3</sup>, R.E. Marioni<sup>1,5,6</sup>, I.J. Deary<sup>3,5</sup>, Q. Tan<sup>1,2</sup>. 1) Human Genetics, Institute of Clinical Research, University of Southern Denmark, Odense, Odense, Denmark; 2) Epidemiology, Biostatistics and Biodemography, SDU, Odense, Denmark; 3) Department of Psychology, University of Edinburgh, Edinburgh, United Kingdom; 4) Centre for Genomic & Experimental Medicine, University of Edinburgh (UE), Edinburgh, United Kingdom; 5) Centre for Cognitive Ageing and Cognitive Epidemiology, UE, Edinburgh, United Kingdom; 6) Queensland Brain Institute, The University of Queensland, Australia.

**Background:** Aging is a complex biological process that involves numerous changes at various levels through remodelling of multiple biological processes and regulatory mechanisms including epigenetics. Recent analysis of the DNA methylome has reported large numbers of epigenetic markers associated with human aging. Validation and characterization of the significant findings are necessary both for obtaining reliable results and for better describing the age-associated epigenetic modifications. **Methods:** Based on genome-wide DNA methylation data measured in a large collection of older individuals in the Lothian Birth Cohorts of 1921 and 1936, we performed an association study to identify age-associated CpGs and replicated the findings in two independent cohorts of Danish twins. The double-replicated CpGs were characterized by distribution over gene regions and by their location in relation to CpG islands conditional on their age-dependent patterns of methylation status. The replicated CpGs were further characterized by their involvement in gene-sets or canonical pathways to study their functional implications. **Results:** We identified 67,604 age-associated CpG sites reaching genome-wide significance of  $\text{FWER} < 0.05$ . The double-replication resulted in 5,168 CpGs with more than 60% displaying decreased methylation with increasing age. The replicated CpGs were characterized by high concentration of age-methylated CpGs at 1stExon and TSS200 and a dominant pattern of age-demethylated CpGs at other gene regions, and by overwhelming age-related methylation in CpG island and demethylation at shore/shelf and open sea. Biological pathway analysis showed that age-dependent methylations were especially involved in cellular signalling activities while demethylations were particularly related to functions of the extracellular matrix. **Conclusion:** Extensive epigenetic remodelling in the DNA methylome could be involved in the aging process. The identified age-methylated and demethylated sites displayed differential distribution patterns over genomic regions and were involved in biological pathways closely related to aging phenotypes and age-related diseases.

**1636W****Accelerated epigenetic aging in middle-aged African Americans and**

**Whites.** S. Tajuddin<sup>1</sup>, D. Hernandez<sup>2</sup>, B. Chen<sup>3</sup>, N. Noren Hooten<sup>1</sup>, N. Mode<sup>1</sup>, M. Nalls<sup>2,4</sup>, A. Singleton<sup>2</sup>, A. Zonderman<sup>1</sup>, M. Evans<sup>1</sup>. 1) Laboratory of Epidemiology and Population Sciences, National Institute on Aging, National Institutes of Health, Baltimore, MD; 2) Laboratory of Neurogenetics, National Institute on Aging, National Institute of Health, Bethesda, MD; 3) Translational Gerontology Branch, National Institute on Aging, National Institute of Health, Baltimore, MD; 4) Data Tecnica International, Glen Echo, MD.

Epigenetic changes including DNA methylation are hallmarks of aging. Biological aging rates vary by sociodemographic, genetic, and environmental factors. Epidemiologic studies suggest ethnic minorities manifest significantly greater rates of premature aging phenotypes, but little is known on extent of the molecular aging rate. DNA methylation, which gradually changes across the life course, could be used to predict age. This DNA methylation predicted age (DNAmAge) also called the “epigenetic clock” correlates with chronological age and was shown to be a good marker of biological age. The objective of this study was to identify factors that influence the epigenetic clock in the Healthy Aging in Neighborhoods of Diversity across the Life Span (HANDLS) study. Participants were men and women African Americans and whites above and below poverty status aged between 30 to 64 years. Using the Illumina MethylationEPIC arrays, we measured methylation levels at 866,836 CpG sites in DNA extracted from PBMCs. DNAmAge was calculated in 441 participants using two methods based on 353 and 71 CpG sites described by Horvath and Hannum *et al.*, respectively. Blood cell counts of granulocytes, CD4+T, CD8+T naïve, CD8+CD28-CD45RA-, monocytes, natural killer cells, and plasmablasts were estimated using DNA methylation data to control for the potential confounding effects of blood cell abundance on DNA methylation. We used three measures of epigenetic age acceleration: (1) universal measure of age acceleration (AgeAccel) - residuals after regressing DNAmAge on chronological age; (2) intrinsic epigenetic age acceleration (IEAA) - residuals after regressing DNAmAge on chronological age and blood cell counts; and (3) extrinsic epigenetic age acceleration (EEAA) which captures epigenetic and immune system cell aging rate. DNAmAge using both 353 and 71 CpG sites were strongly correlated with chronological age ( $r=0.85$ ,  $p=3.8E-122$ ). In multiple linear regression models adjusted for age, sex, race, socioeconomic status (SES), and blood cell counts, African Americans had substantially lower EEAA compared to whites ( $\beta=-2.51$ ,  $p=1.33E-07$ ) while men showed significantly higher EEAA compared to women ( $\beta=0.78$ ,  $p=0.04$ ). Similarly, IEAA was higher among men ( $\beta=0.77$ ,  $p=0.08$ ) but not nominally significant. Surprisingly, the universal AgeAccel measure was not associated with race, sex, or SES. In conclusion, race was associated with EEAA while sex was associated with both IEAA and EEAA.

**1637T****Better statistical methods to predict age from DNA methylation.** Q.

Zhang<sup>1</sup>, R. Marion<sup>2,3</sup>, L. Lloyd-Jones<sup>1</sup>, N. Wray<sup>1,4</sup>, I. Deary<sup>2,5</sup>, A. McRae<sup>1</sup>, P. Visscher<sup>1,4</sup>. 1) Institute for Molecular Bioscience, University of Queensland, Brisbane, Australia; 2) Centre for Cognitive Ageing and Cognitive Epidemiology, University of Edinburgh, Edinburgh EH8 9JZ, UK; 3) Medical Genetics Section, Centre for Genomic and Experimental Medicine, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh EH4 2XU, UK; 4) The Queensland Brain Institute, The University of Queensland, St Lucia, QLD 4072, Australia; 5) Department of Psychology, University of Edinburgh, Edinburgh EH8 9JZ, UK.

DNA methylation age of an individual has been proposed as a biomarker for biological aging and a tool for assessing associations with traits. The relationship between experimental sample size, statistical algorithm and prediction accuracy is not well understood. We used 8,561 samples in the age range of 2 to 104 years from 12 Cohorts (11 from blood and 1 from saliva) measured on Illumina HumanMethylation450 arrays and performed cross-validation prediction analyses. We compared age prediction using Elastic Net, Best Linear Unbiased Prediction (BLUP) and BayesR based on Root Mean Square Error (RMSE) and the correlation between predicted age and chronological age. Our results showed that Elastic Net has the smallest average RMSE (5.3 yrs) and highest average correlation between predictor and outcome ( $r=0.94$ ), but BLUP outperforms Elastic Net when the training sample size is over 6,000. Furthermore, we confirmed that increasing the training sample size can achieve smaller RMSE and higher correlations in test data sets. Our predictors have better accuracy than the widely-used Horvath and Hannum age predictors. Our results imply that with training sample sizes of tens of thousands, predictors with an error of less than 4 years can be achieved. As this error is reduced, the scope of real biological ageing becomes revealed.

**Fasting and solar time independently regulate expression of hundreds of genes in skin and fat tissue in population-level transcriptomes.** A. Couto Alves, K.S. Small. Twins Research Genetic Epidemiology, Kings College London, London, London, United Kingdom.

Intermittent fasting, an acute form of diet restriction, is associated with lower risk biomarkers for diabetes, CVD, cancer and ageing. However, few genes have been robustly implicated in the response to fasting in humans and even fewer in the mediation of its putative disease-protective effects. Here we report on a transcriptome-wide association study (TWAS) of gene expression and hours fasting (5-23h) in fat and skin tissue collected from 615 individuals of the TwinsUK registry, and a secondary TWAS with solar time of sample collection. All data were analysed cross-sectionally. We identified 239 and 30 genes whose expression levels associated ( $P < 2 \times 10^{-6}$ ) with the number of hours fasting in fat and skin respectively, with 15 genes common to both tissues. Genes associated to hours of fasting are enriched for the circadian rhythm gene ontology term (Fat  $P = 3 \times 10^{-7}$ , Skin  $P = 5 \times 10^{-12}$ ). The associations between gene expression and hours of fasting are conditionally independent of the time samples were collected, and the enrichment for circadian rhythm genes persists after restricting the analysis to samples collected in the afternoon only ( $N = 390$ ) (Fat  $P = 1 \times 10^{-9}$ , Skin  $P = 3 \times 10^{-6}$ ). The top genes ( $P < 1 \times 10^{-12}$ ) associated to hours of fasting in fat and skin includes *ARNTL*, *C1orf51*, *DBP*, *PER1*, *TEF*, *NR1D1* which are involved in regulation of circadian rhythm. Other genes of considerable interest include *PPARG*, *PIK3R1*, *PTGER4*, *FOXO{1,2,3}*, *HIF3A* and *DDIT4*. A total of 97 and 5 of the genes identified by the TWAS have regulatory variants (eQTL Permutation FWER  $< 0.01$ ), out of which 7 variants (or proxies in LD,  $r^2 > 0.9$ ) are associated ( $P < 5 \times 10^{-8}$ ) with cardio-metabolic and immune-related conditions in GWAS. Of the 239 and 30 genes found in the TWAS of hours fasting, 21 and 3 had GxE eQTL regulatory variants interacting with hours fasting (permutation FWER  $< 0.05$ ) in fat and skin. The solar time TWAS yielded 61 and 18 genes whose expression levels are associated to the time of biopsy collection ( $P < 2 \times 10^{-6}$ ). Solar-time associated genes were also significantly enriched for circadian rhythm as expected ( $P < 4 \times 10^{-11}$  and  $9 \times 10^{-14}$ ). 50 and 9 genes associated with solar-time overlap with hours fasting-associated genes in fat and skin, including: *ARNTL*, *C1orf51*, *CRY2*, *TEF*, *PER1*, *TSC22D3*, *ZBTB16* but their effect is in the opposite direction to hours of fasting. This study contributes to the characterization of the molecular mechanism of response to fasting and solar time in fat and skin in humans.

**Identifying causal mutations with RNA-seq in mice with Mendelian disorders.** N. Raghupathy, B. Harris, S.Y. Karst, W. Martin, H. Fairfield, D.E Bergstrom, L. Reinholdt. The Jackson Laboratory, Bar Harbor, ME.

Exome and whole genome sequencing has been the mainstay of identifying causal mutations in rare Mendelian disorders in human and mice. Although exome and whole genome sequencing have greatly helped us to identify causal mutations, the success rate of discovery is still less than 50%. In a previous study, we used exome sequencing in 172 distinct, spontaneously arising mouse models of Mendelian disorders and identified the causal mutation in 92 strains. Here, we explore the use of transcriptome sequencing to identify causal mutations in strains where exome sequencing failed. We sequenced transcriptomes of relevant tissues with biological replicates in 30 mouse models of Mendelian disorders. And we primarily analyzed splicing aberrations that could be causal for the Mendelian disorder. We used an integrated analysis framework that uses EM algorithm to account for multi-mapping reads and estimated read depth at known and novel splice junctions. Our preliminary analysis shows many cases of putative splicing aberrations and coding mutations that are potentially causative of rare Mendelian disorders.

**Discover regulatory grammar across 127 human cell types using tree-based recurrent neural network.** Z. Zhang, M. Kellis. EECS, Massachusetts Institute of Technology, Cambridge, MA.

The chromatin state or gene expression of a genomic region are highly governed by the regulatory code in the static DNA sequence, and the study of underlining regulatory grammar has been hindered by the lack of large-scale datasets and its complex nature. To understand the regulatory grammar, some shallow learning algorithms (e.g., SVM, RandomForest) were developed using sequence motifs or k-mers to predict chromatin state or gene expression, which only consider motifs co-occurrence statistics and ignore the relative positions and orientation among motifs in the regulatory regions. Biologically, some regulatory elements function as insulators, and the position of insulators can completely change the semantic meaning of the whole regulatory region. Here, we propose a recurrent neural network (RNN) approach, which has been successfully applied in the natural language processing. The RNN approach models the semantic role of each motif, each phase (motif-pair) and each whole sentence (regulatory region) in a unified high-dimension hidden space. More interestingly, we can explore hidden space to identify the different functional clusters of motifs. The interplay among different motif elements in different positions are naturally encoded during the parsing procedure in the RNN, which empowers to learn more complex regulatory grammars than previous approaches. Using back-propagation technique, the RNN can be trained with multiple regulatory outcomes (e.g., different histone marks), so that single regulatory grammar learned by RNN can explain them simultaneously. With simulated datasets, we show our RNN approach can identify not only activators or repressors and but also insulators, and recover regulatory outcome accurately.

Neuron types have been classified by structure, electrophysiology, connectivity and RNA expression with single-cell resolution. Identifying gene regulatory elements that distinguish specific neuron types also requires single-cell resolution. We developed a method for profiling single neuron methylomes to achieve this goal. Epigenomic marks such as cytosine DNA methylation (mC) have highly diverse patterns across brain cell types. Human and mouse brains accumulate high levels of non-CG methylation (mCH) throughout the genome. In addition, neurons contains differential mCH signatures that allow distinguishing neuronal subtypes by low coverage single cell WGBS (whole-genome bisulfite sequencing). To meet the need of large-scale single cell methylome profiling, we developed a novel workflow using Adaptase, the technology underlying the Accel-NGS Methyl-Seq Library Preparation Kit. Through more efficient adapter attachment to bisulfite converted ssDNA, libraries with greater complexity are generated and single cell pooling enables high-throughput library preparation. Single cell methylomes were generated from 6,000 single neuronal nuclei isolated from human and mouse frontal cortex. From <2M reads per nucleus followed by mCH clustering analysis, we identified 16 mouse and 21 human neuronal subpopulations in the frontal cortex. The observed mCG and mCH patterns exhibited neuron type-specific distributions that recapitulated transcriptome signatures. In addition, ~500,000 putative regulatory elements were identified with differential methylation across neuron types which may be drivers of neuron type differences. When comparing mouse and human results, global mCH and mCG levels were strongly correlated between homologous clusters, suggesting evolutionary conservation. This method is applicable to other studies requiring high resolution cell-type identification based on epigenomic patterns.

**1642W****DNA methylation of *TNF* decreases after an intense bout of eccentric exercise.** B. Hussey, D.J. Hunter, L. Wilson, M.R. Lindley, S.S. Mastana.

Translational Chemical Biology Research Group, School of Sport Exercise and Health Science, Loughborough University, Loughborough, Leicestershire, United Kingdom.

**Introduction:** DNA methylation of CpG sites are modified by the environment, lifestyle factors, and have implications for disease progression. Investigating gene targets within inflammatory pathways may provide insight into how a disease can occur and how the burden may be reduced. Here we focused on the methylation profile of the gene encoding the inflammatory cytokine, Tumour Necrosis Factor alpha (TNF $\alpha$ ). Methylation status of *TNF* [MIM 191160] has been associated with inflammatory diseases, such as Crohn's disease, selective neuronal vulnerability, severe systemic inflammation and age-related inflammatory diseases. The aim of this study was to investigate the short-term changes to the percentage of 5-methylcytosines (%5mC) within *TNF* in response to an intense exercise stimuli. **Method:** Untrained healthy males (n=7) performed a bout of intense eccentric exercise (20 sets, 10 repetitions of maximal eccentric bilateral knee extensions). Venous blood samples were collected before exercise (pre), immediately post exercise (PostEx), 1.5, 3 and 48 hours PostEx. DNA was extracted from blood and bisulfite converted using EpiTect LyseAll kit (Qiagen). Methylation of four CpG sites (+202, +207, +219 and +227 bases from the transcription start site) in exon 1 of *TNF* was measured by pyrosequencing with a PyroMark Q48 Autoprep (Qiagen). This region has previously been demonstrated to correlate with circulating TNF $\alpha$  cytokine levels. Data is presented as mean  $\pm$  standard deviation. **Results:** *TNF* exon 1 was hypomethylated at baseline (10.13 $\pm$ 2.15%5mC). There was a significant difference in %5mC across the time course of the study (p<0.001). *TNF* exon 1 methylation levels decreased from pre-exercise levels immediately (10.13 $\pm$ 2.15%5mC vs 8.34 $\pm$ 1.59%5mC) and 1.5 hours PostEx (10.13 $\pm$ 2.15%5mC vs 6.48 $\pm$ 3.02%5mC). Methylation levels were significantly lower than baseline at 3 hours PostEx (10.13 $\pm$ 2.15%5mC vs 5.89 $\pm$ 1.05%5mC, p=0.01). Methylation levels returned towards baseline 48 hours PostEx. **Conclusion:** This investigation indicates a significant change in methylation post exercise and suggests that there are subtle time course responses to the hypomethylated state of the first exon of *TNF*. Further investigations should focus upon delineating this time course and interrogating the impact of reduced methylation state of the *TNF* exon 1 across a range of biological processes.

**1643T****Common DNA sequence variation leads to variation in 3D genome organization.** Y. Qiu<sup>1,2</sup>, D.G. Gorkin<sup>1,3</sup>, M. Hu<sup>4</sup>, A. Noor<sup>2</sup>, A.D. Schmitt<sup>1</sup>, J. Sebat<sup>2</sup>, B. Ren<sup>1,3</sup>.

1) Ludwig Institute for Cancer Research, 9500 Gilman Drive, La Jolla, CA 92093, USA; 2) Bioinformatics and Systems Biology Graduate Program, 9500 Gilman Drive, La Jolla, CA 92093, USA; 3) Department of Cellular and Molecular Medicine, University of California, San Diego, School of Medicine, 9500 Gilman Drive, La Jolla, CA 92093, USA; 4) Department of Quantitative Health Sciences, Lerner Research Institute, Cleveland Clinic Foundation, 9500 Euclid Avenue, Cleveland, OH 44195, USA.

The 3-dimensional (3D) organization of chromatin inside the nucleus is integral to many genomic processes including transcriptional regulation, DNA replication, and X chromosome inactivation. In addition, several recent studies demonstrate that disruption of normal 3D chromatin organization can cause disease. However, little is known about whether 3D chromatin organization varies in the human population, or what impact DNA sequence variation may have on 3D chromatin organization. To address the critical gap in current knowledge, we performed Hi-C (High-Throughput Chromatin Conformation Capture) on Lymphoblastoid Cell Lines from 20 individuals. While 3D chromatin organization is strikingly similar at megabase scale, we found extensive variations (>10% of the genome) in 3D chromatin organization at a finer resolution. Notably, variations in 3D chromatin organization coincide with variations in other genome functions including gene expression, TF binding, and histone modifications in many cases, suggesting that common mechanisms underlie variations in genome function and 3D organization. Moreover, we found several lines of evidence indicating genetic basis of variations in 3D chromatin organization. We found that SNPs associated with variation in genome activity are enriched in regions of variable 3D organization, and that variation in CTCF motifs can alter the strength of 3D chromatin interactions. Furthermore, we generated chromosome-span haplotypes with high accuracy (~98% accuracy) and high resolution (~90% heterozygous SNPs) using Hi-C. We identified thousands of regions showing allelic-specific variations in 3D chromatin organization and found that in some cases allelic-specific regions show transmission from parents to child, suggesting that 3D chromatin organization is a heritable feature of the human genome. In sum, our study addresses an important gap in our knowledge about how 3D chromatin conformation varies in the human population and provides insight into how, at the molecular level, DNA sequence variation can contribute to phenotypic variation and disease risk.

**Chromatin plasticity during hematopoietic cell differentiation and stimulation.** J.V. Ribado<sup>1</sup>, M.L.T. Nguyen<sup>2</sup>, D. Calderon<sup>3</sup>, A. Mezger<sup>1,4</sup>, B. Wu<sup>1</sup>, A. Kathiria<sup>1</sup>, J.K. Pritchard<sup>1,5,6</sup>, L.A. Criswell<sup>1</sup>, W.J. Greenleaf<sup>1,8,9</sup>, A. Marson<sup>1,2,9</sup>. 1) Department of Genetics, Stanford University, Stanford, CA; 2) Department of Microbiology and Immunology, University of California at San Francisco, San Francisco, CA; 3) Program in Biomedical Informatics, Stanford University, Stanford, CA; 4) Laboratory of Molecular Neurobiology, Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden; 5) Department of Biology, Stanford University, Stanford, CA; 6) Howard Hughes Medical Institute, Stanford University, Stanford, CA; 7) Rosalind Russell/Ephraim P. Engleman Rheumatology Research Center, University of California at San Francisco, San Francisco, CA; 8) Department of Applied Physics, Stanford University; 9) Chan Zuckerberg Biohub, San Francisco, CA 94158.

Little is known about genome-wide changes that contribute to mechanisms of hematopoietic stem cell differentiation and plasticity. Thus, we have conducted ATAC-seq on 25 primary immune cell types in both resting and activated conditions from four healthy individuals to study the epigenetic landscape of immune cells during differentiation. We integrated these data with previously published ATAC-seq data of undifferentiated hematopoietic cells. Unsupervised clustering of chromatin accessible regions is sufficient to distinguish progenitor, T cell, and B cell lineages that are enriched for respective master transcription regulator motifs, such as PU.1, SpiB, Runx1, RORyt, Oct2 and PU.1:IRF8. We found that upon stimulation, cells within a lineage are more similar than when compared to their resting state. Additionally, stimulated suppressive regulatory T cells have a higher proportion of overlapping chromatin accessible regions between unstimulated inflammatory T cell subsets. These results suggest that differentiated cells have the flexibility to respond similarly to TCR activation and lineage-specific chromatin stability may be context specific. Understanding the regulatory structure of immune cells during differentiation and stimulation is important in elucidating the etiology of inflammatory diseases and identifying subsequent targets for therapeutic manipulation.

**Pleiotropic effects of trait-associated genetic variation on DNA methylation: Utility for refining GWAS loci.** E. Hannon<sup>1</sup>, T. Gorrie-Stone<sup>2</sup>, M. Smart<sup>2</sup>, M. Weedon<sup>1</sup>, N.J. Bray<sup>3</sup>, M.C. O'Donovan<sup>3</sup>, M. Kumari<sup>2</sup>, L.C. Schalkwyk<sup>2</sup>, J. Mill<sup>1</sup>. 1) University of Exeter Medical School, University of Exeter, Exeter, United Kingdom; 2) University of Essex, Wivenhoe Park, Colchester, Essex, CO4 3SQ; 3) MRC Centre for Neuropsychiatric Genetics and Genomics, Cardiff University School of Medicine, Cardiff, CF24 4HQ, UK.

Most genetic variants identified in genome-wide association studies (GWAS) of complex traits are thought to act via effects on gene regulation rather than directly altering the protein product. As a consequence, the actual genes involved in disease are not necessarily the most proximal to the associated variants. By integrating data from GWAS analyses with that from genetic studies of regulatory variation, it is possible to identify variants pleiotropically-associated with both a complex trait and measures of gene regulation. In this study, we use Summary data-based Mendelian Randomization (SMR), a method developed to identify variants pleiotropically associated with both complex traits and gene expression, to identify variants that are associated with complex traits and DNA methylation. Building on our previous efforts, we increased our catalogue of DNA methylation quantitative trait loci (mQTL) in whole blood by taking advantage of the latest microarray technology, the Illumina EPIC Beadchip array, profiling DNA methylation at over 800,000 genomic loci. These data were used to prioritize genes for >40 complex traits with robust GWAS data, highlighting overlap with the results of SMR analyses performed using expression QTL (eQTL) data. We identify multiple examples of variable DNA methylation associated with GWAS variants for a range of complex traits, demonstrating the utility of this approach for refining genetic association signals, and highlighting the novel insights the EPIC array provides over previous technologies.

**Fine mapping of interacting functional elements in Hi-C peaks.** *A.T. Jaroszewicz, J. Ernst.* University of California, Los Angeles, Los Angeles, CA.

The advent of high-throughput chromatin conformation assays such as Hi-C has enabled genome-wide detection of long-range chromatin contacts, which are integral to various regulatory mechanisms, including enhancing transcription and demarcating topologically associating domains. However, even ultra-deep sequencing cannot robustly identify specific interacting loci or provide biological interpretation due to its coarse resolution, generally on the order of 5-25kb in most ENCODE cell types. Here, we present a novel computational method to fine map these broad interactions to their functional elements.

Using transcription factor and histone mark ChIP-seq data, which has a much finer resolution, we train a deep neural network (DNN) to discern between true interactions and permuted ones. We then use a masking algorithm along with this DNN to predict which fine-resolution regions (on the order of 100bp) are most important to the Hi-C predicted interaction. This method allows us to assign each pair of subregions in the broad domains a score that corresponds to the importance of its role in the interaction. In contrast to other methods, our method is not limited to certain types of interactions such as promoter-enhancer pairs, but any protein-mediated interaction with available ChIP-seq data. These results can be used to discover novel types of interactions, provide a biological interpretation of interactions, prioritize GWAS hits, and reduce the need for expensive, deeply-sequenced Hi-C experiments. In our preliminary results, we show that our predictions are enriched for promoter-enhancer and cohesin interactions. We validate computationally by taking finer resolution Hi-C peak calls, extending them, and showing that we preferentially recover the original peak. We also compare these predictions to Promoter Capture Hi-C and other fine-resolution chromatin interaction assays.

**Comprehensive functional annotation of the zebrafish genome.** *T. Liu<sup>1</sup>, H. Yang<sup>1</sup>, Y. Wang<sup>1</sup>, G. Gerhard<sup>2</sup>, D. Balciunas<sup>2</sup>, F. Yue<sup>1</sup>.* 1) Dept. Biochemistry and Molecular Biology, Pennsylvania State University College of Medicine, Hershey, PA.17033; 2) Dept of Biology, Temple University 1900 North 12th Street Philadelphia, PA 19122; 3) Dept of Medical Genetics and Molecular Biochemistry, Temple University Room 621 Kresge Hall Philadelphia, PA 19140.

Zebrafish has been widely used for the study of human diseases, as ~70% of the protein-coding genes are conserved between the two species. Moreover, zebrafish embryos are transparent and thus can serve as an ideal model for genetic studies in animal development. Surprisingly, the functional annotation of zebrafish genome itself has been severely lagging when compared with other model systems such as mouse and drosophila. Here we took a similar approach adopted by the ENCODE and Roadmap Epigenomics projects, and performed RNA-Seq and ChIP-Seq for several histone modifications to generate a comprehensive map of transcriptomes and regulatory elements in a variety of zebrafish tissues, including brain, heart, liver, skeletal muscle and kidney. We predicted over 100,000 cis-regulatory elements in the zebrafish genome, the most comprehensive functional annotation effort in zebrafish so far to our knowledge. We also identified tissue-specific and developmental stage-specific regulatory elements. By comparing the data generated by the ENCODE and Roadmap Epigenomics projects, we also defined a set of functionally conserved and species-specific regulatory sequences among zebrafish, mouse and human. In summary, we generated a great genomics/epigenomics resource for the functional annotation in the vertebrate genomes and further expanded the value of zebrafish as a model of human disease.

**DNA methylation and its impact on inter-population differences in disease risk and prognosis.** M. Loh<sup>1,2,3</sup>, F.L. Tai<sup>1</sup>, M. Kalra<sup>1</sup>, S. Tan<sup>4</sup>, F.F. Gan<sup>4</sup>, W.Y. Saw<sup>5</sup>, R. Soong<sup>4,6</sup>, Y.Y. Teo<sup>5,7,8,9,10,11</sup>. 1) Translational Laboratory in Genetic Medicine (TLGM), Singapore, Singapore; 2) Department of Biochemistry, National University of Singapore, Singapore; 3) Department of Epidemiology and Biostatistics, Imperial College London, London, UK; 4) Cancer Science Institute of Singapore, National University of Singapore, Singapore; 5) Saw Swee Hock School of Public Health, National University of Singapore, Singapore; 6) Department of Pathology, National University Hospital, Singapore; 7) Genome Institute of Singapore, Agency for Science, Technology and Research, Singapore; 8) Singapore Eye Research Institute, Singapore National Eye Centre, Singapore; 9) National University of Singapore Graduate School for Integrative Science and Engineering, National University of Singapore, Singapore; 10) Life Sciences Institute, National University of Singapore, Singapore; 11) Department of Statistics and Applied Probability, National University of Singapore, Singapore.

Epigenetic mechanisms such as DNA methylation play a key role in the regulation of numerous biological processes including gene expression and cellular differentiation, with altered methylation shown to be associated with complex human diseases such as cancer and diabetes. However, to date, little is known about variation in DNA methylation between ethnic populations. In this study, we measured methylation in DNA extracted from peripheral blood from 287 healthy individuals (102 Chinese, 87 Malays and 98 Indians) using the Illumina Infinium MethylationEPIC BeadChip which covers >850,000 methylation sites at single-nucleotide resolution. White blood cell subsets were imputed using the Houseman method, with regression analysis used to quantify the associations between methylation and ethnicity status, and adjustment for technical and biological confounding. A total of 1,122 CpG sites were differentially methylated between any two of the three ethnic populations at  $p < 1E-7$ , with 619 sentinel CpG sites remaining after clumping at  $\pm 500$ kb. Among these sentinel CpG sites, 99.8% were significantly differentially methylated between Chinese and Indians, 85.0% between Malays and Indians and only 1.6% were significantly different between Chinese and Malays. Taking a global approach with unsupervised hierarchical clustering, we observed two distinct clusters, with Indians forming a cluster of its own, while the other cluster consisted of Malays and Chinese individuals. This observation was consistent with previous findings from genetic studies. The top hit was located nearest to the gene *VKORC1*, which encodes for the enzyme Vitamin K epoxide Reductase Complex (VKORC) subunit 1. Mutations in this gene are well established to be associated with deficiencies in vitamin-K-dependent clotting factors, with resistance to warfarin previously reported to exhibit ethnic differences in maintenance dose requirements, including between Singapore Chinese, Malays and Indians. Other top hits include genes associated with diseases known to demonstrate ethnic differences in risk and prognosis such as Type 2 Diabetes, insulin resistance and other metabolic disturbances, various cancer types (breast and lung cancer), as well as neurological disease such as Parkinson's. Taken together, preliminary findings from our study suggest that differences in methylation profiles between ethnic populations could potentially account for differences in disease risk, prognosis and response.

**X-chromosome epigenetic markers for age-prediction.** I.C.T. Mello<sup>1</sup>, A.E. Woerner<sup>2</sup>, J. King<sup>2</sup>, B. Budowle<sup>2,3</sup>, R. Moura-Neto<sup>4</sup>, R. Silva<sup>1</sup>. 1) Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; 2) Center for Human Identification, University of North Texas Health Science Center, Fort Worth, Texas, US; 3) Center of Excellence in Genomic Medicine Research (CEGMR), King Abdulaziz University, Jeddah, Saudi Arabia; 4) Instituto de Biologia, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

The epigenetic modifications play a significant role in the regulation of gene expression. Epigenetic patterns can be stable, as they are often preserved during cell division, or they may be transient, and change over an individual's lifetime. With respect to the latter, recent studies have shown that many CpG regions are subject to methylation changes according to the aging process and many autosomal epigenetic markers have been proposed as an age predictor for forensic samples. In order to achieve dosage compensation, one of the two X chromosomes in females is inactivated and these difference in regulation throughout the development generate variability that could be informative as an epigenetic marker. In this study, we investigated the usefulness of methylation status of the X chromosome for age-prediction. We investigated and tested the performance of X chromosome markers using methylation data from three different sources. The first two sources were produced using Illumina Infinium Human Methylation450k Beadchip taken from two separate populations. Identification of age-associated methylation markers was performed by regularized linear regression, using the least absolute shrinkage and selection operator on the data from Hannun et al (GSE40279). We then validated the performance of the 51 markers identified in this process using robust linear regression, as a linear function of age, to predict age using the samples in Liu et al (GSE4286). Our markers were highly predictive of age ( $R^2 = 0.83$ ). Next we selected new 30 CpG islands across the X-chromosome located (1) on gene sites, (2) next to genes sites (<50,000bp of distance) and (3) far from genes sites (>50,000bp of distance) to investigate age-related methylation sites. Our results showed that 51 markers found, in 33 CpG regions have the potential to be used as age predictor in male samples. A group of 150 unrelated male subjects between 20 and 60 years of age from an admixture population were selected and will be tested with these methylation markers applying bisulfite conversion DNA treatment and multiple parallel sequencing technologies. Funding: CAPES, CNPq.

**Genomic DNA methylation changes in myalgic encephalomyelitis.** L. Sarria<sup>1</sup>, M.S. Trivedi<sup>2</sup>, E. Oltra<sup>3</sup>, K. Bauckman<sup>1</sup>, M.A. Fletcher<sup>1</sup>, N.G. Klimas<sup>1</sup>, L. Nathanson<sup>1</sup>. 1) INIM, College of Osteopathic Medicine, Nova Southeastern University, Fort Lauderdale, FL, USA; 2) College of Pharmacy, Nova Southeastern University, Fort Lauderdale, FL, USA; 3) Universidad Catolica de Valencia, C/Quevedo 2, 46001 Valencia, Spain.

**Background:** Myalgic Encephalomyelitis (ME) is a complex condition that is associated with a variety of symptoms including fatigue, memory problems, muscle and joint pain, gastrointestinal issues, neurological problems, hormonal imbalance and immune dysfunction. Currently, treatment relies solely on symptom management but does not address the underlying mechanisms of disease. Our previous research efforts have shown that the transcriptional regulation altered the phenotypic nature of ME. DNA methylation is one of the epigenetic mechanisms that regulates gene transcription without changes in the DNA sequence. It involves the covalent binding of a methyl group to a Cytosine-5 at a C-phosphate-G (CpG) site. Negative associations between methylation and transcription are known to be enriched particularly in promoter regions. **Objectives:** To provide insight into the biological mechanisms of ME, the main objective of this research is to identify novel mechanisms of transcriptional regulation. While previous research efforts in ME have focused on targets further down the pathways that have involved enzyme activation, our research efforts focus at the higher end of the signaling pathway. **Methods:** We evaluated levels of DNA methylation in peripheral mononuclear blood cells isolated from 13 female CFS patients (ME diagnosis was based on the Fukuda and the Canadian criteria) and 12 matching by age and BMI female healthy controls using Illumina MethylationEPIC BeadChip arrays, controlling for the probes with the low detection, invariant probes and probes overlapping polymorphic sequences. DNA methylation analysis was performed using R software with RnBeads package. The mean difference in means across all sites in a region of the two groups, the mean of quotients in mean methylation and combined p-values calculated from all site p-values in the region were used to rank the degree of the differential methylation. **Results:** We found an increased abundance of hypomethylated promoters of genes related to the immune functions, cancer, cellular bioenergetics, neuronal functions in the cells of ME patients. The results have been validated by pyrosequencing using extended cohort of 34 patients and 34 healthy controls. **Conclusion:** This data show the importance of the DNA methylation in the regulation of the changes in gene expression in ME.

**Wnt signaling in neural crest development: A possible mechanism for nonsyndromic cleft lip and palate.** A. Vedenko<sup>1,2</sup>, J.I. Young<sup>1</sup>, K.E. Hatzistergos<sup>2</sup>, S.H. Lang<sup>1</sup>, D. Van-Booven<sup>1</sup>, J.M. Hare<sup>2</sup>, J.T. Hecht<sup>3</sup>, S.H. Blanton<sup>1</sup>. 1) John P. Hussman Institute for Human Genomics, Miller School of Medicine, University of Miami, Miami, FL, Miami, FL; 2) Interdisciplinary Stem Cell Institute, Leonard M. Miller School of Medicine, University of Miami, Miami, FL; 3) Department of Pediatrics, McGovern Medical School, University of Texas Health, Houston, TX.

Nonsyndromic cleft lip, with or without palate (NSCLP), is the most common craniofacial birth defect. Although both genetic and epigenetic factors have been associated with NSCLP, the molecular mechanisms underlying these defects remain poorly understood. Discordant monozygotic (MZ) twins provide a unique opportunity to dissect the underlying causes of complex diseases. Applying this approach, we performed methylation analysis of 3 MZ twin pairs discordant for NSCLP using whole genome bisulfite sequencing (WGBS) on saliva DNA. Two pairs were also subjected to methylation array analysis for validation purposes. We identified significantly distinct methylation patterns within twin pairs. Notably, GO and KEGG analysis, based on differentially methylated genes, revealed an enrichment in cell adhesion-related ontologies and pathways. It is well known that cell adhesion and migration are regulated via Wnt signaling pathways and downstream effectors. Importantly, variation in Wnt genes has been associated with NSCLP. Neural crest cells (NCC) contribute extensively to the formation of head structures including the palate through migration and population of branchial arches. Thus, abnormalities of NCCs are associated with numerous craniofacial defects. These findings lead us to hypothesize that epigenetic perturbations in NCC could be involved in the development of NSCLP, potentially through Wnt signaling alterations. We utilized *Sox10::GFP* reporter human embryonic stem cell line (*Sox10::GFP* hESCs) as an *in vitro* model of human NCC development. We found that canonical Wnt signaling was important for the development of *GFP+* human-NCCs. Activation of Wnt with the GSK3 inhibitor CHIR99021 significantly induced the expression of DNMT1, and to a lesser extent of DNMT3A and DNMT3B, in a dose-dependent manner. Conversely, expression of DNMT1 was significantly downregulated in response to treatment with the porcupine inhibitor IWP2. Moreover, these changes were accompanied by significant differences in the expression of cell adhesion genes, such as CDH1. Together, these correlative findings suggest that NSCLP is associated with changes in methylation of cell adhesion genes, and that canonical Wnt signaling-mediated induction of DNMT1 may be an underlying mechanism of this process. Future studies are underway to confirm these results and determine the role of DNMT1 in epigenetic regulation of human NCCs.

**Shared household environment makes an important contribution to variation in the human methylome.** Y. Zeng<sup>1</sup>, P. Navarro<sup>1</sup>, C. Xia<sup>1</sup>, A. Tenesa<sup>2</sup>, D. Sproul<sup>1</sup>, R. Walker<sup>3</sup>, R. Marioni<sup>3</sup>, S. Morris<sup>3</sup>, K. Rawlik<sup>3</sup>, C. Amador<sup>1</sup>, O. Canela-Xandri<sup>2</sup>, C. Hayward<sup>1</sup>, A. Campbell<sup>3</sup>, R. Nagy<sup>4</sup>, I. Deary<sup>4</sup>, D. Porteous<sup>3</sup>, K. Evans<sup>3</sup>, A. McIntosh<sup>5</sup>, C. Haley<sup>1</sup>. 1) MRC human genetic unit, IGMM, University of Edinburgh, EDINBURGH, United Kingdom; 2) The Roslin Institute and Royal (Dick) School of Veterinary Sciences, University of Edinburgh, UK; 3) Centre for Genomic and Experimental Medicine, Institute of Genetics and Molecular Medicine, University of Edinburgh, Edinburgh EH4 2XU, UK; 4) Department of Psychology, University of Edinburgh, UK; 5) Division of Psychiatry, University of Edinburgh, Edinburgh, UK.

DNA methylation levels at individual sites have been associated with many traits and diseases. To understand the regulatory pathways through which DNA methylation modulation may affect the phenotype, it is important to understand the genetic and environmental determinants of variation in DNA methylation levels. In this study we analysed data from a large family-based cohort (Generation Scotland, N=5200) with DNA methylation in blood measured at ~790,000 sites, genome-wide genotyping of ~500,000 common SNPs, family relationships from complex pedigrees and multiple disease and phenotypic measurements for each participant. We dissected the variation in methylation level at individual sites into genetic and family environmental contributions using variance component analysis. The average heritability, measuring the whole genome contribution to variation across all methylation sites was 19.2% (2.5<sup>th</sup>/97.5<sup>th</sup> percentile: 7.1%/70.8%). The mean contribution of the environment shared by a couple to variation in methylation levels was 4.1% (2.5<sup>th</sup>/97.5<sup>th</sup> percentile: 0%/18.8%) across all measured sites. An elevated contribution from the couple-shared environmental component and a decreased contribution from the genetic component to methylation levels was found close to transcription start sites (TSS) for genes with high levels of expression in blood. Couple-shared environment explained an average of 8.2% (2.5<sup>th</sup>/97.5<sup>th</sup> percentile: 0%/24.5%) of the variance of methylation at sites that were within a CpG Island-located transcription factor binding site (TFBS) within 200 bp of the TSS for the 20% most highly expressed genes in blood. This study identifies important contributions from genetics and couple-shared environment to DNA methylation. Our results further suggest that regulatory regions (TSS, TFBS and CpG Islands) of expressed loci may be especially susceptible to environmental modulation of methylation which could have potential consequences for subsequent phenotypic variation. This work is supported by the UK Medical Research Council, Wellcome Trust (104036/Z/14/Z), and Chief Scientist Office funding (CZD/16/6).

**Rare variants and parent-of-origin effects on whole blood gene expression assessed in large family pedigrees.** A. Brown<sup>1</sup>, A. Viñuela<sup>1</sup>, A. Martínez-Perez<sup>2</sup>, A. Ziyatdinov<sup>2</sup>, M. Sabater-Lleal<sup>3</sup>, A. Hamsten<sup>3</sup>, J. Souto<sup>4</sup>, A. Buil<sup>1</sup>, J. Soria<sup>2</sup>, E. Dermitzakis<sup>1</sup>. 1) Department of Genetic Medicine and Development, University of Geneva Medical School, Geneva, Switzerland; 2) Unit of Genomics of Complex Diseases, Biomedical Research Institute Sant Pau (IIB-Sant Pau), Barcelona, Spain; 3) Karolinska Institute, Medicine, Stockholm, Sweden; 4) Sant Pau Hospital, Hematology, Barcelona, Spain.

Studying genetic regulation of gene expression in related individuals provides insights inaccessible when using unrelated individuals, such as heritability, rare (in population) regulatory variants commonly observed in the pedigree, imprinting, and parent-of-origin effects. We report the GAIT2 study of 935 individuals from 35 pedigrees, with whole blood RNA-seq, blood cell count and extensive phenotypic information available. We identified 11,297 eQTLs (FDR=0.01) using a cis association mapping with variance components to consider the family structure. To test whether these eQTLs were rare in the general population, we looked at their MAF in 1000 Genomes populations. Compared to eQTLs from the DGN study with 922 unrelated individuals, we see an excess of variants with MAF<0.01 (9.6% eQTL vs 0%, median MAF is 0.11 vs 0.27). We used trios within the pedigrees to find parent-of-origin effects on expression, where the effect of an allele depends on whether it is maternally or paternally inherited (parent-of-origin eQTL or poeQTL). A cis scan revealed 12 significant poeQTLs (FDR<0.05). Six of these affect known imprinted genes, implying a cis-eQTL with effect masked on the imprinted haplotype. However, for four other poeQTL genes, measures of allelic ratio from either our data or the GTEx study showed a combination of mono- and bi-allelic expression across individuals, suggesting these genes may be partially imprinted (the other two genes had no allelic ratio calls). We are currently producing higher coverage RNA-seq data for a subset of individuals, to associate partial imprinting with genetic variation and produce a genome-wide assessment of imprinting in general. Both rare variants and parent-of-origin genetic effects have been shown to be relevant for human disease. Studies such as this allow a deeper understanding of their properties, for example revealing that exclusively studying imprinted regions will miss many parent of origin effects.

**1654W**

**Stratified comparison and network analysis of large eQTL-studies reveals factors affecting validity of cis- and trans eQTLs.** *H. Kirsten*<sup>1,2</sup>, *R. Burkhardt*<sup>2,3</sup>, *J. Thiery*<sup>2,3</sup>, *K. Krohn*<sup>4</sup>, *M. Loeffler*<sup>1,2</sup>, *M. Scholz*<sup>1,2</sup>. 1) Medical Faculty / IMISE, University Leipzig, Leipzig, Germany; 2) Medical Faculty / LIFE, University Leipzig, Leipzig, Germany; 3) Medical Faculty / ILM, University Leipzig, Leipzig, Germany; 4) Medical Faculty / IZKF, University Leipzig, Leipzig, Germany.

Associations of genetic variants with gene expression levels (eQTL studies) are increasingly used in the elucidation of the human genetic architecture and causal molecular mechanisms of genetically influenced complex traits and diseases. Typically, eQTL studies are done independently from a certain GWAS that uses the eQTL information. Hence, it is important to understand factors affecting validity of reported eQTLs. Recently, the so far largest single eQTL study done with 5,257 individuals (Joehannes 2017, DOI: 10.1186/s13059-016-1142-6) done in whole blood reported replication rates for trans eQTLs down to 5.2%. However, systematic differences between studies might explain these low numbers, e.g. gene-expression measurement technology, effect size of eQTLs, sample size of the studies, and tissue type. We present novel data of two large eQTL studies (total n=6,741) done in two tissues (PBMC and whole blood) to unravel factors influencing replication rates of cis/trans effects. Factors analyzed include tissue type, technology, sample size, eQTL-effect size, known GWAS association of eQTL-SNPs (i.e. potential functional relevance) and network properties (using the framework of a bipartite eQTL-network). We identify power, namely eQTL-effect size as very critical factors especially for trans-eQTLs replication rate followed by tissue type with up to tenfold higher trans-replication rates than originally reported in the FHS-study. We observe that GWAS-related cis-eQTLs show roughly comparable replication rates whereas GWAS related trans-eQTLs, shows considerably higher replication than the respective non-GWAS related eQTLs. Interestingly, correspondence rate of the direction for eQTLs between our study and the FHS study was even higher for trans-eQTLs than for cis-eQTLs. This difference might be explained by different gene expression technologies (Affymetrix exon array vs. Illumina HT12v4 array) hinting to specific effects of different splice variants of a certain gene. Furthermore, we find similar eQTL-network properties across both studies. Our results contribute to the understanding of the genetic architecture of eQTLs and are important for the interpretation of GWAS results when using data from external eQTL studies.

**Glomerular and tubulointerstitial eQTLs of patients with nephrotic syndrome.** *R. Putler*<sup>1</sup>, *X. Wen*<sup>2</sup>, *C.E. Gillies*<sup>1</sup>, *M.G. Sampson*<sup>1</sup>, *Nephrotic Syndrome Study Network (NEPTUNE)*. 1) Pediatrics-Nephrology, University of Michigan, Ann Arbor, MI; 2) Biostatistics, University of Michigan, Ann Arbor, MI.

**Background** Using intrarenal mRNA expression as molecular phenotypes in expression quantitative trait loci (eQTL) studies of nephrotic syndrome (NS) can lead to the discovery of transcripts under significant genetic control, reveal novel NS-related biology, and identify loci associated with clinically meaningful outcomes. To describe the intrarenal eQTL landscape of NS, we paired whole genome sequencing with glomerular (GLOM) & tubulointerstitial (TI) transcriptomes from patients in the Nephrotic Syndrome Study Network (NEPTUNE). **Methods** NEPTUNE is a prospective, longitudinal study of NS enrolling affected adults and children receiving a clinically indicated biopsy. Rich demographic, clinical, and genomic data is collected and GLOM and TI transcriptomes are derived from a microdissected research biopsy core. We used the Bayesian "Deterministic Approximation of Posteriors" (DAP) to fine-map eQTL signals within each locus while controlling for multiple testing. DAP uses linkage disequilibrium and annotation information to determine independent eSNPs within an eQTL locus. We included age, sex, PEER factors, & the 1st 4 principal components as covariates. We utilized MatrixEQTL for the same data to gain insight into direction of effect for these signals. **Results** At genome-wide significance, we discovered 340 independent eQTL signals in 313 unique genes in GLOM and 862 independent signals in 772 unique genes in TI. *PLCG2*, previously implicated in steroid sensitive NS via burden testing, was one of the strongest glomerular eQTLs. Five of 30 Mendelian NS genes had both a GLOM eQTL and a significant association with eGFR, suggesting that non-Mendelian variation in these genes can impact clinical outcomes. We find 14% and 28% of identified eQTLs are GLOM-specific and TUB-specific, respectively, and 58% of eQTLs are shared between the two tissues. When we compared the significance of GLOM- & TI-eQTLs with those derived from blood (from GTeX), 19% of eQTLs had more significant minimum p-value in GLOM & TI vs blood, despite smaller sample size. **Conclusions** In our GLOM & TI eQTL study of NS patients, we discovered genes under substantial genetic control and can now pursue their biologic & clinical correlates. Making this NS eQTL database publicly available could be a useful resource to inform future molecular & epidemiologic studies of NS.

**Epigenetic marks at major histocompatibility complex affect male fertility.** S. Sarkar, R. Singh. Endocrinology Division, CSIR-Central Drug Research Institute, Sector 10, Jankipuram Extension, Sitapur Road, Lucknow, Uttar Pradesh 226031.

Human leucocyte antigens are membranous glycoproteins playing salient role in immune recognition and response. The expression pattern of HLA class antigens is dubious in nature. However, quite a number of studies have reported the expression of HLA class molecules. Trophoblastic *HLA-C* gene variants have been shown to be associated with pre-eclampsia in African and European women. Maternal *HLA-C* genetic variants are also seen to have effect on high fetal and maternal mortality and morbidity. HLA class 1 molecules were found to be expressed in spermatozoa of infertile patients but showed no significant difference against fertile groups. On the other hand, it was found that mRNA levels of *HLA-G* in normal spermatozoa were significantly higher than the testicular samples with only Sertoli cells and/or spermatogonia, which suggests its involvement in spermatogenesis. A study observed that the predisposition to anti-sperm antigen can increase the levels of some HLA class-1 antigen in vasectomized men. A whole genome epigenetic study on adolescent chemotherapy patients causing infertility also showed differential methylation pattern in *HLA-C* gene. We investigated differential methylation regions present in different classes of *HLA* in patients with different sperm count in order to correlate epigenetic patterns with sperm production ability. To achieve this objective, our experimental method included isolation of sperm DNA from individuals of various sperm count groups followed by Infinium 450K DNA methylation array. Among these groups we have indentified six different classes of *HLA* genes to be differentially methylated. *HLA* class I genes showed higher level of methylation in oligospermic group as compared to normospermics, suggesting the potential role of these genes in spermatogenesis. Similar methylation pattern was also seen in DNA from PBMCs. Out of all immune response gene only *HLA-DRB1* showed disparate methylation pattern in oligospermics (b-value=0.345) than normal men (b-value=0.679). This DNA methylation pattern suggests an important role of these immune responsive genes in sperm production. These observations opened a valuable insight into the cause of infertility which directs the focus to select best sperm for fertilization success. However, more epigenetically focused experimental designs are warranted to draw conclusive insights and theories about the role of immune response genes and reproductive health.

**Low correlation observed between DNA methylation in blood measured between a majority of CpG sites measured on both Illumina 450K and EPIC BeadChips.** M.W. Logue<sup>1,2,3</sup>, A.K. Smith<sup>4,5</sup>, E.J. Wolf<sup>1,2</sup>, H. Maniates<sup>1</sup>, A. Stone<sup>6</sup>, S.A. Schichman<sup>6</sup>, R.E. McGlinchey<sup>7,8</sup>, W. Milberg<sup>7,8</sup>, M.W. Miller<sup>1,2</sup>. 1) National Center for PTSD, VA Boston Healthcare System, Boston, MA; 2) Department of Psychiatry, Boston University School of Medicine, Boston, MA; 3) Biomedical Genetics, Boston University School of Medicine, Boston, MA; 4) Gynecology and Obstetrics, Emory University School of Medicine, Atlanta, GA; 5) Department of Psychiatry and Behavioral Sciences, Emory University, Atlanta, GA; 6) Pharmacogenomics Analysis Laboratory, Research Service, Central Arkansas Veterans Healthcare System, Little Rock, AR; 7) Geriatric Research Educational and Clinical Center and Translational Research Center for TBI and Stress Disorders, VA Boston Healthcare System, Boston, MA; 8) Department of Psychiatry, Harvard Medical School, Boston MA.

BeadChips are the de-facto instrument of choice for genome-wide epigenological investigations of DNA methylation. Many researchers are working with data generated using the Illumina Infinium HumanMethylation450 BeadChip, which measures the proportion of methylated DNA (denoted  $\beta$ ) at nearly 500,000 CpG sites. This chip was recently discontinued and replaced with the Illumina MethylationEPIC BeadChip, which assesses methylation at nearly 850,000 CpG sites, including 90% of sites assessed in the 450K chip. We examined the concordance between 422,524 CpG sites measured by both chips in 145 whole blood DNA samples. The correlation of  $\beta$  values at most sites was quite low; the median correlation for a CpG was  $r=0.15$ , (range  $r=-0.34$  to  $r=0.95$ ). Only 23% had correlation values  $> 0.50$ . We then investigated the association between the number of beads per site, missing rate, and range of observed  $\beta$  values and the correlations for each CpG, with separate models for sites depending on the Beadchip Assay used (Type I or II). For Type I probes, there was a strong positive association between the  $\beta$  range and CpG correlation and with a quadratic effect indicating downward curvature. The other model terms were significant ( $p < 2.2 \times 10^{-16}$ ), but had less of an effect. A comparison of the multiple  $r^2=0.63$  for the full model compared to the multiple  $r^2=0.0048$  for a model excluding the  $\beta$  range variables indicated that the majority of the variance in correlation for the CpG sites was explained by the amount of variability in  $\beta$  values. Results were similar for type II probes. The vast majority of sites with  $\beta$  range  $< 0.05$  had low correlation values (median correlation  $r=0.031$ ), and most were nearly completely methylated or unmethylated (95.81% had a median methylation value  $< 0.05$  or  $> 0.95$ ). The correlation was higher for CpGs with a greater  $\beta$  range. For the CpGs that had a  $\beta$  range of greater than 0.20 ( $n=61,248$ ), the median correlation was  $r=0.71$ . An examination of the intraclass correlation coefficient based on 11 DNA samples assessed repeatedly with the EPIC chip indicated that ICC values depended on the  $\beta$  range ( $p < 2.2 \times 10^{-16}$ ), indicating that ICC values may also be reduced in single-chip studies. Low correlation observed at sites with a small range may be due to the larger proportion of measurement error compared to true signal. Filtering out probes based on the observed correlation or the low variability may increase reproducibility of BeadChip-based methylation studies.

**1658T****DNA methylation of *PPARGC1A* is associated with cycling performance.**

D.J. Hunter, B. Hussey, L. Wilson, M.R. Lindley, S.S. Mastana. Translational Chemical Biology Research Group, School of Sport Exercise and Health Sciences, Loughborough University, Loughborough, UK.

**Introduction:** Exercise and nutritional interventions, such as n-3 polyunsaturated fatty acids (n-3 PUFAs), have been shown to alter DNA methylation and expression of genes involved in metabolism and inflammation. Peroxisome proliferator-activated receptor gamma co-activator 1-alpha encoded by the *PPARGC1A* gene [MIM 604517] regulates exercise adaptation in skeletal muscle via activation of pathways for mitochondrial biogenesis and *PPARGC1A* mRNA expression is linked to inflammation by an inverse correlation with interleukin-6 mRNA. Skeletal muscle *PPARGC1A* is shown to be hypomethylated post exercise; however, it is unknown if this response is tissue specific. The aim of the investigation was to determine if hypomethylation of *PPARGC1A* occurs in blood post exercise and if n-3 PUFAs modulate the response. A second aim was to assess if DNA methylation of *PPARGC1A* associated with phenotypes related to exercise and inflammation. **Method:** Eight male cyclists completed 4 trials, each separated by 4-weeks. Supplementation of n-3 PUFA or olive oil separated the trials, using a double-blind, randomised repeated measures design. Blood samples were collected pre and post a 1h cycling performance test (45 min steady state and 15 min time trial) during each trial. DNA was extracted and bisulfite converted using EpiTect LyseAll kit (Qiagen) and methylation of a CpG -260 bases from the *PPARGC1A* transcription start site was quantified using a Pyromark Q48 Autoprep. **Results:** *PPARGC1A* -260 CpG methylation was unaltered by exercise or supplementation. After correction for cell heterogeneity, a significant decrease in methylation post exercise was detected ( $p < 0.05$ ). Baseline and post-exercise methylation was positively correlated with mean power ( $R > 0.449$ ;  $p < 0.010$ ), and work completed ( $R > 0.396$ ;  $p < 0.024$ ) during the time trial. After correction for cell heterogeneity the correlations with post-exercise *PPARGC1A* methylation and performance remain significant ( $p < 0.05$ ). **Conclusion:** Decreased *PPARGC1A* methylation post exercise in blood, after correction for white blood cell populations, suggests that exercise induced hypomethylation may not be tissue specific. A positive correlation shown between methylation and cycling performance indicates that methylation can affect performance. Comparative studies of skeletal muscle and blood are required to delineate any tissue specificity to determine the efficacy of using blood as a proxy for skeletal muscle in methylation studies.

**1659F****Exploratory transcriptome and methylome analysis in Gilbert's syndrome.**

Unconjugated bilirubin (UCB) is an endogenous metabolite in mammals; its circulating concentration is regulated by the hepatic expression of uridine diphosphate glucuronosyltransferase (UGT1A1). In humans, variants in the UGT1A1 gene lead to reduced enzyme activity, resulting in a moderate increase in circulating UCB beyond the range found in normal serum. Gilbert's Syndrome is one common that arises from homozygosity of variant-carrying UGT1A1 alleles (UGT1A1\*28). While hyperbilirubinemia has been associated with a beneficial metabolic and aging phenotype, much less is known on the effects of UCB on cellular processes. The aim of this exploratory analysis is to identify changes in the epigenomic and transcriptomic regulation that might be driven by acute and chronic hyperbilirubinemia. To this end, reduced representation bisulfite sequencing (RRBS) was performed on peripheral blood samples from an age and sex-matched case-control study ( $n = 60/60$ ) on Gilbert's Syndrome. In addition, we used an Affymetrix GeneChip™ Human Gene 2.1 ST Array on a subset of samples ( $n = 23$  cases/ 23 controls). We performed weighted gene coexpression analyses and identified gene modules related to increased UCB concentration. In addition we identified CpG sites positively or negatively associated with UCB, and the genes associated with these sites. Our preliminary results show a negative relationship between UCB and genes responsible for gene expression, RNA processing and transport as well as vitamin D3 and B3 metabolism and cholesterol biosynthesis. Genes found in close proximity of significant CpGs were associated with heme degradation, de novo pyrimidine and ATP biosynthesis, pentose phosphate metabolism and circadian rhythms, among others. There is little overlap between the two datasets, suggesting the short-term and long-term effects from increased UCB might differ. The findings can greatly contribute to our understanding the role of bilirubin in human biology and the mechanisms by which increased UCB offers protection against age-related disease.

**1660W**

**Various relationships between DNA methylation and gene expression in different tissues and ages.** *K. Wang<sup>1</sup>, R. Dai<sup>1</sup>, Y. Xia<sup>1</sup>, C. Jiao<sup>1</sup>, C. Chen<sup>1</sup>, C. Liu<sup>1,2</sup>.* 1) State Key Laboratory of Medical Genetics, Central South University, Changsha, Hunan, China; 2) Department of Psychiatry, University of Illinois at Chicago, Chicago, IL, USA.

Traditionally, DNA methylation is described as a mechanism that represses gene expression by blocking the binding of transcription factors at promoter regions. However, many studies suggest that DNA methylation variation makes a number of diverse contributions to gene expression and its complex underlying mechanisms. To uncover the relationship between gene expression and DNA methylation, we collected tissues that have matched methylation and expression data from databases and publications. Totally we retained 502 adult prefrontal cortices (PFCs), 43 lymphoblastoid cells, 75 livers, 1201 monocytes, and 247 developmental PFCs across the lifespan. For each region, we defined gene and CpG pairs (GCPs) as CpG site located within the 10kb flanking region of the corresponding gene. We used Spearman's rank test to assess the correlation of GCPs and the FDR to correct for the multiple hypothesis testing. In the adult PFC, 230,087 GCPs were analyzed for the Spearman correlation between gene expression and CpG site methylation, and only 8,828 GCPs were significantly correlated after FDR correction. Of these, 5,530 GCPs were negatively correlated and 3,298 GCPs were positively correlated. The other data also exhibited a small proportion of significant GCPs. Though thousands of significant GCPs have been identified in different tissues, only 3 of them were consistent in all tissues. Additionally, there were 442 negatively and 153 positively correlated GCPs shared between the adult PFC and the developmental PFC. The CpGs that were negatively correlated with genes expression were more likely to locate in the promoter and genebody and the positive ones only preferred genebody. We also explored the epigenetic state of these CpGs using the Roadmap 15-core state annotation. Negatively correlated CpGs were enriched in active regions while positive ones were enriched in repressive regions. For the genes of GCPs, we performed the GO term enrichment analysis using WebGestalt. We found that genes in correlated GCPs in developmental PFC were enriched for neuron projection development, neuron differentiation, and synapse part. In the adult PFC data, genes were also enriched for neuron part, distinct from the GO term referring to genes in the developmental PFC. In other tissue data, the genes of significant GCPs also enriched for tissue-specific functions. Besides, the genes of significant GCPs in developmental and adult PFC showed association with psychiatric related gene sets.

**Nanopore full length mRNA sequencing resolves transcript structure in single auditory hair cells.** *P. Ranum<sup>1,2</sup>, A. Goodwin<sup>2</sup>, R. Smith<sup>1,2,3</sup>.* 1) Interdisciplinary Graduate Program in Molecular & Cellular Biology, The University of Iowa Graduate College, University of Iowa, Iowa City, IA 52242, USA; 2) Molecular Otolaryngology and Renal Research Laboratories, Carver College of Medicine, University of Iowa, Iowa City, IA 52242, USA; 3) Department of Otolaryngology, Head and Neck Surgery, Carver College of Medicine, University of Iowa, Iowa City, IA 52242, USA.

Single cell RNA-Seq (scRNA-Seq) has revealed higher than anticipated levels of heterogeneity both in terms of transcript abundance and transcript structure prompting researchers to rethink assumptions about transcription. We have applied scRNA-Seq technology to auditory hair cells, the critical mechanosensory cells of the auditory system. In a dataset of over 200 individual auditory hair cell and supporting cell samples we were surprised to find unexpected variation in transcript structure of many genes. Our analysis of transcript structure was complicated by the limitations of the Illumina sequencing technologies that require library fragments between 150 and 800 bp and limit read length to 200bp or less. Analysis of Illumina reads allows the identification of splice sites but precludes the reconstruction of full length transcripts especially for long genes with many exons or isoforms. We utilized long read Nanopore sequencing technology to sequence full length mRNA transcripts from single cell cDNA libraries. This analysis revealed the inclusion of previously unreported exons, unreported splicing patterns, and by extension novel isoforms in a variety of genes. By quantifying the abundance of these full length transcripts we can establish the relative abundance of various isoforms and separate very low abundance isoforms from those that are abundantly transcribed and more likely to have biological significance. The identification of previously unappreciated transcript structural diversity at the single cell level in a dataset containing only three cell types indicate that there is likely to be a wealth of similar transcriptional diversity waiting to be characterized in other highly specialized cell types throughout the mammalian body. These findings in auditory hair cells have implications for the study, diagnosis, and treatment of deafness. Similar findings in other cell types may have implications for other diseases.

**Local and systemic alterations in extracellular RNA following traumatic knee injury implicate catabolic and inflammatory biomarkers.** A.J. Griswold<sup>1,2</sup>, J. Perez<sup>2</sup>, N. Hofmann<sup>1</sup>, T. Strong<sup>1</sup>, L. Wang<sup>1,2,3</sup>, D.D. Vance<sup>1</sup>, T.M. Best<sup>1</sup>, J.M. Vance<sup>1,2,3</sup>, M.A. Pericak-Vance<sup>1,2,3</sup>, L.D. Kaplan<sup>2</sup>. 1) John P. Hussman Institute for Human Genomics, University of Miami, Miami Miller School of Medicine, Miami, FL; 2) UHealth Sports Medicine Institute, University of Miami, Miller School of Medicine, Miami, FL; 3) Dr. John T. Macdonald Foundation Department of Human Genetics, University of Miami, Miller School Medicine, Miami, FL; 4) Department of Orthopedic Surgery, New York Presbyterian Hospital, Columbia University Medical Center, New York, NY.

Meniscal and anterior cruciate ligament (ACL) injuries are the most common activity-induced orthopedic traumas, and are risk factors for osteoarthritis (OA). We hypothesize that molecular changes, initiated at the time of or soon after trauma, lead to increased risk of OA. This study set out to characterize local and systemic extracellular RNA (exRNA) altered by traumatic knee injury in synovial fluid and plasma. The cohort consisted of 14 subjects undergoing ACL and/or meniscal repair surgery during which whole blood was collected and synovial fluid was aspirated. Five subjects had synovial fluid collected from the contralateral knee. Radiography found no OA, though Outerbridge assessment indicated varying levels of chondral damage. RNA was extracted from plasma and synovial fluid and analyzed via massively parallel RNA sequencing. More than 30 million reads per sample were generated, aligned to the reference genome, and exRNA abundance quantified. Plasma and synovial samples had >10,000 types of exRNA including protein coding genes and miRNAs. Plasma exRNA expression levels showed no differences when stratifying Outerbridge scores or injury duration. However, there was high expression of inflammatory (*CXCL5*, *CCL5*, and *IL16*), catabolic (*MMP-21*, *-17*, and *-13*, and *ADAMTS8*), and miRNA genes involved in arthritis (including *MIR16*, *MIR20b*, and *MIR146a*). Comparing synovial exRNA between uninjured vs injured revealed 69 differential genes ( $p \leq 0.001$ , 44 increased and 25 decreased) including increases of three matrix metalloproteinase (*MMP3*, *-21*, and *-1*) with roles in cartilage catabolism. Injuries with higher average Outerbridge scores showed 278 differential genes ( $p \leq 0.001$ , 87 increased and 191 decreased). The decreased genes were enriched for translational initiation factors (*EIF1*, *EIF2S1*, and *EIF3E -I*, and *-L*), and a matrix metalloproteinase (*ADAM12*) was increased. Finally, comparing <4 months injury duration to greater indicated 46 differential genes ( $p \leq 0.001$ , 33 increased and 13 decreased). The increased genes include skeletal and muscular function genes including skeletal troponins (*TNNC2* and *TNNI2*), tropomyosin 2 (*TPM2*), myosin light chain 1 (*MYL1*), and skeletal muscle actin (*ACTA1*). Overall, this study demonstrates that exRNA molecules can be isolated and characterized from synovial fluid and plasma. While the mechanism of these exRNAs remains unknown, identification of altered pathways could lead to targets for early intervention against OA.

**An epigenome correlation map using Infinium 450 DNA Methylation Array.** W. Guan<sup>1</sup>, Q. Chen<sup>1</sup>, J.S. Pankow<sup>1</sup>, E.W. Demerath<sup>1</sup>, J. Bressler<sup>2</sup>, M.L. Grove<sup>2</sup>, M. Fornage<sup>2</sup>. 1) University of Minnesota, Minneapolis, MN; 2) University of Texas Health Science Center at Houston, Houston, TX.

DNA methylation is an epigenetic mechanism used by cells to control gene expression and involves the addition of a single methyl group to cytosine at position 5. Linkage disequilibrium (LD), i.e., the correlation of alleles at different loci, of the human genome has been widely studied, which provides insights to the history of recombination in populations. In contrast, the correlation of DNA methylation levels among different CpG sites has only received limited attention. Since the methylation level is mitotically heritable but also sensitive to environmental exposures, both short-range and long-range correlation can exist. As part of the Atherosclerosis Risk in Communities (ARIC) study, the Illumina Infinium HumanMethylation450K (HM450) BeadChip was used to measure DNA methylation at over 480,000 cytosine-guanine (CpG) dinucleotide sites in peripheral blood obtained from ~3000 African American participants. In this project, we computed and characterized epigenome-wide correlation between all pairs of CpG sites using the ARIC data. We compared correlation patterns among CpG sites in close proximity to those in long distance or even on different chromosomes. We also evaluated the impact of adjustment for technical and environmental factors on these correlations. For example, for cg05575921, a CpG site known to be associated with smoking status, the 99<sup>th</sup> percentile of Pearson correlation coefficients between this site and CpG sites within 20 kb is 0.54, and 0.28 with CpG sites >20 kb away. After controlling for age, sex, and smoking, the 99<sup>th</sup> percentile value drops to 0.26 and 0.10, respectively. The results demonstrate stronger correlation among CpG sites over short distances, but many sites also show extensive long-range correlation. This analysis may help identify genes or biological pathways that are coordinately regulated.

**The 5-HTTLPR polymorphism does not moderate the effect of sleep loss on neural responses to implicit threat and fear learning and memory.** V.C. Kodavali<sup>1</sup>, J. Nguyen<sup>1</sup>, R. McNamee<sup>1</sup>, N. Rode<sup>1</sup>, V.L. Nimgaonkar<sup>1,2</sup>, A. Germain<sup>1</sup>. 1) Psychiatry, University of Pittsburgh, Pittsburgh, PA; 2) Human Genetics, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA.

**Introduction:** The short (s) allele variant of the serotonin transporter polymorphism 5-HTTLPR, compared to the long (l) allele variant, has been associated with heightened stress reactivity and greater vulnerability to stress-related psychiatric disorders. We explored the moderating impact of this polymorphism on neural correlates of implicit threat detection and fear-associated learning and memory following normal sleep, total sleep deprivation, or sleep restriction in healthy young adults. **Methods:** 134 participants spent 3 night in the laboratory after being genotyped for 5-HTTLPR. After a baseline night, neural responses to implicit threat cues were assessed in the evening. Participants were then randomized to total sleep deprivation (SD, n = 35), sleep restriction (SR or half of habitual time, n=40), or normal sleep (NS, n = 43). On the morning following the randomization night, participants completed a fear conditioning and extinction protocol. Fear extinction recall was tested in the evening, when neural responses to implicit threat cues were also re-tested. BOLD signals in the amygdala and ventromedial prefrontal cortex (vmPFC) were compared between the three genotypes (s/s vs. s/l vs. l/l carriers). ROI analyses were conducted using SPM8 and SPSS. **Results:** No significant Sleep Group X Genotype interaction was found for fear conditioning, fear extinction, or extinction recall for the right or left amygdala, or vmPFC. For the implicit threat task, a main effect of genotype was detected for the right amygdala ( $F(2,129) = 3.35$ ,  $p < 0.05$ ) at baseline, where the s/l group showed lower BOLD activation in response to threatening vs. neutral cues than the l/l and s/s groups. Following the sleep manipulation, the three genotypes no longer differed. **Conclusion:** The 5-HTTLPR polymorphism does not appear to moderate the effect of sleep loss on neural responses to implicit threat and fear learning and memory. Heterozygotes (s/l carriers) showed the greatest BOLD reactivity to threat cues in the right amygdala at baseline, but this effect was absent following the sleep manipulation. Sleep loss may override the impact of genotype on processes related to fear learning and extinction as well as neural reactivity to salient cues. The extent to which sleep loss may attenuate the effects of other polymorphisms on neural response to emotionally salient cues remains to be determined. .

**Powerful and robust method for XCI-escape inference from bulk RNA-seq.** R. Sauteraud, J. James, D. Liu, L. Carrel. Pennsylvania State University, Hershey, PA.

X chromosome inactivation (XCI) mechanism randomly silences one female X (Xi) and only expressing the alleles on the active X (Xa). ~10% of the X-linked genes escape XCI and express both copies of alleles. Xa/Xi assignment varies between cells (mosaicism), which makes it challenging to identify XCI escape genes from bulk RNA-seq data. We propose a novel binomial mixture model for identifying XCI escape gene. The method proceeds by estimating XCI skewing (i.e. the fraction of cells where one particular haplotype is Xa) from a training set of putative inactivated genes. The genes with more balanced allelic expression than XCI skewing will be deemed as candidates of XCI escape genes. The model accounts for the read depths over-dispersion, while simultaneously accommodating for the possible sequencing error or imperfect training set (e.g. some putative inactivated genes may actually escape XCI). The number of mixture components is automatically determined via a backward elimination procedure, which ensures model parsimony and maximizes power. We experimentally established the validity and power of proposed method using single cell clones and male-female differential gene expression (DGE). In the single cell clone experiment, cells from a single individual with maternal or paternal Xa were isolated and separately cloned. Each clone thus has identical Xa/Xi assignment. Any genes that are mono-allelically/bi-allelically expressed in single cell clones will be identified as inactivated/escape genes. We also created mixtures of single cell clones, with skewing ranging from 50/50 to 90/10 to mimic a randomly X-inactivated sample. Type-I error and power was evaluated by comparing inference results from mixture samples to single cell clones. The type I errors across all scenarios were well controlled. The power increases with XCI skewing and is well above 80% for cell mixtures with a skewing greater than 20/80. We further demonstrate the utility of this method with DGE in the GEUVADIS dataset. Our method correctly predicts all 11 genes in PAR1 region as escape gene. Consistent with existing literature, the genes in non-PAR region predicted as escape tend to be up-regulated in females. On the contrary, genes in the PAR1 region are down-regulated in females due to dosage compensation. The method is implemented as a publicly available R package. We envision that it may be extremely useful for the analysis of broad available bulk RNA-seq data and XCI inference. .

**1666W**

**Prevalence, tissue-specificity and age-dependent heritability of skewed X-inactivation.** A. Zito, P.-C. Tsai, S. Verdi, T. Martin, J.T. Bell, K.S. Small. Department of Twin Research and Genetic Epidemiology, King's College London, London SE1 7EH, UK.

To equalize the X-linked transcriptional dosage between the sexes, one of the two X-chromosomes is inactivated in somatic tissues of female mammals. The long non-coding RNA *XIST* is uniquely expressed from the inactive X and drives the X-chromosome inactivation (XCI) process. Non-random, or skewed XCI, defined where at least 80% of the cells exhibit a preferential inactivation of one parental X chromosome, has been observed in female somatic tissues. Skewed XCI has been associated with ageing and complex traits including autoimmune diseases and cancer. We assessed the prevalence, heritability and phenotypic associations of skewed XCI in a multi-tissue sample of 850 female twins from the TwinsUK cohort (age 38-85, median age = 60). XCI was quantified in LCL (lymphoblastoid cell lines), whole blood, fat and skin biopsies via allele-specific expression (ASE) of *XIST* from paired RNA-seq and WGS data. We validated our quantification of XCI with HUMARA assays (N = 32, rho = 0.71) and repeated blood draws taken 1-3 years apart (N = 16, rho = 0.94). By defining skewed XCI when *XIST*-ASE < 0.2 or *XIST*-ASE > 0.8, we identify a high prevalence of tissue-specific XCI, with skewed XCI patterns being more common in blood-derived tissues (LCL = 35%, blood = 22%) than skin (10%) or fat (12%). Tissue-tissue correlations indicate highest similarities of XCI skewing levels between blood-derived tissues (rho = 0.8) and between skin and fat (rho = 0.47), with lower correlations observed between blood-derived tissues and either skin (rho = 0.3) or fat (rho = 0.3). XCI skew was associated to age (P = 0.001) in blood-derived tissues, with an inflection point at 55 years of age and 42% of individuals >65 demonstrating skewed XCI. No association was detected between XCI skew and age in skin (P = 0.37) or fat (P = 0.7). We confirmed previous reports of heritable XCI skew in blood, but find that heritability of XCI is limited to women >55 years-old (h<sup>2</sup> = 0.25). XCI skew was not heritable in blood of women <55 years-old (h<sup>2</sup> = 0), nor in skin and fat (h<sup>2</sup> = 0) at any age. XCI skew was more extreme in blood-derived tissues in individuals with an autoimmune disease (P = 0.01) and in current smokers (P = 0.02). We conclude that XCI patterns are tissue-specific and that the heritability of XCI skew in blood is dependent on age, representing a Gene x Age interaction that can shift the functional allelic dosage of an entire chromosome in a tissue-restricted manner.

**1667T**

**RIPK3-dependent regulation of cell death switch (live or dye) as major determinant in incontinentia pigmenti.** A. Pescatore, M. Cirigliano, L. Pata-nella, A. Barra, M.V. Ursini. Institute of Genetics and Biophysics "A. Buzzati-Traverso" CNR-Via P. Castellino, 111 80125 Naples, Italy.

Incontinentia pigmenti (IP) is a X-linked neuroecodermal disease. The only causative gene is NEMO (also called IKBKG), encoding for the crucial regulator of the NF- $\kappa$ B transcription pathway. Accordingly, the impaired NF- $\kappa$ B activation and the defective response to pro-apoptotic stimuli induced through the TNF- $\alpha$  receptor1, underline the pathogenesis of this inflammatory disease. Conditional or full Knock out mouse models of the disease have confirmed these knowledges. A conundrum has been to distinguish between the two independent activities of NEMO: the one of NF- $\kappa$ B-mediating gene transcriptional activation and that of inhibition of cell death. The IP-associated NEMO-A323P mutant has provided an answer to that question. Cell expressing the A323P NEMO mutant have a completely abrogated TNF-induced NF- $\kappa$ B activation, nevertheless exhibiting resistance to TNF-induced apoptosis. We demonstrated that NEMO, independently from NF- $\kappa$ B activation, controls structural and functional dynamics of the different TNF-R1-induced complexes by regulating the RIP kinases activities. We observed that while a robust caspase activation is evidenced in NEMO-null cells concomitant with the RIPK3 recruitment to the apoptosis-mediating TNF receptor complex, In contrast, cells expressing the ubiquitin-binding mutant NEMO-A323P did not recruit RIPK3 to complex II, an event that prevented caspase activation. We propose RIP3 as a new crucial player in the IP pathogenesis because in the presence or in the absence of NEMO a different cellular outcome (live or die) or a different cell death process (apoptosis or necroptosis) may result. In this respect, RIP3 represents a putative therapeutic target in Incontinentia Pigmenti and in other NF- $\kappa$ B-related human diseases.

**Identification of genetically associated changes in 3D-chromatin architecture by leveraging haplotype information across a three-generation family.** *W.W. Greenwald<sup>1</sup>, H. Li<sup>2</sup>, P. Benaglio<sup>3</sup>, A. Schmitt<sup>4</sup>, Y. Qiu<sup>1</sup>, B. Ren<sup>2,5,6,7</sup>, M. D'Antonio<sup>3</sup>, E.N. Smith<sup>3</sup>, K.A. Frazer<sup>2,3</sup>. 1) Bioinformatics and Systems Biology Graduate Program, University of California, San Diego, La Jolla, CA, USA; 2) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA, USA; 3) Department of Pediatrics and Rady Children's Hospital, University of California, San Diego, La Jolla, CA, USA; 4) Arima Genomics, San Diego, CA, USA; 5) Ludwig Institute for Cancer Research, La Jolla, CA, USA; 6) Moores Cancer Center, University of California, San Diego, La Jolla, CA, USA; 7) Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA, USA.*

Genetic variation that affects gene expression can occur in regulatory regions that are far from the gene's locus, yet colocalize spatially through 3D-chromatin loops. However, it is unclear if this genetic variation acts by modulating regulatory region activity, or by inducing changes in the 3D-architecture of the genome itself. To study this question, we obtained paired iPSC and iPSC-derived cardiomyocyte (iPSC-CM) lines from 7 individuals in a 3-generation family with whole genome sequence data. We performed in-situ Hi-C and obtained a total of ~6 billion read pairs which we analyzed using Fit-Hi-C and HiCCUPS to identify 17,567 and 19,003 significant loops in iPSCs and iPSC-CMs, respectively, 9,888 of which were common to both cell types. To identify loops associated with genetic variation, we performed allelic imbalance analyses with the HiC reads. To assign reads to either the maternal or paternal haplotype, we initially obtained long-range haplotypes from the HiC data; however, when we compared the resulting haplotypes to expected inheritance patterns, we observed a 1.8% switch error rate. We thus devised a method which leveraged family structure, enabling us to resolve 95% of these switch errors and resulting in 4.7M phased SNVs across the genome. To estimate allelic imbalance, we assigned reads within 25kb of a loop's anchor that carried an allele of a phased heterozygous SNV to the corresponding maternal or paternal haplotype of the individual, performed a binomial test, and combined the individuals' associations at each loop using Fisher's combined p-value. In total, we identified 35 genetically associated chromatin loops with FDR < 0.05 across both cell types. Across all loops, 8 overlapped 2 somatic CNVs identified in these iPSCs, and for both CNVs we observed genetic effects with either a corresponding gain or loss, supporting that our method accurately detects genetically associated changes in chromatin loop formation. These data suggest the 3D-chromatin architecture of the genome may be largely invariant and only modestly affected by genetic variation; we are currently validating this observation by testing whether the genetic variants that are located in the distal end of a chromatin loop and are associated with allele-specific RNA expression at the genic end of the loop are also associated with corresponding differences in chromatin loop formation.

**1669W**

**HyCCAPP uncovers CALR as a novel DNA-binding protein.** *H. Guillen<sup>1</sup>, D.S. Perumalla<sup>1</sup>, P.K. Rao<sup>1</sup>, A.Y. Jadhav<sup>1</sup>, J.M. Proffitt<sup>1</sup>, M.J. Monotya<sup>1</sup>, M.R. Shortreed<sup>2</sup>, L.M. Smith<sup>2</sup>, M. Olivier<sup>1</sup>.* 1) Genetics, Texas Biomedical Research Institute, San Antonio, TX; 2) Chemistry, University of Wisconsin, Madison, WI.

Whole-genome sequencing analyses have greatly improved the identification of disease-associated sequence variants. Most of these associations are located in non-coding regions, suggesting likely expression-modulating mechanisms. Not surprisingly, a number of these sequence variants are strongly associated with both disease-related traits and the expression of individual genes (expression quantitative trait loci, eQTL), reinforcing a functional link between gene expression regulation and disease risk for a large number of human disorders. We recently adapted the Hybridization Capture of Chromatin-Associated Proteins for Proteomics (HyCCAPP) technology by incorporating luciferase reporter plasmid constructs commonly used to assess the impact of sequence variants on promoter activity, to better study selected eQTL variants reported in the literature. We analyzed a promoter variant, -105G/A, upstream of the selenoprotein S (*SELS*) gene. *SELS* is a gene involved in stress response and inflammation control. We tested the two alleles of the -105 variant in luciferase reporter assays introducing promoter-containing plasmids in HepG2 cells. The two variants resulted in differential activity in the reporter assay, suggesting that the two alleles likely result in altered gene expression. ChIP-seq data from ENCODE did not reveal any suggested DNA-binding proteins mediating the observed effect. Through mass spectrometry we identified CALR, PCK2 and HSPA9, among others, to be significantly enriched in the promoters containing the minor allele. The allele-specific binding of the proteins was confirmed by ChIP-qPCR. None of these proteins have been previously reported to bind DNA before in a sequence-specific manner. Even though further analyses are needed to confirm the chromatin enrichment of these proteins and to understand their mechanisms in this context, HyCCAPP is showing its potential to uncover novel DNA-protein interactions.

**Furthering the GTEx project legacy through the GTEx biospecimen resource.** *E. Gelfand, W. Brodeur, K. Larkin, J. Nedzel, K. Ardlie.* Broad Institute, Cambridge, MA.

The Genotype-Tissue Expression (GTEx) project is an NIH Common Fund initiative aimed at providing a resource with which to study human gene expression and regulation and its relationship to genetic variation. This project collected and analyzed multiple tissue types (up to 53) from over 950 healthy donors, to assess the role of genetic variation in regulating gene expression. By analyzing global RNA expression within individual tissues and treating the expression levels of genes as quantitative traits, variations in gene expression that are highly correlated with genetic variation can be identified as expression quantitative trait loci (eQTLs). Correlations between genotype and tissue-specific gene expression levels help identify regions of the genome that influence whether, and how much a gene is expressed. GTEx serves as a resource to study inherited susceptibility to disease, providing a database and tissue bank for many studies in the future. In addition to primary sequence data and analyses available through dbGaP, the residual banked GTEx biospecimens, including DNA, RNA, and tissue, are now housed at the Broad Institute and are available to scientists for additional research projects. The GTEx portal ([www.gtexportal.org](http://www.gtexportal.org)) has a sample request feature to enable searching and requesting access to samples. It is being enhanced to enable linking of samples to the derived and analyzed datasets and the many data visualization tools and views available on the portal. We will describe this resource and demonstrate ways to search it and integrate it with data features on the GTEx portal.

**The components of the human epigenetic machinery are highly co-expressed and very intolerant to variation.** *L. Boukas<sup>1</sup>, H.T. Bjornsson<sup>1,2</sup>, K.D. Hansen<sup>1,3</sup>.* 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD 21205; 2) Department of Pediatrics, Johns Hopkins University School of Medicine, Baltimore, MD 21205; 3) Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore MD 21205.

Recently, mutations in genes encoding for components of the epigenetic machinery have been strongly implicated in multiple types of solid and liquid tumors, complex neuropsychiatric disorders (e.g. Autism, Schizophrenia), and Mendelian disorders (e.g. Kabuki and CHARGE syndromes). Currently however, components with ascribed roles in disease constitute a small fraction of the human epigenetic machinery, which remains largely uncharacterized with respect to disease-relevant properties. Here, using known protein domain annotations, we systematically compiled a list of 305 genes containing at least one domain that classifies them as writers, erasers, or readers of DNA methylation, histone methylation or acetylation, or as chromatin remodelers. Using the pLI score, introduced by the ExAC as a metric of haploinsufficiency, we find that the components of the epigenetic machinery are highly intolerant to heterozygous loss of function variants ( $p < 2.2e-16$ , odds ratio = 7.2 for enrichment in the pLI > 0.9 category), even though many of these genes encode enzymes, a group usually tolerant of heterozygous variation. In fact, the components of the epigenetic machinery demonstrate higher mutational constraint than transcription factors ( $p < 2.2e-16$ , odds ratio = 4 for enrichment in the pLI > 0.9 category), a classical dosage sensitive group of central transcriptional regulators. We then used data from the GTEx project to systematically assess the expression patterns of these genes across different tissues, and find that in general, they are present at high levels, with half of them exhibiting very low tissue specificity. This is in contrast to the known tissue specificity of transcription factors. Finally, we use established methods (WGCNA) to construct a co-expression network of the epigenetic machinery across tissues and individuals. We show that there exist 95 genes that are each coexpressed with more than 10 other epigenetic machinery genes in more than half of the tissues, and this high degree of coexpression is strongly associated with constraint ( $p = 2.3e-13$ , odds ratio = 10.5 for enrichment in the pLI > 0.9 category). The existence of a co-expression network suggests either shared upstream regulation or cross-regulation between these factors, whereas the relationship with constraint implies that this network may play a role in disease pathogenesis. Our study uses a genetic approach to establish the central role of the epigenetic machinery in human homeostasis.

**An integrated -omics analysis of the epigenetic landscape of gene expression in human blood cells.** E.M. Kennedy<sup>1,2</sup>, G.N. Goehring<sup>3</sup>, D. Mehta<sup>4</sup>, T. Klengel<sup>5</sup>, A.K. Smith<sup>1,6,7</sup>, K.N. Conneely<sup>1,2</sup>. 1) Genetics and Molecular Biology Program, Emory University, Atlanta, GA; 2) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA; 3) AT&T Big Data, Alpharetta, GA; 4) School of Psychology and Counseling, Queensland University of Technology, Brisbane, QLD, Australia; 5) Department of Psychiatry, McLean Hospital, Harvard Medical School, Belmont, MA; 6) Department of Gynecology and Obstetrics, Emory University School of Medicine, Atlanta, GA; 7) Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, Atlanta, GA.

Gene expression can be influenced by DNA methylation 1) distally, at regulatory elements such as enhancers, insulators and non-coding RNAs, as well as 2) proximally, at promoters. Our current understanding of the influence of distal DNA methylation changes on gene expression patterns is incomplete. We assessed the correlation of DNA methylation at ~400K CpG sites with gene expression changes at ~13K expression transcripts, using a linear mixed model framework, in two independent datasets. Our data were derived from 333 human whole blood samples collected for the Grady Trauma Project (GTP) and 1,202 purified human monocyte samples collected for the Multi-ethnic Study of Atherosclerosis (MESA) Epigenomics and Transcriptomics Study. Our results indicate that among CpGs at which methylation significantly associates with gene expression ( $p < 10^{-11}$  denoted eCpGs), >50% are distal (>50kb) or trans (different chromosome) to the associated gene. Of the eCpG-transcript pairs found in GTP, 45% of cis (<50kb), 30% of distal and 27% of trans pairs were consistent in MESA results. Likewise, neighboring eCpGs within both datasets tend to associate with the same expression probe (MESA: 89% of eCpGs within 500bp, GTP: 82%), even among trans eCpGs (MESA: 88% of eCpGs within 500bp, GTP: 85%). Like other studies, we find that enhancers are substantially overrepresented in eCpGs (MESA-OR: 2.85,  $p < 1e-183$ ; GTP-OR: 2.54,  $p < 1.9e-46$ ). Contrary to many published findings, our results indicate that the majority (MESA: 68%; GTP: 73%) of eCpG-transcript associations within gene bodies are negative. Gene Ontology analysis suggests that for each gene, we have likely identified a regulatory profile that encompasses the indirect, trans effects (which could include regulatory networks) as well as direct cis effects (including cis and distal DNA methylation). Because we find many eCpGs, genome-wide, that associate with promoter genes and chromatin modifiers, our findings may include scenarios in which gene expression influences DNA methylation patterns, as well as vice-versa. This work sheds new light on the interplay between epigenetic changes and gene expression, and provides a useful tool for mining biologically-relevant results from epigenome-wide association studies.

## 1673T

**DNA methylation changes as an exposure signature of cigarette smoking.** E. Kim<sup>1</sup>, J. Kim<sup>1</sup>, A. Ghantous<sup>2</sup>, Z. Herceg<sup>3</sup>, J. Sung<sup>1,3</sup>. 1) Complex Disease and Genome Epidemiology Branch, Department of Public Health Science, School of Public Health, Seoul National University, Seoul, Republic of Korea; 2) Epigenetics Group, International Agency for Research on Cancer (IARC), Lyon, France; 3) Institute of Health and Environment, Seoul National University, Seoul, Republic of Korea.

**Introduction:** Environment alters DNA methylation (DNAm), but little is known about whether exposure-specific changes exist. In identifying exposure-specific DNAm changes, given that DNAm itself is under genetic control, possible genetic confounding needs to be controlled for. In this study, we aimed to identify DNA methylation markers that are specifically modified by smoking, using twin-family data. **Materials and methods:** We analyzed peripheral blood DNAm data of 385 individuals from the Korean Healthy Twin Study (95 MZ twin pairs and their first-degree relatives from 97 families), using Infinium 450K chips. 147 (134 male and 13 female) individuals were ever-smokers and 26 MZ twin pairs were discordant for smoking status. We investigated >18,000 CpGs that were previously reported to be associated with smoking in the large-scale meta-analysis by Joehanes et al. (2016). We used a linear mixed model to account for familial relatedness. To detect mQTLs, we fitted a linear mixed polygenic model for each of all SNP-CpG pairs. **Results:** 49 CpGs at 28 distinct loci were replicated ( $q < 0.05$ ), including cg05575921 and cg235768551 (*AHRR*) and cg03636183 (*F2RL3*). *AHRR* harbored the greatest number of smoking-associated CpGs (13 CpGs), all of which except for one were hypomethylated in the ever-smokers group. In the mQTL analysis, 415 (2%) of the >18,000 CpG sites tested were significantly associated with at least one SNP at Bonferroni-corrected  $p < 0.05$ . DNAm at two of the smoking-associated CpGs showed significant association with distal SNPs. 511 CpG-SNP pairs showed significant association (438 in *cis* and 73 in *trans*). **Conclusions:** We found that 49 CpGs were differentially methylated in relation to smoking. The mQTL analysis revealed that approximately 2% of the previously reported smoking-associated CpGs were shown to be under genetic control, primarily by *cis*-acting SNPs. This study may provide evidence of increased strength for epigenetic signatures that are specifically sensitive to exposure to cigarette smoking.

**1674F****Targeted DNA methylation *in vivo* using an engineered dCas9-MQ1**

**fusion protein.** Y. Lei<sup>1,2</sup>, X.T. Zhang<sup>1,2</sup>, J.Z. Su<sup>3</sup>, M. Jeong<sup>1,2</sup>, M.C. Gundry<sup>1,2</sup>, YH. Huang<sup>1,2</sup>, YB. Zhou<sup>4</sup>, W. Li<sup>3</sup>, M.A. Goodell<sup>1,2,3</sup>. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas; 2) Stem Cells and Regenerative Medicine Center, Baylor College of Medicine, Houston, Texas; 3) Dan L. Duncan Cancer Center and Department of Molecular and Cellular Biology, Baylor College of Medicine, Houston, Texas; 4) Center for Translational Cancer Research, Institute of Biosciences and Technology, Texas A&M University Health Science Center, Houston, Texas.

Comprehensive studies have shown that DNA methylation plays vital roles in both loss of pluripotency and governance of the transcriptome during embryogenesis and subsequent developmental processes. Aberrant DNA methylation patterns have been widely observed in tumorigenesis, aging, and neurodegenerative diseases, highlighting the importance of a systematic understanding of DNA methylation and the dynamic changes of methylomes during disease onset and progression. Here we describe a facile and convenient approach for efficient targeted DNA methylation by fusing inactive Cas9 (dCas9) with an engineered prokaryotic DNA methyltransferase MQ1. Our study presents a rapid and efficient strategy to achieve locus-specific cytosine modifications in the genome without obvious impact on global methylation in 24 hours. Finally, we demonstrate our tool can induce targeted CpG methylation in mice by zygote microinjection, thereby demonstrating its potential utility in early development. .

**Looking for an epigenetic footprint of music: Behavioral effects of auditory stimulation and its relation to the methylation level of BDNF exon IV within the hippocampus of Wistar rats.** M.M. Velásquez Toledo, M.C. Lattig M., F. Cárdenas. Universidad de los Andes, Bogotá, Colombia.

Musical stimulation has been reported to undermine behavioral responses in animal models and humans, including anxiety reduction. Additionally, musical stimulation induces changes in the expression of the brain-derived neurotrophic factor (BDNF, Gene ID: 24225). This gene, whose expression could be modulated by epigenetic factors, is involved in several processes such as learning, neuroplasticity, memory consolidation and emotional regulation. The aim of this work was to evaluate whether the stimulation with music at high frequencies could induce an anxiolytic effect in rats and if such effect, if any, would be related to epigenetic changes in the promoter region of BDNF. Male Wistar rats were assigned to one of four conditions: control (no auditory stimulation), music (Mozart K.448) transposed to a higher pitch, normal pitch music (Mozart K.448) or white noise. Animals were exposed to the respective stimuli for 21 consecutive days and the anxiety levels were tested in the elevated plus-maze. We measured the global methylation level and the methylation levels of eleven CpG positions within BDNF exon IV through direct sequencing of bisulfite-treated DNA (BSP) from rat hippocampus. No differences were found either in the anxiety levels of the animals or in the methylation levels. Given that this study considered the pitch transposition of the frequencies, our results suggest that the putative anxiolytic effect, reported in other studies, could reflect effects other than the musical stimulation by itself. It also reveals that the behavioral response to the auditory stimulation could be related to the methylation level within the BDNF exon IV, since the homogeneity of the behavior was reflected in similar methylation status. However, further research is needed to assess other epigenetic changes, including modifications to the chromatin structure.

**Novel deep learning approaches reveal sophisticated epigenetic regulation in eukaryotes.** Z. Wei<sup>1</sup>, F. Tan<sup>1</sup>, T. Tian<sup>1</sup>, H. Hakonarson<sup>2,3</sup>. 1) Department of Computer Science, New Jersey Institute of Technology, Newark, NJ; 2) Center for Applied Genomics, The Children's Hospital of Philadelphia, Philadelphia, PA; 3) Division of Human Genetics, Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Recently, the prevalence and significance of DNA N6-methyladenine (6mA) in eukaryotes was revealed. Tens of thousands of 6mA sites have been cataloged across several eukaryote genomes, thanks to new technologies. DNA 6mA is a dynamic process, which can be time and/or tissue specific. Therefore experimental approaches, although precise, may not provide a complete catalog of all 6mA sites. In addition, despite some sequence motifs around 6mA sites have been identified, they represent only a fraction (~10%) of the total methylated adenines. We propose advanced machine learning approaches to address the aforementioned two issues. First, our predictive models provide a complete catalog of 6mA sites for six species, namely, *C. Elegans*, *Arabidopsis*, *Drosophila*, *E. Coli*, *Yeast*, and *Toxoplasma*. Specifically, we collect 209354, 271929, 163493, 41333, 4094, 3342 6mA sites for the six species, respectively. We divide these samples into 90:10:10 for training, validation, and testing, respectively. We develop a novel fully sequence-based algorithmic framework based on deep residual learning for 6mA site prediction. We obtain AUC (Area under the Receiving Operating Curves) of 0.967, 0.930, 0.980, 0.999, 0.909, and 0.829, for the six species in testing, respectively, all outperforming the classical k-mer based learning approaches. Using the trained models, we identify a substantial amount of 6mA candidate sites that are not yet reported by existing studies. Second, we hypothesize that a more sophisticated mechanism exists for 6mA regulation, and propose for the first time a contextual sequence analysis protocol for motif discovery. It has four appealing features: (1) integrating sequence information from a wide sequence context; (2) learning sequence motifs at multiple spatial scales with a hierarchical architecture; (3) visualizing sequence motifs for easy interpretation, and (4) enabling sophisticated pattern representations but with low complexity. As control, we successfully detect the 5'-GAGG-3' motif conserved in the eukaryotic species, as well as the canonical GATC motif in *E. Coli*. This approach also allows us to identify new nonlinear patterns that are missed by conventional motif discovery methods. They account for a much higher fraction (>50%) of the identified 6mA sites. These motifs suggest that sophisticated mechanisms exist for 6mA epigenetics regulation in eukaryotes that may have implications for both health and disease.

**The impact of arsenic exposure on whole blood DNA methylation: An epigenome-wide study of Bangladeshi adults.** B. Pierce<sup>1</sup>, K. Demanelis<sup>1</sup>, M. Argos<sup>2</sup>, L. Tong<sup>1</sup>, J. Shinkle<sup>1</sup>, M. Sabarinathan<sup>1</sup>, F. Jasmine<sup>1</sup>, M. Kibriya<sup>1</sup>, H. Ahsan<sup>1</sup>. 1) Department of Public Health Sciences, University of Chicago, Chicago, IL; 2) University of Illinois at Chicago, Chicago, IL.

Arsenic exposure affects >100 million people worldwide, including ~56 million in Bangladesh. Arsenic is a carcinogen and possible endocrine disruptor. Epigenetic alterations, including DNA methylation modification, are potential mechanisms of toxicity. We assessed associations between arsenic exposure and genome-wide DNA methylation among Bangladeshi adults exposed to naturally-contaminated drinking water obtained from local tube wells. We measured methylation in whole blood DNA at ~850,000 CpG sites using the Illumina EPIC array for 396 individuals participating in the Health Effects of Arsenic Longitudinal Study (HEALS). Association analyses were conducted using the reference-free algorithm proposed by Houseman et al. to adjust for cell-type composition. We attempted replication in an independent set of 400 arsenical skin lesion cases with Illumina 450K array data. HEALS participants had a wide range of arsenic exposure measured in urine (IQR: 114-350 ug/g), and 76% consumed water with concentrations above the WHO guideline of 10 ug/L. Urine arsenic concentration was associated with methylation at 182 CpGs (FDR <0.05). Of these CpGs 80% were also associated with arsenic measured in individuals' primary drinking well (FDR <0.05). Replication was tested for 83 arsenic-associated CpGs present on the 450K array, and 42 (51%) were associated with urine arsenic ( $P < 10^{-4}$ ) with a consistent direction of association. After meta-analyses, the CpGs most strongly associated with urine arsenic were cg15108641 (*UBTD1*;  $p = 2 \times 10^{-20}$ ), cg13480898 (*C19orf66*;  $p = 9 \times 10^{-19}$ ), and cg26390598 (*B3GALT5*;  $p = 9 \times 10^{-17}$ ). Genes with multiple arsenic-associated CpG sites assigned to them included *BMF*, *USHBP1* and *PRDM16*. Methylation at 74% of these 182 CpGs decreased with increasing arsenic. Compared to all CpGs, negatively associated CpGs were enriched in non-CpG islands ( $p = 0.007$ ) and DNaseI hypersensitive sites ( $p = 0.004$ ) but depleted in promoters (among CpGs assigned to genes). We did not detect enrichment in these categories for positively associated CpGs. Among CpGs with  $P < 10^{-4}$ , 7 KEGG pathways were enriched, including *thyroid hormone synthesis*, *endocrine and other factor-regulated calcium reabsorption*, and *estrogen signalling* ( $P < 0.05$ ), suggesting arsenic may dysregulate endocrine pathways. The robust associations between arsenic exposure and DNA methylation observed in this work suggest that epigenetic alterations may be important mediators in arsenic toxicity.

**Characterizing causal *cis*-regulatory variants using computational approaches and CRISPR/Cas9 genome editing.** *M. Brandt*<sup>1,2</sup>, *A. Vasileva*<sup>1,2</sup>, *T. Lappalainen*<sup>1,2</sup>. 1) New York Genome Center, New York, NY; 2) Department of Systems Biology, Columbia University, New York, NY.

Expression quantitative trait loci (eQTL) and splicing quantitative trait loci (sQTL) studies have identified thousands of common human genetic variants associated with gene expression levels and splicing patterns, respectively. Because of linkage disequilibrium, the true causal variants and therefore the mechanisms underlying the effect on gene expression or splicing have yet to be determined at many loci. We aim to both identify characteristics of causal variants genome-wide and discriminate causal variants from those in close linkage on a local scale. We analyzed eQTLs and sQTLs from the GTEx project v6 data, focusing on fibroblast cell line data from 272 individuals. We use a Bayesian hierarchical model *fgwas* for fine-mapping of causal variants accounting for functional genomic annotation. We find that eQTL variants are significantly enriched for annotations affecting both transcriptional regulation, such as promoter-associated variants, and post-transcriptional regulation, such as RNA-binding protein binding sites and miRNA target sites. Comparison of the same data analyzed with *CAVIAR*, another statistical method for identifying causal variants, reveals high concordance between the two methods. We also find that sQTLs are enriched in the ends of exons, canonical splice sites, and synonymous variants. Using these enriched annotations genome-wide, we are able to identify likely causal variants in linkage disequilibrium to further validate experimentally. So far, we have utilized CRISPR/Cas9 editing to edit several common and rare regulatory and splicing variants in HEK293 cells. We are developing a novel approach to experimentally test hundreds of common and rare putative causal regulatory variants in coding regions by pooled editing with CRISPR/Cas9 followed by targeted DNA and RNA sequencing.

**1679T**

**Regulatory role of conserved non-coding elements.** *B. Ambrose*, *J. Fischer*, *G. Elgar*. The Francis Crick Institute, London, United Kingdom.

Comparative genomics has revealed the existence of Conserved Non-coding Elements (CNEs) in vertebrates. It was found that these non-coding units were clustered around key developmental genes. In addition to this reporter assays in zebrafish embryos have showed that CNEs have an enhancer function making them good candidates for possible interaction partners with the promoter regions of genes. In light of recent developments in the study of chromatin interactions within the nucleus and more specifically with the identification of Topologically Associated Domains (TADs), we investigated the spatial organization of CNE cluster across the human genome in different cell types. We found a strong correlation between the boundaries of CNE clusters and TADs, reinforcing the role of CNEs as potential customers-regulator modules of genes. To further investigate potential direct interactions between CNEs and promoter regions, we have performed chromosome conformation capture at selected viewpoints. Our preliminary results in tissue culture suggest that at least some CNEs directly interact with promoter regions supporting our initial hypothesis.

**1680F**

**What we talk about when we talk about enhancers.** *M.L. Benton<sup>1</sup>, D. Kostka<sup>2</sup>, J.A. Capra<sup>3</sup>.* 1) Biomedical Informatics, Vanderbilt University, Nashville, TN; 2) Departments of Developmental Biology and Computational and Systems Biology, University of Pittsburgh School of Medicine, Pittsburgh, PA; 3) Departments of Biological Sciences and Computer Science, Vanderbilt Genetics Institute, Center for Structural Biology, Vanderbilt University, Nashville, TN.

Gene regulatory enhancers are essential to transcription in all mammalian cells. Because they provide a window into the function of the non-protein-coding genome, enhancer annotations have increasingly become critical tools for interpreting candidate disease variants from GWAS and sequencing studies. However, accurate and comprehensive enhancer identification in a biological context of interest is challenging, and as result, many experimental and computational methods have been developed to identify enhancers. No gold standard has yet emerged in the field; nevertheless, it is common for studies to consider enhancers identified by only a single method. To assess the robustness of this approach, we analyzed the consistency of enhancer sets identified using eleven representative identification strategies across four diverse cellular contexts. We found significant dissimilarity between enhancer sets in genomic characteristics, evolutionary conservation, and association with functional loci. The substantial disagreement between enhancer sets within the same biological context is often sufficient to influence downstream biological interpretations and lead to disparate scientific conclusions about enhancer biology. Importantly, these differences are likely to affect conclusions about the function of candidate disease loci, because different methods disagree about enhancer function of the majority of GWAS SNPs and eQTL. Surprisingly, we find that enhancers identified by multiple methods are not more enriched for regulatory function than those identified by a single method. Consistent with the differences in genomic location we observe, functional annotations enriched among genes near enhancer sets identified by different methods in the same context also show low similarity and high uniqueness. These trends hold across all methods and cellular contexts considered. Our work identifies a fundamental challenge in the definition and use of genome-wide enhancer maps, which complicates the use of available approaches to elucidate the molecular underpinnings of disease in non-coding regions. To ensure reproducible results and robust conclusions, we argue that the diversity of current approaches should [m1] be considered until we have more completely characterized the complexity of enhancer biology. Therefore we have developed a database of grouped enhancer annotations from common contexts to facilitate the evaluation the effect of different annotation approaches.

**1681W**

**GGmend: A Mendelian randomization method for finding gene-on-gene regulatory effects in the presence of unobserved confounders.** *R. Brown<sup>1</sup>, J. Joo<sup>2</sup>, R. Smith<sup>3</sup>, B. Pasaniuc<sup>1,4,5</sup>, E. Eskin<sup>1,3</sup>.* 1) Bioinformatics, UCLA, Los Angeles, CA; 2) Department of Computer Science Engineering, Dongguk University-Seoul, South Korea; 3) Computer Science Department, UCLA, Los Angeles, CA; 4) Department of Human Genetics, UCLA, Los Angeles, CA; 5) Department of Pathology, UCLA, Los Angeles, CA.

**Motivation:** Several studies have shown that correlated gene expression levels can be produced by complex biological regulatory networks. Unfortunately, confounding factors, such as shared environmental factors or trans-regulators affecting two genes, may spuriously induce correlations between the gene expressions. These false correlations prevent us from being able to make causal statements about the effect of one gene on another: gene-on-gene effects. By leveraging ideas from Mendelian randomization, it is possible to circumvent the confounding effects and estimate gene-on-gene effects. *cis*-eQTLs are genetic variants that regulate gene expression in nearby genes. These variants are subject to Mendelian randomization and can be used as instrumental variables to determine the direction and effect size of gene-on-gene regulating effects. We introduce a method, GGmend (Gene-on-Gene effect estimator using Mendelian randomization) that identifies gene-on-gene regulatory effects utilizing a quartet of two genes and their two *cis*-eQTLs. **Results:** We use several simulated datasets to show that our method is robust to expression correlations induced by confounding effects and that the family-wise error rate is well calibrated. For small sample sizes, the power of the method is influenced by the correlation in confounders. Further, we applied our method to GTEx data. Although our method has low power for the small sample sizes in the data, we successfully identified a gene pair that has a significant gene-on-gene effect after controlling for the false discovery rate at 0.05.

**1682T**

**A novel computational and experimental approach for allele-specific expression analysis in high-throughput reporter assays.** C. Kalita<sup>1</sup>, C. Brown<sup>2</sup>, X. Wen<sup>3</sup>, R. Pique-Regi<sup>1,2</sup>, F. Luca<sup>1,2</sup>. 1) Center for Molecular Medicine and Genetics, Wayne State University; 2) Department of Obstetrics and Gynecology, Wayne State University; 3) Department of Genetics, University of Pennsylvania; 4) Department of Biostatistics, University of Michigan.

The majority of the human genome is composed of non-coding regions containing regulatory elements such as enhancers, which are crucial for controlling gene expression. Many variants associated with complex traits are in these regions, and may disrupt gene regulatory sequences. Consequently, it is important to not only identify true enhancers but also to test if a variant within an enhancer affects gene regulation. Recently, allele-specific analysis in high-throughput reporter assays, such as massively parallel reporter assays (MPRA) and STARR-seq (self-transcribing active regulatory region sequencing), have been used to functionally validate non-coding variants. However, we are still missing high-quality and robust experimental protocols and data analysis tools for these datasets. Computationally, current data-analysis methods to measure allele specific expression (ASE) are limited in their ability to account for the uncertainty on the original plasmid proportions, over-dispersion, and sequencing errors. Experimentally, methods derived from the STARR-seq protocol do not have a barcoding strategy to remove PCR duplicates. We have further developed our method QuASAR (quantitative allele-specific analysis of reads), to analyze ASE in barcoded read count data. Using a beta-binomial distribution, QuASAR-MPRA better models the variability present in the allelic imbalance of these synthetic reporters and results in a test that is statistically well calibrated under the null. Additionally, the provided allelic skew estimate and its standard error simplifies meta-analysis of replicate experiments. To develop QuASAR-MPRA we re-analyzed a recent MPRA study and identified 602 SNPs with allele-specific signal (FDR 10%). Additionally we validated computational annotations of regulatory variants, for subsequent experimental validation. To this end we modified the standard STARR-seq protocol to include the use of a UMI (unique molecular identifier) and used it to test 50,609 computationally and experimentally predicted regulatory variants. We confirmed the regulatory function of 2234 SNPs (FDR 10%). Our study shows that by having the appropriate data analysis tools and experimental approach, we can greatly improve the power to detect allelic effects in high throughput reporter assays. Furthermore, we can accelerate the discovery of causal variants by iteratively improving our computational models that prioritize genetic variants for reporter assay validation.

**1683F**

**Identifying imprinted genes using parent of origin effects on gene expression in the Hutterites.** S. Mozaffari<sup>1,2</sup>, D. Nicolae<sup>1,2,3,4</sup>, C. Ober<sup>1,2</sup>. 1) Committee on Genetics, Genomics & Systems Biology, University of Chicago, Chicago, IL; 2) Department of Human Genetics, University of Chicago, Chicago, IL; 3) Department of Statistics, University of Chicago, Chicago, IL; 4) Department of Medicine, University of Chicago, Chicago, IL.

Gene expression studies typically treat alleles inherited from the mother and the father as equivalent, although variants can affect gene expression differently depending on whether they are maternal or paternal in origin. Previous studies to identify parent of origin effects (POEs) on gene expression to uncover new imprinted loci have used the gene expression from both inherited chromosomes. However, none have mapped human gene expression transcripts to specific parental haplotypes to either measure POEs on gene expression or identify imprinted genes. In this study, we used RNAseq from lymphoblastoid cell lines (LCLs) from 430 S Dakota Hutterites, who are related to each other in a single pedigree and descendants of 64 founders. Genotypes were imputed and phased, and alleles assigned as maternally- or paternally-inherited, using PRIMAL. We mapped reads to parent of origin depending on the origin of the allele for SNPs within each read for each individual. To identify genes that are expressed more on the maternally- or paternally-inherited chromosomes, we performed two tests of asymmetry. First, we randomly permuted (1000x) the maternal and paternal gene expression values for each gene among all individuals, and then compared the average maternal or paternal expression in the observed data to the randomly permuted average expression patterns to assess significance. Using this test, there were 1,530 significant genes ( $P_{\text{Bonferroni}} < 2.9 \times 10^{-6}$ ), of which 41 were known imprinted genes: 14 maternally expressed, including *ABCC9*, *H19*, *ZNF597*, *KCNQ1*; and 27 paternally expressed, including *FAM50B*, *GNAS-AS1*, *L3MBTL1*, *LIN28B*, *MEST*, *NHP2L1 (DLK1)*, *ZDBF2*, and *PEG10*. In the second test, we calculated a binomial Z-score for each individual for each gene using non-normalized maternal and paternal gene expression. We then tested for normality of Z-scores using a Shapiro-Wilk test. 2,221 genes had asymmetric distributions significantly different from normal, including 29 known imprinted genes, such as *AIM1*, *DNMT1*, *FAM50B*, *H19*, *KCNQ1*, *NAP1L5*, *PEG10*, and *ZDBF2*. Some genes not previously characterized as imprinted were significant in both tests, e.g. *MAP2K3*, *PAPOLB*, *PCGF5*, *PSME2*, and *SSBP4*. These genes with POEs we detected are putative novel imprinted genes. This simple and unique approach to map reads to parental chromosomes provides an accurate estimate of maternal or paternal imbalances to identify POEs and novel imprinted loci in humans.

**1684W**

**Efficient detection of trans-gene regulation via association with predicted gene expression.** J.A. Mefford<sup>1</sup>, X.Y. Liu<sup>2</sup>, A. Dahl<sup>1</sup>, J. Witte<sup>1</sup>, A.L. Price<sup>2</sup>, N. Zaitlen<sup>1</sup>. 1) UCSF, San Francisco, CA; 2) Harvard T.H. Chan School of Public Health, Boston, MA.

Most genetic associations with human disease reside in non-coding regions of the genome, implicating perturbation of gene regulation. Although thousands of cis-eQTLs have been identified, the heavy multiple-testing burden of trans-eQTL scans remains a challenge. Here we present an efficient method that detects trans-genetic regulation of gene expression via gene-based tests of association. The method first predicts each gene's expression from cis-genetic variation using linear mixed models and their sparse extensions which improve accuracy by better modeling genetic architecture. Second, we use the cis-genetic predictions in place of individual SNPs in tests of association with expression of each distal gene. To match the relevant population, tissue-type, and experimental conditions, the cis-genetic predictive models are built using the same dataset in which the trans-analyses are conducted. To prevent overfitting, we developed a computationally efficient cross-validation procedure to generate out-of-sample predictions for each individual's expression level. In addition to reducing the multiple testing burden, our approach enables an efficient adjustment for conditional surrogate variables. We recently showed that naïve adjustment via PCA, PEER, and SVA could both reduce power and induce false positives in eQTL studies (Dahl et al 2017 bioRxiv). While conditional adjustment via SVA addresses these issues, it is computationally prohibitive in traditional trans-QTL studies because factors must be recomputed for each SNP. By using cross-validated gene expression predictions we efficiently adjust for conditional surrogate variables, substantially improving power while minimizing spurious associations. We applied our approach to detect trans-eQTLs in the GEUVADIS RNAseq dataset consisting of 375 samples of European ancestry (Lappalainen et al. 2013 Nature). To prevent false positive trans-associations driven by homologous genes, we removed reads that were mapped to multiple genomic locations (Battle et al 2014 Gen Res). We identified 139 trans-regulation gene pairs at a multiple testing threshold of  $1 \times 10^{-7}$ . We also identified master regulators, including *POLR1B* and *TNFRSF13C*, regulating more than 10 genes. In summary, our gene-based method reduces the burden of multiple testing, and efficient cross-validated in-sample prediction and association tests allow powerful detection of trans-regulation in specific cell-types and experimental conditions.

Intra-sample cell-type heterogeneity is an important confounding factor when disentangling disease associations in molecular assays derived from complex biological samples. Previous work has successfully used HumanMethylation450 BeadArray data to estimate cell type composition in peripheral blood samples to identify DNA methylation changes associated with cell type rather than disease. However, predictions of cell proportions have only had limited direct biological validation, and were untested on next-generation sequencing (NGS) data. Here, we present the first large-scale analysis of high throughput bisulfite sequencing DNA methylation data, examining blood cell type specific methylation and validating against 897 whole blood samples in five NGS datasets with associated white cell count (WBC) data. Combining publicly available NGS methylation data as well as internal datasets from 19 purified blood cell types, we test up to 2.8M CpGs, identifying sites that are specifically hypomethylated (< 20% methylation in all samples for a cell type) or hypermethylated (> 80% methylation in all samples for a cell type). Hypo- and hyper- methylation remains consistent between cell types of the same lineage – myelocytes such as macrophages, monocytes, neutrophils and eosinophils all cluster by methylation similarity on one branch, whereas activated lymphocytes such as memory T-cells and B-cells formed a distinct methylation group. Hypomethylated CpGs directly correlate with measured blood cell proportions of neutrophils (R=-0.92, n=11,481), lymphocytes (R=-0.94, n=486), monocytes (R=-0.82, n=9661). We also observe strong correlations of hypermethylated CpGs for lymphocytes (R=0.97, n=12,342). Putatively eosinophil-specific hypomethylated CpGs (n=20,788) were instead highly correlated to the neutrophil (R=-0.90) and lymphocyte (R=0.95) cell proportions. However, a subset of these CpGs correlated to the eosinophil cell proportions (R=-0.88, n=5615). Finally, observed variation in correlation of cell type specific DNA methylation with WBC across the five cohorts may be linked to the DNA source. Specifically, we noted consistently lower correlation in buffy coat samples vs. whole blood (mean absolute correlation |R|=0.67 vs |R|=0.81, paired t-test  $p=0.02$ ). Next generation sequencing provides a unique tool for discovery of cell-type specific methylation, as well as an effective method for assessing the cell-type composition of heterogeneous tissues such as whole blood.

**Inter-individual variation in microbiome composition controls human gene expression.** A.L. Richards<sup>1</sup>, A.L. Muehlbauer<sup>2,4</sup>, A. Alazizi<sup>1</sup>, M.B. Burns<sup>3,4</sup>, C. Cascardo<sup>1</sup>, R. Pique-Regi<sup>1,2</sup>, R. Blekhan<sup>3,4,5</sup>, F. Luca<sup>1,2,5</sup>. 1) Center for Molecular Medicine and Genetics, Wayne State University, Detroit, Michigan, USA; 2) Department of Obstetrics and Gynecology, Wayne State University, Detroit, Michigan, USA; 3) Department of Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, Minnesota, USA; 4) Department of Ecology, Evolution and Behavior, University of Minnesota, Minneapolis, Minnesota, USA; 5) Corresponding Author.

Although there is large variation in the microbiome across individuals, it is not clear how this variation affects the host, and specifically which microbes and human genes are involved. Here, we used an experimental system to explore the effect of the gut microbiota on gene regulation in human colonic epithelial cells. We treated the colonic epithelial cells with live microbiota samples derived from five healthy individuals. We identified over 5,000 genes that change expression in the host cells following co-culturing (FDR = 10%,  $|\log_{2}FC| > 0.25$ ). Many genes show consistent changes in expression across microbiomes despite differences in microbial composition of the five samples, suggesting that these genes contribute to the host response to general microbiota exposure. Interestingly, we identified 409 host genes that showed varying changes in expression across the five microbiomes, suggesting that these genes are likely responsive to particular microbes that differ in abundance across individuals. To assess this directly, we examined whether the abundance of particular microbes influences expression of specific genes and found 121 genes whose expression was associated with at least one of 46 microbial taxa (FDR = 10%). Furthermore, the taxa with the strongest influence on gene expression (greater than 30 genes at FDR = 20%), alter the response of genes enriched for GWAS traits, including traits previously linked to the microbiome, such as colorectal cancer and obesity. These data demonstrate that we are able to identify specific microbes that are likely to influence host complex traits. We next validated the effect of the genus *Collinsella*, whose abundance has previously been associated with colorectal cancer, on gene expression by manipulating its abundance in the co-culturing system. We identified over 1,000 genes responsive to *Collinsella* that were also 1.5-fold enriched for GWAS traits ( $p < 10^{-10}$ ). Our results demonstrate that inter-individual variation in microbiome composition leads to differential gene expression in host colonic epithelial cells and suggest that this is a potential mechanism by which the microbiota affects human complex trait variation.

**Characterizing tissue-specific lincRNA transcription and regulatory roles.** A.D.H. Gewirtz<sup>1</sup>, I.C. McDowell<sup>2</sup>, A.A. Pai<sup>3</sup>, C. Guo<sup>4,5</sup>, C.M. Vockley<sup>6,10</sup>, C.D. Brown<sup>5</sup>, T.E. Reddy<sup>2,5,9</sup>, B.E. Engelhardt<sup>7,8</sup>. 1) Quantitative and Computational Biology, Princeton University, Princeton, NJ; 2) Computational Biology and Bioinformatics, Duke University, Durham, NC; 3) Department of Biology, Massachusetts Institute of Technology, Cambridge, MA; 4) University Program in Genetics and Genomics, Duke University, Durham, NC; 5) Center for Genomic and Computational Biology, Duke University, Durham, NC; 6) Department of Genetics, University of Pennsylvania, Philadelphia, PA; 7) Department of Computer Science, Princeton University, Princeton, NJ; 8) Center for Statistics and Machine Learning, Princeton University, Princeton, NJ; 9) Department of Biostatistics and Bioinformatics, Duke University, Durham, NC; 10) Department of Cell Biology, Duke University Medical Center Durham, NC.

Understanding genetic regulation is one of the fundamental challenges in biology, yet most studies only examine protein-coding genes. Long intergenic non-coding RNAs (lincRNAs) are enriched for genome-wide association study (GWAS) variants, implicating these non-coding RNAs in complex trait phenotypes. LincRNA expression patterns are more tissue-specific than mRNAs and their roles in mammalian cellular differentiation have been established through knockout studies, suggesting highly tissue-specific functions. Indeed, lincRNAs are often well connected in cell type-specific gene regulatory networks. In this study, we characterize tissue-specific lincRNA transcription and regulatory mechanisms using the NIH Common Fund's Genotype-Tissue Expression (GTEx) V6 project data, consisting of RNA sequencing data for 449 human individuals across 44 tissues. By using the largest cross-tissue human transcriptome study to date, we detect tissue-specific and tissue-shared relationships among lincRNA, mRNA transcription levels, and organismal traits. To examine differential transcription mechanisms between lincRNA and mRNA, we compare cis-regulatory element enrichment among cis linc- and cis protein coding-expression quantitative trait loci (eQTLs). We identify likely trait-associated lincRNAs with eQTLs using GWAS variants and investigate biological properties unique to these lincRNAs. Preliminary results on four GTEx tissues show that obesity-related traits show substantial enrichment of GWAS variants among linc-eQTLs versus protein coding-eQTLs. We use matched-tissue ChIP-Seq and Hi-C data to investigate modes of action for the trait-associated lincRNAs in the context of topologically associating domains and chromosomal architecture. Furthermore, we use a Mendelian randomization framework to examine the mechanistic effects of linc-eQTLs on distal mRNA expression levels in a genome-wide manner. This study provides novel insights into tissue-specific lincRNA transcription and subsequent regulatory roles of lincRNA across 44 human tissues.

**1688T****The landscape of short RNAs in human cell types and tissues.** Y.Y.

*Leung<sup>1,2</sup>, P.P. Kuksa<sup>1,2</sup>, A. Amlie-Wolf<sup>3</sup>, L.-S. Wang<sup>1,2,3,4,5</sup>* 1) Penn Neurodegeneration Genomics Center, Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, PA; 2) Penn Institute for Biomedical Informatics, University of Pennsylvania, Philadelphia, PA; 3) Genomics and Computational Biology Graduate Group, University of Pennsylvania, Philadelphia, PA; 4) Department of Genetics, University of Pennsylvania, Philadelphia, PA; 5) Department of Computer and Information Science, University of Pennsylvania, Philadelphia, PA.

Most of mRNAs are regulated by various non-coding RNAs. One of the classes is small RNAs (<200 nts, sncRNA), that can regulate gene expression through association with transcription factor complexes and binding to target mRNA, e.g., UTRs, promoters, and intronic regions. To identify all human specifically processed sncRNAs, we developed a novel ab initio approach, SPAR, and analyzed all ENCODE small RNA datasets across 62 human cell types and tissues. Unlike the standard approach of mapping sequencing reads to known sncRNA transcripts, our method characterizes sncRNA loci by separating the identification of sncRNA peaks (unsupervised segmentation) from the annotation process. To more accurately delineate sncRNA regions, we developed the following features to capture the specific processing patterns of sncRNAs: 1) read accumulation relative to the genomic background; 2) consistency of read sizes within locus; and 3) non-random specificity of 5' and 3' read ends. This ab initio model ensures that called sncRNAs are specifically processed from precursors rather than from random degradation. We identified 76,189 distinct specifically processed small RNA loci across 12 RNA classes, of which 76% were previously unannotated. The detected loci were highly reproducible (Spearman  $\rho = .82$  across ENCODE replicates). 30% of loci were highly conserved (100-way phastCons >.8) suggesting important functional roles. Expression of the detected loci recapitulated known tissues and cell type lineage (Rand Index = .89). On average, in each tissue or cell type, 40% of the sncRNAs display tissue/cell type-specific expression patterns. We discovered that open chromatin regions are enriched for sncRNA loci (2.4 fold), with 34% of sncRNAs residing in open regions. Interestingly, UTR exons were enriched (4-5x) for sncRNA loci, followed by exonic (2.9) and promoter regions (2.2). However, intronic regions were depleted. 60% of the loci have highly specific start and end points across tissues, while the remaining display tissue-dependent alternative processing patterns with slight variability at the start and end sites. We found multiple distinct sncRNAs derived from the same precursors, with 4 distinct loci per snoRNAs, 5 per tRNAs, and 2 per 5' and 3' 50nt flanking regions of tRNAs. The results have been integrated into DASHR 2.0 (<http://lisanwanglab.org/DASHR/v2>). The compendium of sncRNA loci characterized here is valuable for biomarker development and studying sncRNA biology.

**1689F****Silencing of transposable elements may not be a major driver of regulatory evolution in primate induced pluripotent stem cells.** M.C. Ward<sup>1,2</sup>, S. Zhao<sup>1</sup>, K. Luo<sup>1</sup>, B.J. Pavlovic<sup>1</sup>, M.M. Karim<sup>3,4</sup>, M. Stephens<sup>1,5</sup>, Y. Gilad<sup>1,2</sup>. 1) Department of Human Genetics, University of Chicago, Chicago, IL, USA; 2) Department of Medicine, University of Chicago, Chicago, IL, USA; 3) The Biomedical Research Centre, University of British Columbia, Vancouver, Canada; 4) Qatar Biomedical Research Institute, Hamad Bin Khalifa University, Doha, Qatar; 5) Department of Statistics, University of Chicago, Chicago, IL, USA.

Transposable elements (TEs) comprise a substantial proportion of primate genomes. The regulatory potential of TEs can result in deleterious effects, especially during development. It has been suggested that, in pluripotent stem cells, TEs are targeted for silencing by KRAB-ZNF proteins, which recruit the TRIM28-SETDB1 complex, to deposit the repressive histone modification H3K9me3. TEs, in turn, can acquire mutations that allow them to evade detection by the host, and hence KRAB-ZNF proteins need to rapidly evolve to counteract them. To investigate the short-term evolution of TE silencing, we profiled the genome-wide distribution of H3K9me3 in induced pluripotent stem cells from ten human and seven chimpanzee individuals. We performed chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-seq) for H3K9me3, as well as total RNA sequencing. We focused specifically on cross-species H3K9me3 ChIP-seq data that mapped to four million orthologous TEs. We found that, depending on the TE class, 10-60% of elements are marked by H3K9me3, with SVA, LTR and LINE elements marked most frequently. We found little evidence of inter-species differences in TE silencing, with as many as 80% of orthologous, putatively silenced, TEs marked at similar levels in humans and chimpanzees. Our data suggest limited species-specificity of TE silencing across six million years of primate evolution. Interestingly, the minority of TEs enriched for H3K9me3 in one species are not more likely to be associated with gene expression divergence of nearby orthologous genes. We conclude that orthologous TEs may not play a major role in driving gene regulatory divergence between humans and chimpanzees. .

**Map of the functional domains of the long non-coding RNA XIST generated using CRISPR mediated deletions.** *T. Dixon-McDougall, C. Brown.* Department of Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada.

XIST is a nearly 20kb long non-coding RNA (lncRNA) that coats the X chromosome and triggers the stable inactivation of the nearly 1000 genes along its length, making it one of the most powerful regulatory factors in the epigenome. Like other regulatory lncRNAs, XIST is thought to act as a modular scaffold, binding factors that reorganize chromatin marks, silence gene expression and restructure its chromosome of origin. Many XIST interacting proteins have been identified, yet how these factors coordinate with XIST to inactivate a chromosome is still a mystery. To develop a map of the functional domains of XIST and their contributions to chromosome inactivation, the functionality of inducible full-length and partial XIST constructs were compared to determine the effect of removing various domains of XIST. As the X-chromosome's unique architecture contributes to X-chromosome inactivation, confounding variables were reduced by integrating and expressing the XIST cDNA constructs from an FRT site located on chromosome 8p in a male cell line. Most partial XIST constructs were generated from the full-length construct using CRISPR to remove specific domains, with a focus on the tandem repeats. A minority of the partial constructs were generated by separately integrating custom XIST cDNA sequences into the 8p FRT site. To compare the constructs, we used immunofluorescence and RNA FISH to examine heterochromatin mark recruitment and the chromosome of origin's localization to the perinucleolar compartment; as well as allele-specific pyrosequencing to measure XIST induced gene silencing. The region 3' of XIST's exon 1 and in particular the E repeat is crucial to the recruitment of heterochromatin marks, including H3K27me3, as well as distal gene silencing. Analysis of the XIST D-repeat suggests that even when autosomally expressed it is necessary for maintaining XIST RNA levels. In addition, numerous other internal regions of XIST were found to be necessary for establishing silencing and recruitment of specific heterochromatin marks while also demonstrating which regions are dispensable for these functions, creating the first completed map of the functional domains of human XIST. This research opens the door to identifying novel long non-coding RNA functional domains, the factors that bind these domains, and ultimately the epigenetic pathways employed by regulatory lncRNAs to control the epigenome.

**1691T**

**Recognition of human elements regulating escape from X-chromosome inactivation in mouse.** *S.B. Peeters<sup>1</sup>, A.J. Korecki<sup>1,2</sup>, E.M. Simpson<sup>1,2</sup>, C.J. Brown<sup>1</sup>.* 1) Department of Medical Genetics, University of British Columbia, Vancouver, BC, Canada; 2) Centre for Molecular Medicine and Therapeutics, University of British Columbia, Vancouver, BC, Canada.

X-chromosome inactivation (XCI) epigenetically silences one X chromosome in every cell in female mammals; however, approximately 12–20% of genes escape from XCI in humans and continue to be expressed from both the active and inactive X chromosomes, while only 3–7% of X-linked genes escape in mouse. In light of known species differences between escape gene number and distribution on the X chromosome, we tested whether mouse is a suitable model for studying human escape from XCI through integration of a human BAC at the X-linked *Hprt* gene. Subsequent expression and DNA methylation analysis of transgene activity on an inactive X chromosome in adult female mice demonstrated expression and correspondingly low promoter DNA methylation of human genes *RPS4X* and *CITED1*. Therefore, either the mechanisms of escape are conserved between mouse and human, or at the very least the mouse system is capable of recognizing human elements necessary for escape from XCI. Silencing of a normally subject gene (*ERCC6L*) on the BAC, as well ongoing silencing of genes near the integration site, also suggests retention and recognition of boundary elements between subject and escape regions on the BAC. Preliminary data from developmental time points suggests that transgenic *RPS4X* is expressed from the inactive X in females as early as embryonic day 9.5, arguing for continuous expression from the transgene rather than initial silencing and reactivation. As human embryonic stem cells remain an epigenetically unstable model for studying XCI, we have generated a female mouse embryonic stem cell line with an *Hprt* "docking site" similar to the transgenic mouse system, allowing more rapid assessment of additional human genes for intrinsic escape ability; as well as facilitating further investigation and characterization of the critical regions responsible for continued expression from an inactive X chromosome. Expression of genes escaping from XCI may contribute to the phenotypes of X aneuploidies as well as influence male and female susceptibility to disease, therefore studying their mechanisms may offer insight into sex differences in addition to exploring the gene regulatory mechanisms involved in XCI.

**1692F****Interaction of exocrine and endocrine pancreas in obesity ciliopathies.**

*T. Hostelley, J. Nesmith, S. Lodh, N. Zaghloul.* Division of Endocrinology, Diabetes and Nutrition, Department of Medicine, University of Maryland School of Medicine, Baltimore, MD, USA.

Ciliopathies are rare genetic disorders characterized by dysfunction in primary cilia. Two ciliopathies, Alström Syndrome and Bardet-Biedl Syndrome (BBS), are characterized by high rates of obesity. However, they have strikingly different rates of diabetes. The rate is much higher in Alström patients relative to BBS. To gain insight into genetic mechanisms for this discrepancy we performed whole transcriptome sequencing on zebrafish depleted of the Alström gene, *alms1*, or the BBS gene, *bbs1*. We identified gene expression changes and found 8 genes that were differentially expressed in opposite directions between the two models. Among these, several exocrine pancreas enzymes were downregulated in Alström and/or upregulated in BBS. Based on this, and our previous demonstration of  $\beta$ -cell mass changes in models of both disorders, we hypothesized that the expression of exocrine pancreas enzymes affects endocrine pancreas function. This might suggest that impaired  $\beta$ -cell function in Alström results from reduced expression of exocrine pancreas enzymes, while the opposite may be true in BBS. These findings also support a non-ciliary role for BBS and Alström genes as we found them to be expressed in the non-ciliated acinar cells. To test our hypothesis, we overexpressed each enzyme in transgenic zebrafish embryos, in which  $\beta$ -cells can be visualized. In control animals, overexpression of the exocrine pancreas enzymes significantly increased the number of  $\beta$ -cells, suggesting that these enzymes play a role in regulating  $\beta$ -cell mass and function. Overexpression could also rescue the loss of  $\beta$ -cells observed in animals depleted of *alms1*. We have also found that the inactive, zymogen, form of these enzymes are selectively taken up by  $\beta$ -cells *in vitro* and induce proliferation in cultured *MIN6*  $\beta$ -cells. This suggests a direct interaction between the exocrine and endocrine pancreas. Taken together, these data support the possibility that exocrine pancreatic enzymes may play an important role in the modulation of  $\beta$ -cells in diabetes.

**1693W****Down-regulation of *SRSF3* mRNA expression in mice with *KIF23***

**c.2747C>G mutation known as a cause of congenital dyserythropoietic anemia type III (CDA III): Expression study.** *A.-L. Vikberg, S. Malla, I. Golovleva.* Medical and Clinical Genetics, Medical Biosciences, Umeå University, Sweden.

Congenital dyserythropoietic anemia type III (CDA III) is a rare hereditary disease initially described in a large Swedish family. Affected individuals suffer from mild to moderate hemolytic anemia as a result of cell division failure in erythroblasts. Retinal angioid streaks and monoclonal gammopathy of unknown significance or myeloma are additional features present in some of the CDA III individuals. Recently, we showed that CDA III is caused by a mutation c.2747C>G, p.P916R in kinesin family member 23, *KIF23*, affecting the final step of cell cycle, cytokinesis, and resulting in bi-nuclear cells. Previously, two *KIF23* transcripts, one full-length and another one lacking exon 18 have been described while we reported the third transcript with absence of exon 17 and 18. The aim of this study was to understand the tissue-specific effect of *KIF23* c.2747C>G by investigating an mRNA expression of *KIF23* in different tissues. *KIF23* expression of all three transcripts was studied by reverse transcription of RNA extracted from blood, bone marrow and CFU-E of a CDA III patient and commercially available RNA from 17 normal human tissues and 11 normal mouse tissues followed by digital droplet PCR. We also used a knock-in mouse model with *KIF23* c.2747C>G mutation and quantified expression of *KIF23* and its splicing factor *SRSF3* in blood, bone marrow, CFU-E, brain, heart, kidney, liver, lung, spleen and testis. We showed large variations in *KIF23* expression between different human tissues with the highest level in bone marrow and testis. Full-length transcript was most prevalent in testis, while a transcript lacking exon 18 was dominant in bone marrow. Notably, that a transcript without exon 18 was most prevalent in CFU-E of the CDA III patient, compare to CFU-E of healthy individual where full-length transcript was the most dominant. In mice, the highest *KIF23* expression was in testis, and unlike humans, the shortest transcript lacking both exon 17 and 18 was most prevalent in most tissues. We also examined how knock-in of *KIF23* c.2747C>G mutation in mice affects expression of a splicing factor *SRSF3* known to regulate expression and alternative splicing of *KIF23*. Preliminary results show that homozygous wild type mice exhibit highest levels of *SRSF3* compared to homozygous carriers of c.2747C>G mutation. We conclude that not only *SRSF3* regulates *KIF23* expression but also *KIF23* c.2747C>G down-regulates mRNA expression of splicing factor *SRSF3*.

**1694T**

**Haploinsufficiency of a histone modifier, *Kmt2d*, in a mouse model of Kabuki syndrome leads to widespread defects in the B cell lineage.** G. Pilarowski<sup>1,2</sup>, T. Cazares<sup>3</sup>, L. Zhang<sup>1</sup>, A. Lindsley<sup>2</sup>, H.T. Bjornsson<sup>1,4</sup>. 1) Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 2) Predoctoral Program in Human Genetics, Johns Hopkins University School of Medicine, Baltimore, MD; 3) Division of Allergy & Immunology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 4) Department of Pediatrics, Johns Hopkins University, Baltimore, MD.

Kabuki syndrome (KS) Type 1 is an autosomal dominant Mendelian disorder of the epigenetic machinery caused by loss of function mutations in the histone modifying protein KMT2D. KMT2D adds histone 3, lysine 4 (H3K4) mono- and trimethylation, which are thought to play a major role in the activation of enhancers and promoters, respectively. Individuals with Kabuki syndrome demonstrate intellectual disability, postnatal growth retardation and craniofacial abnormalities, all of which are recapitulated in a mouse model of Kabuki syndrome (*Kmt2d*<sup>+/-Bgeo</sup> mice). Additionally, KS patients have been described to have immune dysfunction with decreased serum IgA although the mechanistic basis is unknown. Our study of *Kmt2d*<sup>+/-Bgeo</sup> mice suggests that defects in B cell mucosal immunity may underlie the phenotypes seen in KS patients. *Kmt2d*<sup>+/-Bgeo</sup> mice have splenomegaly (p<0.03) and slightly elevated serum IgM (p<0.02) levels and a 4 fold decreased serum IgA levels (p<0.0002) compared to WT littermates. IgA is a major component of mucosal immunity that is primarily produced in the gut. Therefore, to investigate the mechanism of observed IgA defects, we examined the secondary lymphoid tissue of the gut, the Peyer's patches (PP). Though the PP compartmental organization was grossly normal, PP's in *Kmt2d*<sup>+/-Bgeo</sup> mice are strikingly smaller and there are significantly fewer PP's compared to WT littermates (*Kmt2d*<sup>+/-Bgeo</sup> mean=2.4; WT mean=7.2; p<0.0001). We detected significantly decreased levels (50%; p<0.02) of a post-IgA-class-switch-recombination transcript in the mesenteric lymph nodes in *Kmt2d*<sup>+/-Bgeo</sup> mice compared to WT littermates. We also observe defects in antigen-specific humoral responses to mucosal vaccination. For further examination, we targeted the B1 cell population of the peritoneal cavity, which has been hypothesized to contribute to IgA-producing plasma cells in the gut. We discovered a decreased B1a cell population in *Kmt2d*<sup>+/-Bgeo</sup> mice compared to WT littermates (24% vs 42% of B1 parent population, p<0.0005). Thus, our data suggest defects in mucosal immunity and widespread defects of the B cell lineage in *Kmt2d*<sup>+/-Bgeo</sup> mice. Epigenomic study of B1a cells may potentiate mechanistic understanding regarding how a primary mutation in an epigenetic modifier can lead to immunological dysfunction through epigenetic dysregulation. Furthermore, these findings will stimulate further studies of the B cell lineage in individuals with Kabuki syndrome.

**Models of human disease available from The Jackson Laboratory.** S. Rockwood, C. Lutz, *The Genetic Resource Science Team*. The Jackson Laboratory, Bar Harbor, ME.

The mouse continues to provide researchers a means by which to address questions related to basic disease mechanisms. The emergence of disruptive genetic engineering technologies have proven to be very applicable to the mouse, spawning a new generation of promising preclinical models. To facilitate access to this flourishing resource, The Jackson Laboratory (JAX) Mouse Repository offers one of the largest sets of well-characterized genetically engineered mutant mouse strains. Hundreds of new mouse lines generated by both the international scientific community and JAX researchers are added to the Repository each year. A growing selection of models with applications as hosts for cancer xenograft modeling, primarily on the NSG platform, is readily available. Strains have been optimized for specific purposes: support of human and murine hematopoietic cell engraftment, reduced xenogeneic graft-versus-host disease response, engraftment of human hematopoietic stem cells without irradiation and stable engraftment of primary human hepatocytes. Mouse strains that recapitulate aspects of specific diseases, such as Alzheimer's disease, Amyotrophic Lateral Sclerosis (ALS), Friedreich's Ataxia and Huntington's disease are available. Exploiting the potential of CRISPR/Cas9 technology to generate precise models of disease is made easier by a large variety of Cas9-expressing lines, including both constitutive expressing and *cre*-inducible lines. In response to the threat posed by the spread of Zika virus, colonies of *lfmr1* deficient mice have been expanded. Several recent studies demonstrate that *lfmr1* knock-out mice represent a model that will facilitate the study of Zika virus pathogenesis and should prove useful in the development related therapies and vaccines. In order to promote reproducibility in research, the Repository maintains a robust quality control and assurance program. Newly arriving strains are assayed to confirm the presence of expected mutations. Equally important, strains are also screened for undesired contaminating alleles and genetic backgrounds. Donating a strain to the Repository is an easy way to fulfill the NIH's requirements for sharing mice. Researchers wishing to have strains considered for inclusion in the Repository are encouraged to submit their strains: [www.jax.org/donate-a-mouse](http://www.jax.org/donate-a-mouse). This work is supported by NIH, The Howard Hughes Medical Institute, and private charitable foundations.

**Circulating cells protect against radiation-induced intestinal injury in a murine parabiosis system.** J. Sung<sup>1</sup>, C. Sodhi<sup>2</sup>, H. Jia<sup>2</sup>, Y. Yamaguchi<sup>2</sup>, P. Lu<sup>2</sup>, L. Voltaggio<sup>3</sup>, D. Hackam<sup>2</sup>. 1) Institute of Genetic Medicine, Johns Hopkins University, School of Medicine, Baltimore, MD; 2) Division of Pediatric Surgery, Johns Hopkins Children's Center and Department of Surgery, Baltimore, MD; 3) Department of Pathology, Johns Hopkins University School of Medicine, Baltimore, MD.

**Background** The small intestine is one of the most radiosensitive organs due to the rapid rate of intestinal stem cells (ISC) division, although the mechanisms providing protection against radiation-induced ISC death remain unknown. We hypothesize that circulating cells participate in healing after radiation-induced intestinal injury in mice, utilizing a model of parabiosis to test this. Specifically, we hypothesize that a parabiotic partner will be protected against radiation-induced enteritis by translocation of healthy bone marrow-derived cells (BMDCs) through the shared vasculature to the site of injury. We propose that the repair mechanisms of recruited BMDCs are due to (1) direct replacement of damaged intestinal epithelial cells by the BMDCs, (2) trans-differentiation of BMDCs into intestinal stem cells, and/or (3) release of biomolecules from BMDCs via the paracrine system. **Methods** Parabiotic mice were constructed by suturing the skin and muscle wall on the flank. Whole-body gamma irradiation was applied to the one partner. Injury and recovery were examined via assessment of body weight, mucosal injury, enterocyte apoptosis (TUNEL), and qRT-PCR determination of cytokines. To tract migration of BMDCs across the parabiosis pair, pairing of fluorescent and non-fluorescent mice were used. To ascertain recruited circulating stem cells are bone marrow origin, non-parabiosis mice were irradiated prior to peripheral injection of tdTomato expressing BMDCs. **Results** After 1-month of pairing, a shared circulation was confirmed by tdTomato positive cells in the blood of the wild-type partner. Significantly decreased body weight loss and injury markers (*TNF- $\alpha$* , *IL-1 $\beta$* ), and increased proliferation (*Lgr5*, *Ki67*) and epithelial differentiation (*Sucrase isomaltase*, *MucII*, *Chromogranin A*), and significant histological improvement in the injured partner confirm protection by the parabiotic pairing. Detection of tdTomato positive cells in injured intestine suggests that circulating BMDCs in peripheral blood could home to the injury site. Strikingly, the recruited BMDCs were observed in lamina propria, but not in the intestinal epithelial tissue, suggesting that the protective effects occurred via paracrine effects of the recruited BMDCs, as opposed to trans-differentiation. **Conclusion** We reveal that circulating stem cells can facilitate intestinal healing using a parabiotic system, suggesting novel cellular approaches to the treatment of radiation induced intestinal injury.

***Xenopus* as a model of precision medicine: Application of CRISPR to mimic the mutations of human CSBS syndrome patients.** S. Cha. Cincinnati Children Hospital Medical Center, Cincinnati, OH.

*Xenopus* research has provided significant clarification of both early developmental events and later processes of organogenesis. I have developed a new methodology for homology-driven repair (HDR), going beyond simple gene editing, which typically causes deletions that inactivate or impair gene function. Because HDR is performed by injecting oocytes, which are uniquely accessible in *Xenopus* system and where recombination enzymes are highly active, very high HDR rates (typically 20%) are seen in developing embryos. This allows efficient insertion of specific sequences at target sites, e.g. to insert tags into protein-coding regions in vivo, to follow protein localization during development, or to insert specific mutations into the genome (e.g. single base mutations emulating a human congenital disease). In this study, we made several *X. tropicalis* lines to model human CSBS patients carrying clinically verified mutations in CLMP and FLNA. With this model animals, we could follow morphogenetic events of the developing intestinal epithelium, aiming to understand the mechanisms of gut tube elongation and differentiation in the context of various major signaling pathways. These studies are highly relevant to understanding human diseases such as congenital short bowel syndrome (CSBS) and intestinal malrotation, which have severely impaired gut tube elongation/rotation. Overall, this study project will propel the *Xenopus* system to a new level, setting in place the potential for significant insights for basic research and greatly improved utility for modeling human disease.

**Gene expression in the developing mouse pituitary gland.** A.S. George, M.L. Brinkmeier, S.A. Camper, R.E. Mills. University of Michigan, Ann Arbor, MI.

Combined Pituitary Hormone Deficiency (CPHD) is a common cause of endocrine referral in children, yet most familial and sporadic CPHD cases have no known genetic cause. In 2009, full-length cDNA libraries were made from mouse pituitaries collected at embryonic time points e12.5 and e14.5 to create a comprehensive developmental pituitary mouse transcriptome. Single pass end sequencing was carried out and the analysis revealed a high degree of novelty among the clones. We sought to identify transcripts that mapped to unannotated genomic regions by analyzing the cDNAs using updated current reference databases. In this analysis of the clone sequences, we assigned ten transcription factors and 351 long non-coding RNA transcripts to cDNAs that were previously marked as unidentified during the initial analysis. We created a publically available online database to house the results of the curated cDNAs and their assigned genes. End sequences that were not assigned to known genes underwent further analysis. Overlapping cDNA end sequences were combined into clusters and groups that did not have any known transcribed regions were compared to RNA-seq of six wild-type postnatal pituitaries. Five clusters were revealed as potential novel transcripts and molecular analysis of the clusters is ongoing. The results of this analysis serve as a resource of embryonic mouse pituitary gene expression that can be used to provide candidate genes for CPHD of unknown etiology and for studying basic pituitary gland development. It also reveals the potential for lncRNA involvement in the developing pituitary.

**The role of *FREM2* and *FRAS1* in the development of congenital diaphragmatic hernia.** V. Jordan<sup>1</sup>, T. Beck<sup>2,3</sup>, A. Hernandez-Garcia<sup>2</sup>, P. Kundert<sup>6</sup>, B.J. Kim<sup>2</sup>, S. Jhangiani<sup>2,3</sup>, T. Gambin<sup>2,9</sup>, M. Starkovich<sup>3,1</sup>, J. Punetha<sup>2</sup>, I. Paine<sup>2</sup>, J. Posey<sup>2</sup>, A. Li<sup>1</sup>, D. Muzny<sup>2,3</sup>, A. Lashua<sup>5</sup>, X. Sun<sup>5,10</sup>, C. Fernandes<sup>8</sup>, M. Dickinson<sup>1</sup>, K. Lally<sup>1</sup>, R. Gibbs<sup>2,3</sup>, E. Boerwinkle<sup>4</sup>, J. Lupski<sup>2,3,6</sup>, D. Scott<sup>1,2</sup>. 1) Department of Molecular Physiology and Biophysics, Baylor College of Medicine, Houston, TX; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, USA; 4) Human Genetics Center, University of Texas Health Science Center, Houston, TX, USA; 5) Department of Medical Genetics, University of Wisconsin-Madison, Madison, WI, USA; 6) Department of Pediatrics, Baylor College of Medicine, Houston, TX, USA; 7) Department of Pediatric Surgery, McGovern Medical School at UT Health, Houston, TX, USA; 8) American Society for Radiation Oncology, Arlington, VA, USA; 9) Warsaw University of Technology, Institute of Computer Science, Warsaw, Poland; 10) Department of Pediatrics, University of California-San Diego, San Diego, CA, USA.

Congenital diaphragmatic hernia (CDH) can occur in isolation, with other birth defects, or as part of a genetic syndrome. In ~20% of human CDH cases, the herniated viscera are encapsulated by a membranous sac. We have shown that isolated sac CDH in humans and mice can be caused by recessive pathogenic variants in *FREM1*. In the extracellular matrix, *FREM1* forms a self-stabilizing ternary complex with *FREM2* and *FRAS1*. CDH has been described in two individuals with a clinical diagnosis of Fraser syndrome which can be caused by mutations in *FREM2* and *FRAS1*. To determine if *FREM2* and *FRAS1* are bona fide CDH genes, we examined *FREM2*- and *FRAS1*-deficient mice and embryos for evidence of CDH. We found sac hernias in 8.2% (5/61) of *FREM2*-deficient mice and 1% (1/102) of *FRAS1*-deficient mice. These hernias were indistinguishable from those seen in *FREM1*-deficient mice. We then screened a cohort of 69 individuals with CDH for changes in *FREM2* and *FRAS1*. Four individuals in this cohort (6%) carried rare, putatively deleterious compound and/or double heterozygous changes in these genes. Three individuals carried a *FREM2* c.4031G>A, p.Arg1344His change whose frequency among Caucasians in our CDH cohort was statistically greater than that seen in ethnically matched control populations ( $P < 0.0001$ ). Next, we sought to determine the morphogenetic and molecular mechanisms underlying this susceptibility to CDH. We found that sac hernias in *FREM1*-deficient mice form when the migrating muscular components of the diaphragm fail to meet at the anterior midline. We also found an absence of mature vasculature and a dramatically increased level of apoptosis in the anterior diaphragm that may contribute to an increased susceptibility to herniation. We went on to demonstrate that *GATA4*, a retinoic acid responsive transcription factor implicated in the development of sac CDH, modulates the transcriptional expression of *Fras1* in the developing diaphragm. This is consistent with previously published data showing that a block in retinoic acid signaling leads to decreased expression of *FREM1*, *FREM2* and *FRAS1* in the developing diaphragm. We conclude that deficiency of *FREM1*, *FREM2*, and possibly *FRAS1*, are associated with an increased risk of developing CDH caused by defects in diaphragmatic muscularization. Our data also suggest that retinoic acid may modulate the expression of these proteins in the developing diaphragm, at least in part, through its effects on *GATA4*.

**Identification of novel candidate genes for 46,XY disorders of sex development (DSD) using a C57BL/6J-Y<sup>POS</sup> mouse model.** E. Vilain<sup>1,4</sup>, A. Symon<sup>2</sup>, M. Zadikyan<sup>1</sup>, M. Almalvez<sup>1,4</sup>, E. Segura<sup>1</sup>, A. Eskin<sup>1</sup>, M. Bramble<sup>1,4</sup>, V. Arboleda<sup>1</sup>, R. Baxter<sup>1</sup>, S. Nelson<sup>1</sup>, E. Delot<sup>1,2</sup>, V. Harley<sup>3</sup>, H. Barseghyan<sup>1,4</sup>. 1) Departments of Human Genetics, David Geffen School of Medicine, University of California, Los Angeles, California 90095, USA; 2) Departments of Pediatrics, David Geffen School of Medicine, University of California, Los Angeles, California 90095, USA; 3) Department of Brain and Gender, Hudson Institute of Medical Research, Clayton, Victoria, 3168, Australia; 4) Center for Genetic Medicine Research, Children's National Health System, Washington D.C.

Disorders of Sex Development (DSD) have an estimated frequency of 0.5-1% of live births encompassing a variety of urogenital abnormalities ranging from mild hypospadias to a discrepancy between sex chromosomes and external genitalia. In order to identify the underlying genetic etiology, we performed exome sequencing in a subset of DSD cases with 46,XY karyotype and were able to identify the causative genetic variant in 35% of cases. While the genetic etiology was not ascertained in more than half of the cases, a large number of variants of unknown clinical significance (VUS) were identified in those exomes. To investigate the relevance of these VUS in regards to the patient's phenotype, we utilized a mouse model in which the presence of a Y chromosome from the *poschiavinus* strain (Y<sup>POS</sup>) on a C57BL/6J (B6) background results in XY undervirilization and sex reversal, a phenotype characteristic to 46,XY DSD cases. We assessed gene expression differences between B6-Y<sup>B6</sup> and undervirilized B6-Y<sup>POS</sup> males at E11.5 and identified 515 genes that were differentially expressed (308 underexpressed and 207 overexpressed in B6-Y<sup>POS</sup> males). We identified 15 novel candidate genes potentially involved in 46,XY DSD pathogenesis by filtering patient exome VUS using the B6-Y<sup>B6</sup> gene list. Using a different animal model with *Sox9* repression in XY gonads we also show that 7 of the candidate genes are under regulation of the a well-known sex determination gene *Sox9*. The use of a DSD specific animal model improves variant interpretation by correlating human sequence variants with transcriptome variation. This method can be universally applied to different diseases for which an animal model is present.

**1701F**

**Kisspeptin and Kisspeptin receptor may be involved in the regulation of adrenocortical development and steroid hormone secretion.** N. Settas, A. Berthon, A. Giannakou, A. Delaney, F.R. Faucz, C.A. Stratakis. Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, United States.

It has been shown that knockout mice for Kisspeptin receptor, *Kiss1r*, (KRKO) and its ligand Kisspeptin, *Kiss1*, (KissKO) replicate the phenotype of isolated hypogonadotropic hypogonadism (IHH) that was described in association with these genes in humans. Puberty and adrenal function are tightly linked in humans. We studied adrenal function and morphology at 5 months of age in both male and female KRKO and KissKO mice that do not go through normal puberty. Two fetal markers, 20 $\alpha$ HSD and Cyp17, were expressed in eosinophilic cells, which are accumulated at the border between the cortex and the medulla. These cells may be derived from the fetal zone that should disappear at puberty in male and during the first pregnancy in female mice. Interestingly, KRKO and KissKO females (but not males) showed corticosterone and aldosterone hypersecretion. Although hypercorticosteronism corrected overtime, hyperaldosteronism persisted at age 14 months and correlated with overexpression of the transcription factor *Star*. To determine if *KISS1* and *KISS1R* genes are involved in the development of primary aldosteronism (PA) and hypercortisolism (Cushing syndrome-CS) in humans, we sequenced them in a cohort of 65 patients. In the *KISS1* gene, we identified two polymorphisms (c.-89G>A and c.417\_417delA) with a higher frequency in our cohort compared to the 1000GP (14% vs 8% and 33% vs 22%, respectively). Interestingly, we found a mutation (p.H90D, rs201073751) previously reported for causing central precocious puberty (CPP) in a patient with CS without CPP. The analysis of this patient's adrenal tumor did not reveal any somatic mutations. Moreover, we discovered three rare variants in *KISS1R* gene, two missense and one synonymous, in three different patients with PA: rs141767649 (p.C95W), rs73507527 (p.A189T) and rs115335009 (p.R229R). The two missense variants have been previously associated with IHH and Kallmann syndrome, respectively. Our findings suggest that *KISS1* and *KISS1R* may play a role in adrenal function in mice and possibly adrenocortical steroid hormone secretion abnormalities in humans. This study is ongoing, as more data are needed to elucidate the potential role of *KISS1* and *KISS1R* in adrenocortical function and development.

**Genome-wide association study of infantile hypertrophic pyloric stenosis identifies four new loci and highlights the importance of embryonic *NKX2-5/BARX1* pathways.** L. Skotte<sup>1</sup>, J. Fadista<sup>1</sup>, F. Geller<sup>1</sup>, J. Bybjerg-Grauholm<sup>2</sup>, S. Gørtz<sup>1</sup>, H. Matsson<sup>3</sup>, H.A. Boyd<sup>4</sup>, D.M. Hougaard<sup>2</sup>, A. Nordenskjöld<sup>2,4</sup>, M. Melbye<sup>5,6</sup>, B. Feenstra<sup>1</sup>. 1) Department of Epidemiology Research, Statens Serum Institut, Copenhagen, Denmark; 2) Danish Centre for Neonatal Screening, Department of Congenital Disorders, Statens Serum Institut, Copenhagen, Denmark; 3) Department of Women's and Children's Health, and Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden; 4) Department of Pediatric Surgery, Astrid Lindgren Children's Hospital, Karolinska University Hospital, Stockholm, Sweden; 5) Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; 6) Department of Medicine, Stanford University School of Medicine, Stanford, California, USA.

**Introduction:** Infantile hypertrophic pyloric stenosis (IHPS) is the most common cause of intestinal obstruction in infancy. IHPS is caused by hypertrophy of the smooth sphincter muscle that surrounds the pylorus, which connects the stomach to the duodenum. **Materials and Methods:** We performed a genome-wide association study of 1,395 Danish surgery-confirmed cases and 4,438 controls in order to detect novel loci associated with IHPS. The analysis was based on 6.6 million variants imputed from the Haplotype Reference Consortium panel, using logistic regression on imputed SNP dosages for association testing. **Results:** In addition to variants at the known *MBNL1*, *ARHGEF26*, *NKX2-5* and *APOA1* loci, we found four new loci with variants reaching genome-wide significance ( $P < 5 \times 10^{-8}$ ). The most strongly associated variant (minor allele frequency; MAF=2%) had an odds ratio (OR) =2.5 ( $P = 5.0 \times 10^{-14}$ ) and is intronic to *MTA3*, a gene that when knocked out in mice leads to decreased levels of circulating LDL cholesterol. The second signal came from a common variant (MAF=26%, OR=1.3,  $P = 2.7 \times 10^{-9}$ ), which is an eQTL for *SLMAP*, a gene with highest expression in smooth muscle. The third variant (MAF=9%, OR=1.5,  $P = 4.6 \times 10^{-9}$ ) is located 1kb downstream of *BARX1*, a gene highly enriched in stomach expression. Like *NKX2-5*, *BARX1* is a homeobox gene and it has been shown that *Barx1* knock-out mice have abnormal stomach morphology and fail to develop the pyloric sphincter. Furthermore, familial syndromes involving duplication of the 9q22.1–q31 region, which harbors *BARX1*, often include IHPS as part of the clinical presentation. Finally, the fourth variant (MAF=12%, OR=1.4,  $P = 3.2 \times 10^{-9}$ ) is in a gene desert at 13q21.31. **Conclusion:** Our findings, undergoing replication genotyping in independent samples at time of submission, identify novel genetic associations with IHPS, and highlight putative functional target genes. **Grant support:** Danish Medical Research council (DFF 4004-00512), Novo Nordisk Foundation, Oak Foundation, Carlsberg Foundation.

**1703T**

**Novel pathogenic variant in *OFD1* results in male lethal oral facial digital syndrome type 1 with pituitary aplasia.** D. Aljeaid<sup>1</sup>, R. Lombardo<sup>1</sup>, D. Witte<sup>2</sup>, R. Hopkin<sup>1</sup>. 1) Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) Division of Pathology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

We report live birth of a male patient with OFD Type I secondary to a novel mutation in *OFD1*, c.515T>C, p.Leu172Pro, and complete pituitary aplasia with severe hypoplasia of peripheral endocrine glands. The infant was first identified with severe brain malformations and multiple congenital anomalies at 22 weeks gestation on routine ultrasound. Subsequent fetal MRI demonstrated polymicrogyria, gray matter heterotopia, ventriculomegaly, corpus callosum agenesis, and abnormalities of the posterior fossa and brainstem concerning for Dandy-Walker malformation and molar tooth sign. Recurrent episodes of hypotension and hypoglycemia after birth prompted evaluation of the adrenal glands which could not be visualized on ultrasound. Postnatal brain MRI confirmed fetal findings and was unable to identify the pituitary. Extensive endocrine work up was consistent with panhypopituitarism. Autopsy confirmed absence of pituitary tissue. Careful analysis revealed two areas of tissue near the kidneys that was identified to be hypoplastic islands of adrenal cortex under the microscope that was consistent with severe adrenal hypoplasia. The thyroid and testes demonstrated similar degrees of hypoplasia and only one parathyroid gland was identified. The pancreas was normal in size with normal histology. OFD type 1 is an X-linked dominant condition with near universal lethality in early gestation in male infants. Live birth is exceedingly rare and has been reported in only 5 patients to date. Although a spectrum of brain malformations have been associated with mutations in *OFD1*, this is the first report of pituitary aplasia. It is likely that most if not all of the other abnormalities in endocrine organs were secondary to the lack of pituitary stimulation. Maternal testing was performed and confirmed carrier status. Extended family history identified a maternal male sibling that died at approximately 30 hours of life from severe brain malformations. The exact function of *OFD1* gene is not fully understood, but it's been shown that *OFD1* gene encodes a protein that localizes to the centromere and basal body of primary cilia, which plays a role in cilia formation and left-right axis specification. It's also been noted that there's an inverse correlation between *OFD1* mutant protein length and the severity of phenotype. It has been suggested that *OFD1* might be involved in the *SHH* signaling pathway via interaction with other genes such as *HOX*, thus affecting pituitary gland development.

**1704F**

**Human knockout of a cell cycle gene *CDC25B*: a novel disease-causing gene for an Alström-like syndrome with cataract, dilated cardiomyopathy and multiple endocrinopathies.** C. Lam, C. Law. The University of Hong Kong, Hong Kong, China.

The cell division cycle 25 (CDC25) phosphatases families are a key player regulating the cell cycle phases during cell divisions and maintaining the genetic stability, and an overexpression of the proto-oncogenes, *CDC25A* or *CDC25B* had been shown in various cancers. Here, we report a loss-of-function mutation of *CDC25B* in a girl who presented with a new syndrome, involving multiple systems. The patient was an 11-year-old Chinese girl born to consanguineous asymptomatic parents with history of one fetal and one infancy death with unknown causes. The proband suffered from intrauterine growth retardation, delayed development, bilateral cataract (at 5 yrs), primary hypothyroidism, growth hormone deficiency and heart failure (at 9 yrs). Echocardiogram showed dilated cardiomyopathy involving mainly the right heart and progressively the left heart. The patient had no intellectual disability. Extensive biochemical workups were unremarkable. Karyotyping was normal. Magnetic resonance imaging of the pituitary gland was also unremarkable. Given the clinical presentations, provisional diagnoses of Alström syndrome and *POLG*-related mitochondrial disorders had been made but later being excluded after a negative sequencing result of *ALMS1* and *POLG* genes respectively. This undiagnosed case was subsequently referred to the Clinics for Rare Diseases Referral (CRareDr) and the Undiagnosed Diseases Program, to end the diagnostic odyssey. Clinical whole exome sequencing (WES) was performed in the proband and we identified a novel homozygous nonsense variant in the *CDC25B* gene, NM\_021873:c.313G>T (p.Glu105\*). This novel variant was located in a runs of homozygosity (ROH) of 25 Mb on chromosome 20. Her parents and two asymptomatic sisters were confirmed to be carriers, and the asymptomatic brother was homozygous for the wild-type allele. The presence of c.313G>T in the proband is expected to produce a truncated protein, terminated at codon 105 and a loss of downstream phosphorylation sites. Importantly, the human phenotypes has not been reported in *Cdc25b* knockout mice. Because *CDC25B* and *ALMS1* are both involved in maintaining centrosome integrity, we propose a loss-of-function *CDC25B* in humans will result in a new autosomal recessive syndrome, mimicking Alström syndrome.

**Gene expression profiling of single oocytes reveals pathways and regulators involved in follicle activation.** Y. Lyu<sup>1,2,3</sup>, G. Lu<sup>1,3</sup>, Z. Xiong<sup>2,3</sup>, J. Ma<sup>2,3</sup>, W. Chan<sup>1,3</sup>. 1) CUHK-SDU Joint Laboratory on Reproductive Genetics, School of Biomedical Sciences, the Chinese University of Hong Kong, Hong Kong, China; 2) Center for Reproductive Medicine, Shandong University, Jinan, Shandong, China; 3) National Research Center for Assisted Reproductive Technology and Reproductive Genetics, Jinan, Shandong, China.

**Introduction** The primordial follicle activation is a crucial process for female fertility which means the quiescent primordial follicle activated to the primary follicle. Under normal circumstances, the majority of primordial follicles stay in a quiescent state, and only a few numbers of primordial follicles could be activated gradually. However, when it comes to some pathological conditions, this balance would be broken and depletion of primordial follicles might be accelerated, diseases such as premature ovarian failure (POF) will be an occurrence. However, the mechanism of follicle activation has remained poorly understood.

**Purpose** In this research, we try to find the novel pathways and regulators related to follicle activation by performing the gene expression profiling of the single oocytes derived from primordial follicles and primary follicles. **Methods** 91 candidate genes of follicle activation and 5 endogenous genes were selected to customize a TaqMan array card. 40 oocytes of primordial follicles and 40 oocytes from primary follicles were picked up from four neonatal mice based on their morphology. Then the single oocytes were prepared using single cell-to-ct Kit (ThermoFisher) and loaded to TaqMan array card for qPCR. The gene expression data was analyzed using statminer single cell qPCR model and then inputted to the IPA for core analysis. **Results** Among the selected genes, 14 undetermined genes were excluded firstly, and the remaining 82 genes were used for data analysis. As expected, a majority of selected genes expressed actively in primary follicle oocytes compared to the primordial follicle oocytes. The hierarchical clustering and principal component analysis were performed, which showed that the two stages of oocytes were separated obviously. Interestingly, subgroups were observed among the same stages oocytes but not due to the source of different animals. Following that, the core analysis was conducted using IPA software, numbers of related pathways and upstream regulators were predicted which might relate to the follicle activation. **Conclusion** In this research, we first conduct gene expression profiling of two early stages oocytes using single cell qPCR. Subgroups were found might exist among the primordial follicle oocytes. Moreover, numbers of predicted upstream regulators including genes and drugs were founded, and their function needs validation in the further study.

Stanier<sup>1</sup>. 1) Genetics and Genomic Medicine, Institute of Child Health, UCL, London, United Kingdom; 2) Cardiovascular Division, James Black Centre, King's College London, London, UK; 3) Laboratory of Genetic Metabolic Disorders, Academic Medical Center, Amsterdam, The Netherlands; 4) The Hatter Cardiovascular Institute, University College London, London, UK; 5) Department of Chemistry, Faculty of Sciences, Kyushu University, Fukuoka, Japan; 6) Clinical Genetics Department, Great Ormond Street Hospital, London, UK; 7) Department of Pediatrics, Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand; 8) Department of Medical Genetics, Children's Memorial Health Institute, Warsaw, Poland; 9) Department of Biology and Medical Genetics, University Hospital Motol and Second Faculty of Medicine, Prague, Czech Republic; 10) Centre de Génétique Humaine, Université de Franche-Comté, Besançon, France; 11) Serviço de Genética Médica, Hospital Pediátrico de Coimbra, Coimbra, Portugal.

**Background:** Lenz-Majewski syndrome (LMS) is a rare sclerosing bone dysplasia associated with intellectual disability and multiple congenital anomalies. It is characterized by progressive skeletal hyperostosis particularly of the cranium, vertebrae and diaphysis of the tubular bones leading to growth restriction and fusing of fingers and toes, together with tooth, skin and brain defects. The condition is caused by an anomaly in the production of phospholipids, which are an essential component of all human cell membranes. We previously identified the genetic basis as de novo gain-of-function (GOF) mutations in *PTDSS1*, which encodes phosphatidylserine synthase (PSS1). **Objectives:** The GOF mutations activate the enzyme and reduce end product inhibition, however, the exact mechanism leading to hyperostosis is not yet understood. Current studies seek to clarify the key events at a cellular and biochemical level. **Methods:** LMS patients and control cell lines as well as a Chinese hamster ovary (CHO) cell line with or without the LMS R95K mutation have been investigated using electrospray ionization mass spectroscopy techniques to generate their phospholipid profiles. To investigate mineralisation, LMS and control fibroblasts have been used to investigate propensity to calcification using a cresolphthalein assay. Matrix vesicles (MV) were also isolated from cell culture media by ultracentrifugation and analysed for PS content using flow cytometry. **Results:** Lipid studies in CHO cells confirmed a generalised overproduction of PS species. Bone mineralization is initiated by MV containing nucleation sites consisting of PS and Annexin A5. We isolated MV from the cell culture media of human control and LMS fibroblast. Notably, LMS4 fibroblast-derived MVs were enriched with PS in comparison to control fibroblasts-derived MV. Next, we stimulated fibroblasts with elevated calcium (2.7mM) and phosphate (2.0mM) and observed rapid cell calcification *in vitro* as detected by Alizarin Red staining and cresolphthalein assay. **Conclusions:** Our findings show that LMS mutations result in a disturbance to the normally tightly regulated production of PS. Furthermore, we found that fibroblasts secrete MVs which were enriched with annexin/PS complexes that could trigger early mineralization. We intend to go on to use our model systems to investigate potential new therapies for disordered bone metabolism, which may have implications for osteopetrosis to osteoporosis and osteoarthritis.

**1707F**

**Skeletal dysplasias in Saudi Arabian population.** M. Faden<sup>1</sup>, A. Sheereen<sup>2</sup>, S. Massadeh<sup>2</sup>, M. Al khawashki<sup>2</sup>, M. Alaamery<sup>2</sup>. 1) King Saud Medical City, Genetics Department/Childrens Hospital; Riyadh,Saudi Arabia; 2) Developmental Medicine Department /King Abdulaziz Medical City(KAMC)/Ministry of National Guard Health Affairs(MNG-HA), King Abdullah International Medical Research Center (KAIMRC)/King Saud bin Abdulaziz University for Health Sciences(KSAU-HS), Riyadh, Saudi Arabia.

Skeletal dysplasias, or osteochondrodysplasias, are a heterogeneous group of more than 430 disorders characterised by abnormalities of cartilage and bone growth, resulting in disproportion of the long bones, spine, and head. However, these disorders were reclassified in 2015, into 42 groups and the number of genes increased to 364. The prevalence of these disorders was reported as 1 in 5000 live births worldwide. In Saudi Arabia, the prevalence of many autosomal recessive disorders is higher than in other known populations because of many factors, including the high rate of consanguineous marriages (56%). On the other hand, an absence of a countrywide registry for skeletal dysplasias is impeding further insight into the matter, as such a registry is rudimentary for determining the incidence and prevalence of these conditions in the Kingdom, which in turn is essential to the success of future prevention campaigns in the nation. Around 93% of all skeletal dysplasias reported in Saudi Arabia are autosomal recessive. The most skeletal dysplasia disorders which have been identified in Saudi Arabia, including those with a novel mutation that has not been reported before in any other population. It includes Spondyloepimetaphyseal dysplasia (Faden-AlKuraya type), Autosomal recessive split hand and foot malformation, the Recessive form of Marshall Syndrome, Osteogenesis Imperfecta Type XIV, a Novel mutation causing Kniest dysplasia, Wolcott-Rallison syndrome, Desbuquois Dysplasia, and Novel mutations in Joubert syndrome affected individuals whom have features of Jeune asphyxiating thoracic dystrophy. .

**Structural optimization of TransCon CNP: Development of a sustained-release prodrug of CNP for achondroplasia.** K. Sprogøe, C. Rasmussen, A. Bernhard, F. Faltinger, T. Woods, S. Schröder, A. Brennauer, J. Zettler, T. Wegge, U. Hersel, V. Miller Breinholt. Ascendis Pharma, Hellerup, DK, Denmark.

**Background** Achondroplasia is caused by an activating mutation in the fibroblast growth factor receptor 3 (FGFR3) gene, thereby inhibiting chondrocyte proliferation and differentiation. C-type natriuretic peptide (CNP) inhibits the effect of FGFR3 signaling via activation of the natriuretic peptide receptor B (NPR-B) pathway. Developing CNP as a therapeutic is challenging, as CNP is rapidly cleared and degraded by natriuretic peptide receptor C (NPR-C) and neutral endopeptidase (NEP). **Objective** Development of a safe and efficacious long-acting CNP candidate requires simultaneously minimizing clearance and degradation by NPR-C and NEP, while preventing overstimulation of vascular NPR-B receptors, which may lead to hypotension. Prodrug candidates fulfilling these requirements were synthesized, in which CNP was transiently bound to a TransCon carrier via a proprietary linker. After auto-hydrolysis of the linker from the prodrug, fully active, unmodified CNP is released. **Methods** In cells expressing either NPR-B or NPR-C, and in a NEP protease incubation assay, the relative receptor binding and stability of TransCon CNP was compared to unmodified CNP. TransCon CNP was then administered as a single subcutaneous (SC) dose of 146 µg/kg to cynomolgus monkeys (n=3) and the pharmacokinetic profile investigated. Subsequently a single SC dose of TransCon CNP 100 µg/kg vs. dose-equivalent daily CNP was administered to telemeterized cynomolgus monkeys (n=4/group) and the systolic arterial blood pressure (SAP) was assessed for up to 48 hours. **Results** The lead TransCon CNP candidate demonstrated an EC<sub>50</sub> of <1% of parent CNP in the potency assay expressing NPR-B. The NPR-C binding affinity was reduced to approximately 1% of parent CNP. NEP stability was increased, with degradation half-life of 4 days compared to 12 hours for parent CNP. Reduced TransCon CNP clearance was confirmed in cynomolgus monkey by a half-life of 79 hours. No decrease in SAP was detected in TransCon CNP-treated monkeys, whereas monkeys receiving an equivalent dose of daily CNP experienced a decrease in SAP. **Conclusion** The TransCon CNP prodrug had minimal CNP binding to the NPR-B and NPR-C receptor and improved NEP stability *in vitro*. *In vivo* TransCon CNP demonstrated the desired half-life extension without adverse hemodynamic effects. These data support clinical development for weekly dosing and suggest TransCon CNP may be a safe and efficacious option for children with achondroplasia.

**Missense and splicing mutations in the retinoic acid catabolizing enzyme CYP26C1 in idiopathic short stature.** G. Rappold<sup>1</sup>, L. Juergensen<sup>2</sup>, C. Thiel<sup>3</sup>, R. Roeth<sup>4</sup>, T. Ogata<sup>4</sup>, M. Fukami<sup>5</sup>, D. Hassel<sup>1</sup>, A. Montalbano<sup>1</sup>. 1) Dept. Human Molecular Genetics, Heidelberg Germany, Heidelberg, Baden-Württemberg, Germany; 2) Department of Internal Medicine III – Cardiology, Heidelberg University, 69120 Heidelberg, Germany; 3) Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91054 Erlangen, Germany; 4) Department of Pediatrics, Hamamatsu University School of Medicine, Hamamatsu, 431-3192, Japan; 5) Department of Molecular Endocrinology, National Research Institute for Child Health and Development, Tokyo, 157-8535, Japan.

Human height is a complex quantitative trait with a high heritability. Short stature is diagnosed when height is significantly below the average of the general population for that person's age and sex. We have recently found that the retinoic acid degrading enzyme CYP26C1 modifies SHOX deficiency phenotypes towards more severe clinical manifestations. Here, we asked whether damaging variants in CYP26C1 alone could lead to short stature. We performed exome and Sanger sequencing to analyze 706 individuals with short stature where SHOX deficiency was previously excluded. Three different damaging missense variants and one splicing variant were identified and their functional significance tested *in vitro* or *in vivo* using Zebrafish as a model. Although incomplete penetrance was observed in one case, the genetic and functional data here reported strongly suggest that CYP26C1 represents a novel gene underlying growth disorders and that damaging variants lead to short stature.

**1710F****The role of p63 isoforms in the epidermal development as replicated in cellular models for normal human skin and genetic skin diseases. I.**

*Barragán Vázquez*<sup>1,2</sup>, *D. Lima Cunha*<sup>1,3,4</sup>, *S. Hockney*<sup>1</sup>, *K.Y. Tang*<sup>1</sup>, *S. Thomforde Kitson*<sup>1</sup>, *K.M. Eckl*<sup>5</sup>, *H.C. Hennies*<sup>1,3,4,6</sup>. 1) Biological Sciences, University of Huddersfield, Huddersfield, United Kingdom; 2) Faculty of Chemical Sciences, Universidad Complutense de Madrid, Spain; 3) Genetics and Genomics, Medical University of Innsbruck, Austria; 4) Cologne Center for Genomics, University of Cologne, Germany; 5) Dept. of Biology, Edge Hill University, Ormskirk, UK; 6) CECAD, University of Cologne, Germany.

Transcription factor p63 is a key regulator of epidermal development. *TP63* codes for two major isoforms, TAp63 and  $\Delta$ Np63. Mutations in *TP63* are associated with severe diseases such as ectrodactyly/ectodermal dysplasia and cleft lip/palate (EEC) and ankyloblepharon/ectodermal defects and cleft lip/palate (AEC) syndromes. These diseases and knockout and transgenic mice pointed to a major role of p63 in ectodermal development. Details about the importance of the isoforms are not clear so far; TAp63 is present early in ectodermal development,  $\Delta$ Np63 is involved in epidermal maturation. In order to study the importance of p63 for epidermal differentiation, we have analysed the expression of *TP63* and its major isoforms in keratinocytes *in vitro*.

Quantitative real time PCR revealed a minor increase early in Ca<sup>2+</sup> induced differentiation of primary human normal epidermal keratinocytes and a decrease during terminal differentiation. Isoform-specific analysis showed that  $\Delta$ Np63, the predominant isoform in epidermis, was present during differentiation with decreasing levels. TAp63, in contrast, showed an increase late in differentiation after 10d in culture. These results are in accordance with an association of  $\Delta$ Np63 with basal epidermal keratins 5 and 14 and a declining expression in suprabasal epidermal layers as shown previously by immunohistochemistry. *KLF*, a transcription factor gene important for gene expression in terminally differentiating keratinocytes, showed a significant increase in parallel with the increase of differentiation markers such as transglutaminase 1 and filaggrin, which is in line with the supposed induction of *KLF* by p63. Keratinocytes of patients with autosomal recessive congenital ichthyosis (ARCI), a disorder of epidermal keratinisation, showed a similar pattern for the expression of *TP63*, indicating that the disturbed keratinisation seen in ARCI is restricted to proteins of terminally differentiating keratinocytes but does not influence their transcription factors. Our findings underpin the importance of switching p63 isoforms during epidermal development and confirm an additional role for TAp63 in terminal differentiation. Moreover, these results corroborate the importance of cellular models based on primary keratinocytes for the study of epidermal keratinisation. Studies with 3D human skin models will give further insight into the regulation of gene expression profiles during epidermal differentiation.

**1711W**

***TP63* is expressed in adult epidermal and iPSC-derived melanocytes supporting the role of  $\Delta$ Np63 in ectodermal gatekeeping and cell migration to the epidermis.** *D. Cunha*<sup>1,2,3</sup>, *H. Tahir*<sup>4</sup>, *K. Golding*<sup>4</sup>, *I. Barragán Vázquez*<sup>1,5</sup>, *T. Saric*<sup>6</sup>, *C. Ploner*<sup>7</sup>, *H.C. Hennies*<sup>1,2,3,8</sup>, *K.M. Eckl*<sup>4</sup>. 1) Department of Biological Sciences, University of Huddersfield, Huddersfield, United Kingdom; 2) Div. of Human Genetics, Innsbruck Medical University, Innsbruck, Austria; 3) Cologne Center for Genomics, University of Cologne, Cologne, Germany; 4) Dept. for Biology, Edge Hill University, Ormskirk, Lancashire, UK; 5) Faculty of Chemical Sciences, Universidad Complutense de Madrid, Spain; 6) Inst. for Neurophysiology, Univ. Hospital Cologne, Cologne, Germany; 7) Univ.-Clinics for Plastic, Reconstructive and Aesthetic Surgery Medical University of Innsbruck, Innsbruck, Austria; 8) CECAD, Univ. of Cologne, Cologne, Germany.

*TP63* encoding p63, is a member of the transcription factor p53 family, which is expressed differentially with six isoforms.  $\Delta$ Np63 is today understood to be a master regulator of epidermal morphogenesis and an essential gatekeeper in ectodermal development. p63-null mice lack stratified epidermis and are born with only one layer of non-proliferating keratinocytes, resulting in massive trans-epidermal water-loss and premature death. Tremendous progress has been made in the understanding of p63 signalling and pathways in keratinocytes and epidermal commitment, but only little is known about the role of p63 in melanocytes. Pre-melanocytes (melanoblasts) arise either from trunk neural crest cells (NCC) or from peripheral Schwann cells. During Carnegie stage 13 melanoblasts emigrate from the NCC and arrive at the basal layer of the epidermis during the third and fourth month of foetal development, where they mature into melanocytes expressing melanin and interacting with surrounding keratinocytes during epidermal development. In this study we analysed  $\Delta$ Np63 expression in melanocytes isolated from skin from a variety of healthy control persons (NHEM), as well as from induced pluripotent stem cell-derived melanocytes (iPSC-derived hM) from patients and controls. NHEM were isolated from surplus skin following plastic surgery and cultured in defined medium, iPSC-derived hM were differentiated from iPSC following our in-house protocol for melanocyte differentiation, all melanocytes were then extensively characterised using immuno-cytochemical methods and expression profiling techniques.  $\Delta$ Np63-isoform specific expression analysis in NHEM and iPSC-hM showed clear evidence of nuclear expression of transcription factor p63 in both, adult, skin-derived melanocytes and stem-cell derived melanocytes. Gene expression analysis with probe-based assays highly specific for isoform  $\Delta$ Np63 revealed expression profiles for NHEM and iPSC-hM similar to basal keratinocytes from healthy donors. All qPCR expression data were normalised to housekeeping genes and to relative expression of  $\Delta$ Np63-isoform found in iPSCs. Preliminary results suggest further that *SATB1*, a p63-regulated genome organiser, essential for remodelling chromatin architecture at the EDC locus, is similarly regulated and expressed in NHEM and iPSC-derived hM as previously reported for keratinocytes, suggesting an even more important role for p63: not only an ectodermal gatekeeper but also an epidermal guidepost.

**1712T**

**Familial dysautonomia: The regulation of *IKBKAP* in the nervous system and therapeutic approaches.** S. Yannai, J. Zonszain, N. Gonceer, S. Naftelberg, M. Donyo, G. Ast. Human Molecular Genetics & Biochemistry, Tel Aviv University, Tel Aviv, Israel.

Familial Dysautonomia (FD) is an autosomal recessive congenital neuropathy that results from a point mutation at the 5' splice site of intron 20 in the *IKBKAP* gene. Alteration in this gene splicing occurs in a tissue-specific manner, reducing the formation of an intact IKAP protein in the nervous system. Although the exact function of the IKAP protein is not clearly understood, poor development and progressive degeneration of the sensory nervous systems and depletion of dorsal root ganglia (DRG) neurons that characterize FD patients indicate a possible role of IKAP in the development of the peripheral nervous system. Phosphatidylserine (PS), an FDA-approved food supplement, was shown by us to elevate *IKBKAP* levels. However, low permeability across the blood-brain barrier led us to pursue new approaches to deliver PS to the brain and the spinal cord. The main goal of my research is to better understand the regulation of *IKBKAP* in the nervous system, and to explore therapeutic approaches which will improve the quality of life for FD patients. For this purpose I will use two approaches: (i) increasing permeability of therapeutic agents in a mouse model for FD and (ii) examining synergistic effects of treatments that can increase *IKBKAP* levels. Moreover I intend to examine the splicing mechanism involved in mediating the splicing regulation of exon 20 following the IVS20+6T>C mutation in FD. My results indicate that intra-nasal administration of PS increased IKAP levels in the DRG, and protected against weight dysfunction, which is observed in FD patients. Further attempts to improve nasal delivery showed a delivery device enables PS transfer to the brain and spinal cord. These results suggest that innovative delivery devices may improve the quality of life for FD patients. In addition I evaluated several potential therapeutic agents that could be combined with PS; such compounds either have effect on splicing or gene expression. The HDAC inhibitor TSA and Kinetin, a plant cytokinin that affects splicing, were examined combined with PS. Both kinetin and TSA successfully elevated IKAP protein level when combined with PS.

**iPSC-derived neurons from patients with idiopathic ASD show deficits in neuronal differentiation and synaptic function.** C. Garcia-Serje<sup>1</sup>, J. el Hokayem<sup>2</sup>, B.A. DeRosa<sup>2</sup>, E. Artimovich<sup>3</sup>, D. Van Booven<sup>1</sup>, J.E. Nestor<sup>3</sup>, M.L. Cuccaro<sup>1</sup>, J.M. Vance<sup>1</sup>, M.A. Pericak-Vance<sup>1</sup>, H.N. Cukier<sup>1</sup>, M.W. Nestor<sup>3</sup>, D.M. Dykxhoorn<sup>1</sup>. 1) Hussman Institute for Human Genomics, University of Miami Miller School of Medicine, Miami, FL., Select a Country; 2) Department of Medical & Molecular Genetics, Oregon Health & Science University, Portland, Oregon, 9723; 3) Hussman Institute for Autism, Baltimore, Maryland, 21229.

Numerous candidate genes have been associated with autism spectrum disorder (ASD), with many of these genes known to have important roles in synaptic function and the development of neural circuits. This suggests that certain neurobiological processes could be commonly altered in ASD. Therefore, although there is a great deal of clinical and genetic heterogeneity in ASDs, there may be convergent deficits in key molecular mechanisms that underlie autism. Lack of appropriate human-based models of genetically complex neurodevelopmental disorders has hindered investigations of nonsyndromic ASD. induced pluripotent stem cells (iPSCs) offer the opportunity to further unravel the intricate biology underlying ASD. To that end, patient-specific iPSC from idiopathic ASD individuals and iPSCs from neurologically normal controls were differentiated into cortical neurons. RNA-seq analysis was performed on these neuronal cultures at an early (day 35) and late (day 135) time point. We then sought to identify common cellular and molecular signatures that distinguish iPSC-derived neurons from our cohort of ASD individuals from neurons derived from controls. We approached this by identifying expression differences both in a single genes and also in a higher-order network level. Transcriptional analyses of the ASD and control neurons showed ASD-specific molecular phenotypes affecting networks involved in neuronal differentiation, the cytoskeletal matrix structure formation, patterning, DNA and RNA metabolism, and synaptic function. We then applied functional analyses to identify disease-specific, cellular phenotypes. We found deficits in calcium transients and synaptic function, as well as, impaired migration in the ASD-specific neurons compared to controls. In conclusion, we have shown that patient-specific iPSCs can be used to model brain region-specific neuronal development permitting the identification of common molecular mechanisms disrupted in ASD opening the door for potential therapeutic development. .

**Multi-system contributions to *Gabrb3*-related neurodevelopmental risk *in utero*.** H. Moon<sup>1</sup>, P. Carpentier<sup>1</sup>, V. Saravanapandian<sup>1</sup>, U. Haditsch<sup>1</sup>, J. Su<sup>1</sup>, M. Chin<sup>1</sup>, K. Muench<sup>1</sup>, A. Moore<sup>1</sup>, A. Bormann<sup>1,2</sup>, N. Nima<sup>1,2</sup>, G. Subramanyam<sup>1,3</sup>, M. Rivera<sup>1</sup>, T. Palmer<sup>1</sup>. 1) Neurosurgery Department, Stanford University, Stanford, CA; 2) The Bridges to Stem Cell Research program, California State University Fullerton, Fullerton, CA; 3) The Bridges to Stem Cell Research program, San Jose State University, San Jose, CA.

Autism spectrum disorder (ASD) is a neurodevelopmental disability defined by social interaction deficits and stereotyped behaviors but the underlying pathophysiological mechanisms are not known. ASD heterogeneity may stem from dynamic interplay between genetic and environmental risk factors. Maternal immune activation (MIA) induced by prenatal infection is the ASD environmental risk factor that increase placental and fetal vulnerability. Here we test the novel hypothesis that *Gabrb3* deficiency combined with prenatal bacteria-like lipopolysaccharide (LPS) challenge may accentuate placental dysfunction-mediated complications and increase neurological impairments in offspring. The present study highlights gene-environment interactions between ASD-related genetic susceptibility and MIA in the *in vivo* mouse models. The GABA type A receptor (GABA<sub>A</sub>R) subunit beta 3 (*GABRB3*) located in the human chromosomal loci 15q11-13 in which copy number variation was associated with ASD, Angelman Syndrome, Prader-Willi Syndrome, and epilepsy. Peripheral GABA<sub>A</sub>Rs are expressed in immune cells and modulates immune signaling. Here we show that *Gabrb3* deficiency combined with LPS-mediated MIA accentuates placental vulnerability and exacerbates neurodevelopmental abnormalities in the developing fetus. *Gabrb3* heterozygous pregnant dams injected with LPS showed elevated maternal cytokine/chemokine relative to wild-type controls. Increased placental necrosis and impaired proliferation of neocortical progenitor cells are found in LPS-treated *Gabrb3* heterozygous placenta and fetal brain, respectively. Alterations in neuronal subtype specification and abundance were also notable in *Gabrb3*-deficient fetal brain. GABA<sub>A</sub>R-selective agonist and antagonist treatment altered cytokine production in macrophages *in vitro*, suggesting a possible convergence of immunomodulatory signaling pathways between GABA<sub>A</sub>R/*GABRB3* and LPS-induced MIA response in the placenta and the developing fetus. Together, our data provide important evidence that *Gabrb3* deficiency and MIA may synergistically increase placental and fetal brain vulnerability by altering the immune micro-environment at the maternal-fetal interface. We anticipate that additional ASD genetic risk factors may also elevate placental and/or fetal brain vulnerability to MIA and these gene-immune interactions may significantly contribute to the spectrum of phenotypes noted in ASD, schizophrenia, and other neurodevelopmental disorders.

## 1715T

**A *Drosophila* model of essential tremor.** L.N. Clark<sup>1,2</sup>, P. Smith<sup>3</sup>, I. Santa-Maria<sup>1</sup>, S. Sonti<sup>1</sup>, B.D. McCabe<sup>4</sup>, K. Tsaneva-Atanasova<sup>5,6</sup>, J.L. Hodge<sup>3</sup>, E.D. Louis<sup>7</sup>. 1) Department of Pathology and Cell Biology, College of Physicians and Surgeons, Columbia University, New York, NY, 10032, USA; 2) Taub Institute for Research on Alzheimer's Disease and the Aging Brain, College of Physicians and Surgeons, Columbia University, New York, NY, 10032, USA; 3) School of Physiology, Pharmacology and Neuroscience, University of Bristol, University Walk, Bristol BS8 1TD, UK; 4) Brain Mind Institute, Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland; 5) Department of Mathematics and Living Systems Institute, University of Exeter, Stocker Road, Exeter, EX4 4QD, UK; 6) EPSRC Centre for Predictive Modelling in Healthcare, University of Exeter, Exeter, EX4 4QJ, UK; 7) Department of Neurology, Yale School of Medicine, Yale University, New Haven, CT, 06520, USA; Center for Neuroepidemiology and Clinical Neurological Research, Yale School of Medicine, Yale University, New Haven, CT, 06520, USA; Department of Chronic Disease Epidemiology, Yale School of Public Health.

Essential Tremor (ET) is one of the most common neurological diseases, with an estimated 7 million affected individuals in the United States. The characteristic clinical feature of ET is a kinetic tremor in the hands or arms, which can progress to become more severe and anatomically widespread (e.g. head or neck). Recently, we identified a mutation (*Kv9.2*, c.1137 T>A, p.(D379E)) in an electrically silent voltage-gated K<sup>+</sup> channel  $\alpha$  subunit, *Kv9.2*, in a family with early onset, autosomal dominant ET, that is highly and selectively expressed in brain, and that modulates the activity of the *Kv2.1* and *Kv2.2* channels by heteromultimerization. Voltage gated potassium (*Kv*) channels play a major role in regulating membrane excitability and synaptic transmission in many central neurons and at the neuromuscular junction and *Kv2* channels encode the majority of delayed rectifier current. To study the disease mechanism we have produced transgenic *Drosophila* lines that express pan-neuronally either the wild type human *Kv9.2* (h*Kv9.2*) subunit or the ET causing mutant human *Kv9.2* (h*Kv9.2*-D379E) subunit. Here, we show that the h*Kv9.2* subunit can modulate the channel activity of endogenous *Shab* (*Kv2* subfamily). Behavioral manifestations of nervous system dysfunction consistent with a hyperexcitable phenotype were observed in flies expressing the h*Kv9.2* or h*Kv9.2*-D379E subunit. The effects of h*Kv9.2* and h*Kv9.2*-D379E on adult neuron activity, were determined using whole cell voltage-clamp. A *Shab* specific toxin was used to isolate the voltage-sensitive non-inactivating K<sup>+</sup> current. The mutant h*Kv9.2*-D379E subunit showed significantly higher levels of inactivation than the wild-type h*Kv9.2* subunit ( $p=0.0462$ ) and a significantly higher frequency of spontaneous firing rate of action potentials ( $p=0.0102$ ) consistent with neuronal hyperexcitability. A biophysical model of the electrical activity of the cell, combining the individual ionic currents in flies expressing h*Kv9.2* subunits, was in agreement with experimental data. This *Drosophila* transgenic model recapitulates several features of ET, and can now be used to advance our understanding of ET disease pathogenesis.

**1716F**

**A mutation in *MAL* is associated with a neurodevelopmental condition characterized by central hypomyelination, cerebellar atrophy and developmental delay.** *M. Elpidorou<sup>1</sup>, J.A. Poulter<sup>1</sup>, J.H. Livingston<sup>2</sup>, E. Sheridan<sup>1</sup>, C.A. Johnson<sup>1</sup>.* 1) Leeds Institute of Biomedical and Clinical Sciences, University of Leeds, Leeds, United Kingdom; 2) Paediatric Neurology, Leeds General Infirmary, Leeds, United Kingdom.

One in every thousand children has abnormalities of the white matter of the brain. Many of these disorders are genetically determined and progressive, associated with a fatal outcome. Here we report a seven-member multiply consanguineous UK family of Pakistani origin. Two affected individuals presented with significant developmental delay, cerebellar developmental defects and cortical white matter abnormalities. The pedigree structure was compatible with autosomal recessive inheritance, and analysis was done under this model. Whole exome sequencing (WES) was performed on DNA from two affected boys and an unaffected sibling. SureSelect<sup>2</sup> Target Enrichment for Illumina Multiplexed Sequencing technologies was used for the library preparation and samples were sequenced on the HiSeq3000 platform. Regions of concordant homozygosity, shared by the affected and not by their unaffected sibling, were identified from WES data using the AgileMultiDeogram analysis program (<http://dna.leeds.ac.uk/agile>). Non-synonymous biallelic variants were filtered by frequency (MAF<1%) and predicted pathogenicity, prioritizing those within homozygous regions. Filtering revealed variants in four possible candidate genes, but only a single homozygous missense variant c.326C>A (p.Ala109Asp) in the myelin and lymphocyte protein *MAL* (RefSeq NM\_002371, GRCh38) segregated within the family. The variant had a CADD score of 28.7, was absent from ExAC and gnomAD, and had deleterious pathogenicity predictions from SIFT (0.02), Polyphen (0.839) and Condel (0.621). *MAL* encodes a tetraspanning transmembrane protein that is implicated in the biogenesis and function of myelin. *MAL* regulates the trafficking of PLP, the major component of myelin, from the Golgi body to the basolateral myelin membranes by transcytosis. We present functional studies in polarized cell-lines to confirm the pathogenicity of the c.326C>A (p.Ala109Asp) variant by co-localization and biochemical interaction studies. Our data suggests that the *MAL* p.Ala109Asp variant disrupts the insertion of the third transmembrane helix into membranes, preventing a conformational shift in PLP that is required for correct intracellular trafficking to basolateral membranes.

**1717W**

**Defective myoblast differentiation in human muscle dysferlin-deficient cells.** *R. Ishiba<sup>1</sup>, A. Bigot<sup>2</sup>, A.F. Ribeiro Jr<sup>1</sup>, V. Mouly<sup>2</sup>, M. Vainzof<sup>1</sup>.* 1) Human Genome and Stem-cell Research Center, Biosciences Institute, University of São Paulo, São Paulo, Brazil; 2) Sorbonne Universités, UPMC Univ Paris 06, INSERM UMRS974, Center for Research in Myology, 47 Boulevard de l'hôpital, 75013 Paris, France.

Limb girdle muscular dystrophy type 2B (LGMD2B) is an autosomal recessive disorder caused by mutations in *DYSF* gene. Dysferlin is a 237 kDa sarcolemmal protein known to interact with several proteins to allow the aggregation and fusion of vesicles to the membrane injury site. Partial or total absence of dysferlin protein is responsible for defective membrane repair. Recent evidences suggest that dysferlin plays a role also in myogenesis, but the underlying mechanism remains poorly understood. Using a model of dysferlin-deficient human muscle cells, we observed the presence of thinner myotubes and reduced frequency of myonuclei per myotube, suggesting a delayed progression of myotube formation in *Dysf*<sup>-/-</sup> cells. mRNA expression of the myogenic factors showed an increase of MYOD levels after 12 hours of differentiation in both lineages, compatible with a normal early muscle differentiation in *Dysf*<sup>-/-</sup> cells. Myogenin expression, however, occurred earlier in *Dysf*<sup>+/+</sup> than in *Dysf*<sup>-/-</sup> cells relative to undifferentiated cells, suggesting a change in its kinetics, which could well explain the smaller myotubes observed in *Dysf*<sup>-/-</sup> cells. Dysferlin deficiency would therefore be less involved in the first events of formation of small myotubes in early differentiation, but seems to regulate later stages of differentiation, which involves growth and elongation of myotubes. We extended our study to investigate the effects of dysferlin deficiency on the expression of the components of the FAM65B-HDAC6-DYSF tricomplex, in the earlier stages of myoblast differentiation. We observed that mRNA levels of *FAM65B* did not statistically differ between control and dysferlin deficient cells, whereas *HDAC6* presented a transient peak, statistically significant, after 24 hours and *DYSF* increased from 48h of differentiation, only in control cells. We, therefore, suggest that the expression of dysferlin and *HDAC6* are increased in the early stages of differentiation in normal cells, and this would be important for the subsequent step of muscle formation, acting on deacetylation of  $\alpha$ -tubulin and on its important role for the elongation of myotubes. Taken together, these results provide interesting targets for further investigation of how dysferlin deficiency affects myogenic regulators during differentiation. FAPESP-CEPID, CNPq-INCT.

**Evolutionary conserved ARX-regulatory pathway in mammals and nematode to find a convergent druggable pathway damaged in neurodevelopmental disorders.** L. Poeta<sup>1</sup>, A. Padula<sup>1</sup>, B. Attianese<sup>1</sup>, M. Valentino<sup>1</sup>, S. Filosa<sup>2</sup>, H. vanBokhoven<sup>3</sup>, L. Altucci<sup>4</sup>, E. Di Schiavi<sup>2</sup>, M.G. Miano<sup>1</sup>. 1) Institute of Genetics and Biophysics "ABT", CNR, Naples, Italy; 2) Institute of Bioscience, CNR, Naples, Italy; 3) Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; 4) University of Campania "Luigi Vanvitelli", Caserta, Italy.

The X-linked *ARX* gene encodes the Aristaless-related homeobox protein, which belongs to a subset of morphogenetic transcription factors with a crucial role in cerebral development and patterning. Mutations in *ARX* cause a wide spectrum of X-linked neurodevelopmental disorders including lissencephaly, a severe cortical malformation, and a catastrophic epileptic encephalopathy with recurrent and resistant seizures. The health problem to find efficient treatments for *ARX*-related diseases highlights the need for understanding the components and pathways that regulate brain development. Because the neuronal functioning is maintained by a complex regulatory network, the use of powerful genetic models like mouse and worm can complement studies on human genetics and physiology by offering new opportunities to dissect complicated and evolutionary conserved regulatory circuits. Here we describe for the first time the conservation of an *ARX*-dependent disease-pathway among human, mouse and worm establishing a gene-phenotype association from one organism to another. Indeed, starting from the homologous gene relationships between *ARX* and its murine (*Arx*) and worm (*alr-1*) counterparts, we established a neuronal phenolog relationship among the human phenotypes associated to *ARX* mutations, *Arx* disease models in mouse, and *alr-1* mutants in *C. elegans*. Expanding our previous study on the identification of disease-related targets of *ARX* in human, we proved that the homologous counterparts of *KDM5C* in mouse (*Kdm5C*) and worm (*rbr-2*) are under the control of *ARX/Alr-1* transcriptional activity. In line with these findings, we established a robust downregulation of *KDM5C/rbr-2* transcript in human, murine and worm mutants defective for *ARX/alr-1*. Given the role of *KDM5C/rbr2* as chromatin JmjC eraser with H3K4me2/3 demethylase activity, we tested the H3K4me3 levels establishing a functional defect in chromatin remodelling. We will also present results on molecular and phenotypic rescue obtained by drug repositioning in each models tested upon *in vivo* epi-treatment. In conclusion, our data allow us to define the *ARX/alr-1* phenolog-disease pathway leading to better understanding how to correct perturbation of neuronal physiology. Therefore our findings constitute a valuable basis for applying mechanism-based therapies aiming to treat neurodevelopmental diseases caused by defects in transcriptional regulators.

**Emerging role and clinical spectrum of DNM1 in intellectual disability and epilepsy.** F. Bolduc, O. Caluseriu, R. He. Dept Pediatrics, Univ Alberta, Edmonton, Alberta, Canada.

**BACKGROUND:** Dynamain-1 (DNM1) is a conserved, large guanosine triphosphatase (GTPase) essential to synaptic vesicle recycling via clathrin-mediated endocytosis. De novo missense mutations in the *DNM1* gene have been identified in patients with severe epileptic encephalopathy, but its role in intellectual disability and cognitive functions are not as well understood. **METHODS:** We performed exome sequencing on patients with intellectual disability. Clinical characterization in addition to neuropsychological testing were performed. Electroencephalogram investigation was also performed. **RESULTS:** We identified *DNM1* mutations in 2 patients from our cohort. The first patient harbored a previously reported de novo missense mutation c.709C>T (p.Arg237Trp) in one patient. Interestingly, the other patient with a similar but less severe phenotype (both at the cognitive and epilepsy level) was found to have a novel in frame deletion c.647\_655del (p.Asp215\_Arg217del) in exon 5 of *DNM1*. **SIGNIFICANCE:** The initial reports on *DNM1* indicated very severe epilepsy. Our results show that patients can have variable degree of severity in epileptic symptoms without infantile spasms, epileptic encephalopathy or very early onset. We would like to create a registry for *DNM1* patients in order to describe more fully its clinical spectrum.

**1720W**

**c-fos transcript profile in adult zebrafish brain after prolonged pentylenetetrazole exposure.** K. Brito<sup>1</sup>, P.G. Barbalho<sup>1</sup>, J.E. Cavazos<sup>2</sup>, C.V. Maurer-Morelli<sup>1</sup>. 1) Department of Medical Genetics, UNICAMP, Campinas, SP, Brazil; 2) Department of Neurology and Physiology, University of Texas Health Science Center at San Antonio, TX, USA.

**Purpose:** Zebrafish has many advantages for genetic investigation and since 2005 it has been used for seizure studies. The *cfos* gene is recognized as a marker for neuronal activity, including in zebrafish brain. Kindling is a classical model by which a subconvulsive stimulation becomes progressively convulsive, offering a great opportunity to investigate the epileptogenic process. The present study aimed to investigate the kindling development in the zebrafish model by analyzing seizure behavior and *cfos* mRNA levels after application of subconvulsive dose of pentylenetetrazol (PTZ). **Methods:** Wild-type adult zebrafish were separated in kindling (KG) and control (CG) groups. Animals from KG were individually exposed to a subconvulsive dose of PTZ (7.5mM) for 2 minutes repeated daily for up to 60 days (5 days per week). Animals from CG were handled for 2 min/day, 5 days/week, but in PTZ-free water. The animals were sacrificed at 5<sup>th</sup>, 15<sup>th</sup>, 30<sup>th</sup> and 60<sup>th</sup> days and their brains were collected for total RNA extraction (n=5 per time point/group). Reverse transcriptase quantitative-PCR amplifications were carried out in triplicates with *cfos* and *ef1a* as endogenous control using TaqMan™ System. The relative quantification (RQ) was calculated by the equation  $RQ=2^{-\Delta\Delta CT}$ . Data are represented as mean  $\pm$  Standard Error of Mean (SEM). Each time point was analyzed by Mann-Whitney test and significance was considered when  $p \leq 0.05$ . **Results:** During 60 days, no induced or spontaneous seizure-like behavior was achieved in the animals exposed daily to PTZ; only a slightly increased swim activity was observed. RT-qPCR showed an up-regulation of the *cfos* mRNA levels in the KG at 5<sup>th</sup>, 15<sup>th</sup>, 30<sup>th</sup> and 60<sup>th</sup> day compared to their respective CG. The mean  $\pm$  SEM of *cfos* gene and the *p* value obtained for comparisons between CG and SG were the following: CG05 1.49  $\pm$  0.28 vs. KG05 5.13  $\pm$  1.60 ( $p=0.004$ ); CG15 0.43  $\pm$  0.23 vs. KG15 0.29  $\pm$  0.06 ( $p=0.34$ ); CG30 0.96  $\pm$  0.12 vs. KG30 0.98  $\pm$  0.14 ( $p=0.05$ ); CG60 0.64  $\pm$  0.2 vs. KG60 1.14  $\pm$  0.2 ( $p=0.008$ ). **Discussion:** So far there is no chronic model of epilepsy described in the literature for zebrafish. Such a model would be of high impact. While we have not yet established a chronic model, our results show a significant difference in *cfos* mRNA levels between the KG and CG groups. This indicates that neurons were more prone to stimulation in the kindling group. Support: FAPESP 14/15640-8, CEPID-BRAINN 13/07559-3.

**Functional evaluation of rare variants in glutamate receptor *GRIN*, *GRIA*, *GRIK*, and *GRID* genes reveals a diversity of effects on receptor activity.** S.J. Myers<sup>1,2</sup>, G. Shaulsky<sup>1,2</sup>, S. Kim<sup>1,2</sup>, H. Yuan<sup>1,2</sup>, S.F. Traynelis<sup>1,2</sup>. 1) Center for Functional Evaluation of Rare Variants; 2) Department of Pharmacology, Emory University School of Medicine, Atlanta, GA.

Whole exome and genome sequencing has identified numerous rare mutations in the glutamate receptor family of *GRIN*, *GRIA*, *GRIK*, and *GRID* genes that are associated with neurological syndromes and phenotypes such as epilepsy (including infantile spasms, Lennox-Gastaut, Landau-Kleffner, and West syndromes), intellectual disability, developmental delay, language disorders, hypotonia and movement disorders, autism and schizophrenia. At the Center for Functional Evaluation of Rare Variants (CFERV), we test specific glutamate receptor gene variants identified in patients in a series of electrophysiological and biochemical studies. Briefly, variant glutamate receptors are expressed in *Xenopus laevis* oocytes and in HEK cells, then used to measure agonist potency (L-glutamate and glycine EC<sub>50</sub>), agonist deactivation kinetics, receptor sensitivity to inhibition by the endogenous modulators Mg<sup>2+</sup>, Zn<sup>2+</sup>, and H<sup>+</sup> (IC<sub>50</sub>, % inhibition), and cell-surface receptor trafficking. Approximately two hundred specific missense, frameshift, or splice-site variants in the *GRIN* gene family (primarily *GRIN1*, *GRIN2A*, and *GRIN2B*) are reported with association to a neurological disorder/disease phenotype, of which over seventy have been functionally characterized by CFERV to date. Approximately 90% of the variants we evaluated possess altered function in at least one functional parameter (up to 8 parameters/mutation measured) with the majority (~65%) of mutations affecting multiple parameters of function. Disease associated variants are not evenly distributed across the gene with 46% residing in the agonist binding domains (ABD), 23% in membrane-spanning (M) domains, and 14% in linker domains connecting ABD to M domains. Most gene mutations (~75%) result in a gain or loss of function of less than 10 fold compared to the wild-type receptor, however several mutations altered L-glutamate agonist affinity by over 100 fold. We present data on over 20 novel glutamate receptor variants and describe the effect of these mutations on receptor function. The goal of CFERV is to expand our understanding of the relationship between genetic variation and health consequences. **Funding:** Supported by NIH awards NIH-NINDS R24NS092989, R01NS036654, and R01NS065371 to SFT, and the NICHD award number R01HD082373 to HY. **Competing Interests:** SFT consults for Janssen Pharmaceutical, Boehringer Ingelheim Pharma GmbH&Co. KG, is on the Scientific Advisory Board Sage Therapeutics, and a co-founder of NeurOp, Inc.

**De novo NMDAR *GRIN* mutations in M2 channel pore-forming domain associated with neurological diseases.** H. Yuan<sup>1,2</sup>, J. Zhang<sup>1</sup>, W. Tang<sup>1</sup>, H. Kusumoto<sup>1</sup>, S.J. Myers<sup>1,2</sup>, S.F. Traynelis<sup>1,2</sup>. 1) Department of Pharmacology; 2) Center for Functional Evaluation of Rare Variants (CFERV), Emory University School of Medicine, Atlanta, GA, 30322.

N-methyl-D-aspartate receptors (NMDAR) bind synaptically released glutamate and mediate a slow component of excitatory synaptic transmission in the brain that plays an important role in brain development. Genetic mutations in multiple NMDAR subunits are associated with various neurological diseases. Here, we summarized clinical information and evaluated functional changes for 12 *de novo* missense mutations in NMDAR subunit gene, *GRIN1*, *GRIN2A*, and *GRIN2B*, located in the M2 loop that lines the NMDAR channel pore. These mutations were identified in children with various neurological diseases including epilepsy syndrome, developmental delay, intellectual disability, hypotonia, autism, or speech disorder. The mutant was introduced into human NMDAR GluN cDNA construct using QuikChange protocol. cRNAs were synthesized from cDNA and injected into *Xenopus laevis* oocytes. Two-electrode voltage clamp current recordings were performed to evaluate agonist (glutamate and glycine) potency, sensitivity to negative modulators (magnesium and proton). Current-voltage relationships were also compared to evaluate changes in voltage-dependent Mg<sup>2+</sup> block. Compared to WT receptors, the mutant NMDARs exhibited a modest or no changes in potency (EC<sub>50</sub> values) for both glutamate and glycine, as well as a modest or no changes in proton inhibition (percentage current inhibition at pH 6.8 compared with the pH 7.6). Mg<sup>2+</sup> inhibition was significantly reduced in all 12 mutants, with significantly increase in IC<sub>50</sub> values (reduced inhibition) and decrease in the degree of Mg<sup>2+</sup> inhibition on agonist-evoked current response. Current-voltage curves revealed marked reduction in Mg<sup>2+</sup> inhibition in all the mutants. Overall, these results suggest these M2 variants are gain-of-function mutations through reduced Mg<sup>2+</sup> channel blockage, which is consistent with its location in the M2 loop of the channel pore and may underlies the patients' phenotypes. **Funding:** This work was supported by the Eunice Kennedy Shriver National Institute Of Child Health & Human Development (NICHD) of NIH under award number R01HD082373 to H.Y., by the National Institute of Neurological Disorders and Stroke (NINDS) of the NIH under award numbers NIH-NINDS R01NS036654, R01NS065371, and R24NS092989 to S.F.T. **Competing Financial Interests:** S.F.T. is a consultant of Janssen Pharmaceuticals, Inc., Boehringer Ingelheim Pharma GmbH & Co. KG, a member of the Scientific Advisory Board for Sage Therapeutics, and co-founder of NeurOp Inc.

**Intracellular mislocalization of mutant proteins as a screen for therapeutic agents to treat genetic diseases.** T. Kouga<sup>1</sup>, H. Osaka<sup>1</sup>, C. Ohba<sup>2</sup>, E. Jimbo<sup>1</sup>, T. Yamagata<sup>1</sup>, H. Saitsu<sup>3</sup>, N. Matsumoto<sup>2</sup>. 1) Jichi Medical University, Shimotsuke-shi, Tochigi, Japan; 2) Department of Human Genetics, Graduate School of Medicine, Yokohama City University, Yokohama, Japan; 3) Department of Biochemistry, Hamamatsu University School of Medicine, Hamamatsu, Japan.

[Background& Objective];Mutant proteins coded by pathogenic gene sequence variants may not fold properly into their normal tertiary structures. A misfolded protein may not be able to target the proper membrane or organelle in which it resides and functions. Thus, confirmation of the distinct localization of a mutant protein can validate the pathogenicity of a particular gene variant. Moreover, this miss-localization can be utilized as a probe to identify chaperone molecules. The objective of this study was to assess the feasibility of visually localizing mutant proteins to identify agents that may correct folding and organelle targeting. [Method];In a previous exome sequencing of pediatric patients with cerebellar ataxia, 9 mutations in 5 genes were found (Ca channel  $\alpha$ -1A subunit, *CACNA1A*; folate receptor family 1, *FOLR1*; peroxisomal membrane protein 16, *PEX16*; catalytic subunit of mitochondria DNA polymerase, *POLG*; and tripeptidyl-peptidase 1, *TPP1*) (Ohba et al. 2013). Their cellular locations are membrane, membrane, peroxisome, mitochondria, and lysosome, respectively. For each mutant gene, we prepared wild-type and mutant FLAG-tagged plasmids and transfected these plasmids into HEK293 cells. We selected plasmids that showed a difference in cellular localization between those with wild-type and mutant gene sequence by immunostaining the transfected cells with anti-FLAG antibody. We also tagged the plasmids with *green fluorescent protein (GFP)* to express as fusion protein for each plasmid and confirmed the localization differences observed with FLAG-tagged proteins. [Result];Of the 9 mutations tested, *PEX16* and *POLG* showed differences in cellular localization between wild-type and mutant plasmid-transfected cells. We isolated stable cell lines that express these mutant proteins fused with GFP. [Conclusion];We demonstrated the usefulness and limitations for visualizing the intracellular localization of mutant proteins found in patients with cerebellar ataxia. The stable cell lines expressing mutant proteins fused with GFP can be used for localization-oriented drug screening to identify agents that may restore activity to misfolded proteins in patients with genetic diseases. .

**Genetics of congenital megacolon in East Asians.** C. Tang<sup>1,2</sup>, X. Zhuang<sup>1</sup>, S. Cherny<sup>2,4</sup>, P. Sham<sup>2,4</sup>, M. Garcia-Barceló<sup>1</sup>, P. Tam<sup>1,2</sup>. 1) Department of Surgery, The University of Hong Kong, Pokfulam, Hong Kong; 2) Dr Li Dak-Sum Research Centre, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong; 3) Department of Psychiatry, The University of Hong Kong, Pokfulam, Hong Kong; 4) Centre for Genomic Sciences, The University of Hong Kong, Pokfulam, Hong Kong.

Hirschsprung disease (HSCR), also known as congenital megacolon, is characterized by the absence of enteric ganglia in the hindgut. HSCR is a multigenic neurocristopathy with a two-fold increase in the incidence among East Asians. The major HSCR gene, *RET*, has both rare and common variants contribute to the disease risk. In particular, ~80% of Asian HSCR patients carry the high risk common enhancer allele. When *in trans* with the recently discovered, Asian-specific missense variant, the *RET* enhancer SNP increases the risk of HSCR by more than 20-fold. Thus far, over 10 HSCR genes were found to have common and/or rare variants attribute to disease susceptibility. To discover novel HSCR-associated gene(s), we performed a whole genome sequencing (WGS) of 443 HSCR cases and 493 controls of East Asian ethnicity. Rare variant association analysis was carried out and, with subsequent follow-up study, we identified a significant excess of rare protein-altering mutations in *BACE2* ( $p=2.9 \times 10^{-6}$ ) in HSCR cases (4%) compared with controls (0.6%). The relevance of *BACE2* in HSCR is highlighted by the facts that i) the encoded protein has recently been proposed as a target for drug-based treatment of HSCR; and ii) *BACE2* maps to the HSCR-Down Syndrome (DS) critical chromosomal region, with DS being the most frequent chromosomal abnormality associated with HSCR. The *BACE2*-HSCR association may represent the missing link between these two disorders. Results of the common variant association analysis will also be presented.

**Pathogenic U2-type 5' GC donor splice site in the *FOLR1* gene causes cerebral folate deficiency with autism and attention deficient hyperactive disorder in three affected from a large consanguineous family.**

M. Alaamery<sup>1</sup>, A. Sheereen<sup>1</sup>, S. Massadeh<sup>1</sup>, W. Eyaide<sup>1</sup>. 1) Developmental Medicine Department, King Abdullah International Medical Research Centre (KAIMRC), Riyadh, Saudi Arabia; 2) Department of Pediatrics, King Abdulaziz Medical City (KAMC) / Ministry of National Guard-Health Affairs (MNG-HA), King Abdullah International Medical Research Center (KAIMRC) /King Saud bin Abdulaziz University for Health Sciences (KSAU-HS), Riyadh, Saudi Arabia.

**Background** Cerebral folate deficiency (CFD) is an inherited brain-specific folate transport defect that is caused by mutations in the folate receptor 1 (*FOLR1*) gene (MIM\*136430) coding for folate receptor alpha (FR $\alpha$ ). This genetic defect gives rise to a progressive neurological disorder with late infantile onset. There are several other diseases associated with CFD and hence expands the clinical spectrum of CFD. The majority of the CFD cases are associated with Autism spectrum disorder (ASD), which is the result of autoantibody against FR $\alpha$ . However, this is the first report of the patient with CFD with ASD and Attention deficient hyperactive disorder (ADHD) caused by the mutation in the *FOLR1* gene. **Aim** We aim to identify the genetic cause of CFD with ASD and ADHD in a large consanguineous Saudi family with three affected members. **Methods** Clinical whole-exome sequencing was performed on the proband and his parents. Later Sanger sequencing was done to validate and confirm segregation in the two affected and other family members. **Results** A novel homozygous splice site variant (c.493+2T>C) at 5' donor splice site in intron 6 of the *FOLR1* gene was identified in three individuals with CFD in addition to ASD and ADHD. Software analysis Alamut (v.2.7.1) and Human Splice Finder (HSF3.0) predict this change to have an effect on splicing and is classified as the pathogenic variant. The splice site variant segregates in the family in autosomal recessive fashion. **Conclusions** This is first case study reporting the mutation in the *FOLR1* causing CFD with ASD and ADHD, thereby expanding the clinical heterogeneity observed in individuals with CFD. The constitutive 5' donor splice site GT-AG in introns possess strong signals at their donor sites for splicing reaction, however, in this patients, the GT-AG is replaced by GC-AG. Although, GC-AG is a rare canonical splice site occurring in 1% of total introns, but could not rescue the phenotype as it does in its constitutive form in the introns. This mutation shows that GC-AG in the intron possesses weak consensus sequences at their donor sites in addition to the surrounding nucleotides around the 5' donor splice site. Thus this change depicted by several *in silico* method causes in altered spliced site, by generating a new cryptic site in an intron to produce a pathogenic variant.

**Impact of defective protein N-glycosylation on the developing mouse cerebellum.** V. Cantagrel<sup>1</sup>, D. Medina-Cano<sup>1</sup>, M. Nicouleau<sup>1</sup>, C. Guerrero<sup>2</sup>, L. Colleaux<sup>1</sup>. 1) INSERM UMR 1163 - Imagine Institut, Paris Descartes - Sorbonne Paris Cité University, France; 2) Proteomic Platform Necker, PPN-3P5, SFR Necker US24, Paris Descartes - Sorbonne Paris Cité University, France.

N-linked glycosylation is the most frequent modification of secreted and membrane-bound proteins in eukaryotic cells. It relies on the synthesis of a precursor called the lipid-linked oligosaccharides (LLO) located in the endoplasmic reticulum (ER). Disruption of the LLO synthesis results in a reduced occupancy of protein N-glycosylation sites (i.e. hypoglycosylation), and is the basis of some congenital disorders of glycosylation (CDG) that are frequently associated with a multi-systemic presentation including motor and cognitive impairments. How this abnormal protein glycosylation affects the development or function of specific organs is often totally unknown. We aim to understand why the developing brain is frequently affected in CDG patients and to describe the underlying global protein glycosylation defect. For this purpose, we generated a conditional knockout (cKO) mouse for the *steroid 5alpha-reductase type 3* gene (*Srd5a3*). This gene codes for an enzyme involved in the synthesis of dolichol, the lipid used to build the LLO precursor. Mutations in this gene cause CDG associated with intellectual disability, ophthalmologic and cerebellar symptoms. The cerebellum specific cKO mouse shows motor coordination impairment associated with a reduced cerebellar volume and histological anomalies affecting granule cell precursors. Transcriptomic and proteomic analyses excluded a significant disruption of the ER homeostasis or a general protein glycosylation defect as the cause of the *Srd5a3* cKO mouse phenotype. These investigations point to a limited set of glycoproteins including mainly one protein family that is down-regulated. Cerebellum cell culture experiments show that the hypoglycosylation of the previously identified protein family significantly impairs neuronal development.

**PEA15 deficiency is associated with striking neurologic and motor abnormalities in *Felis catus*.** J.N. Cochran<sup>1</sup>, E.C. Graff<sup>2</sup>, C.B. Kaelin<sup>1</sup>, K. Day<sup>1</sup>, H.L. Gray-Edwards<sup>2</sup>, R. Watanabe<sup>2</sup>, J.W. Koehler<sup>2</sup>, R. Falgout<sup>2</sup>, B.L. Brunson<sup>2</sup>, J.W. Prokop<sup>1</sup>, B.N. Lasseigne<sup>1</sup>, R.C. Ramaker<sup>1</sup>, K.L. Engel<sup>1</sup>, C. Henegar<sup>1</sup>, J.B. Benito<sup>1</sup>, R.M. Myers<sup>1</sup>, N.R. Cox<sup>2</sup>, D.R. Martin<sup>2</sup>, G.S. Barsh<sup>1</sup>. 1) HudsonAlpha Institute for Biotechnology, Huntsville, AL, USA; 2) College of Veterinary Medicine, Auburn University, Auburn, AL, USA.

A recessively inherited developmental abnormality was recognized in a feline colony. Affected cats have perinatal generalized tremors and are ataxic as they begin to ambulate. The animals partially compensate for motor abnormalities by 6 months of age, but develop aggression and sensory abnormalities (fly biting and stargazing) at approximately 1.5 years of age. At necropsy, affected cats exhibit gross abnormalities including generalized microcephaly, reduced brain weight (~50% reduction in brain weight), and striking cerebral cortex gyrification deficits. These abnormalities are also apparent by MRI. On histologic evaluation, affected animals have less myelin, fewer oligodendrocytes, and disorganized neuronal processes in regions that typically have laminar organization. Through whole genome sequencing of 5 cats, RNA-Seq of cerebral cortex from 16 cats, and subsequent targeted genotyping of a candidate region in 96 cats, we identified a 1.3 MB haplotype on chromosome F1 associated with the phenotype. Within this region, two variants are in 100% agreement with presumed genotype based on phenotype (affected – homozygous alternate, obligate carrier – heterozygous alternate, and normal or possible carrier – not homozygous alternate) in all cats tested (LOD score > 10). One of the variants is a missense variant not predicted to be damaging by PROVEAN in SLAMF1, a gene implicated in immunity and not expressed in the brain. The putatively causative variant is a frameshift variant in PEA15, a gene involved in ERK signaling that is highly expressed in brain. Both count data from all genotype groups and strand bias in heterozygous alternate cats from RNA-Seq suggest that PEA15 is undergoing NMD, and westerns confirm complete ablation of PEA15 in affected cats. In conclusion, we propose that PEA15 may be critical for normal large animal CNS development and function.

**1728F**

**Pathologic characterization of a neurodevelopmental abnormality in the cerebral cortex of domestic cats with loss of PEA15.** E.C. Graff<sup>1</sup>, J.N. Cochran<sup>2</sup>, C.B. Kaelin<sup>2</sup>, K. Day<sup>2</sup>, H.L. Gray-Edwards<sup>1</sup>, R. Watanabe<sup>1</sup>, J.W. Koehler<sup>2</sup>, R.A. Falgoust<sup>1</sup>, B.L. Brunson<sup>1</sup>, J.W. Prokop<sup>2</sup>, B.N. Lasseigne<sup>2</sup>, R.C. Ramaker<sup>2</sup>, K.L. Engel<sup>2</sup>, C. Henegar<sup>2</sup>, N.E. Morrison<sup>1</sup>, J.B. Benito<sup>2</sup>, R.M. Myers<sup>2</sup>, N.R. Cox<sup>1</sup>, G.S. Barsh<sup>2</sup>, D.R. Martin<sup>1</sup>. 1) College of Veterinary Medicine, Auburn University, Auburn, AL; 2) HudsonAlpha Institute for Biotechnology, Huntsville, AL, USA.

A developmental abnormality with an autosomal recessive inheritance pattern was recognized in a feline breeding colony. Through whole genome sequencing of 5 cats, RNA-Seq of cerebral cortex from 16 cats, and subsequent targeted genotyping of a candidate region in 96 cats, we identified a 1.3 MB haplotype on chromosome F1 associated with the phenotype. Within this region, the putatively causative variant is a frameshift variant in PEA15. Perinatal affected kittens have generalized tremors and neurological motor and sensory abnormalities that become apparent as the cats begin to ambulate. As affected cats approach adulthood, they are able to compensate partially for neuromotor deficits. At approximately 1.5 years, affected cats develop sensory abnormalities (fly biting and stargazing), and often become aggressive. Clinicopathologic data, including CSF analysis, suggests a non-progressive, stable disease process. At necropsy, lesions are limited to the cerebral cortex, with an absence of craniofacial or cerebellar abnormalities. Affected cats have marked microcephaly (brain weight ~50% less than normal) and a poorly formed cerebral cortex with smooth, shallow gyri. There is reduced to absent formation of major gyri, including the ectosylvian and sylvian gyri. MRI analysis also identified gyrification abnormalities, including a reduced to absent anterior cingulate gyrus, and flattening of the parietal and temporal lobes. On histologic evaluation of affected cats, the layers of the cerebral cortex are markedly disorganized with a distinct loss of cortical layering. In some cats, polymicrogyria are present. Affected animals have decreased myelin and fewer oligodendrocytes. Cell type deconvolution from RNA-Seq reveals that transcripts specific to oligodendrocyte precursor cells have more counts per million in affected animals, while oligodendrocyte specific transcripts have fewer counts per million, which is consistent with the histological myelin and oligodendrocyte observations. Furthermore, there is an enrichment for transcripts changing in the same direction as transcripts from RNA-Seq of brain samples from a human psychiatric disease study. In conclusion, we propose that PEA15 may be critical for normal large animal CNS development, and functional and neuropathological characterization of loss of PEA15 will lead to a better understanding of neuroembryology and cerebral cortex development.

**1729W**

**Investigation of synergistic interactions among genes in the 15q11.2-q13.1 region using *Drosophila melanogaster*.** K.A. Hope, D. Johnson, D. Kakhniashvili, L.T. Reiter. University of Tennessee Health Science Center, Memphis, TN.

Duplication 15q syndrome (Dup15q) is an autism-associated copy number variation (CNV) disorder resulting from maternally inherited duplications of 15q11.2-q13.1. The E3 ubiquitin ligase *UBE3A* is located within 15q11.2-q13.1 and increased dosage of *UBE3A* is believed to cause Dup15q phenotypes. A second E3 ubiquitin ligase, *HERC2*, is also within the typical duplication boundaries and individuals with Dup15q have elevated dosage of *HERC2* in addition to *UBE3A*. In vitro biochemical work demonstrated a physical interaction between *UBE3A* and *HERC2*, with *HERC2* stimulating the ubiquitin ligase activity of *UBE3A*. Using the GAL4/UAS system in *Drosophila melanogaster*, we investigated the effects of neuronal overexpression of *dHERC2* alone, *Dube3a* alone (the fly homologs of *HERC2* and *UBE3A*), or both *dHERC2+Dube3a*. Overexpression of *dHERC2* reduced *Dube3a* protein levels, indicating that *dHERC2* stimulates the ubiquitin ligase activity of *Dube3a* (*Dube3a* ubiquitinates itself). We performed quantitative mass spectrometry and differential expression analysis to identify global changes in the proteomic landscape of the brain under various *Dube3a/dHERC2* combinations. We reliably identified and quantified approximately 5,000 total proteins, with 1,980 differentially expressed proteins in *Dube3a* overexpression, 3,037 differentially expressed proteins in *dHERC2* overexpression, and 3,224 differentially expressed proteins in *dHERC2+Dube3a* overexpression. Using Protein Set Enrichment Analysis we observed a significant enrichment in the *dHERC2+Dube3a* overexpression group for RNA such as mRNA binding, mRNA splicing, mRNA metabolic process, mRNA processing, ribosome, among others. One particular mRNA binding protein, *FMR1* (fly homolog of *Fragile X Mental Retardation 1*), was significantly upregulated in *dHERC2+Dube3a* overexpression. We are currently identifying other proteins whose expression is regulated by *dHERC2* and *Dube3a* in a synergistic manner, and validating the protein changes observed in *FMR1* and other proteins regulated by *FMR1*. Additionally, we are searching for direct ubiquitin ligase substrates of *Dube3a*. This study demonstrates the importance of approaching CNV disorders holistically, as elevated *HERC2* levels alone appear to influence the proteomic landscape, the activity of *UBE3A*, and the phenotypes observed in Dup15q individuals.

**IBGC mouse model with *SLC20A2* mutation and potential prevention and therapeutics.** J.Y. Liu, C. Wang, X. Xu, Z. Cao, T. Niu. College of Life Science and Technology, Huazhong University of Science and Technology, Wuhan, Hubei, China.

Idiopathic basal ganglia calcification (IBGC, OMIM 213600) is an inheritable neuropsychiatric disorder characterized by mineral deposits in the basal ganglia and other brain regions. Affected individuals could present a wide variety of symptoms that include movement disorders, cognitive impairment and psychiatric signs. So far, no therapeutic drug has been developed for the treatment of IBGC. Loss-of-function mutations in *SLC20A2*, which encodes the type III Na/Pi transporter PIT2, have been reported to account for 40% IBGC cases, suggesting it's a major causative gene of IBGC. In this study, we established an IBGC mouse model with *Slc20a2* p.S602W mutation, and investigated the effect of Chinese herbal medicine SYM on brain calcification. The *Slc20a2*<sup>S602W/S602W</sup> mice developed brain calcification since 3 months old, and the number and volume of calcified nodules increased with age. There was marked elevation of phosphate (Pi) in the cerebrospinal fluid (CSF) of the *Slc20a2*<sup>S602W/S602W</sup> mice relative to the WT mice, whereas serum levels of Pi were nearly identical between groups. Motor incoordination and impaired learning/memory have been observed in *Slc20a2*<sup>S602W/S602W</sup> mice during behavioral tests. The *Slc20a2*<sup>S602W/S602W</sup> mice that drinking SYM decoction since 3 weeks old did not develop brain calcification until 5 months old, and they also showed less brain calcifications at 6 and 7 months of age relative to the controls. We found that CSF protein X, an osteogenic maker protein, was reduced in *Slc20a2*<sup>S602W/S602W</sup> mice from the SYM group. These results suggested that the SYM decoction may produce preventive effect on the formation of brain calcifications, which might be useful for the treatment of IBGC caused by *SLC20A2* mutations.

**CRISPR/Cas9 overcomes the challenges of microsatellite knockin development.** R. Oliveira, J. Thomas, F. Ivankovic, M.S. Swanson. Molecular Genetics and Microbiology, Center for NeuroGenetics, University of Florida, Gainesville, FL.

Myotonic dystrophy (DM) is the most common muscular dystrophy in adults, affecting 1 in 8,000 individuals. There are two types of DM, both caused by microsatellite expansion mutations. Myotonic dystrophy type 1 (DM1) is the most severe form and is caused by a CTG expansion (CTG<sup>exp</sup>) in the 3' untranslated region (3' UTR) of the *DMPK* gene on chromosome 19q13.3. In unaffected individuals, this locus contains 5-37 CTG repeats, but in DM1 these repeats expand into the thousands. Transcription of the expanded *DMPK* allele produces toxic RNAs that sequester multiple RNA-binding proteins, including alternative splicing factors from the muscleblind-like (MBNL) family. MBNL sequestration results in missplicing of developmentally regulated genes, which is a characteristic feature underlying DM1 pathogenesis. Transgenic mice expressing mutant *DMPK* alleles and *Mbnl* knockout models present many of the key molecular and physiological manifestations of DM1, including abnormal alternative splicing, myotonia, heart conduction defects and REM sleep disturbances. Despite these successes, no model has recapitulated the entire spectrum of disease symptoms, a deficiency that has hindered the development of therapeutic strategies that target all tissues affected by DM1. A much needed DM1 model is the knockin of large CTG<sup>exp</sup> at the endogenous mouse *Dmpk* gene, which is expected to express toxic RNA molecules with a spatiotemporal distribution mirroring that observed in affected individuals. Until recently, development of such a model has been hindered by the instability of targeting vectors carrying large CTG<sup>exp</sup> in bacterial strains and the small repeat numbers capable of generating viable mouse ES cells for blastocyst injections. Using a bacteria-free cloning approach based on rolling circle amplification, together with CRISPR/Cas9 genome engineering, we generated a *Dmpk* knockin model carrying 202 CTG repeats, the largest microsatellite knockin developed to date. These mice express wild-type and mutant alleles at similar levels and accumulate toxic RNAs in several tissues following the correct *Dmpk* spatiotemporal distribution. Currently, we are developing additional *Dmpk* knockin mice with even larger CTG repeats, models that will enhance our understanding of earlier and more severe disease onsets, and provide robust platforms to develop effective therapies for myotonic dystrophy. This study was supported by grants from the NIH (NS058901, NS98819) and the MDA (RG 480539) to M.S.S.

**Clec16a knockdown mice develop a neuronal phenotype with ataxia.** *M. Bakay<sup>1</sup>, H. Hain<sup>1</sup>, E. Lancaster<sup>2</sup>, J. Li<sup>2</sup>, R. Pandey<sup>1</sup>, M. Romer<sup>2</sup>, B. Strenkowski<sup>1</sup>, J. Grinspan<sup>2</sup>, S. Scherer<sup>2</sup>, H. Hakonarson<sup>1,3</sup>.* 1) Center for Applied Genomics, Children's Hosp Philadelphia, Philadelphia, PA; 2) Department of Neurology the Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 3) Department of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, PA.

CLEC16A SNPs are associated with multiple autoimmune and inflammatory diseases, including type 1 diabetes, multiple sclerosis, primary adrenal insufficiency, Crohn's disease, primary biliary cirrhosis and rheumatoid arthritis, however, the primary function of this gene and the protein its encodes remains largely unknown. Several studies in different model systems revealed that CLEC16A play an important role in autophagy/mitophagy. Recent publication suggested that CLEC16A is critical autolysosome function and purkinje cell survival. We have generated an inducible whole body (WB) knockdown (KD) mouse model to look into the role of CLEC16A. We hypothesized that CLEC16A plays an important role in the nervous system and UBC-Cre-Clec16a<sup>oxp</sup> mice - *Clec16a* WB KD - will display a phenotype similar to other multiple sclerosis (MS) models. CLEC16A knockdown was induced in adult mice of 10 weeks of age. *Clec16a* KD mice exhibited significant weight loss ( $P < 0.001$ ) as compared to control and a neuronal phenotype including tremors, impaired gait, and spasticity with an increase in severity over time. Over 40 days observation period 100% of the UBC-Cre-Clec16a<sup>oxp</sup> (KD) mice exhibited some disability. About 63% of the mice reached a disability score of '3' and 58% the highest severity score of '4'. No controls showed any impairment. No difference in activity level was noted. 100% of the KD mice exhibited impaired hindlimb splay with both hindlimbs affected as compared to controls. 100% of the KD have many abnormal neurons in the dorsal root ganglia including neurons with vacuoles, myelin debris or myelin-like structures in comparison to control mice. Nerve conduction study revealed statistically significant reduction of neuronal amplitude ( $P = 0.016$ ) and conduction velocity ( $P = 0.021$ ) in CLEC16A KD mice when compared to control littermates. In addition, the UBC-Cre-Clec16a<sup>oxp</sup> KD mice exhibited cerebellar Purkinje cell loss similarly to previously published by Redmann et al, 2016. Taken together, these results demonstrate that CLEC16A is required for normal sensory neuronal function and that CLEC16A risk variants associated with decreased CLEC16A expression may contribute to the pathogenesis of MS and neurodegeneration in humans. Further studies are necessary to understand a precise mechanism of CLEC16A action and to determine if intervention at the CLEC16A level can prevent neurological disorders such as MS in individuals with risk associated CLEC16A SNPs.

**The binding of RNA regulates the formation of nuclear membraneless structures by Matrin 3 and TDP43 in myocytes.** *M.C. Gallego Iradi, R. Davila, A. Crown, H. Brown, J. Lewis, D. Borchelt.* University of Florida, Department of Neuroscience Center for Translational Research in Neurodegenerative Disease Gainesville, FL.

Mutations in Matrin 3 (MATR3) can cause familial amyotrophic lateral sclerosis (fALS) or familial distal myopathy. MATR3 is structurally similar to TDP43 and other RNA binding proteins associated with fALS, but differs in lacking a recognizable prion-like domain (PLD). RNA binding proteins with PLDs have the capacity to undergo liquid phase transition to form membraneless organelles. Similar to wild-type (WT) TDP43, WT MATR3:YFP adopted a diffuse intranuclear distribution with interspersed puncta. To understand the basis for the distribution of WT MATR3, we expressed MATR3:YFP fusions with deletions of DNA and RNA binding motifs [Zn finger domains 1 and 2, and RNA recognition motifs (RRM) 1 and 2]. Deletion of either Zn finger domain had no effect on the distribution of MATR3:YFP. By contrast, deletion of the RRM2 RNA-binding domain ( $\Delta$ RRM2) caused the MATR3:YFP to form intranuclear droplets that fused to form larger structures. Some large droplets were vacuolated and appeared to possess multiple phase-compartments. Deletion of the RRM1 domain of MATR3 also produced droplets, but this case they were smaller and less stable. MATR3:YFP  $\Delta$ RRM2 with the fALS mutation F115C could form large droplets similar to WT MATR3:YFP, but the myopathic S85C mutation produced much smaller and more dispersed droplets. MATR3:YFP  $\Delta$ RRM2 co-expressed with TDP43:mCherry $\Delta$ RRM2 produced large droplets containing both proteins. Our findings demonstrate that MATR3 is similar to TDP43 in possessing an ability to undergo liquid-phase separation, and suggest that these proteins have tendencies to interact through a phase-separation mechanism.

**Neuronal inflammation and dysregulated mitophagy features in ubiquitous *Clec16a* knockdown mice.** H.S. Hain<sup>1</sup>, R. Pandey<sup>1</sup>, M. Bakay<sup>1</sup>, J. Li<sup>2</sup>, M. Romer<sup>2</sup>, B.P. Strenkowski<sup>1</sup>, J.B. Grinspan<sup>2,3</sup>, S.S. Scherer<sup>2</sup>, H. Hakonarson<sup>1,3</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Neurology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Genetic variants in the 16p13 locus harboring the *CLEC16A* gene have been implicated in twelve different autoimmune diseases including multiple sclerosis (MS). However, the role of the gene and variants in the physiology and pathogenesis of autoimmune disorders remains largely unknown. Studies in different model systems revealed that *CLEC16A* plays an important role in autophagy/mitophagy. Ubiquitous inducible knockdown (KD) mice were generated to investigate the role of *CLEC16A* in autoimmune diseases. It was hypothesized that UBC-Cre-*Clec16a*<sup>loxP</sup> KD mice would display a phenotype similar to other MS or neurodegenerative mouse models with inflammatory and autoimmune features. *Clec16a* KD mice exhibited immune dysfunction, weight loss, and a neuronal phenotype with an increase in severity over time leading to morbidity. Accelerated mitophagy in cerebellum, cortex, trigeminal ganglia, dorsal root ganglia, and spinal cord was observed in *Clec16a* KD mice as compared to control mice. This was noted by changes in autophagy and mitophagy-related proteins as measured by Western blots and aberrant mitochondria as observed by transmission electron microscopy. Increases in plasma inflammatory cytokines seen in autoimmune disorders accompanied the behavior and mitophagy. Inflammation rose locally in the central nervous system as exhibited by inflammatory cytokine differences and astrogliosis measured by Western blots and immunohistochemistry. The results establish a connection between *CLEC16A*, dysregulated mitophagy, and inflammation contributing to neurodegeneration in the central nervous system. These results suggest that *CLEC16A* risk variants associated with decreased *CLEC16A* expression may contribute to the pathogenesis of MS and neurodegeneration in humans. Further studies are necessary to understand the precise mechanism and interactions of *CLEC16A*. We conclude that drugs modulating mitophagy/autophagy, particularly in the JAK/STAT pathways associated with cytokine regulation, may be effective to treat or prevent neurological autoimmune disorders such as MS in individuals with risk associated *CLEC16A* variants.

**Impact of rare variants in genes that encode components of the endocannabinoid system.** D. Smith, C. Stanley, T. Foss, K. McKernan. Courtagen Life Science, Woburn, MA.

Rare genetic variants in the core endocannabinoid system genes *CNR1*, *CNR2*, *DAGLA*, *MGLL* and *FAAH* were identified in molecular testing data from up to 5,979 patients with a broad spectrum of neurological disorders including epilepsy, mitochondrial dysfunction, and developmental disorders. The numbers of subjects harboring rare variants were 22 for *CNR1*, 11 for *CNR2*, 35 for *DAGLA*, 34 for *MGLL* and 52 for *FAAH*. Fisher exact tests were performed to evaluate the possible association of phenotypes present in cases with rare variants, compared to controls from the same data set without such variants. Heterozygous rare coding variants in *CNR1* (which encodes the cannabinoid receptor, type 1) were found to be significantly associated with headache or migraine, anxiety, sleep and memory disorders (alone or in combination) compared to controls. Similarly, heterozygous rare variants in *DAGLA* (which encodes diacylglycerol lipase alpha) were found to be significantly associated with seizures and developmental disorders, including abnormalities of brain morphology, compared to controls. Rare variants in *MGLL*, *FAAH* and *CNR2* were not found to be associated with neurological phenotypes in the patients tested. The phenotypes associated with rare *CNR1* variants are similar to those observed in *CNR1* knockout mice, and are also reminiscent of those implicated in the theory of clinical endocannabinoid deficiency syndrome. The severe phenotypes associated with rare *DAGLA* variants underscore the critical role of rapid 2-arachidonoyl glycerol synthesis and the endocannabinoid system in regulating neurological function and development. Mapping of the variants to the 3D structure of the type 1 cannabinoid receptor, or the primary structure of diacylglycerol lipase alpha, reveals clustering of variants in certain regions and is consistent with impacts to function.

**Genetic analysis of Japanese patients with neurofibromatosis type 1 and the neuronal complications.** K. Fujita<sup>1</sup>, K. Yamashita<sup>1</sup>, T. Hoshina<sup>1</sup>, N. Hikita<sup>1</sup>, S. Sakuma<sup>1</sup>, H. Shintaku<sup>1</sup>, K. Fukai<sup>2</sup>, T. Takenouchi<sup>3,4</sup>, T. Uehara<sup>3</sup>, K. Kosaki<sup>3</sup>, H. Saya<sup>5</sup>, T. Seto<sup>1</sup>. 1) Pediatrics, Graduate School of Medicine, Osaka City University, Osaka, Japan; 2) Dermatology, Graduate School of Medicine, Osaka City University, Osaka Japan; 3) Center for Medical Genetics, Keio University School of Medicine; 4) Pediatrics, Keio University School of Medicine; 5) Institute for advanced medical research, Keio University School of Medicine.

Neurofibromatosis type 1 (NF1) is an autosomal dominant disorder. Tumor-like lesions on brain magnetic resonance imaging expressed as unidentified blight object (UBO) rarely develops to pilocytic astrocytoma, optic glioma. We present patients with moderate-to-severe NF1 since we performed genetic analysis. Methods: We analyzed 5 Japanese families including 8 patients with NF1. Patient(P) 1, a proband with NF1 in this family, was a 3-year-old girl who had optic glioma, UBOS in her brain, mild intellectual disability, and autistic spectrum disorder (ASD). P2 was a 21-year-old man who had plexiform neurofibroma. P3 was a 30-year-old man who had obvious neurofibroma. P4 was a 9-year-old boy who had attention deficit/hyperactivity disorder. P5 was his mother with NF1. P6 and P7 were 5-year-old sister and 2-year-old brother. P6 had developmental delay, UBOS in her brain, plexiform neurofibromatosis and ASD. P7 also had UBOS in his brain, optic glioma. P8 was their mother with NF1. Genetic analysis was performed with the patients and their parents after genetic counseling by a medical geneticist and documented informed consent. DNA was purified from their blood samples, and the target region was concentrated by using TruSight One Sequencing Panel that contains coding regions of 4,813 genes and was sequenced on a Miseq platform. This study was approved by the institutional review boards of the participating universities. ; Results: P1 was identified to have c.2350T>C in the 20<sup>th</sup> exon of *NF1* that was missense mutation in the exon thought to be pathogenic, already reported same mutation. P2 did not show any pathogenic mutation in the exons except for the introns, even after performing comparative genomic hybridization array analysis. P3 was c.3527 delG in the 27<sup>th</sup> exon, which is thought to be novel mutation. P4 and his mother showed pathogenic nonsense mutation in the 14<sup>th</sup> exon of *NF1* as c.1603 C>T change causing exon termination, as previously reported. Finally, P5 and P6 and their mother were identified to have c.888+2T>A, which was located in the donor site of the intron, generated owing to splicing causing a pathogenic effect to produce the mRNA, thought to be a novel mutation. Conclusion: We determined the pathogenic mutation in 7 out of 8 patients. Two of them are thought to have a novel mutation. A larger sample size is required in future studies to accurately predict their prognosis, especially regarding the development of malignant tumors in the brain.

**1737F**

**Disruptions to the miRNA regulatory pathway may cause an increased rate of schizophrenia in individuals with 22q11.2 DS.** W. Manley, G. Davis, S. Siecinski, S. Ryan, V. Coulibaly, L. Brzustowicz. Rutgers, Piscataway, NJ.

Schizophrenia is a complex and poorly understood disease caused by the interplay of environmental and genetic factors. The 22q11.2 deletion syndrome (DS) is a disorder that is caused by the microdeletion of part of chromosome 22 leading to a 25-fold greater chance of developing schizophrenia versus the general population. The missing 22q11.2 region contains DGCR8, which is required for the initial step of miRNA biogenesis. However, the 22q11.2 deletion itself is not directly the cause of schizophrenia, since 75% of individuals with this deletion do not develop the disease. We hypothesize that the 22q11.2 deletion increases the risk of schizophrenia through alterations in miRNA regulatory networks via depletion of several miRNAs. This may serve as a buffer against the accumulation of deleterious mutations at other schizophrenia risk loci. We have generated human neural stem cells (NSCs) from six individuals with the 22q11.2 deletion and schizophrenia from iPSCs using Neural Induction Media (Life Technologies). In order to ensure the presence of the 22q11.2 deletion, a FISH probe for 22q11.2 (TUPLE) was used (Cell Line Genetics). DGCR8 was quantified using the 7900HT Fast Real-Time PCR System (Applied Biosystems) along with Taqman Copy Number Assays to ensure DGCR8 reduction in 22q11.2 DS NSCs relative to otherwise healthy control NSCs. Unexpected chromosomal abnormalities associated with iPSC culture methods have made routine detection of the deletion essential. We have characterized disruptions to the miRNA regulatory network in the NSC lines using Taqman Microarray Cards Version 3.0 and Illumina Small RNA-Seq. Here we will present the miRNAs that we have identified to be differentially expressed in otherwise healthy control NSCs versus NSCs with 22q11.2 DS and schizophrenia. Our data shows a subset of miRNAs that have significantly altered expression patterns consistently between the arrays and sequencing results. This list has further been refined to a list of 25 miRNAs previously implicated in having roles in neurological disorders or development including the very well characterized miR-185. We predict that these miRNAs could be involved in the elevated risk of developing schizophrenia in individuals with 22q11.2 deletion syndrome versus the general population. Future studies will focus on further characterizing miRNAs found to be differentially expressed as a result of the 22q11.2 deletion that may be important for schizophrenia.

The limb-girdle muscular dystrophies (LGMD) are a heterogeneous group of incurable muscle wasting disorders. LGMD is caused by about 30 different genes, whose encoded proteins function in diverse, poorly understood pathways critical for normal muscle function. Animal models of muscular dystrophy have been studied for decades but do not faithfully replicate human disease, making *in vitro* models of human skeletal muscle critical for the development of better therapies. Here we describe the development of *in vitro* models of skeletal myotubes to confirm the diagnosis of novel disease genes, facilitate mechanistic understanding of the downstream cellular processes leading to muscular dystrophy, and to develop screening assays to identify therapeutics. We first systematically compared three different protocols for modeling human *in vitro* skeletal myotubes: 1. Transdifferentiation of fibroblasts via MyoD overexpression, 2. Small molecule based 50 day differentiation of human pluripotent stem cells, and 3. Primary human myotubes differentiated from myoblasts. To determine which experimental protocol results in the most mature skeletal myotubes we performed immunofluorescence imaging-based computational analyses, transcriptional profiling, and immunoblotting. We will perform single nucleus RNA sequencing (snNuc-seq) to directly assess and compare the heterogeneity of cell populations within each culture system and the progression towards mature muscle gene expression. We intend to use the best *in vitro* model to systematically characterize the transcriptional and phenotypic changes in LGMD patients across several disease-causing genes, which will illuminate screening targets for identifying therapeutic agents and can also provide a functional validation for novel genes discovered in NGS studies. Ultimately, we will expand this pipeline to all identified disease-associated alleles.

**1739T**

**The chr14.232.a pseudogene in the 14q21.2 region regulates the expression of the contiguous *LRFN5* gene and is deleted in a patient with autism.** G. Cappuccio<sup>1,2</sup>, M. Alagia<sup>1</sup>, S. Attanasio<sup>2</sup>, R. Borzone<sup>2</sup>, R. Genesio<sup>3</sup>, A. Mormile<sup>2</sup>, L. Nitsch<sup>3</sup>, E. Del Giudice<sup>1</sup>, N. Brunetti-Pierri<sup>1,2</sup>. 1) Department of Translational Medicine, Federico II University, Naples, Naples, Italy; 2) Telethon Institute of Genetics and Medicine, Pozzuoli, Naples, Italy; 3) Department of Molecular Medicine and Medical Biotechnology, Federico II University, Naples, Italy.

Autism spectrum disorder (ASD) is a neurodevelopmental disorders with impaired social communication and is frequently associated with intellectual disability (ID). Recent advances have led to the identification of causative mutations in up to 30% of children with ASD. We report a 16 year-old boy with ASD bearing a microdeletion at chromosome 14q21.2 inherited from the father who has borderline cognitive impairment. The deletion affects a 'gene desert' and *LRFN5* is the closest non-deleted gene. *LRFN5* encodes a protein involved in synaptic plasticity that has been heavily implicated in neurobehavioral phenotypes. We hypothesized a positional effect of the pseudogene chr14.232.a included within the deleted region that is predicted to bind the miRNAs targeting the 3'-UTR of the *LRFN5* gene. In agreement with this hypothesis, we found decreased expression of both *LRFN5* gene and chr14.232.a pseudogene in the proband's fibroblasts compared to controls. Interestingly, transfection of the chr14.232.a pseudogene in the patient's fibroblasts resulted in increased *LRFN5* expression. Transfection of pseudogenes chr14.232.a bearing a mutated miRNA binding site resulted in milder increased of *LRFN5* expression. Taken together, these data suggest that the chr14.232.a pseudogene functions as a miRNA decoy to regulate *LRFN5* expression through sequestration of *LRFN5* specific miRNAs. In conclusion, this study may unravel a novel mechanism of gene regulation involved in neurodevelopmental disorders.

**1740F**

**Modeling the effects of autism-related *TBR1* *de novo* mutations on human cortical development.** B.A. DeRosa, R.A. Barnard, S.A. Evans, L.A. Wourms, B.J. O'Roak. Molecular & Medical Genetics, Oregon Health & Science University, Portland, OR.

Recent studies have identified many important brain development genes that are recurrently disrupted by *de novo* mutations in children with autism. Furthermore, many of these, now high confidence, autism risk genes are co-expressed as a network during midfetal human corticogenesis, suggesting a developmental place and time where at least one common autism pathophysiology emerges. Understanding how single mutations in these diverse risk genes alter this network is key to advancing our knowledge of the molecular mechanisms underlying autism. To this end, patient-specific induced pluripotent stem cells (iPSCs) provide a unique opportunity to examine the impact of specific mutations on cortical development, as the *in vitro* differentiation of iPSCs into cortical neurons has been shown to mimic the natural sequence of corticogenesis. We have implemented a method that utilizes iPSCs and mini-bioreactors to generate 3D forebrain-like organoids. These organoids recapitulate cortical lamination patterns and, transcriptionally, closely matches human early and midfetal periods (Qian *et al.* 2016). We have modified the protocol to incorporate AggreWell800 plates to further increase the uniformity of the organoids by seeding ~10,000 cells into individual microwells. We have completed differentiations at 30, 50, and 70 days *in vitro*. Although we see some expected variability in the organization of organoids (e.g. number of ventricular zone (VZ)-like regions per organoid), similar to Qian *et al.*, we observed strong and consistent expression of forebrain, VZ, subventricular zone (SVZ), and deep layer neurons markers; and similar relative thickness of the VZ. Using this approach, we are modeling the effect of three *de novo* mutations in *TBR1*. Experiments are also being replicated in lines where CRISPR/Cas9 genome editing has been used to correct mutations in patient iPSCs. *TBR1* encodes a transcription factor that serves as a "master regulator" of cortical development. Additionally, it has now been demonstrated that the *TBR1*-regulated network contains ~1/3 of high-confidence autism risk genes (Chuang *et al.* 2015). Specifically, we are examining how these mutations effect the acquisition of cellular identity in deep layer cortical neurons and the migration of specific neuronal subtypes to their proper location in the cortex. These studies will revolutionize our understanding of the impact of autism-related mutations on cortical development.

**1741W**

**Does lack of X-inactivation for *SLC6A14* explain the very high male/female ratio in nonsyndromic autism?** F.R. Jimenez-Rondan, A. Ye, Q. Sun, K. Mohan, J. Ge, A.L. Beaudet. Molecular and Human genetics, Baylor College of Medicine, Texas Children' Hospital, Houston, TX.

**Background:** We have proposed a hypothesis that brain carnitine deficiency can cause autism with a non-Mendelian, non-dysmorphic (NoMeND) phenotype characterized by an extremely high male/female ratio, normal physical examination, normal structural brain imaging, and onset between 6 and 36 months of age (*BioEssays*, in press). We have searched for a carnitine-related gene that might explain the high male/female ratio in NoMeND autism. The *SLC6A14* gene in on the X-chromosome, encodes a blood-brain barrier carnitine transporter, and lacks the epigenetic hallmarks of random X-inactivation, suggesting that transport of carnitine across the BBB might be more effective in healthy female mice or humans compared to healthy male counterparts based on higher expression in females. **Methods:** DNA methylation across the *SLC6A14* gene was analyzed in human postmortem brain using a 450K Illumina methylation array. *Slc6a14* null mice from the Knockout Mouse Project (KOMP) and wild-type mice were bred on the C57BL/6NJ background. L-[N-methyl-<sup>14</sup>C]-carnitine hydrochloride was injected by tail vein in young adult mice (6-10 week old) and mice were sacrificed 2 to 6 hours later and radioactivity was quantified in the brain. Free carnitine,  $\gamma$ -butyrobetaine, and trimethyllysine were measured in plasma and breast milk of wild-type and null mice. **Results:** There is no CpG island or differential DNA methylation of the active and inactive X chromosome for the *SLC6A14* gene in human brain. Genome browser data indicate that the same is true for all mammalian species for which data are available. After tail vein injection, transport of [<sup>14</sup>C]-carnitine across the BBB into cerebellum is 35% greater in wild-type female mice compared to male mice likely due to lack of X-inactivation of *Slc6a14*. Findings are similar in brain excluding cerebellum. In *Slc6a14* null mutants compared to wild-type, transport of [<sup>14</sup>C]-carnitine across the BBB is reduced by 68% in females and by 38% in males. The carnitine content of breast milk is substantially reduced in *Slc6a14* null mothers compared to wild-type. **Conclusion:** We propose that the extremely high male/female ratio in milder, nonsyndromic autism may be mediated by *SLC6A14* via susceptibility to autism caused by brain carnitine deficiency. If the brain carnitine hypothesis is correct, it is possible that 10-20% of all autism and a larger fraction of NoMeND autism could be prevented by fortification of infant diets with carnitine.

**1742T****Further evidence supporting the involvement of *ERC1* gene variation in ASD.**

S. Raskin<sup>1</sup>, C.C.V. da Silva-Camargo<sup>1</sup>, P. Liberalesso<sup>2</sup>, V.S. Sotomaior<sup>1</sup>. 1) Group for Advanced Molecular Investigation (NIMA), Pontifícia Universidade Católica do Paraná, Curitiba, PARANÁ, Brazil; 2) Department of Neuropediatrics - Hospital Pequeno Príncipe - Curitiba - PR - Brazil.

Autism spectrum disorder (ASD) is reported in about 1% of children, with the highest heritability among common neuropsychiatric disorders. Chromosomal copy number variations (CNVs), that cannot be detected by conventional cytogenetic analysis, significantly contribute to the development of ASD, and new candidate genes have been associated to this condition through microarray-based comparative genomic hybridization (aCGH) analysis and Whole-Exome and Genome sequencing. We analyze two patients by aCGH and fluorescence in situ hybridization (FISH) confirmation, both patients have an interstitial heterozygous microduplication in 12p13.33. One is a 19-year-old male with ASD, epilepsy, long face and large ears, whose duplication includes the entire *ERC1* and other 11 genes. The other patient has a small 389 kb *ERC1* duplication, a 3-year-old female with ASD, lack of eye contact since 5 months, speech and psychomotor development delay, attention deficit, stereotypies, anxiety, irritability, tendency to social isolation and lack of facial expression. This is the smallest duplication ever observed in this region associated with a phenotype, and resulting in a partial duplication that encompasses only the *ERC1* gene. CNVs in this gene are reported here in patients with ASD for the second and third time, as we previously published a case where a 8-year-old male patient had a 1.5 Mb terminal deletion at 12p13.33, including *ERC1* gene. *ERC1* is related to neuronal functions, and like most genes related to ASD, encodes a member of a family of RIM-binding proteins, a synaptic factor that regulate neurotransmitter release. The large duplication involves 12 genes but *ERC1* is the only one already related to ASD, and the small involves only the *ERC1* gene. These three cases implicates *ERC1* as a new putative ASD gene, but further functional analysis of *ERC1* is needed to improve the understanding about its possible role as a new candidate gene in this disease.

**1743F****Evaluation and co-expression of marker genes of cell types in brain.**

R. Dai<sup>1</sup>, C. Jiao<sup>1</sup>, Y. Chen<sup>1</sup>, C. Chen<sup>1</sup>, C. Liu<sup>1,2</sup>. 1) The State Key Laboratory of Medical Genetics, Central South University, Changsha, Hunan, China; 2) Department of Psychiatry, University of Illinois at Chicago, Chicago, IL, USA.

**Purpose:** We want to use different types of data to evaluate the specificity of marker genes of brain cells and unravel the co-expression of cell type-specific genes in psychiatric disorders. **Methods:** The transcriptome and proteomics data of brain cells from human and mouse, by RNA-Seq and microarray from acutely isolation cell and primary culture cell were collected. We collected 543 "putative" marker genes for ten cell types from literature, in situ hybridization databases and antibody companies. We defined general marker gene as their expressions in claimed target cells is the highest across all cell types tested. The expression difference for the rigorous marker gene defined as dividing the second highest expression level across all the other cell types by the expression level in target cell type. Parietal cortex tissue from human brain included schizophrenia, bipolar disorder, and control samples were used for Weighted Gene Co-Expression Network Analysis. **Results:** With the datasets collected and the criteria provided, we found that 44 general marker genes showed stable specificity across all data collected. That included 29 neuron markers, eight astrocyte markers, seven oligodendrocyte markers. The averaged correlation values of general marker genes between human and mouse, transcriptome and proteome, RNA-Seq and microarray, acutely isolation and primary culture were 0.50, 0.58, 0.51 and 0.43, respectively. According to the criterion for rigorous marker genes, 23 of the 44 marker genes showed more than two-fold changes in at least seven data sets evaluated. The most specific marker gene (FC=710.31) is *RELN*, a neuron marker gene. It is not clear whether the non-specificity of rest of more than 400 claimed marker genes is related to data quality or technical artifacts in the data we can use for the assessment. In the WGCNA analysis, we found general marker genes of astrocyte were significantly enriched ( $p < 2.2e-16$ ) in disease associated module. The enriched six astrocyte marker genes (*ALDH1L1*, *ALDOC*, *CLU*, *GJA1*, *SLC1A3*, and *SLC4A4*) showed co-expression with significant GWAS loci of schizophrenia and bipolar disorder in previous studies. **Conclusions:** We confirmed 44 genes to be cell type-specific in the brain while many other commonly-used marker genes will require additional studies to verify their specificity. Moreover, astrocyte marker genes enriched in disease-associated co-expression module with known GWAS loci for schizophrenia and bipolar disorder.

**1744W**

**Stem cell models for studying the role of epigenetic machinery in abnormal neurogenesis.** *N. Kommu, S. Saxena, P. Naik.* Biological Sciences, BITS Pilani Hyderabad Campus, Hyderabad, India, India.

In addition to genetic mutations, the role of epigenetic abnormalities is widely appreciated in the development of disorders such as schizophrenia and autism. In support of this notion, elevated levels of DNMT1 and DNMT3A have been reported in post-mortem brain samples from patients with schizophrenia. However, the mechanisms by which elevated levels of DNMT1 or DNMT3 result in formation of abnormal neurons is not clear. Towards this goal, we developed a transgenic mouse embryonic stem cell line that overexpresses DNMT1 and observed that neurons obtained from the mutant line shows abnormal branching of dendrites and elevated levels of NMDA receptor activity. To gain more insights into the abnormal effects of increased levels of DNMT1, we performed genome-wide methylation comparisons between wild-type and mutant ES cells to identify loci undergoing aberrant methylation in the mutant ES cells. Results of these experiments will be presented.

**Changes of open chromatin regions reveal stage-specific transcriptional network dynamics in human iPSC-derived neurons.** *W. Moy<sup>1,5</sup>, S. Zhang<sup>1,2,5</sup>, H. Zhang<sup>1</sup>, H. McGowan<sup>3</sup>, J. Shi<sup>4</sup>, C. Leites<sup>1</sup>, A.R. Sanders<sup>1,2</sup>, P.V. Gejman<sup>1,2</sup>, J. Duan<sup>1,2</sup>.* 1) Center for Psychiatric Genetics, NorthShore University HealthSystem, Evanston, IL 60201, USA; 2) Department of Psychiatry and Behavioral Neuroscience, University of Chicago, IL 60637, USA; 3) Department of Neuroscience and Cell Biology and Child Health Institute of New Jersey, Rutgers University, New Brunswick, NJ 08901, USA; 4) Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD 20892, USA; 5) Equal Contribution.

The application of human induced pluripotent stem cells (iPSCs)-differentiated neurons has served as a promising model for gaining insights into the molecular and cellular mechanisms of genetic risk for mental disorders. Multiple factors determine the fate and trajectory of neuronal cell differentiation, of which transcriptional regulation plays a major role. Chromatin accessibility (openness) to transcription factors (TF) strongly influences gene transcription and cell differentiation. However, the dynamic changes of open chromatin and the TF networks during neuronal differentiation from iPSCs are poorly understood. Here, we performed a global mapping of open chromatin regions (OCRs) using the Assay for Transposase-Accessible Chromatin with high throughput sequencing (ATAC-Seq) at different cell stages of glutamatergic neuronal differentiation, examined the correlation of changes of open chromatin and mRNA abundances (assayed by RNA-Seq), and constructed the neuronal stage-specific TF networks through a genome-wide inference of TF-binding footprints in OCRs. We found that OCRs were highly dynamic during neuronal differentiation, and more importantly that OCR accessibility at core promoter regions was positively correlated with mRNA abundances at their respective cell stages. Furthermore, we found that the dynamic changes of OCRs during neuronal differentiation were accompanied by the binding events of cell stage-specific TFs. As expected, binding footprints of *OCT4* and *NANOG*, genes that encode pluripotent stem cell-specific markers, are most enriched in iPSCs. Intriguingly, binding footprints of *NEUROD1* and *NEUROG2*, the two TFs that have been reported to rapidly induce high efficient conversion of iPSCs to excitatory neurons, are among those most enriched in the relatively mature neurons. Further TF network analysis based on the inferred TF binding footprints in OCRs successfully identified core TF networks and their master regulators for different neuronal stages. Interestingly, both *NEUROD1* and *NEUROG2* are in the same core TF network specific to more mature neurons, suggesting their pivotal role in epigenetic control of neuronal differentiation and maturation. Our study provides novel insights into the epigenetic control of glutamatergic neurogenesis and reveals neuronal stage-specific TF networks, which may facilitate the iPSC modelling of mental disorders by generating more homogenous neuronal populations in an accelerated manner.

**Identifying pathogenic genes associated with autism and other developmental disorders by in-depth analysis of chromosome microarray studies.** V. Goitia<sup>1</sup>, R.H. Peretz<sup>1</sup>, G. Bhoojhwon<sup>1</sup>, V. Ragoonanan<sup>1</sup>, C.H. Wang<sup>2</sup>. 1) Department of Pediatrics, Driscoll Children's Hospital, Corpus Christi, TX; 2) Department of Neurology, Driscoll Children's Hospital, Corpus Christi, TX.

Chromosome Microarray (CMA) is a diagnostic test that scans the entire genome to identify chromosomal abnormalities in patients suspected to have multigenic disorders such as congenital anomalies, autism, and other developmental disorders. However, interpreting results of CMA is often problematic due to the large genomic intervals involved and difficulty knowing whether any or all genes detected in these intervals are related to the pathogenesis of the clinical diagnosis. We previously analyzed the results of CMAs among patients at Driscoll Children's Hospital (DCH) and found the following: high positive report rates (56%) in children with both autism and congenital anomalies, hotspots of genomic variation on chromosomes 10, 15, and 16 for autism, and high correlation between size of genomic variation and autism severity. Our current research goal was to identify pathogenic genes associated with autism and other developmental disorders. We included 1069 CMAs that were obtained at DCH from 2008 to 2016. There was an overall positive rate of 26.5% that included all reports which deviated from normal male and normal female. However, a high proportion of these were reported as variants of unknown significance (VUS). To further determine the pathogenicity of these genomic variations, we conducted a genome search to identify genes within each interval of genomic variation for all patients with a positive report. Those genes isolated from the intervals that occurred in multiple individuals with the same clinical diagnosis were considered pathogenic. We isolated many pathogenic genes that were previously reported as VUS. Our findings confirm that a whole genome approach such as CMA, combined with detailed characterization of clinical phenotypes, may be the best way to identify the genetic basis of multigenic disorders such as autism and other developmental disorders.

**Rare family with partial duplication in 7q11.23 link four genes associated with intellectual delay and autistic phenotypes.** J.R. Korenberg<sup>1</sup>, L. Dai<sup>1</sup>, M.C. Burback<sup>1</sup>, A. Ramirez<sup>1</sup>, J.S. Anderson<sup>2</sup>, M.B. Prigge<sup>3</sup>. 1) Department of Pediatrics, Brain Institute, University of Utah, Salt Lake City, UT; 2) Department of Radiology, University of Utah, Salt Lake City, UT; 3) Department of Pediatrics, University of Utah, Salt Lake City, UT.

Parsing the gene(s) associated with human cognition and behaviors is critical yet remains scientifically elusive. Full and partial deletion or duplication of ~28 genes in 7q11.23, has been linked to Williams syndrome (WS) and Autism Spectrum Disorder (ASD) respectively, providing unique opportunities for linking single gene(s) to specific cognitive and behavioral phenotypes. In this report, we show a rare family (one female patient and her two sons) with partial duplication of only four genes (*STX1A*, *ABHD11*, *CLDN3*, *CLDN4*). All three patients present moderate intellectual and behavioral abnormalities. The duplication region was determined using Illumina OMNI5 microarray analysis on DNA isolated from subject derived blood samples. Cognition and social behaviors were also measured with this family. Opposite to the cognitive deficits in WS (verbal IQ > performance IQ), the family presents moderate cognitive delays (IQ=77 to 94) particularly in speech and language development (verbal IQ < performance IQ). They also have mild motor delays, hyperactive distractible behavior and autistic phenotypes. One of the sons has a history of abnormal EEG suggestive a seizure disorder. Compared to a rare family with partial deletion of overlapping genes (from *ABHD11* to *RFC2*), the family with partial duplication reported here show similar mild intellectual disabilities but less tendency to approach strangers as measured by the Salk Institute Sociability Questionnaire (SISQ). This is the first report of partial duplication of genes in 7q11.23. The results implicate that these four genes are associated with cognitive development, mainly in speech and language, and that copy number variant may affect the social behaviors in human being. Future work will include brain structural and functional analyses using magnetic resonance imaging and integration of genetics, cognition and behaviors.

**1748T**

**Behavioral characterization in a mouse model of Bohring–Opitz syndrome.** K. Walz, C. Abad, J. Pascual, J.I. Young. Hussman Inst Human Genomics, Univ Miami, Miami, FL.

Bohring–Opitz syndrome (BOS) is a rare neurodevelopmental condition characterized by intrauterine growth restriction, feeding difficulties, failure to thrive, developmental delay and distinctive facial features and posture. *De novo* frameshift and nonsense mutations in the *additional sex combs like 1* (*ASXL1*) gene, have been detected in the majority of BOS patients. *ASXL1* encodes a polycomb group protein that assembles multi-protein complexes on DNA to mediate transcriptional repression. Somatic mutations in this gene are also associated with myelodysplastic syndromes and chronic myelomonocytic leukemia. It is not yet known whether BOS is caused by haploinsufficiency of *ASXL1* or by gain of function of truncated *ASXL1*. The objective of this study is to characterize phenotypically *Asxl1* heterozygous mutant mice (*Asxl1*<sup>+/−</sup>) to understand BOS pathogenesis. Adult male *Asxl1*<sup>+/−</sup> animals were evaluated with a set of tests oriented to characterize their neurodevelopmental phenotype. All procedures were approved by the IACUC at the Miller School of Medicine, UM. *Asxl1*<sup>+/−</sup> did not have an overt phenotype and were indistinguishable from wild type littermates when superficially observed. However, the open field test revealed significant hypoactivity and on the rotarod test we observed impaired performance. In addition, *Asxl1*<sup>+/−</sup> mice were less sociable as uncovered by the three chamber sociability test, and were deficient in the auditory-cued Pavlovian fear conditioning (despite having normal hearing). Thus, these data suggest perturbed locomotor abilities or alterations in motivation as well as abnormal social behaviors and learning and memory deficiencies. Analysis of expression of *ASXL1*, as detected by  $\beta$ -galactosidase activity from the *ASXL1* locus revealed that it is expressed throughout the brain. Our data demonstrates that *ASXL1* haploinsufficiency results in behavioral alterations and suggest that the heterozygous *Asxl1*<sup>+/−</sup> mouse model resembles behavioral aspects of BOS. Further studies of this mouse model will advance our understanding of the abnormal brain development underlying BOS □ associated behavioral and cognitive symptoms. .

**1749F**

**Multimodal MRI and DTI reveal common systems mechanism underlying Down syndrome and Alzheimer's disease.** L. Dai<sup>1</sup>, O. Abdullah<sup>1</sup>, J.S. Anderson<sup>2</sup>, M.B. Prigge<sup>3</sup>, M.C. Burback<sup>1</sup>, A. Ramirez<sup>2</sup>, J.O. Edgin<sup>4</sup>. 1) Department of Pediatrics, Brain Institute, University of Utah, Salt Lake City, UT; 2) Department of Radiology, University of Utah, Salt Lake City, UT; 3) Department of Pediatrics, University of Utah, Salt Lake City, UT; 4) Department of Psychology, University of Arizona, Tucson, AZ.

Down syndrome (DS) is a major genetic imbalance causing brain disease throughout the lifespan; from intellectual disability in the young to premature aging and Alzheimer's disease (AD) in the old. The partial and full trisomy 21 provide a unique opportunity to link genes to brain architecture, cognitive and behavioural phenotypes. We report a high resolution multimodal map of brain structural Magnetic Resonance Imaging (MRI) and Diffusion Tensor Imaging (DTI) in a cohort of 26 subjects with full trisomy 21 (age 22±6), 17 age and gender matched controls (age 23±5) and five subjects with partial trisomy 21 (age 22±3). Results show decreased volume, increased cortical thickness and decreased surface area in the most significantly changed brain regions in DS. Fractional anisotropy (FA) also differs significantly in the external capsule, fornix, anterior limb of internal capsule, sagittal stratum, inferior and superior cerebellar peduncle, posterior corona radiate and uncinate fasciculus out of 48 white matter tracts (JHU DTI-based white matter atlases). Patterns of white matter changes in DS are highly overlapped with those in AD, particularly in the external capsule, corona radiate, fornix and uncinate fasciculus, suggesting critical white matter metrics disturbed in development also in early onset of AD in DS. Most decreases in FA result from increased radial diffusivity (RD), suggesting abnormal myelination in these white matter tracts. Our results also show a significant positive correlation (R=0.6, P<0.02) between CANTAB Paired Associates Learning test and FA, RD in the external capsule and uncinate fasciculus, indicating a neural basis of deficits of memory, executive function and processing speed in DS. The external capsule and uncinate fasciculus comprise the capsular division of the lateral cholinergic pathway originating in the nucleus basalis of Meynert, a region that frequently degenerates in AD. Further studies are needed to discern if FA reduction in cholinergic circuits including external capsule and uncinate fasciculus in DS is associated with the early onset of AD in DS. Finally, we demonstrate genetic dissection using partial trisomy 21 implicating critical gene(s) associated with brain substrates and cognitive and behavioural functions. Together, our results implicate a system mechanism for the genetic and neural basis of developmental deficits and early onset of AD in DS and provide insightful information for therapeutic treatments.

**Comprehensive catalog of cell types in the developing brain using single-cell transcriptional profiling.** J.M. Simon<sup>1,2,3</sup>, L. Loo<sup>2,4</sup>, J. Niehaus<sup>2,4</sup>, J.D. Welch<sup>5</sup>, E.S. McCoy<sup>2,4</sup>, M.J. Zylka<sup>2,3,4</sup>. 1) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) UNC Neuroscience Center, University of North Carolina at Chapel Hill, Chapel Hill, NC; 3) Carolina Institute for Developmental Disabilities, University of North Carolina at Chapel Hill, Chapel Hill, NC; 4) Department of Cell Biology and Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC; 5) Department of Computer Science, University of North Carolina at Chapel Hill, Chapel Hill, NC.

Understanding complex processes such as differentiation, development, and disease often relies on characterizing the baseline transcriptional landscape of tissues or cells. These experiments are typically performed in bulk on mixed populations of cells or heterogeneous tissues and therefore molecular complexity can be lost as the signal represents the average of that population. The advent of single-cell sequencing has enabled the categorization and characterization of heterogeneous cell types in complex adult tissues, however, the cellular composition of the developing brain has not yet been elucidated in this manner. We have utilized Drop-seq to transcriptionally profile ~20,000 single cells from the cerebral cortex of embryonic and neonatal mice. Due to the plastic nature of the developing tissue and scarcity of certain cell types, existing methods to identify cell clusters failed to resolve mixed populations of distinct but similar cells into their respective independent groups. We therefore developed a new computational procedure that iteratively identifies and refines cell-type classifications to maximize robustness of each intrinsic cell type. Using this approach, we identified 22 distinct cell types in both the embryonic and neonatal cortex, including multiple sub-classes of excitatory and inhibitory neurons, radial glia, and other neuronal and glial precursors, many of which were developmental timepoint-specific. These cell types could be reliably distinguished by the combined expression of known and novel marker genes. Further, within specific cell types, we discovered sub-clusters of cells that corresponded to various cellular states, including phases of the cell cycle and transient activation. Together, these data will serve not only as a novel resource of the different cortical cell types and their molecular markers during development, but also as a platform on which to study numerous neurological diseases and etiology.

**Cytoplasmic FMRP-Interacting Protein 2 (CYFIP2) causes syndromic intellectual disability.** A. Begtrup<sup>1</sup>, K. McWalter<sup>1</sup>, M.T. Cho<sup>1</sup>, E. Heise<sup>1</sup>, K.J. Wierenga<sup>2</sup>, J. Chen<sup>2</sup>, G. Purcarin<sup>2</sup>, C.R. Finnila<sup>3</sup>, G.M. Cooper<sup>3</sup>, J. Screiber<sup>4</sup>, M. Meltzer<sup>5</sup>, R. Mostafavi<sup>6</sup>, D. Goh<sup>7</sup>, B. Baskin<sup>1</sup>, M.J. Guillen Sacoto<sup>1</sup>, K.G. Monaghan<sup>1</sup>, J. Juusola<sup>1</sup>. 1) GeneDx, Inc., Gaithersburg, MD; 2) Oklahoma University Healthy Sciences Center, Oklahoma City, OK; 3) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 4) Children's National Medical Center, Washington, DC; 5) Children's National Healthy System and Pediatric Specialists of Virginia, Fairfax, VA; 6) Le Bonheur Children's Hospital, Memphis, TN; 7) National University Children's Medical Institute, Singapore.

Syndromic intellectual disability is a common indication for genetics consultation, and due to the large degree of genetic heterogeneity, a diagnosis is often made using exome and genome sequencing. During the past four and a half years our clinical diagnostic laboratory has performed exome sequencing on 10,692 probands with intellectual disability or developmental delay as the primary indication for clinical exome sequencing. Utilizing trio-based testing, we identified *de novo* variants in the candidate disease gene *CYFIP2* in six individuals submitted for clinical exome sequencing and an additional individual tested at an outside laboratory, connected via GeneMatcher. Two unrelated probands shared the same *de novo* variant, p.R87C, while a third case had a splice site variant, c.3594+1G>T. The remaining individuals had unique missense variants with damaging *in silico* predictors and were absent from ExAC and our internal database of unaffected individuals. *CYFIP2*, Cytoplasmic FMRP Interacting Protein 2, was previously identified in yeast-two hybrid screening to interact with FMRP, the protein responsible for fragile-X syndrome (FXS) (Schenck *et al.*, 2001). Mice heterozygous for a null *Cyfp2* allele have abnormal behavioral and dendritic spine phenotypes, suggesting a significant role for this novel gene in the pathogenesis of FXS (Han *et al.*, 2015). Common clinical features observed in probands in our cohort, ranging in age from 10 months to 11 years, included developmental delay (7/7), abnormal tone (6/7 with hypotonia, 3/7 with hypertonia in the extremities), seizures (5/7), intellectual disability (4/7), microcephaly (2/7), and gastrointestinal/growth issues (6/7). Two cases, one of whom harbors the splice site variant, have autism. Brain MRI results were normal for 4/7 probands, and revealed atrophy (2/7), and periventricular leukomalacia (1/7) in others. While further characterization of the phenotypes associated with *de novo* *CYFIP2* variants is needed, our study, combined with the functional link of this gene to FMRP, provides additional evidence that *CYFIP2* is a new disease-associated gene causing syndromic intellectual disability.

**1752F**

**Truncating *de novo* mutations in *DLG4* responsible for intellectual disability with Marfanoid habitus.** S. Moutton<sup>1,2</sup>, AL. Bruef<sup>1</sup>, M. Assoum<sup>2</sup>, M. Chevarin<sup>2</sup>, E. Sarrazin<sup>3</sup>, C. Goizet<sup>4</sup>, AM. Guerrot<sup>5</sup>, P. Charles<sup>6</sup>, D. Héron<sup>6</sup>, N. Houcinat<sup>1,2</sup>, A. Vitobello<sup>2</sup>, F. Tran-Mau-Them<sup>2</sup>, C. Philippe<sup>2</sup>, Y. Duffourd<sup>2</sup>, C. Thauvin-Robinet<sup>1,2</sup>, L. Faivre<sup>1,2</sup>. 1) Reference center for developmental anomalies, Dijon University Hospital, Dijon, France; 2) INSERM 1231, LNC UMR1231 GAD, Brugundy University, F-21000, Dijon; 3) Caribbean reference center for rare neurological and neuromuscular diseases, Fort de France University Hospital, Fort de France, France; 4) Reference center for developmental anomalies, Bordeaux University Hospital, Bordeaux, France; 5) Department of Genetics, Rouen University Hospital, Normandy Centre for Genomics and Personalized Medicine, Rouen, France; 6) Reference center for rare intellectual disability disorders, Pitié-Salpêtrière Hospital, Paris, France.

Marfanoid habitus (MH) combined with intellectual disability (ID) is a genetically and clinically heterogeneous group of overlapping disorders. The association of various chromosomal disorders and variations in genes responsible for Marfan syndrome explain no more than 20% of subjects, with examples of digenic inheritance. Different genes responsible for ID have occasionally been described in patients with marfanoid habitus. To identify new genes specific to MH with ID, we performed a combination of trio-based (33 subjects) or single proband (17 subjects) exome sequencing in 50 affected individuals, and searched for variations in non-OMIM genes in at least 2 unrelated patients of the cohort, with a compatible segregation in a given family. We identified 3 patients carrying a potential truncating variant (1 splicing and 2 frameshift variants) of the *DLG4* gene: c.1534+2T>C, c.1009\_1016delTTTATCCT and c.1705delG according to NM\_001128827.1 transcript. In 2 patients, the variant was *de novo*, whereas in one patient, the father was not available for testing but it was absent from the mother. The patients were 35, 21 and 23 years of age and shared mild to moderate ID and similar marfanoid features including long face, high arched palate, dolichostenomelia, long and thin fingers, pectus excavatum and scoliosis. They did not exhibit ophthalmological or cardiac manifestations. The *DLG4* gene encodes Psd-95, a protein expressed in various tissues including the brain. In neurons, Psd-95 is localized at the post-synaptic density, associated with NMDA receptor signaling. It was hypothesized to participate in glutamatergic synapse maturation. Depletion of *DLG4* is thought to change the ratio of excitatory to inhibitory synapses in hippocampal neurons. The variants were absent from databases, the gene was found to be intolerant to loss-of-function variants and it was previously hypothesized to cause ID, as *de novo* truncating variants were significantly enriched in a series of 2,104 trio-based WES, but no clinical description was provided. By describing 3 additional patients, our study emphasizes the role of *DLG4* as a novel post-synaptic associated gene involved in ID. Further descriptions will be needed in order to conclude whether *DLG4* is specific to an ID-MH phenotype.

**1753W**

**Effect of an intronic mutation in the CLIP1 Gene (CLIP-170) in a patient with autosomal recessive intellectual disability.** A. Rincon<sup>1,2</sup>, J. Rojas<sup>1,2</sup>, JC. Prieto<sup>1,3</sup>, P. Ayala<sup>1</sup>, A. Barreto<sup>1</sup>, K. Prieto<sup>1</sup>, C. Serrano<sup>4</sup>, FS. Cabrera-Solano<sup>4</sup>. 1) Pontifical Xavierian University, Bogota, Colombia; 2) San Ignacio University Hospital; 3) Hospital la Victoria SDS, Bogotá, Colombia; 4) Gimnasio Vermont School.

The etiological diagnosis of intellectual disability (ID) remains a challenge. Approximately 80% of ID cases do not have an identified cause. Introduction of new high-throughput DNA sequencing techniques has discovered new genes involved in autosomal recessive ID (ARID) disorders. CLIP1 gene (OMIM 179838), located in 12q14, has been recently linked to ARID. CLIP1 codes for a cytoplasmic protein, member of the microtubule plus-end tracking protein family, associated with the ends of growing microtubules within the cytoskeleton of axons and neuronal dendrites. A previous study in consanguineous families found loss-of-function homozygous mutations in the coding region of CLIP1 in patients with ARID. Functional studies demonstrated absence of CLIP1-protein in patients with ARID. Therefore, CLIP1 was proposed as a novel causing gene for ARID. However, the effect of a homozygous intronic mutation on CLIP1-protein and its correlation with ID has not been analyzed. A patient with ARID, daughter of healthy consanguineous parents underwent genetic testing to identify the genetic cause of ID. A c.2418+1G>T intronic mutation in CLIP1 gene was identified. mRNA and CLIP1-protein expression was tested in fibroblasts and blood of the patient, her mother and two healthy controls. RT-PCR showed no difference in mRNA expression levels in the patient's cell lines compared to the mother and controls. Immunofluorescence analysis of fibroblasts demonstrated no morphological differences and no changes in the localization of the CLIP1-protein among the patient, the mother and controls. However, ROI (region of interest) analysis showed significant decrease of CLIP1 fluorescence in the patient compared to the mother, who had mild decrease in CLIP1 fluorescence respect to the control. These results suggested that CLIP1 mutation may cause a reduction in the amount of CLIP1-protein. Western Blot revealed a lighter protein in the patient compared to the mother and controls, confirming our hypothesis. Predicting models suggest that exon-skipping, caused by a mutation in the donor site of splicing in the intron 11 of CLIP1 gene, yields a shorter protein, affecting the coiled-coil region of CLIP1-protein. Abnormally spliced mRNA was subsequently confirmed by amplification of the patient's cDNA. Our data suggest that c.2418+1G>T intronic mutation in the CLIP1 gene produces an altered protein with inadequate function in microtubular terminations in neuronal cells, which can lead to ARID.

## 1754T

**MECP2 AT-hook1 mutations disrupt DNA binding and chromatin compaction in patients with intellectual disability and schizophrenia.** *T.I. Sheikh<sup>1,2</sup>, M. Ayub<sup>3</sup>, J.B. Vincent<sup>1,2,4</sup>*. 1) Molecular Neuropsychiatry & Development (MiND) Lab, Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, ON, Canada; 2) Institute of Medical Science, University of Toronto, Toronto, ON, Canada; 3) Department of Psychiatry, Queen's University, Kingston, Ontario, K7L 3N6 Canada; 4) Department of Psychiatry, University of Toronto, Toronto, ON, Canada.

Mutations in the Methyl-CpG-binding protein-2 gene (*MECP2*) are most commonly associated with Rett syndrome in females. However, it has long been appreciated that there exists a broader spectrum of neuropsychiatric phenotypes associated with *MECP2* variants. Most Rett causing mutations are either missense mutations located in either the methyl-CpG-binding domain (MBD) or the transcription repression domain (TRD), or lead to premature truncation of the *MECP2* protein. Clear clinical roles for mutations in other known domains such the intervening domain (ID) or in AT-hook domains have yet to be determined. Here, we report on a R190H *MECP2* missense mutation, located in AT-hook1 within the ID, segregating in a large Pakistani family with childhood onset cognitive decline and schizophrenia. We studied the effects on DNA binding and chromatin clustering of this mutation, as well as a second mutation, R190C, previously reported as a *de novo* mutation in a female subject with schizophrenia. We show that both mutations affect the ability of *MECP2* to bind to AT-rich DNA as well as the brain-derived neurotrophic factor (*BDNF*) promoter, with the more drastic effects seen for R190C. Both mutations show similar effects on nuclear chromatin clustering. These data indicate a clear molecular link between *MECP2* AT-hook1 mutations and a major psychiatric disorder, and support a more general link between *MECP2* mutations and psychosis.

## 1755F

***De novo IRF2BPL* pathogenic variants cause severe precocious neurodegenerative disease.** *F. Tran Mau-Them<sup>1,2,3</sup>, A. Vitobello<sup>1,3</sup>, L. Duplomb<sup>3</sup>, K. Jouan<sup>3</sup>, F.E. Jansen<sup>9</sup>, Y. Duffourd<sup>5</sup>, K. van Gassen<sup>7</sup>, C. Pilippe<sup>1,2</sup>, L. Faivre<sup>2,3</sup>, K. Riley<sup>6</sup>, J. Friedman<sup>10</sup>, L.D.M. Pena<sup>6</sup>, C. Thauvin-Robinet<sup>1,2,3</sup>*. 1) UF Innovation en diagnostic génomique des maladies rares, Laboratoire de Cytogénétique-Génétique Moléculaire, CHU Dijon Bourgogne, Dijon, France; 2) Centre de Référence maladies rares « Anomalies du Développement et syndrome malformatifs » de l'Est et Centre de Génétique, Hôpital d'Enfants, FHU TRANSAD, CHU Dijon Bourgogne, Dijon, France; 3) Inserm UMR1231 GAD, F-21000, Dijon, France; 4) Division of Genetics and Metabolism, Phoenix Children's Hospital, Arizona, USA; 5) Département de Génétique, Hôpital Pitié-Salpêtrière 47-83 Boulevard de l'Hôpital 75013 Paris, France; 6) Department of Pediatrics/Division of Medical Genetics, Duke University Medical Center, North Carolina, USA; 7) Department of Genetics, University Medical Center Utrecht, The Netherlands; 8) Institute of Genomic Medicine, Columbia University, New York, N.Y.; 9) Department of Child Neurology, Brain Center Rudolf Magnus, University Medical Center, Utrecht, The Netherlands; 10) Department of Neurosciences and Pediatrics UCSD/Rady Children's Hospital San Diego, Rady Children's Institute for Genomic Medicine, California, USA.

Thanks to whole exome sequencing and international datasharing, we report six individuals with *de novo* heterozygous frameshift or nonsense variants and one additional patient with a *de novo* heterozygous missense variant in the *IRF2BPL* (Interferon Regulatory Factor 2 Binding Protein-Like) intronless gene, encoding a zinc finger/RING finger transcriptional modulator with a predicted ubiquitin ligase activity. The majority of these variants are expected to result in a truncated protein missing the C-terminal RING finger domain. The cases with *IRF2BPL* truncating variants exhibit a progressive neurodegenerative disorder with infantile onset, associated with severe intellectual disability and epilepsy in more than half individuals. Five of seven cases have abnormalities on EEG irrespective of clinical seizures. The function of the *IRF2BPL* gene product is currently unknown, but the gene appears to be highly intolerant to loss of function variants (pLI=0.97), with no nonsense variant in gnomAD. Statistical calculation of the probability that five of the cases had mutations in *IRF2BPL* due to chance had  $p < 0.05$ . Neurodegenerative diseases (NDDs) are a heterogeneous group of progressive disorders characterized by dysfunction and loss of defined neuronal populations, usually associated with additional neurological features, such as seizures, ataxia and microcephaly. NDDs are triggered by abnormal or misfolded proteins that alter the physiological function of neuronal and/or glial populations. Aberrant ubiquitination or degradation of ubiquitinated proteins through the proteasome, as well as epigenetic control of gene expression through transcription factors recruitment, seem to play a relevant role in the molecular pathways leading to NDDs. Functional studies of *IRF2BPL* are ongoing to better characterize the involvement of *IRF2BPL* into neurodevelopment. This clinical cohort of individuals has a number of overlapping symptoms, the majority with *IRF2BPL* truncating mutations. We propose a role for this protein in a new neurodevelopmental disorder.

**1756W**

**DDX3X: Robust phenotype-genotype correlations from recurrent de novo mutations in DDX3X in patients with global developmental delay and intellectual disability.** R. Jiang<sup>1</sup>, L. Suit<sup>1</sup>, S. Floor<sup>2</sup>, B. Fregeau<sup>1</sup>, A.J. Barkovich<sup>3</sup>, E.H. Sherr<sup>1</sup>. 1) Department of Neurology, University of California San Francisco, San Francisco, CA; 2) Department of Cell and Tissue Biology, Helen Diller Family Comprehensive Cancer Center, UCSF, San Francisco, CA; 3) Department of Radiology, University of California, San Francisco, San Francisco, CA.

DEAD-box helicase 3 X-linked (DDX3X), is an RNA helicase that regulates translation and other aspects of RNA biology. Mutations in DDX3X have been reported in 1-3% of intellectual disability cases in females, yet critical unanswered questions about the relationship between these mutations and disease pathogenesis remain. Here we demonstrate that there are many recurrent de novo mutations in DDX3X, using the largest cohort of DDX3X patients assembled to date (n=55). These mutations correspond to consistent clinical and imaging phenotypes that are linked to distinctive biochemical abnormalities. Of the 55 patients, 53 are female (1-22 years old) and 2 male. Of the 51 distinct mutations in DDX3X this cohort, 7 are recurrent and 5 are distinctive mutations but occur at the same amino acid. Clinically, this cohort of 55 patients shows consistent and significant findings including mild (32/50, 64%) to severe (18/50, 36%) global developmental delay, and neurological abnormalities such as microcephaly (17/45, 38%), epilepsy (12/45, 27%), and hypotonia (41/45, 91%). Brain MRI findings were notable for a thin corpus callosum (55%) and enlarged ventricles (79%). A smaller but significant subset, 15%, have polymicrogyria (PMG). The high preponderance of recurrent mutations led us to ask whether these mutations have consistent clinical and imaging characteristics. We found that two recurrent de novo mutations, R326H and T532M, are consistently associated with a more severe clinical phenotype and with PMG as seen by MRI. Whereas, the mutation R376C is found recurrently in 4 mildly affected patients with less impaired MRI scans. We asked whether this range of clinical & imaging severity correlated with the biochemical activity of DDX3X *in vitro*. We employed two widely used assays, one that quantifies the rate of unwinding of dsRNA and one that measures ATP hydrolysis as a function of RNA concentration. We found that for reference alleles, full unwinding occurred by 1-2 min with a  $V_{max}$  0.27  $\mu$ M $\pm$ .076  $\mu$ M ATP/min; mutations that were associated with a milder phenotype (e.g. R376C) had an intermediate helicase unwinding (40 min) and  $V_{max}$  (0.06 $\pm$ .0045  $\mu$ M ATP/min); mutations that resulted in PMG and agenesis of the corpus callosum had no activity in both assays. These findings demonstrate that functional DDX3X is essential for normal brain development, that there are many recurrent mutation hotspots, and that the site of the mutation has a clear impact on degree of pathogenesis.

**Regulating transcriptional activity by phosphorylation of the intellectual disability and seizure associated ARX homeodomain transcription factor.** C. Shoubridge<sup>1,2</sup>, M.H. Tan<sup>1</sup>, O. Dearsley<sup>1</sup>, C.S. Hii<sup>3</sup>, J. Gecz<sup>1,2</sup>, T. Mattiske<sup>1,2</sup>. 1) Intellectual Disability Research, Adelaide School of Medicine, University of Adelaide, Adelaide, Australia; 2) Robinson Research Institute, University of Adelaide, Adelaide, Australia; 3) Department of Immunopathology, SA Pathology, South Australia, Australia.

*Aristaless*-related homeobox (*ARX*) gene encodes a paired-type homeodomain transcription factor with critical roles in forebrain, pancreas and testes development. Mutations in *ARX* give rise to intellectual disability, epilepsy and brain malformations. Here we have identified that *ARX* protein is phosphorylated and using mass spectrometry and *in vitro* kinase assays we identify serine at position 37, 67 and 174 as sites of post-translational modification. We demonstrate that phosphorylation is required for correct transcriptional activity of the *ARX* protein. We chose a transcriptome wide approach to analyse gene expression using phosphoablative mutants (alanines replacing serines) compared to *ARX* wild-type (*ARX*-WT) overexpressed in pancreatic alpha TC cells. When *ARX*-WT was overexpressed compared to non-transfected cells, 70 genes had significantly altered expression (Log2FC >+/-1.0, P-value <0.05). There was a loss of significantly regulated gene expression compared to non-transfected cells with overexpression of the double phosphoablative mutant Ser37Ala+Ser67Ala (26%) and Ser174Ala (39%), respectively. The Ser174Ala mutant significantly altered expression of an additional 45 genes (82% with reduced expression) that were not impacted by *ARX*-WT overexpression, including growth factors (*Hdgfrp3* and *Igf2*), transporters (*Slc2a4*), kinases and signalling molecules as well as cell proliferation and cytoskeletal reorganisation (*Abi3*, *Ablim2*). Using yeast-2-hybrid (confirmed by CoIP) we identified a novel *ARX*-interacting protein, PICK1 (Protein interacting with C kinase 1) binding with the C-terminal region of *ARX*. PICK1 is a scaffold protein known to facilitate phosphorylation of protein partners by protein kinase C alpha (PKC-alpha). We confirm that *ARX* is phosphorylated by PKC-alpha (*in vitro* kinase assays and specific kinase inhibitor) and in particular, demonstrate this kinase is responsible for phosphorylation at serine 174. In conclusion, we show that *ARX* is phosphorylated at several sites and that this modification is important for aspects of transcriptional activity. Phosphorylation at serine 174 occurs via PKC-alpha suggesting the binding of the specific protein partner PICK1 with the C-terminal region of *ARX* is required. We contend that missense mutations in the C-terminal region of *ARX* that cause severe early onset seizure phenotypes in affected children may be due to deficient phosphorylation and subsequent alterations in transcriptional capacity.

**1758F**

**Molecular and biochemical analyses to understand the genotype-phenotype correlation in patients with the maternally inherited MELAS disorder.** A. Gropman<sup>1</sup>, M. Uittenbogaard<sup>2</sup>, C.A. Brantner<sup>3</sup>, A. Chiaramello<sup>2</sup>. 1) Department of Neurology, Children's National Med Center, Washington, DC; 2) Department of Anatomy and Regenerative Medicine, George Washington University School of Medicine and Health Sciences, Washington, DC; 3) George Washington University, Nanofabrication and Imaging Center, Washington, DC.

Mitochondrial respiratory disorders are characterized by a chronic energy deficit due to mutations in the nuclear or mitochondrial genome affecting the oxidative phosphorylation (OXPHOS) system responsible for ATP synthesis. The most common mitochondrial respiratory disorder is MELAS (Mitochondrial Encephalopathy Lactic Acidosis with Stroke-like episodes). MELAS is an intractable childhood-onset progressive neurodegenerative disease that results in devastating multi-organ failure, strokes, and premature death. This orphan disease is mainly caused by a maternally inherited mutation (A3243G) in the mitochondrial-encoded tRNA<sup>Leu(UUR)</sup> gene, which only affects a subset of the multi-copy mitochondrial genome. Thus, MELAS cells harbor a mixed population of functional (healthy) and dysfunctional (diseased) mitochondria, a state known as heteroplasmy. Patients harboring the MELAS mutation become symptomatic only when the mutant load of diseased mitochondria exceeds a certain threshold. However, the heteroplasmic load is not the sole determinant of the phenotypic variability among MELAS patients, as the nuclear background influences clinical manifestations, pathogenesis, and severity of the MELAS disorder. As a first step toward understanding the genotype-phenotype correlation, we recruited a cohort of eight MELAS patients that were genetically diagnosed with the A3243G MELAS mutation and underwent a skin biopsy from which we derived dermal fibroblasts. We performed an in-depth mitochondrial morphometric analysis by transmission electron microscopy combined with functional mitochondrial bioenergetics studies. Although the patients harbor the same MELAS mutation, they exhibited a heterogeneous mixture of abnormal mitochondrial ultrastructural features in terms of shape, number of cristae, abnormal cristae junctions and altered mitochondrial dynamics. Furthermore, the overall number of mitochondria varies among the MELAS patients. Finally, our mitochondrial bioenergetics studies revealed a heterogeneity in terms of their respiratory capacity, bioenergetics reserve and capacity to respond to stress. Our collective results demonstrate the functional impact of the nuclear background on the molecular pathogenesis of the MELAS disorder.

**1759W**

**A recessive variant in forkhead box domain of *FOXF2* is associated with profound hearing loss and inner ear anomaly.** G. Bademci<sup>1</sup>, O. Diaz Horta<sup>1</sup>, A. Incesulu<sup>2</sup>, F.B. Cengiz<sup>1</sup>, C. Abad<sup>1</sup>, C.J. Sineni<sup>3</sup>, J. Foster II<sup>4</sup>, D. Duman<sup>4</sup>, S. Fitoz<sup>5</sup>, S.H. Blanton<sup>1,6,7</sup>, Z. Lu<sup>3</sup>, K. Walz<sup>1</sup>, M. Tekin<sup>1,6,7</sup>. 1) John P. Hussman Institute for Human Genomics, University of Miami, Miller School of Medicine, Miami, FL; 2) Department of Otolaryngology, Head and Neck Surgery, Eskisehir Osmangazi University, Eskisehir, Turkey; 3) Department of Biology, University of Miami, Miami, FL; 4) Division of Pediatric Genetics, Ankara University School of Medicine, Ankara, Turkey; 5) Department of Radiology, Ankara University School of Medicine, Ankara, Turkey; 6) Department of Otolaryngology, Miller School of Medicine, University of Miami, Miami, FL; 7) Dr. John T. Macdonald Foundation Department of Human Genetics, University of Miami, Miller School of Medicine, Miami, FL.

While astonishing progress has been made in identifying causative genes for hereditary hearing loss (HL), molecular mechanisms leading to inner ear anomalies in humans remain largely unknown. As part of our ongoing study of hearing loss associated with inner ear anomalies, we ascertained a Turkish child with consanguineous parents who was born with profound sensorineural HL and a cochlear anomaly (incomplete partition type I). Using whole exome sequencing, we identified a homozygous *FOXF2* c.325A>T (p.Ile109Phe) variant. This variant is not present in public databases or in over 1,000 Turkish controls. *FOXF2* is a member of the FOX protein family of transcription factors that contain a conserved forkhead box sequence of ~100 amino acids. The FOX domain forms a motif that binds to DNA to regulate the expression of genes mainly involved in embryogenesis. p.Ile109 is a highly-conserved residue of the FOX domain of *FOXF2*. By comparing the quantitative expression of wild type and mutant proteins in a mammalian cell line, we show that the abundance of variant *FOXF2* is reduced, which suggests that the variant decreases the stability of the protein. Pathway analysis in RNA-Seq data from the HEK293 cell line shows that knocking down *FOXF2* leads to differential expression of genes involved in DNA methylation, histone deacetylation, and RNA Polymerase I Promoter Opening, which supports its role in embryonic gene regulation. *Foxf2* is expressed in the cochlea of developing and adult mice and is localized to the nucleus of hair cells as well as Reissner's membrane cells, suggesting a role in hearing. We conclude that *FOXF2* plays a major role in the developing cochlea, and its dysfunction leads to an isolated inner ear anomaly and deafness.

## 1760T

**Custom capture high-throughput sequencing for mutation detection: Results from 217 coloboma subjects across 196 genes identifies novel mutations in genes associated with ocular coloboma.** V.K. Kalaskar, R.P. Alur, L.A. Li, R.B. Hufnagel, T. Cogliati, B.P. Brooks. 1) National Eye Institute, NIH, Bethesda, MD; 2) David Geffen School of Medicine at UCLA, Los Angeles, CA.

**Statement of Purpose:** Uveal coloboma is a potentially blinding congenital ocular malformation, accounting for up to 10% of childhood blindness and caused by failure of the optic fissure to close during the fifth week of human gestation. Mutations in several genes have been reported, however, the total yield of mutation detection across known coloboma-associated genes has not been well-established. In this study, we report on novel mutations in known coloboma-associated genes in a large cohort of patients with uveal coloboma and on zebrafish and cell culture studies on a novel mutation in *RARB* gene. **Methods Used:** Custom capture sequencing of 196 genes from 217 study subjects from 66 families was performed on Illumina HiSeq2000 platform. Data were analyzed and variants filtered using Varsifter and confirmed by Sanger sequencing. Mutagenesis and Western blotting were employed to study the effect of mutation on RARB protein formation in cell culture. Zebrafish morpholino studies were performed on *rarga* gene, which is the nearest homologue for human *RARB*. For rescue experiments, wild type and mutant human *RARB* mRNA were used. **Summary of Results:** Custom capture sequencing identified potential variants in *BMP7* and *RARB* (missense), *TFAP2A* (frameshift) and *CHD7* (nonsense) in 4 unrelated families. These variants were predicted deleterious and not reported in HGMD, ClinVar and in population databases such as 1000 genomes, EVS and ExAC. Sanger sequencing segregated these mutations in the affected individuals. The *RARB* mutation was located in the conserved DNA binding domain and predicted to result in p.Arg114Gln substitution. Preliminary studies revealed higher protein levels in cells transfected with *RARB*-mutant compared to *RARB* expression constructs as detected by Western blotting with DYK-Flag and *RARB* antibodies. Moreover, morpholino knockdown of *rarga* gene resulted in a coloboma phenotype in zebrafish embryos and rescue experiments suggests that *RARB*-mutant mRNA may rescue the phenotype better compared to *RARB* mRNA. While further experiments are needed, our study suggests that *RARB* mutation resulted in altered protein levels causing ocular coloboma consistent with previous findings. We conclude that custom capture high-throughput sequencing can identify novel mutations in known genes, however, extensive methods such as whole exome or genome sequencing can better contribute to the identification of novel genes with mutations in individuals with coloboma.

## 1761F

**Characterizations of *NMNAT1* mutants and mouse model of *NMNAT1*-LCA.** X. Feng<sup>1</sup>, S.Y. Ji<sup>2</sup>, C. Weng<sup>3</sup>, J.H. Sun<sup>1</sup>, X.W. Cao<sup>4</sup>, J. Lin<sup>1</sup>, S. Han<sup>1</sup>, Z.J. Xia<sup>1</sup>, H.Y. Fan<sup>2</sup>, M. Qi<sup>1</sup>. 1) Department of Cell Biology and Medical Genetics, Zhejiang university, Zhe Jiang, China; 2) Life Sciences Institute and Innovation Center for Cell Signaling Network, Zhe Jiang university, Zhe Jiang, China; 3) Department of Genetics and Genomics, Case Western Reserve University, Cleveland, USA; 4) School of Optometry and Ophthalmology and Eye Hospital, Wenzhou Medical College, Zhe Jiang, China.

**Background:** The nuclear nicotinamide mononucleotide adenylyltransferase *NMNAT1* catalyzes the formation of NAD<sup>+</sup> from nicotinamide mononucleotide (NMN) and ATP, and acts as a chaperone that protects against neuronal degeneration. We previously reported *NMNAT1* mutations cause a severe dystrophy of the retina-Leber congenital amaurosis 9 (LCA9) because of its central role in metabolism. **Methods:** In this study, LCA-associated *NMNAT1* mutants were tagged with GFP on N-terminus. HELA cells were transfected with recombinant plasmids, and used to confirmed cell localizations of wildtype and mutant *NMNAT1*. Enzymatic activities of wildtype and mutant *NMNAT1* were tested *in vivo* and *in vitro* experiments. Circular dichroism (CD) was used to monitor the secondary structure and stability of wildtype and mutant *NMNAT1*. In addition, CRISPR/Cas9 was used to construct the *NMNAT1*<sup>E257K</sup>-LCA9 mouse model. Electroretinogram (ERG), fundus examination and optical coherence tomography (OCT) were used to analyze its phenotype. **Results:** Two nonsense mutations alter the nuclear localization but no missense mutants disrupt the normal nuclear localization of the protein. Glu257Lys and Asn273Asp mutants have relatively normal enzymatic. Met35Thr, Val98Gly, Val151Phe and Leu153Val reduce the catalytic activity of *NMNAT1*, but only Val98Gly reduce the production of NAD<sup>+</sup> significantly. In contrast, the secondary structure of *NMNAT1* mutants was relatively less stable. Moreover, E257K/E257K mouse appear pigmentary retinopathy around 2 months, and retinal function deteriorates with increasing age. **Conclusion:** These results suggest that prolonged insufficient volume of NAD<sup>+</sup> can result in LCA9 but cannot account for all the pathogenesis, and the pathogenesis of most common mutation Glu257Lys needs further research.

**Purpose** Optic nerve hypoplasia (ONH) is a rare blinding malformation, ONH is often syndromic with MRI pituitary anomalies. We explore genetic causes of isolated ONH **Material and Methods:** Probands (2F/4M) 0.5-6 yrs with normal pituitary MRI were enrolled after consent with Pediatric, dysmorphic and ophthalmologic endocrine examinations SNP aCGH, WES and Sanger validation sequencing. Opth. exam: VEP, ERG, funduscopy, color & acuity testing. Male patients tested for HESX. DNA extracted from lymphoblastoid lines or blood. DNA sequenced 30X in > 92% on Illumina platform; QC used Sam, Picard, Bed tools, variant call GATK, annotation snpEff/snpSift; filter using Autosomal Dominant hypothesis, absence in 1k, 65k 19 genomes, Exac databases. Variants present in subjects but not parents were selected and tested using polyphen2, Sift and mutation taster. 2nd approach for variant filtering using ANOVAR yielded 197 variants with strong deleterious effect; variants present in at least 2 pedigrees were then prioritized **Results:** Patients followed 2-15 yrs had normal intelligence, eye examination showed normal ERG with abnormal VEP, dyschromatopsia VA approx. 20/200. Three subjects had learning difficulties, One female severe dyspraxia, and one male Growth Hormone, Cortisol and testosterone deficit and micropenis. Three subjects had sleeping disorders treated with melatonin. No HESX mutations were identified. All parents were healthy but 3 fathers were unavailable for blood sampling. SNP array CGH revealed a paternally inherited a single 410,4 kb deletion of the 2p26.1 including the *VRK2* gene described in complex intellectual disability. Five genes showed deleterious missense mutations identified and being confirmed by Sanger sequencing **Conclusion:** A 2p16.1 inherited deletion variant of unknown significance was identified on array CGH. WES analysis identified 4 candidate genes confirmed by Sanger sequencing which will need confirmation in a different dataset.

**1763T**

**Integration of whole exome sequencing, expression profiling, and pathway analysis for the identification of novel genes in familial exudative vitreoretinopathy.** M.-Y. Chung<sup>1,2</sup>, J.-H. Wu<sup>3</sup>, S.-J. Chen<sup>4</sup>. 1) Inst Genome Sci, Natl Yang-Ming Univ, Taipei, Taiwan, Taiwan; 2) Medical Research, Taipei Veterans General Hospital; 3) Pediatrics, Taipei Veterans General Hospital; 4) Ophthalmology, Taipei Veterans General Hospital.

Familial exudative vitreoretinopathy (FEVR) is a group of retinal diseases characterized primarily by incomplete development of blood vessels in the retina. Clinical manifestations of FEVR are highly variable with inter- as well as intra- familial variability, ranging from little or mild visual loss to blindness in early childhood, and overlap with other similar retinal vascular diseases, e.g. Coats disease, persistent hyperplastic primary vitreous, and Norrie disease. Currently six FEVR genes have been identified and four of them have been confirmed to be involved in the *wnt* signaling pathway, accounting for mutations in about 50% of the affected individuals. While using whole exome sequencing (WES) to identify genes with disease causing mutations, locus heterogeneity has become a major obstacle to find mutations in the same gene in at least two affected individuals from different families. We sought to prioritize the WES variants with expression profiles. Unique variants were identified in three genes with high priority. They were further analyzed by quantitative PCR and tube formation assay to validate the involvement in *wnt* signaling pathway as well as whether the gene might play a role in angiogenesis. Through this strategy, private mutations may be identified in FEVR and may apply to rare diseases with high locus heterogeneity.

**1764F**

**Evaluation and treatment of nystagmus in a Brazilian boy with septo-optic dysplasia.** L. Gabriel<sup>1</sup>, D. Giroto<sup>1</sup>, P. Maya<sup>2</sup>, M. Avila<sup>1</sup>. 1) Ophthalmology, Federal University of Goias, Goiania, Goiania, Brazil; 2) Neurosurgery, Santa Monica Hospital, Goiania, Brazil.

Herein we present a case of a 7-year old Brazilian boy with a clinical diagnosis of septo-optic dysplasia. He was born with severe hypoglycemia, and with 8 months of age, low levels of cortisol, thyroid-stimulating hormone, thyroxine, growth hormone, and testosterone were identified, characterizing congenital panhypopituitarism. Due to these hormonal imbalances he also had lower height and inguinal testicles. Additionally he presented with low visual acuity and nystagmus which led to an ophthalmology investigation revealing bilateral optic disc hypoplasia on the funduscopy and optic nerve hypoplasia, reduction of the sella turcica, and pituitary parenchyma thinning on the magnetic resonance imaging. Visual evoked potentials were decreased. In order to ameliorate his vision the nystagmus was measured by videonystagmography and treated with gabapentin showing a visual acuity improvement.

**1765W**

**LCA9-associated NMNAT1 mutant protein study in Drosophila.** J. Sun<sup>1</sup>, C. Weng<sup>2</sup>, X. Feng<sup>1</sup>, J. Lin<sup>1</sup>, C. Tong<sup>2</sup>, M. Qi<sup>1</sup>. 1) Department of Genetics and Genomics, School of Medicine Zhejiang University, Hangzhou, China, Zhejiang, China; 2) Department of Genetics and Genomics, Case Western Reserve University, Cleveland, USA; 3) Life Sciences Institute and Innovation Center for Cell Signaling Network, Zhejiang University, Hangzhou, China.

Leber congenital amaurosis (LCA) is an autosomal recessive retinal dystrophy that manifest with genetic heterogeneity. Previously, our team have identified 8 mutations in NMNAT1 could cause LCA9 in human. Study by Hoopfer ED shows that overexpression of Nmnat protein can protect axons from degeneration in drosophila. So we choose the fly as the animal model. As Homozygous Nmnat mutation in *Drosophila melanogaster* is lethal, we construct MARCM mutation system in drosophila eyes. To identify whether the mutant Nmnat1 protein can rescue the retina degeneration or not in drosophila eyes we have created transgenic drosophila by microinjecting the constructed plasmid. First, we cloned 3 homo-nmnat1 mutants and wildtype Nmnat genes into pUASTattB-HA plasmid. These mutants are C.817A>G; C.457C>G; C.507G>A, respectively. Second, these plasmids have been injected into the embryo of flies to express the mutant nmnat1 protein. Use eyFLP system allows us to construct the conditional lethal mutation of Nmnat in drosophila visual system for the study of eye structural integrity. Genotype-phenotype study has been conducted by viewing the integrate rhabdom architecture of ommatidium. The intact rhabdom number in one ommatidium in drosophila eyes for wildtype overexpression of Nmnat, Nmnat knockout, C.817A>G mutation, C.457C>G mutation and C.507G>A mutation are 7, 7, 0.8, 3.4, 3.8 and 2, respectively. Neither point mutations (C.817A>G; C.457C>G) of nmnat1 could rescue the phenotype caused by defected nmnat. Prematured stop codon C.507G>A mutation generates the truncated nmnat1 protein and leads more severe eye cell degeneration than the others. These results are consistent with the LCA9 disease phenotypes in human. This drosophila will provide valuable animal models for further study the molecular mechanism of LCA9.

**1766T**

**Bardet-Biedl syndrome, postaxial polydactyly, Shh signalling pathway and a founder effect in a Libyan extended consanguineous family from Tarhunah Berber tribe.** N.Bouayed, Abdelmoula, S. Aloulou, W. Ben Romdhane, R. Louati, W. Smaoui, F. Abid, N. Abdellaoui, O. Bedoui, H. Fourati, K. Chaker, Kh. Trigui, J. Dammak, Y. Kaabi, A. Kaabi, S. Kammoun, H. Denguir, S. M'rabet, H. Ben Ameer, M. Ben Aziza, W. Ltaif, S. Kammoun, J. Jaber, M.N. Mhiri, N. Moalla. UR17ES36, Medical University of Sfax, Sfax, Tunisia.

BBS is relatively frequent in some isolated populations or areas like the negev bedouins in Israel with confirmed mutations in different BBS genes. Here, we report a Libyan tribe from Tarhunah in which several individuals were diagnosed with BBS. Tarhunah is a Libyan town in which the population generally belongs to a Berber tribe. The extended consanguineous family reported here, is named Bousitta tribe because of the syndromic recurrence of polydactyly ("six" fingers = "6: Sitta" fingers in Arabic) for more than four generations. The primary case who attended our genetic counseling at 2012 was a 34 years old infertile male with cryptozoospermia and failure of ICSI attempts using intra-testicular spermatozoa (implantation failure). Physical examination revealed cardinal features of BBS with middle cognitive impairment, obesity, visual disorders (strabismus and nystagmus) and retinal dystrophy, tetramelic postaxial polydactyly and hyperlipidemia. Craniofacial dysmorphism, convulsive crisis and psychiatric problems were also noted. Genital exploration revealed unilateral right cryptorchidism and normal penis with normal hair distribution, normal level of FSH and spermatozoa in testicular biopsy. Cytogenetic evaluation revealed a normal male 46,XY karyotype. There was a family history of polydactyly with and/or without cardinal signs of BBS, mainly retinal dystrophy, obesity and learning difficulties. The study of BBS illustrates the value of using isolated inbred populations for the study of human genetic diseases and suggests strategies for facilitating the study of complex diseases and traits.

**1767F**

**Acquired ventriculomegaly in a case with SOX 9 mutation.** A. Matsumoto<sup>1</sup>, E. Imagawa<sup>2</sup>, N. Miyake<sup>2</sup>, N. Ikeda<sup>1</sup>, M. Kobashi<sup>1</sup>, M. Goto<sup>1</sup>, T. Yamagata<sup>1</sup>, N. Matsumoto<sup>2</sup>, H. Osaka<sup>1</sup>. 1) Pediatrics, Jichi Medical University, Shimotsukeshi, Tochigi, Japan; 2) Department of human genetics, Yokohama City University graduated school of medicine.

SOX 9 is responsible for campomelic dysplasia (CMD). Symptoms of CMD include recurrent apnea, facial features, and shortening of the lower extremities. Acampomelic CMD (ACMD), a variant, lacks long bone curvature. In mice, Sox 9 is associated with differentiation to oligodendrocytes and astrocytes, but its contributions to neuronal differentiation are unclear in humans. We encountered a two-year-old boy with ACMD presenting with tracheal malacia and macrocephaly. He also had acquired ventriculomegaly, hydrocephalus, and hypoplasia of the corpus callosum, indicating the failure of white matter growth after birth. **Case report** The patient was the second child born to nonconsanguineous parents. His growth parameters were normal, but his occipito-frontal circumference (OFC) was 2.8 standard deviations (SD) at birth and 3.9 SD at 18 months of age. He showed macrocephaly and minor anomalies such as hypertelorism, palpebronasal fold, small mandible, high-arched palate, a cleft soft palate, and micropenis without long bone curvature. His developmental milestones were delayed, as he could not control his head and could not comprehend simple words. His neurological evaluation revealed hypotonia and normal deep tendon reflex. He showed severe hearing loss (100 dB). Cranial magnetic resonance imaging findings were normal at one month of age but showed ventriculomegaly, hydrocephaly, and hypoplasia of the corpus callosum at two years of age. G-banding was 46, XY. Array CGH showed no abnormalities. Exome sequencing revealed a *de novo* novel mutation of c. 236A>C, p (Q79P) in SOX9. **Discussion** Sox 9 is thought to be crucial in neural stem cell development in the central and peripheral nervous system along with Sox 8 and Sox10 in mice. Mice with Sox 9 ablation have defects in specification and a decreased number of oligodendrocytes and astrocytes in the spinal cord in early development. Oligodendrocyte progenitor cells from later stages of development were shown to be compensated by Sox 8 and Sox 10, but astrocytes were not, instead showing a reduced number. In humans, neuronal abnormalities in CMD and ACMD include relative macrocephaly in 11 of 22 and mild lateral ventriculomegaly in 2 of 22. We described for the first time an ACMD patient showing acquired macrocephaly with ventriculomegaly, indicating the failure of oligodendrocyte/astrocyte development postnatally. This phenotype suggests that SOX 9 plays a crucial role in human central nervous system development.

**1768W****The role of WNT regulatory variants in nonsyndromic cleft lip and palate.**

L. Mailli<sup>1,2</sup>, K. Westerman<sup>3</sup>, Q. Yuan<sup>1</sup>, B.T. Chiquet<sup>1,3</sup>, A. Letra<sup>3</sup>, G.T. Eisenhoffer<sup>4</sup>, J.T. Hecht<sup>1,3</sup>. 1) Pediatrics, McGovern Medical School, University of Texas Health Science Center, Houston, TX; 2) Graduate School of Biomedical Sciences, University of Texas Health Science Center, Houston, TX; 3) School of Dentistry, University of Texas Health, Houston, TX; 4) University of Texas MD Anderson Cancer Center, Houston, TX.

Nonsyndromic cleft lip with or without cleft palate (NSCLP) is a common birth defect with a prevalence of 1 in 700 that affects approximately 4000 newborns in the United States annually. Despite improvement in treatments, NSCLP continues to pose major medical, psychosocial, and financial burdens. We and others have shown that perturbation of genes at the receptor level of the WNT pathway causes severe craniofacial anomalies. For example, 1) knockdown or overexpression of *fzd6* causes craniofacial abnormalities in zebrafish, 2) loss of *Irp6* significantly reduces Wnt signaling in mutant mouse embryos resulting in orofacial clefts, 3) knockdown or mutant forms of *Irp5* cause abnormal craniofacial cartilage phenotypes and cleft palate in zebrafish, and 4) the facial region completely fails to form in mice deficient for *dkk1*. The goal of this study was to determine whether variation in regulatory variants upstream of *FZD6*, *LRP5*, *LRP6* and *DKK1* contribute to NSCLP. Prioritization of potential regulatory variants in the upstream noncoding region of each gene was based on bioinformatic analysis using species conservation, epigenetic signatures, and functionality algorithms. Next, three different *in silico* transcription factor binding programs were used to filter variants that had a unique protein binding signature for each allele. Twenty-one variants, 6 in *FZD6*, 5 in *LRP5*, 5 in *LRP6* and 5 in *DKK1* were prioritized using these criteria. These variants were further assessed regarding differential allele-specific protein binding patterns using electrophoretic mobility shift assays (EMSAs). Nine variants resulted in differential protein binding patterns: 1 in *FZD6*, 3 in *LRP5*, 3 in *LRP6* and 2 in *DKK1*. These variants were cloned upstream of luciferase promoter constructs to assess their effect on gene expression. The variant in *FZD6* did not alter luciferase activity in 293T cells and is being evaluated in other embryonic cell lines. Luciferase reporter results for the other variants are pending. Further, variants that have an effect on luciferase expression will be assessed using a dual reporter approach in zebrafish to show the effect of each variant allele on expression *in vivo*. The results of this study will provide important information about the effects of noncoding variants on WNT gene expression during development.

**A dog model of non-syndromic cleft palate.** B. Schutte<sup>1,2</sup>, J. Plassais<sup>3</sup>, B. Stanley<sup>4</sup>, B. Davis<sup>3</sup>, E. Ostrander<sup>3</sup>, J. Fyfe<sup>4</sup>. 1) Microbiol and Molec Gen, Michigan State Univ, East Lansing, MI; 2) Pediatrics and Human Development, Michigan State University, East Lansing, MI; 3) Cancer Genetics and Comparative Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 4) Small Animal Clinical Sciences, College of Veterinary Medicine, Michigan State University, East Lansing, MI.

Cleft palate is a common human birth defect, affecting ~1/1500 live births. The standard of care is surgical repair, which provides satisfactory resolution of facial disfigurement and feeding problems. However, post-operative complications are common, and the long-term outcomes of various surgical approaches are unknown until craniofacial growth is complete when the patient is at least 18 years old. The goal of this work is to generate a clinically-relevant dog model of cleft palate to compare surgical outcomes in 18 months, not 18 years. Toward this goal, we developed an IACUC approved (AUF 11/14-207-00) breeding colony segregating cleft palate at MSU. In a single sibship of mixed genetic background 17% of pups (11 of 63) were born with a uniform cleft of the hard and soft palate. Morphological analysis and CT scans failed to detect any other obvious abnormality of the face. In addition, the cleft of four pups, 1 male and 3 females, was repaired and all are thriving, consistent with a cleft palate that is non-syndromic. To assess the genetic etiology of the cleft, we performed whole genome sequencing in five affected individuals. We identified a single variant at the *PITX2* promoter that was homozygous in all five affected individuals sequenced and found in only 1 of 121 control dog breeds. To test for association, we genotyped 10 affected and 15 unaffected offspring of the sibship. The observed genotypes were not statistically different from Mendelian ratios ( $p = 0.7$ ), suggesting that the variant near *PITX2* is not associated with cleft palate in this sibship. In addition, we performed genome wide linkage analysis on 8 affected and 35 unaffected dogs and identified three large regions (CFA 10, 20 and 32) with suggestive linkage (LOD scores >2.4). To reduce the genetic complexity of this phenotype, we mated the repaired affected male to his dam, and 2 of 8 pups were affected. We also mated the affected male with a repaired affected female, and 6 of 6 pups had cleft palate. In conclusion, we have a breeding colony of dogs with high incidence of non-syndromic cleft palate. We are using this model to better understand the complex genetics of cleft palate, to evaluate long-term outcomes of surgical repair and to develop new therapies. This work supported in part by the College of Veterinary Medicine, Michigan State University.

**Syndromic and nonsyndromic congenitally missing teeth: Prevalence, clinical manifestations and patterns.** E. Severin<sup>1</sup>, R. Baltag<sup>2</sup>. 1) Dept Human Genetics, Carol Davila Univ Med Pharm, Bucharest, Romania; 2) Department of Orthodontics and Dentofacial Orthopedics, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

**Background:** Tooth agenesis is the most common developmental anomaly in humans. The reported prevalence of permanent dentition tooth agenesis excluding the third molars was 15.7% for European population. Syndrome and isolated forms of tooth agenesis have been described and can occur sporadically or in families showing etiologic heterogeneity. Dental agenesis does not only represent an individual clinical problem but also a public health problem.

**Objectives:** Study aims were to describe the variability of clinical phenotypes, to observe similarities/differences of familial tooth agenesis forms among affected relatives, to characterize the mode of inheritance and to identify distinct groups of patients for further molecular investigations. **Patients and Methods:** A total of 2305 subjects were included in the study. Clinical and radiographical assessments were performed, followed by detailed investigation into the personal and family medical history of the patients with tooth agenesis. If necessary chromosome or molecular tests were performed. **Results:** Tooth agenesis was observed in following two forms, hypodontia and oligodontia. More severe expression of both syndromic hypodontia and oligodontia were noticed comparing with non-syndromic tooth agenesis. All teeth were affected but not equally. Tooth agenesis was found in conjunction with other dental anomalies. In many genetic syndromes there is a typical pattern of dental agenesis but comparative analysis of patterns of dental agenesis revealed common, rare and individual dental findings. **Conclusions:** Predictive genetic testing has potential for accurate risk assessment in families with a history of tooth agenesis that may be inherited. Using the results of these tests, the dentist will be able to develop a targeted prevention plan to minimize the functional complications and esthetic and psychological stress.

**A PITX1 variant in a large pedigree with dominant lower extremity anomalies.** Y. Guo<sup>1</sup>, W. Sankar<sup>2</sup>, M. Deardorff<sup>3,4</sup>, H. Hakonarson<sup>1,2</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA19104, USA; 2) Department of Surgery, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA; 3) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA 19104, USA; 4) Division of Human Genetics and Molecular Biology, The Children's Hospital of Philadelphia, Philadelphia, PA 19104, USA.

Here we present a large autosomal dominant pedigree with variably penetrant lower extremity anomalies. The severe end of the clinical spectrum includes preaxial polydactyly. Intermediate phenotypes include metatarsus adductus and pes planus. The mild end of the spectrum comprises mild hip dysplasia, resulting in short femoral neck or trochanteric overgrowth, and shortened first toe. All individuals with hip abnormalities demonstrate abnormal toes, but not all individuals with toe findings have hip problems. This suggests that toe and hip findings share a dominant etiology with variable penetrance. No congenital clubfoot, upper limb or other skeletal abnormalities were noted. All individuals were cognitively normal with no other known organ system involvement. Based on a presumed autosomal dominant inheritance pattern, whole exome sequencing (WES) of two affected siblings and an unaffected child was performed. Through bioinformatics analysis and variant filtering steps, we identified a nonsense variant c.454C>T:p.Q152X in *PITX1* (paired like homeodomain 1) in both affected individuals but absent from the unaffected one. Subsequent Sanger sequencing results showed that the variant is seen in the affected father and all affected siblings in the immediate family, and is absent in unaffected family members. Additional analysis of the extended family is underway. Previously, a single large pedigree with variably penetrant preaxial foot polydactyly and clubfoot was reported with a *PITX1* missense mutation in the homeodomain that disrupted DNA binding (Gurnett, 2008). The *PITX1* nonsense variant in our family resides in the terminal exon, suggesting that it could escape nonsense-mediated decay to lead to a *PITX1* protein that is truncated after the homeodomain protein, which could act in a dominant negative manner, but perhaps less damaging than a homeodomain mutation. In contrast to Gurnett et al, 2008, we did not observe severe clubfoot in our family. We also did not note upper extremity involvement that has been reported in a family with a complex rearrangement of this region (OMIM 186550).

**Multidisciplinary assessment of 49, XXXYY, a rare X and Y chromosomal variation (XYV).** P. Lasutschinkow<sup>1</sup>, C. Cappello<sup>1</sup>, A. Gropman<sup>2,3</sup>, F. Mitchell<sup>1</sup>, G. Harmon<sup>1</sup>, A. Ganges<sup>1</sup>, M. McLeod<sup>1</sup>, C. Samango-Sprouse<sup>1,2,3,4</sup>. 1) The Focus Foundation, Davidsonville, MD; 2) Dept of Neurodevelopmental Disabilities and Neurogenetics, Children's National Medical Center, Washington, DC; 3) Dept of Pediatrics, George Washington University School of Medicine & Health Sciences, Washington, DC; 4) Dept of Human and Molecular Genetics, Florida International University, Miami, FL.

**Introduction:** We present the profile of a 9 year-old Italian Caucasian male with 49, XXXYY. To our knowledge, there have only been 7 reported cases of this XYV, including only one since 1995. **Statement of Purpose:** We present this boy's phenotypic profile and compare it to prior cases of 49, XXXYY. The neurodevelopmental profile for this disorder is expanded because this boy was evaluated from a multisystemic perspective. **Methods:** Neurodevelopmental testing included Receptive One Word Picture Vocabulary Test (ROWPVT-4) and Leiter International Performance Scale (LIPS-III). The Child Behavior Checklist (CBCL) was completed by the mother. The multidisciplinary care team that evaluated this patient included pediatric specialists in: neurodevelopment, neurogenetics, immunology, speech language pathology, and physical therapy. **Results:** He had increased height (76<sup>th</sup> percentile) and weight (93<sup>rd</sup> percentile). Neither parent's age was advanced. Ambulation occurred at 29 months and first words were spoken at 3 years of age. He scored below the first percentile on ROWPVT-4 (SS=57). Of the 3 subtests completed on LIPS-III, his scores ranged from slightly below average to severely delayed (SS=7, 5, 1). He was in the clinical range for 18 of 24 subscores on the CBCL, including Total, Externalizing, and Internalizing Problems (T-Scores=78, 79, 70 respectively). **Discussion:** Test scores on the ROWPVT-4 and LIPS-III support the presence of cognitive impairment. CBCL scores reflect his significant behavioral issues including low frustration tolerance, which has been reported in two other cases. His scores in Anxious/Depressed, Anxiety Problems, Attention Problems, and ADHD Problems (T-scores=70, 70, 79, 80 respectively) support anxiety disorder and ADHD. Salient features that he shares with past cases include: prognathism, prominent cheek bones, strabismus, cryptorchidism, radio-ulnar synostosis, clinodactyly, low set ears, hypotonia and epicanthal folds. Ambulation and speech were delayed, and pronounced dysfluency persists. Expressive speech problems have been reported in prior cases, and this boy likely has Childhood Apraxia of Speech (CAS). He also presents with pes planus, left torticollis, and a leg length discrepancy. His immunological profile is unremarkable besides a neonatal pneumonia. He has not had testosterone treatment, which could help manage his complex deficits to some degree.

We previously identified the genetic basis of a X-linked, infantile lethal Mendelian disorder, involving a p.S37P missense mutation in *NAA10*, encoding the catalytic subunit of NatA, involved in amino terminal-acetylation (NTA) of proteins. To date, there are >20 individuals with damaging mutations in *NAA10* or *NAA15*, with the latter gene encoding the dimeric binding partner for Naa10. Both *NAA10* and *NAA15* are relatively intolerant of variation. Phenotypic features of patients carrying disruptive variation in NatA include craniofacial anomalies, hypotonia, global developmental delays, cardiac arrhythmia, and/or cardiomyopathy. Functional analysis of the *NAA10* missense mutations has demonstrated impaired biochemical activity and/or a reduced capacity to form a stable NatA complex, although there is no proteome-wide decrease in NTA, thus implying tissue-specific and/or temporal substrate-specific effects. Attempts to knockdown or knockout *NAA10* in human cells results in cell death, making it difficult to assess proteome-wide NTA in human KO cells. Mice with decreased or absent *Naa10* survive throughout embryogenesis, but display a range of phenotypes that are variably expressive and include increased early neonatal lethality (likely related to congenital heart defects), supernumerary thoracic rib and vertebrae, piebaldism, and/or urogenital and renal abnormalities. Some of these phenotypes overlap with that seen with the missense mutation in humans, but survival of the knockout mice was unexpected, given the mutation intolerance of this gene in humans. Extensive proteomic analysis of mouse embryonic fibroblasts has not shown any proteome-wide decrease in NTA in the KO cells, with one possible explanation being our discovery of a previously unannotated *NAA10*-like gene in mice, which lacks a human ortholog, and which we refer to as *NAA12*. A rabbit polyclonal antibody raised with specificity to Naa12 shows expression of Naa12 in many mouse tissues. Given the potential redundancy in mice, fibroblasts from one affected human proband control were reprogrammed into induced pluripotent stem-cells and differentiated into cardiomyocytes (CMs). Electrophysiological experiments show rate-dependent prolongation of the effective refractory period in patient CMs, suggesting a cell-autonomous defect in the CMs. Overall, our data show that the process of NTA, carried out in part by the NatA complex, is important for normal development in mice and humans.

**Protective mechanisms in Cornelia de Lange patients with early truncating variants in *NIPBL* generate an N-terminal truncated protein that is able to mediate cohesin loading in the absence of *MAU2*.** I. Parenti<sup>1</sup>, J. Pozojevic<sup>1</sup>, S. Ruiz Gil<sup>1</sup>, B. Brouwer<sup>2</sup>, F. Diab<sup>3</sup>, V. Dupé<sup>3</sup>, E. Mulugeta<sup>2</sup>, W. van Ijcken<sup>2</sup>, E. Watrin<sup>3</sup>, K.S. Wendt<sup>3</sup>, F.J. Kaiser<sup>1</sup>. 1) Institute of Human Genetics, University of Lübeck, Lübeck, Germany; 2) Department of Cell Biology, Erasmus MC, Rotterdam, The Netherlands; 3) Faculté de Médecine, Institut de Génétique et Développement de Rennes, Rennes, France.

Cornelia de Lange syndrome (CdLS) is a rare developmental disorder. The majority of CdLS patients show mutations in *NIPBL*. The *NIPBL* protein interacts via its N-terminus with *MAU2* to generate a complex named kollerin, engaged in loading the cohesin complex onto DNA. In addition, *NIPBL* is known to mediate transcriptional regulation independently from its role in cohesin loading. By analyzing a very large cohort of CdLS patients with causative mutations in *NIPBL*, we noticed that some patients with early truncating variants presented with milder phenotypes and a lower frequency of severe limb reductions as compared to those with truncating variants affecting the more C-terminal part of the protein. To investigate this particular genotype/phenotype correlation, we performed CRISPR/Cas9 genome editing targeted to exon 2 of *NIPBL*; by this, we were able to isolate three independent viable clones carrying a homozygous out-of-frame insertion in *NIPBL*. Analyses of these cells on protein level revealed the presence of an N-terminal truncated *NIPBL*, translated from an aberrant but stable mRNA by use of an alternative ATG start codon. Interestingly, the truncated *NIPBL* is incapable to form heterodimers with *MAU2*. Quantitative RNA analyses showed an increase of *NIPBL* transcript and unchanged level of *MAU2*. However, the inability of the kollerin subunits to interact with each other leads to a decrease of *NIPBL* on protein level and to a total loss of *MAU2*. Next, we evaluated the ability of the N-terminally truncated *NIPBL* to mediate cohesin loading. Fractionation experiments revealed an equal amount of total chromatin-bound cohesin compared to wild type cells, indicating that the *NIPBL/MAU2* heterodimer is not essential for overall cohesin loading onto chromatin. Consistently, determination of cohesin binding sites by ChIP-sequencing showed slight changes in cohesin binding sites. Taken together, our data strongly indicate the existence of protective mechanisms preventing a total loss of *NIPBL* gene product by the use of alternative start codons in *NIPBL* transcripts with early truncating mutations to ensure the synthesis of the essential C-terminus of *NIPBL*. Furthermore, our data give new insights into molecular mechanisms responsible for the pathogenesis of CdLS, suggesting a CdLS-relevant function of *NIPBL* not related to cohesin loading.

**11q terminal deletion associated with mild phenotype of Jacobsen syndrome.** C. da Silva-Camargo<sup>1</sup>, H. Salomão<sup>1</sup>, F.R. Faucz<sup>1</sup>, A. Bonalumi<sup>1</sup>, J. Souza<sup>1</sup>, P. Grossfeld<sup>2</sup>, J. Rosenfeld<sup>2</sup>, G.S. Rigoni<sup>3</sup>, B.L. Haliski<sup>3</sup>, L.S. Benatti<sup>3</sup>, V.S. Sotomaior<sup>3</sup>, S. Raskin<sup>1,4</sup>. 1) Group for Advanced Molecular Investigation (NIMA), Pontifícia Universidade Católica do Paraná, Curitiba, PARANÁ, Brazil; 2) Division of Pediatric Cardiology, Department of Pediatrics/Rady Children's Hospital of San Diego, California, USA; 3) Department of Molecular & Human Genetics, Baylor College of Medicine, Houston, Texas, USA; 4) Medical School, Universidade Positivo, Curitiba, Paraná, Brazil.

Jacobsen syndrome (JBS) is caused by a partial terminal deletion at 11q23.4-q25 and demonstrates variable phenotypic expression. The incidence of deletions in this region is estimated to be less than 1 in 100,000 in live births with a female/male ratio of 2:1 and with few cases with molecular analysis reported. The characteristic clinical picture includes mainly pre- and postnatal physical growth retardation, psychomotor retardation, intellectual disability, skull deformities, characteristic dysmorphic face, congenital cardiopathy and thrombocytopenia (Paris-Trousseau syndrome) or pancytopenia. In this research deletions were identified by microarray-based comparative genomic hybridization (aCGH) between 11q23.4 - q25 in four patients, 3 females and 1 male, with clinical features overlapping JBS, generating a mild phenotype compared to classical cases. Two patients also carry other deletions in chromosomal regions not significantly associated with the clinical picture typically presented of this syndrome. The four patients do not present some of the typical clinical alterations, such as thrombocytopenia, platelet dysfunction and cardiac abnormalities, although they have JBS similar phenotypic components such as speech difficulties, facial dysmorphism, neuropsychomotor development delay, cognitive deficit, and intellectual disability. Previously published papers implicates *ETS-1* and *JAM3* as putative causative genes for cardiac abnormalities, and there is evidence that the genes that play a fundamental role in thrombocytopenia are *FLI1*, *ETS1*, *NFRKB*, and *JAM3*. Two of our female patients have alterations in *JAM3*, and one of them also has alterations in *NFRKB*, questioning the involvement of these genes in the etiology of cardiac abnormalities and thrombocytopenia. The others two patients have no changes in these genes. Further research is still needed to define the platelet function critical genes in JBS. Our results reiterate the benefits of aCGH for the description of new phenotype/genotype associations and refinement of previously established ones, in addition, this reports demonstrates the importance of thorough phenotypic characterization of patients with JBS, thereby contributing to a better understanding of the spectrum of this syndrome.

**1776F**

**Deciphering the mechanisms of developmental disorders (DMDD): Shedding light on human genetic disease using embryonic lethal knockout mice.** A. Galli<sup>1,2</sup>, A. Green<sup>1,2</sup>, DMDD Consortium. 1) Wellcome Trust Sanger Institute, Cambridgeshire, United Kingdom; 2) dmdd.org.uk.

**Statement of purpose** Around one third of all mammalian genes are essential for life, their removal resulting in embryonic or perinatal lethality. Studying these genes is therefore a powerful way to gain understanding of the genetic mechanisms that underlie both normal development and the mutations that lead to congenital birth defects. **Methods** The DMDD consortium studies embryonic and perinatal lethal knockouts in mice. Multiple embryos from each line are imaged in 3D at near-histological resolution to allow comprehensive morphological phenotyping. Parallel screens identify placental abnormalities and provide gene expression profiles for each line. All DMDD data is freely available (dmdd.org.uk). **Results** 3D image analysis of morphological defects identified in 70 lines (more than 550 embryos) examined at E14.5 (the middle of organogenesis) shows that almost all embryos exhibit multiple phenotypes, affecting many tissues and organ systems. Prevalent abnormalities include subcutaneous oedema, malformations of the forebrain and eye muscles, and loss or abnormality of the hypoglossal nerve. Remarkably, around 80% of the lines have cardiovascular phenotypes. The dataset is a particularly valuable source of information for those researching the genetic basis of cardiovascular defects. Surprisingly, the phenotypes of individual embryos from the same line form distinct but overlapping sets. Across all lines the phenotype penetrance is highly variable and typically incomplete. Data mining studies have shown that the phenotypes scored in eleven of the lines replicate the detailed phenotypic spectra of human genetic disorders, including Meckel and Joubert syndromes. This suggests that data from the remaining lines could be valuable in identifying and linking gene mutations with currently undiagnosed rare diseases. Systematic placental analysis has revealed a much higher prevalence of placental phenotypes than previously appreciated. Around two thirds of embryonic lethal lines have a defective placenta. In particular, around one third of lines with a cardiovascular defect also have a placental phenotype, suggesting a link between abnormalities in the two organs.

**1777W**

**On the significance of craniosynostosis in a case of Kabuki syndrome with a concomitant *KMT2D* mutation and 3.2 Mbp de novo 10q22.3q23.1 deletion.** A. Topa<sup>1,2</sup>, L. Samuelsson<sup>2</sup>, L. Lovmar<sup>2</sup>, G. Stenman<sup>1,2</sup>, L. Kölby<sup>2</sup>. 1) Department of Pathology and Genetics, University of Gothenburg, The Sahlgrenska Academy, Gothenburg, Sweden; 2) Department of Clinical Pathology and Genetics, Sahlgrenska University Hospital, Gothenburg, Sweden; 3) Department of Plastic Surgery, University of Gothenburg, The Sahlgrenska Academy, Gothenburg, Sweden.

Craniosynostosis has rarely been described in patients with Kabuki syndrome. We report here a boy with facial asymmetry due to combined premature synostosis of the right coronal and sagittal sutures as well as several symptoms reminiscent of Kabuki syndrome (KS). Our case supports previous observations and suggests that craniosynostosis is a part of the KS phenotype. The uniqueness of our case is the sporadic co-occurrence of two genetic disorders, that is, a de novo frameshift variant in the *KMT2D* gene and a de novo 3.2 Mbp 10q22.3q23.1 deletion. Our findings emphasize the importance of the initial clinical assessment of children with craniosynostosis and that genomic and monogenic disorders, such as Kabuki syndrome, should be considered among the differential diagnoses of syndromic forms of craniosynostosis.

*De novo* truncating mutations in the *KAT6A* gene cause a clinically distinct congenital syndrome characterized by neurodevelopmental impairments, global developmental delay, cardiac and other congenital malformations. *KAT6A* is a multifunctional lysine acetyltransferase protein that controls gene expression through histone lysine acetylation and post-translational acetylation. Through an international collaboration, we have clinically characterized over 63 patients with *de novo* and rare mutations in *KAT6A*, 45 which have never been published in the literature significantly expanding the mutational and phenotypic spectrum of *KAT6A* syndrome. Early studies identified primarily *de novo* truncating mutations in the last exon of *KAT6A*, however newer cases have been identified throughout the protein, including a number of missense mutations in highly conserved functional regions of the gene. The degree of intellectual disability and delay, as characterized by the treating clinician, is most severe for patients with truncating mutations in the last exon and least severe in those with mutations earlier in the gene. In combination with the previously reported cases, there is expansion of the phenotypic variability and newly identified features include behavioral difficulties, sensory issues, high frequency of recurrent infections and several patients with proven immune or hematological dysfunction. To explore the underlying biology of the *KAT6A* protein, we performed RNAseq and differential expression (DE) analysis on fibroblasts derived from 5 patients with *KAT6A* truncating mutations and compared the gene expression profile to 5 unaffected individuals. DE genes are overrepresented in GO biological processes pertaining to systemic development, nervous system development, visual perception and skeletal development, as well as adhesion and protein glycosylation pathways. The most DE genes (qval < 10<sup>-6</sup>) are involved in neurite migration and fibrosis. These data provide insight into the pathology of late-exon *KAT6A* truncations and further implicate

aberrant p53 mediated senescence pathways in *KAT6A* phenotypic variation. Our work in fibroblasts suggests that *KAT6A* is a key protein underlying cellular processes in fetal and childhood brain development and DNA damage response. Future directions include creating an induced pluripotent stem cell model system to investigate the role of *KAT6A* in early cell development and tissue-specific cell types.

**The IMPC: A global research infrastructure for understanding the role of genes in human development and disease.** V. Munoz Fuentes<sup>1</sup>, P. Flicek<sup>1</sup>, A.-M. Mallon<sup>2</sup>, T. Meehan<sup>1</sup>, H. Parkinson<sup>1</sup>, D. Smedley<sup>3</sup> on behalf of the IMPC consortium. 1) European Molecular Biology Laboratory, European Bioinformatics Institute (EMBL-EBI), Wellcome Trust Genome Campus, Hinxton, Cambridge CB10 1SD, UK; 2) Medical Research Council Harwell (Mammalian Genetics Unit and Mary Lyon Centre), Harwell, Oxfordshire OX11 0RD, UK; 3) Clinical Pharmacology, William Harvey Research Institute, School of Medicine and Dentistry, Queen Mary, University of London, Charterhouse Square, London EC1M 6BQ, UK.

The International Mouse Phenotyping Consortium (IMPC) is building a functional catalogue of the mammalian genome by producing and phenotyping a knockout mouse strain for every protein-coding gene. To date, over 4,000 knockout mouse lines, many for poorly understood genes, have been characterized and made available to the research community. The IMPC is a coordinated effort involving more than a dozen research centers and a dedicated publicly-available online resource. Using a standardized adult phenotyping pipeline, centers measure each mouse for more than 250 phenotypic parameters including metabolite content in blood, hearing capacity, and skeletal malformations. In addition, over 1,000 embryonic lethal mouse lines are analyzed in a specialized embryonic development pipeline that uses high-resolution 3D imaging. All data is quality controlled and analyzed by a dedicated informatics consortium and all abnormal phenotypes automatically compared to clinical features of human disease populations to identify robust mouse models of disease. We will present our discoveries into the enrichment of human Mendelian disease genes among the embryonic lethal strains, the wide-ranging sexual dimorphism of phenotypic traits in both wildtype and mutant mice, and the over 300 new mouse models of human disease now available for further studies. We will also discuss the latest findings in relation to metabolism, hearing and aging. The plethora of new genetic disease models as well as the basic and translational knowledge that has arisen from our analysis has recently earned the IMPC recognition by the G7 for being the first global research infrastructure for the life sciences.

**Associated anomalies in cases with esophageal atresia.** C. Stoll, Y. Alembik, B. Dott, M.P. Roth. Faculté de Médecine, Strasbourg, France, France.

Esophageal atresia (EA) is a common type of congenital anomaly. The etiology of esophageal atresia is unclear and its pathogenesis is controversial. Infants with esophageal atresia often have other non-EA associated congenital anomalies. The purpose of this investigation was to assess the prevalence and the types of these associated anomalies in a defined population. The associated anomalies in cases with EA were collected in all livebirths, stillbirths and terminations of pregnancy during 29 years in 387,067 consecutive births in the area covered by our population-based registry of congenital malformations. Of the 116 cases with esophageal atresia, representing a prevalence of 2.99 per 10,000, 54 (46.6%) had associated anomalies. There were 9 (7.8%) cases with chromosomal abnormalities including 6 trisomies 18, and 20 (17.2%) nonchromosomal recognized dysmorphic conditions including 12 cases with VACTERL association and 2 cases with CHARGE syndrome. Twenty five (21.6%) of the cases had multiple congenital anomalies (MCA). Anomalies in the cardiovascular, the digestive, the urogenital, the musculoskeletal, and the central nervous systems were the most common other anomalies. The anomalies associated with esophageal atresia could be classified into a recognizable malformation syndrome or pattern in 29 out of 54 cases (53.7%). This study included special strengths: each affected child was examined by a geneticist, all elective terminations were ascertained, and the surveillance for anomalies was continued until 2 years of age. In conclusion the overall prevalence of associated anomalies, which was close to one in two cases, emphasizes the need for a thorough investigation of cases with EA. A routine screening for other anomalies may be considered in infants and in fetuses with EA.

**Defining requirements for cleavage of prelamin A by the zinc metalloprotease ZMPSTE24.** T. Babatz<sup>1</sup>, E. Spear<sup>2</sup>, S. Michaelis<sup>1,2</sup>. 1) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Cell Biology, Johns Hopkins University School of Medicine, Baltimore, MD.

Lamins are a family of intermediate filament proteins that polymerize to form the nuclear lamina, a structural network underlying the nuclear envelope. The nuclear lamina plays a role in nucleus structural integrity, heterochromatin organization, and nuclear pore complex distribution. The lamin A precursor, prelamin A, undergoes a multi-step maturation process which concludes with C-terminal cleavage of a 15 amino acid farnesylated tail, yielding mature lamin A. When this final cleavage is disrupted either by mutations of the gene encoding the substrate, prelamin A, or the protease, ZMPSTE24, accumulation of the persistently farnesylated form of lamin A causes a spectrum of genetic disorders including the premature aging disease Hutchinson Gilford Progeria Syndrome (HGPS) and the related progeroid disorders mandibuloacral dysplasia (MAD-B) and restrictive dermopathy (RD). The structure of ZMPSTE24 has recently been solved, revealing a novel and fascinating integral membrane CAAX protease. The seven membrane spans form a hollow chamber enclosing an interior active site with narrow side portals through which substrates access the chamber. Prelamin A is the only known mammalian substrate for ZMPSTE24, however, the basis of this specificity remains unclear. To further define the sequence requirements for recognition of prelamin A by ZMPSTE24, we are performing a comprehensive mutagenesis experiment of residues flanking the cleavage site, using degenerate oligonucleotide mutagenesis to mutate each of the ten residues flanking the scissile bond (VTRSY $\epsilon$ LLGNS). These mutants are tested in an *in vivo* humanized yeast assay for prelamin A cleavage by ZMPSTE24. Prelamin A and ZMPSTE24 are exogenously expressed in yeast and cleavage efficiency is visualized on an SDS-PAGE gel. Already we can begin to discern a pattern for one position, L647, of which mutation to arginine has long been known to be "uncleavable." After assaying all 19 possible mutants of L647, charged residues, aromatics, and proline disrupt cleavage, while hydrophobic residues are well-tolerated. We expect a comprehensive analysis of the 10 residues surrounding the cleavage site will yield a "heat map" of cleavage efficacy for ZMPSTE24, provide mechanistic insights into the highly specific recognition of prelamin A by the protease, and define a consensus motif with predictive value to identify other ZMPSTE24 substrates.

**A mouse model of Proteus syndrome.** M.J. Lindhurst<sup>1</sup>, L.R. Brinster<sup>2</sup>, H.C. Kondolf<sup>1</sup>, M.R. Yourick<sup>1</sup>, G. Elliott<sup>3</sup>, C. Rivas<sup>3</sup>, L. Garrett<sup>3</sup>, J. Gomez-Rodriguez<sup>3</sup>, P.L. Schwartzberg<sup>3</sup>, L.G. Biesecker<sup>3</sup>. 1) MGMGB, National Human Genome Research Institute, Bethesda, MD; 2) Division of Veterinary Resources, Office of Research Services, NIH, Bethesda, MD; 3) GDRB, National Human Genome Research Institute, Bethesda, MD.

Proteus syndrome (PS) is characterized by progressive, mosaic, sporadic overgrowth that can affect any tissue of the body and is caused by the somatic activating mutation *AKT1* c.49G>A, p.(E17K). Common manifestations include bony overgrowth, cerebriform connective tissue nevi and vascular malformations that are often a mix of venous, capillary and lymphatic vessels and contain enlarged vascular channels. Many types of cysts, benign tumors and hyperplasia have been seen in patients with Proteus syndrome as well as overgrowth due to expansion of extracellular matrix in the tissue. Due to the observational nature of human studies, we have only been able to describe the natural history of the disorder in patients and survey tissues collected by biopsy, surgery and occasionally autopsy, for abnormal growth, histology and mutation burden. Therefore, we developed a mouse model that allows us to investigate the role the PS mutation plays in many different tissue types. Using two different methodologies, we have been able to generate mice mosaic for activated AKT1. As in the human disease, each mouse had a unique constellation of abnormalities with affected and phenotypically normal tissues containing both mutation-positive and -negative cells. Average mutation levels in mosaic mice ranged from 5 to 40%. The most common finding was vascular malformations (VM) of mixed type that contained large ectatic vessels very similar to what is seen in patients with PS. VM were often found in lymph nodes, though they also occurred in the spleen, kidney and adipose tissue. Cysts, hyperplasia and ductal ectasias were also noted. Mammary hyperplasia with ductal ectasia was found in 9 of 10 mice. However, there were some important differences. In human PS, manifestations of the disorder are usually detected in infancy or early childhood, usually between six and 18 months of age. In most of the mice, abnormalities were not detected until between 12 and 18 months, well into adulthood. In addition, very little expansion of extracellular tissue was observed in the mice. Finally, unlike in patients where the mutation is absent in peripheral blood samples, nearly all mosaic animals were positive at levels that ranged from 15 to 47%. Currently we are using immunohistochemistry to identify mutation-positive cells in several types of tissue to determine which cell types are most frequently positive in affected tissue and therefore are likely candidates to be driving the overgrowth.

**1783W****Sex differences in mtDNA content and its relationship to mitochondrial enzyme activities in the context of human skeletal muscle aging.**

*M. Tesarova, M. Hülková, J. Křížová, K. Beránková, H. Kolářová, H. Hansíková, J. Zeman.* Dept. of Pediatrics and Adolescent Medicine, Charles University, Faculty of Medicine and General University Hospital, Prague, Czech Republic.

The mitochondrial functional state is assessed mainly by respiratory chain enzyme activities. The coupling of mitochondrial DNA (mtDNA) content with enzyme activity could provide a more integrated view of the state. However, the context of age and gender is necessary to include in the view. The aim of this study was to analyze mtDNA content during aging, to compare its differences between males and females, and to characterize relation between mtDNA content and enzyme activities of COX, CS and SQR in set of 205 human skeletal muscle samples (age from 2 weeks to 78 years). The Spearman's correlations between age and mtDNA content were significantly positive in both genders, although the more distinct correlation was observed in males ( $r = 0.626$ ;  $p = 0.000$ ) compared to females ( $r = 0.275$ ;  $p = 0.008$ ). Significantly positive correlation was found between COX, CS and SQR activities and mtDNA content in isolated mitochondria and COX activity and mtDNA content in muscle homogenate. The CS, COX and SQR activities were not found as age-group dependent but the activities normalized on mtDNA content depended significantly on the age-group (Kruskal-Wallis test:  $p = 0.002$ ;  $p = 0.014$ ;  $p = 0.023$ ). Considering gender, the normalized activities of all three enzymes were significantly dependent on the age-groups only in males (Kruskal-Wallis test:  $p = 0.010$ ,  $p = 0.005$ ,  $p = 0.013$ ). MtDNA content is changing during aging with gender specific scale and it may be considered an important normalization factor of mitochondrial enzymes especially in context of age and gender. Supported by grants AZV 17-30965A, RVO-VFN64165, Progres Q26/LF1, and GACR 14-36804G..

**1784T****Mechanistic insight of inactivation of mouse chitinase-like protein Ym1.**

*F. Oyama, M. Sakaguchi, Y. Sugahara, K. Okawa.* Dept Chemistry and Life Science, Kogakuin Univ, Hachioji, Tokyo, Japan.

Chitinase-like proteins (CLPs) are structurally homologous to chitinases but lack the ability to degrade chitin, a widespread environmental biopolymer of *N*-acetyl-D-glucosamine. Several CLPs have been identified in mice and humans. Mice express primarily breast regression protein-39 (BRP-39), Ym1 and Ym2, whereas humans produce YKL-40, the human homologue of BRP-39, but do not synthesize Ym1 and Ym2. Based on sequence similarities, CLPs belong to the family 18 of the glycosyl hydrolases. Family 18 of the glycosyl hydrolases includes two catalytically active mammalian chitinases, chitotri-oxidase (Chit1) and acidic mammalian chitinase (AMCase). It is generally assumed that the lack of chitinase activity in CLPs is due to the mutation of crucial residues within the conserved catalytic domain during evolution from a common ancestor. Ym1, one of the CLPs, is expressed in mouse and is overexpressed during inflammation caused by parasitic infections or allergic pulmonary inflammation, but its biological functions remain unknown. Ym1 is highly homologous to AMCase, but lack chitin hydrolyzing activity. To understand the structure and function relationship of Ym1, we introduced amino acid substitutions (N136D and Q140E), which compose the active site of family 18 chitinases. Although the mutated Ym1 possessed the same sequence of the conserved active site with AMCase, it remains inactive. This result indicates that lack of chitinase activity in Ym1 is not due to merely the simple amino acid substitution in the active site.

**Gene expression profiling of puberty-associated genes reveals abundant tissue and sex-specific changes across postnatal development.** *H. Hou*<sup>1,2</sup>, *L. Uusküla-Reimand*<sup>1,3</sup>, *M. Makarem*<sup>1</sup>, *S. Saleh*<sup>1,4</sup>, *C. Corre*<sup>1</sup>, *A. Metcalf*<sup>1</sup>, *A. Goldenberg*<sup>1,4</sup>, *M. Palmert*<sup>1,5,6</sup>, *M. Wilson*<sup>1,2</sup>. 1) Sickkids Research Institute, Toronto, ON, Canada; Genetics and Genome Biology Program, SickKids Research Institute, M5G 0A4, Toronto, Ontario, Canada; 2) Department of Molecular Genetics, University of Toronto, M5S 1A8, Toronto, Ontario, Canada; 3) Department of Gene Technology, Tallinn University of Technology, 12616 Tallinn, Estonia; 4) Department of Computer Science, University of Toronto, M5S 2E5, Toronto, Ontario, Canada; 5) Division of Endocrinology, Hospital for Sick Children, M5G 1X8, Toronto, Ontario, Canada; 6) Departments of Paediatrics and Physiology, University of Toronto, M5S 1A8, Toronto, Ontario, Canada.

The timing of human puberty is highly variable, sexually dimorphic, and associated with adverse health outcomes. However, we still know little about the spatial, temporal or postnatal expression patterns of the majority of these candidate puberty-associated genes. Rare mutations have been identified for over 20 pubertal disorders, many of which disrupt critical components of the hypothalamic-pituitary-gonadal (HPG) axis. More than 200 candidate genes at loci associated with age at menarche or voice breaking in males have been identified by genome-wide association studies (GWAS). To gain insight into the tissue and cell-type specific expression of candidate puberty associate genes, we first leveraged large-scale human and mouse gene expression data sets including microarray, bulk and single cell RNA-seq data. We found enrichments for pituitary gland, pineal gland, hypothalamus, and several additional brain regions. To gain insight into the temporal and sex specific expression of candidate puberty genes we used a high-throughput and sensitive microfluidic quantitative PCR strategy, to profile the gene expression patterns of the mouse orthologs of more than 175 puberty-associated genes in male and female mouse HPG axis tissues, the pineal gland, and the liver at five postnatal ages spanning the pubertal transition. The most dynamic gene expression changes were observed prior to puberty in all tissues. We detected known and novel tissue-enhanced gene expression patterns, with the hypothalamus expressing the largest number of the puberty-associated genes. While few hypothalamus genes showed sex-biased gene expression, over 40 puberty-associated genes in the pituitary gland showed sex-biased gene expression, most of which occurred peri-puberty. These sex-biased genes included the orthologs of candidate genes at GWAS loci that show sex-discordant effects on pubertal timing. Overall, our findings provide new insights into the expression of puberty-associated genes and support the possibility that the pituitary plays a role in determining sex differences in the timing of puberty.

**SRY potentially regulates early dopaminergic differentiation from male hiPSCs.** *D.D. Cao*, *W.N. Law*, *K.K. Miu*, *J.J. Tu*, *T.Y. Ha*, *H.H. Chueng*, *W.Y. Chan*. School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Hong Kong.

Protein of Sry, the sex-determining gene, was found to co-localize with Tyrosine Hydroxylase (TH) positive neurons in male rat substantia nigra and in postmortem male human brains. Knockdown of Sry in male rats caused motor dysfunction making it a candidate capable of exerting male-specific effects on brain sexual dimorphism. However, it is unknown if SRY is a gene that affects neurodevelopmental process in male. To answer this question, we utilized human induced pluripotent stem cells (hiPSCs) to establish an in vitro floor plate (FP) based dopaminergic (DA) neuron differentiation system. We also generated stable male hiPSC line with ectopic activation of SRY. Our results showed that endogenous SRY was upregulated during the early DA neuron differentiation stage. When we ectopically overexpressed SRY during early differentiation, several midbrain DA neuron progenitor markers FOXA1, FOXA2, LMX1A, and MSX1 were significantly upregulated which indicated a possible enhancing role of SRY in early DA neuron differentiation. In addition, from published CHIP-seq datasets of SRY, we found that SHH and FOXA1 (important mediators in the development of DA neurons) are two potential downstream targets of SRY. In the future, knockout of SRY will be conducted utilizing CRISPR/Cas9 technology to examine if early DA neuron differentiation was inhibited after SRY knockout. Furthermore, RNA-seq will be performed to examine global gene expression changes under different SRY expression status. Finally, CHIP-qPCR will be used to testify the candidate downstream targets bound by SRY in the early DA neuron differentiation process. We hope, through our study, we can understand better the molecular regulatory function of SRY in male-specific neurogenic process.

**An iPSC approach to examine the molecular mechanisms underlying SRCAP mutations in Floating-Harbor syndrome.** R.L. Hood<sup>1,2</sup>, K.M. Boycott<sup>3,4</sup>, W.L. Stanford<sup>1,5,6</sup>, D.E. Bulman<sup>2,4</sup>. 1) Department of Biochemistry, Microbiology and Immunology, University of Ottawa; 2) Children's Hospital of Eastern Ontario Research Institute, University of Ottawa; 3) Department of Genetics, Children's Hospital of Eastern Ontario; 4) Department of Pediatrics, University of Ottawa; 5) The Sprott Centre for Stem Cell Research, Regenerative Medicine Program, Ottawa Hospital Research Institute; 6) Department of Cellular and Molecular Medicine, University of Ottawa.

Floating-Harbor Syndrome (FHS; OMIM# 136140) is characterized by short stature, delayed osseous maturation, cognitive deficit, and unique dysmorphic facial features. We previously employed an exome-sequencing approach and identified heterozygous truncating mutations of *SRCAP* as the cause underlying FHS. More recently, we identified a specific DNA methylation "epi-signature" in the peripheral blood of FHS individuals by high resolution genome-wide DNA methylation analysis. *SRCAP* has been described as having coactivator roles in CREB and CBP-mediated and nuclear (steroid) hormone receptor signaling pathways and has also been shown to co-precipitate as part of a large chromatin remodeling complex which catalyzes ATP-dependent displacement of the histone variant H2A by H2A.Z. Based on the described roles for *SRCAP* and our finding that FHS-causing *SRCAP* mutations result in global methylation alterations, we expect that these mutations result in widespread gene dysregulation. Furthermore, the existence of individuals with deletions encompassing all of *SRCAP* who do not have FHS, leads us to postulate that the mechanism of disease is not due to haploinsufficiency. To examine the functional consequences of *SRCAP* mutations in cell lineages implicated in the FHS phenotype, we have utilized an induced pluripotent stem cell (iPSC) disease-modeling approach. FHS patient and gender-matched control fibroblast samples were reprogrammed into iPSCs using an episomal vector approach and subsequently characterized by pluripotency cell surface marker expression, in vitro embryoid body differentiation, and in vivo teratoma formation assays. We are currently differentiating these cells into: chondroprogenitors, to examine the growth deficiency; neural crest cells, to investigate the facial dysmorphism; and a neural lineage, to examine the cognitive deficiency aspect of FHS. RNAseq will be employed to examine global transcript expression and identify downstream targets and/or pathways which are perturbed within the specific cell lineages of FHS patients. These results will rationalize the various phenotypic aspects seen in this disease in a precise tissue specific manner and provide insight into the disease mechanisms seen in FHS.

**1788F**

**ROS induced oxidative stress up-regulates DNA repair gene uracil DNA glycosylase, a potential anti-leishmania drug target.** A. Mishra<sup>1</sup>, M.I. Khan<sup>1</sup>, P.K. Jha<sup>1</sup>, P. Das<sup>1,2</sup>, K.K. Sinha<sup>1</sup>. 1) Biotechnology, National Institute of Pharmaceutical Education and Research, Hajipur, Bihar, India; 2) Rajendra Memorial Research Institute of Medical Sciences Agamkuan, Patna, Bihar-800007, India.

**Introduction** Currently used anti-leishmanial drugs are experiencing resistance and toxicity concerns, making identification of novel drug targets of seminal importance. *Leishmania donovani* is an intracellular parasite that able to survive and replicate concomitantly under lethal oxidative environment of host macrophages. Between different survival strategies for parasite, DNA repair mechanisms have its own exquisite importance due their ability to repair different type of oxidative lesions. Base excision repair (BER) is the predominant in correcting oxidative damage, but details of BER have not been explored in *L. donovani*. Uracil DNA Glycosylase (UNG) is one of the essential enzymes involved in BER pathway, solely for its upfront capability of detecting and isolating the lesions. **Methods** Initially, *Leishmania* cell extract and recombinant purified LdUNG was checked for the glycosylase activity using synthetic 47 base pair oligonucleotide as a substrate at different physiological conditions. The effect of overexpression of UNG on survival and growth of *L. donovani* was checked by MTT and ARP assay against oxidative agents. The ex-vivo infectivity of UNG overexpressed cells were determined in macrophages. Transcriptional level of LdUNG was determined in different condition of oxidative stress induced by ROS or antileishmanial drugs by qRT-PCR. **Results** We demonstrate the role of LdUNG in protection against DNA damaging agents and oxidative stress. Apart from this, we show that UNG is indirectly related to the mechanisms involving drug resistance in Leishmania. First, we demonstrated the presence of glycosylase activity in leishmanial lysate and then, in heterologously produced and purified recombinant LdUNG. We find that over-expression of enzyme in the parasite confers tolerance against oxidative stress by correcting DNA damage and surprisingly against antileishmanial drugs which are in use. Also, our studies revealed that stressed parasites or resistant isolates exhibit an up-regulated levels LdUNG transcription. Interestingly, overexpression of UNG enhances the ex-vivo macrophage infectivity of the parasite. **Conclusion** Our results emphasize the role of BER pathway in establishment of infection in human macrophage. Added to this, association of UNG expression with resistance against commonly used antileishmanial drugs opens a new window of opportunity to target LdUNG for development of combination therapy against leishmaniasis.

**1789W**

**Generation of humanized CD4 knock-in mice using CRISPR/Cas9.** K.C. Chen<sup>1</sup>, P.L. Chen<sup>1,2,3,4</sup>. 1) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan; 2) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 3) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 4) Research Center for Developmental Biology and Regenerative Medicine, National Taiwan University, Taipei, Taiwan.

CD4, a glycoprotein expressed on the surface of helper T lymphocytes, is a critical molecule for immune regulation. CD4 is necessary to activate helper T cell by binding to class II major histocompatibility complex (MHC) molecules. Among the 4 domains, the D1 and D2 domains of CD4 are important regions to interact with class II MHC molecule. With the goal to study human immunity and autoimmunity using mouse as a model organism, we constructed a humanized CD4 knock-in mice which retains the promoter and regulatory elements of the endogenous mouse *Cd4* gene and produced the chimeric CD4 molecule that contains all D1 and D2 domains of human CD4. The exons 3-5 of the endogenous mouse *Cd4* allele were replaced with the homologous human *CD4* gene sequence via CRISPR/Cas9 approach to make a humanized CD4 knock-in mouse strain. Through another project, we are also working on a humanized MHC class II knock-in mouse. Combination of the humanized chimeric CD4 mouse and humanized MHC class II knock-in mouse will benefit immunological modeling applications in the future.

**The association of haploinsufficiency of ARID2 with Ras-MAPK signaling pathway.** M. Kang<sup>1</sup>, B. Lee<sup>1,2</sup>, J. Lee<sup>1</sup>, G. Kim<sup>2</sup>, I. Cho<sup>2</sup>, J. Choi<sup>2</sup>, E. Seo<sup>2</sup>, H. Yoo<sup>1,2</sup>. 1) Asan Institute for Life Sciences, Seoul, South Korea; 2) Medical Genetics Center, Asan Medical Center Children's Hospital, University of Ulsan College of Medicine, Seoul, Korea.

Somatic haploinsufficiency of *ARID2* has been reported in human cancer tissues including hepatic cellular carcinomas. Recently, its germline heterozygous loss-of-function mutations were identified in patients with neurodevelopmental disorders and Coffin-Siris like phenotype. Previous investigations on the tumor tissues with *ARID2* haploinsufficiency suggested that its suppression is related to increased activity of Ras-MAPK pathway. In the current study, we described one patient with 12q12 microdeletion including *ARID2*. This patient had facial dysmorphism, short stature, cardiac defect, and intellectual disability. *ARID2* haploinsufficiency was confirmed by chromosome microarray, RNA and protein expression study. Transient knock-out study using sh-RNA-*ARID2* in HeLa cells indicated that suppression of *ARID2* is related with increased Ras-MAPK activity but no significant changes in the activity of AKT and mTOR signaling pathway was observed. In addition, transient KO study of two other genes, included in the deletion region, did not show any change of activity of Ras-MAPK, AKT and mTOR signaling pathway. *ARID2* is a member of BAF (SWI/SNF-B) chromatin remodeling complex, and is expected to regulate transcriptional activation and repression of select genes by chromatin remodeling. The results of study indicates that haploinsufficiency of *ARID2* is related with enhanced Ras-MAPK pathway. Further study is required for the association of its deficiency with dysmorphism and intellectual disability.

**1791F**

**30 kDa fragment of beta-dystroglycan co-immunoprecipitates with Dp71 isoforms in PC12 cells.** C.O. Azotla Vilchis, J. Aragón Medrano, V. Ceja Orozco, R.M. Bermúdez Cruz, S.C. Montañez Ojeda. Department of Genetics and Molecular Biology, CINVESTAV, Mexico city, Mexico.

Dystrophin Dp71 is a protein encoded by the *DMD* gene (MIM 300377) and its expression is relevant for nervous system function. Dp71 isoforms are generated by alternative RNA splicing, which are grouped according their carboxi terminal end in Dp71d, Dp71f and Dp71e. Each isoform has different subcellular localization; however, specific function of each isoform remains unknown. Beta-dystroglycan is part of the dystrophin-associated protein complex (DAPC). This complex allows multiple protein interactions and regulates intracellular localization and function of other proteins. A matrix metalloproteinase cleaves the extracellular domain of beta-dystroglycan and creates a 30 kDa fragment of this protein. Our group aim is to elucidate the function of Dp71 isoforms. For this, we are studying the protein complexes in which Dp71 isoforms are involved. Experimental strategy: PC12 cell stable clones overexpressing recombinant Myc-Dp71a, Myc-Dp71c and Myc-Dp40 proteins were generated. The cross-link with paraformaldehyde was standardized and total protein lysates of each clone were obtained. Cross-linked complexes were immunoprecipitated with Myc polyclonal antibody/protein G-sepharose and analyzed by blue native polyacrylamide gel electrophoresis (BN-PAGE). To visualize complexes containing recombinant Myc-Dp71 and beta- dystroglycan proteins, Western blot assays were carried out. Results: We found at least 3 complexes of different molecular weight containing specific Dp71 isoform in PC12 cells. Abundance of each complex is different between the different complexes. Beta-dystroglycan co-immunoprecipitated with Dp71/Dp40, being the 30 kDa beta-dystroglycan present in these complexes. These results demonstrate that 30 kDa beta-dystroglycan is one of the components of DAP-Dp71 complexes in PC12 cells, a well-established cell line model to study neuronal functions.

**Analysis of copy number variation and association with facial shape in a large cohort of Bantu African children.** F. Yilmaz<sup>1,2</sup>, M. Sorenson<sup>3</sup>, D. Astling<sup>2,4</sup>, H-C. Yu<sup>2</sup>, J. Cole<sup>2,5</sup>, S.A. Santorico<sup>3,5,6</sup>, R.A. Spritz<sup>2,5</sup>, A.E. Hendricks<sup>3,5,6</sup>, T.H. Shaikh<sup>2,5</sup>. 1) Integrative and Systems Biology Program, University of Colorado Denver, Denver, CO; 2) School of Medicine, University of Colorado Denver, Aurora, CO; 3) Mathematical and Statistical Sciences, University of Colorado Denver, Denver, CO; 4) Department of Biochemistry and Molecular Genetics, University of Colorado Denver, Aurora, CO; 5) Human Medical Genetics and Genomics Program, University of Colorado Denver, Aurora, CO; 6) Biostatistics and Informatics, Colorado School of Public Health, Aurora, CO.

Recent genomewide association studies by the FaceBase Consortium have identified several genes associated with normal facial shape and appearance. These studies focused on analyzing SNPs in population based cohorts with normal facial characteristics. Images from 3D morphometric cameras were used to quantify facial distances and shapes. Copy number variations (CNVs), are a considerable source of genetic variation. While CNVs have been implicated in numerous genetic disorders, they are understudied in genetic association studies of normal traits including normal facial variation. We hypothesize that CNVs may play a role in the variability observed in normal facial appearance. To test this, we analyzed genotype and phenotype data from ~3700 Bantu Africans. CNV calls were generated by applying PennCNV, DNACopy, and VanillalCE, to the raw intensity files obtained from the SNP array-based genotyping. After quality control to remove low-quality samples and CNVs, > 410,000 CNVs from 3463 individuals remained (~120 CNVs/individual). CNVs were further classified by size and probe content and annotated for overlap with known genes and CNVs. Although the vast majority of the CNVs were < 100 Kb in size, we identified 1482 CNVs that were ≥ 300 Kb, many of which overlapped regions previously implicated in genetic syndromes. CNVs were further classified based on the number of times they were observed in unrelated individuals. We observed ~500 CNVs in over 5% of the cohort, and ~2000 CNVs in 1-5% of the cohort, while the vast majority were seen in <1% of the cohort. We next examined the association between CNVs and 28 quantitative facial measurements, including 25 linear distances and 3 measures of overall face size, using a linear mixed effects model to control for cryptic relatedness and including known covariates (e.g., age, sex). We used two primary models; in model 1, deletions and duplications, have the same direction and magnitude of effect, while in model 2, deletions and duplications have opposite direction of effect. We identified several CNVs associated with facial measurements and many of our top hits overlap genes relevant to craniofacial development. For example, a CNV associated with centroid size (p-value = 5.92e-5, effect size = -4.44) overlaps *SLC2A3*, a gene expressed in craniofacial precursors. In addition to assessing the role of CNVs in facial shape and morphology, this study also provides a resource of CNVs generated from a large cohort of Africans.

**1793T****ARMC5 and PMAH: From human genetic defects to the *Armc5*<sup>-/-</sup> mouse.**

F.R. Faucz<sup>1</sup>, A. Berthon<sup>1</sup>, S. Espiard<sup>2</sup>, L. Drougat<sup>1</sup>, J. Bertherat<sup>2,3</sup>, C.A. Strat-  
akis<sup>1</sup>. 1) Section on Endocrinology and Genetics, Eunice Kennedy Shriver

ral Center for Rare Adrenal Diseases, Assistance Publique Hôpitaux de Paris,  
Hôpital Cochin, 75014 Paris, France.

Bilateral adrenal hyperplasias (BAH) that lead to Cushing syndrome (CS) are linked to abnormalities of the protein kinase A (PKA) pathway. Almost half of all cortisol-producing adenomas harbor somatic mutations of the main PKA catalytic subunit *PRKACA* or *Ca*. In 2013, the first inactivating mutations in the Armadillo repeat-containing 5 (*ARMC5*) gene were identified in a form of BAH called primary macronodular adrenal hyperplasia (PMAH). Since, we have reported several new germline *ARMC5* mutations in patients with PMAH (*J Clin Endocrinol Metab.* 2014;99:E1113 and *J Clin Endocrinol Metab.* 2015;100:E926) and additional ones in patients with primary hyperaldosteronism (*J Clin Endocrinol Metab.* 2015;100:E900). To better understand PMAH caused by *Armc5* haploinsufficiency, we generated and characterized a new mouse model of *Armc5* deficiency. *Armc5* heterozygote mice (*Armc5*<sup>-/-</sup>) developed normally but at the age of 1 year, their corticosterone levels decreased, and this was associated with a decrease of PKA activity that was associated with a reduction of *Ca* expression at the RNA and protein levels. Similar decreases in PKA activity and *Ca* expression were also seen in tumors from patients with PMAH and *ARMC5* defects. Like in humans with PMAH, a subgroup of *Armc5*<sup>-/-</sup> mice developed hypercorticosteronemia at 18 months of age; interestingly, this was then associated with increases in both PKA activity and *Ca* expression. Adrenocortical tissue analysis from *Armc5*<sup>-/-</sup> mice at 18 months showed an abnormal activation of the *Wnt/b*-catenin signaling pathway in a subset of zona fasciculata cells. In conclusion, *Armc5* haploinsufficiency leads to age-dependent changes and CS in mice and this involves PKA, its catalytic subunit *Ca*, and the *Wnt/b*-catenin pathway. \*F.R.F. and A.B. contributed equally to this work .

**1794F****Establishment of primary cell lines from normal and abnormal human products of conception.** D. O'Day, T. Nalwai-Cecchini, I. Glass. Department of Pediatrics, University of Washington, Seattle, WA.

Cell lines established from normal and abnormal human fetal donors can be a vital resource for molecular and cellular analyses of human development. For example, dermal fibroblasts are a mitotically active cell enabling observation of cell cycle dependent processes, such as ciliogenesis; they are validated starting materials for the generation of induced pluripotent stem cells (iPSCs); and they can be used to test for the presence of mosaicism. Here, we establish several primary cell lines from multiple fetal tissues including skin, brain, lung, spleen, liver, and kidney from both normal and abnormal human fetal donors. From 46 donor skin samples, we successfully established 38 different fibroblast cell lines derived from a wide range of congenital disorders such as Trisomy 21 and multiple congenital anomaly cases. For the 8 cases that failed to establish stable cell lines, 6 were exposed to unusually long intra-uterine fetal demise intervals (more than 24 hours) and 2 cases were lost as the result of technical failures. For 50 additional cases, we established astrocyte cell culture from cerebral cortex collected from donors 7 to 19 post-conception weeks (PCW); 16 of these cases have been successfully distributed to recipients of the laboratory for downstream applications. As a collaborative effort, we have also isolated 4 lung epithelial cell lines from 16 to 19 PCW cases as well as splenic stromal cell lines from 7 cases at 11 to 18 PCW for distribution to researchers for their specific projects. Cryogenically preserved cell lines generated from these otherwise difficult to obtain human fetal samples are a valuable resource for biomedical research. To facilitate research on normal and abnormal human development, the Laboratory of Developmental Biology will continue to establish, distribute, and store such cell lines for future use by biomedical researchers.

**Genomic characterization of human induced pluripotent stem cells after CRISPR/Cas9 fluorescent tagging.** *T.S. Grancharova, R.N. Gunawardane, Allen Institute for Cell Science.* Allen Institute for Cell Science, Seattle, WA.

The goal of the Allen Institute for Cell Science is to study and model cell behavior using image-derived data from human induced pluripotent stem cells (hiPSCs). We use the CRISPR/Cas9 system to fluorescently tag gene targets comprising the major signaling complexes and molecular machines in WTC hiPSCs. Because our goal is to model normal, non-cancer cell behavior, we are assessing the effects of gene editing and prolonged culturing on the transcriptomes and genomes of edited cell lines as part of our quality control protocol. To establish the baseline state of our unedited WTC line, we performed RNA-Seq on cell populations from passage numbers 8, 10, and 14 and found that their expression profiles are highly correlated indicating a relatively stable transcriptome in early passage unedited populations. Differential expression analysis comparing independently isolated clones from multiple edited lines (at passage ~25-35) to the unedited parental line revealed a set of ~50 genes that are down regulated ( $\log_2$  fold change  $< -1$ ;  $p < 0.05$ ) in all edited lines. This set of genes is enriched for gene ontology terms related to developmental processes suggesting that the editing/culturing process selects for cells in a more stem like state. In addition to characterizing the transcriptional profiles of edited cell lines, we looked for signatures of off-target Cas9 cutting using Sanger sequencing. For our initial assessment of off-target editing, we sequenced the top 8-10 predicted off-target locations for each crRNA used in generating ten clonal lines fluorescently tagged at different locations. Looking at 3-5 candidate clones for each line, we found no indels at the predicted cut sites indicating the absence of off-target cutting. We identified the baseline genomic variants in the unedited WTC line from 100X whole genome sequencing data and will use whole exome sequencing of each fluorescently tagged line to further assess Cas9 off-target editing and to identify other genomic aberrations that may arise during standard culturing and the clonal line generation process. All edited cell lines and their associated image and genomic data will be openly available to the non-profit scientific community.

**1796T****Assessment of the impact of variants in constrained non-essential splice sites in fifty-two thousand type 2 diabetes cases and controls.**

*J.M. Mercader<sup>1,2</sup>, J. Flannick<sup>1,2,3</sup>, M. Udler<sup>1,2</sup>, A. Mahajan<sup>4</sup>, C. Fuchsberger<sup>5</sup>, Sidi Zhang<sup>6,7,8</sup> for the AMP-T2D Consortium.* 1) Programs in Metabolism and Medical & Population Genetics, Broad Institute of Harvard and MIT, Cambridge, Massachusetts, USA; 2) Diabetes Unit and Center for Genomic Medicine, Massachusetts General Hospital, Boston, Massachusetts, USA; 3) Department of Molecular Biology, Harvard Medical School, Boston, Massachusetts, USA. University of Oxford, Oxford, OX3 7BN, UK; 4) Wellcome Trust Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford, OX3 7BN, UK; 5) Department of Biostatistics and Center for Statistical Genetics, University of Michigan, Ann Arbor, Michigan, USA; 6) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, Massachusetts 02114, USA; 7) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, Massachusetts 02142, USA; 8) Program in Biological and Biomedical Sciences, Harvard Medical School, Boston, Massachusetts 02115, USA.

Previous studies of genetic variation in type 2 diabetes (T2D) have uncovered more than 100 susceptibility loci for type 2 diabetes, most of them driven by common variants in regulatory regions. While low-frequency and rare coding variants have been recently shown to play a minor role, the potential for identification of rare coding variation associated with T2D may be enhanced by increasing the sample size and by improving our understanding of the functional impact of coding variation. Recent findings reported by Zhang et al. (Biorxiv, <https://doi.org/10.1101/129312>) identified specific nucleotide substitutions in non-essential splice sites near exon-intron boundaries that are on average more deleterious than missense variants and have higher likelihood of having an impact on splicing. To assess whether these non-essential splice-variants contribute to the susceptibility of T2D, we tested the association of this group of variants with T2D in a multi-ethnic study comprising whole exome sequences from 24,444 T2D cases and 24,502 controls. A total of 60,214 variants disrupted non-essential donor or acceptor sites, of which 11,697 were observed in at least 5 individuals. The most significant variant was located 5 base-pairs 5' to an exon-intron boundary of *WDR13* and was associated with 3.5 fold increased risk of developing T2D (MAF=0.0006, OR=3.45,  $p=3.6 \times 10^{-6}$ ). Multiple lines of evidence converge on a potential contribution of this gene to T2D risk. *WDR13* is a loss-of-function intolerant gene ( $pLI=0.94$ , ExAC), and lack of this gene in mice results in enhanced pancreatic beta cell proliferation, hyperinsulinemia and mild obesity. We also show that individuals carrying this variant have higher triglyceride levels. Replication in additional datasets and functional analyses will be needed to confirm the association with T2D and its impact on splicing of the *WDR13* gene. The second top variant was located 5 base-pairs 5' to an exon-intron boundary of the *HMG2* gene, which despite not reaching experiment-wide significance (MAF=0.04, OR=1.26,  $p=5.5 \times 10^{-4}$ ) is located in a region previously associated with T2D, and therefore suggesting an effector gene for this locus. In summary, analyzing constrained non-essential splice sites in the largest T2D exome sequencing project to date, we identified a novel large effect association with T2D, point to a possible effector transcript for a known T2D locus, and begin to demonstrate the impact of such type of variation in T2D.

**1797F****Replication of newly identified type 2 diabetes candidate gene variants in Northwest Indian population groups.**

*V. Sharma<sup>1</sup>, I. Sethi<sup>1</sup>, I. Sharma<sup>1</sup>, G. Singh<sup>1,3</sup>, A. Mahajan<sup>2</sup>, A. Angural<sup>1</sup>, A.J.S. Bhanwer<sup>2</sup>, M.K. Dhar<sup>2</sup>, V. Singh<sup>1</sup>, E. Rai<sup>1</sup>, S. Sharma<sup>1</sup>.* 1) Human Genetics Research Group, Department of Biotechnology, Shri Mata Vaishno Devi University, Katra, Katra, India; 2) Department of Biotechnology, University of Jammu, 180006, India; 3) Department of Human Genetics, Guru Nanak Dev University, Amritsar, Punjab, India.

Recent large-scale common and rare variant genome-wide association studies (GWAS) have proven to be a powerful tool for the identification of new susceptible loci of T2D. Replication of those variants in different populations are of paramount importance, especially in Indian population which actually is conglomeration of different ethnic groups.

**Aim**

The aim of the study is to replicate newly identified T2D susceptibility loci, variants rs998451 and rs6723108 of *TMEM163*; rs7607980 of *COBLL1* and rs2296172 of *MACF1* in different ethnic groups of Northwest Indian population.

**Method**

We perform genotyping of the variants using Taqman allele discrimination assay using Real time Pcr. **Results** Out of 4 SNPs examined in this study 3 did not show any significant association with T2D. The variant rs2296172 of gene *MACF1* shows significant association with T2D with an expected odds ratio of 1.3 with confidence interval of 1.07-1.60 ( $p = 0.0009$ ). We further evaluate variation rs2296172 of *MACF1* in endogamous Bania group specifically of Punjab region from the pooled population of Northwest India.

**Discussion**

Interestingly the results showed enhanced risk of T2D in Bania endogamous group than pooled population. These findings suggest the higher importance of studies within specific ethnic groups rather than conventional practice of pooling samples based on Geographical/Regional or Linguist affiliations like North or South Indian etc.

## 1798W

**HLA imputation and allelic associations with type 1 diabetes in African Americans.** C.C. Robertson, S. Onengut-Gumuscu, W.M. Chen, S.S. Rich. Center of Public Health Genomics, University of Virginia, Charlottesville, VA.

**Background:** Type 1 diabetes (T1D) is an autoimmune disease due to destruction of beta-cells in the pancreas. Risk of T1D is ~50% due to genetic factors, with the HLA region accounting for a majority of genetic risk. HLA allelic associations with T1D are robustly characterized in Europeans. Studies in African ancestry populations have been limited. **Methods:** We used the Illumina ImmunoChip and SNP2HLA software to impute classical HLA alleles in 1,036 T1D cases and 2,913 controls of African ancestry. Imputation used the Type 1 Diabetes Genetics Consortium (T1DGC) reference panel: 4,323 subjects of European, 251 African, and 622 with "other" ancestry. A lower bound of imputation accuracy was estimated using 50 previously HLA-typed subjects while excluding related subjects from the reference panel. Association with T1D was assessed for class I and II HLA loci and for classical alleles using logistic regression. Class II HLA haplotypes (*DRB1-DQA1-DQB1*) were inferred and haplotype associations were analyzed using logistic regression. Regression models were adjusted for population stratification using principal components. Likelihood ratio tests were used to assess association with T1D. **Results:** Estimated imputation accuracy ( $\rho$ ) of 4-digit classical alleles varied by locus. Lowest accuracy was seen at *HLA-B* and *HLA-DRB1* ( $\rho=0.88$ ). Accuracy was  $\geq 0.93$  at remaining loci, and highest accuracy was seen at *HLA-DQA1* ( $\rho=0.99$ ). All 8 class I and II HLA genes tested (*A, B, C, DRB1, DQA1, DQB1, DPA1, DPB1*) were significantly associated with T1D ( $p < 1 \times 10^{-7}$ ). The most significantly associated gene was *HLA-DQB1* ( $p = 2.2 \times 10^{-282}$ ). After adjusting for *HLA-DQB1*, four genes (*HLA-A, HLA-B, HLA-DRB1, and HLA-DQA1*) remained significant. The most significant classical allele was *HLA-DQA1\*03:01* (odds ratio (OR) = 5.5,  $p = 1.7 \times 10^{-14}$ ), and the most significant class II haplotype was *HLA-DRB1\*03:01-HLA-DQA1\*05:01-HLA-DQB1\*02:01* (OR = 3.9,  $p = 1.3 \times 10^{-73}$ ). While known European allelic and haplotype associations were recapitulated, African-specific associations were also identified, including the protective African-specific DR3 haplotype *HLA-DRB1\*03:02-HLA-DQA1\*04:01-HLA-DQB1\*04:02* (OR = 0.15,  $p = 8.6 \times 10^{-16}$ ). Evaluation of HLA associations with T1D in non-European populations may provide insights on the role of this most critically important locus on etiology of disease.

## 1799T

**Genetic variability in energy expenditure and the risk of severe obesity.** A.C.P. Fonseca<sup>1</sup>, B. Marchesini<sup>1</sup>, V.M. Zembruski<sup>1</sup>, J.R.I. Carneiro<sup>2</sup>, J.F. Nogueira Neto<sup>3</sup>, P.H. Cabello<sup>1,4</sup>, G.M.K. Cabello<sup>1</sup>. 1) Laboratory of Human Genetics, Oswaldo Cruz Institute, Rio de Janeiro, Rio de Janeiro, Brazil; 2) Clementino Fraga Filho University Hospital, Rio de Janeiro, Brazil; 3) Department of Pathology and Laboratory, Rio de Janeiro State University, Rio de Janeiro, Brazil; 4) Laboratory of Human Genetics, Grande Rio University, Rio de Janeiro, Brazil.

Obesity is defined as an increase in body fat mass which is enough to cause adverse health effects. The prevalence of obesity has increased rapidly, becoming a major public health problem worldwide. Such disease has a complex etiology, being clearly influenced by environmental and genetic factors. In this study, we aimed to investigate the difference in the molecular mechanism of individuals controlling energy expenditure which could disrupt the body homeostasis and may be a risk factor for obesity. A total of 391 adults subjects were selected, in which 189 were normal weight subjects (Body mass index, BMI: 22.8 [21.1; 23.9]) and 202 were severely obese individuals (BMI: 45.3 [39.7; 51.8]). Peripheral blood was collected for each patient, and we performed the biochemical (glucose, triglycerides, total cholesterol and fractions) and molecular analyzes. After genomic DNA was extracted, genotyping of *PPARGC1A* (rs8192678, rs3736265, rs2970847 and rs3755863) and *UCP1* genes (rs6536991 and rs12502572) were carried out by real time PCR (Taqman® assay). For the *FNDC5* gene, screening of exons 3, 4 and 5 as well as their intron-exon boundaries were performed using automatic sequencing. Clinical characteristic of the study population showed that anthropometric and biochemical data were significantly increased in the obese group. The exceptions were in HDL-cholesterol and height. Genotype and allele frequencies for all variants were obtained. Our results demonstrate a strong association between *PPARGC1A* rs2970847 and severe obesity susceptibility ( $\chi^2=7.71$ ;  $p=0.021$ ). Allelic analysis showed that individuals carrying the rs2979847 (C) allele had a 1.91-fold increased risk of severe obesity (OR: 1.91 [1,2-3,03];  $P = 0.003$ ). The effect of *PPARGC1A* and *UCP1* polymorphisms on anthropometric and biochemical in the sample was analyzed by linear regression (adjusted by gender and age). *PPARGC1A* rs2970847 was associated with body weight ( $P = 0.039$ ) and BMI ( $P = 0.030$ ). Additionally, *UCP1* rs12502572 was associated with body weight ( $P=0.049$ ). Furthermore, five rare variants were identified in *FNDC5* gene, which one is a novel missense mutation. The frequency of rs113173936 (AG) and rs72882318 (AG) were higher in severe obese group; however no statistic difference was found ( $P = 0.372$  and  $P = 0.317$ , respectively). In conclusion, our study demonstrated that *PPARGC1A* and *UCP1* polymorphisms impact on severe obesity susceptibility.

**1800F****Genome-wide meta-analysis of macronutrient intake identifies two novel loci: Cohorts for heart and aging research in genomic epidemiology.**

J. Merino<sup>1,2</sup>, H.S. Dashti<sup>1,2</sup>, S.X. Li<sup>3</sup>, A.E. Justice<sup>4</sup>, M. Graff<sup>5</sup>, C. Papoutsakis<sup>6</sup>, C.E. Smith<sup>6</sup>, G. Dedoussis<sup>7</sup>, D.I. Chasman<sup>2,8,9</sup>, T. Tanaka<sup>10</sup>, A.Y. Chu<sup>8,9</sup> on behalf of the CHARGE Nutrition Working Group. 1) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA; 2) Programs in Metabolism and Medical & Population Genetics, Broad Institute, Cambridge, MA, USA; 3) MRC Epidemiology Unit, University of Cambridge, Cambridge, UK; 4) Department of Epidemiology, University of North Carolina, Chapel Hill, NC, USA; 5) Research International and Scientific Affairs, Academy of Nutrition and Dietetics Chicago, IL, USA; 6) Nutrition and Genomics Laboratory, Jean Mayer USDA Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA; 7) Department of Nutrition and Dietetics, School of Health Science and Education, Harokopio University, Athens, Greece; 8) Division of Genetics, Brigham and Women's Hospital, Boston, MA, USA; 9) Division of Preventive Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, USA; 10) National Institute on Aging, NIH, Baltimore, MD, USA.

Genome-wide association studies (GWAS) have facilitated the discovery of two relevant loci (*FGF21* and *FTO*) for macronutrient intake, an important modifiable risk factor for complex diseases with a significant heritable basis ( $h^2$  ranging between 10 to 70%). Incomplete coverage of genetic variation and limited sample size in previous GWAS have precluded the discovery of additional loci. We conducted the largest GWAS to date of self-reported macronutrient intake in 91,112 participants from Cohorts for Heart and Aging Research in Genomic Epidemiology followed by replication in 32,545 participants and lookups in the UK Biobank ( $n=58,787$ ). In addition, we applied complementary computational approaches to investigate mechanistic insights of loci associated with macronutrient intake. We identified 12 suggestively significant loci ( $P < 10^{-6}$ ) associated with intake of at least one macronutrient (expressed as percentage of total energy intake from carbohydrate, fat, and protein) in discovery meta-analysis. Four loci successfully replicated, revealing a novel common locus for carbohydrate intake [rs7619139 placed in a long-non coding RNA gene (*AC133680.1*),  $\beta=0.2$ ,  $SE=0.05$ ,  $P_{1-sided}=4 \times 10^{-3}$ ] and a novel low-frequency variant (MAF=0.01) for protein intake [rs77694286 near *DRAM1* ( $\beta=0.55$ ,  $SE=0.19$ ,  $P_{1-sided}=2.3 \times 10^{-3}$ )]. Both loci achieved genome-wide significance in the combined meta-analysis including results from discovery and replication cohorts (*AC133680.1*,  $P_{combined}=4.1 \times 10^{-11}$ ; *DRAM1*,  $P_{combined}=1.9 \times 10^{-9}$ ). Additionally, we confirmed previous findings between *FTO* and higher protein intake and *FGF21* with higher carbohydrate and lower protein and fat intake. All, but *DRAM1* locus, showed consistent directionality and effect-sizes in the UK Biobank lookups. We found a moderate concordant genetic correlation between protein intake and BMI ( $r=0.23$ ,  $P=4 \times 10^{-4}$ ) indicating that genetic effects of higher protein intake are shared with higher BMI genome-wide. The novel variant in the *AC133680.1* gene is highly conserved across different species, involved in H1-neuronal progenitor cell differentiation (3.7 fold-change increase,  $P=1 \times 10^{-3}$ ) and primarily active in several brain regions, but not co-expressed with other quantitative loci linked mRNAs. Overall, the newly identified loci are likely to highlight relevant biological functions related to central nervous system control of food intake and body weight. Our findings reinforce current understanding of macronutrient intake biology.

**1801W****Diabetes in cystic fibrosis and type 2 diabetes (T2D) have overlapping genetic risk architecture.**

M. Atalar<sup>1</sup>, B. Vecchio-Pagan<sup>2</sup>, L.J. Strug<sup>3</sup>, R.G. Pace<sup>4</sup>, H. Corvo<sup>1,7</sup>, J.M. Rommens<sup>5</sup>, M.L. Drumm<sup>6</sup>, M.R. Knowles<sup>5</sup>, G.R. Cutting<sup>1</sup>, S.M. Blackman<sup>1</sup>. 1) Johns Hopkins University School of Medicine, Baltimore, MD; 2) The Johns Hopkins University Applied Physics Laboratory, Laurel, MD; 3) The Hospital for Sick Children, Toronto, Ontario, Canada; 4) Université Pierre et Marie Curie, Paris, France; 5) The University of North Carolina at Chapel Hill, Chapel Hill, NC; 6) Case Western Reserve University, Cleveland, OH; 7) Pediatric Pulmonology, Hôpital Trousseau, Paris, France.

Diabetes is a common age-dependent complication of cystic fibrosis (CF), affecting 40% of affected individuals by 30 years of age and 80% by 50 years of age. CF is an autosomal recessive disease caused by dysfunction of CFTR, a cAMP regulated chloride channel expressed in pancreas, intestine, lungs and sweat gland. Twin and sibling analysis indicated that variation in the age at onset of diabetes in CF is primarily determined by modifier genes. We report the results of genome-wide association and polygenic risk score analyses of 5364 unrelated subjects with CF derived from 4 study cohorts, 1307 of which had CF-related diabetes (CFRD). Association was tested using Cox proportional hazard regression within each cohort and fixed-effects meta-analysis on combined cohorts. Variants at two loci, *TCF7L2* (rs7903146;  $P=2.4E-11$ ) and *SLC26A9* (rs4077468;  $P=8.29E-11$ ), exceeded genome-wide significance. *TCF7L2* is the major genetic risk factor for type 2 diabetes (T2D) and *SLC26A9* encodes a chloride/bicarbonate exchanger that interacts with CFTR. The same *TCF7L2* SNV achieves the highest significance in CFRD and in T2D, and in the same direction. These findings provide critical replication of results derived from candidate studies (*TCF7L2*) and genome-wide association with a subset of subjects from the current study (*SLC26A9*). To further investigate genetic overlap between CFRD and T2D, polygenic risk scores were constructed using T2D-associated variants in the NHGRI-EBI Catalog of published GWASs. After pruning for MAF ( $\geq 5\%$ ) and LD ( $r^2 < 0.8$ ), genotypes were available for 155 T2D-associated SNVs. The T2D risk score was associated with CFRD (HR=1.02 per allele, 95% CI 1.02-1.03,  $P=6.0E-13$ , one-sided). A modified T2D risk score (removing 4 variants from previously reported candidate loci *TCF7L2*, *CDKAL1*, *CDKN2A/B*, and *IGF2BP2*), was also associated with CFRD (HR=1.02,  $P=5.0E-10$ , one-sided), indicating that additional T2D loci contribute to CFRD. A type 1 diabetes (T1D) risk score constructed with 30 SNVs (none typed in the *HLA* region) showed some evidence of association with CFRD (HR = 1.01,  $P=0.048$ , one-sided), suggesting that T1D risk alleles might also play a role in CFRD onset. These studies support overlap of disease mechanisms in T2D and CFRD. The high prevalence and early onset of diabetes in CF provide a unique opportunity to dissect the molecular mechanisms underlying CFRD and T2D. Supported by CFF, NIH, Gilead Sciences, CF Canada, CIHR, Genome Canada.

**Impact of genetic variants identified in genome-wide association studies of diabetic retinopathy in Chinese patients with type 2 diabetes.** C.Y.Y. Cheung<sup>1</sup>, C.H. Lee<sup>1</sup>, K.H.M. Kwok<sup>1</sup>, Y.C. Woo<sup>1</sup>, M.M.A. Yuen<sup>1</sup>, W.S. Chow<sup>1</sup>, C.H.Y. Fong<sup>1</sup>, R.L.C. Wong<sup>1</sup>, A. Xu<sup>1,2,3</sup>, P.C. Sham<sup>1,5</sup>, K.S.L. Lam<sup>1,2,3</sup>. 1) Department of Medicine, The University of Hong Kong, Hong Kong; 2) Research Centre of Heart, Brain, Hormone and Healthy Aging, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong; 3) State Key Laboratory of Pharmaceutical Biotechnology, The University of Hong Kong, Hong Kong; 4) Department of Psychiatry, The University of Hong Kong, Hong Kong; 5) Centre for Genomic Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong.

**Background:** Diabetic retinopathy (DR) is the most common microvascular complication of type 2 diabetes (T2DM). Novel DR-susceptibility loci have been identified from recent genome-wide association studies (GWAS) in various populations. If validated, these genetic markers may be used for risk profiling of DR in diabetic patients. This study aimed to examine the associations of these DR-associated single nucleotide polymorphisms (SNPs) with sight-threatening DR (STDR) in Chinese patients with T2DM. **Methods:** A total of 68 SNPs showing top association signals with DR ( $P < 5 \times 10^{-4}$ ,  $r^2 < 0.9$ ) in previous GWAS were genotyped in 3 groups of subjects: 1000 T2DM patients with STDR (STDR-cases), 2000 T2DM patients without retinopathy (non-STDR controls), and 1000 non-diabetic subjects recruited from the general population of Hong Kong (healthy-controls). STDR cases were defined as patients with either proliferative DR (PDR) or pre-PDR, or with clinically significant macular oedema. Multiple logistic regression models with adjustment for confounding factors were employed to examine for the independent association between the SNPs with STDR (STDR cases versus non-STDR controls; and STDR cases versus healthy controls). **Results:** When the STDR cases were compared with non-STDR controls, significant associations were observed at *IGSF21-KLHDC7A* rs3007729 ( $P=0.020$ ; OR[95%CI]:0.86[0.76-0.98]), *SLC25A32* rs3098241 ( $P=0.046$ ; OR[95%CI]:0.88[0.78-1.00]), and *COL5A1* rs7861012 ( $P=0.046$ ; OR[95%CI]:0.88[0.78-1.00]), after adjustment for age, gender, duration of diabetes, hemoglobin A1c (HbA1c) and presence of hypertension. When the STDR cases were compared with healthy controls, significant association between *IGSF21-KLHDC7A* rs3007729 ( $P=0.021$ ; OR[95%CI]:0.84[0.73-0.97]) was also detected. *BFSP2* rs1197310 ( $P=3.71 \times 10^{-3}$ ; OR[95%CI]:1.23[1.07-1.41]), *CNTN5* rs10501943 ( $P=0.022$ ; OR[95%CI]:1.66[1.08-2.57]), *FMN1* rs10519765 ( $P=0.037$ ; OR[95%CI]:0.80[0.64-0.99]), and *MAP3K7IP2* rs7772697 ( $P=0.044$ ; OR[95%CI]:0.84[0.70-0.99]) also demonstrated significant associations with STDR after adjustment for age, sex, HbA1c and presence of hypertension. None of these SNPs were associated with T2DM. **Conclusion:** We have successfully validated the significant and independent associations of several SNPs identified in previous GWAS with STDR in Chinese patients with T2DM. **Acknowledgement:** This study was supported by the Health and Medical Research Fund of the Food and Health Bureau, HKSAR (Project No. 03144016).

Mohlke<sup>1</sup>. 1) University of North Carolina, NC.1.Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA; 2) Department of Pediatrics, Division of Medical Genetics, Duke University, NC, USA; 3) Department of Medicine, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finl.

Epigenomic annotations can guide identification of regulatory variants at GWAS loci. We sought to functionally annotate cardiometabolic GWAS loci using adipose tissue chromatin accessibility and existing chromatin state data. We performed open chromatin profiling using ATAC-seq in the SGBS preadipocyte cell strain (2 replicates) and in frozen subcutaneous adipose tissue from 3 individuals from the METSIM study. We observed higher signal-to-noise and identified more ATAC-seq peaks in SGBS (~173,000-196,000) compared to adipose tissue (~36,000-58,000)(FDR<5%), which could reflect higher ATAC-seq efficiency in cells compared to frozen tissue. Compared to tissue-derived adipose nuclei promoter and enhancer chromatin states from the Epigenomic Roadmap, we observed more overlap with adipose tissue ATAC-seq peaks (85% of peak bases) than with SGBS ATAC-seq peaks (49% of peak bases). We tested for enrichment of GWAS loci for 11 cardiometabolic traits in our ATAC peaks and Roadmap adipose nuclei promoters and enhancers, controlling for gene proximity, allele frequency, and number of LD proxies. Loci for 6 traits, including waist-hip ratio adjusted for BMI, type 2 diabetes, and HDL, showed significant enrichment (Bonferroni  $P < 4 \times 10^{-4}$ ) in both SGBS and adipose tissue peaks. Loci for 4 traits (triglycerides, LDL, cardiovascular endpoints, blood pressure) were significantly enriched in tissue peaks but not SGBS, suggesting that these loci may act through mature adipocytes or other adipose tissue cell types such as immune cells, vascular endothelial cells, or fibroblasts. Eight traits showed a stronger enrichment in tissue or SGBS peaks compared to the Roadmap adipose nuclei enhancers, suggesting that chromatin accessibility can pinpoint disease-relevant subsets of enhancers. We next compared our ATAC-seq peaks to variants at 110 cardiometabolic GWAS loci with coincident adipose eQTLs. Of 6,746 LD proxies ( $r^2 > 0.8$ ) at these loci, 124 proxies at 52 loci overlapped both a tissue and SGBS peak, including 73 variants overlapping transcription factor motifs from JASPAR. Several of these motifs correspond to core adipose transcription factors, including PPARG, RXRA, ETS1, and RFX2. While a subset of cardiometabolic loci may act through non-adipocyte cells found in adipose tissue, our results suggest many loci may alter the function of preadipocyte active regulatory elements present in cell culture and primary tissue.

**Multivariate genome wide association study uncouples “favourable” from “unfavourable” adiposity alleles.** Y. Ji, J. Tyrrell, S. Jones, R. Beaumont, M. Tuke, K. Ruth, R. Freathy, A. Murray, M. Weedon, A. Wood, T. Frayling, H. Yaghoobkar. Institute of Biomedical and Clinical Science, University of Exeter Medical School, Exeter, UK.

It is not clear if higher adiposity itself, or the adverse metabolic effects of higher adiposity, increases susceptibility to diseases such as colorectal cancer, depression and osteoarthritis. We aimed to identify genetic variants associated with “favourable adiposity” as a tool to test the effects of higher adiposity independently of adverse metabolic effects on non-metabolic outcomes. First, we identified alleles associated with higher body fat % ( $P < 5 \times 10^{-8}$ ) using 220,000 individuals from UK Biobank and published studies. Next, we performed a multivariate genome wide association study (GWAS) using published GWAS summary statistics of biomarkers of metabolic health: HDL-C, Triglycerides, fasting insulin, adiponectin, SHBG and a marker of liver fat. We defined “favourable adiposity” alleles as those which (i) had a multivariate  $P < 5 \times 10^{-4}$  (multiple test corrected) and (ii) were associated with the multivariate model stronger than body fat % alone. The latter criterion was set to uncouple “favourable” from “unfavourable” adiposity alleles. To validate the variants, we calculated the protective effect of “favourable adiposity” genetic score against cardiometabolic diseases. We performed Instrumental Variable analysis (IV) to estimate the causal effect of “favourable adiposity” on non-metabolic outcomes available in UK Biobank. We identified 85 independent genetic variants associated with 1.66-6.44% standard deviation (SD) per allele differences in body fat% ( $P < 5 \times 10^{-8}$ ). The multivariate model uncoupled “favourable adiposity” (e.g. the *PPARG* allele) from “unfavourable adiposity” alleles (e.g. *FTO* allele). We defined 14 “favourable adiposity” alleles; 10 previously published. In the genetic score analysis, each allele was associated with a 0.068 Kg/m<sup>2</sup> higher BMI ( $p = 2 \times 10^{-62}$ ) but lower risk of type 2 diabetes (0.96 OR;  $2 \times 10^{-21}$ ), lower heart disease (0.98 OR;  $6 \times 10^{-8}$ ) and lower systolic blood pressure (-0.156 mmHg;  $1 \times 10^{-7}$ ). The IV analysis did not support causal association with depression, bone mineral density, bowel disease, cancer (any type) and osteoporosis (all  $P > 0.3$ ), but we could not exclude observational estimates of the associations. Our study supports the use of a multivariate analysis approach in identifying variants associated with higher body fat % but lower risk of cardiometabolic diseases. The identification of more “favourable adiposity” variants will provide additional power to test the role of higher adiposity without its adverse metabolic effects.

**Whole exome sequencing and exome array genotyping in 3,943 Korean type 2 diabetes cases and controls.** S. Kwak<sup>1</sup>, J. Chae<sup>2</sup>, S. Lee<sup>2</sup>, S.K. Choi<sup>2</sup>, T. Park<sup>3</sup>, K.A. Kim<sup>4</sup>, J. Kim<sup>2</sup>, K.S. Park<sup>1</sup>. 1) Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea; 2) Department of Biochemistry and Molecular Biology, Seoul National University College of Medicine, Seoul, South Korea; 3) Department of Statistics, Seoul National University, Seoul, South Korea; 4) Biostatistics and Clinical Epidemiology Center, Samsung Medical Center, Seoul, Korea.

Type 2 diabetes (T2D) is a common complex disorder with strong genetic predisposition. Although different ethnic groups share most of the common variants of T2D, there might be rare or low frequency nonsynonymous variants that are specific to an ethnic group. In this study, we used whole exome sequencing to identify rare variants in 917 Korean T2D cases and controls (stage 1) and validated the findings in an independent set of 3,026 T2D cases and controls using customized exome genotyping array (stage 2). Whole exome capture was prepared using Agilent SureSelect version 4+UTR and sequencing was performed by Illumina HiSeq 2000. Nonsynonymous variants were incorporated into customized Axiom Biobank Plus Genotyping array. Genotype imputation was performed with 1,000 Genomes Project phase 3 reference. EPACTS software was used for association testing and METAL was used for meta-analysis of stage 1 and 2 results. We identified 728,838 variants using whole exome sequencing, which include 258,463 novel variants. A nonsynonymous variant in *PAX4* (rs2233580, R192H) was the only variant that was associated with T2D in genome-wide significance (OR = 1.81,  $P = 6.36 \times 10^{-9}$ ). This variant was associated with lower age at diagnosis and decreased C-peptide level in T2D cases ( $P < 0.05$ ). Other nonsynonymous variants that had suggestive association ( $P < 1.0 \times 10^{-5}$ ) were located at *UVSSA*, *CRIPAK*, *GLP1R*, *TSPAN8*, *ARRDC2*, *KCNQ1*, *JMJD1C*, and *PLEKHG4B*. We also validated five known common variant loci (*MAEA*, *CDKAL1*, *PAX4*, *CDKN2A/2B*, and *KCNQ1*) to have genome-wide significant association in Koreans. Gene-wise analysis revealed that *SLC30A8* was most significantly associated with decreased risk of T2D ( $P = 0.00010$ ) by Madsen and Browning method. We constructed a weighted genotype risk score using 32 variants that were confirmed in East Asians. T2D cases had significantly increased genotype risk score compared to controls ( $4.26 \pm 0.51$  vs.  $3.98 \pm 0.53$ ,  $P = 1.32 \times 10^{-9}$ ). The genotype risk score was significantly associated with lower age at diagnosis, lower body mass index, decreased C-peptide level, and decreased renal function in T2D cases ( $P < 0.05$ ). It was also associated with increased HbA1c in controls ( $P < 0.05$ ). In summary, we have identified several nonsynonymous variants suggestive to be associated with T2D in Koreans and validated previously confirmed common variants and gene-wise association using exome sequencing and exome array genotyping.

**Identifying novel genetic variants associated with EHR-derived serum zinc in DiscovEHR study cohort.** R.P. Metpally, S. Krishnamurthy, D.T. Smelser, G.E. Breitwieser, D.C. Carey on behalf of the DiscovEHR collaboration. Department of Molecular and Functional Genomics, GEISINGER CLINIC, DANVILLE, PA.

**Background:** Zinc ( $Zn^{2+}$ ) is commonly measured in serum, and plays important roles in maintaining metabolism, cellular growth, wound healing, immune system and the breakdown of carbohydrates.  $Zn^{2+}$  is also needed for the senses of smell and taste.  $Zn^{2+}$  deficiency or overload can result in abnormal cellular function or damage. **Purpose:** Our goal was to evaluate the contribution of common genetic variation to normal physiologic variation in serum concentrations of the divalent metal. **Method:** We analyzed both whole exome sequencing (WES) and imputed Human Omni Express Exome bead-chip data from 2609 individuals with available outpatient serum  $Zn^{2+}$  values in the DiscovEHR cohort as described in Dewey et al 2016. We randomly split our data into two datasets to allow for discovery (70%) and replication (30%) by applying the two-step iterative resampling (TSIR) approach as described in Kang et al 2015. Mixed linear model based association analysis (MLMA) was performed on both the WES and imputed chip data using GCTA-v12.6 using median  $Zn^{2+}$  values. **Results:** A cut-off of discovering and replicating SNPs at least 20 times in 100 replications provided multiple variants associated with serum Zinc. Significant associations were found at two loci on 3q27.3 (most significant SNP rs7625980, P-value  $9e^{-09}$ ; *HRG* gene) and 2p22.2 (most significant SNP rs11678807, P-value  $1.18e^{-06}$ ; *VIT* nearest gene) from the imputed chip data. Coding variants from 3q27.3 locus were also identified from the WES analysis (most significant SNP rs1042445, P-value  $2.3e^{-08}$ ; missense variant of *HRG* gene). The 3q27.3 locus contains multiple genes including the Histidine Rich Glycoprotein (*HRG*) gene which has been found to play a major role in transport and homeostasis of zinc and other metals. **Conclusion:** Zinc, an HRG ligand is essential in regulating the many processes of HRG protein such as regulating immune complex and pathogen clearance. HRG protein have potential prognostic/diagnostic value for cancer and the absence of the protein is also known to be associated with thrombophilia. This study provides important insights into genetic association with serum  $Zn^{2+}$  and identified genes that probably have important role in regulation of serum  $Zn^{2+}$  levels.

**Evaluating tyrosine hydroxylase (*TH*) as a type 2 diabetes candidate gene in American Indians.** A. Nair, J. Sutherland, M. Traurig, S. Kobes, R. Hanson, C. Bogardus, L. Baier. National Institute of Diabetes and Digestive and Kidney Diseases, NIH, Phoenix, AZ.

We recently conducted a GWAS study in 7659 American Indians using a custom designed Affymetrix array. Among the top signals for type 2 diabetes (T2D) was rs10743152; this SNP had a significant sex interaction ( $P=0.0008$ ) such that the T2D association was only significant in females ( $P_{\text{FEMALES}}=4 \times 10^{-7}$ , OR=1.44). The nearest gene encodes tyrosine hydroxylase (*TH*) a rate limiting enzyme for the biosynthesis of catecholamines. Studies have shown a role of catecholamines, including dopamine, in the regulation of insulin secretion. Dopamine is synthesized in the beta-cells from circulating L-dopa and is co-secreted with insulin to provide a negative feedback loop for glucose stimulated insulin secretion in an autocrine manner. Based on the role of *TH* in dopamine synthesis, we hypothesized that *TH* may be the effector gene contributing to the T2D signal at rs10743152. Screening of the *TH* promoter identified two SNPs, rs10770140 (-581A/G) and rs10770141 (-824C/T) that are highly correlated ( $r^2=0.99$ ) with our GWAS lead SNP rs10743152. Both SNPs have previously been shown to influence *TH* promoter activity in chromaffin cells, and rs10770141 has been shown to disrupt a SRY binding site. *SRY* is a male specific gene located on the Y chromosome, which could potentially explain the sex specific association seen with rs10743152. Direct genotyping of these 2 promoter SNPs identified an association with T2D only in females ( $P_{\text{T2D}} < 1 \times 10^{-6}$ ,  $P_{\text{Sex Interaction}} < 0.001$ ). Based on the role of catecholamines in the regulation of blood pressure, we also analyzed the association of rs10770141 with hypertension and identified a significant association only in females ( $P_{\text{FEMALES}}=0.0007$ , OR=1.28). *TH* and *SRY* gene expression analyses using a human cDNA panel and pancreatic cell lines (NIT-1, NIT-2,  $\alpha$ -TC6, 266-6 and AR42J) confirmed that *TH* is expressed in human pancreas and pancreatic cell lines, while *SRY* was detected in human pancreas and rat AR42J acinar cells. For functional studies, we cloned 1500 bps of the *TH* promoter, which contains 8 SNPs and forms 4 haplotypes (Hap 1-4), proximal to the luciferase gene in a pGL4.10 vector. All 4 haplotypes were examined in luciferase assays using NIT-1 beta-cells and a significantly higher luciferase activity was observed for Hap 1 and 3 compared to Hap 2 and 4. Hap 1 includes the diabetes risk alleles for rs10770141 and rs10770140. Further studies to identify the functional SNPs in Hap 1 and Hap 3 and to determine the effect of *SRY* are ongoing.

**Background:** Insulin resistance (IR) is mainly defined by a progressive impairment in insulin-stimulated uptake of circulating glucose. IR is an important risk factor for type 2 diabetes and cardiovascular disease. Metabolic challenges like the oral glucose tolerance test (OGTT) can reveal early pathogenic mechanisms not apparent in the fasting state. **Methods:** We studied 470 non-diabetic 71-year-old men in whom plasma samples obtained at 0 min, 30 min and 120 min during a 2-hour-OGTT were analyzed by untargeted metabolomics (ultraperformance liquid chromatography-time-of-flight mass spectrometry). IR was assessed by whole-body glucose uptake measured by hyperinsulinemic-euglycemic clamp. Our aim was to discover associations between IR and 192 metabolite trajectories during OGTT. **Results:** Nine trajectories were associated with IR. The most significant associations were observed for the medium-chain acylcarnitines C10 and C12. No associations between IR and OGTT trajectories were detected for short- or long-chain acylcarnitines. Concentrations of C10- and C12-carnitine decreased during OGTT in all men, but the decline was blunted in the most insulin resistant compared to more insulin sensitive persons. Acylcarnitines are intermediates of lipid metabolism and enable the transfer of activated fatty acids into mitochondria for beta-oxidation. Conflicting theories on their potential contribution to IR exist. To explore a possible causal role for medium-chain acylcarnitines in IR, we exposed murine 3T3-L1 adipocytes to different acylcarnitine species. We found evidence of blunted insulin-stimulated glucose uptake after exposure to C10- or C12-carnitine compared to other acylcarnitines and the control condition. **Conclusions:** These results suggest a possible causal role of C10- and C12-carnitine in the development of IR and highlight the importance of perturbation studies when dissecting complex polygenic traits.

**1809F**

**A rare frameshift mutation in exon 9 of glucokinase regulator (GCKR) is associated with a severe progressive histological form of Nonalcoholic Fatty Liver Disease (NAFLD).** C.J. Pirota<sup>1</sup>, T. Fernandez Gianotti<sup>1</sup>, H. Dopazo<sup>2</sup>, C. Rohr<sup>3</sup>, G. Castaño<sup>3</sup>, S. Sookoian<sup>1</sup>. 1) IDIM. University of Buenos Aires-CONICET, CABA, Buenos Aires, Argentina; 2) Biomedical Genomics and Evolution Laboratory. University of Buenos Aires-CONICET; 3) Liver Unit, Medicine and Surgery Department, Hospital Abel Zubizarreta, GCBA.

**Background:** Significant progress towards understanding the genetic component of NAFLD has been made, which uncovered common variants associated with small effects in the disease susceptibility. Exploration of plasma metabolome revealed that patients with NAFLD and Metabolic Syndrome show deregulated levels of amino acids, including enhanced glutamic acid/glutamine ratio. NAFLD is associated with changes in the expression of mitochondrial genes of the oxidative phosphorylation chain, as well as metabolic perturbations at the Krebs cycle (TCA)-level. We hypothesized that rare disease-associated variants in metabolic enzyme genes might be involved in NAFLD development. We performed an exploration of sequence variation in fourteen genomic loci that encode metabolic enzymes of the TCA-cycle, which included enzymes of the mitochondrial-matrix involved in glutamine and glutamate metabolism (*GLUD1/GLUD2/GLUL/GLS*), *ACO2* (second step of the TCA-cycle), *DLST* (2-oxoglutarate-dehydrogenase complex), isocitrate (*IDH1/IDH2/IDH3A/IDH3B*), malate and oxoglutarate dehydrogenases (*MDH1* and *OGDH*), and glucokinase regulator (*GCKR*). **Methods:** Sequencing of exons, exon-intron boundaries and 5' and 3'-UTR regions (62.1 Kb) was performed by next generation sequencing (> 60X coverage). Patients with NAFLD diagnosed by liver biopsy were included ( $n = 64$ ); subjects without NAFLD ( $n = 32$ ) served as controls. **Results:** Deep sequencing revealed 132 single nucleotide polymorphisms (SNPs), including 17 novel SNPs. Clinical associations focused on nonsynonymous-SNPs showed a rare frameshift-mutation in exon 9 of *GCKR* (rs149847328 p.Arg227Ter, MAF<0.001) in a 48-years old patient with NAFLD, who had personal/family history of diabetes and hypertension in youth. Analysis of paired-liver biopsies at baseline and follow-up (5-years apart) showed progression of liver fibrosis from stage 0 to cirrhosis. Functional variant effect-prediction showed a high probability of deleterious effect (this variant introduces a stop-codon). **Conclusions:** The NAFLD phenotype could be modulated by rare variants, in particular its metabolic profile. *GCKR*, which is considered a susceptibility candidate gene for the Maturity-Onset Diabetes of the Young (MODY), might be involved in the pathogenesis of NAFLD. A search for this mutation might be recommended in NAFLD patients, particularly if they are young, and have family history of diabetes and hypertension.

Florez<sup>2,3</sup>.* 1) University of California, San Diego, La Jolla, CA; 2) Broad Institute of MIT and Harvard, Cambridge, MA; 3) Massachusetts General Hospital, Boston, MA; 4) Boston Children's Hospital, Boston, MA; 5) Helsinki University Hospital, Finland; 6) Folkhälsan Research Center, Finland; 7) University of Toronto, Canada; 8) SickKids, Toronto, Canada; 9) University of Utah, Salt Lake City, Utah; 10) Joslin Diabetes Center, Boston, MA; 11) The University of Edinburgh, Scotland; 12) University of Virginia, Charlottesville, VA; 13) University of Michigan, Ann Arbor, MI; 14) University of Pennsylvania, Philadelphia, PA; 15) University College Dublin, Ireland; 16) Queen's University Belfast, Belfast, United Kingdom.

Diabetic kidney disease (DKD) is a common and devastating complication affecting ~40% of those with type 1 diabetes (T1D). DKD is the leading cause of end stage renal disease (ESRD) and a significant independent risk factor for cardiovascular disease. No cure for DKD exists, although optimal glucose control may slow progression. Although there is strong evidence of a genetic component to DKD (heritability ~35% in persons with T1D), few DKD loci have been consistently identified. To enhance genetic discovery, we performed the largest genome-wide association study (GWAS) to date for DKD in 19,491 European ancestry participants with T1D, drawn from 20 individual cohorts genotyped on the Illumina HumanCoreExome BeadArray. We identified two novel loci attaining genome-wide significance, both in plausible candidate genes. SNP rs55703767, a common (MAF=21%) missense mutation in *COL4A3*, is associated with DKD defined by either macroalbuminuria or ESRD in T1D (OR = 0.80; P = 5.7 x 10<sup>-10</sup>; P<sub>het</sub> = 0.92). This variant is associated with both macroalbuminuria alone (OR = 0.79; P = 1.6 x 10<sup>-7</sup>; P<sub>het</sub> = 0.94) and ESRD alone (OR = 0.81; P = 3.4 x 10<sup>-5</sup>; P<sub>het</sub> = 0.95), although not at genome-wide levels of significance. *COL4A3* encodes the alpha 3 subunit of Type IV collagen, a major structural component of basement membranes, particularly in the kidney. Pathogenic risk variants in *COL4A3* have been previously associated with thin basement membrane nephropathy, Alport Syndrome, and Goodpasture Syndrome. The second SNP, rs5872572, an infrequent variant (MAF = 4.3%), lies in a region near *EBF1*, a gene annotated as an enhancer in the kidney. This SNP is protective against macroalbuminuria (OR = 0.57, P = 1.1 x 10<sup>-5</sup>; P<sub>het</sub> = 0.18). The *EBF1* gene is an essential transcription factor in postnatal glomerular maturation, and the murine *Ebf1* knockout exhibits phenotypes similar to human DKD, including decreased glomerular filtration rate, albuminuria, and morphological kidney damage. These mice also have improper glomerular basement membrane differentiation with decreased *COL4A3* expression. Our work is the first to identify genome-wide significant loci associated with DKD or macroalbuminuria in T1D. Both genes implicated in DKD are key determinants of glomerular basement membrane function, suggesting that this aspect of kidney biology should be a focus of future research on the pathology, prevention, and treatment of DKD.

**Diabetome: A comprehensive collection of diabetes phenotype and genotype data.** *S. Shah<sup>1</sup>, R.M. Anjana<sup>2</sup>, S. Jebaran<sup>2</sup>, V. Srinivasan<sup>1</sup>, V. Radha<sup>2</sup>, R. Praveen<sup>1</sup>, B. Muthu Narayanan<sup>1</sup>, R. Pradeepa<sup>2</sup>, R. Unnikrishnan<sup>2</sup>, J. Somasekar<sup>1</sup>, S. Sumit<sup>1</sup>, G. Rohit<sup>1</sup>, S. Santhosh<sup>1</sup>, V. Mohan<sup>2</sup>.* 1) MedGenome Inc. Foster City, CA; 2) Madras Diabetes Research Foundation & Dr.Mohan's Diabetes Specialities Centre, Chennai India.

Diabetes is a chronic disorder of glucose metabolism, with complications including cardiovascular and end-stage renal disease, blindness, nontraumatic lower-extremity amputations, and premature mortality. It is a complex disease with many contributing genetic and environmental factors. Epidemiological and genetic studies, using large patient cohorts, with comprehensive phenotype, genotype and family pedigree information are needed to uncover novel mechanisms of diabetes complication and develop improved disease management and treatment strategies. Here we present the Diabetome Knowledgebase, a large database of diabetes-related phenotype and genotype data, that contains over 300,000 diverse patient records, including well-characterized clinical characteristics, biochemical results, family and treatment history, drug responses, genotype mapping, as well as secondary complications of diabetes, spanning over 25 years. In addition, whole genome or whole exome sequence data is also available for about 2500 patients with or without microvascular complications. The platform also provides analytical tools to facilitate data interpretation and analysis by conducting customized statistical analyses on large-scale patient data, to gain useful research insights and to identify patient cohorts for clinical trials and research studies. Findings from association studies using available information providing new insights into the biology, disease etiology, and a richer understanding of population-specific genetic and environmental risk factors, will be presented.

**Measures of body composition and muscle fitness associate with non-alcoholic fatty liver disease (NAFLD).** E.K. Speliotes<sup>1</sup>, A.P. Wright<sup>2</sup>, V. Chen<sup>2</sup>, Y. Chen<sup>2</sup>, B.D. Halligan<sup>2</sup>. 1) Dept of Internal Med, Gastroenterology & Dept of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 2) Dept of Internal Med. Gastroenterology, University of Michigan, Ann Arbor, MI.

**Background:** Up to 25% of patients with NAFLD are not obese but may have abnormalities in body composition or muscle fitness that contribute to NAFLD. **Methods:** We investigated the effects of dual-energy X-ray absorptiometry (DXA) derived measures of body composition (appendicular lean mass (ALM)/height<sup>2</sup>, central fat mass/height<sup>2</sup>, and lower extremity fat mass/height<sup>2</sup>), and grip and quadriceps strength measurements on computed tomography (CT) measured NAFLD in cross sectional data from 1306 individuals with all these measures in the population based Framingham Heart Study using logistic regression. We tested reported genetic variants that affect body composition and muscle fitness for effects on 7176 individuals with CT measured NAFLD. **Results:** 356 subjects (27%) had NAFLD based on imaging criteria. Subjects with NAFLD were more often male (64% vs. 50%), had diabetes (16.9% vs. 3.9%), hypertension (51.6% vs. 22.1%), and metabolic syndrome (52.9% vs. 15.2%) than patients without NAFLD;  $p < 0.0001$  for all comparisons. Subjects with NAFLD had lower skeletal mass index (58.4 vs. 63.2 kg/kg), and greater indices of appendicular lean mass (8.4 vs. 7.5 kg/m<sup>2</sup>), total lean mass (18.6 vs. 16.7 kg/m<sup>2</sup>), total body fat (12.2 vs. 8.8 kg/m<sup>2</sup>), lower extremity fat (3.6 vs. 2.9 kg/m<sup>2</sup>), and central fat (2.2 vs. 1.9 kg/m<sup>2</sup>);  $p < 0.0001$  for all comparisons. Across both genders there was no difference in quadriceps or hand grip strength between patients with and without NAFLD; however, males with NAFLD had weaker hand grip strength (45.9 vs. 47.9 kg,  $p = 0.004$ ) and females with NAFLD had weaker quadriceps strength (24.6 vs. 26.2 kg,  $p = 0.04$ ). On multivariate logistic regression, central fat/height<sup>2</sup> (OR 2.22 95% CI (1.95-253)) and ALM/height<sup>2</sup> (OR 1.39 95% CI (1.15-1.63)) are positively associated with NAFLD, while lower extremity fat/height<sup>2</sup> (OR 0.59 95% CI (0.48-0.71)), quadriceps strength (OR 0.98 95% CI (0.97-0.99)), and hand grip strength (OR 0.97 95% CI (0.95-0.99)) are negatively associated with NAFLD. rs6689335 near LYPLAL1 that associates with waist-to-hip ratio at genome wide levels also associates with NAFLD ( $P < 0.05$ ). **Conclusions:** Higher ALM was associated with NAFLD. Central fat is positively and lower extremity fat, quadriceps strength, and hand grip strength are negatively associated with NAFLD. Genetic influences on central fat distribution also associate with NAFLD.

**Background** Fatty acid binding protein (FABP4), estimated  $h^2=0.38$ , is produced by adipocytes and has been implicated in cardiovascular disease (CVD), type 2 diabetes (T2D), obesity, kidney function, and insulin resistance. A functional mutation in *FABP4* that reduces expression in adipocytes and plaques, has been associated with lower T2D risk and reduced visceral fat. Preclinical studies suggest that FABP4 inhibition may lower cardiometabolic disease risk. To further explore the genetic architecture of plasma FABP4 levels, we performed a GWAS meta-analysis and evaluated its genetic correlation to associated traits. **Methods** We meta-analyzed up to 8,270 individuals from 5 studies of plasma FABP4 measurements with 1000G-imputed data using a fixed-effects model. As FABP4 is strongly associated with BMI and estimated glomerular filtration rate (eGFR), we tested three models: 1) adjusted for age, sex, and principal components; 2) model 1 plus BMI; and 3) model 2 plus eGFR. To increase power of discovery, we performed gene-based analyses using MAGMA. To better understand the etiology of FABP4 levels, we used LD score regression (LDSC) to assess genetic correlation with BMI, kidney function and disease, glucose and insulin levels, CVD, and T2D. **Results** After correction for BMI, we identified two independent loci associated with plasma FABP4 near *FABP4* at 8q21.13. The novel lead variant was rs72684477[A] with  $\beta(\text{se})=-0.09(0.02)$ ,  $p=3.5 \times 10^{-8}$ , EAF=0.18. The previously described functional mutation (rs77878271[G],  $\beta(\text{se})=-0.23(0.04)$ ,  $p=4.5 \times 10^{-8}$ , EAF=0.03) was also independently associated with FABP4 levels. Model 3 yielded similar results. Gene-based analysis identified 5 genes associated with FABP4 levels ( $p < 2.5 \times 10^{-6}$ ), including *FABP4*, *JADE1*, *SCLT1*, *STK36*, and *MOB2*. We applied LDSC revealing a correlation with BMI ( $r^2(\text{se})=0.56(0.16)$ ,  $p=4.0 \times 10^{-7}$ ) and nominal correlations with CVD, T2D, and chronic kidney disease ( $p < 0.03$ ) in model 1. In model 2, the strongest correlation was with serum creatinine levels ( $p=5.5 \times 10^{-5}$ ) and nominally with CVD ( $p=0.03$ ); no correlation was seen for model 3. **Conclusions** Two independent loci at 8q21.13 (one novel rs72684477) are associated with plasma FABP4 in models corrected for BMI and eGFR. LDSC suggests that FABP4 levels are partly modulated by loci also associated with BMI and kidney function. Given the estimated heritability of FABP4 plasma levels, including more samples in future meta-analyses of GWAS is likely to identify even more loci.

**1814T**

**Systemic approach to understand human non-alcoholic fatty liver disease.** T. Yoo<sup>1</sup>, Y. Lee<sup>1</sup>, S.K. Joo<sup>2</sup>, W. Kim<sup>2</sup>, M. Choi<sup>1</sup>. 1) Department of Biomedical Sciences, Seoul National University College of Medicine, Seoul, South Korea; 2) Department of Internal Medicine, Seoul National University Boramae Medical Center, Seoul, Republic of Korea.

Non-alcoholic fatty liver disease (NAFLD) features accumulation of fat in liver. NAFLD can be simply divided into 2 groups - non-alcoholic steatohepatitis (NASH) and simple steatosis (SS) - based on the degrees of liver damage and inflammation. However, the diagnostic criteria, molecular pathogenesis and prognosis mechanisms of the disease still need further investigation. To understand the molecular queues that differentiate pathogenesis and exacerbation of the disease, we collected ~100 human liver biopsy samples from Korean individuals and subjected them into the expression quantitative trait loci (eQTL) analysis through generating genome-wide gene expression and SNP genotyping data. The liver samples used in the analysis were divided into several groups according to their pathologic scores including fibrosis, steatosis and other inflammatory features. Among the 1,971 significantly differentially expressed genes (DEG), 64 DEGs were associated with significant cis-eQTL, and 3,197 significant trans-eQTL directed expression of 630 DEGs ( $P < 2.2 \times 10^{-16}$ ). Notably, distinct associations involving several trans-eQTL regulating immunoglobulin chains implicates genetic association between immune components and NAFLD pathophysiology. Through a series of conditional association tests, we are to identify the genotype-expression-phenotype relationships of variations in the immune loci and how they might induce the disease phenotype. This study will lead to the elucidation of molecular and functional immune mechanisms of human liver disease and potentially discovery of novel therapeutic targets of the disease.

**Expanding the spectrum of type 2 diabetes risk alleles through a genome-wide association study imputed to the Haplotype Reference Consortium Panel.** D. Taliun<sup>1</sup>, A. Mahajan<sup>2</sup> on behalf of the DIAMANTE, AMP-T2D, and DIAGRAM Consortia. 1) Department of Biostatistics and Center for Statistical Genetics, University of Michigan, Ann Arbor, MI, USA; 2) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, UK.

To identify and characterize genetic loci associated with type 2 diabetes (T2D), we conducted the largest meta-analysis of T2D genome-wide association studies (GWAS) to date in Europeans. We aggregated data on 50,160 T2D cases and 465,272 controls from 24 GWAS, each imputed up to HRC reference panel or study-specific reference panel of whole-genome sequences. We combined association summary statistics at >20M genetic variants across studies in a fixed-effects inverse-variance weighted meta-analysis. We performed approximate conditional analyses to identify distinct signals of T2D association within 500kb of each lead variant attaining genome-wide significance ( $p < 5 \times 10^{-8}$ ). We estimated the genetic correlations between T2D and a range of phenotypes with publically available GWAS summary statistics using LD score regression. Initial analyses revealed 105 loci at genome-wide significance, 38 of which did not overlap with established T2D susceptibility loci. The minor allele frequency (MAF) of lead variants at the 38 novel loci ranged from 2.7% to 46.3%; only the lead variant rs11820019 near *CCND1* gene had MAF < 5% (MAF = 2.7%,  $p = 4.8 \times 10^{-8}$ , OR = 1.17 [1.11-1.23]). Conditional analyses revealed 44 additional (3 rare MAF < 0.5%; 12 low-frequency MAF < 5%) distinct association signals ( $p < 10^{-5}$ ) across the loci including 2 low-frequency variants at *TCF7L2* (rs182771291, MAF = 0.4%,  $p = 1 \times 10^{-8}$ , OR = 1.64 [1.40-1.93] and rs142511108, MAF = 1.1%,  $p = 3 \times 10^{-6}$ , OR = 1.24 [1.14-1.35]). Applying LD score regression, we confirmed the previously observed genetic correlations between T2D and obesity, fasting glucose, birth weight, lipids, and cardiovascular disease. In addition, we found novel negative genetic correlations with age of first birth ( $p = 1 \times 10^{-28}$ ), age at menarche ( $p = 3 \times 10^{-13}$ ), and father's age at death ( $p = 3 \times 10^{-7}$ ), and positive correlations with several metabolites including isoleucine ( $p = 3 \times 10^{-6}$ ) and glycoprotein acetyls ( $p = 3 \times 10^{-6}$ ). Our findings demonstrate that larger samples and reference panels continue to identify additional T2D variants, but that nearly all identified variants are common, suggesting the preponderant impact of common variants on T2D risk.

**Profiling of the long non-coding RNA (lncRNA) *MALAT1* in the liver of patients with nonalcoholic fatty liver disease (NAFLD) shows association with an aggressive histological phenotype.** S. Sookoian<sup>1</sup>, M.E. Garaycochea<sup>2</sup>, D.G. Rodriguez<sup>2</sup>, C. Gazzari<sup>3</sup>, G. Castano<sup>4</sup>, D.M. Flichman<sup>5</sup>, C.J. Pirola<sup>6</sup>.

1) Clinical and Molecular Hepatology, Institute of Medical Research (IDIM), School of Medicine, Buenos Aires University and National Scientific and Technical Research Council (CONICET), Buenos Aires, Argentina; 2) Hospital de Alta Complejidad en Red El Cruce, Buenos Aires, Argentina; 3) Department of Pathology, Institute of Medical Research A Lanari, School of Medicine-University of Buenos Aires, Buenos Aires Argentina; 4) Medicine and Surgery, Liver Unit, Hospital Abel Zubizarreta, Buenos Aires, Argentina; 5) Department of Virology, School of Pharmacy and Biochemistry, University of Buenos Aires and National Scientific and Technical Research Council (CONICET), Buenos Aires, Buenos Aires, Argentina; 6) Molecular Genetics and Biology of Complex Diseases, Institute of Medical Research (IDIM), School of Medicine, University of Buenos Aires and National Scientific and Technical Research Council (CONICET), Buenos Aires, Argentina.

**Background:** lncRNAs orchestrate gene expression by modulating a plethora of molecular pathways. To identify lncRNAs involved in NAFLD severity we performed a multi-stage study that included: a) a systems biology screening-strategy, b) exploration of lncRNA-mRNAs interactions, and c) expression profiling of selected lncRNAs. **Methods:** Mining of biological interactions was performed by VisANT platform; lncRNA2Target dataset was used to predict lncRNAs-target genes interactions. Liver profiling of a candidate lncRNA was performed by qRT-PCR ( $n=81$ ); *RPL19* was used for data normalization. Patients were selected from two different hospital-based settings, a cohort of morbid-obese subjects who underwent bariatric surgery (discovery-set) and a cross-sectional study of patients with NAFLD and MetSyn (replication-set). The histological phenotype was characterized by liver biopsy. **Results:** The NAFLD-interaction network yield a list of 494 genes; prioritization of mRNA-lncRNAs interactions showed ten candidate-lncRNAs potentially involved in gene expression regulation. Based on assessment of tissue-specific and co-expression patterns, we selected for further exploration the lncRNA *MALAT1* (metastasis-associated lung adenocarcinoma transcript 1), a ~7kb single-exon transcript located in Chr 11q13 that is highly conserved across species. We found that *MALAT1*, which is involved in regulation of cell-cycle and tumorigenesis, is constitutively expressed in the liver. However, liver abundance of *MALAT1* was significantly associated with NAFLD severity ( $p=0.00011$ ). Specifically, liver-*MALAT1* expression was significantly up-regulated by 1.75-fold ( $p=0.029$ ) and 5.81-fold ( $p=0.0038$ ) in patients with NASH compared with simple steatosis (SS) (discovery and replication set, respectively, ANCOVA adjusted by age, HOMA and BMI). *MALAT1*-expression levels significantly correlate with the full spectrum of histological severity, including the degree of steatosis ( $R: 0.47$   $p=0.000007$ ) and fibrosis ( $R: 0.45$   $p=0.00002$ ). Exploration of liver *VEGF $\alpha$* -mRNA, a proangiogenic factor driving tumor angiogenesis, which is a target of *MALAT1*, showed levels of both transcripts positively correlated ( $R: 0.59$ ,  $p=0.00002$ ). **Conclusion:** This step-wise analysis of lncRNAs uncovered *MALAT1* as implicated in the molecular pathogenesis of NASH. Dysregulated expression of *MALAT1* seems to tip the transition from simple steatosis to a more aggressive phenotype. The AUROC for distinguishing NASH from SS was  $0.84\pm 0.07$ .

**Multifactor dimensionality reduction (MDR) method to study association of type 2 diabetes mellitus with *ENPP1* (K121Q), *TCF7L2* (G>T) and *GYS1* (A1>A2) gene variants in Punjabi population, India.** B. Doza<sup>1</sup>, B. Barna<sup>2</sup>, A.J.S. Bhanwer<sup>3</sup>, K. Matharoo<sup>3</sup>, M. Kaur<sup>3</sup>. 1) Aligarh Muslim University Murshidabad Centre, Murshidabad, West Bengal, India; 2) Guru Nanak Dev University, Amritsar, Punjab; 3) Government Medical College, Amritsar, Punjab.

**Introduction:** The Multifactor Dimensionality Reduction (MDR) method detects and characterizes high order gene-gene interactions in case-control studies. The MDR method is model free and it does not assume any particular genetic model. Despite its high importance almost no study is available with this model approach to detect the status of T2DM Punjabi population. Hence, the present study tested the hypothesis that T2DM related gene variants (*ENPP1* (K121Q), *TCF7L2* (G>T) and *GYS1* (A1>A2)) contribute to etiology of type 2 diabetes mellitus in the Punjabi population or not. **Material and Methods:** It was a case control study in Punjabi population. A total of 500 subjects (250 T2DM patients and 250 controls) have been recruited from different clinical centers of Punjab and unrelated healthy controls were also selected from the same community and area. The entire data were analyzed with respect to three most important candidate gene polymorphisms such as *ENPP1* (K121Q), *TCF7L2* (G>T) and *GYS1* (A1/A2). **Results:** The present study found a strong association of *ENPP1* and *TCF7L2* variant with T2DM in Punjabi population but an insignificant association of the XbaI (A1>A2) polymorphism in *GYS1* with T2DM. The MDR analysis effectively found evidence for a significant gene-gene interaction among the three loci (*ENPP1*-K121Q, *TCF7L2*-G>T and *GYS1*-A1>A2) for pooled (male and female) T2DM patients and non-diabetic controls; two loci (*GYS1*-A1>A2 and *TCF7L2*-G>T) for males and two loci (*ENPP1*-K121Q and *GYS1*-A1>A2) for females among T2DM patients and non-diabetic controls. **Conclusion:** The present study showed MDR method to be effective in detecting multi-genetic interaction among different loci. It is suggested that gene-gene interaction is ubiquitous in determining the susceptibility of complex human diseases. Further studies on epistatic interactions are warranted to elucidate their possible underlying role in pathogenesis of T2DM.

**1818F****A type 1 diabetes genetic risk score developed in Europeans discriminates between type 1 and type 2 diabetes in South Asian Indians in India.**

J. Harrison<sup>1</sup>, D.S.P Tallapragada<sup>2</sup>, S. Sharp<sup>1</sup>, K.A. Patel<sup>1,3</sup>, A.T. Hattersley<sup>1,3</sup>, G. Chandak<sup>2</sup>, C.S. Yajnick<sup>4</sup>, R. Oram<sup>1,3</sup>, M.N. Weedon<sup>1</sup>. 1) Institute of biomedical and clinical science, University of Exeter Medical School, Exeter, Devon, United Kingdom; 2) CSIR-Centre for Cellular and Molecular Biology (CSIR-CCMB), Hyderabad, 500 007, India; 3) National Institute for Health Research Exeter, Clinical Research Facility, Exeter, UK; 4) KEM Hospital, 489 Rasta Peth, Sardar Moodliar Road, Pune, 411011, India.

Many young adult patients with diabetes receive incorrect treatment because the type of diabetes they have is misdiagnosed and the problem is increasing with rising obesity rates. Misclassification is a particular problem in individuals of South Asian ancestry due to the high prevalence of early-onset Type 2 diabetes (T2D). Type 1 diabetes (T1D) patients require insulin treatment whereas patients with T2D or monogenic diabetes are often best treated with diet or tablets. We have previously shown that a T1D genetic risk score made up of 30 SNPs can be a useful tool for aiding the discrimination of T1D and T2D in Europeans. The aim of this study was to determine whether the T1D GRS discriminates T1D from T2D as well in South Asians as it does in white Europeans? We used two cohorts in this study: Indo-Europeans from Pune, India (clinically diagnosed) T1D (n=176), T2D (n=344), controls (n=171) and individuals of European ancestry (EUR) in UK Biobank (UKBB) T1D(n=251), T2D(n=6,357), controls(n=139,652). We genotyped 9 SNPs that capture the majority of the discriminatory ability of the T1D GRS. Comparison of individuals of European and South Asian ancestry showed that the background T1D GRS scores are significantly different between these two ethnic groups: (med(IQR)) controls Pune (0.65(0.62-0.71)) v UKBB EUR (0.63 (0.54-0.71)) p<0.0001, T2D cases UKBB EUR (0.63(0.55-0.72)) v Pune (0.64(0.60-0.70)) p=0.0016, T1D cases UKBB EUR (0.80(0.73-0.88)) v Pune (0.75(0.67-0.80)) p<0.0001. The T1D GRS was highly discriminative of T1D (AUC (95% CI)) 0.80 (0.75-0.84) in South Asians, but the ROC-AUC was significantly lower than in Europeans 0.86(0.84-0.88) p=0.0094. HLA variants alone were an independent predictor of T1D: 0.76 (0.72-0.81) but the T1D GRS performed better than an HLA score alone HLA v T1D GRS: 0.76(0.72-0.81) v 0.80(0.75-0.84), p=0.0001. The discriminative power of the HLA only score was significantly lower in the Pune cohort than in the European cohort Pune v EUR: 0.76(0.72-0.81) v 0.84(0.82-0.87), p=0.0026. We have shown a T1D GRS using SNPs defined in Europeans is still highly discriminative of T1D in South Asians despite genetic risk of T1D differing between the two populations. Refining the T1D-GRS for individuals of South Asian ancestry may increase the discriminative power. The T1D-GRS will be useful for classifying T1D in South Asian groups and help to ensure the correct treatment is given to patients diagnosed with diabetes.

**1819W****Genetic factors influencing glycosylated hemoglobin, fasting glucose, and fasting insulin levels in the Population Architecture using Genomics and Epidemiology Study.**

H.M. Highland<sup>1</sup>, S. Bien<sup>2</sup>, Y.M. Patel<sup>3</sup>, M. Graff<sup>4</sup>, A. Vishnu<sup>4</sup>, B. Lin<sup>5</sup>, R. Tao<sup>6</sup>, D. Lin<sup>5</sup>, K.L. Loos<sup>4</sup>. 1) Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA; 3) Keck School of Medicine, University of Southern California, Pasadena, CA; 4) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY; 5) Department of Biostatistics, University of North Carolina, Chapel Hill, NC; 6) Department of Biostatistics, Vanderbilt University Medical Center, Nashville, TN; 7) Department of Medicine, the Alpert Warren Medical School, Brown University, Providence, RI; 8) Brown Center for Global Cardiometabolic Health and Department of Epidemiology, Brown University, Providence, RI; 9) Atlanta Vanguard Clinical Center, Atlanta, GA; 10) Albert Einstein College of Med, Bronx, NY; 11) Institute for Translational Genomics and Population Sciences, LABiomed/Harbor-UCLA Medical Ctr, Torrance, CA; 12) National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 13) Department of Genetics, Rutgers University, Piscataway, NJ; 14) Department of Statistics and Biostatistics, Rutgers University, Piscataway, NJ; 15) Division of Epidemiology and Community Health, University of Minnesota, Minneapolis, MN.

There are notable disparities in risk of type 2 diabetes (T2D) across ancestrally diverse populations. Knowledge of the genetic basis of related biomarkers for T2D-related traits, such as fasting glucose (FG), fasting insulin (FI) and glycosylated hemoglobin (HbA1c), is very limited in ancestrally diverse populations. In primarily European descent populations, nearly 100 loci have been identified for FG, FI, and HbA1c. Elevated levels of fasting glucose and fasting insulin precede the development T2D. To better understand the genetic basis of glucose dysregulation, the Population Architecture using Genetic Epidemiology (PAGE) Consortium genotyped 12,801 Hispanic/Latinos, 5,696 African Americans, 1,405 Native Hawaiians, 398 Native Americans, and 1,727 Asians without diabetes using the Multi-Ethnic Global Array (MEGA). This platform is enriched for coding variation and ancestrally diverse markers to improve the imputation of allelic dosages unmeasured variants across admixed populations. We performed imputation using 1000 Genomes Phase 3 reference panel, resulting in 40 million well-imputed variants. The association of these variants with FG, FI and HbA1c were tested using a GEE model that accounts for relatedness of individuals in our ancestry-combined samples. We identified a potentially novel association for HbA1c with variants near *KLHL29* ( $P = 4.0 \times 10^{-11}$ ). Other associations with HbA1c included the sickle cell anemia variant (rs334) in *HBB*, and an association with a *G6PD* variant known to cause X-linked hemolytic anemia (rs1050828,  $P_{\text{women}} = 5.05 \times 10^{-62}$ ,  $P_{\text{men}} = 5.08 \times 10^{-99}$ ), further highlighting the importance of both variation in hemoglobin genes and variants impacting red-blood cell lifespan when using HbA1c as a measure of glycemic control. Novel associations for FG include variants in *HDAC9* (rs118084662,  $P = 1.9 \times 10^{-5}$ ) and *DHRS7B* (rs540671238,  $P = 2.9 \times 10^{-5}$ ). We also replicated several known associations between FG and variants near *G6PC2*, *GCKR*, *MTNR1B*, and *FOXA2*. We observed a novel association between FI and intergenic variant rs116210206 ( $P = 7.8 \times 10^{-5}$ ) near the known *GRB14/COBLL1* locus. Further analyses including SNP by BMI interaction and gene-based tests of rare variants are underway. These additional tests will increase power to detect associations with ancestry-specific rare variants. Despite a modest sample size, we have identified novel associations with glycemic traits, in large part due to the diverse ancestral composition of the PAGE sample.

**1820T****Association study of ENPP1 (K121Q), TCF7L2 (G>T), GYS1 (A1/A2) variants with type 2 diabetes mellitus (T2DM) in north Indian Punjabi population.**

*M. Kaur*<sup>1</sup>, *B. Doza*<sup>2</sup>, *B. Barna*<sup>3</sup>, *A.J.S. Bhanwer*<sup>3</sup>, *K. Matharoo*<sup>3</sup>.  
1) Government Medical College, Amritsar, Punjab, India; 2) Aligarh Muslim University Murshidabad Centre, Murshidabad, India; 3) Guru Nanak Dev University, Amritsar, Punjab, India.

**Introduction:** Over past decades genetic and genome wide association study (GWAS) on *ENPP1* (K121Q), *TCF7L2* (G>T), *GYS1* (A1/A2) have suggested a possible relationship between allele and genotype frequencies and pathogenesis of type 2 diabetes mellitus (T2DM). The purpose of this study was to confirm the reported association between these variants and increased risk of type 2 diabetes mellitus in north Indian Punjabi population. **Material and Methods:** A total of 500 participants (250 with T2DM and 250 healthy subjects) were recruited for this study. Genotyping was performed by PCR-RFLP method. Anthropometric and physiometric variables such as height, weight, body mass index (BMI), waist to hip ratio (WHR), waist circumference (WC), hip circumference (HC), biceps skinfold, triceps skinfold, SBP, DBP, MBP, pulse rate and pulse pressure were measured using standard protocol. The statistical analyses were performed to include chi-square, correlation, regression, principal component analysis and genetic association analysis. **Results:** The results revealed that anthropometric and clinical characteristics such as WHR, fasting and random glucose levels, SBP, DBP, pulse rate and pulse pressure have significant ( $p < 0.001$ ) differences between T2DM and control subjects. However, none of the anthropometric and clinical characteristics have found a significant difference with respect to their genotypic distributions for both of genes except DBP for *ENPP1* K121Q polymorphism. The association analysis of the present results showed K121Q variant of *ENPP1* and G/T variant of *TCF7L2* gene have a significant association with type 2 diabetes with dominant and recessive model of action, respectively, in north Indian Punjabi populations. Overall, the present study presented a strong association of *ENPP1* and *TCF7L2* variant with T2DM in north Indian Punjabi population and provided evidence of its key role in the pathophysiology of T2DM by influencing both insulin secretion and insulin resistance. However an insignificant association of the *GYS1* variant with T2DM was observed. The present investigation did not support a significant positive association of *ENPP1*, *TCF7L2* or *GYS1* variant with obesity and cardiovascular diseases in T2DM patients.

**1821F****Pathway-informed genetic testing and analysis for type 2 diabetes.** *C. Ma*<sup>1</sup>, *M. Roth*<sup>1</sup>, *K. Zhang*<sup>2</sup>, *L. Shen*<sup>1</sup>. 1) GB HealthWatch, San Diego, CA; 2) School of Medicine, University of California at San Diego, San Diego, CA.

**Background:** It remains a great challenge to predict genetic risk of complex diseases, such as type 2 diabetes (T2D), at the individual level. Twin studies show that genetics accounts for nearly 70% of disease susceptibility, however, with conventional statistical analysis, only about 10% of heritability can be explained with GWAS variants and an additional 2-3% when rare pathogenic variants are included. We developed a novel T2D risk model with a call accuracy reaching 80%. **Methods:** GBinsight T2D NGS panel analyzes coding and non-coding variants that are in or near genes within pathways known to affect T2D risk. 143 candidate genes are selected from the following T2D relevant pathways: Beta cell development and function Glucose sensor and insulin release Insulin signaling (organ resistance) Hypertriglyceridemia Obesity Low cholesterol Susceptibility to autoimmune diseases Choline, Betaine and Folate Methyl-cycle Pathways A novel pathway-based hierarchical structure model is used in risk score calculation. 1000 genomes data is used as population reference. 60 early-onset (diagnosed before age 60) T2D case samples from 4 ancestry groups: European (EUR), Hispanic (AMR), African American (AFR) and East Asian (EAS) and control samples are from 40 ancestry-matched volunteers without T2D over 70 years of age. Type 1 diabetes cases are excluded. **Results:** 1. GBinsight model provides a call accuracy of 0.83, 0.86, 0.77 and 0.73 in EUR, AFR, AMR and EAS samples respectively, with average true positive rate 0.78 and true negative rate 0.82. 2. Each individual has a unique combination of risk and protective variants. Five known pathogenic variants in hypertriglyceridemia (LPL and APOC2), six rare damaging coding variants in MODY (BLK, PAX4 and PDX1) and eight in obesity genes (MC3R, SIM1, ADIPOQ, TUB, NROB2, CCKAR) are detected in case samples only. Common variants in APOA5, APOB, APOE, BHMT, HNF4A, LPL, MC4R, PCSK9, PSORS1C1 and UCP2 genes account for significant T2D risk. 3. Combined effect of defects in multiple pathways account for risk of T2D at individual level. Case samples detected an average of 4.3 (95%CI 1.2-7.3) pathways scored as "high risk" (scored above 70% of reference population), and control samples detected an average of 1.9 (95%CI 0-4.3) pathways scored as high risk, two sample Wilcoxon-test  $P = 7.5 \times 10^{-14}$ . **Conclusion:** Genetic etiology of T2D is heterogeneous and complex. Pathway-based modeling significantly improves T2D risk assessment and may have clinical utility.

**Fine-mapping fasting glucose and fasting insulin loci with whole genome sequence data from the Trans-Omics for Precision Medicine (TOPMed) Program.** A. Manning<sup>1,2</sup>, J. Wessel<sup>3</sup>, B. Hidalgo<sup>4</sup> on behalf of the Trans-Omics for Precision Medicine (TOPMed) Program Diabetes Working Group. 1)

Clinical and Translational Epidemiology Unit, Massachusetts General Hospital, Boston, MA; 2) Department of Medicine, Harvard Medical School, Boston, MA; 3) Department of Epidemiology, Fairbanks School of Public Health, Indianapolis, IN; 4) Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL.

The majority of genetic variants significantly associated with diabetes-related glycemic traits reside in the non-coding genome, with many causal variants still unknown. Whole genome sequence association (WGSA) analysis allows us to fine-map known and novel loci across the non-coding genome without depending on imputation. Here, we present an initial WGSA of fasting insulin (FI) and fasting glucose (FG) levels in phase 1 (released in the fall of 2016) TOPMed data (N=7,121) with deep (>30x) sequence coverage in five cohorts, three European-ancestry (EA): Framingham Heart Study, N=3,209; Old Order Amish Studies, N=980, Cleveland Family Study, N=197, and two African-American (AA): Jackson Heart Study, N=2,487, Cleveland Family Study, N=248. For each cohort, we used linear mixed effects models (as implemented in EMMAX or MMAP software) adjusting for sex, age and BMI, with empirical kinship for relatedness and population structure. We restricted to variants with minor allele count > 5 in more than 1 cohort and meta-analyzed within and across ancestry with METAL. In EA+AA analysis, common (minor allele frequency [MAF]>0.05) variant associations ( $P < 5 \times 10^{-8}$ ) were identified for FG at known loci: *MTNR1B* (rs10830963,  $P = 2.5 \times 10^{-16}$ ; rs12792753,  $P = 1.4 \times 10^{-8}$ ), *GCK* (rs4607517,  $P = 1.16 \times 10^{-10}$ , and 13 additional variants), and *G6PC2* (rs560887,  $P = 5.4 \times 10^{-10}$ ). At the *MTNR1B* locus, fine-mapping across ancestries reduced the significant FG associations from 46 (EA) to 2 (AA+EA). Novel FI associations were seen in rare (MAF<1%) variants: 18q12.1 (rs146884135,  $P = 2.1 \times 10^{-8}$ ), 4p12 (rs193168677,  $P = 1.2 \times 10^{-8}$ ), 1q25.3 (rs550837507,  $P = 3.8 \times 10^{-8}$ ), and *DCLK3* (rs573417731,  $P = 4.8 \times 10^{-8}$ ). These results, which are being extended with phase 2 TOPMed cohorts (expected release is in the summer of 2017; expected total N=27,830), highlight the value of multi-ancestry WGSA to refine known and discover novel associations for complex traits. Future analyses with combined phase 1 and phase 2 data will assess (1) enrichment of sub-significant associations using diabetes-specific functional annotations of the non-coding genome, and (2) the association of rare variants within these diabetes-specific functional annotations with fasting glucose and fasting insulin levels.

**Glucose metabolism in pregnancy: Analysis of diabetes related genetic risk scores against glucose curve trajectories.** G.H. Moen<sup>1,2</sup>, M. LeBlanc<sup>3</sup>, C. Sommer<sup>4</sup>, T. Lekva<sup>5</sup>, E. Qvigstad<sup>6</sup>, K.I. Birkeland<sup>2,5</sup>, K.F. Frøslie<sup>6</sup>. 1) Endocrinology Morbid Obesity and Preventive Medicine, Oslo University Hospital, Oslo, Norway; 2) Faculty of Medicine, University of Oslo, Institute of Clinical Medicine, Oslo, Norway; 3) Oslo Centre for Biostatistics and Epidemiology, Oslo University Hospital, Oslo, Norway; 4) Research Institute of Internal Medicine, Oslo University Hospital, Oslo, Norway; 5) Department of Transplantation Medicine, Oslo University Hospital, Oslo, Norway; 6) Norwegian National Advisory Unit on Women's Health, Oslo, Norway.

Little is known about the genetic risk factors for gestational diabetes (GDM), and few studies have been published, but observational studies have shown that high body mass index (BMI) is one of the many risk factors. Moreover, women with previously known GDM have a higher risk of developing type 2 diabetes (T2DM), and it has been suggested that similar underlying risk factors, including genetic markers, could be important. GDM is diagnosed in gestational week 24-28 by measuring blood glucose in the fasting state or after an oral glucose tolerance test (OGTT). Functional data analysis (FDA) of repeated measurements from OGTTs has found that more than 95% of the temporal variance in the glucose curves may be attributed to the glucose curve features "general level" and "timing of the peak", expressed by the first two functional principal components of OGTT curves. Genome-wide association studies (GWAS) associating a large number of SNPs to fasting blood glucose, 2-h post- OGTT glucose, T2DM, fasting insulin and BMI have previously been published. The aim of the present study was to examine whether the temporal variance in glucose curves could be explained by a genetic risk score for these traits using the publicly available GWAS data. The analyses were done on 529 healthy pregnant women of Norwegian background. The women underwent two OGTTs during pregnancy. The genetic risk scores were constructed using genome-wide significant SNPs of previously published GWAS. FDA was used to extract the general curve features, and the corresponding individual principal component (PC) scores from the OGTT data. We analyzed the correlation of weighted and unweighted genetic risk scores against the PC scores, the fasting glucose and 2h glucose at two time points in pregnancy, as well as BMI before pregnancy and in first trimester. We will discuss the results of the analysis and their potential implications in the understanding of glucose metabolism in pregnancy as well as the understanding and treatment of GDM.

**Tissue specific isoform annotations in rare variant analysis.** A. Ndungu<sup>1</sup>, M. van de Bunt<sup>1,2</sup>, A. Mahajan<sup>1</sup>, P.E MacDonald<sup>1</sup>, A.L. Gloyn<sup>1,2,3</sup>, M.I McCarthy<sup>1,2,3</sup>, T2D-GENES consortium. 1) Wellcome Trust Centre for Human Genetics, University of Oxford, Oxford, United Kingdom; 2) Oxford Centre for Diabetes, Endocrinology & Metabolism, University of Oxford, Oxford, United Kingdom; 3) Oxford NIHR Biomedical Research Centre, Oxford University Hospitals Trust, Oxford, UK; 4) Alberta Diabetes Institute, University of Alberta, Edmonton, Canada.

Due to ubiquitous alternative splicing in multi-exon genes, coding variants will often have more than one annotated consequence across multiple transcripts of the same gene. For such variants, the common practice is to assign the most severe consequence across all transcripts. However, the selected transcript might be rare, tissue-specific, or not expressed in tissues relevant to disease, leading to inaccurate annotation. To address this, we introduce an integrated 'omics approach in rare variant analysis that incorporates tissue-specific transcriptomic profiles to prioritise functional variants for gene-based analysis in type 2 diabetes (T2D). We use exon-level RNA-Seq data from human islets (118 cadaveric donors) to define the repertoire of expressed transcripts using a conservative exon-union based approach. Complete transcripts were defined as having all associated exons, (GENCODE.v19 transcripts), exceeding a minimum expression threshold (> 6 reads in  $\geq 10$  samples and TPM > 0.1 in  $\geq 10$ ). There were 94,569 transcripts in 17,642 genes with robust expression in islets. We explored whether applying an islet transcript filter when aggregating variants in gene based methods improved power to detect an association with T2D using whole exome sequence data across 12,940 individuals from 5 ancestries in the T2D-GENES consortium. For protein-truncating variants (PTVs), the commonly used approach had 69,956 PTVs across 14,415 genes while the islet-transcript filtered method had 39,776 PTVs in 9,392 genes. There were no genes reaching  $p < 2.5 \times 10^{-6}$  in the conventional analysis and incorporating islet-transcript filters did not yield new signals. There were however notable differences with the two methods. For example, in the monogenic diabetes gene *HNF4A*, 3 previously identified PTVs in this gene were intronic in all islet-expressed transcripts due to an alternative promoter in islets. Variant prioritization based on transcript expression in disease relevant tissue could not only improve current methods of analysis, but also provide guided insight into disease mechanism. These analyses will be expanded to a much larger dataset of 52,000 individuals with exome sequence data providing increased power to detect rare variants associating with T2D. Furthermore, as full-length isoform reconstruction from short read data is challenging, incorporating long-read sequence data will be necessary for accurate estimation of isoform proportions in the human islet transcriptome.

People with type 1 diabetes (T1D) vary in the progression of beta cell loss as measured by serum C-peptide. The factors beyond diabetes duration, e.g. genetic, that influence this heterogeneity are mostly unknown. Here, we aimed to identify genetic variants associated with C-peptide in T1D through a meta-genome-wide association study (meta-GWAS). We performed GWAS of stimulated, fasting or random C-peptide measured cross-sectionally in subjects from five T1D studies (n=3479): 1. Diabetes Control and Complications Trial (DCCT)(stimulated, n=1303) 2. Coronary Artery Calcification in Type 1 Diabetes (CACTI)(fasting, n=529) 3. Pittsburgh Epidemiology of Diabetes Complications (EDC)(fasting, n=150) 4. Joslin 50-Year Medialist Study (random, n=906) 5. Wisconsin Epidemiologic Study of Diabetic Retinopathy (WESDR) (random, n=591) Subsequently, the p-values across studies were combined through meta-GWAS taking into account direction of effect a study-specific sample-size weight. We identified a locus on chromosome 1, rs559047 (Chr1:238753916, T>A, minor allele frequency (MAF)=0.24-0.26), associated with lower C-peptide (p=4.13E-8) meeting the genome-wide significance threshold (p<5E-8). We also identified 3 independent loci with p-values close to genome-wide significance in the major histocompatibility complex (MHC) region where major known T1D risk loci are located. These included an indel, rs61211515 (Chr6:30100975, T/-, MAF=0.17-0.19), associated with lower C-peptide (p=1.51E-6); and rs3135002 (Chr6:32668439, C>A, MAF=0.02-0.06, p=7.19E-8) and rs9260151 (Chr6:29911030, C>T, MAF=0.07-0.10, p=8.43E-8) associated with higher C-peptide. Of these, rs61211515 was also associated with accelerated rate of C-peptide decline over time in a subset of individuals from DCCT (n=258) with repeated annual C-peptide measures (p=0.02). Conditional analyses suggested that all these loci are independent of known T1D risk loci in the MHC region. We also investigated association of all known T1D risk loci with C-peptide but only *IL27* (rs4788084, Chr16:28539848, risk allele (RA):C) and *INS* (rs689, Chr11:2182224, RA:T) showed nominal association with lower C-peptide. In conclusion, we identified a locus on chromosome 1 and multiple loci in the MHC, all distinct from T1D risk loci, associated with C-peptide. These associations need to be validated in independent populations. They could eventually provide insight into mechanisms of beta-cell loss and opportunities to preserve beta-cell function.

**Replication of 93 T2D associated SNPs in Jat Sikhs, population of Punjab, India.** G. Singh<sup>1,2</sup>, E. Rai<sup>1</sup>, V. Singh<sup>1</sup>, A.J.S. Bhanwer<sup>2</sup>, R.N.K. Bameza<sup>2</sup>, S. Sharma<sup>1</sup>. 1) Department of Biotechnology, Shri Mata Vaishno Devi University, Katra, Jammu, India; 2) Department of Human Genetics, Guru Nanak Dev University, Amritsar, Punjab, India; 3) National Centre of Applied Human Genetics, School of Life Sciences, Jawahar Lal Nehru University, New Delhi, India.

Type 2 Diabetes (T2D) is a complex, chronic illness in which both environmental and genetic factors interact and contribute to the etiology of the disease. Outcomes of the disease warrant continuous medical care with heterogeneous risk-reduction approaches which are not restricted to glycemic control only. In the present preliminary case-control study, a total of 430 subjects (204 Healthy Controls and 226 T2D Cases) were enrolled. Our focus was to study an endogamous community, Jat Sikhs from Punjab, India. In this association study, we included 93 SNPs from 56 different genes reported to be associated with T2D in literature. Anthropometric parameters like age, gender, BMI, SBP and DBP were also compared. Six SNPs showed significant association ( $p < 0.05$ ) with T2D i.e. rs1044498, rs1801278, rs3813929, rs7961581, rs199925 and rs668514. This preliminary study indicated that genes ENPP1, IRS1, HTR2C, TSPAN8/LGR5, UCP2/UCP3 and CACNA1E are the respective most promising candidate genes associated with T2D in Jat Sikh population of Punjab. However, an extension of study in a larger sample size is required to make conclusive arguments.

**Type 1 diabetes genetic risk score identifies neonatal diabetes patients with highest probability of mutations in Iranian population.** H. Yaghoobkar<sup>1</sup>, E. De Franco<sup>1</sup>, S. Hosseini<sup>2</sup>, M.R. Abbaszadegan<sup>2</sup>, K. Colclough<sup>1</sup>, S. Vakili<sup>2</sup>, M. Ghahraman<sup>2</sup>, A. Moleirinho<sup>1</sup>, R. Maroufian<sup>2</sup>, A. Haghighi<sup>2</sup>, M. Razzaghy-Azar<sup>2</sup>, K. Patel<sup>1</sup>, F. Abbas<sup>2</sup>, M.M. Amoli<sup>2</sup>, S. Ellard<sup>1</sup>, R. Vakili<sup>2</sup>, A.T. Hattersley<sup>1</sup>. 1) University of Exeter Medical School, Exeter, Devon, United Kingdom; 2) Mashhad University of Medical Science, Mashhad, Iran; 3) Tehran University of Medical Sciences, Tehran, Iran; 4) Harvard Medical School, Boston, USA.

Studies of white Europeans have indicated a type 1 diabetes genetic risk score test (T1D-GRS) as a tool to discriminate between T1D and other causes of diabetes. Iran is a Middle Eastern country with a high prevalence of diabetes (11.1%), obesity and consanguinity (37% of marriages). High rates of consanguinity mean undiscovered monogenic recessive forms of diabetes may exist in the population. We aimed to assess the utility of T1D-GRS in prioritizing patients for whole genome sequencing in the Iranian population. We studied patients with neonatal diabetes (diagnosed < 6 months) who were referred from Iran. We generated T1D-GRS using 10 common genetic variants associated with T1D and performed a comprehensive genetic testing including 6q24 methylation analysis and targeted next-generation sequencing of all known neonatal diabetes genes. Our cohort included 103 cases of neonatal diabetes including 50 females and 53 males from 62 consanguineous families (65%). Genetic testing identified the genetic cause of neonatal diabetes in 76 patients (74%). The common genetic causes were different from European patients. Mutations in *KCNJ11* and *ABCC8* account for 46% of NDM cases in Europeans while in our Iranian cohort, mutations in *EIF2AK3* (23%) and *PTF1A* (10%) are the most common causes of neonatal diabetes accounting for 33% of cases. We used T1D-GRS to divide the 26% of patients (n=27) with unknown diabetes etiology into 2 groups: probable T1D (patients with T1D-GRS > 50th T1D centile, n=10) and probable monogenic (patients with T1D-GRS ≤ 50th T1D centile, n=13). Probable T1D patients were diagnosed later (5 months vs. 2 months,  $P=0.001$ ), had fewer syndromic features (11% vs. 43%,  $P<0.001$ ), were less consanguineous (33% vs. 73%,  $P<0.001$ ), were more males (70% vs. 51%,  $P=0.006$ ) and had higher birth weight (3150 g vs. 2400 g,  $P=0.01$ ) than patients with monogenic neonatal diabetes. In contrast, the clinical characteristics of patients with probable monogenic neonatal diabetes were similar ( $P>0.05$ ) to those of patients with genetically confirmed neonatal diabetes except that they were less consanguineous (46% vs. 73%,  $P<0.001$ ). T1D-GRS can be used in the Iranian population to identify neonatal diabetes patients with the highest probability of a novel cause of monogenic diabetes. Our study suggests that 13% of patients in our cohort are likely to have a novel cause of neonatal diabetes. These patients have been prioritized for novel gene discovery by genome sequencing.

**1828W****Trans-ethnic discovery of the genetic architecture of glycaemic control.**

C. Langenberg on behalf of the Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC). University of Cambridge, Cambridge, United Kingdom.

**Background/aims:** We performed the first large-scale trans-ethnic discovery for fasting glucose (FG), fasting insulin (FI), glycated haemoglobin (HbA1c) and 2-hour glucose (2hG) to identify additional glycaemic trait-associated loci, evaluate heterogeneity across ancestries and conduct fine-mapping. **Materials and methods:** We ran ancestry-specific and trans-ethnic meta-analyses of 1000 genomes imputed data in up to 281,416 individuals without diagnosed diabetes from five ancestries (71% Europeans, 13% East Asian, 7% Hispanic, 6% African-American and 3% South Asian). Cohort-level association results were combined assuming a fixed-effects model in METAL, followed by trans-ethnic meta-analyses in MANTRA, where a  $\log_{10}$  Bayes factor ( $\log_{10}$ BF) threshold of 6 was considered genome-wide significant. We used glycaemic and blood/iron-related summary statistics to classify the HbA1c signals as erythrocytic or glycaemic using a fuzzy clustering approach. GARFIELD and DEPICT (FDR<5%) were used to perform functional, tissue and pathway enrichment analyses and eQTLs in blood, islets and adipose were used to identify candidate genes. **Results:** We identified 102 trans-ethnic signals associated with FG, of which 48 did not overlap known FG-associated regions. The most significant novel FG signals, not previously known to be involved in diabetes, include those at or close to *NFX1* and *ZBTB38* genes ( $\log_{10}$ BF=12.42 and 11.79, respectively). We also identified 62 FI-associated trans-ethnic signals (43 novel), 130 HbA1c-associated trans-ethnic signals (57 novel) and 21 2hG-associated trans-ethnic signals (10 novel). The most significant novel signals for FI, HbA1c and 2hG, not previously known to be involved in diabetes, fall within or close to *BCL2*, *LRR16A* and *CLEC14A* genes ( $\log_{10}$ BF = 11.66, 18.60 and 9.68, respectively). HbA1c signals were mostly classified as influencing HbA1c via erythrocytic pathways (~70%). Pathway analyses highlighted insulin signalling in HbA1c; insulin and MTOR signalling, maturity onset diabetes of the young, type 2 diabetes and circadian rhythm in FG; and cancer in FI, the latter being consistent with Mendelian Randomization analyses investigating the causal link between insulin resistance and cancer. **Conclusion:** This large international effort has identified over a hundred novel loci underlying glycaemic traits that pose new hypotheses about the biology and the genetic architecture of glucose and insulin-related traits.

**1829T****Characterization of potential regulatory variants at the *SH2B1* body-mass index GWAS locus.**

M.E. Cannon<sup>1</sup>, K.W. Currin<sup>1</sup>, S. Vadlamudi<sup>1</sup>, A. Safi<sup>2</sup>, L. Song<sup>2</sup>, M. Laakso<sup>3</sup>, G.E. Crawford<sup>2</sup>, K.L. Mohlke<sup>1</sup>. 1) Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; 2) Department of Pediatrics, Division of Medical Genetics, Duke University, NC; 3) Department of Medicine, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland.

Hundreds of loci have been identified in obesity GWAS, but the mechanisms at most loci are unknown. One body mass index (BMI) locus is located on chromosome 16 ( $P=3 \times 10^{-25}$ ,  $\beta=0.031$ ). eQTL associations have been observed for at least nine nearby genes; however, only two coincident eQTLs have been identified, for *SH2B1* ( $P=4.7 \times 10^{-15}$ ,  $\beta=-0.39$ ) and *ATXN2L* ( $P=2.5 \times 10^{-11}$ ,  $\beta=-0.34$ ) in adipose tissue. Rare *SH2B1* coding variants are also associated with obesity. *SH2B1* is an Src homology 2B family member involved in the regulation of leptin and insulin signaling. *Sh2b1* knockout mice exhibit hyperlipidemia, insulin resistance, and obesity. *SH2B1* has at least four isoforms that are expressed differentially across tissues. Neuron-specific restoration of *Sh2b1* reverses metabolic dysfunction in mice, *Sh2b1* over-expression in islets promotes beta cell growth and insulin secretion, *Sh2b1* regulates lipid metabolism in the liver, and its role in adipose remains unclear. The mechanism of the GWAS and eQTL signals are not known. At this locus, 124 variants exhibit strong LD ( $r^2>0.8$ ) with both the GWAS and eQTL lead variants. In ATAC-seq chromatin accessibility data in adipose tissue and SGBS preadipocyte cells, only 4 of the 124 variants overlapped ATAC-seq peaks. These 4 variants also overlapped regulatory histone marks of promoters and enhancers in adipose, brain, liver, and islets. At one variant, we observed a transcription factor motif for PU.1 (*SPI1*) and an allelic imbalance in ATAC-seq reads. rs7187776-G creates a stronger PU.1 motif and showed fewer reads (G=3, A=25) suggesting that the G-allele may alter PU.1 binding and/or chromatin accessibility. rs7187776 is located in the promoter of a long *SH2B1* isoform. In electrophoretic mobility shift assays, rs7187776-G showed increased protein binding compared to rs7187776-A using nuclear extract from SW872 cells or using purified PU.1 protein. In transcriptional reporter assays of a 456-bp element in SW872 adipocyte and SGBS preadipocyte cells, we observed extremely strong transcriptional activity (>200-fold compared to background); inconsistently, we observe no allelic differences between rs7187776 alleles. Taken together, rs7187776-G showed fewer ATAC-seq reads and stronger PU.1 binding and is associated with decreased expression level of *ATXN2L* and *SH2B1* and increased BMI. These data suggest that, in adipose tissue, a regulatory mechanism involving rs7187776 may contribute to the BMI GWAS and eQTL associations near *SH2B1*.
