Whole exome and genome sequencing has identified numerous rare variants in the glutamate receptor family of *GRIN*, *GRIA*, *GRIK*, and *GRID* genes associated with neurological syndromes and phenotypes such as epilepsy (including infantile spasms, Lennox-Gastaut, Landau-Kleffner, and West syndromes), intellectual disability, developmental delay, language disorders, hypotonia and movement disorders, autism and schizophrenia. We compared specific glutamate receptor gene variant function identified in patients to those identified in a control population in a series of *in vitro* electrophysiological and biochemical studies. Briefly, variant glutamate receptors were expressed in *Xenopus laevis* oocytes and HEK cells and used to measure agonist potency (L-glutamate and glycine EC<sub>50</sub>), agonist deactivation kinetics, receptor sensitivity to inhibition by the endogenous modulators Mg<sup>2+</sup>, Zn<sup>2+</sup>, and H<sup>+</sup> (IC<sub>50</sub>, % inhibition), and cell-surface receptor trafficking. Over 90 specific missense, frameshift, or short indel variants in the *GRIN* gene family (primarily *GRIN1*, *GRIN2A*, and *GRIN2B*) were functionally characterized by CFERV. Approximately 51% of the disease associated variants we evaluated possess altered function in at least one functional parameter (up to 8 parameters/variant measured), with 25% of disease variants with multiple functional parameters altered. Agonist potency for receptor activation (30%) was the most common functional parameter altered in the patient population of variants whereas the potencies for the endogenous negative modulators (pH, Mg<sup>2+</sup>, and Zn<sup>2+</sup>) were altered in 10-20% of these variants. Over twenty disease-associated variants resulted in a significant gain or loss of function of >5 fold shifts compared to the wild-type receptor; however several rare variants altered L-glutamate agonist affinity by over 100 fold. We present data on novel glutamate receptor variants and describe the effect of these mutations on receptor function. The goal of CFERV is to increase our understanding of the relationship between specific genetic variations in the glutamate receptor gene families and health consequences and to use these data to define limits of *in vitro* functional change that drive genetic phenotype.

**De novo hotspot variants in CYFIP2 cause early-onset epileptic encephalopathy.** M. Nakashima<sup>1,2</sup>, M. Kato<sup>3,4</sup>, K. Aoto<sup>1</sup>, S. Masaaki<sup>5</sup>, H. Belal<sup>1</sup>, S. Mukaida<sup>6</sup>, S. Kumada<sup>6</sup>, A. Sato<sup>6,7</sup>, A. Zerem<sup>8</sup>, T. Lerman-Sagie<sup>6</sup>, D. Lev<sup>6</sup>, H.Y. Leong<sup>9</sup>, Y. Tsurusaki<sup>2</sup>, T. Mizuguchi<sup>2</sup>, S. Miyatake<sup>2</sup>, N. Miyake<sup>2</sup>, K. Ogata<sup>2</sup>, H. Saitsu<sup>1</sup>, N. Matsumoto<sup>2</sup>. 1) Hamamatsu University School of Medicine, Hamamatsu, Shizuoka, Japan; 2) Yokohama City University Graduate School of Medicine, Yokohama, Japan; 3) Showa University School of Medicine, Tokyo, Japan; 4) Yamagata University Faculty of Medicine, Yamagata, Japan; 5) National Hospital Organization Utano Hospital, Kyoto, Japan; 6) Tokyo Metropolitan Neurological Hospital, Tokyo, Japan; 7) The University of Tokyo Hospital, Tokyo, Japan; 8) Wolfson Medical Center, Tel-Aviv, Israel; 9) Hospital Kuala Lumpur, Kuala Lumpur, Malaysia.

The cytoplasmic fragile X mental retardation 1 interacting proteins 2 (CYFIP2) is a component of the WAVE regulatory complex, which is involved in actin dynamics. An obvious association of *CYFIP2* variants with human neurological disorders has never been reported. Here, we identified *de novo* hotspot *CYFIP2* variants in neurodevelopmental disorders and explore the possible involvement of the *CYFIP2* mutants in the WAVE signaling pathway. Our findings suggest that *de novo* Arg87 variants in *CYFIP2* have gain-of-function effects on the WAVE signaling pathway, and are associated with severe neurological disorders. We performed trio-based whole exome sequencing (WES) in 210 families and case-only WES in 489 individuals with epileptic encephalopathies. The functional effect of *CYFIP2* variants on WAVE signaling was evaluated by computational structural analysis and *in vitro* transfection experiments. We identified three *de novo* *CYFIP2* variants at the Arg87 residue in four unrelated individuals with early-onset epileptic encephalopathy. Structural analysis indicated that the Arg87 residue is buried at an interface between *CYFIP2* and WAVE1, and the Arg87 variant may disrupt hydrogen bonding, leading to structural instability and aberrant activation of the WAVE regulatory complex. All mutant *CYFIP2* showed comparatively weaker interactions to the VCA domain than wild type *CYFIP2*. Immunofluorescence revealed that ectopic speckled accumulation of actin and *CYFIP2* was significantly increased in cells transfected with mutant *CYFIP2*. Our findings suggest that *de novo* Arg87 variants in *CYFIP2* have gain-of-function effects on the WAVE signaling pathway, and are associated with severe neurological disorders.

**Fragile X syndrome drosophila mutants display defects in stress odorant response: A new model for sensory processing dysfunction.** *F. Bolduc, A. Androschuk, C. Rosenfelt, R. He.* University of Alberta, Edmonton, Alberta, Canada.

Neurodevelopmental disorders such as intellectual disability (ID) and autism spectrum disorder (ASD) affect significantly sensory perception and therefore behavior in most affected individuals. Silencing expression of the Fragile X mental retardation 1 (*FMR1*) gene leads to Fragile X syndrome (FXS), the most common single gene cause of ID and ASD. Individuals with FXS frequently present with significant changes in their sensitivity to sound and pain for instance. The molecular basis of these changes in sensory processing remain largely unknown. *Drosophila* have a highly conserved *FMR1* orthologue, *dfmr1*. We and others have shown before that the *dfmr1* mutants display cognitive and social defects reminiscent of symptoms seen in individuals with FXS. To explore sensory processing, we took advantage of a well-established behavioral assay for sensory processing of the *Drosophila* stress odorant (dSO). Here, we show that *dfmr1* mutant flies present significant defects in dSO response. Importantly, using pharmacological manipulations, we show that the response defects to dSO in *dfmr1* mutant flies can be ameliorated. Together, our results show that treatment in FXS should be considered with the perspective of behavior specificity. Moreover, our results provide a novel model to further understand the impact of FXS on social interaction and sensory processing.

**2045F**

**Additional fragile X related 2 (Fxr2) KO mice exhibit severe phenotypes.** *Y. Gu, D.L. Nelson.* Human and Molecular Genetics, Baylor College of Medicine, Houston, TX.

Fragile X syndrome is the most common cause of inherited monogenic intellectual disability, often associated with autism spectrum disorder. To understand the function of FMR1 gene product, FMRP, it is important to determine how the paralogs FXR1 and FXR2 compensate for its absence in Fragile X syndrome. We have developed *Fmr1*, *Fxr1*, *Fxr2* knockout, and *Fmr1* and *Fxr1* conditional knockout mouse models, and analyzed these models at molecular, pathological, electrophysiological and behavioral levels. To develop comprehensive FMR1 gene family mouse model tools, we recently characterized a conditional knockout mouse model for *Fxr2*, developed through the Knockout Mouse Project (KOMP). We obtained the *Fxr2* knockout first model (*Fxr2* Tm2a), which was created by insertion of lacZ and neomycin genes into *Fxr2* intron 3. FRT sites surround lacZ and neomycin genes and three LoxP sites are included; two surround exons 4 and 5, and the other loxP site is located between lacZ and neomycin genes. We created an *Fxr2* conditional knockout model (*Fxr2* Tm2c) after lacZ and neomycin genes were deleted using ubiquitously expressed flip recombinase (FLP). A new *Fxr2* knockout model (*Fxr2* Tm2d) was developed by deletion of exons 4 and 5 through universally expressed Cre recombinase. The new *Fxr2* KO (*Fxr2* Tm2d) showed low body weight and reduced levels of anxiety in behavioral tests in contrast to the original *Fxr2* KO mice, which did not show these abnormalities. Using RT-PCR, we found *Fxr2* mRNA expressed by both KO lines. The original KO expresses *Fxr2* mRNA lacking exon 7, leading to a predicted *Fxr2* protein deleting 39 amino acids in KH0 region. The new *Fxr2* KO (*Fxr2* Tm2d) expresses *Fxr2* mRNA without exons 4 and 5, leading to a predicted *Fxr2* protein containing only the first 77 amino acids of the N-terminal region. We also characterized several lines containing insertion of lacZ and/or neomycin. All these lines showed partial lethality and body weight reduction, in addition to severe differences in behavioral tests. RT-PCR analysis showed *Fxr2* mRNA contains inserted exogenous 115 bps immediately after exon 3, leading to new truncated proteins. In summary, we have developed several new *Fxr2* mutant lines including the first *Fxr2* conditional knockout line. These mice showed more severe phenotypes compared with the originally reported *Fxr2* knockout due to different splicing mRNA. These new mouse models will provide new additional tools to further understand FMR1 gene family function.

**2046W**

**CRISPR/Cas9 mediated repair of Gaucher-type 2 patient mutations in iPSC-derived neural progenitor cells.** *K.M. Baumgarner<sup>1,2</sup>, J. Dizon<sup>1,2</sup>, C.E. McKinney<sup>1,2</sup>.* 1) Edward Via College of Osteopathic Medicine, Spartanburg, SC; 2) Gibbs Cancer Center and Research Institute, Spartanburg, SC.

Gaucher disease type 2 (GD2) is a lethal autosomal recessive disorder with a life expectancy less than 2 years of age. This disease results from a defect in the glucocerebrosidase enzyme encoded by *GBA1*. Since glucocerebrosidase breaks down glucocerebroside, an accumulation of this lipid occurs in GD2 patient's cells throughout the body affecting the spleen, liver, lungs, bones, and the brain. With no therapies available for this form of the disease, studying the molecular mechanisms involved in neuronopathic Gaucher disease could lead to future treatments. Using patient-derived GD2 fibroblasts lines, we have produced induced pluripotent stem cell lines (iPSC) differentiated into neurons. To better understand the mechanisms involved in GD2 disease, we are also creating an isogenic control line for GM02627 through CRISPR/Cas9 directed homologous repair. GM02627 is a compound heterozygote in exon 8 of *GBA1*: one allele has a G>A transition that results in substitution of arginine for glycine (G325R), and the second allele has a T>G transition that results in a glycine to cysteine substitution (C342G). CRISPR targeting of this cell line occurred at the neural progenitor cell (NPC) stage of differentiation. GM02627 NPCs were co-transfected with CAS9 ribonucleoprotein and a 122bp oligo containing a wildtype sequence for exon 8 of *GBA1*. Three gRNA combinations were tested to find one that simultaneously repaired both alleles. After CRISPR/Cas9 targeting, the pools of NPCs were cloned using limiting dilution to produce clonally derived cell lines. Additionally, the NPC positive controls were analyzed for CRISPR/Cas9 efficiency using a genomic cleavage assay and the number of recombination events were quantified using amplicon next generation sequencing PCR products from NPC pooled DNA samples. By creating isogenic control lines for multiple GD2 cell lines, we will be able to compare the GD2 and 2627 repaired isogenic control. Exosome composition, electrophysiological status, global gene and protein expression data will be obtained from neurons that would normally be inaccessible for study.

**2047T**

**Modeling microcephaly in a monkey model by disrupting the ASPM gene via CRISPR/Cas9.** *X. Guo<sup>1</sup>, Z. Tu<sup>1</sup>, W. Yang<sup>1</sup>, S. Yan<sup>1</sup>, S. Li<sup>1,2</sup>, X. Li<sup>1,2</sup>.* 1) Guangdong-Hongkong-Macau Institute of CNS Regeneration, Jinan University, Guangzhou, Guangdong, China; 2) Department of Human Genetics, Emory University, Atlanta, USA.

The ASPM (abnormal spindle-like primary microcephaly) gene is evolutionarily critical for brain volume expansion and intelligence development. Loss of function or down-regulation of the ASPM gene is the most common genetic cause for primary microcephaly in humans. To investigate the function of the ASPM gene in the primate brains, we disrupted the ASPM gene in one-cell stage embryos of cynomolgus monkeys (*Macaca fascicularis*) by injecting guide RNA and CRISPR/Cas9 into fertilized monkey eggs. We obtained 6 live monkeys in which the ASPM gene has been targeted. PCR and sequencing analysis revealed mosaic mutations in these targeted monkeys. One monkey exhibited strikingly head circumference decrease (<2SD to age-matched and same gender animals), which recapitulates the important clinical feature of microcephaly. Our findings demonstrated that the ASPM gene possess evolutionarily similar function between old world monkeys and humans and also suggest that the ASPM gene knockout monkeys can provide an important animal model to investigate the ASPM function in primate brains.

**2048F**

**Mutations in transmembrane domain 4 of *GRIA3* are responsible for a specific movement disorder.** *J. Piard<sup>1</sup>, M. Bereau<sup>2</sup>, T. Wirth<sup>3</sup>, D. Amsalem<sup>4</sup>, M. Raynaud<sup>5</sup>, J. Chelly<sup>5</sup>, L. Van Maldergem<sup>1</sup>.* 1) Centre de Génétique Humaine, CHU Besançon, Besançon, France; 2) Service de Neurologie, CHU Besançon, Besançon, France; 3) Département Médecine translationnelle et neurogénétiq ue, IGBMC, Strasbourg, France; 4) Service de Pédiatrie, CHU Besançon, Besançon, France; 5) Laboratoire de génétique moléculaire, CHU Tours, Tours, France.

Ionotropic amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) glutamate receptors mediate the majority of excitatory synaptic transmission in the central nervous system. *GRIA3* is located on X chromosome and encodes the GLUA3 subunit of AMPA receptor. Mutations in *GRIA3* have been associated with intellectual disability, autism spectrum disorder and epilepsy in males. By whole exome sequencing, we identified the missense variant G826D in *GRIA3* in three male patients from a large Caucasian family and their unaffected mothers. The mutation involves a highly conserved residue in a key functional domain of iGluR3, the fourth transmembrane domain (TM4). Patients 1 and 2 are twin brothers evaluated for moderate intellectual disability and a specific movement disorder which started at three years of age and predominantly affects the upper limbs. Brain MRI is normal in both brothers. Examination showed generalized myoclonic jerks, mild ataxia and brisk reflexes. Patient 3 is a male proband evaluated for learning difficulties and continuous generalized myoclonic jerks. A diagnosis of hyperekplexia was initially suggested but not confirmed by molecular analyses. Examination showed brisk reflexes. Brain MRI was normal. In 2007, Wu et al. studied a patient with ID and myoclonic jerks and the G833R *GRIA3* missense variant localized in TM4 domain. Our observation suggests that missense *GRIA3* mutations in TM4 domain could be responsible for a specific movement disorder in patient with X-linked ID.

**2049W**

**A *Drosophila* model of *PIGA* deficiency, an ultra-rare X-linked intellectual developmental disorder.** *E. Coelho, C.Y. Chow.* Department of Human Genetics, University of Utah, Salt Lake City, UT.

Mutations in the *Phosphatidylinositol glycan class A (PIGA)* gene cause *PIGA* deficiency, a type of X-linked intellectual developmental disorder. *PIGA* deficiency is an ultra-rare disease with fewer than 12 patients reported. *PIGA* deficiency is characterized by neonatal hypotonia, myoclonic seizures, dysmorphic features, and a number of congenital anomalies. *PIGA* is involved in the first step of glycosylphosphatidylinositol (GPI) anchor biosynthesis by transferring N-acetylglucosamine (GlcNAc) from uridine 5'-diphospho N-acetylglucosamide (UDP-GlcNAc) to PI to form GlcNAc-PI. GPI is a glycoprotein that attaches the C-terminus of a protein to the cell surface. GPI-anchored proteins play a number of roles in cell-cell signaling, cell migration, and immunity. Here we report the development of a *Drosophila* model of *PIGA* deficiency using CRISPR technology. We generated a null allele and demonstrate that loss of *PIGA* function in *Drosophila* results in multisystem dysfunction and larval lethality. Because a number of the patient phenotypes include nervous system abnormalities, we use RNAi technology to knockdown *PIGA* expression in neurons. Neuron-specific loss of *PIGA* function results in behavioral and neurological abnormalities that are reminiscent of those observed in patients. We will also present a number of other tissue-specific knockdown studies, including muscle, to identify the primary defects caused by loss of *PIGA* function. The majority of human mutations in *PIGA* are missense variants in evolutionarily conserved amino acid residues. This provides the opportunity to study the structure and function of the *PIGA* protein and how missense variants contribute to disease. We are generating transgenic *Drosophila* strains expressing a number of the disease-causing missense variants that will be crossed into the null background we generated. Comparing the disease allele phenotypes to the null model will provide insight into the disease pathogenesis, how much function is retained, and genotype/phenotype relationships. Importantly, this study paves the way for identification of genetic modifiers and small molecule screens that may lead to therapeutic approaches for this ultra-rare disease.

**2050T**

**The different regions in the central of exon 7 (+11~+40) has different effect on the splicing of SMN exon7.** Y. Qu, J. Bai, Y. Cao, H. Wang, Y. Jin, F. Song. Capital Institute of Pediatrics, Beijing, China.

Humans have two copies of Survival Motor Neuron gene: SMN1 and SMN2. Homozygous deletions or subtle variants of survival motor neuron gene 1 (SMN1) can cause spinal muscular atrophy (SMA). Using site-specific mutations and ex vivo splicing assay we revealed that the site +11~+15, site +15~+21, site +17~+21, site 31~+35, and site +36~+40 in exon 7 of SMN gene might be the exonic splicing silencer regions. For the deletion of these regions can cause the increase of exon7 inclusion. While site from +22 to +30 might be exonic splicing enhancer region, and the key site were +22, +27, +29. For the rate of exon7 skipping were increased in the deletion vectors of region +22~+27 (93%), region +27~+31 (70%), and region +22~+30 (100%) in SMN1 gene. Here, we also revealed that the antisense-oligonucleotide targeting the intronic splicing silencer N1 (ISS-N1) fully corrects SMN2 exon 7 splicing and restores high levels of SMN both in homozygous deletions SMA patient cells and in the subtle variants SMA patient cells. Based our previous results and this research results, it might be one silencer regions binding with hnRNP A1 in the central of SMN exon 7 and the Tra2 $\beta$ 1 binding region might be in site +22 to site +30 of SMN exon 7. Our results demonstrated that different regions in the central of exon 7 (site +11 to +40) has different effect on the splicing of SMN1 exon7. This research was supported by the Beijing Natural Science Foundation (Project No.7172039), the Science Foundation of the Capital of Institute of Pediatrics (Project No.Fangxiang-2017-02), the National Key Research and Development Program of China (No. 2016YFC0901505), CAMS Initiative for Innovative Medicine (CAMS-I2M), and the National Natural Science Foundation of China (Project Nos. 81100933, 85009719, 81501850)

**Over-expression of human *SMOOTHENED (SMO)* induces an abnormal head phenotype in zebrafish.** M. Tanimi-Nagai, S. Hong, E. Roessler, M. Muenke. The Medical Genetics Branch, National Human Genome Research Institute (NHGRI), National Institutes of Health (NIH), Bethesda, MD.

**Background:** The Hedgehog (Hh) signaling pathway plays several crucial roles in the development of most of animals, including the brain and neurogenesis. Accordingly, aberrant Hh pathway function has been implicated in many human disorders ranging from birth defects to cancer. Holoprosencephaly (HPE) is the most common congenital anomaly of the forebrain and face in humans. *SONIC HEDGEHOG (SHH)* is one of the best known HPE genes. Recent clinical and molecular data have identified mutations in *SMOOTHENED (SMO)*, which is an obligate part of the Shh pathway, in HPE patients. Here we describe experimental approaches to reveal the function of *SMO* variants for forebrain or craniofacial development using zebrafish. **Materials and methods:** Wild-type (TAB5) zebrafish were used in this study under an NHGRI animal protocol. For micro-injection assays, *SHH* and *SMO* synthetic mRNA was injected separately or co-injected into fertilized embryos at the one or two-cell stage. A 100 pg bolus of *gfp* was used as a negative control. After 24 hours post fertilization (hpf) and 48 hpf, the phenotype of the injected embryos were analyzed. Expression of Shh pathway gene markers (*shh*, *smo*, *ptch2*, *nk2.2a*, *pax6*, *Gli1*, *Gli2a*) were confirmed via whole mount *in situ* hybridization. All experimental mRNA injections were performed in triplicate and on different days. **Results:** Single injection of *SMO* (100, 200, 300, 600 pg) alone typically did not induce any abnormal phenotypes. Low dose *SHH* (1, 2 pg) injections most frequently caused a normal phenotype. Interestingly, co-injection of a low amount of *SHH* (1 or 2 pg) and *SMO* 200 pg or higher dose(s) induced an abnormal phenotype. This phenotype showed less pigmentation of the eye region at 24 hpf and an incomplete eye shape at 48 hpf. *ptch2* expression at 48 hpf (a known target of the Hh pathway) showed more intensity in co-injection of *SHH* and *SMO* than *SMO* single injection alone. **Conclusion:** These experiments show that co-injection of high amounts of *SMO* and a minimal dose of *SHH* induces eye abnormalities. We are currently investigating the mechanism of this synergy. We plan to investigate the consequences to gene expression targets, which related to the Shh pathway, via whole mount *in situ* hybridization and western blotting. Ultimately, we hope this work will lead to a better understanding of pathway dynamics and opportunities for variant assay testing.

**2052W**

**Establishment of cell lines for drug screening for Alexander disease using glial fibrillary acidic protein cellular localization.** J. Tulyeu, E. Jimbo, Sh. Aoki, T. Yamagata, H. Osaka. Jichi Medical University, Tochigi, Japan.

**Background:** Alexander disease (AxD) is a devastating leukodystrophy caused by mutations in the *glial fibrillary acidic protein* (GFAP) gene. The pathological feature of the disease is the cytosolic aggregation of Rosenthal fibers in astrocytes. The clinical symptoms of severe AxD are motor and mental retardation, bulbar dysfunction, seizures, microcephalus and early death. Mild AxD patients manifest muscle weakness, spasticity and ataxia in later in life. No effective treatments have been established for any type of AxD. In this study, we screened drugs using *in vitro* cell lines with an Incell Analyzer to quantify aggregate formation. **Methods:** We transiently transfected GFAP wild-type and eight mutants (R79C, F80S, R88C, R239C, R239P, A244V, R258C and R416W) fused to green fluorescent protein [GFP] into HeLa and U2-OS cell lines, and quantified the aggregate formation using an Incell Analyzer. We then screened chemical libraries to quantify the aggregate formation in HeLa cell line expressing GFAP-F80S. **Results:** In both cell lines, all GFAP-GFP mutants made more aggregate compared to wild type. Using HeLa cells expressing GFAP-F80S, we performed *in vitro* screen of 138 chemicals and identified 7 that reduced the formation of aggregates. **Discussion:** The Incell Analyzer quantitatively proved the enhanced aggregate formation in GFP mutants. We are now undertaking to screen drugs that reduce the aggregate formation using this system.

**2053T**

**De novo AMPAR GRIA variants associated with neurological diseases.** W. Xiangwei<sup>1,2</sup>, H. Yuan<sup>1,3</sup>, S.J. Myers<sup>1,3</sup>, Y. Jiang<sup>2</sup>, S.F. Traynelis<sup>1,3</sup>. 1) Department of Pharmacology, Emory University School of Medicine, Atlanta, GA, 30322; 2) Department of Pediatrics, Peking University First Hospital, Beijing, 100034, China; 3) Center for Functional Evaluation of Rare Variants (CFERV), Emory University School of Medicine, Atlanta, GA, 30322.

$\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPA receptors) play important roles in brain development and a wide range of pathological conditions. Here, we evaluated functional changes on 11 missense *GRIA* variants (1 *GRIA1* variants, 2 *GRIA2* variants and 8 *GRIA3* variants) associated with epilepsy and/or intellectual disabilities. Of these 11 patients, 45% (5/11) show epilepsy and intellectual disability, and 27% (3/11) present only with intellectual disability with no seizures. 18% (2/11) are in the agonist binding domain (ABD), 46% (5/11) are in transmembrane domains (TMs), and 36% (4/11) of variants are in linker regions. Functional evaluation using two-electrode voltage clamp current recordings revealed 2 gain-of-function variants that enhanced glutamate and kainate potency by 13~52-fold, compared to the corresponding WT receptors. We also found 7 loss-of-function variants that reduced glutamate and kainate potency by 3~5-fold, compared to the WT receptors. All of the gain-of-function variants and 6 of the 7 loss-of-function variants are located in TMs or the linker regions. Notably, similar diseases were associated with both gain- and loss-of-function variants in the same gene. Overall, our results suggest that AMPAR variants are highly relevant with epilepsy and intellectual disabilities in children, and the transmembrane domain or the linker regions between transmembrane domains were particularly intolerant to functional variation.

**Relapsing remitting multiple sclerosis and its relationship with the immunology system and with the oxidative stress.** A.P. Soto Brambila<sup>1</sup>, P. Rivero Moragrega<sup>2</sup>, G. Gabriel Ortiz<sup>3</sup>, F.P. Pacheco Moises<sup>4</sup>. 1) División de Genética Humana, Centro De Investigación Biomédica de Occidente, Cibo, Imss, Universidad De Guadalajara, Cucs, Mexico. Sierra Mojada; 2) División de Genética Humana, Centro De Investigación Biomédica de Occidente, Cibo, Imss, Universidad De Guadalajara, Cucs, Mexico. Sierra Mojada; 3) División de Genética Humana, Centro De Investigación Biomédica de Occidente, Cibo, Imss, Universidad De Guadalajara, Cucs Neurociencias, Mexico; 4) División de Genética Humana, Centro De Investigación Biomédica de Occidente, Cibo, Imss, Universidad De Guadalajara, Cucei, Departamento de Bioquímica, Mexico.

**Background.** Multiple Sclerosis (MS) is a chronic autoimmune neurological disease characterized by a demyelinating inflammatory response of the Central Nervous System (CNS). During the natural evolution of the disease there are episodes of inflammation and high levels of oxidative stress products that have been related to the progression and severity of the disease. **Objective.** To evaluate the expression of the mRNA of the genes that encode inducible and constitutive nitric oxide synthase and its association with the indicators of oxidative stress in plasma (Nitric Oxide Synthase activity, Glutathione Peroxidase enzymatic activity, Nitrate-Nitrite, Lipoperoxide, Fluidity Membrane) in patients with Relapsing Remitting Multiple Sclerosis (RRMS). **Conclusions.** The MRI of patients with RRMS had a very similar pattern in terms of the presence or recent appearance of new lesions. The expression of *iNOS* is increased in leukocytes from patients with RRMS compared to healthy controls. The expression of *iNOS* is decreased in leukocytes of patients with RRMS at the end of the month of evolution with respect to the first intake and at the end of the week of the outbreak compared with healthy controls. Also nitric oxide metabolites, lipid peroxidation products, nitric oxide synthase activity and glutathione peroxidase activity were significantly increased in plasma from subjects with RRMS compared to healthy controls. The plasma membrane fluidity of subjects with RRMS has values similar to that of plasma of healthy controls. Both the biochemical indicators of oxidative stress and the expression of the *iNOS* gene are increased in the plasma of patients with RRMS. Therefore, there is a positive association of the biochemical indicators of oxidative stress in plasma with the expression of *iNOS*.

**Homozygous variants in newly described genes in early childhood-onset autism spectrum disorder: How to proceed?** Y. Anikster<sup>1,2</sup>, D. Marek-Ya-ge<sup>1,2</sup>, E. Ganelin-Cohen<sup>2</sup>, B. Pode-Shakked<sup>1,2</sup>, L. Gabis<sup>1,2</sup>, H. Cassuto<sup>1,3</sup>. 1) Metabolic Disease Unit, Edmond and Lily Safra Children's Hospital, Tel Hashomer, Israel; 2) Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel; 3) Child Development, Leumit HMO, Jerusalem.

Next Generation Sequencing (NGS) techniques have revolutionized molecular diagnosis and brought to the identification of numerous genes not previously associated with human disease. Occasionally, NGS can unveil rare biallelic deleterious variants in such genes in a single family, posing a challenge for the clinician in inferring and establishing their pathogenicity. Two illustrative examples in families with early childhood-onset Autism Spectrum Disorder (ASD) are described. In family A, the proband, 5.5 year old boy diagnosed with high functioning ASD presented with acute psychosis and significant developmental regression. His younger 3 years-old brother had also been diagnosed with ASD. The siblings were born to non-consanguineous parents of Sephardic-Jewish descent. As an extensive neurological evaluation failed to yield a diagnosis, whole exome sequencing (WES) was pursued for the proband and his parents, followed by targeted Sanger sequencing in additional family members. This brought to the identification of a novel nonsense mutation in *TMEM101*, for which both affected siblings are homozygous, and which further fully segregated in the extended family. In family B, the proband is a 4 years-old girl who was referred due to ASD diagnosed at 30 months of age. She is the first child born to non-consanguineous parents of Ashkenazi-Jewish descent. The patient has no clear dysmorphic features and her cognitive status is age-appropriate. Single WES revealed a novel homozygous mutation in *CHRNA7*, which encodes the alpha7 subunit of the neuronal nicotinic acetylcholine receptor, and has long been suggested as a candidate gene associated with ASD. Data sharing, via match-making software or networks of clinicians and researchers may facilitate the recognition of additional affected families worldwide and aid in the elucidation of further monogenic causes of autism spectrum disorder and ultra-rare neurodevelopmental disorders.

**2056T**

**Evaluating genetic causation and personalized pharmacological treatment of an ultra-rare disease associated with deletion of *CACNG2*.** M.L. Kleiber<sup>1</sup>, T.R. Chapman<sup>1</sup>, M.L. Maile<sup>1,3</sup>, O. Hong<sup>1</sup>, R. Purcell<sup>2</sup>, A. Lipka<sup>2</sup>, A. Roberts<sup>4</sup>, J.L. Sebat<sup>1</sup>. 1) University of California, San Diego, San Diego, CA; 2) RespireRx Pharmaceuticals, Glen Rock, NJ; 3) Neuropore Therapies, San Diego, CA; 4) The Scripps Research Institute, San Diego, CA.

The characterization of genomic sequence variants in autism spectrum disorder (ASD) and neurodevelopmental disorders (NDD) studies has led to the identification of causal genes that may provide novel opportunities for individualized treatment strategies. Effective treatments for most ASDs and NDDs have been elusive due to a lack of understanding of how a genetic variant within a patient plays a causal role, as well as the establishment of an intervention that can demonstrably target the underlying molecular pathology and improve cognitive function *in vivo*. To demonstrate the feasibility of personalized medicine for a rare ASD/NDD, we have generated and evaluated a mouse model using CRISPR/Cas9 genome editing. This model recapitulates a previously reported case of autosomal dominant mental retardation 10 (MRD10, OMIM: 614256) and is characterized by an exon 2 in-frame deletion of the AMPA-receptor binding domain of *Cacng2* (*Cacng2*<sup>Δex2</sup>), a transmembrane AMPA receptor regulatory protein that mediates rapid glutamatergic excitatory signaling facilitating receptor trafficking, gating, and developmental synaptic plasticity. In *Cacng2*<sup>Δex2/Δex2</sup> mice, mRNA is expressed at normal levels in the cerebellum; however, no protein is detectable in cerebellar whole-cell lysate or post-synaptic fractions, suggesting that the mutant protein may be targeted to the lysosome for degradation. Behaviourally, homozygous *Cacng2*<sup>Δex2/Δex2</sup> C57BL/6J mice present with severe motor ataxia. Heterozygous *Cacng2*<sup>Δex2/Δex2</sup> males and females show significant cognitive and behavioral phenotypes such as hyperactivity, decreased anxiety-related behaviour, decreased startle response, deficits in reversal learning, and heightened male aggression. Maternal care deficits in female *Cacng2*<sup>Δex2/Δex2</sup> carriers resulted in significant loss of fecundity (<40% pup survival by postnatal day 5). With the goal of reversing cognitive impairments associated with MRD10, we have initiated treatment studies using the ampakine compound CX717 at doses of 0.3 and 3 mg/kg. Given the function of CX717 as a positive allosteric modulator of AMPA receptor activity, this represents a valuable opportunity to evaluate a potential treatment for MRD10. Ultimately, ASD is a complex and challenging disorder that chronically affects both individuals and families. The biological causes for ASD and associated disorders are diverse – our data suggests that a personalized approach may provide valuable insights and effective treatment options.

***NSD1* overexpression recapitulates the phenotype of the 5q35.2-5q35.3 duplication syndrome and unveils a potential treatment for its undergrowth phenotype.** C.C. Eno<sup>1</sup>, K. Jones<sup>2</sup>, M. Nowaczyk<sup>3</sup>, D. Wong<sup>4</sup>, G. Mirzazaa<sup>5</sup>, A. Beck<sup>6</sup>, J.A. Martinez-Agosto<sup>4,7,8</sup>, F. Quintero-Rivera<sup>1,9</sup>. 1) Pathology and Laboratory Medicine, University of California, Los Angeles, Los Angeles, CA; 2) Children's Hospital of The King's Daughters, Norfolk, Virginia; 3) McMaster University, Hamilton, Ontario, Canada; 4) Department of Pediatrics, UCLA Health, Los Angeles, California; 5) University of Washington, Seattle, Washington; 6) Seattle Children's Hospital, Seattle, Washington; 7) Department of Human Genetics, David Geffen School of Medicine at UCLA; 8) Department of Psychiatry, Semel Institute for Neuroscience and Human Behavior David Geffen School of Medicine at UCLA; 9) UCLA Medical Center, UCLA Clinical Genomics Center, David Geffen School of Medicine at UCLA.

Due to gene dosage sensitivity, Nuclear receptor binding SET domain protein 1 (*NSD1*), a H3K36 histone methyl transferase, located at 5q35.3, is a candidate gene responsible for the phenotype of the reciprocal microdeletion-microduplication syndromes. Heterozygous deletions of or variants in *NSD1* are associated with Sotos syndrome, which is characterized by overgrowth with advanced bone age, and height and head circumference (OFC)  $\geq 2$  standard deviations (SD). In contrast, the duplication of 5q35.2-q35.3, encompassing *NSD1*, is characterized by undergrowth with delayed bone age, as well as height and OFC  $\leq 2$  SD. We report nine new patients (ages: 1 month to 33 years) with a duplication of 5q35.2-q35.3, thus contributing to the emerging phenotype, the long-term prognosis, penetrance, and expressivity of this recently described microduplication syndrome. It also highlights psychiatric phenotypes of the syndrome, and suggests its inclusion as part of a differential diagnosis for children with delayed bone age and short stature. Focusing specifically on the main phenotype, undergrowth, we have modeled the effects of *NSD1* overexpression in *Drosophila melanogaster*. *Mes-4* (*NSD1* *Drosophila* homolog) overexpression results in growth restriction through increased cell death associated with decreased PI3K signaling downstream Insulin Receptor (InR). Nutrients (i.e. leucine) can activate mTOR independent of PI3K upstream signaling, thus bypassing the InR/PI3K pathway. We also show that a leucine-rich diet throughout all larval stages rescues *Mes-4/NSD1* induced cell death and suggests a possible treatment to ameliorate the human phenotype. Our findings emphasize the tight regulation of epigenetic factors involved in tissue growth and organism size. We provide the first evidence in a model organism of the effect of *NSD1* dosage on growth, and its association with opposing phenotypes in human syndromes.

Lorenzo<sup>7,8,9</sup>, E. Davis<sup>2</sup>, L. Iakoucheva<sup>3</sup>, Y. Herault<sup>7,8,9</sup>, N. Katsanis<sup>2</sup>, K. Messer<sup>1</sup>, J. Sebat<sup>2,10,11,12,13</sup>. 1) Division of Biostatistics and Bioinformatics, Department of Family Medicine and Public Health, University of California San Diego, La Jolla, CA; 2) Center for Human Disease Modeling, Duke University, Durham, NC; 3) Department of Psychiatry, University of California San Diego, La Jolla, CA; 4) Department of Electrical Engineering, University of California San Diego, La Jolla, CA; 5) Rady Children's Hospital, San Diego, CA; 6) Eunice Kennedy Shriver Center UMMS, Charlestown and Worcester MA; 7) Institut de Génétique et de Biologie Moléculaire et Cellulaire, Université de Strasbourg, Illkirch, France; 8) Centre National de la Recherche Scientifique, UMR7104, Illkirch, France; 9) Institut National de la Santé et de la Recherche Médicale, U964, Illkirch, France; 10) Beyster Center for Genomics of Psychiatric Diseases, University of California, San Diego, La Jolla, CA; 11) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA; 12) Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA; 13) Department of Pediatrics, University of California, San Diego, La Jolla, CA.

Copy number variation (CNV) of *16p11.2* (*BP4-BP5*) is associated with developmental and psychiatric disorders and differences in head size. However, the effect of *16p11.2* genes on craniofacial development is not understood. We investigated the effect of *16p11.2* copy number on craniofacial development in humans, mice and zebrafish. 3D morphometric facial imaging was performed on 228 subjects including 45 deletion carriers, 44 duplication carriers and 139 familial controls. We used a series of linear mixed-effects models to test for the effect of the deletion and the duplication on human facial features. We show that copy number of *16p11.2* is positively correlated with growth of the nose and mandible and negatively correlated with growth of the brow and maxilla. Results were then validated by computed tomography (CT) scans of skulls from mouse models of the deletion and duplication. Structure-specific effects of gene dosage on mandible and frontonasal growth were recapitulated in zebrafish by modulating the expression of the genes *MAPK3*, *MVP* and *KCTD13* in combination, and we find evidence for synergistic effects between genes. Our results suggest that the deletion and duplication of *16p11.2* have distinctive facial features. These effects are attributable the combined influence of multiple genes and their differential effects on growth of the major orofacial processes.

**2059T**

**Alternative splicing of *FMR1* gene is complex: More spliced products and more splicing patterns are discerned in the single-gene transcriptome from the disease gene of fragile X syndrome and FXTAS.** F. Lan, P. Qiu, W. Yang, J. Liao, X. Guo, X. Fu, A. Yan, D. Zhang. DongFang Hospital, Medical College of Xiamen University, Fuzhou, Fujian Province, China.

Fragile X syndrome (FXS) is a common inherited mental retardation disorder. Its disease-determining gene is fragile X mental retardation 1 gene (*FMR1*), encoding fragile X mental retardation protein (FMRP). The *FMR1* gene contains 17 exons and 16 introns, and complex alternative splicing phenomenon of *FMR1* gene was observed in its initial transcript. Different alternatively spliced variants of *FMR1* gene may encode FMRPs with different structures and functions. However, how many alternatively spliced isoforms are present and what are their biological functions remain largely elusive. To investigate the alternative splicing of *FMR1* gene in human peripheral blood, RT-PCR and cloning-sequencing technology was employed to detect the types of alternatively spliced products of peripheral blood leukocytes in 10 normal individuals and to statistically analyze their expression abundance. The results showed that a total of 50 alternatively spliced products were identified from 505 PCR product-T vector recombinant plasmids, including 27 novel alternatively spliced products that have not been reported. The highest abundance in the alternatively spliced products belongs to ISO 17 and ISO 7, both of which involve exon 12 skipping, followed by ISO 1 (containing the full-length sequence of the coding region) and ISO 13 (using the second acceptor site of exon 17), while the frequency of other types of spliced products is not higher than 5.0%. The novel alternatively spliced variants identified in this study involved skipping of exons 3, 4, and 11, insertion of 30bp and 87bp sequence spliced from the middle of intron 7, and 46 bp and 140bp sequence spliced from the middle of intron 9. We further focused on the 140bp exon and revealed that this novel exon from the middle of intron 9 of human *FMR1* gene was commonly expressed in various human tissues and cells. Hybrid minigene splicing assay and bioinformatics analysis also provided evidences that the 140bp sequence held the potentiality of being an alternative exon. To explore the biological functions of the new transcript, recombinant eukaryotic expression vectors and lentiviral overexpression vectors were constructed. Our experiments showed the spliced transcript encoded a truncated protein with altered subcellular localization, and RNA microarray revealed that the expression of a few genes involved in FXS-related signaling pathways was significantly influenced when the truncated FMRP was overexpressed.

**The hnRNP gene family as a model for understanding neurodevelopmental disorder subtypes.** M.A. Gillentine<sup>1</sup>, T. Wang<sup>1</sup>, B. Coe<sup>1</sup>, J. Rosenfeld<sup>2</sup>, E. Torti<sup>3</sup>, A.S.I.D Network<sup>4</sup>, R. Bernier<sup>5,6,7</sup>, E.E. Eichler<sup>1</sup>. 1) Genome Sciences, University of Washington, Seattle, WA; 2) Baylor College of Medicine, Houston, TX; 3) GeneDx, Gaithersburg, MD; 4) ASID Network; 5) Seattle Children's Autism Center, Seattle, WA; 6) Psychiatry and Behavioral Sciences, University of Washington; 7) Center on Human Development and Disability, University of Washington.

With the increasing number of whole-exome and -genome sequencing studies, the number of genes implicated in neurodevelopmental disorders (NDDs) has risen dramatically. It is likely that gene families and cellular pathways will have shared clinical presentations and molecular pathomechanisms, potentially allowing for targeted therapies. We performed an analysis of 10,927 published exomes of NDD probands from denovo-db (<http://denovo-db.gs.washington.edu/denovo-db/>) to identify potential risk genes. Among the genes with an excess of *de novo* mutations ( $p < 2.5 \times 10^{-6}$ ), genes associated with RNA processing, specifically heterogeneous ribonucleoproteins (hnRNPs), stood out with significantly more *de novo* likely gene-disruptive (LGD) variants than expected ( $p < 2.2 \times 10^{-16}$ ). In total, variations in ten hnRNPs were identified. The top two hnRNPs, *HNRNPU* and *SYNCRIP*, were significantly enriched for both LGD and missense variants for all NDDs, as well as intellectual disability/developmental delay alone. We targeted six hnRNP genes for sequencing using molecular inversion probes in a cohort (ASID Network) of 18,836 patients and identified ten LGD, three severe missense mutations, and two splice variants in 17 new patients. Combining these data with clinical exome sequencing data generated from Baylor Genetics Laboratories and GeneDx, we have identified a total of 117 new patients (a third of which are variations in *HNRNPU* and *SYNCRIP*), with a subset having further phenotypic information available or are being clinically assessed. Using this information and published cases, we are expanding the phenotypes associated with hnRNP variation and determining if these are shared across the gene family. hnRNPs are RNA-binding proteins implicated in many processes, including neuronal development, and often work cooperatively and/or compensatorily. To assess the functional impact of these mutations, molecular phenotypes are being assessed with CRISPR-edited induced pluripotent stem cells and differentiated cortical neurons with both proband-specific variants and gene knockouts. We hypothesize that variation in hnRNP-encoding genes may result in shared, targetable neuronal phenotypes, including changes in including cell viability and proliferation, neuronal morphology, and neuronal activity, as well as hnRNP-specific functionality, such as splicing and RNA/protein localization. Additionally, we will attempt to rescue these phenotypes at the cellular level.

**2061W**

**Using *Xenopus laevis* as a model for studying genes associated with intellectual disabilities.** M. Lasser<sup>1</sup>, L. Pizzo<sup>2</sup>, J. Tiber<sup>1</sup>, C. Monahan<sup>1</sup>, S. Kim<sup>1</sup>, S. Lee<sup>1</sup>, S. Girirajan<sup>2</sup>, L.A. Lowery<sup>1</sup>. 1) Boston College, Chestnut Hill, MA; 2) Penn State University, State College, PA.

Intellectual disabilities are complex neurodevelopmental disorders that affect a significant portion of the general population and can be an immense health issue. Genetic mutations caused by rare copy number variants (CNVs) have been shown to play a role in intellectual disabilities or severe developmental delays. It has been previously shown that one such CNV results in a deletion within chromosome 16 in a subset of children clinically diagnosed with an intellectual disability. In addition to having intellectual disabilities, individuals with this deletion, located at 16p12.1, also have severe craniofacial abnormalities, microcephaly, cardiac defects, seizures, and growth retardation. This deletion encompasses six genes, many of which have not yet been studied in relation to neurodevelopment. In order to elucidate the role of these six genes during development, we have created antisense morpholino oligonucleotides to knock down gene function and observe phenotypic differences in *Xenopus laevis*. Importantly, each gene is highly conserved between humans and *Xenopus laevis*, making it an ideal model organism to understand the developmental mechanisms of this genetic deletion. Here, we show phenotypic differences of the 16p12.1 deletion by quantifying changes in craniofacial morphology, cartilage morphology, brain morphology, and axon outgrowth patterns of each individual gene knock down. We have found that reduction of three of these genes, *POLR3E*, *UQCRC2*, and *C16orf52* leads to severe craniofacial and cartilage defects. Additionally, we have found that reduction of *C16orf52* also decreases axon length, and that knockdown of *POLR3E* and *C16orf52* causes smaller brain size. Together, our results suggest that several of the 16p12.1 genes do play an important role during neurodevelopment and future studies will focus on the effect of combinatorial knockdown of these genes, as well as the mechanisms by which they modulate aspects of craniofacial morphology, brain morphology, and axon outgrowth patterns.

**2062T****Linking chromatin biology to autism neuropathology with ASXL3.** S.E.

Marlow<sup>1</sup>, Y.C. Tsan<sup>1</sup>, A. Srivastava<sup>1</sup>, R. KC<sup>1</sup>, B.T. McGrath<sup>2</sup>, S.L. Bielas<sup>1</sup>. 1) Department of Human Genetics, University of Michigan, Ann Arbor, MI; 2) Cellular and Molecular Biology Graduate Program, University of Michigan, Ann Arbor, MI.

Human genetics studies aimed at understanding the genetic etiology of autism spectrum disorders (ASD) implicate chromatin as a nexus of convergent neuropathology, with genetic variants enriched in gene networks linked to chromatin regulation. In particular, histone modifications contribute to transcriptional plasticity pivotal to differentiation and acquisition of new cellular identities. Mono-ubiquitination of histone H2A (H2AUb1) is a reversible, transcriptionally repressive histone modification. We identified *de novo* dominant truncating variants in ASXL3 as the genetic basis of Bainbridge Ropers Syndrome (BRS) and ASD, characterized by failure to thrive, global developmental delay, feeding problems, hypotonia, profound speech deficits, and intellectual disability. ASXL3 is a component of the polycomb repressive deubiquitinase (PR-DUB) complex which deubiquitinates H2A. We identified dysregulation of H2AUb1 as a key molecular pathology in primary cells derived from individuals with BRS, a finding we have confirmed in mouse and human neural progenitor cells (NPCs). 3D human cerebral organoids histologically and molecularly recapitulate the context-dependent features of *in vivo* cortical development, allowing prominent characteristics of early corticogenesis to be reproducibly evaluated. We generated cerebral organoid models from CRISPR-edited ESC and iPSC lines to investigate ASXL3-dependent neuropathology. We observe ASXL3-dependent defects in neural differentiation of pluripotent cells to the full spectrum of mature cortical neuron subtypes, confirming post-mortem evidence that ASD can result from cytoarchitectural disorganization of the cerebral cortex. We utilize transcriptomic and epigenomic techniques to probe the role of ASXL3-dependent H2AUb1 deubiquitination in regulating transcriptional profiles critical to NPC fate decisions during corticogenesis, providing molecular insights gained by functional investigation of genetic variants and uncovering the elusive role of H2AUb1 in neural development.

**2063F**

**A novel homozygous splice site donor alteration in NT5C2 gene leading to spastic diplegia cerebral palsy, developmental delay and microcephaly.** M.I Naseer<sup>1</sup>, A.A Abdulkareem<sup>1</sup>, A.M Abuzenadah<sup>1</sup>, A.G Chaudhary<sup>1,4,5</sup>, M.K Alwasayah<sup>1,2</sup>, C. Trujillo<sup>3</sup>, M.H Al-Qahtani<sup>1</sup>. 1) King Abdulaziz University, CEGMR, Jeddah, Saudi Arabia; 2) Aziziah Maternity & Children Hospital, Jeddah, Saudi Arabia; 3) Erfan & Bagedo Hospital, Genetics Unit, Jeddah, Saudi Arabia; 4) Center for Innovation in Personalized Medicine, King Abdulaziz University, 21589, Jeddah, Kingdom of Saudi Arabia; 5) Faculty of Applied Medical Sciences, King Abdulaziz University, 21589, Jeddah, Kingdom of Saudi Arabia.

NT5C2 gene (OMIM: 600417) encode a hydrolase enzyme 5'-Nucleotidase, Cytosolic II play an important role in maintaining the balance of purine nucleotides and free nucleobases in the spinal cord and brain. In this study we report a novel homozygous splice site donor alteration in NT5C2 gene leading to spastic diplegia cerebral palsy, developmental delay and microcephaly. We have identified a large consanguineous Saudi family segregating developmental delay, spastic diplegia cerebral palsy and intellectual disability along with microcephaly. Whole exome sequencing was performed for the affected members of the family to study the novel mutation. Whole exome sequencing data analysis, confirmed by subsequent Sanger sequencing validation, identifies a homozygous splice site donor alteration of possible interest in NT5C2 (ENST00000343289: c.539+1G>T). The mutation was ruled out in 100 unrelated healthy controls. The homozygous mutation detected in this study has not yet been reported as pathogenic in literature or variant databases. In conclusion, the here first time detected homozygous mutation in the intronic region of NT5C2 gene in Saudi family further explain the possibility that NT5C2 gene may play important role and essential for multiple aspects of normal human neurodevelopment.

**2064W**

**Baraitser Winter cerebrofrontofacial syndrome patient iPSC derived cerebral organoids show abnormal neuronal development.** I. Niehaus<sup>1</sup>, K. Sekeres<sup>2</sup>, K. Guan<sup>2</sup>, A. Haase<sup>3</sup>, G. Goehring<sup>3</sup>, E. Schrock<sup>1</sup>, W. Huttner<sup>1</sup>, M. Heide<sup>4</sup>, N. Di Donato<sup>1</sup>. 1) Institute for Clinical Genetics, Faculty of Medicine Carl Gustav Carus, TU Dresden, Germany; 2) Institute of Pharmacology and Toxicology, Technische Universität Dresden, Dresden, Germany; 3) Leibniz Research Laboratories for Biotechnology and Artificial Organs (LEBAO), Department of Cardiac, Thoracic, Transplantation, and Vascular Surgery, Hannover Medical School, Hannover, Germany; 4) Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany.

Baraitser Winter cerebrofrontofacial syndrome (BWCF) is caused by different mutations in one of the two cytoplasmic actin genes *ACTB* and *ACTG1*. BWCF patients show multiple physical disabilities as well as cortical malformations, e.g. pachygyria. Pachygyria is considered to be a neuronal migration disorder, however the precise pathomechanism remains unknown. Therefore, we aim to assess neuronal development in cerebral organoids differentiated from BWCF patient derived induced pluripotent stem cells (iPSC). For generating cerebral organoids, we used two iPSC lines from two different patients (Patient 1: NM\_001101.3 (*ACTB*): c.359C>T, p.(Thr120Ile), and Patient 2: NM\_001614.3 (*ACTG1*): c.608C>T, p.(Thr203Met)). As control we used the commercially available iPSC lines SC102A-1 (System Biosciences), 409B2 (RIKEN BRC cell bank). The differentiation of iPSC to organoids was performed according to the self-patterning Lancaster *et al.*, 2013 protocol to generate cerebral organoids as well as the pre-patterning Qian *et al.*, 2016 protocol to generate forebrain-specific organoids. Additionally we applied a directed differentiation to obtain forebrain-type organoids. After 30 days in culture, organoids were fixed, cryosectioned and stained for an immunocytochemical analysis. All BWCF embryoid bodies (EBs) showed abnormal neuroectoderm formation in comparison to EBs derived from the control iPSC lines. Accordingly, the organoids of patient derived iPSC showed macroscopically abnormal ventricle formation and morphology. Sox2 and Pax6 positive progenitor cells were significantly reduced indicating premature neuronal differentiation with an enrichment of cells in advanced stages of differentiation. Intriguingly, iPSC-derived organoids from patients with another classical neuronal migration disorder - Miller-Dieker syndrome - also demonstrated considerably more complex developmental mechanisms beyond abnormal migration. We will present results of an extended immunocytochemical analysis for neuronal differentiation, proliferation and apoptosis, as well as transcriptome analyses of the EBs at neural induction phase. Isogenic control organoids will be generated using CRISPR repair of the actin missense mutations in both patient derived iPSC lines.

***NUP50* biallelic pathogenic variants as a novel genetic cause of neurodevelopmental disorder?** S. Moutton<sup>1,2</sup>, AL. Bruehl<sup>3</sup>, C. Coubes<sup>3</sup>, A. Vitobello<sup>3</sup>, F. Tran-Mau-Them<sup>2</sup>, A. Sorlin<sup>1,2</sup>, S. Nambot<sup>1,2</sup>, Y. Duffourd<sup>2</sup>, C. Philippe<sup>2</sup>, L. Faivre<sup>1,2</sup>, C. Thauvin-Robinet<sup>1,2</sup>. 1) Reference Center for Developmental Anomalies, Department of Medical Genetics, Dijon University Hospital, Dijon, France; 2) INSERM U1231, LNC UMR1231 GAD, Burgundy University, F-21000, Dijon; 3) Department of medical genetics, Hôpital Arnaud de Villeneuve, Montpellier University Hospital.

We investigated by whole exome sequencing (WES) a proband who presented with intellectual disability (ID), attention deficiency, seizures and vermiform hypoplasia. Solo clinical WES analysis focusing on known disease-causing gene was negative. Reinterpretation in a research point of view allowed to highlight 2 variants within *NUP50* gene. This gene had previously been hypothesized to be associated with ID in a consanguineous North-African family where two sisters were affected by non-syndromic ID. A homozygous c.502C>T (p.R168W) missense variant had been identified within the largest region of identity by descent. This variant remains absent from ExAC and gnomAD databases and is predicted to be probably damaging. Our patient was found to carry a truncating variant absent from databases at the eighth codon inherited from the mother with a subsequent potential translation initiation codon at the 29<sup>th</sup> codon, and a missense variant p.Asn371Ser inherited from the father (2 occurrences in gnomAD). Prediction scores are conflicting. International datasharing, including genematcher, was non-contributory. Nucleoporins have been involved in various human diseases including some immune, viral, neurological, cardio-vascular and cancer diseases but *NUP50* is not associated with any of them. *NUP50* (or *NPAP60*) encodes for a component of the nuclear pore complex (NPC). It has also been shown to be located in the nucleoplasm and to regulate developmental gene expression in *Drosophila*. *NUP50* is expressed in various human tissues (brain, liver, lung, kidney, and testis). Homozygous knock-out mice present with neural tube defects and intrauterine growth retardation and die *in utero*. Two functional isoforms of *NUP50* exist in humans, *NUP50-L* (1-469 aa) also present in other organisms whereas *NUP50-S* (29-469 aa) is specifically expressed in humans. Both isoforms are affected by the missense variants. Instead, the frameshift variant only affects the longest isoform. *NUP50-S* was shown to stabilize the binding of importin- $\alpha$  to classical Nuclear Localization Signal-cargo, while *NUP50-L* promotes the release of importin- $\alpha$  from the NLS-cargo. Therefore, these variants could create an imbalance between these antagonizing roles of *NUP50* isoforms at the NPC and/or disrupt gene expression regulation. Additional clinical observations are required to better characterize the potential role of *NUP50* in neurodevelopmental disorders. An international collaborative study would be useful.

**2066F**

**Biallelic mutations in the death domain of PIDD disrupt interactions between PIDD and CRADD and cause intellectual disability.** *T.I. Sheikh<sup>1</sup>, N. Vasli<sup>2</sup>, K. Kharizi<sup>4</sup>, R. Harripaul<sup>1,3</sup>, Z. Fattahi<sup>4</sup>, A. Mir<sup>5</sup>, M. Ayub<sup>6,7</sup>, H. Najmabadi<sup>8,9</sup>, J.B. Vincent<sup>1,3,9</sup>.* 1) Center for Addiction & Mental Health, Toronto, ON, Canada; 2) Department of Pediatric Laboratory Medicine, Hospital for Sick Children, Toronto, Ontario, Canada; 3) Institute of Medical Science, University of Toronto, Toronto, Ontario, Canada; 4) Genetics Research Center, University of Social Welfare and Rehabilitation Sciences, Tehran 19857, Iran; 5) Human Molecular Genetics Lab, Department of Bioinformatics and Biotechnology, FBAS, International Islamic University, Islamabad, Pakistan; 6) Lahore Institute of Research & Development, Lahore, 51000 Pakistan; 7) Department of Psychiatry, Queen's University, Kingston, Ontario, K7L 3N6 Canada; 8) Kariminejad-Najmabadi Pathology and Genetics Center, Tehran 14667, Iran; 9) Department of Psychiatry, University of Toronto, Toronto, ON M5T 1R8, Canada.

*PIDD1* encodes p53-Induced Death Domain protein (PIDD), which has a key role in DNA damage/stress response, acting as a cell-fate switch, either through interaction with pro-survival molecule, RIP1 and activation of NF- $\kappa$ B signaling, or via interacting with a pro-death factor, CRADD, and activation of caspase-2 and apoptotic cell death. Biallelic truncating mutations in CRADD have been reported in intellectual disability (ID), and in a form of lissencephaly. Here, we identified four families with ID from Iran and Pakistan with three different biallelic mutations in PIDD, all potentially impacting the Death Domain, through which PIDD interacts with CRADD and other DD proteins such as RIP1 or CRADD/RAIDD. A nonsense mutation, Gln863\*, in two apparently unrelated Pakistani families directly truncates the death domain (DD);, a missense mutation in DD, Arg815Trp, is also predicted to be damaging. A splice acceptor mutation in the fourth family is predicted to disrupt splicing upstream of the DD. In HEK293 cells, we showed that, while WT PIDD co-localizes with CRADD in the cytoplasm, both Gln863\* and Arg815Trp not only prevent PIDD/CRADD co-localization, but also cause mis-localization of CRADD. Also both Gln863\* and Arg815Trp fail to precipitate CRADD from co-expressing HEK293T cells. Together, this evidence along with identification of biallelic mutations in CRADD in ID points towards a significant role for PIDD-CRADD interactions, and the PIDDosome in general, in normal human neurodevelopment.

**2067W**

**Characterizing the phenotypic presentation of an international sample of children with 48, XXY and the impact of testosterone replacement therapy (TRT).** *P. Lasutschinkow<sup>1</sup>, C. Samango-Sprouse<sup>1,2,3</sup>, G. Harmon<sup>5,1</sup>, F. Mitchell<sup>4</sup>, M. McLeod<sup>1</sup>, A. Gropman<sup>4,1</sup>.* 1) The Focus Foundation, Davidsonville, MD; 2) George Washington University, Washington, DC; 3) Florida International University, Miami, FL; 4) Children's National Health System, Washington, DC; 5) Nemours Pediatrics, Wilmington, DE.

48, XXY(48s) occurs in 1:50,000 male births & is a more severe variant of 47, XXY (Klinefelter syndrome). Clinical features may include delayed speech, androgen deficiency, gait disturbance & moderate intellectual disability. Physical characteristics include hypertelorism, epicanthal folds & upslanting palpebral fissures. Previous studies indicated that IQ averaged 40-60 with a range between 20-79. We characterize the phenotypic profile of the largest cohort of 48, XXY to date & report on the influence of TRT. An international cohort of 23 48s under the age of six had multidisciplinary evaluations in neurocognition, motor & speech. A subset of 48s had previously been treated with TRT. Language development was assessed with the Preschool Language Scale (PLS-5). Intelligence was measured using the Weschler Intelligence Scale (WISC-IV) & Leiter International Performance Scale (LIPS-III). Behavior was assessed through questionnaires completed by caregivers, including the Behavior Rating Inventory of Executive Function (BRIEF-2) & Child Behavior Checklist (CBCL). 48s presented with an increase of childhood apraxia of speech, immunologic difficulties & motor planning deficiencies. Dysmorphic features included clinodactyly, cryptochordism, tremors & radioulnar synostosis. In speech, untreated and treated 48s showed no significant differences in auditory comprehension with scores ranging from 85-118. In expressive communication, there was a significant difference between the groups ( $P=0.045$ ) with an average of 82.17 in untreated boys and 98.67 in treated boys, with scores spanning from 67-117. On the LIPS-III, Brief IQs ranged from 49-98, with an average of 84. On the WISC-IV, there was only one untreated boy compared to 7 treated boys. The treated boys performed better in Verbal IQ (90.67 vs 81) and Performance IQ (104 vs 94) with respective ranges of 69-103 and 84-138. CBCL and BRIEF-2 showed increased difficulties in withdrawn, pervasive developmental delays, shift & flexibility. This study reports on a novel international sample of 48s, which is the largest cohort to date. The variability in the group demonstrates a large range of capabilities & outcomes and a possible improvement in the treated sample. 48s had deficits in planning, speech & motor function similar to but more complex than 47, XXY. These results show a much more capable developmental profile than previously appreciated & possible improvement in selected developmental domains with TRT.

**Role of RIPK3-mediated necroptosis on the pathogenesis of incontinentia pigmenti.** M.V. Ursini<sup>1</sup>, M.G. Cirigliano<sup>1</sup>, A. El-Sharkawy<sup>1</sup>, F. Fusco<sup>1</sup>, M.B. Lio<sup>2</sup>, A. Pescatore<sup>1</sup>. 1) CNR, Institute of Genetics and Biophysics, Naples, Italy; 2) Università della Basilicata, Potenza, Italy.

Incontinentia pigmenti (IP) is a X-linked neuroecodermal disease. In IP, dermatologic manifestations appearing at birth are essential for the clinical diagnosis. One third of patients show neurological symptoms. The only causative gene of IP is NEMO (also called IKBKG), encoding for the regulatory subunit of the I $\kappa$ B-kinase (IKK) complex. The current mechanistic model suggests that NEMO functions as a crucial component mediating the recruitment of the IKK complex to the tumor necrosis factor receptor 1 (TNF-R1), thus allowing activation of the pro-survival NF- $\kappa$ B response. Accordingly, NEMO deficiency impairs NF- $\kappa$ B activation and induces the pro-apoptotic stimuli through the cytoplasmic FADD-containing complex. Recently, we discovered as an IP-NEMO mutant unable to activate NF- $\kappa$ B in response to TNF, partially retains NEMO antiapoptotic function and licenses cells to die through necroptosis by inhibiting the recruitment of RIPK3 to the FADD-containing complex following TNF/zVAD stimulation. Importantly, targeting the kinase domain of RIPK1 with necrostatin 1 inhibits the interaction between RIPK1 and RIPK3 and blocks necroptosis in these settings. Indeed, we evidence a correlation between the absence of NEMO and the protein expression level of RIPK3 in cells and affected tissues derived from mice model of IP. Our study evidence as de-regulation of NEMO in different ways can have a profound impact on whether cells die by apoptosis or necroptosis, underlining the importance of address the role of TNF-induced cell death in the pathogenesis of IP.

**TAF1's association with X-linked intellectual disability: Essential neuro-specific function established by zebrafish knockout.** S. Gudmundsson<sup>1</sup>, M. Wilbe<sup>2</sup>, B. Filippek-Górnio<sup>2</sup>, A.M. Molin<sup>1</sup>, S. Ekvall<sup>1</sup>, J. Johansson<sup>1</sup>, H. Gylje<sup>3</sup>, V.M. Kalscheuer<sup>4</sup>, J. Ledin<sup>2</sup>, G. Annerén<sup>1</sup>, M-L. Bondeson<sup>1</sup>. 1) Department of Immunology, Genetics and Pathology, Uppsala University, Science for Life Laboratory, Uppsala, Sweden; 2) Department of Organismal Biology, Genome Engineering Zebrafish, Science for Life Laboratory, Uppsala University, Uppsala, Sweden; 3) Department of Paediatrics, Central Hospital, Västerås, Sweden; 4) Research Group Development and Disease, Max Planck Institute for Molecular Genetics, Berlin, Germany.

The TATA-box binding protein associated factor 1 (TAF1) protein is a key unit of the transcription factor II D complex that serves a vital function during initiation of transcription. The *TAF1* gene has repeatedly been highlighted in disease biology, recently associated with intellectual disability. *TAF1* has been detected in elevated levels in mice during the first three weeks of development suggesting an important function during early embryogenesis, but no suitable animal models of orthologues to mutant *TAF1* genes have so far been presented, hence its molecular function remains elusive. We present clinical, genetic, and molecular results of a five-generation family affected with a *TAF1* c.3568C>T, p.(Arg1190Cys) variant, which co-segregated with the phenotype. We report six hemizygous affected males that presented with intellectual disability and dysmorphic features such as long face, pointed chin, large hands, prominent forehead, short neck, low-set, protruding, and large ears, a long philtrum, prominent supraorbital ridge, deep-set eyes, and large feet. Five heterozygous females were asymptomatic and had completely skewed X-chromosome inactivation. We investigate *taf1* function further by creating the first complete knockout model of *TAF1* orthologue using CRISPR/Cas9 system in zebrafish. A crucial role of proper human *TAF1* function during early developmental processes can be inferred from the knockout model demonstrating that an intact *taf1* is essential for life from early embryonic development and onwards. Transcriptome sequencing was performed on *taf1*<sup>-/-</sup> zebrafish embryos 3 days post fertilization. Pathway enrichment analysis of differentially expressed genes revealed enrichment for pathways associated with neurodevelopmental processes, such as chromatin and DNA assembly and ion transport. In conclusion, this work strengthens the molecular understanding of pathogenic *TAF1* variants causing syndromic X-linked intellectual disability in humans. We describe the clinical and genetic effect of the pathogenic *TAF1* c.3568C>T, p.(Arg1190Cys) in a large family. The zebrafish model suggests that *TAF1* is essential for life and that pathogenic *TAF1* variants cause syndromic X-linked intellectual disability in humans by dysregulation of genes essential for normal neurodevelopment.

**2070W**

**TAF1 mutations in kinase domains associated with reduced RAP74 phosphorylation in patients with X-linked intellectual disability.** M. Han<sup>1</sup>, S. Srikanth<sup>2</sup>, R. Wang<sup>1</sup>, C. Skinner<sup>2</sup>, T. Niranjana<sup>1</sup>, R. Stevenson<sup>2</sup>, C. Schwartz<sup>2</sup>, T. Wand<sup>1</sup>. 1) Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 2) Greenwood Genetic Center, Greenwood, SC.

TATA box binding protein-associated factor 1 (TAF1) is the largest subunit of transcriptional initiation complex, TFIID. *TAF1* mutations have recently been found in patients with X-linked intellectual disability and dystonia-parkinsonism syndromes. The mechanisms responsible for the cognitive and neurological phenotypes in the patients remain unknown. *TAF1* encodes a protein serine kinase that selectively phosphorylates the basal transcription factor, RAP74. Both N-terminal and C-terminal kinase domains are important for efficient transphosphorylation of serine residues. We report two novel *TAF1* missense mutations that segregate with intellectual disability phenotypes in two XLID families. One mutation, p.M21L, is located in the N-terminal domain and the other, p.Q1428P, in the C-terminal domain. Both mutations involve highly conserved amino acids residues and are predicted to have a deleterious effect on protein function. We studied RAP74 phosphorylation in lymphoblast cell lines from patients and normal controls using a phosphorylation site-specific antibody for RAP74. The results showed a significant reduction in RAP74 phosphorylation in lymphoblasts from one affected male carrying the p.M21L mutation and two affected males carrying the p.Q1428P mutation as compared to lymphoblasts from three normal males. RNAseq and quantitative RT-PCR analysis are being conducted on these cell lines to identify signaling proteins and neural pathways that are affected by the TAF1-mediated RAP74 phosphorylation defects. Our results suggest that both N- and C-terminal kinase domains are important for RAP74 phosphorylation and reduced RAP74 phosphorylation contribute to intellectual disability and congenital malformations in patients with *TAF1* deficiency.

**2071T**

**Dual diagnosis of *CLTC* and *DNMT3A* mutation: DeMari syndrome and Tatton-Brown-Rahman syndrome (TBRS).** Z. Mohamed<sup>1</sup>, C. Mroske<sup>2</sup>, S. Tang<sup>2</sup>, J. Nimeh<sup>3</sup>, M. Byler<sup>4</sup>, N. Dosa<sup>3</sup>, J. Kalish<sup>4</sup>, R.R. Lebel<sup>1</sup>. 1) Section of Medical Genetics, SUNY Upstate Medical University, Syracuse, NY; 2) Ambry Genetics Corporation, Aliso Viejo, California; 3) Department of Pediatrics, SUNY Upstate Medical University, Syracuse, NY; 4) Clinical Genetics Center, Children's Hospital of Philadelphia, Philadelphia, PA.

Our patient was born at 35 weeks of gestation to a 27-year-old Caucasian woman, after pregnancy complicated by pre-eclampsia. There was no exposure to a suspected teratogen, and the union is not known to be consanguineous. The father was also 27 years old at that time. Neonatal period was notable for hypoglycemia, apnea, bradycardia, hyperbilirubinemia, Grade I intraventricular hemorrhage, subdural hematoma, laryngomalacia and hypotonia with feeding difficulties. She had several minor dysmorphic features and evolved global developmental delays. Whole-exome sequencing (WES) revealed a *de novo* mutation (c.2737\_2738dupGA; p.D913EFs\*59) in *CLTC* gene. The *CLTC* gene encodes clathrin heavy chain 1, one of the subunits of clathrin. Clathrin participates in vesicle formation. The synapses of neurons rely on clathrin vesicles to release and recycle neurotransmitters. Further, during mitosis vesicle formation is suspended and clathrin then plays a role in stabilizing spindle fibers. The gene function in neuronal transmission is consistent with the patient's neurological features. Animal models with the *CLTC* gene disrupted show a defect in neurotransmission at the synapses. At 26 months of age, the patient was also found to have a ganglioneuroblastoma. Imaging revealed interval growth of the tumor. She underwent surgical debulking. Next generation sequencing of the tumor revealed a variant (c.2645G>A; p.R882H) in the *DNMT3A* gene. Reanalysis of the exome data confirmed the variant to be germline and likely pathogenic. Germline mutations in *DNMT3A* causes Tatton-Brown-Rahman syndrome (TBRS). TBRS is an autosomal dominant condition characterized by tall stature, intellectual disability, macrocephaly, round face. Neuroblastoma has not been reported previously in a patient with *DNMT3A* mutation. The present patient has been reported previously when we were conscious of only her *CLTC* mutation.

**2072F**

**Correction of the reduced GluA2 and TIMP2 in *Fmr1* KO mice with adult restoration of *Fmr1*.** R. Zong, D. Nelson. Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030.

Loss of *FMR1* function results in fragile X syndrome (FXS), a common form of intellectual disability. *FMR1* encodes an RNA binding protein that regulates translation of its targets. FXS appears to result from dysregulated translation, and elevated synthesis of several proteins has been described in the brains of mice lacking *Fmr1*. *Fmr1* protein (FMRP) is also involved in RNA transport and stability, regulation of the miRNA pathway and chromatin remodeling. Two Fmrp targets identified from the RNA and protein expression assays in brains of mouse *Fmr1* KO models showed greatly reduced expression, *GluA2*, the AMPA receptor subunit 2, and *Timp2*, the tissue inhibitor of MMP2. Both are interesting as potential therapeutic targets in fragile X syndrome. *GluA2* has a role in regulation of dendritic spine development, and *Timp2* has been shown to restore memory in aged mice. *GluA2* expression (mRNA and protein) is greatly reduced in *Fmr1* KO mouse brain. Fmrp interacts with miR-124 in a co-immunoprecipitation assay, and miR-124 directly targets *GluA2* mRNA. Consistent with the observation that *GluA2* expression level was reduced, the level of miR-124 was found to be increased in *Fmr1* KO mice in a quantitative PCR assay. We show that this reduction of *GluA2* can be rescued with adult restoration of Fmrp in *Fmr1* cON-CreER mice after tamoxifen induction indicating that reduction is closely associated with the Fmrp expression. In order to model potential gene therapy for Fragile X syndrome, we have developed a pAAV-*Fmr1* viral construct to restore Fmrp in adult *Fmr1* KO mice to determine whether reduced *GluA2* and *TIMP2* levels in *Fmr1* KO mice can be corrected. The pAAV-*Fmr1* vector was shown to have a good expression of Fmrp in cell cultures, and the AAV viral particles have been produced for mouse injection. Mice will be assessed for neuronal and behavioral phenotypes after *Fmr1* restoration via viral gene transfer. Overall, we propose that a balance correction both up-regulated and down-regulated Fmrp targets could be a key to be successful in the therapeutics treatment for FXS.

**Beyond a molecular diagnosis: Functional studies of AHDC1 in Xia-Gibbs syndrome.** M.M. Khayat<sup>1,2</sup>, J. Traynelis<sup>1,2</sup>, Q. Meng<sup>1,2</sup>, V. Chander<sup>1,2</sup>, H. Li<sup>1,2</sup>, A.C. Salvador<sup>6</sup>, Y. Jiang<sup>1,2</sup>, M.F. Wangler<sup>2,3</sup>, D.R. Murdock<sup>1,2</sup>, A. Sabo<sup>1,2</sup>, J.E. Posey<sup>2</sup>, J.R. Lupski<sup>1,2,4,5</sup>, R.A. Gibbs<sup>1,2</sup>. 1) Human Genome Sequencing Center, Baylor College of Medicine, Houston, Texas; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas; 3) Department of Pediatric Radiology, Texas Children's Hospital, Houston, TX, 77030; 4) Department of Pediatric Radiology, Texas Children's Hospital, Houston, TX, 77030; 5) Texas Children's Hospital, Houston, TX, 77030; 6) Texas A&M University Health Science Center, College Station, TX, 77843.

The effect of mutations on gene function have been difficult to characterize in neurodevelopmental disorders (NDDs) due to underlying genetic and phenotypic heterogeneity. Thus, each individual case warrants thorough genotype/phenotype analyses and follow-up functional studies. Xia-Gibbs syndrome (OMIM: 615829; XGS) is a recently described severe developmental disorder characterized by hypotonia, limited speech and sleep apnea (Xia et al, 2014). The mechanism of pathogenesis in XGS is not known and may involve either a dominant gain of function or else a haploinsufficient model of disease. This disorder is emblematic of many NDDs where patients display a spectrum of phenotypes with a driving *de novo* autosomal dominant truncating mutation, in a gene where little is known about the normal function. To advance XGS studies we have recruited more than 30 XGS families and have verified their molecular diagnoses. The phenotypes and molecular data have been collected in an XGS Registry permitting deeper analysis. In addition, blood samples have been stored in a biobank for future research. Homology analyses have shown similarities to proteins (REV3L and KIAA2022) implicated in DNA repair and neurological development. Specifically, 4 domains share homology with AHDC1 and 3 AT-Hook DNA binding domains are observed. Protein expression has been achieved in insect cells and commercial antibodies have been validated for detection of AHDC1. Transient expression of cloned *AHDC1* in human embryonic kidney cells shows nuclear localization of the wildtype protein with increased expression in the nucleoli. Studies of deletion breakpoints in individual patients and patterns of RNA expression are underway. In addition to elucidating disease mechanism in XGS, these studies will inform our general understanding of autosomal dominant NDDs and their underlying causes.

Mediator is a large complex conserved from yeast to humans. The complex is a master coordinator of cell lineage determination. In response to various stimuli, mediator undergoes conformational changes and creates a DNA loop between activated enhancer elements and promoter. Mediator physically bridges transcription factors bound at enhancer elements with the RNA polymerase II transcription machinery at core promoter regions. The complex is organized into four modules, namely the tail-, the middle-, the head-, and the CDK8-kinase module. In vertebrates, the latter module is composed of CCNT1 and three additional proteins: CDK8, MED12, and MED13; or their respective paralogs: CDK19, MED12L, and MED13L. Molecular anomalies in *MED13L*, leading to haploinsufficiency, have been reported in patients with moderate to severe intellectual disability and distinct facial features, with or without congenital heart defects. Until recently, clinical relevance of *MED13L* missense variants was unclear. We identified 7 de novo missense variants, clustered in mutational hot-spots, *i.e.* exons 15-17 and 25-31. We noted that patients with a variant located in exon 15 showed a more severe phenotype and were more at risk for epilepsy. In silico analyses suggested that variants located in exons 25 to 31 impair potential ubiquitination sites and that variants located in exon 15 to 17 impair potential phosphorylation sites. Through FBXW7-dependant ubiquitination assays, phosphorylation assays, MED13L subcellular localization analysis and RNA rescue assays in zebrafish, we propose to unravel molecular consequences of *MED13L* missense variants. This work gives clues to understand molecular basis of genotype-phenotype correlations observed in the patients.

**2075F**

**A new *SMN1* variant (c.835G>C, p.Gly279Arg) in YG box domain causing exon 7 skipping and is responsible for spinal muscular atrophy.** J.L. Bai, Y.J. Qu, F. Song, Y.Y. Cao, M.M. Chen, Y.W. Jin, H. Wang. Capital Institute of Pediatrics, Bei Jing, China.

**Background:** Spinal muscular atrophy (SMA) is an autosomal recessive neuromuscular disorder caused by deletion or subtle mutation of *SMN1* (survival motor neuron 1). The highly conserved YG box domain encoded by exons 6 and 7 is important for SMN binding to other proteins and for SMN self-association. **Methods:** We detected the *SMN1* subtle mutations in two non-homozygous patients by MLPA, genomic sequencing and T-A cloning on cDNA level. Then quantitative real-time PCR (qRT-PCR) was used to measure the effect of the *SMN1* variant on levels of full-length *SMN1* (fl-*SMN1*) transcripts in patient's blood and also in immortalized lymphocytes. The fragments of RT-PCR were sequenced to confirm whether it exits exon 7 skipping. To further evaluate its splicing effects on exon 7, we constructed mutant *SMN1* minigene with c.835G>C and a positive control splicing minigene including the classical splicing site c.835-1G>A in the *SMN1*-Short plasmid. After transfecting them in HEK293 cells respectively, we measured the percentage of fl-*SMN1* transcripts. **Results:** We identified two novel variants in two SMA patients: one with c.835G>C(p.Gly279Arg) in exon 7 and the other with c.211del A(p.Lys71Lysfs\*78) in exon 2b of *SMN1* gene. For the c.835G>C, fl-*SMN1* transcripts was significantly decreased both in the peripheral bloods and in the immortalized lymphocytes of the patient ( $p < 0.05$ ). And we observed two fragments by RT-PCR, and part exon 7 skipping was confirmed by direct sequencing. In ex vivo splicing analysis, it showed that positive control splicing minigene yielded 100% exclusion of *SMN1* exon 7 and the mutant minigene reduced its inclusion to 54%. **Conclusion:** We reported two novel *SMN1* mutations in two SMA patients. And our study clearly demonstrates that the c.835G>C(p.Gly279Arg) missense variant can lead to partly exon 7 skipping of *SMN1* transcripts. What's more, it emphasizes that the *SMN1* missense variant (c.835G>C) in the YG box domain does influence the correct splicing of exon 7 and is responsible for spinal muscular atrophy. **Acknowledgments:** This study was supported by National Natural Science Foundation of China (Nos. 81501850, 81100933, 81470056, 81500979), Beijing Municipal Administration of Hospitals' Youth Program (QML20161303), National Key Research and Development Program of China (2016YFC0901505), CAMS Initiative for Innovative Medicine (CAMS-I2M), Beijing Natural Science Foundation (No.7172039). \*Corresponding author: F Song.

**Complex genetic etiology of congenital diaphragmatic hernias, a common structural birth defect.** E. Bogenschutz<sup>1</sup>, Z. Fox<sup>1</sup>, R. Layer<sup>1,2</sup>, A. Farrell<sup>1,2</sup>, J. Wynn<sup>3</sup>, B. Moore<sup>1,2</sup>, L. Yu<sup>3</sup>, G. Aspelund<sup>4</sup>, A. Quinlan<sup>1,2,5</sup>, G. Marth<sup>1,2</sup>, M. Yandell<sup>1,2</sup>, Y. Shen<sup>6,7,8</sup>, W. Chung<sup>3,9,10</sup>, G. Kardon<sup>1</sup>. 1) Department of Human Genetics, University of Utah School of Medicine, Salt Lake City, UT; 2) USTAR Center for Genetic Discovery, University of Utah School of Medicine, Salt Lake City, UT; 3) Department of Pediatrics, Columbia University, New York, NY; 4) Department of Surgery, Columbia University Medical Center, New York, NY; 5) Department of Biomedical Informatics, University of Utah, Salt Lake City, UT; 6) Department of Systems Biology, Columbia University, New York, NY; 7) Department of Biomedical Informatics, Columbia University, New York, NY; 8) JP Sulzberger Columbia Genome Center, Columbia University, New York, NY; 9) Department of Medicine, Columbia University Medical Center, New York, NY; 10) Herbert Irving Comprehensive Cancer Center, Columbia University, New York, NY.

The diaphragm is an essential mammalian skeletal muscle, as it is critical for respiration and serves as a barrier between the thoracic and abdominal cavities. Defects in the diaphragm are the cause of a common (1 in 3000 births) birth defect, congenital diaphragmatic hernia (CDH). In CDH, weaknesses in the developing diaphragm allow abdominal contents to herniate into the thoracic cavity and impairs normal lung development. The resulting lung hypoplasia and pulmonary hypertension are the most significant contributors to the 50% neonatal mortality. The genetic etiology of CDH is complex and poorly understood. More than 100 genes have been implicated, but all genes are incompletely penetrant. Using mouse genetics, we have demonstrated (e.g. Merrell *et al.* 2015) that several CDH-implicated genes, including *GATA4*, are specifically required in the muscle connective tissue fibroblasts of the early developing diaphragm, and our data suggest that somatic mutations in these fibroblasts may play a role in CDH etiology. To test this hypothesis and probe more deeply into the etiology of CDH, we performed whole genome sequencing in multiple tissues from four CDH families: blood, skin, and diaphragm connective tissue from the proband, along with maternal and paternal blood. We have developed a pipeline to identify structural variants, insertions/deletions, and single nucleotide variants in coding and non-coding regions that could contribute to CDH etiology. Genes with variants identified with this pipeline were prioritized based on expression levels within mouse developing connective tissue fibroblasts, and we identified 18 novel candidate genes, none of which were recurrent across the families. No patients were found to harbor damaging somatic mutations. However, an inherited non-coding deletion was found in two unrelated patients, potentially impacting the function of a putative enhancer of *GATA4*. In summary, our in-depth analysis has revealed that the etiology of CDH is complex, with potentially each CDH patient harboring a unique set of mutations.

**Near infrared light exposure uncouples electron transport from ATP synthesis in epithelial cells.** T.O Oliver, V.B Brown, D.C Coleman, A.J.S Johnson-Stewart. Biology, Spelman College, Atlanta, GA.

Near infrared red (NIR) light exposure (2.88 J/cm<sup>2</sup>, 632 nm) mediates cytoprotective effects in epithelial cells exposed to a pulse of 2 μm laser radiation. This is similar to the outcomes mediated by exogenous NO-donors. The overall goal of our research is to identify pathways by which red light exposures inhibit apoptosis. Light of various wavelengths and intensities has been found to affect various aspects of cellular respiration. This led us to examine the effects of NIR light on various aspects of cellular respiration, namely mitochondrial polarization, electron transport, and ATP synthesis. We also examined the effect of red light exposure on cGMP, due to its role in inhibiting apoptosis. In our approach, retinal pigmented epithelial (RPE) cells were exposed to NIR light (2.88 J/cm<sup>2</sup>, 632 nm). The compounds TMRE, SNARF-1, and the CellTiter-Glo kit were used to assess various aspects of cellular respiration. The Direct cGMP ELISA by ENZO was used to quantify cGMP levels. Results from NIR light exposed and unexposed cells were compared. Near infrared light exposure was found to be associated with increased electron transport, and the increased pumping of protons into the mitochondrial inner membrane space, which, under normal circumstances are associated with ATP production. Interestingly, we did not find differences in ATP synthesis between exposed and unexposed RPE cells. cGMP levels were found to increase immediately after exposure. This difference was not detected three hours after exposure, but reappeared at the 6 hour time point. Differences in cGMP levels were not detected 24 hours after exposure. These data suggest that NIR light exposure affects cellular respiration by uncoupling electron transport from ATP synthesis, a novel finding.

**Polymorphism rs1052536 in base excision repair gene is a risk factor in a high-risk area of neural tube defects in China.** X. Wang, G. Li, X. Wang, Z. Guan, J. Guo, F. Wang, J. Zhang, B. Niu, T. Zhang, J. Yang, J. Wang. Capital Institute of Pediatrics, Beijing, China.

**Background:** DNA Base Excision Repair Gene-DNA LigaseIII (LIG3) is an important repair gene in the repair pathway and plays an important role in maintaining the integrity of mitochondria. Rs1052536 and rs3135967 polymorphisms of the gene are associated with lung cancer, keratoconus, and Fuchs endothelial corneal dystrophy. There is no previously published report on the relationship between the polymorphisms and neural tube defects (NTDs). **Methods:** Mass ARRAY iPLEX was used to determine the distribution of the polymorphisms in the case group of 108 NTD pregnant women and a control group of 233 normal healthy pregnant women to examine the relevance of their polymorphisms and NTD occurrence. **Results:** The homozygotes of rs1052536 TT were associated with an increased risk for NTDs than CC ( $P=0.014$ , OR=2.31, 95%CI [1.17–4.54]), and variants of rs1052536 T were associated with an increased risk of NTDs ( $P=0.024$ , OR=1.50, 95%CI [1.06–2.13]). The stratified analysis showed that TT genotype of rs1052536 increased the risk of anencephaly ( $P=0.016$ , OR=2.69, 95%CI [1.18–6.10]) and the T allele significantly increased the risk of cranial NTDs ( $P=0.033$ , OR=1.56, 95%CI [1.04–2.35]). **Conclusions:** Rs1052536 in LIG3 gene might be a potential genetic risk factor in a high-risk area of NTDs in China.

**MA-43: Potential drug for mitochondrial diseases.** A. Miyauchi<sup>1</sup>, T. Kouga<sup>1</sup>, E. Jimbo<sup>1</sup>, T. Matsuhashi<sup>2</sup>, T. Abe<sup>2</sup>, T. Yamagata<sup>1</sup>, H. Osaka<sup>1</sup>. 1) Pediatrics, Jichi Medical University, Shimotsuke, Tochigi, Japan; 2) Clinical Biology and Hormonal Regulation, Tohoku University Graduate School of Medicine, Sendai, Japan.

**Introduction:** Leigh syndrome (LS) and MELAS (myopathy encephalopathy lactic acidosis and stroke-like episodes) are common phenotype in children. However, there is no curative treatment and effective treatment options are highly expected. We examined a chemical library using fibroblasts from patients with LS and MELAS, and identified MA-43 as a potential therapeutic drug for mitochondrial disease. **Methods & Results:** Our study was carried out in four fibroblast cell lines from LS and MELAS patients after obtaining their informed consent. We examined firstly cell viability assay under oxidative stress condition induced by L-butionine (S, R)-sulfoximine (BSO), a glutathione synthesis inhibitor. Idebenone, an analogue of coenzyme Q10, was used as a positive control. In our chemical library, 3 chemicals were more effective greater than idebenone on all kind of fibroblasts and MA-43 was the most effective among them. Subsequently, we examined mitochondrial bioenergetic functions in LS patient fibroblast under treatment of effective 3 chemicals using Extracellular Flux Analyzer Seahorse XFe 96. Among 3 chemicals, only MA-43 significantly improved all kinds of the oxygen consumption rate (OCR) values; basal OCR, ATP-linked OCR and maximal OCR. In addition, to investigate the mechanism of action, we performed a microarray analysis of ~63,000 genes in MA-43-treated fibroblasts from a patient with Leigh syndrome and we found 475 MA-43-responsive genes. **Conclusion:** We identified that MA-43 rescued fibroblasts from cell death under oxidative stress. MA-43 also improved the mitochondrial respiratory activity. While further studies are needed in order to reveal mechanism of action, MA-43 appears to be potential drug for mitochondrial diseases with the effects of anti-cell death and increase in mitochondrial respiratory activity.

**Transcriptomic analysis of mammalian cell cultures deficient for enzymes involved in the TCA cycle.** A.C. Santos de Medeiros, B.H. Graham. Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN.

The tricarboxylic citric acid (TCA) cycle is the central metabolic pathway for energy production and oxidation of carbohydrates, fatty and amino acids. Pathogenic variants in several of the genes encoding enzymes of the TCA cycle have been associated with recessive genetic disorders featuring metabolic and mitochondrial dysfunction. These disorders can manifest a spectrum of neurological, muscular and other phenotypes and the mechanism(s) of pathogenicity are not fully understood. Previous work from our lab demonstrated energy metabolism defects and mitochondrial DNA (mtDNA) depletion in fibroblasts from patients with mutations in either *ACO2* or *SUCLG1* that encodes mitochondrial Aconitase or  $\alpha$ -subunit of Succinyl-CoA (SCS), respectively. In addition, our lab developed a mouse deficient for *Sucla2* that encodes the ADP-specific  $\beta$ -subunit of SCS. *Sucla2* deficient embryonic fibroblasts also exhibit energy metabolism defects and mtDNA depletion. To further characterize these disorders, our lab performed RNAseq using three genotypes (controls, mutant and mutant rescue lines) for each gene. The main goal of this project is to determine differential expression patterns for each cell line group and compare and contrast among the cell line groups to understand the global transcriptomic effects of these TCA cycle defects. Our preliminary data revealed 3331 significant changes associated with *Sucla2* deficiency where 56% of transcripts were downregulated. In the *SUCLG1* deficient line, 1799 significant changes (37% downregulated transcripts) were detected. In the *ACO2* deficient line, 1947 significant changes (54% downregulated transcripts) were detected. The transcript level of the mutated locus in each cell line was reduced, a result in alignment with the reduced protein levels previously reported. For initial bioinformatics analysis, we used DAVID Software and selected the 5 most enriched functional clusters for each cell line. The majority of the functional groups detected were specifically associated to each line and common functions included secreted pathways, signaling pathways, glycoprotein, and glycosylation. Additional bioinformatics analyses are underway to narrow down the list of candidate genes and unravel pathways either common to all disorders or specific to each disorder. Ultimately, the pathways identified will be used in our models for better understanding of the pathophysiological mechanism(s) of disorders associated with components of the TCA cycle.

**Polymorphism in the *POU4F2* influences the severity of normal tension glaucoma.** J. Lee<sup>1,2</sup>, J. Jeoung<sup>3</sup>, S. Oh<sup>4</sup>, D. Kim<sup>5</sup>, J. Ahn<sup>5</sup>, Y. Oh<sup>5</sup>, M. Kim<sup>1</sup>, M. Seong<sup>1</sup>, S. Park<sup>1,5</sup>, J. Kim<sup>5</sup>. 1) Department of Laboratory Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea; 2) Department of Laboratory Medicine, Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; 3) Department of Ophthalmology, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Republic of Korea; 4) Department of Biostatistics SMG-SNU Boramae Medical Center, Seoul, Republic of Korea; 5) Biomedical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea.

**Introduction:** Normal tension glaucoma (NTG) occurs despite normal intraocular pressure. Neurodegeneration of retinal ganglion cells (RGCs) and the ischemic condition are thought to be the main causes increasing the risk of NTG development. Genes mediating RGC development have been recently identified. Here, aimed to investigate the association of polymorphisms in RGC development genes with NTG and clinical characteristics. **Methods:** A total of 435 NTG patients and 419 normal controls were evaluated. We genotyped four single nucleotide polymorphisms (SNPs) in genes responsible for RGC development including *POU4F1* (rs9601092), *POU4F2* (rs13152799 and rs1504360) and *ISL1* (rs2288468). NTG patients were evaluated on visual field defect severity (mean deviation, MD; pattern standard deviation, PSD) and presence of optic disc hemorrhage (DH). The influence of four SNPs on risk of NTG and DH development was analyzed using Pearson's  $\chi^2$  test or Fisher's exact test, and multiple logistic regressions. The associations for each SNP with MD and PSD were assessed using multiple linear regression analysis. **Results:** No significant association was observed between candidate SNPs and NTG development. However, minor allele T at rs1504360 in *POU4F2* was strongly associated with lower MD and higher PSD after adjustment for covariates (MD, coefficient -1.363,  $P = 0.012$ ; PSD, coefficient 1.416,  $P = 0.001$ ). In addition, major allele T at rs9601092 in *POU4F1* was significantly associated with DH development: The frequency of the major allele T was 1.65 times higher in the DH group, when compared to no DH group ( $P = 0.005$ ). **Conclusions:** rs1504360 and rs9601092 in RGC development genes, *POU4F2* and *POU4F1*, were associated with the clinical severity of NTG. Carriers of these risk alleles are thought to be predisposed to severe visual field defect and DH development. These findings suggest that *POU4F2* and *POU4F1* variants would be important genetic markers for predicting clinical progression of NTG.

## 2082W

**Ocular biometry measurements using SD-OCT in zebrafish models of myopia.** *W.H. Quint<sup>1</sup>, A.I. Iglesias<sup>1,2,3</sup>, M. Meester-Smoor<sup>1,2</sup>, R. Willemsen<sup>3</sup>, C.W. Klaver<sup>1,2,4</sup>.* 1) Department of Ophthalmology, Erasmus Medical Center, Rotterdam, The Netherlands; 2) Department of Epidemiology, Erasmus Medical Center, Rotterdam, The Netherlands; 3) Department of Clinical Genetics, Erasmus Medical Center, Rotterdam, The Netherlands; 4) Department of Ophthalmology, Radboud University Medical Center, Nijmegen, The Netherlands.

**Purpose:** In this study, we aim to establish a method to perform high-resolution eye biometry measurements in zebrafish in order to study myopia-associated candidate genes. We evaluated changes in axial length (AL) using spectral-domain optical coherence tomography (SD-OCT) in a *gjd2* and *lrp2* knock-out (KO) model. In humans, *GJD2* influences the risk of complex myopia while *LRP2* causes syndromic myopia. **Methods:** The *lrp2* and *gjd2* KO fish zebrafish were obtained from the Medical College of Wisconsin and the University of Oregon, respectively. In total, three experimental groups were studied, wild-type (WT), *gjd2*<sup>-/-</sup> and *lrp2*<sup>-/-</sup>. Each group consisted of n=40 eyes (i.e., 20 fish per group). SD-OCT was performed in adult zebrafish at 110 days post-fertilization. Fish were anesthetized by standard methods, and eyes were measured using a 900nm Ganymede OCT system (Thorlabs). AL was measured from the front of cornea to the most anterior part of the retina pigmented epithelium. Further, body length (BL) was measured from the tip of the head to the end of the trunk. To normalize the eye metrics, the ratio between the AL and BL (AL:BL ratio) was calculated. Wilcoxon rank sum test (95% CI) was used to evaluate statistical differences between WT and KO fish (i.e., *gjd2* and *lrp2*). Inter-observer variability was tested in a sub-set of *lrp2* and WT fish (n=20 eyes). Furthermore, we used a 7Tesla MRI system to validate the SD-OCT measurements. **Results:** The AL of the *lrp2* mutants was significantly larger than in WT (1.83mm vs 1.36mm, p=9.88e-12). In the *gjd2* mutant we also found a bigger AL (1.41mm vs 1.36mm, p=7.83e-4). Analysis of the AL:BL ratio, confirmed the larger eye phenotype of the *lrp2* (p=2.34e-13). However, in the *gjd2* we observed a smaller AL:BL ratio compared to WT, suggesting a relatively smaller eye (p=1.24e-3). Inter-observer correlation was high (r=0.96, p<2.2e-16), and the difference between OCT and MRI measurements was < 1.5%. **Conclusions:** SD-OCT allows consistent, high-resolution assessment of *in-vivo* eye biometry in zebrafish. We found differences in AL of *lrp2* and *gjd2* mutants compared to WT. Further analyses need to be performed to confirm the effect of *gjd2* in eye size. Given the observed variability in body length among fish lines, careful control of husbandry conditions is essential. Future studies will include other myopia KO models, additional time points and an increased sample size.

## 2083T

**Gjb2, encoding the gap junction protein Connexin26, is required in supporting cells of the organ of Corti in a developmental stage- and cell type-specific manner.** *D.M Martin, J.M Skidmore, L.A. Beyer, D.L. Swiderski, L. Kabara, D. Dolan, Y. Raphael.* University of Michigan, Ann Arbor, MI.

Mutations in *GJB2*, encoding Connexin26 (Cx26), are the most common cause of autosomal recessive hereditary deafness. Despite this high prevalence, specific pathogenic mechanisms leading to *GJB2*-related hearing loss are not understood, and there are no curative treatments. Individuals with *GJB2*-related hearing loss exhibit normal organ of Corti morphology and spiral ganglion neurons (SGNs), suggesting the mechanisms of hearing loss do not involve major disruptions in morphology of auditory epithelia or nerves. In contrast, mice with conditional loss of *Gjb2* in auditory epithelial supporting cells (*Sox10Cre;Gjb2<sup>lox/lox</sup>*) exhibit profound loss of hair cells and SGNs. Here we used inducible *Sox10Cre<sup>ERT2</sup>*-mediated loss of *Gjb2* to test whether auditory epithelial integrity and function are sensitive to *Gjb2* loss in supporting cells at various developmental stages (i.e. embryonic, early postnatal, and adult). To delete *Gjb2*, tamoxifen was given to *Gjb2<sup>lox/lox</sup>* and *Gjb2<sup>lox/lox</sup>;Sox10Cre<sup>ERT2</sup>* littermate mice by gavage at postnatal day 1 (P1) or by intraperitoneal injection at P14. Mice injected at P1 were allowed to mature until P21, and mice injected at P14 were allowed to mature until P21 or P35 to determine if Connexin26 is required for the maintenance of hearing. Hearing was analyzed using ABR audiometry and Distortion Product Otoacoustic Emissions (DPOAE), and ears were collected and analyzed histologically. Deletion of *Gjb2* was confirmed by reduced anti-Connexin26 staining in ears from mice injected at P1 and P14. Interestingly, *Gjb2* deletion at P1 led to coat hypopigmentation, severe to profound hearing loss, and no major changes in hair cell organization. Similarly, *Gjb2* deletion at P14 resulted in no changes in hair cell organization and progressively decreased hearing, with prolonged *Gjb2* loss in supporting cells at later stages (analysis at P35 vs P21). In contrast, *Gjb2* deletion at P14 had no effects on coat color. These results indicate that reduced *Gjb2* dosage has important developmental stage- and cell type-specific effects on both coat color and on auditory epithelial morphology and function. These findings shed light on specific developmental stages and cell types that are critical for Cx26 function. This unique mouse model has a phenotype that more closely mimics human *GJB2*-related hearing loss than germline mutant mice, and may be suitable for designing therapies to correct *GJB2*-related hearing loss in humans.

**2084F****Rhesus macaques provide new spontaneous animal models of human inherited retinal diseases.**

*M. Raveendran<sup>1</sup>, R.A. Harris<sup>1</sup>, J. Wang<sup>1</sup>, S. Thomasy<sup>2</sup>, A. Moshiri<sup>3</sup>, J.A. Roberts<sup>4</sup>, R. Wiseman<sup>5</sup>, N. Artemyev<sup>6</sup>, T. Stout<sup>1</sup>, R. Chen<sup>1</sup>, J. Rogers<sup>1</sup>.* 1) Baylor College of Medicine, Houston, TX; 2) School of Veterinary Medicine, University of California, Davis, CA; 3) School of Medicine, University of California-Davis, Sacramento, CA; 4) California National Primate Research Center, University of California, Davis, CA; 5) University of Wisconsin-Madison, Madison, WI; 6) University of Iowa, Iowa City, IA.

Rhesus macaques (*Macaca mulatta*) are widely used as animal models for the study of many questions regarding human health and disease, including cardiovascular, metabolic and neurological disorders. Here we describe the development of novel rhesus macaque models of inherited retinal diseases (IRDs). IRDs constitute a major cause of progressive vision loss and visual impairment. One gene-based therapy has been FDA-approved for IRD, but much more work is needed to develop effective therapies for the broad scope of IRDs. Most prior animal studies have used mice as the model organism, but results from mouse models often fail to translate to the human situation. The retina and overall visual system of nonhuman primates is much more similar to the human than are non-primate mammals that lack a cone-rich macula. We have sequenced the whole genomes of >550 rhesus macaques and screened another 1200 for a panel of 225 genes known to cause human IRDs. We identified predicted damaging mutations in multiple IRD genes, and have validated with Sanger sequencing damaging mutations in macaque *NPHP4*, *CRB1*, *USH2A*, *ATF6* and *EYS*. In one case, we performed extensive phenotyping (electroretinography, retinal imaging, etc.) on four visually impaired rhesus macaques from the California National Primate Research Center and validated a naturally occurring macaque model of achromatopsia. All four affected animals are homozygous for the same missense mutation in *PDE6C*, a gene known to cause achromatopsia in humans. The macaque mutation changes an arginine to glutamine in the catalytic domain of the protein, and *in vitro* assays confirm that the altered enzyme has dramatically reduced activity. The *PDE6C* model of achromatopsia illustrates the translational value of nonhuman primate models of IRD and creates new opportunities for the testing of gene- or cell-based therapies. On-going studies of identified mutations in other IRD genes suggest that this approach (i.e. screening of primates for damaging mutations in known human disease loci) will produce valuable new genetic models of disorders for which non-primate models are unsatisfactory.

**2085W****SPECC1L regulates oral epithelial cell integrity downstream of IRF6 in palatogenesis.**

*E.G. Hall<sup>1</sup>, N.R. Wilson<sup>1</sup>, L.W. Wenger<sup>1</sup>, J.P. Goering<sup>1</sup>, Y. Kousa<sup>2</sup>, D.S. Acevedo<sup>3</sup>, L. Pitstick<sup>3</sup>, M. Dunnwald<sup>4</sup>, B.C. Bjork<sup>3</sup>, B.C. Schutte<sup>2</sup>, I. Saadi<sup>1</sup>.* 1) Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS; 2) Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI; 3) Department of Biochemistry, Midwestern University, Downers Grove, IL; 4) Department of Anatomy and Cell Biology, University of Iowa, Iowa City, IA.

Craniofacial anomalies constitute a third of all congenital malformations. Cleft lip with or without cleft palate (CL/P), one of the most common craniofacial birth defects, is a multifactorial disease that manifests in affected families with incomplete penetrance. Pathogenic *SPECC1L* variants identified in patients with rare atypical clefts and syndromic CL/P suggest the gene plays a primary role in face and palate development. To elucidate the role of *SPECC1L* in palatogenesis, we generated null and hypomorphic *Specc1l* deficient mouse alleles. Null mutants are lethal at embryonic day 9.5 (E9.5) with defective neural tube closure and cranial neural crest cell delamination. Hypomorphic *Specc1l*<sup>Δ200</sup> mutants die perinatally, but do not show cleft palate. We argued that further deficiency of *SPECC1L* dosage may be required. Indeed, *Specc1l*<sup>Null/Δ200</sup> compound mutants exhibited transient oral adhesions, subepidermal blebbing, and a delay in palate elevation in 60% of embryos at E14.5, when the palate is adhered in all controls. By E15.5, approximately 15% of embryos showed permanent cleft palate. We hypothesized that defects in the oral epithelium are responsible for the ectopic oral adhesions, which result in delayed palate elevation. Immunostaining of mutant palatal shelves revealed abnormalities in the periderm layer, which serves to prevent adhesion between oral epithelia during early embryonic development. We observed increased actin filaments and ectopic apical distribution of adherens junction markers in the oral adhesions of mutant palate periderm. Heterozygous mouse mutants for known clefting genes, *Irf6*, *Grhl3* and *Arhgap29*, also show periderm defects and ectopic oral adhesions. Accordingly, we found that *SPECC1L* expression in the oral epithelium requires IRF6. Loss of IRF6 has been shown to cause increased ROCK1 activation and subsequent actin stress fiber formation through a reduction in Rho-GTPase ARHGAP29. *Specc1l* mutants also show an increase in actin filaments, but with no change in ARHGAP29 and a reduction in ROCK1 levels, indicating that *SPECC1L* acts downstream of IRF6, but in a ROCK1-independent manner. Together, our data show that *SPECC1L* regulates embryonic palate epithelial integrity, and that delayed palate elevation may represent a predisposing factor in this complex disease. Our results extend the understanding of human CL/P etiology by placing *SPECC1L* within the IRF6/GRHL3 pathway, which plays a major role in lip and palate development.

Chitayat<sup>1,2</sup>. 1) The Prenatal Diagnosis and Medical Genetics Program, Department of Obstetrics and Gynecology, Mount Sinai Hospital, University of Toronto, Toronto, Ontario, Canada; 2) Division of Clinical and Metabolic Genetics, Department of Pediatrics, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 3) Department of Genetics, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; 4) Laboratory of Molecular Gerontology, National Institute on Aging, National Institutes of Health, NIH Biomedical Research Center, 251 Bayview Blvd, Baltimore, MD 21224, USA; 5) Cytogenomics Laboratory, Division of Genome Diagnostics, Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 6) Department of Clinical Genetics, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 7) Department of Medical Genetics, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia; 8) Division of Neuroradiology, Department of Diagnostic Imaging, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 9) Department of Otolaryngology - Head & Neck Surgery, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; 10) Department of Anatomy and Cell Biology, College of Medicine, Alfaisal University, Riyadh, Saudi Arabia; 11) Saudi Human Genome Program, King Abdulaziz City for Science and Technology, Riyadh, Saudi Arabia.

Warsaw breakage syndrome (WBS) is a recently recognized *DDX11*-related rare cohesinopathy, characterized by severe prenatal and postnatal growth restriction, microcephaly, developmental delay, cochlear anomalies and sensorineural hearing loss. Only seven cases have been reported in the English literature, and thus the information on the phenotype and genotype of this interesting condition is limited. We provide clinical and molecular information on five additional unrelated patients carrying novel bi-allelic variants in the *DDX11* gene, identified via whole exome sequencing. One of the variants was found to be a novel Saudi founder variant. All identified variants were classified as pathogenic or likely pathogenic except for one which was initially classified as a variant of unknown significance (VOUS) (p.Arg378Pro). Functional characterization of this VOUS using heterologous expression of wild type and mutant *DDX11* revealed a marked effect on protein stability, thus confirming pathogenicity of this variant. The phenotypic data of the seven WBS reported patients were compared to our patients for further phenotypic delineation. Although all the reported patients had cochlear hypoplasia, one patient also had posterior labyrinthine anomaly. We conclude that while the cardinal clinical features in WBS (microcephaly, growth retardation and cochlear anomalies) are almost universally present, the "breakage" phenotype is highly variable and can be absent in some cases. This report further expands the knowledge of the phenotypic and molecular features of WBS.

**2087F**

**An iPSC approach towards understanding the molecular mechanisms underlying SRCAP mutations in Floating-Harbor syndrome.** R.L. Hood<sup>1,2</sup>, K.M. Boycott<sup>3,4</sup>, M.J.M. Nowaczyk<sup>5</sup>, W.L. Stanford<sup>1,6,7</sup>, D.E. Bulman<sup>1,2,4,7</sup>. 1) Department of Biochemistry, Microbiology and Immunology, University of Ottawa; 2) CHEO Research Institute, University of Ottawa, Ottawa, Ontario, Canada; 3) Department of Genetics, Children's Hospital of Eastern Ontario; 4) Department of Pediatrics, University of Ottawa; 5) Department of Molecular Medicine and Pathology, McMaster University, Hamilton; 6) The Sprott Centre for Stem Cell Research, Regenerative Medicine Program, Ottawa Hospital Research Institute; 7) Department of Cellular and Molecular Medicine, University of Ottawa.

Floating-Harbor Syndrome (FHS; OMIM# 136140) is characterized by short stature, delayed osseous maturation, cognitive deficit, and unique dysmorphic facial features. We previously employed an exome-sequencing strategy which identified heterozygous truncating mutations clustered in the 3' end of *SRCAP* as the genetic cause underlying FHS. More recently, using a high-resolution genome-wide DNA methylation analysis method we identified a specific methylation "epi-signature" in the peripheral blood of FHS individuals. *SRCAP* has been described as having coactivator roles in CREB and CBP-mediated and nuclear (steroid) hormone receptor signaling pathways. It has also been shown to co-precipitate as part of a large chromatin remodeling complex which catalyzes ATP-dependent displacement of the histone variant H2A by H2A.Z. Based on the described roles of *SRCAP*, the clustered nature of truncating *SRCAP* mutations in FHS, and the knowledge that these mutations result in global methylation alterations, we expect that mutations in *SRCAP* to result in widespread gene dysregulation. The existence of individuals with deletions encompassing *SRCAP* who do not have FHS leads us to postulate that the mechanism of disease is not due to haploinsufficiency. To examine the functional consequences of *SRCAP* mutations in cell lineages implicated in the FHS phenotype, we have utilized an induced pluripotent stem cell (iPSC) disease-modeling approach. FHS patient and gender-matched control fibroblast cells were reprogrammed into iPSCs using an episomal vector system and subsequently characterized by pluripotency cell surface marker expression, in vitro embryoid body differentiation, and in vivo teratoma formation assays. iPSCs were plated into Aggrewell™ plates and differentiated into neural crest cells using a dual SMAD inhibition approach. Expression of neural crest markers p75, HNK-1, and SOX10 were confirmed by immunofluorescence staining. Lines were FACS sorted (p75<sup>+</sup>/PI<sup>-</sup>) to isolate pure neural crest cell populations. A combination of RNA-seq and ATAC-seq and will be employed to examine differences in global transcript expression and genomic architecture. Taken together, these analyses will identify downstream targets and pathways which are perturbed within the developing neural crest of FHS patients. These results will provide valuable insight into FHS disease mechanism and the dysmorphology seen in FHS in a precise tissue specific manner.

**2088W**

**Hypomorphic mutations in the replication complex member *GINS3* result in a Meier-Gorlin phenotype.** K. Ahmed<sup>1</sup>, M. McQuaid<sup>4</sup>, K. Kernohan<sup>5</sup>, S. Tran<sup>6</sup>, P. Grover<sup>3</sup>, L. Dupuis<sup>3</sup>, R. Mendoza-Londono<sup>3</sup>, A. Howard<sup>7</sup>, J. Stimec<sup>8</sup>, K. Boycott<sup>5</sup>, F. Boisvert<sup>9</sup>, R. Shaheen<sup>10</sup>, Z. Alhassnan<sup>10</sup>, F. Alkuraya<sup>10</sup>, H. Wurtele<sup>4</sup>, E. Campos<sup>6</sup>, P. Kannu<sup>1,2,3</sup>. 1) Developmental and Stem Cell Biology, Hospital for Sick Children, Toronto, ON, Canada; 2) Institute of Medical Science, University of Toronto, Toronto, ON, Canada; 3) Division of Clinical and Metabolic Genetics, Hospital for Sick Children, Toronto, ON, Canada; 4) Université de Montréal, Maisonneuve-Rosemont Hospital Research Center, Montreal, QC, Canada; 5) Department of Genetics, Children's Hospital of Eastern Ontario, Ottawa, Canada; 6) Genetics & Genome Biology, Hospital for Sick Children, Toronto, ON, Canada; 7) Division of Orthopaedics, Hospital for Sick Children, Toronto, ON, Canada; 8) Body Imaging Division, Hospital for Sick Children, Toronto, ON, Canada; 9) Département d'anatomie et de biologie cellulaire, Université de Sherbrooke, Sherbrooke, QC, Canada; 10) Department of Genetics, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.

To ensure efficient duplication of the genome, numerous factors promoting unperturbed DNA replication have evolved. The evolutionarily conserved CDC45/MCM2-7/GINS1-4 (CMG) protein complex is an essential helicase that unwinds DNA during DNA replication. Interestingly, a causative link was recently made between germline mutations in CMG-encoding genes and Meier-Gorlin syndrome (MGS). MGS is clinically defined by absent or hypoplastic patella, microtia and pre- and postnatal growth restriction leading to short stature. Here we report the identification of four individuals from two unrelated families presenting a Meier-Gorlin-like phenotype, characterized by unreported recessive hypomorphic mutations in the *GINS3* gene, which encodes a subunit of the CMG helicase. Affected individuals were all characterized by global growth failure. We found that mutations in *GINS3* limit cellular proliferation, providing a potential mechanism for the dwarfism phenotype. Furthermore, the mutations seem to destabilize the GINS subcomplex, and the entire CMG helicase altogether. Cells with the *GINS3* mutations accumulate in the S and G2-phases of the cell cycle. We also show that the loss of *GINS3* was associated with replication-associated DNA damage. In summary, we have identified mutations in *GINS3* as a new cause of Meier-Gorlin syndrome and established *GINS3* as a critical component required for efficient DNA replication and genome stability.

**2089T**

**A 61 base-pair intronic deletion in *Snrpb* causes abnormal phenotypes in mice.** S. Alam<sup>1</sup>, J. Majewski<sup>1,2</sup>, L.A.J. Majewska<sup>1,2,3</sup>. 1) Human Genetics, McGill University, Montreal, Quebec, Canada; 2) McGill University Health Centre at Glen Site, Montreal, QC, Canada; 3) Department of Pediatrics, McGill University, Montreal, Quebec, Canada.

*SNRPB*, which codes for a core component of the spliceosomal small nuclear ribonucleoproteins (snRNPs) is mutated in patients with a rare autosomal dominant disorder known as Cerebrocostomandibular Syndrome (CCMS). Patients mostly have craniofacial abnormalities and rib defects. Exome sequencing has revealed mutations mostly in the highly conserved alternative exon 2 (AE2) of the gene, where it plays an instrumental role in autoregulating SNRPB. Using Crispr/Cas9, we have generated a mutant mouse line with a 61 base-pair (bp) intronic deletion upstream of the AE2 of *Snrpb*. Heterozygous and homozygous mice and embryos for this intronic deletion show phenotypic abnormalities that are seen in CCMS patients. Intriguingly, heterozygous and homozygous embryos show reduced SNRPB protein levels, suggesting that this 61 bp sequence plays a critical role in regulating SNRPB levels. Our preliminary data suggests that the splicing of the gene is changed due to the 61-bp intronic deletion where the AE2 is preferentially included in the transcript. Future studies will elucidate the mechanism by which this intronic sequence regulates SNRPB. The importance of this 61-bp intronic sequence near the AE2 might shed light on CCMS studies in cases where the patients do not have mutation in the exons.

**Craniofacial development requires glycosphosphatidylinositol biosynthesis.** *M. Lukacs, P. Chaturvedi, R. Stottmann.* Cincinnati Children's Hospital Medical Center, Cincinnati, OH., USA.

Post-translational protein modification via glycosphosphatidylinositol (GPI) attachment is a multi-step process resulting in the plasma membrane anchoring of nearly 150 proteins. Patients with mutations in GPI biosynthetic pathway genes display an array of phenotypes including brain malformations and neurocristopathies. There is virtually no mechanism to explain the pathology or therapy for patients with germline GPI deficiency. Through a forward genetic screen we identified a mouse mutant (*cleft lip/palate, edema, and exencephaly; Clpex*) with a hypomorphic mutation in *Post-Glycosphosphatidylinositol Attachment to Proteins-2 (Pgap2)*. *Pgap2* is required for GPI anchor lipid maturation by promoting the addition of stearic acid to the lipid portion of the anchor in the golgi apparatus. We hypothesized the *Clpex* mutation results in a lack of surface expression of a critical GPI-anchored protein, Folate Receptor 1 (FOLR1), which is required for neural tube closure and neural crest cell survival. *In vitro* overexpression of tagged FOLR1 in *PGAP2*<sup>-/-</sup> cells demonstrates an inability to present FOLR1 on the plasma membrane. We found the cleft lip/palate phenotype in *Clpex* mutants is due to apoptosis of neural crest cells in the first branchial arch. *In utero* dietary supplementation with folic acid can rescue the cleft lip phenotype and partially rescue the neural crest cell apoptosis in *Clpex* but not the exencephaly or cleft palate. Surprisingly, RNA sequencing of *Clpex* mutants identified decreased expression of anterior patterning genes and a reciprocal increase in posterior patterning genes. Defects in GPI-anchored Cripto may underlie these changes in gene expression as Cripto regulates anterior-posterior patterning through Nodal. Similar defects in A/P patterning have been identified in other GPI biosynthesis mutants. Loss of anterior patterning gene expression may underlie the folic acid resistant neural crest cell apoptosis in *Clpex*. These findings advance our understanding of the pathology of GPI deficiency and provide potential targets for therapy.

**New candidate gene for CAKUT: Exome sequencing in human bladder exstrophy and knockdown studies in zebrafish implicate SLC20A1 as disease gene and major regulator of urinary tract development.** *J.M. Schmidt<sup>1,2</sup>, O. Yilmaz<sup>2</sup>, R. Zhang<sup>1</sup>, A.S. Japp<sup>3</sup>, M. Pleschka<sup>2</sup>, H.M. Reutter<sup>1,4</sup>, B. Odermatt<sup>2</sup>.*

1) Institute of Human Genetics, Faculty of Medicine, University of Bonn, Bonn, Germany; 2) Institute of Anatomy, Faculty of Medicine, University of Bonn, Bonn, Germany; 3) Institute of Neuropathology, Faculty of Medicine, University of Bonn, Bonn, Germany; 4) Department of Neonatology and Pediatric Intensive Care, Faculty of Medicine, University of Bonn, Bonn, Germany.

**Introduction:** The bladder exstrophy-epispadias complex (BEEC) represents the severe end of human congenital anomalies of the kidney and urinary tract (CAKUT). Previously exome sequencing in eight case-parent trios with cloacal exstrophy identified one novel *de novo* variant (p.G237R) in *SLC20A1* in a single patient. Re-sequencing of 526 BEEC patients identified one additional novel *de novo* variant (p.V298A) and one novel maternally transmitted variant (p.K441Q) from an affected mother. The amino acid change p.G237R is highly conserved and localizes to a transmembrane domain of *SLC20A1*. p.V298A and p.K441Q localize to cytosolic domains and are less conserved among species. *SLC20A1* encodes for a Na<sup>+</sup>/PO<sub>4</sub> cotransporter known to play a role in proliferation and TNF-induced apoptosis. We investigated the developmental function of *slc20a1a* in developing zebrafish larvae (zfl) performing Morpholino (MO) knockdown (KD) experiments. The urinary tract in zfl consists of two pronephric ducts, similar in segmentation to human nephrons, that fuse at the cloaca. *Slc20a1a* is frequently used as a pronephric in situ hybridization (ISH) marker. **Methods:** *Slc20a1a* KD in zfl was done by injecting antisense oligonucleotides with a morpholino<sup>®</sup> backbone into 1-2 cell staged eggs, blocking the gene's translation. Specificity of the MO was shown by Western Blot and rescue experiments, co-injecting human mRNA transcripts of *SLC20A1*. We characterized the MO phenotypes using different assays such as sulforhodamine 101 excretion, ISH with several urogenital marker probes, immunohistochemistry (IHC) staining and the transgenic zf reporter line *Tg(wt1b:GFP)*. **Results:** MO KD of *slc20a1a* in zfl results in a severe lethal phenotype that affects multiple organ systems. Focusing on urinary tract, we see formation of pronephric cysts and disorganization of the cloaca. Excretion assay uncovers severe opening defects of the cloaca for the intestine, similar to our index patient with cloacal exstrophy. Yolk endocytosis defects resemble abdominal wall fusion deficiencies. IHC shows defects in proliferation and apoptosis. **Discussion:** In conclusion, exome sequencing in human bladder exstrophy and developmental biology studies in zfl implicate *SLC20A1* as disease gene for human BEEC and therefore CAKUT and as major regulator of urinary tract development. Severe MO phenotypes present with a high lethality among zfl, underlining the overall importance of *slc20a1a* during embryonic development in zfl.

**2092T****Loss-of-function mutations of *TMEM260* cause autosomal recessive polycystic kidney, cerebral atrophy and cardiac malformation. T.M. Keszthelyi<sup>1,2</sup>, M. Varga<sup>1,3</sup>, D. Ralbovszki<sup>3</sup>, L. Ablonczy<sup>4</sup>, C. Bole<sup>5</sup>, C. Antignac<sup>5</sup>, K. Tory<sup>1,2</sup>.**

1) MTA-SE Lendület Nephrogenetic Laboratory, Budapest, Hungary; 2) Semmelweis University, 1st Department of Pediatrics, Budapest, Hungary; 3) Department of Genetics, Eötvös Loránd University, Budapest, Hungary; 4) Gottsegen György National Institute of Cardiology, Budapest, Hungary; 5) INSERM, UMR 1163, Imagine Institute, Paris, France.

Association of polycystic kidney, cerebral atrophy and truncus arteriosus had not been reported in the medical literature at the time of consulting a child with this phenotype. We aimed to identify the causal gene and to characterize the encoded protein. Whole exome sequencing was performed to identify the causal mutations. Gene expression was studied in PBMC. The localization of the *TMEM260* protein was studied by immunofluorescence staining under confocal microscopy in transiently transfected IMCD3 cells after the induction of ciliogenesis. Mutant zebrafish lines were generated by the CRISPR/Cas9 system. We identified two heterozygous truncating mutations in the *TMEM260* gene: c.592\_593delTT, p.Leu198Valfs44\* and c.1854C>A (p.Tyr618\*). They were in trans as verified by Sanger sequencing of the parental samples. We found both mutated alleles to be equally expressed in the parental samples, indicating that none of them leads to nonsense-mediated decay. Out of the two *TMEM260* isoforms, only the long is affected by the p.Tyr618\* mutation, allowing the short isoform to be properly translated. We generated several *tmem260* loss-of-function mutations and found the adult zebra danio mutants with biallelic loss-of-function mutations in a mendelian ratio with no obvious phenotype. Interestingly, in contrast to the proteins implicated in ciliary kidney disorders, the N-terminal myc-tagged *TMEM260* protein showed a cytoplasmic localization, but was not detectable in the primary cilium. The affected boy is currently 7-year-old with extremely enlarged polycystic kidneys (+9SD), preserved renal function, severe developmental delay, epilepsy, muscle hypotonia, strabismus, ptosis, cystic liver and bilateral bronchial stenosis. His phenotype is consistent with the phenotype of four children recently reported with *TMEM260* mutations from two families. In conclusion, we confirm that mutations of *TMEM260* cause a severe autosomal recessive disorder with severe neurological, renal, cardiac, hepatic and bronchial involvement. *TMEM260* is the first protein mutated in a cystic kidney disease which is not localized to the primary cilium. The preserved translation of the short isoform in the two previously published and the current family suggest that the dysfunction of the short isoform is intrauterine lethal. Supported by MTA-SE Lendület Research Grant (LP2015-11/2015), NKFIA/OTKA K109718, FK124230 and KH125566.

**2093F****Elucidating molecular mechanisms for the expanding phenotype of *POLR1A*-related disorders. K.N. Weaver<sup>1</sup>, K. Baltrunaite<sup>1</sup>, C. Brunswick<sup>1</sup>, M.P. Adam<sup>2</sup>, A. Begtrup<sup>3</sup>, D. Bertola<sup>4</sup>, M. Cho<sup>5</sup>, L. Demmer<sup>6</sup>, E. Demo<sup>6</sup>, O. Devinsky<sup>7</sup>, E. Gallagher<sup>8</sup>, M.J. Guillen Sacoto<sup>9</sup>, J. Keller-Ramey<sup>9</sup>, R. Ladda<sup>8</sup>, H. McLaughlin<sup>3</sup>, K. McWalter<sup>8</sup>, K. Menzer<sup>8</sup>, R. Person<sup>3</sup>, R. Schnur<sup>8</sup>, S. Sell<sup>8</sup>, J.D. Symonds<sup>9</sup>, R. Willaert<sup>2</sup>, T. Wenger<sup>2</sup>, S.M. Zuber<sup>10</sup>, R.W. Stottmann<sup>1</sup>.**

1) Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) University of Washington, Seattle, WA; 3) GeneDx, Gaithersburg, MD; 4) University of São Paulo, Brazil; 5) Levine Children's Specialty Center, Charlotte, NC; 6) Sibley Heart Center, Atlanta, GA; 7) Department of Neurology, Comprehensive Epilepsy Center, New York University School of Medicine, New York, NY; 8) Hershey Medical Center, Hershey, PA; 9) Pediatric Neurosciences Research Group, Royal Hospital for Children, University of Glasgow, Glasgow, UK.

Pathogenic variants in *POLR1A* were identified as the cause of autosomal dominant Acrofacial dysostosis, Cincinnati type (AFD-CIN) in 2015. *POLR1A* encodes a subunit of RNA polymerase I, which transcribes ribosomal RNA. Zebrafish lacking *polr1a* exhibit deficient ribosome biogenesis. Thus, AFD-CIN is a ribosomopathy, a congenital malformation syndrome caused by ribosome dysfunction. The 3 index patients with AFD-CIN only had craniofacial and limb anomalies. Other ribosomopathies are associated with pleiotropic phenotypes (including craniofacial, limb, heart, and neurodevelopmental abnormalities) as well as with reduced penetrance and variable expression. We describe expansion of phenotypes beyond the face and limbs in a growing cohort of individuals with suspected pathogenic variants in *POLR1A*. Among 13 patients, there is an increased incidence of developmental delay, congenital heart defects, and seizures. Novel craniofacial phenotypes include cleft lip/palate, craniosynostosis, ptosis, and vocal cord paralysis. Novel limb anomalies include distal contractures, duplicated thumb, and short radii and ulnae. Three individuals inherited variants from a mildly affected or unaffected parent, consistent with reduced penetrance and/or variable expressivity. In this cohort there are 9 missense variants which affect different domains of the *POLR1A* protein. The third cleft domain is the most commonly affected (3 variants). It is thought to be important for transformation of RNA Polymerase I between active and inactive conformations. To test pathogenicity for new variants and elucidate molecular mechanisms for observed phenotypes, we are pursuing *in vitro* studies to characterize each mutant protein as well as *in vivo* studies with a new *Polr1a* loss-of-function mouse model. Preliminary results demonstrate that none of the missense variants lead to decay of mutant *POLR1A* protein. Mice with conditional deletion of *Polr1a* in neural crest cells, an embryonic cell population essential for facial development, exhibit severe deficiency of craniofacial primordia and die mid-gestation. Therefore, our data suggest that variable phenotypes observed among patients with *POLR1A* variants are due to dominant-negative or gain-of-function effects of specific variants rather than haploinsufficiency. Our studies will enhance understanding of the disease pathogenesis and molecular mechanisms associated with *POLR1A*-related disorders and ultimately will improve the care of affected individuals.

**2094W**

**Ubiquitous expression of *Akt1* p.(E17K) results in vascular defects and embryonic lethality in mice.** M.J. Lindhurst<sup>1</sup>, W. Li<sup>1</sup>, J.J. Shweta<sup>1</sup>, H.C. Kondolf<sup>1</sup>, M.R. Yourick<sup>1</sup>, Y. Mukouyama<sup>2</sup>, L.G. Biesecker<sup>1</sup>. 1) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, NIH, Bethesda, MD; 2) Laboratory of Stem Cell and Neuro-Vascular Biology, Genetics and Developmental Biology Center, National Heart, Lung, and Blood Institute, NIH, Bethesda, MD.

Heterozygous mosaic expression of the activating variant, c.49G>A, p.(E17K) *AKT1*, results in Proteus syndrome (PS), a rare disorder characterized by disproportionate, progressive, asymmetric overgrowth that can affect any tissue in the body. In 1986, Happle hypothesized that if the PS mutation were present in the germ line it would be lethal. Using knock-in technology, we created a conditional *Akt1* p.(E17K) allele and developed an inducible mouse model of PS. To test the Happle hypothesis, we activated the variant ubiquitously by crossing *Akt1* conditional and ACTB-cre expressing mice. No live born mutant offspring from this cross were identified (n=62). Timed matings were performed and expected numbers of mutant embryos were seen through E12.5, though some mutants were clearly dead by this time point. Mutant embryos from E13.5-E17.5 were pale, had fewer visible blood vessels and increased hemorrhage. At each time point, there were reduced numbers of mutant embryos with the phenotype varying from mild to severe. Angiogenesis defects were seen in the skin of mutant embryos as they had fewer mural cells and failed to undergo proper arteriovenous remodeling. Histological evaluation of mutant embryos revealed angiectasia in the liver and mild structural defects in the heart. Because the phenotype of the ACTB-Cre mutant embryos suggested that the lethality was due to a vascular defect, we restricted *Akt1* p.(E17K) expression to specific cell types using three additional Cre lines, Tek-cre (endothelial cells), Tagln-cre (smooth muscle cells), Nkx2.5-cre (cardiac cells). Live born offspring heterozygous for both Cre and the *Akt1* conditional allele were found for each line. Evaluation of skin vasculature, liver and heart structures in double heterozygous embryos is underway, but to date only mild liver angiectasia has been found in some of the Tek-Cre embryos. These data show that activation of the PS mutation in endothelial cells, smooth muscle cells or heart is not sufficient for the lethality and vascular defects seen with ubiquitous expression. This suggests that another component of the vascular system is responsible, or alternatively, that activation of the mutation in multiple cell types is necessary to disrupt vascular development and cause the lethality seen with ubiquitous expression of the PS mutation.

**2095T**

**Mutation of mouse *Snap29* models CEDNIK and 22q11.2 deletion syndrome.** L.A. Jerome-Majewska<sup>1,3,5</sup>, V. Keser<sup>1</sup>, S.S. Shameen<sup>1</sup>, Y. Lim<sup>2</sup>, E. Scarlata<sup>3</sup>, C. O'Flaherty<sup>3,4</sup>. 1) Department of Human Genetics, McGill University, Montreal, Quebec, Canada; 2) Department of Pathology, Brigham and Women's Hospital, Harvard Medical School Boston, Massachusetts, United States of America; 3) McGill University Health Centre at Glen Site, Montreal, QC, Canada; 4) Departments of Surgery (Urology Division); 5) Department of Pediatrics, McGill University, Montreal, Quebec, Canada.

Synaptosomal-associated protein 29 (SNAP29) is a member of the SNARE family of proteins and is implicated in a number of intracellular protein trafficking pathways. *SNAP29* maps to human 22q11.2 and mutations in this gene are associated with two developmental syndromes: Cerebral dysgenesis, neuropathy, ichthyosis, and palmoplantar keratoderma (CEDNIK) and 22q11.2 deletion syndrome (22q11.2DS). Unfortunately, existing *Snap29* mutant mouse lines only model skin abnormalities found in CEDNIK patients. Our goals were to describe expression of *Snap29* during embryogenesis and to create a mutant mouse line that can be used to uncover the etiology of malformations shared between CEDNIK and 22q11.2DS patients. *In situ* hybridization was used to characterize expression of *Snap29* throughout embryogenesis, and CRISPR/Cas9 was used to generate a mouse line with deletion in *Snap29*. Morphological abnormalities in *Snap29* mutant embryos and mice were analyzed using standard histological and molecular methods. Herein, we report that *Snap29* was widely expressed in the precursors of organs affected in CEDNIK and 22q11.2DS patients, in addition to many other tissues that were not reported to be affected. Mice and pups with homozygous mutation in *Snap29* survived until adulthood and showed skin, motor, and craniofacial abnormalities, enabling us to study the consequences of mutation in this gene in the neonatal and the postnatal period. In addition, our studies revealed a previously unknown requirement for *Snap29* in the reproductive system. Our study indicates that this novel *Snap29* mutant mouse line models most abnormalities observed in CEDNIK patients and suggest that deletion of *SNAP29* contributes to the phenotypic spectrum of abnormalities found in 22q11.2DS.

**2096F**

**Loss of function mutation of *Eftud2*, the gene responsible for mandibulo-facial dysostosis with microcephaly (MFDM), leads to pre-implantation arrest in mouse.** M. Beauchamp<sup>1</sup>, A. Djedid<sup>2</sup>, K. Daupin<sup>1</sup>, K. Clokie<sup>1</sup>, J. Majewski<sup>2</sup>, L. Jerome-Majewska<sup>1,2,3</sup>. 1) Research Institute of McGill University Health Center, Montreal, Quebec, Canada; 2) Department of Human Genetics, McGill University; 3) Department of Anatomy and Cell Biology, McGill University.

Haploinsufficiency of *EFTUD2* is associated with MFDM (mandibulo-facial dysostosis with microcephaly), but how mutations of *EFTUD2* cause abnormalities associated with this syndrome remains unknown. In the present study, we first aimed to characterize the expression of *Eftud2* during mouse development and to generate a mutant mouse line carrying *Eftud2* mutation. *In situ* hybridization revealed expression of *Eftud2* throughout embryonic development, with tissue-specific expression in ectodermal and mesodermal components of the developing head and craniofacial region. The CRISPR/Cas9 system was used to delete exon 2 of *Eftud2*. *Eftud2* heterozygous animals were viable and fertile despite a 38% and a 30% reduction of *Eftud2* mRNA and protein expression, respectively. Furthermore, heterozygous embryos showed delayed development during embryogenesis, which disappears by organogenesis. Noticeably, RNA sequencing revealed that *Eftud2* was the only transcript affected in heterozygous mice. After collection of embryos from embryonic day (E)3.5 to E18.5 from matings between *Eftud2* heterozygous males and heterozygous females, homozygous mutant embryos were found only at E3.5 stage, indicating pre-implantation arrest. Further *ex vivo* analysis of E3.5 embryos from *Eftud2*<sup>+/−</sup> inter se crosses showed a 32% embryonic death compared to embryos collected from wild-type crosses. Those embryos never grew beyond the blastocyst stage and were unable to hatch. Our observations indicate that reduced levels of *Eftud2* is associated with developmental delay at the embryonic stage, and that *Eftud2* homozygous mutant embryos do not survive post-implantation. Thus, a conditional *Eftud2* knock-out mouse model is necessary to specifically study the requirement of this splicing factor in the developing neural crest cells during craniofacial development.

**Genome-wide chromatin accessibility and transcriptome profiling identifies dysregulated hedgehog signaling in Danforth's short tail mice.** C.E. Keegan, J.S. White, P. Orchard, P.E. Thomas, A. Mychalowych, A. Kiseleva, J. Hensley, B. Allen, S.C.J. Parker. University of Michigan, Ann Arbor, MI.

Caudal birth defects are a group of clinically well-recognized disorders affecting proper development of the spine, kidneys, reproductive organs, intestines and lower limbs, occurring in 1:10,000 pregnancies. The Danforth's Short Tail (*Sd*) mouse exhibits a fully penetrant, semi-dominant phenotype characterized by complete lack of tail, a severely shortened spinal column, persistent cloaca and anal atresia in homozygous *Sd/Sd* mutants. The *Sd* mutant phenotype is caused by an endogenous retrovirus (ERV) insertion, resulting in ectopic expression of the transcription factor *Ptf1a* at E9.5 in the developing tailbud. The *Sd* mutant phenotype has substantial overlap with human caudal dysgenesis disorders, including caudal regression, VACTERL association, and persistent cloaca, thus providing a model to investigate developmental signaling pathways that are disrupted in human caudal dysgenesis. The goal of this project was to investigate epigenomic and transcriptomic changes resulting from ectopic *Ptf1a* expression in embryonic tailbuds from *Sd* mutant embryos to identify the downstream signaling pathways that are disrupted in *Sd* embryos. We performed ATAC-seq and mRNA-seq on tailbuds from E9.5 wildtype and *Sd/Sd* mutant embryos. ATAC-seq analysis identified a region of significantly ( $P=4.5 \times 10^{-7}$ ;  $\text{Log}_2\text{FC}=0.90$ ) increased chromatin accessibility in *Sd* mutants at the lncRNA *Gm13344* adjacent to the ERV insertion near the *Ptf1a* locus, which corresponds to a previously identified autoregulatory enhancer of *Ptf1a*. *Ptf1a* and *Gm13344* were significantly upregulated by mRNA-seq (*Ptf1a*  $P=4.7 \times 10^{-11}$ ,  $\text{Log}_2\text{FC}=8.4$ ; *Gm13344*  $P=2.7 \times 10^{-16}$ ,  $\text{Log}_2\text{FC}=8.4$ ). In total, 49 genes were significantly differentially expressed (5% FDR), including known targets of *Ptf1a*, such as *Kirrel2*, *Nphs1* and *Cpa*. KEGG pathway analysis identified the Hedgehog signaling pathway as being significantly ( $P=1.1 \times 10^{-4}$ ) downregulated, which was confirmed by whole mount *in situ* hybridization with *Shh* and crossing to *Gli1-LacZ* reporter mice. In addition, we found reduced expression of *Shh* and *Foxa2* in the notochord and floorplate and aberrant patterning of the neural tube at E10.5 as a consequence of reduced *Shh* signaling. More generally, we have shown how a single non-coding regulatory mutation propagates through a molecular cascade to perturb a critical signaling pathway. This work can help provide insight into how regulatory changes in gene expression underlie caudal structural birth defects.

**2098T**

**De novo insertion in the *CHD7* gene causing a CHARGE syndrome.** L. Pranckeniene<sup>1</sup>, E. Preiksaitiene<sup>1</sup>, V. Kucinskas<sup>1</sup>, A. Reymond<sup>2</sup>, L. Gueneau<sup>2</sup>. 1) Vilnius university, Vilnius, Lithuania; 2) Center for Integrative Genomics, Faculty of Biology and Medicine, Lausanne University, Switzerland.

CHARGE syndrome is an autosomal dominant development disorder with a broad phenotype that can involve almost all organ and sensory systems. CHARGE syndrome is characterized by a pattern of congenital anomalies including choanal atresia and malformations of the heart, inner ear, and retina. Variants in the *CHD7* gene on chromosome 8q12.1 cause CHARGE syndrome in most patients. We report a novel *de novo* pathogenic p.Y2114delinsYHILNDH insertion in *CHD7* gene causing severe features of CHARGE syndrome. In this research whole exome sequencing (WES) of a Lithuanian trio (affected individual and healthy parents) was performed. WES was generated by sequencer Illumina™ HiSeq 2500 and primary analysis was performed by GATK™. Exomes were mapped according to the human reference genome build 38. *De novo* variants (DNVs) called by VarScan. To discard a false positive *de novo* calls when it was not known whether all of the individuals in the trio are identified correctly conservative filters by SnpSift software on detected DNMs quality parameters were applied: 1) genotype quality of the individual  $\geq 50$ ; 2) number of reads at each site  $> 35$ . Called potentially DNVs manually reviewed by the IGV and validated by Sanger sequencing by ABI PRISM 3130xl Genetic Analyzer. Functional annotation of all identified DNMs were performed using ANNOVAR and hg38 reference human genome sequence. The insertion c.6340\_6341insATCACATCCTCAATGACC identified in patient is in a region of *CHD7* which is highly conserved between species. According *in silico* analysis this insertion causes an important structural change on the protein level: from polar tyrosine into a chain of histidine, isoleucine, leucine, asparagine which forms a short alpha helix instead the linear chain. Considering the size of p.Y2114delinsYHILNDH nonframeshift insertion, which possibly forms a new structure of protein domain, we provide evidence, that insertion in this region causes severe phenotype of CHARGE syndrome. This study was supported by the Lithuanian–Swiss cooperation program under UNIGENE project agreement no. CH-3-□MM-01/04.

**Analysis of molecular pathway in primary fibroblasts and myoblasts of Wolf-Hirschhorn patients (WHS) by RNA-seq.** P.N. Doronzio, G. Marangi, S. Lattante, S. Frangella, M. Zollino. Istituto di Medicina Genomica, Università Cattolica del Sacro Cuore, Roma, RM, Italy.

Wolf-Hirschhorn Syndrome (OMIM: 194190) is a contiguous gene syndrome caused by partial 4p deletion, which core phenotype include intellectual disability (ID), the typical “greek warrior helmet profile”, growth delay and seizures. All these signs are regarded as minimal diagnostic criteria for WHS and they all map within the terminal 1.9 Mb on 4p, where the WHS critical region (WHSCR-2) was described. Pathogenesis of WHS appears to be multigenic, being *WHSC1* the major candidate gene for growth delay and the typical facial dysmorphism, and *LETM1* and *CPLX1* the major synergic genes for seizures. We aimed to investigate by RNA Seq impaired molecular pathways at a whole transcriptome level in fibroblast and myoblast cell lines obtained from 4 WHS patients and from 3 healthy controls. Extent of the 4p deletion was of 6.5 Mb in two patients, 3.1 Mb and 16.5 Mb in individual patients. RNA samples has been used to prepare RNA-Seq libraries for ION Proton platform. The results has been analyzed with “Cufflinks” and “Salmon” workflows, while the DAVID functional annotation tool has been used for pathway enrichment analysis. We observed a differential expression of genes related to cell growth / proliferation and to cell adhesion pathways both in fibroblasts and myoblasts. With respect to these subset of transcripts, results were to large extent comparable to each other independently from the 4p deletion size.

**2100W**

**Background:** We recently reported on 8 individuals from 6 families with loss of function variants in *ZNF462* who presented with metopic craniosynostosis, ptosis, agenesis of the corpus callosum, and developmental delay. Subsequently, Cosemans et al. reported on an individual with a *de novo* balanced translocation affecting *ZNF462*; this individual presented with 46,XY,t(9;13)(q31.2;q22.1) and intellectual disability, metopic craniosynostosis, dysgenesis of the corpus callosum, and ptosis. Little is known about the function of *ZNF462* in humans. Chang et al. showed that *Zfp462*, an ortholog of *ZNF462*, is expressed in the developing forebrain, brainstem, and spinal cord in mice. To further understand the pathogenicity of loss of function of *ZNF462*, we have continued phenotyping patients and are studying loss of function of *znf462* in zebrafish. **Methods:** Additional cases of *ZNF462* variants were collected from correspondence associated with the Weiss et al. paper published by our group and GeneMatcher. Zebrafish morpholino oligonucleotide (MO) and in situ hybridization experiments are being conducted. An MO was designed to target the *znf462* translation start site. Anti-sense RNA probes are being used to target *znf462* in wild type zebrafish and dorsal and ventral markers, including *chrd* and *bmp2b*, in morphants. **Results:** In addition to the 9 published reports, we have identified 10 new individuals from 9 families with variants in *ZNF462*; six of these variants are truncating variants with predicted loss of function and one variant is a missense variant. Thirteen of the 19 (68%) total cases (including previously published cases) exhibit dysgenesis of the corpus callosum, 12 of 19 (63%) have ptosis, and 9 of 19 total are affected with intellectual disability or autism spectrum disorder. Preliminary results in our zebrafish experiments have shown that morphant embryos display varying severities of a ventralized phenotype, which involves a reduction in the size of dorsally derived structures such as the neural plate and somites. The morphant phenotype first appears with injections of 2.5 ug of MO. In situ hybridization experiments show that morphant embryos have decreased *chrd* expression and increased *bmp2b* expression at the 6 hpf and 8 hpf stages, respectively. **Conclusions:** Loss of function in *ZNF462* results in a distinctive phenotype in both humans and zebrafish. Preliminary data in the zebrafish model suggest that *znf462* may play a role in dorsoventral patterning.

**2101T**

**Impaired pro-angiogenesis in mesenchymal stem cells of Werner syndrome.** H.H. Cheung, J. Tu, W.Y. Chan. School of Biomedical Sciences, The Chinese University of Hong Kong, Hong Kong, China.

Werner syndrome (WS) is an autosomal recessive genetic disorder characterized by premature aging. Progressive degeneration is found in a variety of tissues indicated by symptoms such as premature graying and loss of hairs, osteoporosis, arteriosclerosis, early onset of bilateral cataracts, type 2 diabetes, skin atrophy and ulcers. Arteriosclerosis, malignancies and the associated abnormalities result in potentially life-threatening complications. Premature arteriosclerosis, caused by thickening, hardening and loss of elasticity of artery walls, gives rise to a number of vascular diseases such as myocardial infarction, ischemic legs, skin atrophy and ulcers. These clinical symptoms suggest a predisposed vascular disorder, whereas the mechanistic origin remains largely unclear. Our current work employs reprogramming and gene editing technologies to generate patient-specific mesenchymal stem cells (MSCs) and the isogenic MSCs with the causative mutation (*WRN*) corrected. The gene-corrected MSC has an enhanced function in promoting angiogenesis of endothelial cells (ECs). We compared the pro-angiogenic trophic factors secreted by these MSCs, and found hepatocyte growth factor (HGF) diminished in WS MSC. HGF plays a central role in supporting angiogenesis, morphogenesis, tissue regeneration and homeostasis. Knockdown of HGF in MSC decreased angiogenesis of ECs. Therefore, we suggest that deficit of HGF engenders the impaired pro-angiogenesis function of stem cells, signifying a mechanism for the pathogenesis of vascular aging in WS.

**2102F**

**The Impact of prenatal diagnosis and early hormonal therapy (EHT) on autism spectrum traits (AST) in boys with 47,XXY (Klinefelter syndrome).** S. Chea<sup>1</sup>, C. Samango-Sprouse<sup>1,2,3</sup>, T. Sadeghin<sup>1</sup>, A. Gropman<sup>4</sup>. 1) The Focus Foundation, Davidsonville, MD; 2) Department of Pediatrics at George Washington University, Washington, DC; 3) Department of Human and Molecular Genetics at Florida International University, Miami, FL; 4) Children's National Medical Center, Washington, DC.

**Background:** 47,XXY is the most frequently occurring X&Y chromosomal variation (1:650), yet 75% of cases remain unidentified in their lifetime. The social-cognitive phenotype of these boys includes language-based learning disorders, speech and motor delays, and executive dysfunction. Autism Spectrum Disorder (ASD) has been reported to be increased in this population, but research has been confounded by many salient factors. This study investigated the incidence of Autism Spectrum Traits (AST) within the social-cognitive pathway, as well as the effects of Early Hormonal Therapy (EHT) and prenatal diagnosis on AST in boys with 47,XXY. **Method:** 74 boys with 47,XXY between the ages of 2-7 years underwent neurodevelopmental evaluations, including the Gilliam Autism Rating Scale, 2<sup>nd</sup> Edition (GARS-2) and Social Responsiveness Scale, 2<sup>nd</sup> Edition (SRS-2). 22 boys (30%) with 47,XXY received EHT; 52 (70%) did not. EHT was administered based on patients' pediatric endocrinologist's assessment of phallus size compared to neurotypical boys of the same age. 57 of the 74 boys (77%) were prenatally diagnosed (PRE); 17 (23%) were postnatally diagnosed (POST). **Results:** On the GARS-2, boys in the EHT group showed significant improvement in their social interaction compared to the non-EHT group ( $P=.026$ ). There was also a significant difference in the probability of ASD between the two ( $P=.038$ ), where the non-EHT group had a 30.1% likelihood for ASD traits compared to 13.6% in the EHT group. Positive effects of EHT were seen in the social cognition domain of the SRS-2 ( $P=.041$ ) for the treated group. Within the non-EHT group, PRE boys with 47,XXY had greater communication ( $P=.033$ ) and social interaction ( $P=.002$ ) than POST on the GARS-2. The probability of ASD was also significantly less in the non-EHT PRE boys compared to POST ( $P=.004$ ). Untreated PRE boys had significantly better social awareness ( $P=.046$ ) and motivation ( $P=.004$ ), and less autistic mannerisms ( $P=.026$ ) on the SRS-2. **Conclusion:** This study provides further evidence that this subset of boys with 47,XXY present with an increased risk for disturbances on the social-pragmatic pathway within ASD. The etiology of this vulnerability is unknown but could be derived from family history of ASD, parental origin of the additive X, timing of diagnosis, EHT, and/or other unknown factors. This origin of the vulnerability warrants further investigation to identify those infants at greatest risk who then need more specialized support.

**The genetics of situs inversus totalis without primary ciliary dyskinesia.** M.C. Postema<sup>1</sup>, A. Carrion-Castillo<sup>1</sup>, S.E. Fisher<sup>1,2</sup>, G. Vingerhoets<sup>3</sup>, C. Francks<sup>1,2</sup>. 1) Department of Language & Genetics, Max Planck Institute for Psycholinguistics, Nijmegen, Netherlands; 2) Donders Institute for Brain, Cognition and Behaviour, Radboud University, Nijmegen, Netherlands; 3) Department of Experimental Psychology, Ghent University, Belgium.

*Situs inversus totalis* (SIT), a left-right mirror reversal of the viscera, sometimes occurs with recessive Primary Ciliary Dyskinesia (PCD). However, most people with SIT do not have PCD, and the etiology of their condition remains poorly studied. Those without PCD may have an elevated rate of left-handedness, implying developmental mechanisms linking brain and body laterality. We sequenced the genomes of 15 people with SIT, of which six had PCD, and 15 controls. The SIT subjects with PCD all had likely recessive mutations in genes already known to cause PCD and SIT. Two non-PCD cases also had recessive mutations in known PCD genes, suggesting reduced penetrance for PCD in some SIT cases. One non-PCD SIT case had a recessive mutation in *PKD1L1*, which has previously been linked to SIT. However, six of the nine non-PCD SIT cases, including most of the left-handers, had no obvious monogenic basis for their condition. Environmental influences, or possible random effects in early development, must be considered.

**The rare diseases clinical research network (RDCRN): Translational research in action.** *T.K. Urv<sup>1</sup>, L. Reineck<sup>2</sup>, L. Griffith<sup>3</sup>, J. Witter<sup>4</sup>, J. Wan<sup>5</sup>, T. King<sup>6</sup>, W. Merritt<sup>7</sup>, C. Roy<sup>8</sup>, J. Morris<sup>9</sup>.* 1) NCATS/ORDR, NIH, Bethesda, MD., USA; 2) NHLBI, NIH, Bethesda, MD., USA; 3) NIAID, NIH, Bethesda, MD., USA; 4) NIAMS, NIH, Bethesda, MD., USA; 5) NIDCR, NIH, Bethesda, MD., USA; 6) NICHD, NIH, Bethesda, MD., USA; 7) NCI, NIH, Bethesda, MD., USA; 8) NIDDK, NIH, Bethesda, MD., USA; 9) NINDS, NIH, Bethesda, MD., USA.

A Rare Disease is one that affects no more than 200,000 individuals in the United States. Collectively there are an estimated 7,000 diseases that fall into this category; cumulatively there are approximately 25 million people in the United States who are affected by rare diseases indicating that 'Rare Diseases' are a significant public health concern. Despite advances in our understanding of the causes and mechanisms of many rare diseases, effective treatments are available for fewer than 5%. Although advances in technologies have recently led to promising and potentially transformative treatments, there are challenges in bringing effective treatments to individuals living with rare diseases. First, making a diagnosis can be challenging with many patients experiencing a "diagnostic odyssey" of months or years because of limited knowledge of the range of disease manifestations. Second, there are often no high quality natural history datasets documenting how the disease affects patients' functioning, and how it progresses over time. Third, there are often no adequate clinical or biological markers to support the clinical development of new therapeutics. Fourth, the small number of patients lead to challenges in the design and implementation of studies. Finally, the resources available for therapeutics development are limited, making it critical to establish partnerships among patient groups, industry, academic investigators and federal funding agencies. To address these challenges the Rare Diseases Act of 2002 directed the NIH to support consortia for advancing prevention, diagnosis, clinical readiness, and treatment of rare diseases. Since its inception, numerous NIH institutes and centers have partnered to support the Rare Diseases Clinical Research Network (RDCRN). The RDCRN is a collaborative network of investigators and patient groups committed to the investigation of rare diseases working in partnership with leaders in technology to enhance communication and sharing of resources through a multidisciplinary approach. To date this program has successfully supported 31 individual consortia that conducted research on 238 individual disorders. This presentation will outline the successes and challenges of this translational research network for rare diseases. It will also highlight the goals of the latest iteration of the network and will highlight opportunities to build bridges from basic to clinical research and beyond research to therapy.

**2105F**

**The Birth Defects Research Laboratory biorepository of human fetal tissue.** *D. O'Day<sup>1</sup>, K. Aldinger<sup>2</sup>, B. Nelson<sup>2</sup>, K. Millen<sup>2</sup>, D. Doherty<sup>1</sup>, I. Glass<sup>1</sup>.* 1) University of Washington, Seattle, WA; 2) Seattle Children's Research Institute, Seattle, WA.

The Birth Defects Research Laboratory (BDRL), a NIH funded repository of both normal and abnormal human fetal tissue collected from elective terminations and spontaneous loss, provides research material to academic and non-profit organizations. We systematically undertake assessments of tissue and organ preparation and storage protocol's for histological analyses, bulk nucleic acid or protein analyses, cultured cell lines and single cell/nuclei analyses. We are currently evaluating protocols to optimize collection and processing of fetal tissues to facilitate entry into whole tissue and single cell/nuclei protocols. Methods vary by starting material, dissociation method, and storage conditions, as well as downstream applications. For example, we performed RNA-sequencing of whole tissue and single cell RNA-sequencing of fixed cells from the same specimen for several organ systems that were isolated either immediately or after storage in Hibernate E at 4°C for 24 hours. While few differences were detected between whole tissue RNA, using several next-generation single cell approaches, we observed decreased representation of certain cell types, including progenitor and neuronal subpopulations, in the 24 hour brain sample possibly due to increased storage time prior to processing. Our results highlight the importance of immediate processing for brain tissue for single cell RNA-sequencing analysis to minimize the potential loss of certain cell populations. In addition to providing bulk tissues, we collaborate with recipients to optimize the storage conditions of tissues and processing methods based on their biological questions and techniques. All tissues, cultured cells, and single cell/nuclei preparations that are not distributed to recipients are stored for future use. Tissues and their derivatives provided by BDRL have been instrumental for major impact research projects such as ENCODE-Roadmap, BrainSpan Atlas of the Developing Human Brain, and over 60 additional NIH-funded investigators over the past 2 years.

**2106W**

**Non-coding mutations causing NCMD in a new family: Multimodal imaging provides insight into the development of the human macula.** *K.W. Small<sup>1,2</sup>, F.S. Shaya<sup>1,2</sup>, L.R. Small<sup>3</sup>, N. Udar<sup>1,2</sup>, E.M. Stone<sup>4</sup>.* 1) Macula & Retina Institute, Glendale, CA; 2) Molecular Insight Research Foundation, Glendale and Los Angeles, CA; 3) Bascom Palmer Eye Institute, University of Miami, Miami, FL, United States; 4) University of Iowa, Iowa City, IA, United States.

**Purpose:** To describe multimodal imaging and corresponding functional studies in a new family with North Carolina Macular Dystrophy (NCMD/MCDR1) incorporating OCT angiography (OCT-A) for the first time to our knowledge. **Methods:** A descriptive, retrospective study of a family with NCMD. Diagnostic multimodal imaging and functional testing of the retina included color fundus photographs, fundus auto fluorescence, fluorescein angiography (IVFA), spectral domain OCT (SD-OCT), OCT angiography (OCT-A), multifocal ERG (mf-ERG), full field ERG, and microperimetry. DNA sequencing was performed using Sanger sequencing. IRB approval was obtained. **Results:** Three subjects, representing 3 generations of a single family each demonstrating a different grade of NCMD, underwent clinical and genetic testing. Multimodal imaging helped to demonstrate the developmental nature of the retinal and choroidal lesions in each and the extent of visual function that was suggestive of the stage of development that is affected by methylation at the 6q16 locus. Genetic testing demonstrated the V2 point mutation (French / German mutation) in the DNASE 1 hypersensitivity binding site on chromosome 6q16 causing overexpression of the retinal transcription factor PRDM13. The oldest family member has many similarities to foveal hypoplasia / foveal plana. **Conclusion:** NCMD has great phenotypic variability, which can only be appreciated by examining multiple family members. This is the first report to our knowledge showing a correlation of functional studies with multimodal imaging including OCT-A. All layers of the retina and choroid demonstrate mal-development and varying degrees of malfunction. Although PRDM13 is over expressed in the amacrine cells, we have yet to demonstrate an abnormality specific to this cellular layer. The retinal vasculature seems surprisingly well preserved / intact by OCT-A when compared to the IVFA. OCT-A suggests foveal hypoplasia to be a phenocopy of grade 1 NCMD. OCT-A does reveal vascular abnormalities not found with standard IVFA. We propose that the grade of severity is determined by the embryonic stage that methylation occurs at the DNASE1 hypersensitivity binding site which regulates the expression / overexpression of the retinal transcription factor PRDM13. We propose that there is a similar control of expression at the MCDR3 / IRX1 site.

**2107T**

**Genetics of cortical dysplasias and epilepsy treated surgically.** *C.A.B. Garcia<sup>1</sup>, H.R. Machado<sup>1</sup>, W.A. Junior<sup>1</sup>, T.L. Teixeira<sup>1</sup>, M.S. Volponi<sup>1</sup>, L.L. Ball<sup>2</sup>, K.N. James<sup>2</sup>, J.J. Gleeson<sup>2</sup>.* 1) University of São Paulo, Ribeirão Preto, Brazil; 2) Howard Hughes Medical Institute (HHMI).

Focal cortical dysplasias are a group of cerebral cortical developmental malformations characterized by changes in the microarchitecture of the cerebral cortex, whether or not accompanied by abnormal cells, mainly dysmorphic (giant, dysplastic) neurons and balloon cells, is considered the most common cause of epilepsy refractory to drug treatment in the pediatric population. Hemimegalencephaly is a clinically devastating malformation of cortical development in children. Studies demonstrated that genetic factors are involved in the HME. Ten patients diagnosed with HME were selected, with an indication for surgical treatment in the Neuropediatrics outpatient clinic of the Hospital das Clínicas of the Medical School of Ribeirão Preto - USP. The surgical protocol consists of a biopsy of the damaged tissue, being fractionated in two parts, one for the morphological analysis and another frozen fraction in liquid nitrogen for analysis through the exome sequencing. The objective of this study is to identify the specific genetic alterations leading to HME by analyzing the genes of mTOR signaling pathways as well as other parallel tracks. The microscopic exam of most patients show histological sections of the neocortex stained by H&E show extensive areas of neuronal loss and neuronal bodies grouped, resulting in architectural distortion, mainly of the laminar distribution. Additionally, there are some rare foci of giant neurons, with large nuclei and wide cytoplasm. In some areas, the cortex presents reduction of the number of layers (four layers), with fusion of the gyri. The analysis of the results identified somatic mutations in the same PIK3CA gene, in two cases, being considered one of the genetic causes for patients diagnosed with HME. For case 1, with a rate of 22%, c.1258T> C (p.C420R) and case 2, with a rate of 11%, c.1624G> A (p.E542K). The selection of 50 most expressed genes, with several types of mutations, and their impact on the phenotype were also performed in these patients. We conclude that these mutations are associated with increased mTOR signaling in affected brain regions. These results may contribute to the identification of the genes responsible for HME and thus to understand the mechanisms associated with the evolution of the pathology. In addition, to contribute to the discovery of new therapies for epileptic seizures caused by these developmental lesions, with modulators for the mTOR pathway.

**2108F**

**Optimization of CRISPR/Cas9-mediated gene editing in monkey embryos.** *J. Jiang*<sup>1,2</sup>, *X. Luo*<sup>1,2</sup>, *B. Su*<sup>1</sup>. 1) State Key Laboratory of Genetic Resources and Evolution, Kunming Institute of Zoology, Chinese Academy of Sciences, Kunming 650223, China; 2) Kunming College of Life Science, University of Chinese Academy of Sciences, Kunming 650204, Yunnan, China.

The RNA-guided Cas9 nuclease from the microbial clustered regularly interspaced short palindromic repeats (CRISPR) adaptive immune system have been used to facilitate efficient genome editing in many model and non-model animals. However, its application in non-human primates is still at early stage, and the efficiency of gene modification in primate embryos remains rather low. Here, using zygotic injection of Cas9 mRNA and multiple single-guide RNAs with an optimized protocol, we achieved a high knockout efficiency of 86.6% for MCPH1- a human autosomal recessive primary microcephaly gene. Furthermore, through homology directed repair (HDR), we obtained monkey embryos with humanized MCPH1, and the efficiency is 21.4%. The improved gene editing efficiency in monkeys may serve as a useful tool in human disease and human evolution studies.

**Pharmacogenomics role in tuberculosis treatment: A view in Peruvian patients.** *H. Guio*<sup>1</sup>, *K. Levano*<sup>1</sup>, *D. Tarazona*<sup>1</sup>, *C. Sanchez*<sup>1</sup>, *L. Jaramillo*<sup>1</sup>, *S. Capristano*<sup>1</sup>, *R. Zegarra*<sup>1</sup>, *L. Solarí*<sup>1</sup>, *A. Soto*<sup>2</sup>, *A. Mendoza*<sup>3</sup>, *J. Cabrera*<sup>3</sup>, *C. Rojas*<sup>1</sup>. 1) Instituto Nacional de Salud, Lima, Peru; 2) National Hospital Hipolito Unanue; 3) Peruvian National Health Strategy for Prevention and Control of Tuberculosis.

**INTRODUCTION:** N-acetyltransferase 2 (NAT2), cytochrome P4502E1 (CYP2E1) and arylacetamide deacetylase (AADAC) are the enzymes responsible for metabolizing isoniazid (INH) and rifampicin (RIF), first-line anti-tuberculosis drugs. Variation in the genes responsible for these enzymes could affect the metabolism of INH and RIF and thus its efficacy in tuberculosis. This study is the first to analyze NAT2, CYP2E1 and AADAC genotypes in a Peruvian population with tuberculosis. 500 drug-sensitive tuberculosis patients were genotyped for NAT2, CYP2E1 and AADAC gene polymorphisms by sanger sequencing. **RESULTS:** We found seven haplotypes consisting of 6 SNPs and 14 NAT2 genotype variations in Peruvian population. According to bimodal distribution, the predicted phenotype was composed of 53% rapid and 47% slow acetylator, CYP2E1 phenotype was composed of 37% rapid and 63% slow acetylator, together 25.2% was slow acetylator and could have risk of developing hepatotoxicity to isoniazid. On the other hand, AADAC phenotype was composed of 82% rapid and 18% slow acetylator, however present similar CLiNT values to rifampicin. We did not find any association between slow acetylator to isoniazid or rifampicin and hepatotoxicity ( $p > 0.05$ ). In addition, we found hepatotoxicity to isoniazid in patients with higher cholesterol levels and received their anti-tuberculosis treatment in a specific health region ( $p < 0.05$ ). We continue to evaluate the genotypes of glutathione S-transferase (GST) as an important phase II detoxification enzyme and be able to complete the metabolic cycle. **CONCLUSION:** Different genotypes identification and association with different comorbidity would help to determine a new treatment scheme adjusting frequency and dose, foresee MDR-TB development in Peruvian population and allow future proposals to personalized medicine that represents a challenge in environments with limited resources.

**Cohen syndrome-associated gene *VPS13B* is required for male fertility and spermiogenesis in mice.** *M. Bordessoules<sup>1</sup>, M. Guillemant<sup>2</sup>, V. Carmignac-Quere<sup>1</sup>, V. Lhussiez<sup>1</sup>, C. Bruno<sup>2</sup>, P. Fauque<sup>2</sup>, C. Choux<sup>2</sup>, J. Barberet<sup>2</sup>, C. Thauvin-Robinet<sup>1,3</sup>, L. Faivre<sup>1,3</sup>, L. Duplomb<sup>1</sup>, R. Da Costa<sup>1</sup>.* 1) INSERM UMR 1231 GAD team, Genetics of developmental disorders, University of Bourgogne Franche-Comté, F-21000 Dijon, France; 2) Service de biologie de la reproduction et centre d'étude et de conservation des œufs et du sperme humains (CECOS), F-21000 Dijon, France; 3) Centre de Référence maladies rares "Anomalies du Développement et syndromes malformatifs" de l'Est, Centre de Génétique, FHU TRANSLAD, CHU Dijon, F-21000 Dijon, France.

Cohen syndrome is a polymalformative autosomic recessive disorder due to mutations and chromosomal rearrangements affecting the *VPS13B* gene. Individuals with CS display microcephaly, intellectual disability, progressive retinopathy, facial dysmorphism, truncal obesity and intermittent neutropenia. In order to comprehend the cellular and molecular basis causing those symptoms, we generated a novel *Vps13b*<sup>Δex3/Δex3</sup> mouse model. Among the first and most striking phenotypes, we observed male infertility. Intellectual disability does not permit CS individuals to care for children and become parents, and therefore no fertility issues have yet been reported in patients. In *Vps13b*<sup>Δex3/Δex3</sup> mice, while dissections showed a fully developed reproductive tract, epididymal dilacerations revealed a low count of non-motile and structurally abnormal spermatozoa. Histological analysis of testicular sections demonstrated a reduction in late-stage spermatids compared to controls. TUNEL assay was performed to confirm spermatid death. Periodic Acid Schiff staining failed to evidence acrosomes in all spermatid stages. As in patient fibroblasts and cellular models for CS, electron microscopy showed a disorganized Golgi apparatus. In addition, no pro-acrosomal vesicle was found docking onto the spermatid nuclear membrane. Altogether, our data supports the putative function of *VPS13B* in cellular trafficking and suggests that (1) male individuals with CS are likely to be affected with oligoasthenoatozoospermia and (2) other spermiogenesis factors may be hidden among genes associated with rare syndromic forms of intellectual disability for which there is no data on the patients' fertility.

**2111F**

**Identification of novel transcription factor in mid-brain development using alternative transcription factor binding site prediction method.** *H.S. Lee<sup>1,2,3</sup>, H.J. Lee<sup>1,3</sup>, Y.H. Shin<sup>2</sup>, S.H. Bae<sup>2</sup>, J.M. Kang<sup>2</sup>, Y.E. Lee<sup>2</sup>, J. Moon<sup>2</sup>.* 1) Biomarker Center, Biomedical Research Institute, Seoul National University Hospital, Seoul, Republic of Korea.; 2) General Medical Research Institute, Bundang Medical Center, CHA University, Seoul, Republic of Korea.; 3) co-author.

Embryonic development in mammals involves function of a plethora of transcription factors. Cell fate specification relies on the action of critical transcription factors that become available at distinct stages of embryonic development. The development of mid-brain Dopaminergic neurons (mDAN) is controlled by a combination of between cell extrinsic pathway (SHH-FGF8 or Wnt1) and intrinsic signals (FOXA2, LMX1A). Both *Nurr1* and *Pitx3* are required for mDAN differentiation and survival. Human neural progenitor cells were more efficient differentiation into dopamine neurons in the treatment to the small chemical compound X (sCCX) than other conventional differentiating factors such as SHH&FGF8, confirmed by in vitro results. To understand the developmental patterns of gene expression in the dopamine differentiation of human neural progenitor cells, we performed transcriptome analysis of targeting neurons at different treatment time points by in vitro culture with or without small molecules or SHH or negative control condition using next-generation RNA sequencing (RNA-seq). We showed that distinct gene expressions shown by different factor-treated cells (negative, SHH & FGF8 and sCCX) and most genes were down-regulated and four genes uniquely upregulated by sCCX and predicted to be related to neurogenesis by bioinformatics data analysis. Furthermore, that genes uniquely up-regulated by sCCX, *Nurr1* and *TH* act in a coordinated manner for dopamine differentiation and they have motifs in its promoters which novel transcription factor X (nTFX) binds by alternative transcription factor binding site prediction method. We found that nTFX expressed midbrain of E10 embryonic mouse but not midbrain of over E12 embryonic mouse brain. The nTFX protein merged with TH+ cells and bind to the promoter of *TH* gene. Our results suggest that a nTFX is one of the required factor for mDAN specification during brain development.

**2112W**

**Ret loss of function leads to changes in developmental trajectories of single cells in the developing enteric nervous system of a mouse model of Hirschsprung disease.** E.A. Vincent<sup>1</sup>, S. Chatterjee<sup>2</sup>, G. Cannon<sup>1</sup>, D. Auer<sup>1</sup>, H. Ross<sup>1</sup>, A. Chakravarti<sup>2</sup>, L.A. Goff<sup>1,3</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins School of Medicine, Baltimore, MD; 2) Center for Human Genetics and Genomics, NYU Langone Medical Center, New York, NY; 3) Department of Neuroscience, Johns Hopkins School of Medicine, Baltimore, MD.

During development enteric neural crest cells (ENCC) migrate rostro-caudally along the intestinal tract where these progenitors eventually differentiate into the neurons and glia that form the enteric nervous system (ENS). In Hirschsprung disease (HSCR) the ENS fails to form in the distal colon, leading to pseudo-obstruction and severe distension. The majority of HSCR cases are attributed to loss of function (LOF) of *RET*, which encodes a tyrosine kinase receptor expressed by all ENCC, yet the precise mechanisms by which *RET* LOF leads to HSCR remain unknown. We hypothesize that *RET* LOF leads to precocious differentiation of ENCC, thereby depleting the progenitor pool prior to reaching the distal colon, and leading to changes in acquired cell fate. To address our hypotheses, we performed single-cell RNA sequencing on FACS-enriched ENCC in the developing gut of *Ret*<sup>+/+</sup> and *Ret*<sup>-/-</sup> mice. These cells include uncommitted progenitors, maturing glial, and neuronal cell types. In developing glial cells, differential gene expression analysis with respect to genotype identified genes associated with cell cycle regulation and neuronal differentiation. *Ret*<sup>-/-</sup> cells were enriched for mature glial markers, consistent with a model of precocious differentiation. Pseudotemporal analysis of the neuronal lineage identified several developmental trajectories associated with maturation of distinct neuronal cell types. Within this context, *Ret* LOF leads to restriction in the lineage potential of developing neurons. One lineage associated with decreased expression of *Ret* remains accessible to *Ret*<sup>-/-</sup> cells, while another, in which *Ret* expression is maintained, is inaccessible to *Ret*<sup>-/-</sup> cells. Importantly, while neural trajectories that require *Ret* also express the canonical Ret co-receptor Gfra1, trajectories that do not require *Ret* express other, noncanonical co-receptors in the Gfra family. Additional analyses identified differential genes with respect to genotype, sex, developmental age, and cell type. These results provide key insights into how the organization and development of the ENS are affected in HSCR, and identify sex-dependent changes in differentiation rate and cell fate commitment in a *Ret* LOF context. These data yield insights into the complex developmental processes involved in establishment of the mammalian ENS, and demonstrate the specific roles for Ret signaling in regulation of ENS progenitor proliferation, differentiation, and cell fate commitment.

**Biallelic inactivation of HEPHL1 impairs ferroxidase activity and causes abnormal hair phenotype.** P. Sharma<sup>1</sup>, M. Reichert<sup>1</sup>, T.C. Markello<sup>1,2,3</sup>, G. Golas<sup>1</sup>, D.R. Adams<sup>1,2,3</sup>, P.J. Steinbach<sup>4</sup>, Y. Lu<sup>5</sup>, B. Fuqua<sup>6</sup>, C.D. Vulpe<sup>6</sup>, G.J. Anderson<sup>5</sup>, W.A. Gahl<sup>1,2,3</sup>, M.C.V. Malicdan<sup>1,2,3</sup>. 1) NIH Undiagnosed Diseases Program, Common Fund, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA; 2) Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA; 3) Office of the Clinical Director, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA; 4) Center for Molecular Modeling, Center for Information Technology, National Institutes of Health, Bethesda, MD, USA; 5) Iron Metabolism Laboratory, QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia; 6) Center for Environmental and Human Toxicology, Department of Physiological Sciences, University of Florida, Gainesville, Florida, USA.

The maintenance of the correct redox status of iron is functionally important for several critical biological processes. At the molecular level, multicopper ferroxidases play an important role in oxidizing ferrous iron, released from cells, into ferric iron, which is subsequently distributed by transferrin. There are two well-characterized ferroxidases, ceruloplasmin (CP) and hephaestin (HEPH) that facilitate this reaction in diverse tissues. Recently, a novel ferroxidase has been identified called Hephaestin like 1 (HEPHL1), also known as Zyklopen. Here we report a child with compound heterozygous mutations in *HEPHL1* (NM\_001098672), who presented with abnormal hair (pili torti and trichorrhexis nodosa), combined-type ADHD, speech articulation disorder, severe heat intolerance, and chronic leg pain. The maternally inherited mutation (c.809\_1063del; p.ala270\_ala355del) affects mRNA splicing and eliminates exon 5, causing an in-frame deletion of 85 amino acids. The paternally inherited mutation (c.3176T>C; p.Met1059Thr) changes a highly conserved methionine that is part of a typical type I copper binding site in HEPHL1. We further demonstrate that HEPHL1 has ferroxidase activity and that the two mutants found in this patient exhibit loss of this activity, likely due to loss of copper binding. These results suggest that the biallelic mutations we identified in our proband are loss-of-function mutations. We subsequently generated a loss-of-function *Heph1* model in mice. *Heph1* knockout mice are viable, and have curly whiskers throughout their life, consistent with the hair phenotype in the patient with loss-of-function *HEPHL1* mutations. Overall, our results enhance our understanding of the function of HEPHL1 and implicate altered ferroxidase activity in hair growth and hair disorders.

**aPKC modifier genetic screen for suppressors of epithelial junctional defects in *C. elegans*.** *J.G. Montoyo-Rosario<sup>1</sup>, J. Nance<sup>1,2</sup>*. 1) Helen L. and Martin S. Kimmel Center for Biology and Medicine at the Skirball Institute of Biomolecular Medicine, NYU School of Medicine, New York, New York 10016, USA; 2) Department of Cell Biology, NYU School of Medicine, New York, New York 10016.

Epithelial cells are specialized cells that line our organs that possess adhesive junctions enabling them to function as a barrier to the outside environment. Loss of junctions compromises tissue structure and has been linked to human diseases such as kidney disease, cancer, and birth defects. The scaffolding protein PAR-6 is a conserved regulator of junction maturation. PAR-6 is known to function together with the kinase aPKC, but the targets of aPKC that are important for junction formation are largely unknown. We found that junctions in the *C. elegans* spermatheca can break in animals carrying a temperature-sensitive allele of *pkc-3* (aPKC), leading to sterility. We also used a PKC-3 protein degradation strategy and found that junctions in embryos failed to condense into continuous junctions. To find genes that may function with *pkc-3* in regulating junctions, we performed a large-scale suppressor screen to find *pkc-3* mutant animals that are now fertile. In addition to intragenic mutations in the *pkc-3* gene, we identified a new allele of a known *pkc-3* regulator (*gl-1*). In addition, we identified two different alleles of *F22F4.1*, an uncharacterized gene that encodes a secreted protein expressed in a subset of embryonic epithelia. We will report on our characterization of these *pkc-3* suppressors and their function in junction maturation.

**Fetal echocardiographic features and whole exome sequencing results of ventricular non-compaction cardiomyopathy.** *X.Y Hao<sup>1</sup>, X.W Liu<sup>2</sup>, H.R Sun<sup>3</sup>, Y.H He<sup>4</sup>.* 1) Echocardiography Department, Beijing An Zhen Hospital, Capital Medical University, Beijing, China; 2) Echocardiography Department, Beijing An Zhen Hospital Beijing, China; 3) Beijing An Zhen Hospital, Capital Medical University, Beijing, China; 4) Beijing Key Laboratory of Maternal-Fetal Medicine and Fetal Heart Disease, Beijing Anzhen Hospital, Capital Medical University, Beijing, China.

**Objective:** To investigate the echocardiographic diagnosis for fetal ventricular non-compaction cardiomyopathy (VNCC) and to analyze the genetic associations with VNCC. **Methods:** A total of 13 fetuses were diagnosed as VNCC from 30009 fetal echocardiographic studies in Beijing Key Laboratory of Maternal-Fetal Medicine and Fetal Heart Disease from October 2010 to March 2018. Fetal umbilical cord tissue samples and the parental peripheral blood were collected after the families opted for termination of the pregnancy. Whole exome and Sanger sequencing were performed using the biological specimens. **Results:** In this cohort, 6 fetuses were diagnosed with biventricular, 5 were with left ventricle, and 2 were with right ventricle and the gestational weeks of the fetuses range from 20 to 34 weeks (median week, 25 weeks). Among the 13 fetuses with VNCC, 11 cases were terminated after a detailed prognosis consultation during pregnancy, 1 fetus was born, 1 case lost follow-up. In addition, 8 cases were associated with congenital heart disease (CHD), and 4 cases with fetal arrhythmia, and the average cardiovascular profile score of fetuses was 7.15. There were VNCC mostly involved the apical and lateral wall of the LV. The non-compacted layer to compaction layer ratio of RV was more than LV. For genomic study, 1 case had LDB3 gene mutation (c. T964C / p. S322P), and 1 had PRKAG2 gene mutation (c. G1592A / p. Arg531Gln), both of the two mutations were de novo. In addition, 3 cases came from one family were associated with pathologically significant mutation which inherited from their mother who didn't combine any representation. **Conclusion:** Fetal VNCC can involve both the left and the right ventricles. Prenatal echocardiography combined with WES could play an important role in the timely diagnosis, prognosis and parental counseling of patients with VNCC.

**449T**

**Comparison of the prevalence of pathogenic copy number variation in tetralogy of fallot and associated congenital heart defect diagnosed between fetuses and children.** *T. Man<sup>1</sup>, Y. He<sup>1</sup>, X. Hao<sup>1</sup>, H. Sun<sup>1</sup>, S. Ge<sup>2</sup>.* 1) Beijing Anzhen Hospital and Capital Medical University, Beijing, China; 2) Pediatrics, St. Christopher's Hospital for Children, Blue Bell, PA, USA.

**Objectives** To ascertain the use of whole genome low coverage sequencing in TOF and associated defects in fetuses and children. **Methods** A total of 143 with TOF (70 fetuses, and 73 children) confirmed by pathological anatomy were analyzed from the data base at the Beijing Key Laboratory of Fetal Heart Defect/Maternal Fetal Medicine. Demographic, echocardiography and whole genome low coverage sequencing (×1) data were reviewed to investigate the association between genetic abnormalities and TOF. **Results** 21 cases (21/70; 30%) in fetuses had pathogenic CNVs. 1 with Smith-Magenis syndrome, 12 with 22q11.2 microdeletion syndrome, 1 with 22q11.2 microduplication, 1 with 1p36 microdeletion syndrome, 1 with 17p12 microdeletion, 1 with Down syndrome, 2 with Edward syndrome and 1 case of Patau syndrome. While 8 cases (8/73; 11%) in fetuses had pathogenic CNVs. 5 with 22q11.2 microdeletion syndrome, 1 with 22q11.2 microduplication, and 1 with Xp22.2 microduplication. There was significant difference in pathogenic CNVs between fetuses and children ( $p < 0.01$ ). In this cohort, 38 cases (38/70; 54%) in fetuses and 39 cases (39/73; 53%) in children were complicated with other intracardiac malformations. For the cases with pathogenic CNVs, 13 cases (13/21; 62%) in fetuses were complicated with other intracardiac malformations. 7 with right aortic arch, 5 with absent ductus arteriosus, 4 with aberrant left subclavian artery, and 3 cases of persistent left superior vena cava. And 5 cases (5/8; 63%) in children were complicated with other intracardiac malformations. 3 with right aortic arch, 3 with intramuscular ventricular septal defect, 1 with atrial septal defect, 1 with patent ductus arteriosus, and 1 case of persistent left superior vena cava. There was no significant difference in associated other intracardiac malformations between fetuses and children, with both the whole cohort and pathogenic CNVs ( $p > 0.05$ ). **Conclusions** There was a significant yield of pathogenic CNVs by whole genome low coverage sequencing in fetuses and children with TOF. The prevalence of CNVs in fetuses was higher than children with TOF.

**450F**

**A gene-by-gene interaction associated with the risk of conotruncal heart defects.** C. Lyu<sup>1</sup>, D.M. Webber<sup>2</sup>, X. Tang<sup>3</sup>, S.L. MacLeod<sup>4</sup>, C.A. Hobbs<sup>3</sup>, M. Li<sup>1</sup>, the National Birth Defects Prevention Study. 1) School of Public Health, Indiana University Bloomington, Bloomington, IN; 2) Department of Pathology and Immunology, Washington University at St. Louis, St. Louis, MO; 3) Department of Pediatrics, University of Arkansas for Medical Sciences, Little Rock, AR; 4) Center for Translational Pediatric Research, Arkansas Children's Research Institute, Little Rock, AR.

Congenital heart defects (CHDs) are the most common birth defects and the leading cause of infant mortality attributable to birth defects. Conotruncal heart defects (CTDs) are a subtype of CHDs accounting for 20 ~ 30% of CHD cases. It is widely believed that the cause of disease involves a complex relationship among genetic variants and parental lifestyle factors. Nevertheless, most of the existing studies have evaluated each single genetic variant for association with the disease risk. In this article, we focused on the interactions between 13 candidate genes within folate, homocysteine, and transsulfuration pathways for potential association with CTD risk. The discovery phase includes 328 case-parental trios enrolled in the National Birth Defects Prevention Study (NBDPS). To evaluate the interaction of two genes, we applied a conditional logistic regression model to estimate the interaction effect for all possible SNP pairs within two respective genes by contrasting the affected infants with their pseudo-controls. The findings were replicated with an independent replication phase of 86 additional case-parental trios enrolled in the NBDPS. The results of two phases were further integrated by a fixed-effect meta-analysis. One SNP pair (i.e. rs56219526 and rs11892646) located in gene *MTRR* and *DNMT3A*, respectively, involving in homocysteine pathway, were found to be associated with CTD risk (nominal p-value of 6.55e-06). After multiple testing adjustment, the association was marginally significant with an adjusted p-value of 0.06. Further studies with larger sample sizes are needed to confirm and elucidate this potential interaction between two genes.

**451W**

**Risk of congenital anomalies is associated with birth weight in infants of diabetic mothers.** S. Ramanathan<sup>1</sup>, B. Becerra<sup>2</sup>, N. Kraus<sup>1</sup>, R.D. Clark<sup>1</sup>. 1) Pediatrics, Loma Linda University Medical Center, Loma Linda, CA, CA; 2) Allied Health Studies, Loma Linda University.

Maternal diabetes is well-known to increase the risk for birth defects. The purpose of this study was to determine the cumulative incidence of infants of diabetic mothers (IDMs) and of congenital anomalies in these infants over a five year period at Loma Linda University Children's Hospital. This was a retrospective chart review of all infants with the International Classification of Diseases (ICD)-9 code 775.0 (Infant of Diabetic Mother- IDM), admitted to the nursery or neonatal intensive care unit (NICU) between 2010 and 2014. There were 465 infants with this code among their diagnoses. Of these, 418 met inclusion criteria (excluded for insufficient clinical data, other teratogenic exposures, genetic syndromes or chromosome abnormalities). Of these, 65 mothers had type 1 diabetes mellitus (T1DM), 125 have type 2 diabetes (T2DM) and 217 had gestational diabetes (GDM). About 21% of the infants (86/418) identified as IDMs at our institution had at least one birth defect over this time period which is double the 10% risk that is reported in the literature. Of these, 48 were born to women with pregestational diabetes mellitus (PGDM): 35 to women with T2DM (41%) and 13 to women with T1DM (15%). Thirty-seven were born to women with GDM (43%) The risk for birth defects was significantly increased in infants who were small or appropriate for gestational age (SGA/AGA), when compared to large for gestational age (LGA) babies. 26% of SGA/AGA babies had birth defects, while 13% of LGA babies had birth defects (Chi-square test =10.919, p<0.05). While only 6% of the IDMs were SGA (25/418), 40% of them had congenital anomalies (10/25). While 50% of the IDMs were AGA (205/418), 25% of had congenital anomalies (51/205). About 45% of the IDMs were LGA (188/218); however, only 13% (35/188) had congenital anomalies. **IDMs with and without congenital anomalies and type of maternal diabetes:**

All (n= 418)	T1DM	T2DM	GDM	Not known
Average for gestational age	25	54	121	5
Small for gestational age	1	9	15	
Large for gestational age	39	62	82	5
<b>With congenital anomalies (n= 86)</b>				
Average for gestational age	7	21	23	
Small for gestational age	1	4	5	
Large for gestational age	5	8	11	1

In our patient population, the risk for congenital anomalies is highest for SGA infants and is lowest for LGA infants. This suggests that the factors that drive the disruption of the embryonic development during the first trimester may be different from those that drive diabetic fetopathy in the second and third trimesters in IDMs.

**Targeted cfDNA analysis using DANSR assays for determination of fetal RHD status.** S. Saini, R. Foley, P. Hartley, C. Kingsley, E. Wang, P. Bogard, M. Schmid. Roche Sequencing Solutions, 5945 Optical Court, San Jose, CA 95138.

**Objective:** Cell-free DNA (cfDNA) testing provides high sensitivity for common trisomies and a lower false positive rate than traditional prenatal screening methods. Here we aim to develop a targeted cell-free (cfDNA) test, the Harmony® prenatal test, enhancement that allows determination of fetal RhD status in RhD-negative pregnant women. **Methods:** 12 simulated pregnancy plasma samples with known RHD genotype were prepared by titrating non-pregnant, RHD-positive cfDNA (fetal source) into non-pregnant, female RHD-negative cfDNA (maternal source) to simulate fetal fractions of 5%, 10% and 15%. A 0% sample served as a negative control. Digital Analysis of Selected Regions (DANSR) assays targeting exons 2, 3, 4, 5 and 7 of the RHD gene were added to existing DANSR assays and the generated DANSR products were hybridized onto a custom DNA microarray for analysis of fetal fraction and determination of fetal RHD status using the fetal fraction optimized algorithm FORTE. **Results:** In all 12 simulated pregnancy samples, RHD sequences were detected. The mean RHD signal in each case correlated with fetal fraction and was therefore consistent with an RHD-positive fetal source on the background of an RHD-negative maternal source. As expected, no RHD sequences were detected for samples with 0% fetal fraction. **Conclusions:** Targeted cfDNA testing using DANSR assays has the potential to determine fetal RHD status and be used as a noninvasive screening method to identify pregnancies at increased risk for RhD immunization. .

**453F**

**Prenatal diagnosis of unbalanced XY translocation following a sex discordance between prenatal cell-free DNA screening and ultrasound examination results.** L. Lai, A. Wiita, Z. Qi, J. Yu. Laboratory Medicine, University of California San Francisco, San Francisco, CA.

With the general acceptance of prenatal cell-free DNA (cfDNA) screening, more women have access to fetal DNA information. Gender discordance is observed in 1 in 1500 to 2000 pregnancy in patients who undertake prenatal cfDNA screening. The phenotypic females with male cfDNA screening result have been reported in one patient with 9p24 deletion including *DMRT1* gene which encodes a male-specific transcriptional regulator and one patient with mosaic monosomy X/XY (90%/10%), but not yet in patient with unbalanced XY translocation. We report a case involved a 37-year-old G1 woman who was seen at 21 weeks GA for genetic counseling because of female gender on ultrasound with male gender reported on cfDNA screening. She underwent cfDNA screening (MaterniT21 PLUS test, Sequenom Laboratories, San Diego, CA, USA) at 12 weeks gestation based on advanced maternal age. Her cfDNA screening was negative for trisomy 21, 18, and 13 and positive for Y chromosomal material. The fetal fraction was reported at 10%. Subsequent amniocentesis with chromosome analysis and SNP microarray revealed an unbalanced XY translocation with the breakpoints at Xp22 and Yq11, in addition to a normal X chromosome (ISCN nomenclature: 46,X,der(X)t(X;Y)(p22.33;q11.21).arr[GRCh37] Xp22.33(60814\_2697868)x1,Xp22.32q28(2834723\_154927199)x2, Yq11.21q12(14604583\_28817458)x1). This unbalanced XY translocation resulted in one copy loss within the terminal pseudoautosomal region 1 (PAR1), two copies of non-PAR1 region of X chromosome, and one copy of Yq11qter excluding *SRY* gene. Further metaphase FISH analysis confirmed the loss of *SRY* gene. XY translocations are relatively rare and females with t(X;Y)(p22;q11) are typically phenotypically normal except for short stature due to haploinsufficiency of *SHOX* gene, while the males may have various abnormalities including intellectual disability, infertility, or more severe anomalies. However, a recent long-term follow-up study suggests that additional phenotypes, including intellectual disability, facial dysmorphism, eye abnormalities, or skeletal defects, may be present in a minority of female t(X;Y) carriers. To our knowledge, this is the first reported case of a rare unbalanced XY translocation with prenatal sex discordance between cfDNA screening and ultrasound results and demonstrating the importance of chromosomal/microarray analysis in detecting rare structure rearrangements relevant to the diagnosis of ambiguous genitalia in fetus.

**Case report: Heterozygous FGF10 deletion associated with severe pulmonary hypoplasia causing neonatal deaths in a family with Lacrimo-auriculo-dento-digital (LADD) Syndrome.** *T.M. Bartell, M.H. Lipson.* Genetics, Kaiser Permanente, Sacramento, CA.

Lacrimo-auriculo-dento-digital (LADD) syndrome results from pathogenic variants in FGFR2, FGFR3 and FGF10 genes. It is associated with abnormalities of the lacrimal and salivary glands, teeth, ears, digits, limbs and genitourinary system. LADD Syndrome demonstrates variable expressivity and autosomal dominant inheritance with a few sporadic cases. We report a family with LADD syndrome who lost two neonates in two generations to severe pulmonary hypoplasia. The family has a large, interstitial deletion of 2.08 Mb at 5p11p12 which contains the entire FGF10 gene. FGF10 is responsible for the branching morphogenesis of many organs including the lungs. Homozygous and heterozygous mutations of the FGF10 gene are reported to cause severe pulmonary hypoplasia in mice. There are no cases of isolated severe pulmonary hypoplasia in humans with heterozygous FGF10 mutations in the literature. The occurrence of severe pulmonary hypoplasia is underreported in LADD Syndrome caused by pathogenic FGF10 variants, and is an important aspect for prenatal genetic counseling.

**Preimplantation genetic diagnosis for nephrotic syndrome.** *M.T. Akbari<sup>1,2</sup>, F. Khordadpoor Deilamani<sup>2</sup>.* 1) Tarbiat Modares University Faculty of Medical Sciences, Tehran, Iran; 2) Tehran Medical Genetics laboratory, Tehran, Iran.

**Introduction:** *NPHS2* is a causative gene for autosomal recessive steroid-resistant nephrotic syndrome. This syndrome is characterized by proteinuria, hypoalbuminaemia and oedema. Carrier couples are at 25% risk for producing an affected child. Here we report the first successful pregnancy in Iran in a family with a previous affected child following single cell embryo biopsy and PGD for the detection of c.156del (p.(Thr53Profs\*46)) mutation in the *NPHS2* gene. **Materials and Methods:** Two different tests (STR based linkage analysis and Cycle sequencing of exon 1 of *NPHS2* gene) were used to study the transmission of c.156del (p.(Thr53Profs\*46)) mutation in *NPHS2* gene to the embryos. The PGD workup started with DNA sample analysis of the prospective parents and their affected son. STR haplotyping for family members was performed, in order to identify the most informative STR markers linked to the disease causing gene, to be used in the following clinical PGD cycle. Blastomeres from 6 embryos were received from IVF center. Cell lysis, DNA extraction and whole genome amplification (WGA) were performed on each blastomere. The WGA products were then analyzed using the above mentioned tests in order to determine the mutation status. **Results:** WGA was not successful for two embryos. One embryo was homozygous for mutant allele and one another embryo was homozygous for normal allele which was transferred to the uterus. Two embryos showed discrepancy between sequencing and linkage analysis which may be due to allele drop out. **Conclusions:** Preimplantation genetic diagnosis of nephrotic syndrome resulted in successful pregnancy.

**Development of a polycystic ovarian syndrome algorithm to identify cases in electronic health records.** K. Actkins<sup>1,3</sup>, D. Hucks<sup>2,3</sup>, P. Straub<sup>2,3</sup>, M. Wellons<sup>4</sup>, L. Davis<sup>2,3</sup>. 1) Department of Microbiology, Immunology, and Physiology, Meharry Medical College, Nashville, TN; 2) Division of Genetic Medicine, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN; 3) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 4) Division of Diabetes, Endocrinology, and Metabolism, Vanderbilt University Medical Center, Nashville, TN.

Polycystic ovarian syndrome (PCOS) is one of the most common endocrine disorders among reproductive-aged women and one of the leading causes of infertility<sup>1,2</sup>. It has been characterized by polycystic ovaries, excess androgens, excessive hair growth, and irregular menses. Although a small number of genetic loci contributing to PCOS have been identified, the exact molecular mechanisms underlying the disease are still unknown. Women who are diagnosed with PCOS often demonstrate features of metabolic disorders such as increased body mass index (BMI), insulin resistance, dysglycemia, and dyslipidemia which are also risk factors for cardiovascular diseases (CVD) including, but not limited to, type 2 diabetes, hypertension, and heart disease<sup>1,3</sup>. Furthermore, PCOS is associated with greater CVD risk suggesting there could be similar underlying mechanisms regulating CVD and PCOS<sup>3,4</sup>. Even though PCOS does not demonstrate higher prevalence among minority populations, the comorbid metabolic dysfunction is more often observed in African American and Hispanic populations. Moreover, evidence has shown that Hispanic women tend to have a more severe PCOS phenotype due to hyperandrogenism and dysmetabolism<sup>2</sup>. To better understand PCOS, greater attention should be focused on the racial and ethnic differences in risk factors and comorbidities including metabolic syndrome. To achieve this goal, we developed an algorithm designed to identify PCOS cases across a diverse hospital population using the information in the de-identified electronic health records (EHRs) at Vanderbilt University Medical Center. Using a combination of structured and unstructured data, we developed two PCOS algorithms. The first algorithm relied solely on International Classification of Disease codes, Ninth and Tenth Revision, to identify a set of PCOS cases whereas the second algorithm included text mining for PCOS keywords. A positive predictive value (PPV) of 40% was obtained for the first dataset and a PPV of 78% was obtained for the second dataset. Inclusion of specific PCOS keywords increased the accuracy of the algorithm and prevented the inclusion of false positives in the dataset. The PCOS algorithm will be validated through an eMERGE collaboration using Northwestern EHRs.

**Prenatal characterization of osteogenesis imperfecta type V caused by *IFITM5*.** T.K. Ha<sup>1</sup>, D. Belefrod<sup>1</sup>, J.T. Shieh<sup>1,2</sup>, S. Chetty<sup>2</sup>, M.E. Norton<sup>3</sup>, \*Both authors contributed equally to this work. 1) Department of Medical Genetics, University of California San Francisco, San Francisco, CA; 2) Institute for Human Genetics, University of California, San Francisco; 3) Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California, San Francisco.

Osteogenesis imperfecta (OI) is heterogeneous connective tissue condition with a variable phenotype ranging from perinatal lethal to subclinical fractures. About 95% of cases are caused by autosomal dominant or *de novo* variants in *COL1A1/2*. Recently, an interferon induced transmembrane protein 5 (*IFITM5*)-related OI Type V (OMIM 610967) was characterized by distinctive findings. We describe, to our knowledge, the earliest prenatal diagnosis of OI Type V at 18 weeks gestation caused by a paternally inherited c.119C>T (p.40S>L) missense variant in *IFITM5*. The patient was a G4P0A4 woman with 2 prior spontaneous abortions. During her third and fourth pregnancies at 22 and 18 weeks, respectively, ultrasound showed bilateral bowed femurs, fractured tibias, and decreased skull ossification. Autopsies after termination revealed blue sclerae, generalized osteopenia, and fractures thought to be consistent with perinatal lethal osteogenesis imperfecta Type II. The father had an unremarkable family history and normal stature; however, imaging noted subclinical bone lesions that were nondiagnostic on biopsy. High resolution chromosomal analysis, chromosomal microarray, captured gene panel sequencing of known OI genes, and deletion/duplication analysis of *COL1A1/2* on genomic DNA extracted from cultured amniocytes were nondiagnostic. Sequence analysis of *IFITM5* on fetal amniocytes and paternal blood showed a pathogenic missense variant c.119C>T (p.40S>L). Maternal testing was negative. We report the earliest prenatal diagnosis of *IFITM5*-related OI Type V at 18 weeks gestation caused by a paternally inherited missense variant. While Glorieux *et al.* 2000 first described OI Type V in patients with fractures, distinctive radiographic findings, and mesh-like pattern in lamellae, the full phenotypic spectrum is ongoing. The paternal subclinical lesions and severe prenatal findings in two fetuses suggest markedly variable expressivity. As the phenotype of OI Type V continues to be delineated, we recommend prenatal sequence analysis for *IFITM5* in *COL1A1/2*-negative cases where radiographic evidence is highly suggestive of OI. Our findings expand the characterization of OI type V and the recurrence in this case illustrates the need for suspicion for this condition and consideration of prenatal diagnosis.

**458T**

**Clinical exome sequencing identifies a *COL1A1* splice altering mutation in a prenatally diagnosed skeletal dysplasia patient.** M. Mulatinho<sup>1</sup>, H. Lee<sup>1</sup>, D. Krakow<sup>2</sup>, UCLA Clinical Genomics Center. 1) Department of Pathology and Laboratory Medicine, University of California, Los Angeles, Los Angeles, CA; 2) Department of Obstetrics and Gynecology, University of California, Los Angeles, Los Angeles, CA.

Prenatal imaging scans performed by ultrasound (US) have been successfully used to identify fetal anomalies; depending on the findings, parents are offered invasive procedures followed by genetic tests, in order to identify their clinical significance. Recently, clinical exome sequencing (CES) is being introduced as a prenatal diagnostic tool because it can provide results with higher resolution down to the single base-pair level, compared to traditional methods (karyotype, FISH and CMA), with its turnaround time improving to be reasonable for prenatal cases. Nevertheless, CES data interpretation and clinical relevance in the prenatal setting remain complex due to limited phenotype. Here we describe a 24 weeks old female fetus with possible skeletal dysplasia (SD) due to bowing of the bilateral femurs identified by US. These findings were suggestive of a moderate form of osteogenesis imperfecta (OI) and were discussed with both parents that declined invasive diagnostic test or termination of pregnancy. The infant was born by spontaneous vaginal delivery at 39 weeks gestation [7 lb 1.6 oz (3.22 kg)], and after birth a complete skeletal survey was obtained. The radiographs revealed poor mineralization of the calvarium, appendicular skeleton - thin cortices, mild bowing/upper extremities, and more severe bowing in the lower extremities. Cortical irregularity of the left proximal humerus was also noted. Widened squamosal and coronal sutures were noted in the skull. The SD clinical features present in the newborn is more severe than seen by US. CES performed on the patient's cord blood and the parents blood samples revealed a novel *de novo* heterozygous c.2451+1G>C splice site variant in the *COL1A1* gene. Although this exact variant has not been reported in other patient, c.2451+1G>A and c.2451+1G>T have been reported to cause OI type I, one of the most common clinical phenotypes associated with *COL1A1*. Although our patient has more severe skeletal findings than OI type I, it is not uncommon to see a spectrum of phenotypes with the same mutation. Here, we show how we successfully interpreted the US prenatal findings, and their genotype-phenotype correlation was confirmed postnatally by CES. In addition, this study shows that even though CES is available for prenatal diagnostic, not all families are willing to make decisions during pregnancy but how the US findings still played an important role on the immediate clinical management postnatally.

**459F**

**Non-invasive prenatal sequencing for pregnancies with fetal skeletal dysplasia using cell-free fetal DNA.** Y. Jiang<sup>1</sup>, G. Wang<sup>1</sup>, L. Lu<sup>1</sup>, L. Wang<sup>1</sup>, J. Xiao<sup>1</sup>, J. Yang<sup>1</sup>, Y. Feng<sup>1</sup>, D. Chen<sup>1</sup>, S. Mullegama<sup>1,2</sup>, X. Wang<sup>1,2</sup>, Z. Chen<sup>1,2</sup>, Y. Wang<sup>1,2</sup>, I. Veyve<sup>1,2,3</sup>, C. Eng<sup>1,2</sup>, J. Zhang<sup>1,2</sup>. 1) Baylor Genetics Laboratories, Houston, TX; 2) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 3) Obstetrics and Gynecology, Baylor College of Medicine, Houston, TX.

We developed a cell-free fetal DNA based non-invasive prenatal sequencing test for multiple Mendelian monogenic disorders that includes 30 genes associated with common dominant disorders. A total of 638 samples were tested between January 2017 and June 2018 and 40 of them had positive molecular findings. Pathogenic or likely pathogenic variants were detected in 28 cases affected with achondroplasia (n=3), thanatophoric dysplasia (n=12), osteogenesis imperfecta (n=9), Cornelia de Lange syndrome (n=2) and craniosynostosis syndromes (n=2). For these 28 cases, the mean maternal age was 32.4 years (SD=6.3, range: 21-44) and the mean paternal age was 36.0 years (SD=6.0, range 22-48). The average gestational age at diagnosis was 23.7 weeks (SD=5.8, range: 13.0-36.6). 218 fetuses (35.4%) had abnormal ultrasound findings and 85 (13.3%) had at least one of the following skeletal dysplasia-related features on fetal ultrasound screening: shortened long bones, bowed and/or fractured bones, small thorax and craniosynostosis. While the overall positive detection rate was 6.3% (40/638), it was 16.5% (36/218) for fetuses with any abnormal ultrasound finding and increased to 25.9% (22/85) with ultrasound findings suggesting fetal skeletal dysplasia. Our test had the highest positive detection rate (66.7%, 10/15) in fetuses suspected with a single etiology based on the sonographic findings consistent with achondroplasia, thanatophoric dysplasia or osteogenesis imperfecta. Six fetuses harbored pathogenic variants in *FGFR3* and four in *COL1A1*. In comparison, the positive detection rate for *FGFR3* mutations was 55.3% in a targeted non-invasive NGS study for pregnancies affected with achondroplasia or thanatophoric dysplasia. In another recent study of non-invasive prenatal testing for achondroplasia using high-resolution melting PCR, the positive detection rate was 21.9%. Additionally, in four cases pathogenic variants inherited from an affected father were detected and clarified that these fetuses inherited the paternal variant at an earlier gestational age than would be possible with other approaches. In conclusion, we found that our non-invasive test adds valuable molecular information for suspected diagnoses based on sonographic findings that can help guide physicians for evaluation of fetal skeletal abnormalities. This test also has potential as a screening test for pregnancies at risk of such conditions.

**460W**

**Lethal skeletal dysplasias (SD): A clinical-epidemiological study based on 131 Brazilian fetuses including molecular investigation.** *D.P. Cavalcanti, T.Y. Kanazawa, C.A. Moreno, K.C. Silveira, G.V.A. França.* 1) Medical Genetics, University of Campinas, Campinas, Campinas, Brazil; 2) Secretariat of Health Surveillance, Brazilian Ministry of Health, Brasília, Brazil.

Epidemiological information regarding lethal-SD is very limited and outdated. The aim of this work was to conduct a descriptive clinical-epidemiological study based on a Brazilian series of 131 fetuses registered over 26 years (1990–2016) by the Campinas Skeletal Dysplasia Group. While 75 patients were born in our Hospital, 31 were evaluated during prenatal, but were born in neighborhood cities, and the remaining (25) were evaluated after birth in our site ([www.ocd.med.br](http://www.ocd.med.br)). For the analysis of risk factors, a healthy control sample of 41,186 live births born in the same period was used. Considering the 75 fetuses born among 79,745 births from the local hospital, the birth prevalence was 9.4 per 10,000 births (95% CI = 7.4–11.8). Although most cases (61.1%) had been detected during prenatal US examination, the specific diagnosis required a postnatal evaluation. Most fetuses born alive (75; 57%), however, 60% of them died in the 1<sup>st</sup> day. Among the stillbirths (56; 43%), 29% were due to pregnancy termination. Parental ages (father 33,1±7.2 and mother 28.0±5.7), and parental consanguinity (12.8%) were higher in cases than in controls ( $p < 0.001$ ). Likewise, cases presented lower birth weight, and lower gestational age than controls. The most common groups (71%) were the FGFR3 group (43; 32.8%), mainly represented by DT-I (36; 83.7%); the OI group (33; 25.2%) with OI-IIA as the most common (22; 66.7%); and the collagenopathies type 2 group (17; 13%), being the achondrogenesis type II (ACG-II) the most frequent condition (10; 58.8%). Molecular investigation was performed in most of the cases (75; 57.3%) and confirmed the radiological diagnosis in 63 of them (84%). Among the negative cases, two fetuses presented an identical and novel clinical-radiological pattern, however, the WES failed to show an associated pathogenic variant. In conclusion, the epidemiological evaluation of the present series of fetuses shows a high prevalence of lethal-SD in our hospital due to its reference role in the region. The main SD found were DT-I (FGFR3 group), OI-IIA (OI group) and ACG-II (type 2 collagenopathies group). Although most cases of lethal-SD were suspected during pregnancy, a specific diagnosis was only reached after postnatal evaluation. The main risk factors were high paternal age and high parental consanguinity. Finally, a novel lethal-SD was found in this series. Financial Support: CNPq #590148/2011-7 / Faepex #402/15 / FAPESP # 98/16006-6; 2015/22145-6.

**461T**

**Clubfoot as a prenatal clue to the diagnosis of the 22q11.2 deletion syndrome (22q11.2DS).** *J.F. Homans<sup>1</sup>, T.B. Crowley<sup>2</sup>, E. Chen<sup>2</sup>, D.E. McGinn<sup>2</sup>, V.F.X. Deeney<sup>3</sup>, R.M. Castelein<sup>1</sup>, R.S. Davidson<sup>3</sup>, D.M. McDonald-McGinn<sup>2</sup>.* 1) Department of Orthopedic Surgery, University medical Center, Utrecht, Utrecht, Netherlands; 2) Division of Human Genetics, The 22q and You Center, Children's Hospital of Philadelphia, Philadelphia, PA, USA; 3) Department of Orthopaedic Surgery, The University of Pennsylvania School of Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA, USA.

**Background:** 22q11.2DS is the most common microdeletion syndrome occurring in ~1:2000 - 4000 live births and ~1:1000 fetuses. The presentation is complicated by significant intra and inter familial variability across the lifespan. Patients diagnosed neonatally generally present with severe features such as Tetralogy of Fallot +/- pulmonary atresia. However, patients without severe classically associated congenital malformations can either be diagnosed later in life, sending their families on a diagnostic odyssey, or not diagnosed at all, despite significant structural anomalies such as a solitary kidney. Thus, features less typically associated with 22q11.2DS may be overlooked or may not lead to appropriate diagnostic testing. Orthopedic manifestations are a prime example. Clubfoot has a general population prevalence of ~1:1000 and has been occasionally described in association with 22q11.2DS. However, this has not been systematically investigated. We hypothesize the prevalence of clubfoot is higher in patients with 22q11.2DS and suggest diagnosis of clubfoot prenatally should evoke suspicion of 22q11.2DS. **Methods:** We performed a retrospective review under IRB approval on the world's largest database of patients with 22q11.2DS to determine the prevalence of clubfoot. Clubfoot is a clinical diagnosis and can be mistaken for other malformations. "True clubfoot" requires treatment (either conservative or surgical), therefore we only included those patients with proof of treatment. **Results:** Records were reviewed on 1339 patients. Of these, 43 (3.2%) had confirmation of clubfoot (95% Confidence Interval: 2.4–4.3): 20 (46%) had bilateral clubfoot, nine (21%) left clubfoot, and 14 (33%) right clubfoot. Twelve patients were noted to have clubfoot on parental ultrasound, including one child whose father had a history of repaired VSD and cleft palate, but the diagnosis of 22q11.2DS was not considered in the differential. The latter child was discharged to home from the outside hospital and transferred emergently in cardiac extremis due to a previously unrecognized diagnosis of an interrupted aortic arch type B. **Conclusion:** We report the prevalence of club foot in 22q11.2DS to be 30 times higher than that observed in the general population. This suggests the diagnosis of clubfoot, especially in the face of other typically associated abnormalities, should provoke consideration of 22q11.2DS as an underlying diagnosis in particular in the prenatal setting.

**Combining familial genetic diagnosis with prenatal genetic testing for Mendelian disorders reduces recurrence risk.** Z. Schlachetzki<sup>1</sup>, M.Y. Issa<sup>2</sup>, V. Stanley<sup>1</sup>, R.D. George<sup>1</sup>, M. Zaki<sup>2</sup>, J.G. Gleeson<sup>1</sup>. 1) Departments of Neurosciences and Pediatrics, Rady Children's Institute for Genomic Medicine, Howard Hughes Medical Institute, University of California San Diego, La Jolla, California 92093; 2) Clinical Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo 12311, Egypt.

Congenital malformations and birth defects are a leading cause of infant mortality. About half of them have a genetic cause and are therefore potentially preventable. Prenatal genetic screening is the current method of choice for detecting carriers of known pathogenic variants. However, the variants tested generally include only those with population allele frequencies greater than 1:100, and omit more rarely observed variants. Rare disease-causing variants can be identified with high certainty in about 50% of families with recessive Mendelian disorders that undergo whole-exome sequencing (WES). This genetic diagnosis can then be used to genotype subsequent pregnancies and to counsel families based on the results of the prenatal testing. However, there are no clear guidelines or large-scale studies of such practices, and each prenatal center follows its own best practice. We designed a retrospective study to determine the effect of prenatal genetic testing on disease recurrence risk in families with an established genetic diagnosis. Of 1172 families with severe recessive disease that were counseled between 2009 and 2015, 526 families received a conclusive genetic diagnosis following WES. This prompted fetal genetic testing through amniocentesis for 84 subsequent pregnancies. Of 59 fetuses that genotyped negative for the pathogenic variant and were carried to term, all were phenotypically normal for the tested disease at clinical follow-ups, which resulted in a 100% negative predictive value for our test. Of 24 fetuses that genotyped positive for the pathogenic variant, 8 were carried to term and developed a disease concordant with their affected siblings. The remaining 16 pregnancies were terminated and this reduced the disease recurrence from expected 25% to the observed 12% (95% Confidence Interval [CI], 0.04 to 0.20;  $p=0.011$ ). This is the first comprehensive report that 1) demonstrates how next generation sequencing and prenatal testing can be combined to significantly reduce disease burden and positively impact family planning, and 2) offers an accessible and effective workflow for medical professionals to provide genetic counseling to families with severe and rare recessive disorders, thus ensuring informed reproductive decisions.

**SCN1A mutations in a SIDS cohort.** C.A. Brownstein, I.A. Holm, R.D. Goldstein, A.H. Poduri. Boston Children's Hospital, Boston, MA.

Sudden infant death syndrome (SIDS), the death of an infant <1 year of age that remains unexplained after complete autopsy and death scene investigation, is the leading cause of postneonatal infant mortality in the United States. We identified *SCN1A* variants in 2 infants who died of SIDS with hippocampal abnormalities from an exome sequencing study of 10 cases of SIDS but no history of seizures. One harbored *SCN1A* G682V, and the other had 2 *SCN1A* variants in cis: L1296M and E1308D, a variant previously associated with epilepsy. Functional evaluation in a heterologous expression system demonstrated partial loss of function for both G682V and the compound variant L1296M/E1308D. This novel association of *SCN1A* with SIDS supports further intense efforts to understand epilepsy-related mechanisms into sudden death across the age spectrum in individuals with and without an overt history of seizures or epilepsy.

**The genetic landscape of sperm mosaicism: Implications for the recurrence risk of neutral and autism-causing mutations.** *M.W. Breuss<sup>1,2</sup>, D. Antak<sup>3,4,5</sup>, R.D. George<sup>1,2</sup>, M. Kleiber<sup>3,4,5</sup>, K.N. James<sup>1,2</sup>, L.L. Ball<sup>1,2</sup>, O. Hong<sup>3,4,5</sup>, I. Mitra<sup>6,7</sup>, S.A. Wirth<sup>1,2</sup>, J. Gu<sup>1,2</sup>, C.A.B. Garcia<sup>1,2</sup>, W.M. Brandler<sup>3,4,5</sup>, D. Musaevi<sup>1,2</sup>, A. Nguyen<sup>1,2</sup>, J. McEvoy-Venneri<sup>1,2</sup>, R. Knox<sup>1,2</sup>, E. Sticca<sup>1,2</sup>, O. Devinsky<sup>6</sup>, M. Gymrek<sup>6,7</sup>, J. Sebat<sup>3,4,5</sup>, J.G. Gleeson<sup>1,2,3</sup>*. 1) Department of Neurosciences, Howard Hughes Medical Institute, University of California, San Diego, La Jolla, CA; 2) Rady Children's Institute for Genomic Medicine, San Diego, CA; 3) Beyster Center for Genomics of Psychiatric Diseases, University of California, San Diego, La Jolla, CA; 4) Department of Psychiatry, University of California, San Diego, La Jolla, CA; 5) Department of Cellular and Molecular Medicine, University of California, San Diego, La Jolla, CA; 6) Department of Medicine, University of California San Diego, La Jolla, CA; 7) Department of Computer Science and Engineering, University of California San Diego, La Jolla, CA; 8) Department of Neurology, Epilepsy Division, New York University School of Medicine, New York, NY.

*De novo* genetic mutations represent a major contributor to pediatric disease, including autism spectrum disorders (ASD), congenital heart disease, and muscular dystrophies, but there are currently no methods to prevent or predict them. These mutations are classically thought to occur either at low levels in progenitor cells or at the time of fertilization and are often assigned a low risk of recurrence in siblings. Here, we directly assessed the presence of *de novo* mutations in paternal sperm and discovered abundant, germline-restricted mosaicism. In 8 families with 14 children we evaluated the allelic fractions of 912 *de novo* single nucleotide variants (dSNVs) in paternal blood and sperm, employing deep (200x) whole genome sequencing (WGS). 23 of these variants showed evidence of mosaicism of up to 17% allelic fraction; and almost two thirds were either exclusively found or highly enriched (>3 times) in sperm. Unbiased analysis using MuTect 2 and Strelka 2 uncovered >50 additional, mosaic variants at a similar range of allelic fractions. We discovered germline-restricted mosaicism for structural variants (SVs) at similar rates and allelic fractions, demonstrating that germline mosaicism is present across different classes of *de novo* mutations (DNMs). Employing single-molecule genotyping, we found that this phenomenon was also observed in likely-pathogenic mutations in ASD, where 4/20 variants showed similar germline mosaicism and, consequently, an increased risk of recurrent transmission. This included one family, for which the mosaicism of a *GRIN2A* variant reached close to 15% in paternal sperm, but only around 1% in saliva. The disease allele was recurrently inherited by all three children, a fact which was missed before due to the previously reported, variable expressivity of this mutation. Our results demonstrate that germline mosaicism is an underestimated phenomenon with important implications for clinical practice and our understanding of the basis of human disease. Genetic analysis of sperm, rather than of blood or saliva, can accurately assess the individualized recurrence risk following the birth of a child with a *de novo* disease, as well as the risk for any male planning to have children.

**465F**

**Rapid detection of Trisomy 13, 18, 21 and sex chromosomes aneuploidies – experience of a clinical hospital laboratory.** *K. Tan, K.S. Poon, L. Chiu, S.S.Y. Ho, E.S.C. Koay, M. Choolani*. National University Hospital Singapore.

Background: Aneuploidies of chromosomes 13, 18, 21, X and Y account for more than 80% of the clinically significant chromosomal abnormalities diagnosed prenatally. Rapid tests for prenatal diagnosis of these chromosomal aneuploidies can improve pregnancy management. We describe our experience with prenatal testing of chromosomal aneuploidies in a clinical genetics laboratory of a tertiary hospital in Singapore. Methods: Rapid detection of trisomy 13, 18, 21 and sex chromosomes aneuploidies was performed using an in-house developed Quantitative Fluorescent Polymerase Chain Reaction (QF-PCR) assay (Baig et al, Singapore Med J 2010; 51(4): 343-348). This assay contains 19 microsatellite markers located on chromosomes 13, 18, 21, X and Y. The turnaround time is 2 working days. Results: In our molecular diagnostics laboratory, 1226 QF-PCR assays were performed on 935 amniocentesis samples and 291 chorionic villus samples since June 2007. Majority of samples were obtained at gestational week 16+. Out of the 1226 cases tested, 124 cases of Trisomy 21 (10.1%), 42 cases of Trisomy 18 (3.4%), 6 cases of Trisomy 13 (0.5%), 10 cases of Monosomy X (Turner's syndrome) (0.8%) and 4 cases of XXY (Klinefelter's syndrome) (0.3%) were identified. Trisomy 21, 18 and 13 cases were 100% concordant between karyotyping and QF-PCR (n = 150). Since the availability of non-invasive prenatal screening (NIPS) testing around 2014, the number of test requests have decreased by approximately 50%. Co-testing of NIPS was performed in 39 cases. Out of these, 21 were reported as high risk for Trisomy 21 and 18 of these were confirmed Trisomy 21 by QF-PCR (86%). Nine were reported as high risk for Trisomy 18 and 7 of these were confirmed Trisomy 21 by QF-PCR (78%). One was reported by NIPS to be high risk for Trisomy 13, 18, and 21 but was not confirmed by QF-PCR. Conclusion: Rapid detection of trisomies 13, 18, and 21 by QF-PCR on amniocentesis and chorionic villus samples is a useful test in the management of high risk pregnancies. More importantly it serves as a confirmatory test to ascertain the trisomy cases predicted by NIPS, in which a relatively high rate of false-positives had been encountered.

**A component of sperm fibrous sheath has major effect on testis morphology and functionality.** *N. Li.* Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong, China.

The fibrous sheath is a unique cytoskeletal structure located in the principle piece of the sperm flagellum with more than 13 protein components. AKAP4 is the most abundant protein in the fibrous sheath, which interacts with at least 3 other proteins. The molecular structure and functionality of the fibrous sheath are largely unknown. We collected a clinic sample of sperms featured by dysplasia of fibrous sheath (DFS), leading to a failure of natural conception. The sperm donor is an offspring of consanguineous family, and we identified an inherited homozygous truncating mutation in his genome by whole-exome sequencing. The affected protein is one of the components of fibrous sheath, and this mutation caused a shortened protein which lost part of the original functions. The mice model with this mutation introduced by CRISPR-Cas9 technique showed similar phenotype to the human, with sperms of reduced number and lower motility due to flagellum malfunction. Strikingly, we observed that, unlike AKAP4 knock-out mice model, the knock-out mice model we constructed for the novel gene exerted major effect on testis, manifested by significant size/weight reduction and azoospermia. Microscopic observation of testis slices and in-situ hybridization showed abnormal cross-section of the seminal vesicles and disorganized progression from spermatogonia to spermatid, when comparing the knock-out mice model with the control ones. Therefore, we concluded that this gene is of critical importance to normal spermatogenesis and testis development.

**De novo mutations in caudal type homeo box transcription factor 2 (CDX2) in patients with persistent cloaca.** *J.S.J Hsu<sup>1,4</sup>, M.T. So<sup>2</sup>, C.S.M. Tang<sup>2,4</sup>, A. Karim<sup>2</sup>, R. Porsch<sup>1,4</sup>, C. Wong<sup>2</sup>, M. Yu<sup>2</sup>, F. Yeung<sup>2</sup>, H. Xia<sup>3</sup>, R.Z. Zhang<sup>3</sup>, S.S. Cherny<sup>1,4</sup>, P.H.Y. Chung<sup>2</sup>, K.Y. Wong<sup>2</sup>, P.C. Sham<sup>1,4</sup>, N.D. Ngo<sup>5</sup>, P.K.H. Tam<sup>2,4</sup>, V.C.H. Liu<sup>4</sup>, M.M. Garcia-Barcelo<sup>2,4</sup>.* 1) Department of Psychiatry, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong; 2) Department of Surgery, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong; 3) Department of Pediatric Surgery, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong, China; 4) Centre for Genomic Sciences, Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong, China; 5) Department of Human Genetics, National Hospital of Pediatrics, Hà Nội, Vietnam.

The cloaca is an embryonic cavity that is divided into the urogenital sinus and rectum upon differentiation of the cloacal epithelium triggered by tissue-specific transcription factors including Caudal Type Homeo Box Transcription Factor 2 (*CDX2*). Defective septation anomalies during the development lead to persistent cloaca in humans (PC), a phenotype recapitulated in *Cdx2* mutant mice. PC is linked to hypo/hypervitaminosis A. Although no gene has ever been identified, there is a strong evidence for a genetic contribution to PC. We applied whole-exome sequencing and copy-number-variants analyses to 21 PC patients and their unaffected parents. The damaging p.Cys132\* and p.Arg237His *de novo CDX2* variants were identified in two unrelated patients. Both variants were novel among hundred thousand whole exome sequencing sample in the gnomAD database ( $N > 123,136$ ). Not only the predictive model from Phyre2 Investigator indicated the p.Arg237His is located on DNA binding domain with higher mutation sensitivity compared with adjacent regions, but also SWISS-MODEL indicated a secondary structural change in the DNA binding domain. Moreover, these variants functionally altered the expression of *CYP26A1*, a direct *CDX2* target encoding the major retinoic acid (RA)-degrading enzyme. Other RA genes, including the RA-receptor alpha, were also mutated. Genes governing the development of cloaca-derived structures were recurrently mutated and over-represented in the basement-membrane components set ( $q\text{-value} < 1.65 \times 10^{-6}$ ). Joint analysis of the patients' profile highlighted the extracellular matrix–receptor interaction pathway (MsigDBID: M7098, FDR:  $q\text{-value} < 7.16 \times 10^{-9}$ ). This is the first evidence that PC is genetic, with genes involved in the RA metabolism at the lead. Given the *CDX2 de novo* variants and the role of RA, our observations could potentiate preventive measures. For the first time, a gene recapitulating PC in mouse models is found mutated in humans. Despite the severity, the rarity of PC, establishing disease causality for any given gene is extremely difficult. As patients with the identical rare disease are limited, data sharing and re-analysis should be fully considered and should be conducted under proper regulations.

**468F**

**Oculocerebrocutaneous (Delleman) syndrome. Prenatal manifestations and failure to identify tumors' somatic mutation using whole exome sequencing.** *N. Damseh<sup>1,2</sup>, D.J. Stavropoulos<sup>3</sup>, K. Chong<sup>4</sup>, S. Blaser<sup>5</sup>, I. Miron<sup>4</sup>, S. Carmona<sup>4</sup>, D. Chitayat<sup>4</sup>.* 1) Division of Clinical and Metabolic Genetics, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; 2) Medical Genetics Residency Training Program, University of Toronto, Toronto, ON, Canada; 3) Department of Paediatric Laboratory Medicine, Division of Genome Diagnostics, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 4) The Prenatal Diagnosis and Medical Genetics Program, Mount Sinai Hospital, University of Toronto, Toronto, ON, Canada; 5) Department of Pediatrics, Division of Radioimaging, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

Oculocerebrocutaneous syndrome (Delleman syndrome) is characterized by orbital cysts, microphthalmia/anophthalmia, focal skin defects, facial skin appendages and a variety of cerebral malformations. All cases so far have been sporadic and the condition is thought to be due to somatic mutation of an autosomal dominant lethal gene important in early development. We report the prenatal and postnatal findings in a female newborn with Delleman syndrome. Our patient was born to a 29-year-old primigravida mother who presented at 26 weeks gestation with fetal ultrasound finding of a solid mass on the left cheek inferior to the left orbit. Follow up ultrasounds showed an abnormally shaped cerebellum and two fetal facial tags with no blood flow. A fetal MRI confirmed a left cheek subcutaneous, finger-like tissue lesion, hypoplastic cerebellar vermis and dysplastic cerebellar hemispheres. Delivery of the infant at term confirmed the prenatal findings and the diagnosis of Delleman syndrome. In an attempt to find the causative gene mutation we performed WES on DNA extracted from the tumor but no gene mutations was identified. Delleman syndrome is a rare disorder characterized by eye, cutaneous, and central nervous system anomalies. Typically, neonates present with microphthalmia or orbital cysts, orbital skin tags, dermal aplasia, or hypoplasia. Brain abnormalities including such as agenesis of the corpus callosum, hydrocephalus, enlarged ventricles, and cerebellar hypoplasia have been reported. In most cases the periorbital skin tags are unilateral and as in our patient, most frequently left-sided. Some of the patients experience seizures and intellectual disability. This is the second reported patient with Delleman syndrome diagnosed prenatally based on the finding of skin appendages in the periorbital area and cerebellar abnormalities. To our best knowledge this is the only case where whole exome sequencing was done on DNA extracted from the facial tumor and unfortunately it failed to identify the genetic basis of this condition.

**Prenatal detection and clinical outcomes of trisomy 16 using massive parallel sequencing of total cell-free DNA (cfDNA).** *A. McFaddin<sup>1</sup>, A. Jacobson<sup>1</sup>, C. Lockwood<sup>1</sup>, B. Shirts<sup>1</sup>, B. Colbert<sup>1</sup>, E. Oehler<sup>2</sup>, J. Rietzler<sup>2</sup>, S. Paolucci<sup>2</sup>, S. Ball<sup>2</sup>, C. Albright<sup>2</sup>, J. Hitti<sup>2</sup>.* 1) Laboratory Medicine, University of Washington Medical Center, Seattle, WA; 2) Maternal Fetal Medicine, University of Washington Medical Center, Seattle, WA.

Trisomy for chromosome 16 (T16) is the most common autosomal trisomy detected in spontaneous abortions, and is predicted to be present in as many as 1.5% of all conceptions. The majority of pregnancies with full T16 are spontaneously lost by week 12 of pregnancy, but cases of fetal mosaicism as well as confined placental mosaicism have been reported in later gestational ages as well as live births. Historically, maternal serum screening and ultrasound were the only available options for noninvasive aneuploidy screening; however, these techniques are not optimized for rare trisomies such as T16. Non-invasive screening using cell-free DNA (cfDNA) from maternal blood has greatly improved the reliable detection of autosomal aneuploidies in recent years. Many clinically available cfDNA screening tests only report findings for the more common trisomies of 13, 18, and 21 and have not reported rare autosomal aneuploidies, such as T16. If present, these rare aneuploidies may be of clinical importance and have impact on pregnancy outcomes and decisions. The University of Washington Genetics laboratory performs a cfDNA prenatal screen that assesses aneuploidy for all chromosomes using massively parallel sequencing of total cfDNA from maternal plasma. Since clinical implementation of this screen in 2017, 1110 cfDNA samples have been tested. Of these, 4 cases of T16 have been detected and reported, with varying clinical outcomes. Case A was detected in the setting of abnormal ultrasound findings that ended in an elective pregnancy termination. Case B was detected in the setting of a mother of advanced maternal age (AMA) and normal first trimester ultrasound, with delivery of growth restricted infant at 27 weeks with negative peripheral blood testing and confined placental mosaicism for T16 confirmed postnatally. Case C was detected in the setting of a mother of AMA and normal first trimester ultrasound with subsequent fetal demise at 16 weeks and confirmed mosaicism for T16 in fetal tissue post-demise. Case D was detected in the setting of a positive serum screen indicating a 1/20 risk for trisomy 21 with abnormal ultrasound findings of a ventricular septal defect and shortened femur bones. The family declined confirmatory testing at time of submission and pregnancy is currently continuing. This data highlights the variability in clinical presentation for T16 detected by cfDNA and the potential utility of reporting this information in the prenatal setting.

Yonath<sup>12,2</sup>, R. Berger<sup>13</sup>, T. Naiman<sup>1</sup>, A. Singer<sup>14</sup>, L. Sagi-Dain<sup>15</sup>. 1) Genetics Institute, Tel Aviv Sourasky Medical Center,<sup>1</sup>; 2) Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 3) Recanati Genetics Institute, Beilinson Hospital, Rabin Medical Center, Petach Tikva, Israel; 4) Department of Genetics and Metabolic Diseases, Hadassah, Hebrew University Medical Center, Jerusalem, Israel; 5) Genetic Institute, Assaf Harofeh Medical Center, Zerifin, Israel; 6) Medical Genetics Institute, Shaare Zedek Medical Center and the Hebrew University School of Medicine, Jerusalem, Israel; 7) Genetic Institute, Soroka University Medical Center, Faculty of Health Sciences Ben-Gurion University of the Negev, Israel; 8) Institute of Human Genetics, Haemek Medical Center, Afula, Israel; 9) Medical Genetics Institute, Meir Medical Center, Israel; 10) Genetics Institute, Kaplan Medical Center, Rehovot, Israel, affiliated to the Hebrew University and Hadassah Medical School, Jerusalem, Israel; 11) Simon Winter Institute for Human Genetics, Bnai Zion Medical Center, Haifa, Israel; 12) Gertner Institute of Human Genetics, Sheba Medical Center, Israel; 13) Cytogenetic Maccabi Health Care, Israel; 14) Community Genetics, Public Health Services, Ministry of Health, Jerusalem, Israel; 15) Genetics Institute, Carmel Medical Center, Haifa, Israel.

**OBJECTIVE:** To examine the role of chromosomal microarray analysis (CMA) in pregnancies with various sonographic anomalies, and to characterize the copy number variants (CNVs) in diverse fetal phenotypes. **METHODS:** We retrospectively examined CMA analyses performed nationwide due to fetal sonographic anomalies (structural defects, intrauterine growth restriction and polyhydramnios) between 1/2013 and 09/2017. The rate of abnormal CMA findings was compared between the different phenotypes. **RESULTS:** Clinically significant CMA aberrations were detected in 272 of 5750 cases (4.7%): 115 (2%) karyotype-detectable and 157 (2.7%) submicroscopic. Unlike the submicroscopic findings, the prevalence of karyotype-detectable findings varied notably between different phenotypes (0.2%-9.7% vs. 2.2-3.7%, respectively). Most commonly detected CNVs were 22q11.21 deletions (0.4%), followed by 22q11.21 gain of copy number (0.2%). Specific CNVs detected among pregnancies with abnormal sonographic findings were up to 20-fold more prevalent compared to low-risk pregnancies. Some CNVs were associated with specific phenotypes (e.g., 22q11.21 and 17q12 microdeletions with cardiovascular and genitourinary defects, respectively). **CONCLUSION:** Our data demonstrate the importance of performing CMA in pregnancies with non-major anomalies and non-structural sonographic abnormal findings. Thus, CMA in pregnancies with sonographic aberrations should not be limited only to major anomalies.

## 471F

**Whole exome sequencing improves the genetic diagnosis in fetuses with increased nuchal translucency.** H. Wang<sup>1,2</sup>, Z. Dong<sup>3,4</sup>, H. Zhang<sup>1</sup>, R. Zhang<sup>2</sup>, H. Lan<sup>1,2</sup>, X. Yang<sup>2</sup>, J. Lei<sup>1</sup>, X. Xu<sup>1</sup>, L. Xiong<sup>1,2</sup>, Y. Zhu<sup>2</sup>, K. Choy<sup>3,4</sup>. 1) Department of Central Laboratory, Bao'an Maternity and Child Healthcare Hospital, Jinan University, Shenzhen, China; 2) Department of prenatal diagnosis center, Bao'an Maternity and Child Healthcare Hospital, Jinan University, Shenzhen, China; 3) Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong, Hong Kong; 4) Shenzhen Research Institute, The Chinese University of Hong Kong, Shenzhen, China.

**Background:** High nuchal translucency (NT >3.5mm) detected in the first trimester is a well-known and widely accepted indicator for aneuploidy or genomic disorders in prenatal care. Our pilot study reported ~8.1% fetus with high NT carries pathogenic copy number variants (CNVs), there are still more than 90% of cases without a genetic diagnosis. **Objectives:** We aim to investigate the detection yield of combination of whole-exome sequencing (WES) and CMA in fetuses with high NT. **Methods:** The study comprised 247 singleton pregnancies with increased fetal NT (NT>3.5mm) and DNAs from amniotic fluid were used for genetic testing. Parental DNAs were used for further confirmation of inheritance. Karyotyping and CMA were carried out for each case and classification of CNVs follow the guidelines of American College of Medical Genetics and Genomics (ACMG). Ten cases with negative findings from karyotyping and CMA testing were further subjected for whole-exome sequencing with their parental DNAs. SNV interpretation also followed ACMG guidelines. **Results:** The maternal age was 32.1 on average and the median fetal NT thickness was 4.3 mm. Karyotyping/CMA identified 33 cases (13.3%) with chromosomal abnormalities, including three cases of balanced chromosomal abnormalities, 15 cases with aneuploidies and 15 cases with pathogenic microdeletion or microduplication. In addition, variants of unknown significance (VOUS) were also detected in six cases (2.4%, 6/247). Whole-exome sequencing was carried out in each of ten cases with negative results from karyotyping/CMA with their parental DNAs and identified two *de novo* pathogenic SNVs. For instance, a pathogenic mutation was detected in autosomal dominant (AD) gene of *PTPN11* known to cause Noonan syndrome, while another pathogenic mutation was identified in gene *BRAF* (AD), which is related to cardio-facial-cutaneous (CFC) syndrome. **Conclusions:** Whole-exome sequencing can have 20% (2/10) additional diagnostic yield in the fetuses with high NT without a genetic diagnosis from karyotyping and CMA. It indicates that combination of whole-exome sequencing with current standard assays (karyotyping and CMA) can help to increase diagnostic yield in fetuses with high NT. A larger prospective study is warranted for further investigation due to the limited sample size in current study. This study was supported by the National Natural Science Foundation of China (Grant no. 81741004).

## 472W

**Prenatal diagnosis of Cri-du-Chat (5p-) syndrome with persistent isolated fetal ascites: A case report.** L. Mota-Vieira<sup>1,2</sup>, I. Raposo<sup>3</sup>, M. Ormonde<sup>3</sup>, R. Monteiro<sup>4</sup>, A. Sampaio<sup>3</sup>, P. Cosme<sup>3</sup>, M. Cardoso<sup>3</sup>. 1) Molecular Genetics and Pathology Unit, Hospital of Divino Espírito Santo of Ponta Delgada, Azores, Portugal; 2) BiolSI - Biosystems & Integrative Sciences Institute, Faculty of Sciences, University of Lisboa, Portugal; 3) Department of Obstetrics and Gynecology, Hospital of Divino Espírito Santo of Ponta Delgada, Azores, Portugal; 4) Synlab - Genética Médica e Diagnóstico Pré-Natal, Porto, Portugal.

Cri-du-chat syndrome (CdCS) and isolated fetal ascites are two very rare conditions that have never been reported together. The former is a genetic disorder (OMIM #123450) caused by haploinsufficiency of contiguous genes in the critical region of 5p15.2 to the entire short arm of chromosome 5 (5p-). The second is defined as fluid accumulation in the abdominal cavity without fluid accumulation in any other serosal cavities or subcutaneous tissues, being thus a distinct entity from hydrops fetalis. Here, we describe a unique case of a prenatally diagnosed CdCS with persistent isolated fetal ascites. A 43-year-old Caucasian woman (gravida 4, para 3) was referred due to advanced maternal age. There was no history of consanguinity, teratogen exposure, miscarriages, mental retardation, or other inherited conditions. At the first ultrasound scan (12<sup>+</sup>WG) the only remarkable finding was a moderate to severe fetal ascites. Maternal blood group was O Rh-positive and indirect Coombs test was negative. Serologies were negative for parvovirus B19, CMV, HBV, HCV, VZV, HSV and *Toxoplasma gondii*. Maternal rubella IgG levels were consistent with previous infection. Due to advanced age, the pregnant woman underwent NIPT, which results revealed a low risk for trisomies 21, 18 and 13 (fetal fraction, 10.7%). At 16<sup>+</sup> WG, the follow-up scan showed that isolated fetal ascites was still present with no signs of generalized hydrops. Taking these findings, an amniocentesis was performed and showed an abnormal female karyotype with terminal deletion of the short arm of chromosome 5 [46,XX,-del(5)(p15.2)], spanning the critical region for the CdCS, a result confirmed by MLPA. After counseling, the couple opted for the pregnancy termination at 19<sup>+</sup> WG. Postmortem examination of the female infant (209g) revealed absence of dysmorphic features, although there was evidence of bilateral temporal lobe atrophy, coarctation of the aorta and an extra-hepatic cyst. Placental assessment showed villous dysmaturity and calcifications. Since parents refused genetic testing, we were unable to confirm whether this deletion was *de novo*, an inherited unbalanced translocation, or a rare aberration. Consequently, there is a potential genetic (familial) risk for CdCS, particularly in the parents' offspring. To conclude, we hypothesize that isolated fetal ascites has to be considered an antenatal ultrasonographic marker for cri-du-chat syndrome, a finding that should be confirmed in further cases.

## 473T

**A systematic evaluation of 450 fetuses: Phenotypes, genetic causes and impact on genetic counseling.** S.S. Nayak, P. Radhakrishnan, A. Shukla, A. Moirangthem, K.M. Girisha. Department of Medical Genetics, Kasturba Medical College, Manipal Academy of Higher Education, Manipal, India.

**Introduction:** Congenital anomalies occur in about 1 in 40 pregnancies and are common causes of perinatal loss. Perinatal losses manifest with diverse phenotypes, demonstrate etiological heterogeneity and challenge accurate genetic counseling. Perinatal autopsy is considered gold standard for evaluation of these conditions. New developments in genomic testing and experience of the perinatal team contribute to continual improvement in the performance of perinatal autopsy as a diagnostic tool. In this study we report the phenotypes and genetic cause of fetal losses in a large cohort and how it affected genetic counseling. **Materials and Methods:** A detailed perinatal autopsy was performed in all perinatal losses after taking informed consent. Antenatal history, sonographic findings, biometric measurements, photography, radiographs, external and internal examinations and histopathologic findings were systematically recorded. Cytogenetic tests, candidate gene sequencing and exome sequencing were carried out in fetuses as feasible. **Results:** Four fifty fetuses (251 male, 191 female and 8 undetermined) were evaluated over nine years with gestational age ranging 10-39 weeks. Radiographs were obtained in 433 (96%), cytogenetic tests in 94, candidate gene sequencing 14 and exome sequencing was performed in 19 fetuses. A definitive diagnosis was established in 375/450 (83%) fetuses on perinatal autopsy. Central nervous system (78/450, 17%) was most frequently affected followed by cardiovascular and urogenital system. We noted skeletal dysplasia in 30/450 (6.6%) cases. Hydrops (29/450), limb body wall complex /amniotic band disruption (19/450), arthrogryposis/fetal akinesia deformation sequence (17/450), neural tube defect (16/450) and Meckel syndrome (11/450) were the common diagnoses. Genomic diagnoses were established in 43 fetuses (22 fetuses with a cytogenetic abnormality and 21 fetuses with a monogenic syndrome). Autopsy redefined risk of recurrence in 55% fetuses tested. The work helped us to delineate new phenotypes and new genetic causes. **Conclusion:** Perinatal autopsy continues to evolve with new genomic testing facilities improving diagnosis and counseling for affected families.

**Imputed transcriptome analysis and phenome-wide association studies link the NAD metabolic pathway genes and congenital malformations in a biobank population.** T.W. Miller-Fleming<sup>1,2</sup>, D.R. Velez-Edwards<sup>2,3</sup>, G. Chenevix-Trench<sup>4</sup>, N.J. Cox<sup>1,2</sup>. 1) Department of Medicine, Division of Genetic Medicine, Vanderbilt University Medical Center, Nashville, TN; 2) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 3) Department of Obstetrics and Gynecology, Vanderbilt University Medical Center, Nashville, TN; 4) QIMR Berghofer Medical Research Institute, Brisbane, Queensland, 4029, Australia.

Congenital malformations (CM) occur in 3% of births and are a leading cause of infant mortality. Toxic environmental exposures, nutritional deficiency, and maternal age are known risk factors; however, many defects arise due to undetected genetic variation. Identifying the genetic risk factors, and the individuals at greatest risk for CM, could provide insight into the prevention of these disorders. Recent work uncovered rare genetic variation within the NAD metabolic pathway in four families presenting with CM (Shi et al. 2017). This study proposed a novel therapeutic for the prevention of birth defects in these families, as niacin supplementation can increase NAD levels in mice and humans; however, it was unclear whether these results could be replicated in larger populations. De-identified electronic health records (EHR) linked to genomic information allow researchers to evaluate genotype-phenotype relationships in extensive sample sizes among populations with strong phenotypic diversity. We evaluated the relationship between NAD pathway genes and congenital phenotypes using Vanderbilt's EHR-linked biobank, BioVU. A phenome-wide association study (PheWAS) across 23,000 individuals of European descent revealed an association between variants in *HAAO* (3-hydroxyanthranilate 3,4-dioxygenase) and *KYNU* (kynureninase) with CM phenotypes: vesicoureteral reflux, anatomical abnormalities of kidneys, and unspecified congenital anomalies ( $p < 3 \times 10^{-5}$ ). Imputed expression levels of these genes were calculated using PrediXcan, a computational tool that derives genetically-predicted transcript levels from a reference transcriptome dataset (GTEx). We observed a significant association between decreased predicted expression of *HAAO* with respiratory conditions of fetus ( $p < 3 \times 10^{-4}$ ) and *KYNU* with congenital anomalies of kidneys and limbs ( $p < 0.005$  and  $p < 0.004$ ). Additionally, we calculated a CM phenotype risk score (PheRS) for 23,000 individuals and uncovered an association between the burden of *HAAO/KYNU* pathogenic variants and the congenital PheRS within the BioVU cohort ( $p < 0.05$ ). Our findings support a connection between the NAD pathway genes and CM phenotypes in our biobank population. Future studies will take advantage of the diverse medical phenome in BioVU to determine the relationship between lab values across the genome and phenome, uncover endophenotypes associated with CM, and leverage the congenital PheRS to identify novel genetic underpinnings of birth defects.

Loss of a pregnancy or neonate has a major impact on families in Australia and overseas. Despite pathological examination and genetic tests as part of standard care, ~25% of cases are currently unexplained. Understanding the (genetic) cause of perinatal death is essential to counsel these families for future pregnancies. The Genomic Autopsy Study was started to identify molecular defects underlying fetal and newborn abnormalities that result in termination of pregnancy, death *in utero* or death in the newborn period. To date, exome (WES) and genome (WGS) sequencing have been performed on 51 trios (parent-fetus). In this cohort, we have identified (likely) pathogenic mutations in known disease genes, leading to fetal (*in utero*) or neonatal presentations of developmental disorders for 13 families. Candidate (novel) variants affecting known disease genes were identified for 6 cases. Strong candidate variants in potentially novel disease genes were identified for 12 cases. We have gained sufficient evidence to confirm causality of the genetic variants for 3 of these families, resulting in 3 novel disease genes. For the remaining 9 cases, functional studies to characterise the effect of the genetic variant are planned or ongoing. Taken together, we have identified disease causing variants for 16 (32%) cases and strong candidate variants for another 15 (29%). Recently we have become the national referral centre for Genomic Autopsy in Australia, expecting to receive an increasing number of samples from centres nation-wide. This rapidly growing cohort will provide a great opportunity to gain knowledge about the genetic factors involved in perinatal death.

**Avoiding unnecessary trade-offs: Clinical experience for a noninvasive prenatal screen with both low no-call rate and high accuracy.** S.E. Hancock, R. BenShachar, C. Adusei, C. Haverty, D. Muzzey. Counsyl, Inc, South San Francisco, CA.

**Noninvasive Prenatal Screening (NIPS) via cell-free DNA analysis (cfDNA) has been rapidly incorporated into prenatal care since it became clinically available in 2011. The Counsyl Prelude Prenatal Screen utilizes a whole genome sequencing (WGS) approach to NIPS that has been widely reported upon by various laboratories. Here we describe the clinical experience of offering Prelude in our laboratory. We retrospectively analyzed results from 58,403 patients who underwent NIPS during a nine month period to assess clinical performance for Trisomy 21, Trisomy 18, and Trisomy 13 in singleton pregnancies. The patient cohort included both average-risk (48%, n=28,089) and high-risk patients (52%, n=30,315). Median maternal age of the patient population was 34 years (interquartile range (IQR): 29-37 years). Median gestational age was 12.4 weeks (IQR: 11.3-13.7 weeks). Unlike several NIPS offerings unable to provide a result for samples with fetal fraction below a specified threshold, Prelude does not have such limitations. The screen yielded a result for 99.9% of patients; no result was issued for the remaining 0.1% of cases (n=59) that failed for technical reasons. Median turnaround time was three days (IQR: 2-4 days). 572 cases (1%) screened positive ("aneuploidy detected" or "aneuploidy suspected") for common aneuploidies (362 positive for Trisomy 21, 142 positive for Trisomy 18, and 68 positive for Trisomy 13). "Aneuploidy suspected" reports were issued to 6.5% (n=37) of patients with positive results (0.06% of the total patient cohort). We sought pregnancy outcomes for all positive results and for 10% of negative results. Voluntarily reported false negatives were included in the analysis. Informative outcomes were received for 221 (38.6%) positive results and 700 negative results (12% of those requested). Based on cytogenetically confirmed cases and adjusting cohort size for ascertainment bias, observed sensitivities for Trisomy 21, Trisomy 18, and Trisomy 13 were 99.1%, 97.3%, and 92.3%, respectively. Outcome collection revealed 18 false positives overall (five for Trisomy 21, four for Trisomy 18, and nine for Trisomy 13). Importantly, this level of clinical performance is consistent with other characterizations of WGS-based NIPS, and was achieved in the absence of a fetal-fraction failure threshold. Our results spanning tens of thousands of patients demonstrate that Prelude achieves high accuracy and a low test-failure rate in a general obstetric population..**

**Prenatal diagnosis of tuberous sclerosis complex using high-throughput DNA sequencing combined with fetal echocardiography.** J. Chen<sup>1</sup>, J. Wang<sup>2</sup>, W.D. Kitchener<sup>3</sup>, L. Han<sup>1</sup>, X. Gu<sup>1</sup>, X. Hao<sup>1</sup>, Y. Fu<sup>1</sup>, Z. Weng<sup>4</sup>, J. Shang<sup>5</sup>, Y. Huang<sup>6</sup>, Y. Xiong<sup>7</sup>, B. Liu<sup>8</sup>, H. Zhang<sup>9</sup>, Y. He<sup>1</sup>. 1) Maternal-Fetal Consultation Center of Congenital Heart Disease, Department of echocardiography, Beijing An Zhen Hospital, Capital Medical University, Beijing, China; 2) College of life science, Tsinghua University, Beijing, China; 3) Department of Pathology, Stanford University, CA, USA; 4) Department of Ultrasonography, Fujian maternal and child hospital, Fujian, China; 5) Department of Pathology, An Zhen Hospital affiliated to Capital Medical University, Beijing, China; 6) Biodynamic Optical Imaging Center (BIOPIIC), Peking University, Beijing, China; 7) Department of Ultrasonography, Shenzhen People's Hospital, Shenzhen, China; 8) Department of Ultrasonography, the Second Affiliated Hospital, Medical College of Xi'an Jiao Tong University, Xi'an, China; 9) Department of cardiac surgery, Beijing An Zhen Hospital affiliated to Capital Medical University, Beijing, China.

**Objective** To describe the role of high-throughput DNA sequencing and fetal echocardiography in the risk assessment and diagnosis of tuberous sclerosis complex (TSC) in high risk pregnancies. **Methods** This was a prospective cohort study, 45 pregnant women with family histories of TSC or fetal cardiac tumours were recruited. Amniotic fluid or umbilical cord blood samples from pregnant women and peripheral blood samples from all family members were collected. Fetuses and family members were further analyzed for potential TSC1 and TSC2 mutations using next-generation DNA sequencing. **Results** Of all 45 families, 42 families (31 in group □, 11 in group □) had members and/or probands with TSC gene abnormalities; 9 of which were family genetic mutations and 33 were caused by sporadic mutations. For prenatal diagnosis, TSC gene abnormalities were detected in 17 out of 45 fetuses (6 in group □, 11 in group □). Among these 17 fetuses, 16 had single or multiple cardiac rhabdomyoma (CR) by FE. **Conclusions** TSC target gene detection combined with FE assessment was obtained within a timeframe suitable for the prenatal setting in families with high-risk of TSC and that this information assisted in the genetic counselling and informed decision-making in a large proportion of pregnancies.

**Application of clinical next generation panel sequencing using exome enrichment for the genetic assessment of fetal malformations.** U. Hehr<sup>1</sup>, T. Roedl<sup>2</sup>, R. Chaoui<sup>3</sup>, U. Germer<sup>4</sup>, G. Schlueter<sup>5</sup>, A. Ovens-Raeder<sup>5</sup>, S. Hinreiner<sup>5</sup>. 1) Center of Human Genetics, Regensburg, Bavaria, Germany; 2) Center for Prenatal Diagnosis and Human Genetics Berlin, Germany; 3) Center for Prenatal Medicine, Caritas Hospital St. Josef, Regensburg, Germany; 4) Prenatal medicine Nuernberg, Nuernberg, Germany; 5) Private Practice for Human Genetics, Muenchen, Germany.

**Introduction:** Advances in imaging technologies and clinical expertise result in an ever increasing rate of sonographically detected fetal malformations, while starting to shift the time of detection from midgestation to earlier weeks of gestation for some of the more severe forms. However, sonography still uncovers only a small part of the fetal phenotype, commonly associated with a broad differential diagnosis. Rapid identification of the underlying mutations allows more precise counseling of the families on the expected clinical spectrum and long-term course, directly relevant for therapeutic options regarding the ongoing pregnancy. We here report first results of our lab on prenatal genetic testing of 82 fetal samples with sonographically detected fetal malformations consecutively tested by next generation sequencing (NGS) after exome enrichment. **Methods:** After Nextera exome enrichment for all 82 fetal samples an individual virtual gene panel, considering provided findings in fetal imaging, was applied for each case (mean: 7.8 genes/case), followed by bioinformatic assessment of called variants and evaluation for copy number variations with our in house pipeline. Variants were categorized according to the ACMG guidelines and validated with conventional sanger sequencing and MLPA, respectively. **Results and discussion:** 82 prenatal cases were referred for diagnostic genetic testing in the context of either fetal brain malformations (N = 57) or fetal skeletal disorder (N = 25). Overall causal mutations (ACMG class 5) or likely pathogenic variants (ACMG class 4) were identified for 24 cases (29.3%). For 8 of the fetal samples variants of unknown clinical significance (ACMG class 3) were detected. For 23 fetal samples within the holoprosencephaly spectrum a causal mutation was observed for 6 families. 17 fetal samples with hydrocephalus or suspected Walker Warburg syndrome resulted in mutation detection for 2 families. Testing for other brain malformations including lissencephaly, Microcephaly or cerebellar hypoplasia (N = 17) allowed mutation detection for 8 families. 25 fetal samples were referred with suspected fetal skeletal disorder, resulting in a genetic diagnosis for 8 families. **Conclusion:** Clinical next generation panel sequencing is a fast and cost-effective tool in the differential diagnosis of fetal malformations. Detailed pretest counseling of the families is mandatory and should include the option, that the obtained results may remain inconclusive.

**479T**

**Smith-Magenis syndrome in two fetuses diagnosed with congenital heart defect.** Y. Li<sup>1</sup>, X. Hao<sup>1</sup>, H. Sun<sup>1</sup>, X. Gu<sup>1</sup>, X. Liu<sup>1</sup>, Y. He<sup>1</sup>, S. Ge<sup>2</sup>. 1) Department of echocardiography, Beijing Anzhen hospital, Capital medical university, Beijing, Beijing, China; 2) Section of Cardiology, Heart Center for Children St. Christopher's Hospital for Children Erie Avenue at Front Street Philadelphia.

**Background:** Smith-Magenis Syndrome (SMS) is a rare genetic disorder with an estimated prevalence of 1:15,000 to 1:25,000 live births, which is characterized by congenital heart defect (CHD), mental retardation, distinct facial appearances, sleep abnormalities, neurological and behavioral features and obesity. Approximately 90% cases of SMS are caused by a microdeletion in chromosome 17p11.2. RAI1 gene within this region can also cause this disorder. **Method:** A multi-center network was established to pool data of fetal echocardiography and fetal tissue samples after the families opted for termination of pregnancy for whole genome sequencing (WGS) and whole exome sequencing (WES). **Result:** A total of 649 fetal cases of fetal CHD were collected from 2013 to 2018, in which there were 2 fetuses identified as SMS. The first fetus was noted to have ventriculomegaly and Tetralogy of Fallot. The second fetus had Tetralogy of Fallot, right aortic arch and ectopic ductus arteriosus. There was a 3.63Mb and a 4.86Mb micro-deletion in their chromosome 17p11.2 by WGS, respectively. **Conclusion:** Prenatal diagnosis of SMS requires high index of suspicion of fetuses with CHD, especially TOF, and associated anomalies, e.g. ventriculomegaly. WGS and WES of high risk cases may identify SMS and aid in improved prenatal diagnosis, prognosis and parental counseling.

**480F**

**Clinical and genetic description of Mexican patients with prenatally identified cardiac tumors.** L.F. Mariscal<sup>1</sup>, R. Sevilla<sup>1</sup>, A.J. Martínez<sup>1</sup>, I.E. Monroy<sup>1</sup>, K. Carrillo<sup>2</sup>, C. Molina<sup>2</sup>, L.L. Flores<sup>2</sup>, C. Alaez<sup>2</sup>, M. Aguinaga<sup>1</sup>: 1) Genetics, Genomics and cardiology, Instituto Nacional de Perinatología, Mexico, Mexico city, Mexico; 2) Genetics, Instituto Nacional de Medicina Genómica, Mexico, Mexico city, Mexico.

**Introduction:** Rhabdomyomas represent the most common type of prenatal cardiac tumors. When isolated, 50-70% are related to tuberous sclerosis complex (TSC), this number increases to 80-90% when multiple. Commonly, they are asymptomatic and have a natural history of involution at birth, 10% persist and might alter heart hemodynamics, valvular function and heart rhythm. The aim of this study was to reinforce the importance of additional clinical data in patients with prenatal heart tumor(s). **Methodology:** From 2010 to 2017, 10 prenatally detected cardiac tumors were referred to the Genetics Department and a complete family history with parent's clinical evaluation was done. Postnatal echocardiographic and full clinical evaluation was completed. NGS sequencing of the *TSC1* and *TSC2* genes was performed. **Results:** Five female and 5 male patients were prenatally detected with cardiac tumor(s) at 29.2 to 33 weeks of gestation, all cases were confirmed postnatally as rhabdomyomas. Four had pericardial effusion, 2 supraventricular tachycardia and 1 hydrops fetalis with subsequent prenatal death. Extra cardiac manifestations included cortical tubers, Shagreen patch and hypomelanotic macules. Four *de novo* and 4 family cases were detected, only 1 case was previously aware of the TSC diagnosis. Two cases had familial manifestations of TSC but did not meet the criteria for a definite diagnosis. Molecular analysis by NGS was performed in 4 patients finding 3 *TSC2* mutations. One case reported as pathogenic in exon 34, rs45517340 (NM\_000548.3: c.4375C<T, NP\_000539.2: p.(Arg1459Ter), this patient had a giant tumor and received Everolimus with a good outcome. Another case had a pathogenic variant in exon 10 with a reported rs397515108 and described as NM\_000548.3: c.910T>C, NP\_000539.2: p.(Trp304Arg) with an *in silico* prediction as probably pathogenic. A mutation with no previous registry (June 2017) was found in *TSC2* with an *in silico* prediction as probably pathogenic. In 1 case, we were not able to identify a mutation by NGS in these 2 genes, family history describes mother an uncle with definitive diagnosis for TSC; we are still working on further molecular analysis. **Discussion:** We report a high sensitivity rate in prenatal diagnosis of cardiac tumors with a 60% association with TSC as reported in literature. An early diagnosis enables early treatment and permits a further analysis of family members using the fetus as a clue for familial disease diagnosis.

**481W**

**Pre- and perinatal history in kabuki syndrome.** C.E. Rosenberg<sup>1</sup>, T. Daly<sup>2</sup>, C. Hung<sup>2</sup>, E. Gusson<sup>2</sup>, A.W. Lindsley<sup>1</sup>, O. Bodamer<sup>2</sup>: 1) Division of Allergy and Immunology, Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) Division of Genetics and Genomics, Department of Pediatrics, Boston Children's Hospital, Boston, MA.

**Background:** Kabuki Syndrome (KS), a disorder of epigenetic dysregulation, is due to heterozygous mutations in either *KMT2D* or *KDM6A*, genes which encode a lysine specific methyltransferase and a lysine specific demethylase, respectively. The clinical phenotype of KS is highly variable, including congenital cardiac and renal anomalies, developmental delay, hypotonia, failure to thrive, short stature and immune dysfunction. All affected individuals have characteristic facial features. As the natural history of KS has not been fully delineated, limited information exists on the pre- and perinatal history of patients with KS. **Methods:** Two tertiary centers (Boston Children's Hospital and Cincinnati Children's Hospital Medical Center) collected retrospective pre- and perinatal historical data from patients with KS (N=33) using a questionnaire followed by in-depth review of medical records. **Results:** Data from 33 patients with KS (age: 19m-33y; 14 male; 14 with mutations in *KMT2D*, 1 with mutation in *KDM6A*, 18 diagnosed clinically) were included in the analysis. Maternal age at conception was 22-39 years (average: 30.2 years) and paternal age was 26-43 years (average: 33.5 years). Eleven of 33 (33%) pregnancies were complicated by polyhydramnios, including one where the fetus was diagnosed with cystic hygroma and shortened femur length on ultrasound. One pregnancy was complicated by gestational diabetes and pre-eclampsia. Delivery mode was vaginal in 17 of 29 patients, with C-section due to various indications in the remainder. **Discussion:** These data comprise the first large dataset on pre- and perinatal history in patients with confirmed, either genetically or clinically, KS. A relatively large number of pregnancies were complicated by the identification of polyhydramnios on ultrasound, which may be secondary to abnormal craniofacial structures and functional impairment of swallowing. **Conclusion:** Kabuki syndrome needs to be considered in the differential diagnosis in pregnancies complicated by polyhydramnios.

## 482T

**Rapid diagnostic testing for fetuses with multiple congenital anomalies detected through ultrasound scan using exome sequencing.** B. Sikke-ma-Raddatz, N. Corsten-Janssen, J.C.D. Diphorn, J. el Mecky, K. Bouman, J.B.G.M. Verheij, R. Kinds, A.J. Scheper, R.F. Suijkerbuijk, Y.J. Vos, I.M. van Langen, R.J. Sinke, R.H. Sijmons, H. Westers, C.C. van Diemen. Genetics, University of Groningen, University Medical Center, Groningen, Groningen, Netherlands.

**Introduction** Identifying the cause of fetal anomalies seen on ultrasound provides important information to improve perinatal management. Conventional genetic testing (QF-PCR, microarray) leads to a diagnosis in approximately 40% of fetuses with multiple congenital anomalies. Implementing exome sequencing (ES) in the prenatal setting is challenging due to uncertainties about fetal phenotyping, variant interpretation, counseling of incidental findings, and the requirement of short turnaround times. ES was implemented in prenatal care to increase the number of genetic diagnoses to aid in medical decision-making for parents and physicians. **Methods** Phase 1: Retrospective anonymous ES analysis of six fetuses (including parents) with known postnatal genetic diagnosis to test if this diagnosis could be made based on the fetal phenotype only. Variants were filtered using human phenotype ontology (HPO) or using our custom virtual gene panel (approximately 3850 disease genes, excluding late-onset disease genes). Phase 2: Prospective study of rapid trio WES analysis in addition to conventional genetic tests for twenty-five fetuses with abnormalities detected through ultrasound. Inclusion criteria are at least the presence of two congenital malformations as seen on ultrasound or one congenital malformation in addition to a previous pregnancy with a fetus with a similar phenotype. Questionnaires and interviews with patients about the test will be conducted. **Results** Phase 1: Five out of six known diagnoses could be confirmed using our gene panel. One causal pathogenic *PTPN11* mutation was missed due to low coverage of the variant. Filtering with HPO terms was not helpful given the continuously changing fetal phenotype. Phase 2: the first six fetuses have been included (May 2018), resulting in a genetic diagnosis in three: (1) unclear sex, club feet, possible ASD and a *de novo* mutation in *SAMD9* (MIRAGE syndrome) (2) nuchal translucency, fluid surrounding thorax and abdomen, club feet and compound heterozygous mutations in *PEX1* (Zellweger syndrome) (3) severe hydrocephaly, also seen in a previous pregnancy and homozygous mutations in *POMGNT1* (Walker Warburg syndrome). Four incidental findings were reported. The turnaround time was 6-14 working days. **Conclusion** First results from our prospective study show that implementing ES as a routine test in the prenatal setting is feasible. The test has a promising diagnostic yield, helping parents in decision making.

Congenital diaphragmatic hernia (CDH) is a major congenital abnormality that is associated with significant mortality, long term morbidity, and developmental impairment in some but not all individuals. To identify genetic associations with differential developmental and clinical outcomes of CDH patients, we prospectively enrolled neonates with CDH and followed for up to five years. We performed whole genome or exome sequencing in 409 parent offspring trios to identify *de novo* variants. We classified CDH patients into three groups based on the type of *de novo* variant: (a) likely gene disrupting (LGD) and predicted deleterious missense variants in constrained genes or known risk genes of CDH or common comorbid disorders (Group A, n=72); (b) LGD in other genes or predicted mildly deleterious missense variants in any gene (Group B, n=133); (c) other variants (Group C, n=204). We assessed seven outcomes: pulmonary hypertension at one month (n=299) and three months of age (n=245), mortality prior to initial discharge (n=407), Bayley Scales of Infant Development (BSID-III, n=183) and Vineland Adaptive Behavior Scales (VABS-II, n=224) at two years of age, Wechsler Preschool and Primary Scale of Intelligence (WPPSI-IV, n=65) and VABS-II (n=80) at five years of age. We also collected baseline clinical factors and socioeconomic data. We tested the association separately in complex (CDH with additional anomalies, n=152, 37% of all cases) and isolated (n=256) cases. We observed an association of lower intelligence score assessed by WPPSI with group A in complex cases (P-value=0.02), especially significant when adjusted for neonatal factors (P-value=4.5×10<sup>-3</sup>). There is a marginal association of language delay (by the BSID-III) with group A variants (p=0.03) in isolated cases. The severity of pulmonary hypertension at three months were correlated with genetic risk variants in group A (P-value=0.03). No significant difference was observed in pulmonary hypertension at one month or mortality prior to initial discharge comparing the three genetic groups. In summary, we found *de novo* deleterious variants in constrained or CDH candidate risk genes to be associated with lower intelligence score of CDH patients at five years of age and marginally associated with pulmonary hypertension at three months of age and language scores at two years of age. These results have important implications for prognosis and potential intervention and long term follow up for children with CDH.

**Introduction:** Germline or post-zygotic activating mutations of *PI3K/AKT/mTOR* pathway lead to a spectrum of segmental overgrowth syndromes that can be detected during the prenatal period. We report the first cohort of prenatal phenotypes related to activating mutation of *PI3K/AKT/mTOR* pathway. **Material and methods:** We gathered fetal cases suspected of activating mutations of *PI3K/AKT/mTOR* pathway that led to fatal issues and tested in the reference molecular diagnostic laboratory of Dijon University Hospital. After precise phenotyping with prenatal and fetopathological data, we performed ultra-deep targeted sequencing of genes of the pathway on a MiSeq platform (*PIK3CA*, *PIK3R2*, *AKT3*, *CCND2*, *PTEN*) in several tissues depending on the fetal phenotype. **Results:** We ranked 14 fetuses from termination of pregnancies (12/14) and perinatal death (2/14) into two main groups of fetuses: fetuses without cerebral overgrowth and fetuses with cerebral overgrowth, symmetrical (megalencephaly) or asymmetrical (hemimegalencephaly). Eight fetuses had an asymmetrical cerebral overgrowth corresponding to a hemimegalencephaly detected prenatally, isolated in 6 cases, with the identification of a post zygotic *PIK3CA* or a germline *PTEN* mutation, and with significant extracerebral abnormalities discovered during autopsy in 2 fetuses, especially dermatological, corresponding to MCAP/CLOVES fetal phenotype secondary to a post-zygotic *PIK3CA* mutation. For the 6 fetuses with isolated hemimegalencephaly, the fetal phenotype was secondary to a. [A2] Three fetuses [A3] had a prenatal extended lymphangioma associated with wide feet with plantar hypertrophy, toe abnormalities with a wide sandal gap suggesting a CLOVES syndrome, with identification of a postzygotic *PIK3CA* variant for 2 of them. Three fetuses had a prenatal mild ventriculomegaly associated with macrocephaly corresponding to megalencephaly and diffuse polymicrogyria suggesting a MPPH syndrome, all carrying a *PIK3R2* variant, 2 germline *de novo* and one post-zygotic (mosaicism level=8.51%). **Conclusion:** This is the first prenatal cohort of extreme forms of phenotypes related to activating mutation of *PI3K/AKT/mTOR* pathway, which demonstrates a high clinical and molecular heterogeneity. Thanks to its results, we propose a decision tree according to the fetal phenotype to guide the targeted sequencing.

## 485T

**Maternal factors associated with DNA methylation-based placental aging.**

T. Workalemahu<sup>1</sup>, D. Shrestha<sup>1</sup>, S. Tajuddin<sup>2</sup>, F. Tekola-Ayele<sup>1</sup>. 1) Epidemiology Branch, Division of Intramural Population Health Research, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD; 2) Laboratory of Epidemiology and Population Sciences, National Institute on Aging, National Institutes of Health, Baltimore, MD, USA.

Disruption of the physiological aging of the placenta can deter its hormonal and transport function and may lead to several adverse pregnancy outcomes. Recent "epigenetic clock" studies have begun profiling lifestyle and socio-demographic factors that influence tissue age in adults. Understanding the maternal factors that predict DNA methylation-based placental aging provides intervention opportunities to improve pregnancy outcomes, but these factors are largely unknown. We investigated whether maternal socio-demographic factors and genetic ancestry are associated with placental aging. Participants with placental DNA methylation and genotype data (n=301) were obtained from a sub-cohort of low-risk pregnant women of the NICHD Fetal Growth Studies. Participants were composed of self-identified Non-Hispanic Black (n=72), Non-Hispanic White (n=77), Hispanic (n=102), and Asian/Pacific Islander (n=50) race/ethnicities. The Illumina Infinium 450 BeadChip array was used to quantify over 400k CpG sites. Placental DNA methylation age was predicted using 62 CpG sites that were known to predict placental aging. Placental age acceleration was defined to be the difference between gestational age at birth and placental DNA methylation age. Genome-wide proportions of African, European, Native American, and East Asian genetic ancestries of the mothers were estimated using ADMIXTURE. Placental DNA methylation age was positively correlated with gestational age at birth (r=0.20; p<0.01). Placental age acceleration was positively correlated with maternal age (r=0.13; p=0.03), proportion of European ancestry among non-Hispanic Whites (r=0.27; p=0.02), and proportion of Native American ancestry among Hispanics (r=0.26; p=0.01), and negatively correlated with proportion of African ancestry among Hispanics (r=-0.24; p=0.01). In multivariable models adjusted for maternal age, pre-pregnancy body-mass-index, infant sex, parity, medical insurance, marital status, education, mode of onset of labor, intra-uterine growth restriction status and preeclampsia status, the associations with African and Native American ancestry among Hispanics remained significant. In summary, findings suggest that mother's age and genetic ancestry may influence molecular markers of placental aging. Future studies are needed to understand whether adverse pregnancy outcomes known to be associated with advanced maternal age and population groups are mediated through accelerated aging of the placenta.

**486F**

**Comparative Genomic Hybridization (aCGH) and Next Generation Sequencing (NGS) combine together give a comprehensive genetic diagnosis approach for prenatal anomalies.** S.S. Chettiar<sup>1,2</sup>, A.R. Patel<sup>1,2</sup>, D.D. Jhala<sup>3</sup>, J.J. Dattani<sup>3</sup>, U. Radhakrishna<sup>4</sup>. 1) Human Genomics, Genexplore Diagnostics and Research Centre, Ahmedabad, Gujarat, India; 2) Department of Human Genetics, Gujarat University, Ahmedabad, India; 3) NVBBDP, Ministry of Health and Family Welfare, Government of India; 4) Department of Obstetrics and Gynecology, Oakland University- William Beaumont School of Medicine, Royal Oak, MI, USA.

Fetal anomalies are identified in 2-5% of normal pregnancies and are reported as high as 12-18% in high risk pregnancies, which also attributes to 28% perinatal deaths. Most common developmental anomalies observed are in Central nervous system, Cardiovascular system, Gastrointestinal tract and Urinary tract. Diagnosis and prognosis approach vary in different anomalies observed, although most common and conventional approach adopted is karyotype followed by aCGH. Karyotype identifies 30% of aneuploidy and 5% of balanced translocation. While aCGH can detect additional 6.5% of CNVs, deletion and duplication. But together karyotype and aCGH only constitute to 37% of genetic changes contributing to the fetal anomalies observed, still leaving majority of cases undiagnosed. Thus there is need to add another dimension of approach to ascertain genetic etiology. Next generation sequencing give much more resolution upto single base pair level and at the same time encompassing a large number of genes or entire exome which will transcribe in to set of amino acid sequences in protein. In our study NGS has demonstrated 22% of diagnostic yield which was not been picked up by conventional methods. We studied 238 amniotic fluid samples with varied clinically reported radiological indications. Following conventional method cytogenetically 72 (30.25%) samples were found to have causative variation, CMA showed CNVs in 18 (7.54%) samples and NGS approach provided positive hits in 51 (21.42%) of cases. CMA data revealed CNVs in novel loci like Chr19p13.11-p12 duplication in fetus with echogenic intracardiac focus, 4q35.2 microdeletion in retrognathia, 15q11.1-11.2 duplication in intrauterine growth retardation, deletion in Chr8p11.22 associated with atrioventricular septal defect, fetus with bilateral Ventriculomegaly and facial dimorphism showed deletion in Chr3p26.2-26.1, ChrX22.33 and duplication in Chr10q26.3. NGS analysis provided novel mutation in genes DSC2, 2687GA with fetus reported presenting Arrhythmogenic right ventricular dysplasia; KCNQ1, G229D associated to fetal atrial fibrillation; FBN1, 5280G fetus with aortic aneurysm; DSG2, ARG48HIS associated to Arrhythmogenic right ventricular dysplasia; MYBPC3, ASP745GLY in aortic aneurysm and TNNT2,3-BP DEL, 285GGA in cardiac anomalies. Although data show no one method suffices to have significant mutation detection, we recommend a comprehensive parallel approach with all three methods.

**Aspirin enhances trophoblast invasion and represses sFlt-1 production: A putative mechanism for preventing preeclampsia.** M. Su<sup>1</sup>, C. Wang<sup>2</sup>, H. Tsai<sup>1</sup>. 1) Depart. of OBGYN, National Cheng Kung University Hospital, Tainan, Taiwan; 2) Department of Cell Biology and Anatomy, National Cheng Kung University, Tainan, Taiwan.

**BACKGROUND** Preeclampsia is a severe gestational hypertensive disorder that represents a major threat to mortality and morbidity in maternal and fetal health worldwide. Recent studies suggested that prophylactic aspirin prior to 16 weeks of gestation in high-risk patients may reduce the risk of developing preeclampsia, however, the exact mechanism of aspirin's effect on the pathophysiology of preeclampsia is not clear. **OBJECTIVE** This study was designed to investigate the effect of aspirin on trophoblast cell function and its effect on soluble Flt-1 (sFlt-1) production to elucidate the underlying molecular mechanisms in vitro. **STUDY DESIGN** We used two human trophoblastic cell lines (HTR-8/SVneo and JRA cells) to determine the effect of aspirin on trophoblast cell function. Trophoblasts were pretreated with aspirin, and then cell functions (cell proliferation, cell invasion) and sFlt-1 expression were assessed. In addition to RNA level and the activity of matrix metalloproteinase (MMP) 2 and MMP9 by real-time PCR and gelatin zymography, respectively, we also evaluated ERK and Akt signaling to decipher the underlying mechanism by which aspirin regulates trophoblast biology. The effect of sFlt-1 on trophoblast invasion and MMP2/9 was further validated by treating HTR-8/SVneo cells with human Flt-1 recombinant protein and performing siRNA knockdown studies. **RESULTS** We observed that aspirin promoted trophoblast invasion in HTR-8/SVneo and JAR cells. sFlt-1 protein production was repressed by aspirin in a dose-dependent manner in HTR-8/SVneo cells, but sFlt-1 expression was barely detected in JAR cells. By adding human Flt-1 recombinant protein, the invasion ability of HTR-8/SVneo cells was inhibited, which was reversed by FLT-1 siRNA knockdown. In addition, we found that MMP2/9 expression and activity in HTR-8/SVneo cells was activated by aspirin treatment but inhibited by sFlt-1. Aspirin also downregulated Akt phosphorylation at Thr308 and Ser473 and trophoblast invasiveness was facilitated under Akt inhibitor treatment. **CONCLUSION** Aspirin enhances cell invasion ability and inhibits sFlt-1 production in trophoblasts. Moreover, sFlt-1 itself also inhibits trophoblast invasion. Our data suggest that the preeclampsia prevention effect of aspirin may be exerted through two mechanisms: the effect of aspirin itself on promoting trophoblast invasion and the effect of aspirin in repressing sFlt-1 production.

**488T****Improved non-invasive prenatal testing by mitigating false predictions caused by maternal mosaic aneuploidy using size-based DNA.** H.J.

Kwon<sup>1</sup>, S.Y. Yun<sup>1</sup>, A. Goyal<sup>1</sup>, J.H. Kim<sup>1</sup>, H.S. Im<sup>1</sup>, J.S. Joo<sup>1</sup>, J.S. Bae<sup>1</sup>, M.S. Lee<sup>1,2,3</sup>, S.H. Lee<sup>1</sup>. 1) Eone-Diagnomics Genome Center, Inc., 291 Harmony-ro, Yeonsu-gu, Incheon, 22014, Republic of Korea; 2) Diagnomics, 5775 Kearny Villa Rd., San Diego, CA 92123, USA; 3) Incheon Nat'l University, 119 Academy-ro Yeonsu-gu, Incheon, 22012, Republic of Korea.

**Background** A noninvasive prenatal test (NIPT) is a method of identifying fetal chromosomal abnormalities using cell-free DNA in the maternal plasma. Although many new algorithms have been developed and improved in accuracy, the false positives caused by the low fetal fraction and the maternal mosaic aneuploidy are still difficult to avoid. Circulating fetal DNA molecules are generally shorter in size than the corresponding maternal DNA molecules. In view of fact that the DNA fragment size can be used as diagnostic parameter, we calculated z-score of enriched fetal and maternal DNA respectively and found a solution to reduce the false NIPT results which might be caused by low fetal fraction, partial duplication and deletion of target chromosome or maternal mosaic aneuploidy. **Method** We used paired-end sequencing reads to identify the size distribution of fetal and maternal DNA in cell-free maternal plasma. First, paired-end reads from short cfDNA fragments of less than 150bp, "fetal reads", were selected to enrich cfDNAs derived from fetus cells while those from larger fragments of over 185 bp, "maternal reads" were used to enrich cfDNAs from maternal cells. Second, we calculated z-scores using GC corrected fetal and maternal reads across all chromosomes and analyzed the presence of aneuploidies of both fetal and maternal reads. Finally, we assessed how the maternal cfDNA affected the overall results or how the NIPT algorithm can be more adequate to detect the fetus aneuploidy. Finally, we made final decision by comparing the two results from fetal and maternal reads. **Results** Compared to conventional NIPT algorithm, our method could detect aneuploidy more clearly by comparing the results from fetal and maternal reads when analyzing trisomy 21 samples of very low fetal fractions of 3~5%. In addition, our algorithm could distinguish correctly fetal X monosomy from maternal mosaic aneuploidy that can cause false prediction result. **Conclusion** We amplified the fetal signal by distinguishing the maternal DNA specific fragments by size selection and consequently reduced the false negative or false positive detection due to the low fetal fraction or maternal mosaic aneuploidy and partial duplication/deletion, respectively. .

**489F****GWAS for gestational hypertension using time-series home blood pressure data in maternity log study.** Y. Tsunemoto<sup>1</sup>, T. Yamauchi<sup>1,2</sup>, D. Ochi<sup>1,2</sup>, K.

Kojima<sup>2</sup>, T. Mimori<sup>2</sup>, S. Kumatani<sup>1</sup>, R. Yamashita<sup>2</sup>, M. Wagata<sup>2</sup>, Y. Harada<sup>2</sup>, F. Katsuoka<sup>2</sup>, N. Minegishi<sup>2</sup>, O. Tanabe<sup>2</sup>, S. Hiyama<sup>1</sup>, M. Nagasaki<sup>2</sup>, J. Sugawara<sup>2,3</sup>, Maternity Log Study Group. 1) Research Laboratories, NTT DOCOMO, INC., Hikarino-oka, Yokosuka, Kanagawa, Japan; 2) Tohoku Medical Megabank Organization, Tohoku University, Seiryomachi, Aobaku, Sendai, Miyagi, Japan; 3) Department of Gynecology and Obstetrics, Tohoku University Graduate school of Medicine, Seiryomachi, Aobaku, Sendai, Miyagi, Japan.

**Objective:** Hypertensive disorders of pregnancy (HDP) including gestational hypertension (GH) and preeclampsia (PE) is a major cause of perinatal mortality in both mothers and children, but the pathogenic mechanisms of HDP have not been clarified. Although there exist several genome-wide association studies (GWASs) for HDP, most of the studies considered only the binary disease status, and significant loci identified in these studies are limited. In order to overcome this limitation, we conducted a GWAS for a continuous phenotype on daily home blood pressure of pregnant women. Since most of HDP patients in this study were diagnosed as GH and since there were fewer reports of GWASs for GH compared to PE, we focused on GH in this study. **Methods:** We used daily home blood pressure data and whole genome sequencing data of 190 pregnant women including GH patients (n=16) and controls (n=174), who participated in Maternity log study (MLOG). MLOG is an add-on cohort study on a part of participants of a prospective cohort study by Tohoku Medical Megabank Organization in Japan. In MLOG, pregnant women were recruited in the first or second trimester of pregnancy at Tohoku University Hospital. By using a smart phone and monitoring devices, participants uploaded daily life-logs such as home blood pressure. Furthermore, specimens such as blood samples for genome sequencing and multi-omics analyses were collected. Blood pressure of GH patients showed greater increments during pregnancy than controls. Therefore, we conducted a GWAS for the increment of daily home blood pressure as a continuous phenotype, not only GWASs for binary phenotypes. **Results:** We identified several significant ( $p < 5 \times 10^{-8}$ ) SNPs by conducting a GWAS for the continuous phenotype instead of binary phenotypes. Moreover, these significant SNPs were located near the genes related to hypertension or placental function. **Discussions:** In this study, we conducted an unprecedented GWAS for GH using time-series data of home blood pressure. Despite the small number of samples, we could identify significant SNPs that were not found by GWASs with binary phenotypes. This result suggests that using detailed and continuous biometric information is effective for GWAS with a limited sample size.

**Deciphering the causes of early human pregnancy loss by exome analysis of abortuses.** S.K. Garushyants<sup>1</sup>, E. Nabieva<sup>1</sup>, M.D. Logacheva<sup>1</sup>, T.V. Neretina<sup>2</sup>, A. Zhdanova<sup>2</sup>, N. Libman<sup>3</sup>, D. Pyankov<sup>4</sup>, G.A. Bazykin<sup>1</sup>. 1) Skolkovo Institute of Science and technology, Moscow, Russia; 2) Lomonosov Moscow State University, Moscow, Russia; 3) Genetico LLC, Moscow, Russia; 4) Genomed, Moscow, Russia.

Only a third of human conceptions result in live births, which comprises a substantial burden to human reproduction. A large fraction of pregnancy losses are associated with chromosomal abnormalities. The genetic basis of embryonic lethality in the remaining euploid embryos has been the subject of a few recent analyses employing whole exome sequencing. However, those studies have focused on embryos of advanced gestational age. The causes of early pregnancy loss in karyotypically normal embryos remain largely unknown. Here, we present the early results of a whole exome sequencing study of spontaneous euploid abortuses below 16 weeks gestational age, aiming to determine the inherited or *de novo* genetic variation (DNV) that could have led to pregnancy loss. We plan to sequence 100 mother-father-abortus trios; to date, we have sequenced eight trios. The mean gestational age was 10.5 weeks. As candidate causative variants, we considered inherited or *de novo* variants in genes associated with embryonic lethality in mice, and in genes with high intolerance to protein truncating variants (PTVs). We considered nonsynonymous variants with Polyphen score >0.996. For inherited variants, we required allele frequency below 1% and absence in homozygous state in the general population. For *de novo* variants, we required absence in the general population. In 3/8 cases, we detected no candidate variants. In one case, we detected two possible causative DNVs: one DNV in *SOX4* (p.Gly420Asp), a gene whose knockouts in mice were shown to cause embryonic lethality; and one DNV in *BCL9L* (p.Lys275Asn), which is known to be PTV intolerant, while mutations in this gene are predicted to be autosomal dominant. In another case, we detected a possible causative DNV at splice site of *DLG2* (c.40-2A>G); a knockout of this gene causes embryonic lethality in mice. In three additional cases, we detected compound heterozygotes in essential genes *PNPT1*, *LAMA5*, and *PTPN6*. This study will add to the emerging picture of the diversity of causes of embryonic lethality.

**491T**

**Cell-free DNA in embryo culture medium of in-vitro fertilization (IVF) for preimplantation genetic testing (PGT) for aneuploidy.** K.W. Choy, Q. Yeung, Y. Zhang, T.C. Li, G.W.S. Kong, J.P.W. Chung. Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong, Hong Kong, China.

To circumvent the risk of causing irreversible damage to a preimplantation embryo, the development of Non-Invasive Prenatal Testing (NIPT) on prenatal diagnosis provides a new insight to the methodology of genetic screening. Literatures have proven that embryonic DNA is released when an embryo begins to divide and grow during its preimplantation development. Since an embryo is confined to an in-vitro environment during IVF, the culture media in which the embryo has been handled and cultured provide a valuable source for sampling for PGT. We aim to study could the same genome profile be identified if spent culture media (SCM) instead of trophectoderm (TE) were used for aneuploidy screening (PGT-A). This is a prospective study comparing PGT-A results of SCM samples to the routine results based on TE of the same embryos. Couples undergoing PGT-A cycles were recruited from a university hospital infertility centre. The study is still ongoing, and this interim review is consisted of 70 blastocysts from 24 PGT-A cycles between March 2017 and September 2017. All recruited cycles underwent intracytoplasmic sperm injection (ICSI). All TE samples were subjected to routine PGT-A by aCGH (GenetiSure Pre-Screen 8x60K microarray, Agilent), from which 69 (98.6%) produced an interpretable result. For SCM from the 70 corresponding embryos, 60 samples (85.7%) had cell free DNA that were successfully amplified, then subjected to NGS (Veriseq, Illumina). Thirty-nine of them (65.0%) giving an interpretable result. There was an 88.2% concordance rate in sex determination. When SCM results were classified into euploid and aneuploid, the concordance rate with TE results was 71.8%. Overall, 12 euploids were identified by SCM, in which 6 were also euploids based on TE biopsy, 3 contained low level of mosaicism, 1 involved a segmental error on one chromosome, and 2 false negatives probably due to presence of cumulus cells in the SCM. Interestingly, there were 3 aneuploids identified by SCM which were euploids by TE biopsy. These three embryos were already transferred based on their euploid status as established from TE, resulting in 2 miscarriages and 1 ongoing pregnancy. In summary, SCM from embryos have the potential to become the first non-invasive method in euploid identification and gender determination. Much research is needed to elucidate the origin of cell free DNA found in SCM.

**492F**

**Correlation of hemolysis and fetal fraction in cell-free DNA blood collection tubes for noninvasive prenatal testing.** R. Stokowski, C. Hacker, K. White, R. Jones, M. Schmid. Ariosa Diagnostics Inc., Roche Sequencing Solutions Inc., San Jose, CA.

**Objective:** Lysis of maternal white blood cells in prenatal cell-free DNA (cfDNA) test samples will increase the level of maternal genomic DNA and consequently decrease fetal fraction. The objective of this study was to determine whether hemolysis, traditionally used as a marker for cell lysis, is correlated with a decrease in fetal fraction in maternal blood samples collected in specialized cfDNA tubes for noninvasive prenatal testing. **Methods:** Blood from pregnant women was collected into multiple cfDNA blood tubes. First, paired samples from the same subject were evaluated for a visual difference in hemoglobin level as a measure of hemolysis and fetal fraction measured using polymorphic DANSR assays. In a second arm of the study, clinical Harmony® test samples with hemoglobin levels of 500mg/dL and higher were tracked through the laboratory and their fetal fraction distribution compared to concurrently processed samples with lower hemoglobin levels. **Results:** There was no significant difference in fetal fraction in 170 paired samples with a difference in hemoglobin levels ranging from 30 to 980 mg/dL. The fetal fraction distribution in 203 tracked clinical samples with hemoglobin levels greater than or equal to 500mg/dL was statistically equivalent to the distribution in a concurrent series of 12,705 samples. **Conclusion:** Hemolysis as a measure of cell lysis in maternal blood samples collected in specialized cfDNA tubes does not correlate with a decrease in fetal fraction; therefore, it should not be a cause for rejection of samples submitted for prenatal cfDNA testing.

**493W**

**Pan-ethnic expanded carrier testing for fatty acid oxidation disorders.** N. Echeverri<sup>1</sup>, J. Bardos<sup>1</sup>, C. Terhaar<sup>2</sup>, K. Hill-Harfe<sup>2</sup>, R.E. Longman<sup>1</sup>. 1) University of Miami Miller School of Medicine, Miami, FL; 2) Progenity, Inc., Ann Arbor, MI.

**Introduction:** Fatty Acid Oxidation Disorders (FAOD) are a group of autosomal recessive conditions characterized by impaired catabolism of mitochondrial fatty acid oxidation. The most common clinical presentation is hypoketotic hypoglycemia and sudden death in the neonatal period after an episode of fasting or infection. Individuals with milder defects may present later in life or even be asymptomatic. Historically, carrier testing guidelines were ethnicity-based and did not include testing for FAODs. New technologies and increasing ethnic diversity have enabled expanded carrier testing as an acceptable clinical practice. This study assesses how many individuals screened positive for five different types of FAOD when a pan-ethnic expanded carrier testing panel was implemented. **Methods:** A retrospective database analysis was performed on samples received for expanded carrier testing via a commercially-available genotyping platform. Expected number of positive carriers for five different types of FAOD were calculated and compared to observed rates: Carnitine palmitoyltransferase I deficiency (CPT I), Carnitine palmitoyltransferase II deficiency (CPT II), Long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency (LCHAD), Medium-chain acyl-CoA dehydrogenase deficiency (MCAD), and Very long-chain acyl-CoA dehydrogenase deficiency (VLCHAD). Chi-squared analysis was performed to assess for statistical significance ( $p < 0.05$ ). **Results:** A higher-than-expected number of individuals tested positive for CPT II deficiency ( $p < 0.001$ ) and MCAD ( $p < 0.001$ ). A lower-than-expected number of individuals tested positive for LCHAD ( $p < 0.001$ ) and VLCAD ( $p = 0.009$ ). The number of individuals that screened positive for CPT I deficiency was consistent with expected values ( $p = 0.405$ ).

Disease	Total tested	Observed Positives	Expected Positives	p-value
Carnitine palmitoyltransferase I deficiency	24158	3	4.84	0.405
Carnitine palmitoyltransferase II deficiency	24150	121	37.19	<0.001
Long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency	24158	28	84.07	<0.001
Medium-chain acyl-CoA dehydrogenase deficiency	24155	308	151.5	<0.001
Very long-chain acyl-CoA dehydrogenase deficiency	24157	14	27.77	0.009

**Conclusion:** Carriers of CPT II deficiency and MCAD were more common than expected in this cohort. Pan-ethnic expanded carrier testing will identify carriers of FAODs, allowing for more complete genetic counseling, family planning options, and prompt treatment of affected neonates.

**494T**

**Conflicting cfDNA and microarray prenatal results: A unique repair process in a chromosomally normal fetus.** V.R. Potluri<sup>1</sup>, T. Boomer<sup>2</sup>, S. Caldwell<sup>2</sup>, M.K. Rudd<sup>2</sup>, R. Mccullough<sup>2</sup>, P. Papenhausen<sup>2</sup>, S. Schwartz<sup>2</sup>. 1) Laboratory Corporation of America Holdings, Houston, TX; 2) Laboratory Corporation of America Holdings, Research Triangle Park, NC; 3) Sequenom Inc., San Diego, CA.

The field of prenatal diagnosis has evolved considerably over the past decade to include new screening tests (e.g cfDNA) as well as improved diagnostic testing (e.g. microarray analysis and exome sequencing). These tests are often complementary but on occasions provide conflicting results. This presents an interesting patient with seemingly conflicting results but in reality provide a unique underlying mechanism to illustrate how the results are inter-related. Initial cfDNA analysis suggested the presence of a deletion of part of the long arm of chromosome 13. Follow-up microarray analysis at 16.4 weeks gestation did not confirm the deletion, but indicated a long stretch of homozygosity (~57.4 Mb) in the long arm of chromosome 13 (13q21.1->13qter). Parental analysis indicated that while the proximal region of chromosome 13 was inherited in a biparental manner, it confirmed maternal segmental uniparental disomy for this terminal region. The pregnancy continued to term at which time placental microarray studies demonstrated a 57.5 Mb mosaic terminal deletion and allelic mosaicism of 13q21.1->13qter. This study is important clinically and mechanistically for a number of reasons including: (1)The cfDNA result clearly detected an anomaly in the placenta; (2) The follow-up microarray studies indicated that the fetus did not appear to have a deletion, but indicated the possibility of a repair process; (3) Standard cytogenetic analysis would not have provided an explanation for the cfDNA findings, just indicating that both chromosome 13s were structurally normal; (4) The placenta studies confirmed that there was a deletion in the placenta, but that a repaired process occurred leading to the normal fetal findings; (5) Although no fetal deletion was detected, there always remains a possibility of a phenotype due to developmental effects of the deficit before complete repair or a recessive disorder associated with the homozygosity and the patient needs to be counseled to these possibilities.

**495F**

**Genome-wide trans-ethnic meta-analysis identifies a novel locus influencing longitudinal fetal growth at sensitive periods in pregnancy.** F. Tekola-Ayele, J. Wu, M. Ouidir, M. Rahman, K.L. Grantz, C. Zhang, J. Grewal, T. Workalemahu. Division of Intramural Population Health Research, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, USA.

Fetal growth is an important predictor of infant morbidity and mortality, and is associated with cardiometabolic diseases in children and adults. Genome-wide association studies (GWASs) involving European ancestry populations have identified genetic loci associated with birthweight. However, genetic influences on fetal growth vary at different windows of pregnancy and birthweight may not reflect *in utero* growth trajectory. We conducted GWAS meta-analyses of fetal weight at end of first trimester (13 gestational weeks), mid-gestation (20 weeks), late second trimester (27 weeks), and third trimester (40 weeks) of pregnancy in 1,849 self-identified African American, Asian, White, and Hispanic pregnant women recruited through the NICHD Fetal Growth Studies. SNPs were genotyped with the Infinium Multiethnic Global BeadChip and imputed using the 1000 Genomes reference panel. We carried out random-effects GWAS meta-analyses followed by trans-ethnic GWAS meta-analysis using a Bayesian approach to account for variations in allelic effects and linkage disequilibrium among ethnicities. We identified a genome-wide significant association of a novel SNP in the inositol 1,4,5-triphosphate receptor type 1 (*ITPR1*) gene with 30.8 g reduced fetal weight at second trimester of pregnancy (95% CI -41.9, -19.8,  $\log_{10}BF=6.297$ ;  $P=4.09 \times 10^{-6}$ ). The locus was also associated with reduced fetal weight at first trimester ( $P=3.91 \times 10^{-6}$ ), mid-gestation ( $P=2.55 \times 10^{-7}$ ), and third trimester ( $P=4.41 \times 10^{-4}$ ) of pregnancy. Fine-mapping showed that the fetal weight reducing allele was common among African-Americans, Hispanics and Whites (12.5%-20.8%), and had low frequency among Asians (1.6%) in our cohort. The significantly associated *ITPR1* locus is within regulatory histone marks in several tissues including the placenta, and knockout of *itpr1* in mice has been shown to lead to extra-embryonic vascular defects, early growth retardation and embryonic lethality. Together, the present study sheds new light on the role of common genetic variants in the inositol receptor signaling pathway on fetal growth, potentially by regulating vascular development at the embryonic-maternal interface. The study also demonstrates that longitudinal fetal growth measures, beyond birth size, are valuable for discovering novel genetic loci, particularly through trans-ethnic genomic approaches.

**German Neonatal Network: Resource for genetic analyses in very low birth weight infants.** *T.K. Rausch<sup>1,2</sup>, I.R. König<sup>1</sup>, W. Göpel<sup>2</sup>.* 1) Institut für Medizinische Biometrie und Statistik, Universität zu Lübeck, Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Lübeck, Germany; 2) Department of Pediatrics, Universität zu Lübeck, Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Lübeck, Germany.

Founded in 2009, the German Neonatal Network examines the development of very low birth weight infants until the age of five in Germany with 63 study centers. During their stay in hospital after birth the assessment includes the infants' basic data, medication, surgeries and therapies. After discharge from hospital, the parents report on their infants' development via an annual questionnaire. A follow-up team of study nurses and a medical doctor from Lübeck visits all study sites to examine the infants at the age of five years. Besides recording basic data they conduct several tests to examine eyes, ears, lung, movement and development. Umbilical cord tissue frozen after birth is used to genotype the DNA of the infants. Affymetrix Axiom™ Genome-Wide CEU 1 Array Plate 2.0 and Illumina Infinium® Global Screening Array-24 v1.0 were used for chip genotyping. Our continuously growing database already contains clinical data of 17,900 very low birth weight infants, genetic data of 7,400, and five-year follow-up data of 1,850 infants. In the main data set 49.1 % of 15,462 very low birth weight infants are female, the mean birth weight is 1,059.82 ± 306.76 g and the mean gestational age is 28.7 ± 2.76 weeks. Ultimately, genetic information will be available from all infants who were examined at the age of five years. A resource is already available providing answers to a wide variety of research questions.

**497T**

**Whole exome sequencing of genomes of Korean patients with non-obstructive azoospermia.** *M. Go<sup>1</sup>, S. Sung<sup>2</sup>, J. Park<sup>2</sup>, K. Kang<sup>2</sup>, Y. Shin<sup>2</sup>, S. Song<sup>3</sup>, S. Shim<sup>1,2</sup>.* 1) Biomedical Science Dept., College of Life Science, CHA University, Seoul, South Korea; 2) Genetic laboratory, Fertility Center of CHA Gangnam Medical Center, Seoul, South Korea; 3) Department of Urology, CHA Gangnam Medical Center, Seoul, South Korea.

Azoospermia affects approximately 1% or more of adult men. The most of genetic causes of non-obstructive azoospermia (NOA) cases are idiopathic except AZF (Azoospermia factor) microdeletion and Klinefelter syndrome. To date, whole exome sequencing (WES) technologies allow fast identification of variants in causative genes of target disease such as NOA (He et al. 2018; Nakamura et al, 2015). In this study, we used WES to identify possible pathogenic variants in genomes of Korean patients with idiopathic non-obstructive azoospermia. Sixteen Korean patients who diagnosed as idiopathic non-obstructive azoospermia were subjected to whole exome sequencing (WES). The Illumina HighSeq 2500 platform (Illumina, San Francisco, USA) was used and the libraries are prepared using SureSelect Exome V5 library kit. Cytological examination showed maturation arrest in all patients. As a result, we identified total 77 variants in 40 genes (data not shown) that might cause azoospermia. Two variants (c.551T>C of *TEX11* (NM\_001003811) and c.724G>T in *DMRT1* (NM\_021951)) were filtered with databases (1000G or ExAC) and prediction software (Mutation taster, SIFT, Polyphen-2, M-CAP, and CADD). *TEX11* and *DMRT1* are causative genes of non-obstructive azoospermia which were identified in previous studies (Nakamura *et al.*, 2015; Don *et al.*, 2011.). *TEX11* variant (c.551T>C) was expected to cause p.Leu-184Pro and might affect the activity of domain of *TEX11*. Likewise, c.724G>T in *DMRT1* could cause p.Gly242Trp and predicted to alter the structure of *DMRT1*. As a further study, 74 patients with azoospermia and 96 normal males were screened. Because no one showed same variants on each *TEX11* and *DMRT1*, the variants that we identified have a possibility to be pathogenic. To summarize, we identified two novel variants that were predicted to be pathogenic in *TEX11* and *DMRT1*, respectively. Our result could not fully elucidate functional impacts of variants on spermatogenesis and therefore further studies are required. However, this study showed WES is a useful tool to identify variants in causative genes of non-obstructive azoospermia.

## 498F

**CETN1 variants are associated with idiopathic male infertility: Genetic and functional perspectives.** D.V.S. Sudhakar<sup>1</sup>, R. Phanindranath<sup>1</sup>, S. Jayashankar<sup>2</sup>, A. Pawar<sup>3</sup>, D. Verma<sup>4</sup>, P. Nagarajuna<sup>5</sup>, M. Deenadayal<sup>6</sup>, K.V. Chary<sup>7</sup>, R. Singh<sup>8</sup>, K. Singh<sup>9</sup>, R. Dada<sup>9</sup>, A. Anand<sup>9</sup>, Y. Sharma<sup>10</sup>, J. Gopalakrishnan<sup>10</sup>, N.J. Gupta<sup>8</sup>, K. Thangaraj<sup>1</sup>. 1) Centre for Cellular and Molecular Biology, Hyderabad, India; 2) JNCASR, Bangalore, India; 3) TIFR, Mumbai, India; 4) CSIR-CDRI, Lucknow, India; 5) Mangalore University, Mangalore, India; 6) IIRM, Kolkata, India; 7) IIRC, Secunderabad, India; 8) Banaras Hindu University, Varanasi, India; 9) All India Institute of Medical Sciences, New Delhi, India; 10) Center of Molecular Medicine, Cologne, Germany.

**Introduction:** Approximately, one out of every seven couples are infertile worldwide and the male factor infertility accounts for 30-50% of the infertility cases. The etiology of large proportion of infertile men still remains unknown. Therefore, to identify novel genetic factors associated with idiopathic male infertility, we selected *CETN1* based on our gene expression and exome sequencing studies and sequenced it in large cohort of case-controls and performed various functional studies. **Materials and methods:** We have performed exome sequencing of 44 idiopathic infertile men (azoospermia and severe oligozoospermia) using Illumina HiSeq-2000 platform with 100X coverage. Various bioinformatics tools and custom pipelines were used for data analysis and prioritizing the variants. We have identified 61 novel and rare variants (from 58 genes) and genotyped (using Sequenom) them in 740 cases and 700 ethnically matched controls. Of the novel genes identified, *CETN1* has been found to be a potential candidate; hence we have sequenced *CETN1* in additional 1073 infertile men and 874 ethnically matched fertile control men. Functional characterization of two significantly associated variants was performed using biophysical (circular dichroism, 2D-HSQC and ITC etc.), cell biology approaches and luciferase reporter assays. **Results:** rs61734344 (p.Met72Thr) and rs367716858 (5'UTR) showed significant association with infertility (p-values: 8.46e-06 and 0.001, respectively). Biophysical studies showed that mutation p.Met72Thr alters calcium binding affinity, surface hydrophobicity, calcium induced changes in Centrin-1. Somatic cells (HEK293T and RPE) and differentiated iPSC over-expressing mutant Centrin-1 (p.Met72Thr) showed higher multipolar cells, fragmented nuclei and cell death. Studies using RPE cell lines and germ cell lines (derived from iPSC) showed that the mutation p.Met72Thr affects ciliary assembly dynamics and cell proliferation, respectively. The 5'UTR mutant expressing cells showed 3-fold higher luciferase activity compared to wild type (p-value < 0.05), due to loss of a potential methylation site. Thus, rs61734344 causes defective cell division and rs367716858 leads to dysregulation of *CETN1* expression, affecting spermatogenesis and male fertility. This is the first study to demonstrate the role of *CETN1* gene variants in human male infertility.

## 499W

**Genotoxicity of interferon beta in pregnant women with multiple sclerosis.** M. Bouhlel<sup>1</sup>, M. Guirat<sup>1</sup>, N. Gharbi<sup>1</sup>, I. Benayed<sup>1</sup>, S. Hammami<sup>2</sup>, A. Dammak<sup>3</sup>, R. Frikha<sup>1</sup>, F. Abdelhedi<sup>1</sup>, S. Guidara<sup>1</sup>, N. Belguith<sup>1</sup>, H. Kamoun<sup>1</sup>. 1) Genetics, Hospital Hedi Chaker, Sfax, Tunisia; 2) Pharmacology department, Faculty of medicine, Sfax, Tunisia; 3) Gynecology department, Hospital Hedi Chaker, Sfax, Tunisia.

Multiple sclerosis (MS) has a female preponderance and affects people during their reproductive years. Thus, evaluating the reproductive effects of interferon  $\beta$ , a commonly used therapy for MS, is clinically important. The literature review indicates that there is an increased risk of spontaneous abortion related to the use of INF  $\beta$ . However, the effects of this drug on fertility have not been well studied. So, we propose to evaluate the genotoxicity of INF  $\beta$  in a tunisian case. Our patient is a 36-years-old female who has been treated by Rebif for multiple sclerosis since 2010. She was referred for genetic counseling. A family history of multiple sclerosis in a sibling was reported. Married in 2016, she had 3 spontaneous abortions in the first trimester with a therapeutic window of one or two weeks prior to conception without B9 vitamin therapy. A standard karyotype on G-band blood lymphocytes was done. This test showed a structural chromosome abnormality that involves a translocation affecting chromosomes 10 and 14 in one mitose from 31 mitoses analysed (0.032%). Rebif, interferon  $\beta$ -1a, is a pregnancy category C drug. There is no evidence of infertility or teratogenicity with the INF $\beta$ s; however, exposure during the first trimester was reported to cause a dose-dependent abortive effect in monkeys. Our patient had 3 spontaneous abortions while she was under treatment. Her karyotype showed a structural abnormality that may be due to the effect of Rebif. Her brother who has also MS treated with INF  $\beta$  married, his wife had two spontaneous abortions. To support the hypothesis of the genotoxicity of this drug, we propose to complete with a Sister chromatids exchange test.

**500T**

**Toll-like receptor 1 (TLR1) is key gene in TLR6-TLR1-TLR10 gene cluster associated with preterm birth in Wisconsin cohort.** *D.M. Pillers<sup>1</sup>, C. Hoffman<sup>2</sup>, T. Ranade<sup>2</sup>, J. Eickhoff<sup>2</sup>, B.R. Pattnaik<sup>2</sup>, M. Baker<sup>2</sup>, S.A. Tokarz<sup>2</sup>, W. Luo<sup>1</sup>.* 1) University of Illinois, Chicago, IL; 2) University of Wisconsin, Madison, WI.

Preterm birth (PTB) occurs in 11% of US births, causing significant morbidity and mortality. A subset of PTB is complicated by infection and potential aberrations in the microbiome. The innate immune system via the Toll-like receptors (TLR) is associated with susceptibility to infectious diseases. We speculated that the SNPs in fetal TLR genes may be associated with PTB. We have previously reported results for SNPs in three TLRs (1, 2, and 4) in Wisconsin infants, with only TLR1 SNP (N248S) and SNP (H305L) associated with preterm birth. TLR1 is part of the TLR6-TLR1-TLR10 gene cluster reported to be associated with inflammation and infection. We hypothesized that TLR1 SNP rs5743618 (S602I) would similarly mark an increased risk for PTB. In addition, we sought to determine whether SNP rs5743810 (P249S) in TLR6 or SNP rs11096957 (N241H) in TLR10 in the TLR6-TLR1-TLR10 cluster are also associated with PTB. Residual newborn screening DNA was tested with IRB approval. 3000 samples were used for TLR1 SNP (N248S) analysis, with 1616, 1813, 866, and 581 samples adequate for subsequent TLR1 (H305L), TLR1 (S602I), TLR6 (P249S) and TLR10 (N241H) testing. SNP genotype was by TaqMan SNP Genotyping Assay (Lifetechnologies, CA). Ancestral background was by maternal declaration. The TLR1 (S602I) minor allele T was associated with PTB: GA < 34 wks, Odds Ratio (OR) 1.72 (P < 0.0001); GA < 37 wks, OR 1.34 (P = 0.0004). The minor allele combined effects of TLR1 305 (T) and TLR1 248 (C) showed a significant association with PTB (GA < 34 and < 28 wks) (P < 0.00004), as well as low birth weight (< 1250g) (P < 0.0000015) and were most prominent in the Wisconsin Black cohort (GA < 34 wks; OR for Whites is 1.81 vs. 3.27 for Blacks). The TLR6 SNP (P249S) minor allele T was associated with preterm GA < 34 wks, OR 1.41 (P < 0.00087) and with GA < 37 wks, OR 1.30 (P < 0.032). However, in GA < 28 wks, the TLR6 SNP (P249S) minor allele T was not consistent with those in GA < 37 wks and GA < 34 wks. TLR 10 SNP (N241H) was not associated with PTB. In the TLR6-TLR1-TLR10 gene cluster, TLR1 SNPs in discrete locations were consistently associated with PTB in a Wisconsin cohort. TLR1 is part of a tightly linked cluster of TLR genes that act as co-receptors with TLR2, a key step in the inflammation cascade. Aberrant TLR1 may lead to PTB via an altered downstream pathway causing disturbed commensal homeostasis leading to an altered microbiome and finally, to pathogen invasion.

**Real-time variant interpretation for full-exon sequenced expanded carrier screening panels.** *C. Lo, K. Kaseniit, M. Rasmussen, D. Muzzey.* Counsyl, South San Francisco, CA.

**INTRODUCTION:** Next-generation sequencing (NGS) of entire exons in disease-relevant genes is now common in clinical genomic tests. When such sequencing identifies novel variants, they must be classified (e.g., as benign, pathogenic, or unknown) in a timely manner in order for the test results to be clinically meaningful to providers and their patients. Because variant classification is a time-sensitive and resource-intensive process, it is important to understand the feasibility, dynamics, and operator-dependence of performing reliable interpretation in response to changes in test volume and panel size. **METHODS:** We analyzed the empirical variant-interpretation volume, duration, operator, and method (i.e., manual or automatic) in a clinical laboratory running a 176-condition NGS-based expanded carrier screening panel. We evaluated hypotheses to explain the observed trends using simulations leveraging data in public repositories (e.g., allele frequency in gnomAD). **RESULTS:** The rate at which novel alleles are detected depended on the number of screened patients and the size of the genomic region sequenced. We compiled the empirical distribution of novel-allele detection per condition as a function of sequenced patients and found that, for most conditions, novel-allele detection reached steady state before 20,000 patients had been tested. The trajectory is comparable to simulated cohorts of variable size using condition-specific allele frequency data from gnomAD. For 94.7% of variants, interpretation according to ACMG guidelines can be performed automatically based on allele frequency and other in-silico methods (e.g., conservation). Manual consideration is needed for the remaining variants. Based on the self-reported estimates of variant-interpretation operators, the median time required to manually curate a variant was 42 minutes (average was 67.8 minutes). Permutation testing revealed low classification bias among operators. **CONCLUSION:** We demonstrate how real-time variant interpretation scales as a function of ECS panel content and the number of patients tested. Performing this characterization is important to maintain prompt reporting of results and proper downstream patient care, especially as panel content and test volume grows. .

## 502W

**Clinical validity of expanded carrier screening: High concordance of inter-lab variant classifications.** D. Muzzey, E. Collins, K.E. Kaseniit, C. Lo, K. Moyer, H.P. Kang. Counsyl, South San Francisco, CA.

**Introduction** Consensus on the classifications of individual variants among submitters to databases such as ClinVar is often used to assess the clinical validity of a genetic test. The ACMG/AMP variant classification guidelines recommend requiring more evidence for pathogenic assertions in an unaffected population, e.g., in expanded carrier screening (ECS), where most patients are asymptomatic. We evaluated the clinical validity of ECS by analyzing variant-classification concordance between Counsyl's Foresight ECS and ClinVar submissions. **Methods** Concordance was assessed between ClinVar entries (April 2018; ignoring old entries, submitters with few entries, and common variants) and Counsyl interpretations, and discordances were categorized by their underlying cause. To estimate the worst-case scenario for Foresight performance, disease-level positive predictive value (PPV) and sensitivity were calculated from carrier rates of different variant categories assuming ClinVar assertions are correct, e.g., "false positives" arose from variants considered pathogenic by Counsyl but not in ClinVar. **Results** Out of 12,834 variants evaluated, 98.2% were concordant. Most discordances (76.8%) were due to pathogenic assertions in ClinVar that we considered not to be reportable (VUS or benign). Many discordances had a clear explanation: 25.7% were due to unclear submitter classifications, 14.8% were variants with no published cases, 3.4% were variants with homozygotes observed in the population, and 4.6% were due to categories where reporting of variants in a carrier-screening setting might not be appropriate compared to a diagnostic setting. The remaining 51.5% of discordances could not be clearly categorized. Overall, 31.7% of Foresight patients are carriers for concordant alleles, and only 0.9% carry uncategorized discordant alleles (0.7% carry variants that do not meet our ECS threshold for pathogenicity, while 0.2% carry variants that do). Importantly, our concordance data suggest a level of clinical validity for ECS diseases that yields high estimated clinical sensitivity and PPV. For example, the estimated clinical sensitivity for cystic fibrosis was 99.7% (PPV: 99.8%), comparable to levels reported for hereditary cancer screening. **Conclusions** With a proper variant-interpretation workflow, ECS has high clinical validity. Residual discordances relative to ClinVar may be unavoidable because submitters sample from different patient populations (e.g., affected vs. unaffected).

## 503T

**Genome-wide association study of a refined sub-phenotype of pregnancy duration: Pre-labor rupture of membranes.** P. Sole-Navais<sup>1</sup>, J. Juodakis<sup>1</sup>, H. de Haan<sup>2</sup>, T. Laisk<sup>3</sup>, R. Mägi<sup>3</sup>, G. Zhang<sup>4</sup>, L.J. Muglia<sup>4</sup>, J. Bacelis<sup>1</sup>, B. Jacobsson<sup>1,2</sup>. 1) Department of Obstetrics and Gynecology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2) Division of Health Data and Digitalization, Department of Genetics and Bioinformatics, Norwegian Institute of Public Health, Oslo, Norway; 3) Estonian Genome Center, University of Tartu, Tartu, Estonia; 4) Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA.

While pregnancy duration is a heterogeneous phenotype, where different onsets of delivery may reflect different etiologies, most genetic studies have treated gestational age (GA) as a single entity. Furthermore, GA is a time-to-event phenotype, and should be analyzed with statistical techniques developed for this purpose (survival models). Because of these analytical simplifications, the only successful attempts of identifying genetic components of GA so far required very large sample sizes. Here, we aimed to discover genetic variants associated with pre-labor rupture of membranes (PROM), a sub-phenotype of GA affecting 10-15% of all pregnancies, by using survival models. HARVEST (discovery sample) is a Norwegian genotyping (Human-CoreExome chip) effort on 11000 family trios from the MoBa Cohort. Only live-born singleton pregnancies were genotyped and imputation of non-genotyped variants was performed against the reference haplotypes of the HRC (release 1.1). Samples with major ethnicity other than CEU or cryptic relatedness to other samples were excluded. Association analysis was restricted to pregnancies without risk factors of PROM and to genetic variants with  $MAF > 0.01$ . We conducted a genome-wide analysis to test for the association of ~10M genetic variants with time-to-PROM on 9196 unrelated women (1117 PROM events). Time-to-event (GA) was estimated by ultrasound or last menstrual period. The effect of each SNP on time to event was estimated by Cox regression (implemented in ProbABEL). We used the Estonian Biobank ( $n = 21956$ , PROM cases = 936) to test for replication of candidate from the discovery cohort loci with genome-wide or suggestive ( $p < 1e-5$ ) evidence of association with PROM by using logistic regression. We identified two variants (rs11978196 and rs6463018) in perfect LD showing genome-wide significant association with PROM near *INHBA* gene (hazard ratio: 1.65, 95% CI: 1.38-1.96,  $p = 2.4 \times 1e-9$ ,  $MAF = 0.10$ ). Previous studies suggest a role for inhibin in both preterm delivery and preterm PROM. In the Estonian Biobank, none of the discovery-stage associations were considered significant (most extreme  $p = 0.04$ , 70 variants tested), but top variants effect direction was identical to that in the discovery-stage. Our genome-wide survival analysis of PROM as a sub-phenotype of GA identified a suggestive locus previously implicated in preterm PROM pathophysiology, but warrants follow-up in large independent replication cohorts with a well-characterized phenotype.

**Revealing aging-related transcriptome and methylome dynamics in mouse oocytes development by single-cell parallel sequencing.** *TL. Lee<sup>1</sup>, Y. Qian<sup>1</sup>, DYL. Chan<sup>2</sup>, MP. Zhao<sup>2</sup>, KYL. Yip<sup>3</sup>, Q. Chao<sup>3</sup>, KL. Chow<sup>4</sup>, TY. Leung<sup>2</sup>, NLS. Tang<sup>5</sup>, JY. Liao<sup>1</sup>, ACS. Luk<sup>1</sup>, WT. Lee<sup>1</sup>, TC. Li<sup>2</sup>.* 1) School of Biomedical Sciences, The Chinese University of Hong Kong, Shatin NT, Hong Kong, China; 2) Department of Obstetrics and Gynaecology, The Chinese University of Hong Kong, Shatin NT, Hong Kong, China; 3) Department of Computer Science and Engineering, The Chinese University of Hong Kong, Shatin NT, Hong Kong, China; 4) Department of Chemical Pathology, The Chinese University of Hong Kong, Shatin NT, Hong Kong, China; 5) Division of Life Science, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China.

The decline in oocyte quality at advanced maternal age (AMA) is a major factor of female infertility. As such, identifying AMA oocytes with good developmental competence is critical for in vitro fertilization (IVF) success. Currently, oocyte quality measurement largely relies on morphological assessment. However, the method is subject to personal bias and the diverse approaches adopted in different clinics. As a result, the assessment failed to accurately define the respective developmental competence. To establish a foundation for precise gene-based assessment, we aimed to dissect the genomic landscapes of oocyte maturation and aging by applying an unbiased single-cell genomics approach. Mouse oocytes at both germinal vesicle (GV) stage and metaphases II (MII) stage from young female mice (6 weeks) and aged female mice (12 months) were collected. Single-cell parallel methylome and transcriptome sequencing (scM&T-seq) was then performed on individual oocytes. Overall, we identified 1377 and 1432 aging-related differentially expressed genes (DEGs) in GV and MII stage respectively. Gene ontology and KEGG pathways analysis showed that DEGs in GV stage were enriched in mitochondrial function, cell cycle process, and RNA splicing. In contrast, DEGs in MII stage were associated with microtubule and spindle formation. Repression of novel gene targets like maturation-specific oocyte-secreted factors and interleukins in both GV and MII stages were identified. Interestingly, expression of repetitive elements (RE) such as long terminal repeat (LTR) family was not affected by age, which is to our surprise as retrotransposition of RE was suggested to be activated during normal aging. Similar to transcriptome, the methylome exhibited dynamic changes in CpG sites and non-CpG sites. Global methylation level of non-CpG sites increased in GV stage but decreased in MII stage during oocyte aging. It was consistent with the expression dynamics of Dnmt3s, especially in GV stage. Methylation level of CpG sites declined during GV oocyte aging but increased in MII stage. Besides, global methylation level of non-CpG sites increased during maturation. In summary, we successfully revealed the transcriptome and epigenetic landscapes in mouse oocyte development and identified novel targets that may reflect oocyte quality. We suggest the use of high-resolution genomic data, along with morphological evidence, would improve IVF outcomes.

**Unlocking the mysteries of preterm birth: Meta-analysis of maternal and fetal transcriptomic data elucidates the role of adaptive and innate immunity.** *B. Vora, A. Wang, I. Kostic, H. Huang, I. Paranjpe, T. Woodruff, T. MacKenzie, M. Sirota.* University of California, San Francisco, San Francisco, CA.

Preterm birth (PTB) is the leading cause of newborn deaths around the world. Spontaneous preterm birth (sPTB) accounts for two-thirds of all PTBs; however, there remains an unmet need of detecting and preventing sPTB. Although the dysregulation of the immune system has been implicated in various studies, small sizes and irreproducibility of results have limited identification of its role. Here, we present a cross-study meta-analysis to evaluate genome-wide differential gene expression signals in sPTB. A comprehensive search of the NIH genomic database for studies related to sPTB with maternal whole blood samples resulted in data from three separate studies consisting of 339 samples. After aggregating and normalizing these transcriptomic datasets and performing a meta-analysis, we identified 210 genes that were differentially expressed in sPTB relative to term birth. These genes were enriched in immune-related pathways, showing upregulation of innate immunity and downregulation of adaptive immunity in women who delivered preterm. An additional analysis found several of these differentially expressed at mid-gestation, suggesting their potential to be clinically relevant biomarkers. Furthermore, a complementary analysis identified 473 genes differentially expressed in preterm cord blood samples. However, these genes demonstrated downregulation of the innate immune system, a stark contrast to findings using maternal blood samples. These immune-related findings were further confirmed by cell deconvolution as well as upstream transcription and cytokine regulation analyses. Overall, this study identified a strong immune signature related to sPTB as well as several potential biomarkers that could be translated to clinical use.

**506T**

**Parent-of-origin determined allelic expression of imprinting candidate genes in the human placenta.** *M. Laan, D. Pilvar, M. Reiman, A. Pilvar.* Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia.

Imprinting adjusts the gene dosage via parent-of-origin specific silencing of a gene copy. The emergence of imprinting coincides with the evolution of placenta and seminal discoveries of imprinted loci reported genes critical for placental and fetal development. Recently, the analysis of human imprinted genes has been facilitated by RNA-Seq and/or allele-specific WGBS applications. However, the published data has reached inconsistent claims and family-based studies are limited. We aimed to analyse parent-of-origin of placental transcripts of nearly 400 imprinting candidate genes retrieved from the Geneimprint database and recent literature. In total, 54 families (38 parental-placental trios, 16 maternal-placental duos) representing normal 1st, 2nd and term pregnancies as well as pregnancy complications were included. The study utilized our published genome-wide genotyping data of trios/duos (Kasak et al 2015, 2017 Sci Rep) and the placental RNA-Seq dataset of the same cases (Sõber et al 2015, 2016 Sci Rep). The data shows that nearly half of the imprinting candidate genes have no or minimal transcription in the human placenta. Among the genes with adequate read counts for the assessment of parental allelic expression, the vast majority of the analysed genes showed convincingly biallelic origin of the transcripts. Only a small fraction of genes exhibited clear signals of imprinting, i.e. nearly monoallelic parent-of-origin specific gene expression. These loci represent previously well-established placenta-enhanced imprinted genes (e.g. *IGF2*, *H19*, *DLK1*, *MEG3* etc). Imprinting status of these genes was conserved across gestation, and was unaffected by the occurrence of pregnancy complications such as preeclampsia. In addition, some loci demonstrated parent-of-origin biased expression, but not complete silencing of one parental allele (>65%, but <90% of reads from one parental copy). This group of genes is expressed in a broad range of human tissues and showed rather variable proportions of maternal/paternal reads across gestation and among individual placentas. As these loci were mostly biased towards paternal expression, it could be explained by incomplete demethylation of maternal and/or remethylation of paternal alleles during epigenetic reprogramming in the trophoblast lineage. This hypothesis is also consistent with polymorphic imprinted methylation that has been shown for the human placental genome. Grant support: Estonian Research Council IUT34-12.

**Serotonin transporter (5-HTTLPR) genotypes and trinucleotide repeats of androgen receptor exert a combinatorial effect on hormonal milieu in patients with lifelong premature ejaculation.** *S. Bhatti<sup>1,2</sup>, H. Latif Khan<sup>1</sup>, S. Abbas<sup>1</sup>, Y. Latif Khan<sup>1</sup>, R. Gonzalez<sup>3</sup>, M. Aslamkhan<sup>2</sup>, G. Gonzalez<sup>4</sup>, H. Hakan Aydin<sup>5</sup>.* 1) Department of Human genetics, Lahore Institute of Fertility and Endocrinology, Lahore, Punjab, Pakistan; 2) Department of Human Genetics and Molecular biology, University of Health Sciences Lahore-54600, Pakistan; 3) Centro de investigacion Biomedica de Occidente, IMSS, Universidad de Guadalajara, Jalisco Maxico; 4) Universidad De Guadalajara CIBO, IMSS Sierra Mojada 800 Independencia, 44340 Guadalajara, Jalisco Maxico; 5) Department of Medical Biochemistry, Ege University School of Medicine, Bornova Izmir, Turkey.

Premature ejaculation (PE) is one of the most common sexual disorders in men due to uncontrolled modulation of spinal reflexes which are controlled by cortico-limbic centers in the brain. In the present study, we investigate the combinatorial effects of tri-nucleotide repeats of androgen receptor and allelic variants of the 5-HTTLPR gene on sex steroids, hypophyseal hormones, sexual performance, and premature ejaculation assessment parameters among evidence-based lifelong PE subjects. A total of 571 outpatients (age:  $26.6 \pm 1.9$ ) consulting for evidence-based lifelong premature ejaculatory dysfunction (LPE) were selected in this study. The control group consists of 255 men with normal IELT (>4 minutes). The study revealed that the subjects who have the highest ( $\geq 26$ ) CAG stretches depicted a significantly high serum oxytocin levels (102.1 pg/ml;  $n = 126$ ,  $p < 0.001$ ) compared with the patients with the medium (22-25) and short ( $\leq 21$ ) CAG stretches (76.63 ng/ml;  $n = 64$ ,  $p < 0.001$  versus 77.4ng/ml;  $n = 81$ ,  $p < 0.001$ ) and the control group (71.2 pg/ml;  $n = 75$ ,  $p = < 0.001$ ). Almost 33 (26.1%) LPE patients had AR variant of longer ( $\geq 26$ ) CAG repeats were homozygous for S alleles (SS), 45 (35.7%) was homozygous for L allele (LL), and 48 (38%) had the L/S or S/L genotype of 5-HTTLPR gene. Homozygous (SS) alleles have a significant positive correlation ( $r = 0.44$ ,  $p < 0.0001$ ) with the high score of BDI-II (39.1,  $n = 126$ ,  $p < 0.001$ ). However, LL alleles have shown a significant positive correlation with PEDT ( $r = 0.46$ ,  $p < 0.001$ ) and negative correlation with self-estimated IELT and intercourse satisfaction ( $r = -0.35$ ,  $p < 0.001$ ). The innovative study design elaborates that Androgen receptor trinucleotide repeats and 5-HTTLPR genotypes have a combinatorial impact on hormonal milieu and sexual function regarding evidence-based lifelong premature ejaculatory dysfunction patients.

**508W*****FANCM* biallelic mutations cause non-obstructive azoospermia. L.**

Infertility is a highly complex and multifactorial condition affecting around 7% of men worldwide. Unexplained non-obstructive azoospermia (NOA) is defined as the absence of spermatozoa in the ejaculate due to failure of spermatogenesis. Around a quarter of azoospermia cases can be explained by genetic causes, but a large number still remains idiopathic. Whole-exome sequencing (WES) in two brothers diagnosed with NOA and Sertoli cell-only syndrome (SCOS) led to the discovery of compound heterozygous loss-of-function (LoF) variants in the *FANCM* (Fanconi anemia complementation group M) gene as the most likely cause for their condition. A previously undescribed paternally inherited splicing variant and a rare frameshift variant derived from the mother introduce a premature STOP codon leading to a truncated protein missing critical functional domains. *FANCM* shows enhanced testicular expression and is involved in maintaining genomic stability in meiosis and mitosis. In controls with normal spermatogenesis, immunohistochemical staining localized *FANCM* to the Sertoli and spermatogenic cells of seminiferous tubules with gradually enhanced intensity along germ cell maturation stages. In the SCOS case carrying biallelic *FANCM* LoF variants, none or only faint expression was detected in the Sertoli cells. Identification of two further unrelated NOA cases with independent *FANCM* homozygous nonsense variants omitting the protein domain for DNA repair activity provided additional support to the link between *FANCM* LoF variants and male infertility. Our study demonstrates that biallelic recessive *FANCM* LoF variants cause azoospermia. *FANCM* pathogenic variants show also implications for somatic health, being linked with doubled risk of familial breast and ovarian cancer. This provides a possible mechanism for the known epidemiological association between infertility and cancer risk, supported by published data on *Fancm*-mutant mouse models. Grant support: Estonian Research Council IUT34-12.

**509T****Identifying genetic factors that contribute to human female infertility.**

K.M. Tyc<sup>1</sup>, W. El Yakoubi<sup>1</sup>, X. Tao<sup>2</sup>, J. Landis<sup>2</sup>, Y. Zhan<sup>2</sup>, N. Treff<sup>3</sup>, R.T.Jr. Scott<sup>3</sup>, K. Schindler<sup>1</sup>, J. Xing<sup>1</sup>. 1) Department of Genetics, Human Genetics Institute of New Jersey, Rutgers, the State University of New Jersey, 145 Bevier Rd. Piscataway, NJ 08854, USA; 2) Foundation for Embryonic Competence, 140 Allen Rd, Basking Ridge, NJ 07920, USA; 3) Reproductive Medicine Associates of New Jersey, 140 Allen Rd, Basking Ridge, NJ 07920, USA.

Infertility is a common health issue that affects about 10% of women. Maternal age is an established contributing factor that correlates with an increased production of aneuploid eggs—a major cause of early miscarriage and infertility. Nevertheless, clinical data report cases of reproductively young (<35y) women producing unusually high percent of aneuploid concepti, and women of advanced maternal age (≥35y) producing lower than average percent of aneuploid concepti for their respective age categories. This observation suggests genetic factors contribute to fertility decline. Understanding the contribution of genetics in female infertility is the first step towards a genetic-based approach to reach a clinical efficacy in treating infertility. The scope of this work is to identify mutations that could be used as predictors of egg quality which would help in advancing assisted reproduction. Moreover, identification of key mutations and genes contributing to the risk of aneuploidy will allow prescreening patients that have better chances to benefit from preimplantation genetic screening. We obtained whole-exome sequencing data from over 500 reproductively challenged women, and performed a search for functional mutations that cause gametogenesis defects. Thus far we identified several candidate genes that could be linked to processes important for proper chromosome packaging and/or cell division. For instance, we identified nuclear pore components mutated in women with high rate of aneuploid concepti. Studies in lower eukaryotes show that nucleoporins are essential for timely nuclear import of cytosolic proteins involved in centromere formation before the completion of meiosis I. Moreover, we identified a condensin gene whose product is an important player in compacting the genetic material before meiotic divisions. Thus far, we established a list of mutations likely contributing to the production of poor quality eggs. Using a mouse model for assessing meiotic functions, we are currently validating the impact of the identified mutations on regulating chromosome segregation in oocytes.

**Clinical impact and cost effectiveness of a 176 condition expanded carrier screen.** K.A. Beauchamp, K.K. Wong, K.J. Taber, G. Lizarin, E.A. Evans, J.D. Goldberg, D. Muzzey. Counsyl, South San Francisco, CA.

**Introduction**Carrier screening identifies couples at high risk for conceiving offspring affected with severe heritable conditions. Minimal screening guidelines mandate testing for two diseases (cystic fibrosis and spinal muscular atrophy), but expanded carrier screening (ECS) assesses reproductive risk for hundreds of conditions simultaneously. Although key medical societies consider ECS an acceptable practice, and hundreds of thousands of patients have undergone ECS testing, the health economics of ECS remain incompletely understood. **Methods**The clinical impact and cost effectiveness of a 176-condition ECS panel were investigated using a decision-tree model comparing minimal screening and ECS in a preconception setting. Carrier rates from >50,000 ECS patients informed disease-incidence estimates, while cost and life-years-lost data were aggregated from the literature and a cost-of-care database. Model robustness was evaluated using one-way and probabilistic sensitivity analyses. **Results**For every 100,000 pregnancies, approximately 300 are predicted to be affected by conditions on the ECS panel, which individually incur approximately \$1,000,000 in lifetime costs and increase mortality by approximately 30 undiscounted life years on average. Relative to minimal screening, ECS reduces the affected-birth rate by 66% and is cost-effective (i.e., <\$50,000 incremental cost per life year), findings that are robust to reasonable model-parameter perturbation. Increased cost-effectiveness is observed when the net impact of downstream costs is included (e.g., savings from averted disease and spending on in vitro fertilization). **Conclusions**ECS is predicted to substantially reduce the population burden of Mendelian disease in a manner that is cost-effective compared to many other common medical interventions.

**Embracing the challenges of isochromosomes in cell-free DNA prenatal screening.** T. Boomer, E. Soster, J. Chibuk, S. Caldwell, E. Almasri, J. Wardrop, S. Boshes, M. Hackbardt, P. Cacheris, R. McCullough. Sequenom / Integrated Genetics, 3595 John Hopkins Court, San Diego, CA 92121.

**Background:** Cell-free DNA (cfDNA) prenatal screening continues to increase insight into early gestational placental findings not previously recognized or well understood. Genome-wide sequencing combined with advanced bioinformatics enables detailed interrogation of a variety of complex chromosomal changes, including isochromosome formation. Herein we review our laboratory experience with a variety of isochromosome rearrangements.

**Methods:** Maternal blood samples submitted for cfDNA screening were subjected to DNA extraction, library preparation, and whole-genome massively parallel sequencing as described by Jensen et al. Sequencing data were analyzed using a novel algorithm as described by Lefkowitz et al. **Results:** Over 60 cases involving isochromosomes were detailed in our clinical database, including: i(9) – 5 cases i(12) – 7 cases i(13) – 6 cases i(15) – 3 cases i(18) – 9 cases i(20) – 1 case i(21) – 9 cases i(22) – 2 cases i(X) – 8 cases i(Y) – 16 cases. Over half of these cases (57%) were correctly identified via cfDNA screening and confirmed as ‘true positives’, a subset (18%) pending outcome, and a minority (6%) were not confirmed via diagnostic testing and thus considered ‘false positives’. Interestingly and unique to this particular chromosomal subset are the 19% reported to have eluded cfDNA screening and reported as ‘false negatives’, consistent with four European / Australian laboratories’ cfDNA i(21) experience (ISPD 2017) and the chorionic villus sampling (CVS) literature. Mosaicism was commonly suggested and reported in cfDNA data, as well as diagnostic testing. Discrepancy for fetal sex was common among i(Y) cases. [Totals will be updated prior to final publication.] **Conclusion:** Isochromosomes arise from an error in centromere division during meiosis or mitosis. Most cases are *de novo* and mosaic in origin, consequently having variable impact on developing embryologic tissues. Since cfDNA screening is thought to primarily reflect early developing placental tissue (cytotrophoblast), results may be concordant or discordant with downstream diagnostic studies. It is essential for clinicians to remain mindful of the unique biologic limitation that isochromosomes pose for cfDNA screening. The contribution of cfDNA data can lend new and important insight into the timing and origin of such complex events, as well as help to explain recurrent and unavoidable inconsistencies between a variety of fetoplacental testing modalities.

**512T**

**Trisomy 8 mosaicism detected by NIPT: A +30 week diagnostic odyssey for fetus, parents, and clinicians.** J.L. Giordano<sup>1</sup>, A. Thomas<sup>2</sup>, C. Buchovecky<sup>2</sup>, A. Tanaka<sup>2</sup>, N. Hoffman<sup>2</sup>, S. Caldwell<sup>3</sup>, E. Bonifero<sup>4</sup>, D. Lewis<sup>2</sup>, R. Wapner<sup>2</sup>, B. Levy<sup>2</sup>. 1) Dept of OBGYN-MFM, Columbia University, New York, NY; 2) Dept of Pathology and Cell Biology, Columbia University, New York, NY; 3) Sequenom Laboratories, 3595 John Hopkins Ct, San Diego, CA 92121; 4) Mount Sinai West 1000 10th Avenue, Suite 11A, NY NY 10019.

NIPT for common trisomies has become standard practice for AMA pts. Screening all aneuploidies is the next logical step in NIPT. However, the clinical utility remains unclear. Our 35 yr old pt consented to a whole genome NIPT at 10 weeks, which revealed an increased risk for Trisomy 8 (T8) mosaicism (20% z score 11.33 FF 10%). Her 1st trimester screening revealed normal NT (1.26 MoM) and analytes (hCG 1.15 MoM PAPP-A 2.40 MoM). The NIPT laboratory recommended an amnio follow up, which the patient pursued after genetic counseling. Amniocytes showed a normal chr 8 FISH (100 interphase cells), karyotype, and CMA. The fetal anatomy was nl. As T8 can elude detection in cultured amniocytes and the pt was highly motivated to investigate the etiology of the abn NIPT, the pt opted for a placental biopsy, repeat NIPT, and mat blood karyotype with FISH at 17w4d. The placental biopsy and mat blood karyotype were normal (620 & 270 cells counted respectively, direct FISH + 20 G-banded metaphase) and the repeat NIPT reaffirmed the finding of T8 mosaicism (18.8% z score 7.93 FF 8%) at 10 wks. This led to concern for occult maternal malignancy or subclinical T8 in an otherwise healthy individual. The pt had a 2<sup>nd</sup> blood karyotype (20 G-banded metaphases), FISH on buccal sample and skin biopsy, which were all nl (250 direct, 600 direct & 500 cultured cells by FISH, respectively). Given the association of T8 and hematological cancers, CBC w/ differential and flow cytometry were ordered and nl. The patient pursued cordocentesis and FISH analysis with a dual locus probe for chr 8, which revealed 5 of 900 cells with T8. The pt continued the pregnancy and delivered a full term healthy appearing female. The placenta was sectioned to 12 parts and screened using dual locus probes. 2,450 cells were scored, 32 cells positive for T8 (1.3% Average; Range: 0 – 5%). Cord blood with a dual locus probe found 1/100 (1%) had T8. Repeat NIPT was drawn 6 weeks postpartum and no evidence of T8 was seen, suggesting that the T8 cells were indeed placental in origin. Since adverse outcomes have been observed in the many rare autosomal trisomy cases followed up after NIPT, T8 mosaicism by NIPT could not be ignored. The extensive work up in this case proved the NIPT was an accurate reflection of placental mosaic aneuploidy, despite its absence in placental biopsy at 17wks. However, the findings did not affect pregnancy outcome and the NIPT proved to have low clinical utility.

**Real-time quantification of cell free fetal DNA (cffDNA) in maternal plasma and its applications for non-invasive prenatal diagnosis.** D. Misra<sup>1</sup>, R. Singhal<sup>2</sup>, S.R. Phadke<sup>3</sup>, NS. Verma<sup>4</sup>, M. Banerjee<sup>1</sup>. 1) Molecular & Human Genetics Laboratory, Department of Zoology, University of Lucknow, Lucknow-226007, Uttar Pradesh, India; 2) Department of Obstetrics and Gynecology, King George's Medical University, Lucknow-226003, Uttar Pradesh, India; 3) Department of Medical Genetics, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow-226023, Uttar Pradesh, India; 4) Department of Physiology, King George's Medical University, Lucknow-226003, Uttar Pradesh, India.

**Background:** A step towards better management of healthy births lies in prenatal diagnosis of genetic disorders. The quantitative measurement technique (QMT) was used to analyze different quantities of cell free fetal DNA (cffDNA) in total plasma DNA (pDNA) using non-pregnant, healthy pregnant and high risk pregnant cases. **Purpose of the Study:** Presence of certain pregnancy related complications and fetal abnormalities manifest as changes in pDNA or cffDNA amounts in maternal plasma when compared to normal pregnancies. **Objective:** The aim was to quantitatively analyse cffDNA present in pDNA and its application as an early non-invasive prenatal diagnostic tool. **Method Used:** The Circulating DNA from Plasma Kit was used to obtain pDNA. The primers used to quantitate pDNA were  $\beta$ -actin and GAPDH and Y-specific viz. *DYS* and *SRY* for cffDNA using SYBR Green I based assay in real-time quantitative PCR (qPCR). **Key Results:** During gestation, the average copy number of pDNA was  $1.05 \times 10^{10}$  and  $1.04 \times 10^9$  using  $\beta$ -actin and GAPDH primers and the percentage of cffDNA was 2.87 and 28.94 respectively. A significant rise in concentration of pDNA in maternal circulation was observed in pregnancies suspected of Down syndrome (DS), preeclampsia (PE) and gestational diabetes mellitus (GDM). The amount of cffDNA showed highly significant ( $<0.0001$ ) and significant ( $P \leq 0.05$ ) rise in pregnancies suspected with PE and Duchenne muscular dystrophy (DMD) respectively. **Conclusion:** The pDNA and cffDNA concentrations could be a prenatal indicator of genetic abnormalities. The study indicates that quantitative measurement of pDNA/cffDNA in qPCR may be used as a screening marker for ascertaining pregnancy associated complications.

**Maternal fragile sites resulting in maternal mosaic deletions: An additional explanation for false positive cell-free DNA.** V. Nitibhon, B. Dyer, T. Boomer, J. Chibuk. Sequenom Inc., Laboratory Corporation of America Holdings, San Diego, CA.

**Objectives** Genome wide cell-free DNA (cfDNA) allows for the potential to detect copy number variants due to maternal low level mosaicism leading to false positive screening results. As previously reported, deletions detected at 10q25-qter are associated with maternal FRA10B expansions. FRA10B is a known rare fragile site that is not associated with a clinical phenotype. Expanded FRA10B alleles have been noted to delay replication distal from the expansion and can predispose to deletions. This case series explores our experience with seven positive 10q25.2 deletion results and is consistent with recent literature as a possible cause of some false positive cfDNA results in that genomic region. **Methods** Maternal blood samples submitted to Sequenom Laboratories® for MaterniT® GENOME testing were subjected to DNA extraction, library preparation, and genome-wide massively parallel sequencing as described by Jensen et al. Sequencing data were analyzed using a novel algorithm to detect trisomies, select microdeletions, and genome wide events 7 Mb and larger, as described by Lefkowitz et al. Follow-up information and pregnancy outcomes were elicited from the clinicians as part of routine, ongoing laboratory protocol for positive cases. **Results** Seven MaterniT® GENOME samples returned a positive result for a 10q25.2 deletion, where the fragile site FRA10B is located. Among these, one was confirmed as a maternal mosaic deletion, three were false positive following prenatal diagnostic testing with no maternal testing performed, two were lost to follow up and one had a second cfDNA screening drawn confirming the same deletion but no diagnostic testing. For six of the cases no phenotypic abnormalities or adverse outcomes were reported. **Conclusions** These positive cfDNA results may be attributed to maternal mosaic deletions associated with expansion of the fragile site FRA10B. Although the sample size is limited, preliminary conclusions can be drawn from this cohort as it is reflective of literature previously published correlating positive genome wide cfDNA for 10q25.2 deletions with maternal low-level mosaic deletions and FRA10B expansions. When a maternal mosaic deletion is identified there is concern for repeat false positive cfDNA results in future pregnancies. The available data provides further evidence that maternal fragile sites might explain false positive cfDNA results.

**515T**

**Assessing causality in associations between maternal adiposity and obstetric and perinatal outcomes: A Mendelian randomization study.** M. Taylor, M.C. Borges, R.C. Richmond, R. McEachan, J. West, J. Wright, EGG Consortium. 1) MRC Integrative Epidemiology Unit, Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom; 2) Bradford Institute for Health Research, University of Bradford, UK.

**Background:** Observational studies consistently suggest that maternal obesity is related to a number of adverse perinatal outcomes. However, which of these are causal or confounding is unclear. We used Mendelian randomization (MR), which uses genetic variants as instrumental variables (IV), to determine the causal effect of maternal BMI on obstetric and perinatal outcomes. **Methods:** Data from eight cohorts (ALSPAC, BiB, HAPO, EFSOCH, Generation R, GOYA, Project Viva and Gen3G) were used (N=3,554-19,244 depending on outcome). We performed multivariable regression between maternal BMI (pre-pregnancy or at the start of pregnancy) and 23 outcomes. We then combined genetic variants shown to be robustly associated with BMI in a weighted allele score and used this in IV analyses to obtain causal estimates (Wald ratios) of maternal BMI on each outcome. We used MR-Egger and other sensitivity methods to explore potential bias due to horizontal pleiotropy. When available, MR analyses for outcomes that could be influenced by offspring genetic predisposition to higher BMI were adjusted for offspring genotype. **Results:** In multivariable analysis, a 1 standard deviation (SD, ~4.95 kg/m<sup>2</sup>) higher maternal BMI was associated with a 0.12 SD (95%CI 0.11-0.14) higher offspring birthweight, and 1.68 (95%CI 1.60-1.77) odds ratio (OR) of hypertensive disorders of pregnancy (HDP). In MR analyses, a 1 SD higher maternal BMI was associated with a 0.19 SD (95%CI 0.01-0.37) higher offspring birthweight and 3.06 (95%CI 1.20-7.85) OR of HDP. We also found positive associations of maternal BMI with birth ponderal index and early membrane rupture in multivariable regression analyses. MR point estimates for effects of BMI on these outcomes were in the same direction and of a similar magnitude to multivariable results, but the 95% CIs were wide and included the null. Lastly, in multivariable regression analyses we found a positive association of BMI with gestational diabetes and caesarean section, which was not supported by MR results. Results from MR Egger regression and other sensitivity methods were generally consistent and did not suggest strong bias by pleiotropy. **Conclusions:** Our findings support a causal effect of increased maternal BMI on hypertensive disorders of pregnancy and offspring birthweight, suggest the same for birth ponderal index and early membrane rupture, but not for caesarean section and gestational diabetes.

**Genetically determined modulation of NLRP7-associated inflammatory response in the context of reproductive failure.** U. Wysocka<sup>1</sup>, A. Gach<sup>1</sup>, A. Sakowicz<sup>2</sup>, I. Pinkier<sup>1</sup>, M. Rybak-Krzyszowska<sup>3</sup>, W. Alaszewski<sup>1</sup>, L. Dudarewicz<sup>1</sup>, M. Kozłowska<sup>1</sup>, L. Jakubowski<sup>1</sup>. 1) Department of Genetics, Polish Mother's Memorial Hospital Research Institute, Lodz, Poland; 2) Department of Medical Biotechnology, Medical University of Lodz, Poland; 3) Department of Obstetrics and Perinatology, Jagiellonian Medical University of Cracow, Poland.

**Introduction** Recurrent reproductive wastage is a global health issue affecting a significant number of women. Miscarriages occur in up to 30% of pregnancies. It is a severe problem for diagnostics and healthcare system. Repeatability of recurrent reproductive wastage in a certain number of couples shows that the phenomenon is not random and urges to define a cause. Genetic variation may have a high impact on reproductive failure and thus delineating of specific genetic factors is of great importance for genetic counselling. The c.1441G>A polymorphism (p.Ala481Thr) in the *NLRP7* (MIM 609661) gene has a proven functional character and its presence is directly linked to a decreased levels of cytokines IL1 $\beta$  and TNF in the plasma. It is possible that proinflammatory cytokine secretion and as a consequence altered inflammatory response in patients with c.1441G>A variant of *NLRP7* gene can promote the occurrence of miscarriages. In the current study the relationship of recurrent reproductive wastage and non-synonymous *NLRP7* variant in Polish population have been investigated. **Materials and Methods** The study was carried out on the blood samples from women with a history of recurrent miscarriages (study group) and from women with unremarkable obstetric history (control group). Additionally, material from CVS (chorionic villus sampling) with confirmed fetal chromosomal aberration (study group) and normal fetal karyotype (control group) was investigated. Study of the c.1441G>A polymorphism in the *NLRP7* gene was performed by Sanger sequencing. The frequencies of genotypes were compared with using the Chi-square test and the Statistica 10 software. **Results** The study was conducted in a group of 369 patients with reproductive failure, 178 patients from the control group and in 73 trophoblast samples (41 from the study group and 32 from the control group). The polymorphic variant (GA and AA genotypes) was demonstrated in 118 tested blood samples (82 from the study group and 36 from the control group) and in 16 trophoblast samples (8 in the study group and 8 in the control group). **Conclusions** Obtained results suggest that the link between reproductive failure and non-synonymous variant of *NLRP7* gene in Polish population is not statistically significant because the c.1441G>A polymorphism in the *NLRP7* gene appears with the similar frequency in the general population. To explore consequences of genetic variation in recurrent reproductive wastage further analysis should be carried out.

**517W**

**Embryo sample tracking and identification during PGT using the mitochondrial genome.** M.J. Jasper<sup>1</sup>, M. Barry<sup>2</sup>, S.A. Myers<sup>1</sup>. 1) RHS Ltd, Thebarton, South Australia, Australia; 2) FertilitySA, Adelaide, South Australia, Australia.

The mitochondrial genome is maternally inherited and contains single nucleotide variants (SNVs) that can be used to differentiate individuals. This combination of characteristics provides a novel opportunity for DNA-based confirmation of maternal origin of embryo biopsies, and sibling embryo identification. Mitochondrial DNA (mtDNA) is sequenced during Preimplantation Genetic Testing for Aneuploidy (PGT-A) by Next Generation Sequencing (NGS), and the depth and breadth of coverage of the mitochondrial genome obtained from PG-Seq™ readily allows SNV analysis, even from a 48 sample NGS run. Our aim was to demonstrate the use of the RHS Embryo ID panel for accurate and economical embryo identification as part of routine PGT-A using the PG-Seq™ kit. A large putative panel of mtDNA SNVs was collated from published literature and PG-Seq™ data. SNVs associated with disease-related markers or in regions with low depth of coverage were excluded. A panel comprising 48 SNVs was compiled for evaluation. Three PG-Seq™ kit run scenarios were modelled, wherein 1, 2 or 4 sibling embryos were analysed per individual. The performance of the panel in each scenario was tested across 10,000 in-silico PG-Seq™ runs using randomly selected mtDNA genomes from (1) a globally-diverse database of 377 individuals and (2) embryo mtDNA genomes from 52 individuals. For analysis of the embryo dataset, a population-specific panel comprising another 23 SNVs was added. Using the global mtDNA genome database and modelling embryos from 12, 24 or 48 individuals, on average the SNV panel differentiated 91.5%, 84.6% and 75.0% of embryos, respectively. For the embryo PG-Seq™ NGS files analysed using the RHS Embryo ID SNV panel and an additional population-specific SNV panel, with embryos from 12, 24 or 48 individuals, on average 99.3%, 98.3% and 96.3% of embryos were differentiated, respectively. If the panel failed to differentiate individuals, other regions of mtDNA could be analysed to achieve differentiation. It should be noted that maternally-related individuals will share mitochondrial genomes. In this case, it will not be possible to distinguish between embryos from these individuals using mtDNA. PG-Seq™ and the RHS Embryo ID panel readily generates a unique embryo signature, potentially improving PGT-A practice by providing a DNA-based confirmation of maternal origin and sibling embryo identification.

**518T**

**A novel single tube approach for combined PGT-A and PGT-M using Ion Torrent™ NGS.** S.A. Myers, M.J. Jasper. RHS Ltd, Thebarton, South Australia, Australia.

Preparing embryo biopsies for Next Generation Sequencing (NGS) for Preimplantation Genetic Testing for Aneuploidy (PGT-A) typically requires a laborious, multi-step process wherein Whole Genome Amplification (WGA) and library preparation are performed separately. The DOPlify® kit (RHS Ltd) provides a flexible technology to not only amplify whole genomes but also target sequences for PGT for Monogenic disorders (PGT-M) using RHS' Target Sequence Enrichment (TSE) protocol. Furthermore, the attributes of the DOPlify® kit also present a unique mechanism to incorporate the specific sequences needed for NGS, bypassing the need for a separate library preparation step. PCR barcoding during WGA provides laboratory efficiencies compared to typical workflows, including a reduction of hands on and total protocol time, and decreased reagent requirements for sample preparation. Our aim was to develop a novel approach that allows combined amplification and PCR barcoding of low template samples in a single tube for Ion Torrent™ NGS. Five-cell samples were manually sorted from aneuploid cell lines (Coriell Institute) and prepared for sequencing using a two-stage, single tube protocol. DNA was amplified using standard DOPlify® kit reagents with a modified primer (RHS Ltd). Subsequently, publicly available Ion Torrent™ (Thermo Fisher) NGS adapter sequences and barcodes were incorporated utilising a second PCR step within the same PCR tube. The barcoded samples were pooled and sequenced on an Ion Torrent™ instrument. The sequencing data was aligned to hg19, sequencing metrics collated and the data analysed to determine sample ploidy status. Whole chromosome aneuploidy and sub-chromosomal 7-32 Mb duplication and deletion results were concordant with the expected karyotypes of the cell lines, and TSE using haemoglobin subunit beta gene-specific PCR primers in PGT-M for  $\beta$ -Thalassemia was achieved. The protocol produced sequencing ready samples within 3 hours, including clean-up time. Leveraging the unique characteristics of the DOPlify® kit this novel method provides a single tube amplification and barcoding protocol for Ion Torrent™ NGS to allow rapid, scalable and economical sequencing for PGT-A, and the incorporation of RHS' TSE protocol for combined PGT-M and PGT-A from a single embryo biopsy.

**Generation and validation of reference standards for non-invasive prenatal testing (NIPT).** A. Mele<sup>1</sup>, E. Surmann<sup>1</sup>, R. Santos<sup>1</sup>, D. Anderson<sup>1</sup>, J. Wickenden<sup>1</sup>, D. Pasupathy<sup>2</sup>, B. Thilaganathan<sup>3</sup>, A. Khalil<sup>3</sup>. 1) Horizon Discovery Ltd, 8100 Beach Drive, Cambridge Research Park, Waterbeach, Cambridge CB25 9TL, United Kingdom; 2) St Thomas Hospital, Department of Women and Children's Health, School of Life Course Sciences, 10th Floor North Wing, London SE1 7EH, United Kingdom; 3) St George's Hospital, Fetal Medicine Unit, Department of Obstetrics and Gynaecology, St George's University of London, 4th floor Lanesborough Wing, London SW17 0QT, United Kingdom.

Non-invasive prenatal testing (NIPT) has been widely adopted in clinical practice as a screening tool for fetal chromosomal abnormalities. However, there is little regulatory oversight on test performance underlining the need for appropriate reference standards that accurately mimic the complexity of NIPT samples to establish assay sensitivity, specificity and reproducibility. Here we describe our unique approach on generating NIPT reference materials from clinical fetal tissues with or without chromosomal aneuploidies, as well as from corresponding maternal and paternal samples. We have generated immortalized cell lines that have been extensively characterized by karyotyping and quantitative polymerase chain reaction (qPCR) to confirm genomic stability and retainment of the additional chromosome over several cell culture passages. We show that fragmentation of maternal and fetal DNA to 160 base pairs and subsequent blending into buffer or synthetic plasma at different fetal fractions can closely mimic the size distribution profile of clinical cell-free DNA (cfDNA). This reference material demonstrated superior performance across various NIPT platforms in our beta testing study. We are the first to generate commutable NIPT reference standards containing defined fractions of fetal DNA in a matched maternal DNA background that can be used by platform developers and laboratories to validate and routinely monitor assay performance. The addition of the corresponding paternal cell lines will allow us to further extend our material in the future by introducing mutations that mimic single gene disorders inherited by the father. .

**Whole genome amplification for STR profiling on single cells in cell-based non-invasive prenatal testing.** A.S. Vander Plaetsen<sup>1</sup>, J. Weymaere<sup>1</sup>, S. Cornelis<sup>1,2</sup>, D. Deforce<sup>1</sup>, F. Van Nieuwerburgh<sup>1</sup>. 1) Faculty of Pharmaceutical Sciences, Ghent University, Ghent, Belgium; 2) Department of Life Science Technologies, imec, Leuven, Belgium.

Novel emerging isolation techniques and the rapidly evolving field of next generation sequencing have invigorated the interest in single cell analysis within cell-based non-invasive prenatal testing (cbNIPT). Although the presence of fetal cells in peripheral maternal blood has been recognized for a few decades, cbNIPT is still very challenging due to the extreme rarity and fragility of these fetal cells in maternal blood. Furthermore, the absence of a unique fetal biomarker necessitates fetal identity confirmation of each isolated cell before further downstream genetic analyses can occur. To allow both fetal identification, by means of short tandem repeat (STR) profiling, and copy number variant (CNV) analysis on a single fetal cell, unbiased whole genome amplification (WGA) is essential. This study investigates the performance of three WGA methods for STR profiling on single cells, isolated from a blood sample. To imitate a beginning-to-end workflow within cbNIPT, peripheral blood samples are first collected in blood tubes that contain a cell preservative. Next, cell-fixation and cell-permeabilization are performed to allow intracellular immunostaining of target cells, using fluorescently labeled antibodies. Then, single white blood cells are isolated and amplified, using three WGA methods in parallel: an advanced degenerate oligonucleotide primed PCR (DOP-PCR WGA) method, a ligation-adaptor PCR-based (LA-PCR WGA) method and a semi-linear WGA method that combines multiple displacement amplification and PCR (MDA-PCR WGA). Finally, STR analysis is performed on all WGA products by simultaneously amplifying the Amelogenin locus *AMEL* and 15 tetrameric STR loci across the human genome: *D8S1179*, *D21S11*, *D7S820*, *CSF1PO*, *D3S1358*, *TH01*, *D13S317*, *D16S539*, *D2S1338*, *D19S433*, *VWA*, *TPOX*, *D18S51*, *D5S818*, and *FGA*. Results demonstrate that the LA-PCR WGA method and the MDA-PCR WGA method yield STR profiles that show several dropouts, but are nevertheless adequate to allow fetal cell identification. Unfortunately, DOP-PCR WGA yields unusable STR profiles in the tested cbNIPT workflow.

**Full-gene sequencing based expanded carrier screening of over 150 disorders.** C. Gijvanekar<sup>1</sup>, B. Yuan<sup>1,2</sup>, J. Scull<sup>1,2</sup>, Z. Chen<sup>1,2</sup>, L. Meng<sup>1,2</sup>, S. Wen<sup>1,2</sup>, R. Xiao<sup>1,2</sup>, J. Zhang<sup>1,2</sup>, E. Schmitt<sup>1,2</sup>, S. Peacock<sup>1,2</sup>, J. Dong<sup>1</sup>, H. Cheng<sup>1,2</sup>, D. Muzny<sup>3</sup>, R. Gibbs<sup>2,3</sup>, A. Beaudet<sup>2</sup>, F. Xia<sup>1,2</sup>, C. Eng<sup>1,2</sup>. 1) Baylor Genetics, Houston, TX; 2) Department of Molecular and Human Genetics, Baylor College of Medicine, One Baylor Plaza, Houston, TX; 3) Human Genome Sequencing Center, Baylor College of Medicine, One Baylor Plaza, Houston, TX.

**Background:** While the American College of Obstetricians and Gynecologists recommends carrier-screening of only 22 conditions, next-generation high-throughput full-gene sequencing has the potential to identify all known and predicted pathogenic variants associated with far more conditions. Based on the American College of Medical Genetics and Genomics (ACMG) policy statement (2013), GeneAware™ was designed to provide comprehensive pan-ethnic carrier screening of 159 genes for single nucleotide variants (SNV), indels, copy number variants (CNV), and CGG repeat expansion of the *FMR1* gene. **Methods:** We screened 6,291 females and 2,965 male samples by GeneAware. The test includes full-gene sequencing of 152 genes; full-gene CNV scan for *CFTR* and *DMD*; targeted CNV detection of 13 genes, including *MECP2*, *HBA1/2* etc., *FMR1* analyzed by CGG repeat expansion PCR, and *SMN1* carrier and silent carrier analysis were performed. Detection rates were >95% and varied by ethnicity for some conditions. Variant classification and interpretation used modified ACMG guidelines for automated or exhaustive manual curation to augment clinical sensitivity. Phenotype correlation was provided when possible. Reporting was limited to pathogenic or likely pathogenic variants. **Results:** Of the 9,256 individuals screened, three major ethnicities were Caucasian, Hispanic American and, African American. Notably, 53.3% were carriers of at least one disorder, with 16.9% being carriers of two or more disorders. Depending on ethnicities, 42% to 64% of individuals were identified as carriers for at least one disorder. The top five genes with positive findings were *HBA1/2* (10.4%), *SERPINA1* (7.5%), *CFTR* (4.1%), *HBB* (4%), and *GJB2* (3.4%). *FMR1* repeat expansion analysis in females detected 120 (1.3%) intermediate allele carriers and 25 (0.2%) premutation carriers. Caucasians had the highest incidence of *FMR1* expansions (0.65%). Of 1,011 couples, 30 (1.4%) were found to be carrier-couples. Half of the carrier couples had indicated a family history of an affected child. Six high-risk couples underwent prenatal testing for the identified variants in our laboratory. **Conclusion:** GeneAware is an expanded, full-gene sequencing based, pan-ethnic carrier screening panel which uses a variety of high-throughput technologies to increase the detection of carriers and carrier-couples. This expanded screening facilitates informed reproductive counseling.

**Fine mapping the MHC region identified two independent loci associated with non-obstructive azoospermia in Han Chinese males.** M. Huang<sup>1</sup>, M. Zhu<sup>1</sup>, T. Jiang<sup>1</sup>, Y. Jiang<sup>1</sup>, G. Jin<sup>1</sup>, Z. Hu<sup>1,2</sup>. 1) Department of Epidemiology and Biostatistics, School of Public Health, Nanjing Medical University, Nanjing, China; 2) State Key Laboratory of Reproductive Medicine, Nanjing Medical University, Nanjing, China.

**Objectives:** Previous genome-wide association studies (GWAS) studies have identified the association between genetic variants in the major histocompatibility complex (MHC) region and non-obstructive azoospermia (NOA). However, the mechanism underlying the association remain unclear because of the extensive linkage disequilibrium (LD) existing in the MHC region. **Materials and Methods:** In the present study, using the specific Chinese Han-MHC database as a reference panel, we imputed all missing SNPs and HLA variants in the MHC region of GWAS data from 981 Chinese NOA patients and 1,657 controls. Combined with in silico bioinformatics analysis, we explored MHC variations in relation to NOA susceptibility comprehensively.

**Results:** We identified two independent risk loci: rs7194 (OR = 1.37, 95% CI = 1.21-1.56,  $P = 1.43 \times 10^{-6}$ ) at MHC class II molecules, and rs4997052 (OR = 1.30, 95% CI = 1.15-1.46,  $P = 2.26 \times 10^{-5}$ ) at MHC class I molecules. Functional annotation showed rs7194 was probably tag the effect of multiple amino acid residues and the expression of *HLA-DQB1* and *HLA-DRB1*; while rs4997052 showed the effect of amino acid changes of *HLA-B* at position 116 as well as the expression of *HLA-B* and *CCHCR1*, which co-expressed with genes enriched in pathways of spermatogenesis and male gamete generation. Combined novel findings with previously identified variants, approximately 6.71% of the phenotypic variances can be explained according to our study.

**Conclusion:** We fine mapped the MHC region and identified two loci that independently drove the NOA susceptibility. The results provided a deeper understanding of the association mechanisms of MHC and NOA risk.

**Association analysis of HLA-G gene 3'UTR variant (rs1063320) with recurrent miscarriage.** V. Kalotra<sup>1,2</sup>, G. Singh<sup>1</sup>, V. Sharma<sup>3</sup>, I. Sharma<sup>3</sup>, M. La<sup>1</sup>, I.C. Verma<sup>3</sup>, S. Sharma<sup>3</sup>, A. Kaur<sup>1</sup>. 1) Department of Human Genetics, Guru Nanak Dev University, Amritsar, India; 2) Cytogenetics laboratory, Institute of Medical Genetics and Genomics, Sir Ganga Ram Hospital, New Delhi, India; 3) Human Genetics Research Group, School of Biotechnology, Shri Mata Vaishno Devi University, Katra, Jammu and Kashmir, India.

Recurrent miscarriage (RM) is defined as the loss of two or more clinical pregnancies and affects 15-20% of couples. About 50% cases of RM are idiopathic. A successful pregnancy is the outcome of coordinated interaction of several components between mother and fetus. Human leukocyte antigen (*HLA*)-G gene is a non-classical HLA class Ib gene and favours maternal acceptance of the semi-allogenic fetus by modulating the maternal immune system during pregnancy. It undergoes alternative splicing which produces seven different isoforms (four are membrane bound proteins three are soluble forms). *HLA-G* +3142G/C variant is located in 3' untranslated region (UTR) of the gene and is involved in micro (mi) RNA mediated post transcriptional regulation. We analyzed the association of *HLA-G* rs1063320 (+3142G/C) variant in 91 RM women who had experienced at least two or more consecutive miscarriages, their 91 male partners and 100 healthy control females who had at least one healthy live born and no history of miscarriage. The genotyping was performed by using AGENA MassARRAY system. The distribution of variants followed the Hardy-Weinberg equilibrium ( $p > 0.05$ ). The study depicted no significant association for rs1063320 variant and recurrent miscarriage. We also analyzed the association of allele sharing between the partners of 91 RM couples and number of miscarriages in RM couples. However, the study revealed no significant association for this comparison. Thus, it is suggested that further investigations involving other variants of the *HLA-G* 3'UTR and their haplotype analysis on a larger sample size may help to understand their role in RM. **Keywords:** Recurrent miscarriage, Human leukocyte antigen, 3'UTR The financial assistance to Vishali Kalotra (DST/INSPIRE Fellowship/2013/889) from Govt. of India is duly acknowledged. No conflicts of interest are declared by the authors.

**A comprehensive roadmap of murine spermatogenesis defined by single-cell RNA-seq.** Q. Ma<sup>1</sup>, C.D. Green<sup>1</sup>, G.L. Manske<sup>2</sup>, A.N. Shami<sup>1</sup>, X. Zheng<sup>1</sup>, C. Sultan<sup>1</sup>, S.J. Gurczynski<sup>3</sup>, B.B. Moore<sup>3,5</sup>, J.Z. Li<sup>1,4</sup>, S.S. Hammoud<sup>1,2,6,7</sup>. 1) Department of Human Genetics, University of Michigan, Ann Arbor, MI; 2) Cellular and Molecular Biology Program, University of Michigan, Ann Arbor, MI; 3) Department of Internal Medicine, University of Michigan, Ann Arbor, MI; 4) Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 5) Department of Microbiology and Immunology, University of Michigan, Ann Arbor, MI; 6) Department of Obstetrics and Gynecology, University of Michigan, Ann Arbor, MI; 7) Department of Urology, University of Michigan, Ann Arbor, MI.

The process of spermatogenesis requires intricate interactions between the germline and the somatic cells. Within a given cross-section of a seminiferous tubule in mammalian testis, multiple germ and somatic cell types co-occur and these are different from the cell ensemble in the next cross-section. Thus, cellular heterogeneity is coupled with spatial complexity, making it difficult to understand the interaction among distinct cell types at different stages of germ cell development. To address this challenge, we collected single-cell RNA sequencing data from ~35K cells from the adult mouse testis, and identified all known germ and somatic cells, as well as two novel somatic cell types. Unlike previous datasets from similar studies we increased the representation of rare cell types by targeted experimental enrichment using a series of transgenic models. Our analysis revealed a continuous developmental trajectory of germ cell maturation from spermatogonia to the elongated spermatids, and identified candidate transcriptional regulators at several critical transition points during differentiation. Focused analyses delineated the presence of four subtypes of spermatogonial cells and nine subtypes of Sertoli cells, the latter can be linked to histologically defined developmental stages over the seminiferous epithelial cycle. Overall, this high-resolution cellular atlas represents a community resource to study germ cell development and *in vivo* gametogenesis. **Optimization of advanced DOP-PCR WGA for STR profiling in cell-based non-invasive prenatal testing.** J. Weymaere, A.S. Vander Plaetsen, P. Caenen, L. Tilleman, D. Deforce, F. Van Nieuwerburgh. Faculty of Pharmaceutical Sciences, Ghent University, Ghent, Belgium.

In the context of cell-based non-invasive prenatal testing (cbNIPT), fetal cells are isolated from the maternal peripheral bloodstream and used to perform prenatal testing such as copy number variant (CNV) analysis. Unfortunately, fetal cells in the maternal bloodstream are extremely rare and cannot be identified with a unique fetal marker. Therefore, short tandem repeat (STR) profiling is performed to verify the fetal identity of the isolated cell before prenatal diagnosis. As a single cell contains only 6-7 pg DNA, whole genome amplification (WGA) is essential to increase the amount of DNA up to ng- or µg- levels to allow both STR profiling and CNV analysis on a single cell. Since each WGA method introduces bias and thereby influences the outcome of downstream assays, the WGA method is selected based on the required downstream applications. Until now, there is no WGA method well suited for both STR- and CNV analysis. For instance, WGA based on Multiple Displacement Amplification (MDA) give rise to faultless and complete STR profiles but CNV profiles show extreme representation bias. In return, advanced Degenerate Oligonucleotide Primed PCR (DOP-PCR) is well fitted for CNV analysis although STR profiles are incomplete. The aim of this work was to optimize advanced DOP-PCR and increase the quality of the STR profiles. Therefore, specific STR primers were added to the advanced DOP-PCR WGA, which is called advanced DOP-PCR with Targeted Sequence Enrichment (TSE). In that way, STR amplicons are already selectively amplified during WGA. The STR primers that were used, originate from the Identifiler Plus AmpFISTR PCR kit. Four different concentrations of STR primers were tested: no primers, 2.67 µM, 4 µM, and 8 µM of the STR primer pool. The performance of this advanced DOP-PCR with TSE was assessed using one and three micromanipulated cells from the Loucy cell line. STR profiles were generated using the same Identifiler Plus AmpFISTR kit, which is a multiplex PCR kit that amplifies 15 STR loci (*D8S1179*, *D21S11*, *D7S820*, *CSF1PO*, *D3S1358*, *TH01*, *D13S317*, *D16S539*, *D2S1338*, *D19S433*, *VWA*, *TPOX*, *D18S51*, *D5S818*, *FGA*) and the Amelogenin locus *AMEL*. Results demonstrate that implementation of TSE has a positive effect on the drop-out rate, which increases the quality of the STR profiles. Addition of STR primers in an 8 µM concentration results in the lowest drop-out rate and most complete profiles.

**Transcriptional profiling of circulating exosomes defines molecular phenotypes of preeclampsia.** *J. Schuster*<sup>1,2</sup>, *V. Zarate*<sup>1</sup>, *C. Felber*<sup>1</sup>, *A. Uzun*<sup>1,2,3</sup>, *J. Padbury*<sup>1,2,3</sup>. 1) Pediatrics, Women and Infants Hospital of Rhode Island, Providence, RI; 2) Pediatrics, Brown University, Providence, RI; 3) Center for Computational and Molecular Biology, Brown University, Providence, RI.

Preeclampsia is a multi-system hypertensive disorder of pregnancy, characterized by variable degrees of maternal symptoms including elevated blood pressure, proteinuria and fetal growth retardation. There is currently no effective intervention for preeclampsia short of delivery of the fetus. Although the heritability of preeclampsia has been well documented, specific genetic contributions have not been identified. We have shown that genes associated with preeclampsia are phenotype specific. To better understand the underlying mechanism, we are investigating the transcriptional profile of exosomes from the plasma of women with the extreme phenotype of early onset severe preeclampsia. Nearly all tissues and cell types release vesicles from their plasma membrane. The contents of extracellular vesicles, including both mRNA and miRNA, are tissue specific can be functionally transferred to recipient cells and lead to alterations in downstream signaling. We hypothesize that the mechanism for severe preeclampsia can be revealed by comparing the transcript profile of the extracellular vesicles from women with severe preeclampsia to gestational age matched normotensive women. To test this hypothesis, we are enrolling a cohort of patients, isolating plasma derived exosomes and sequencing the exosome RNA. We have successfully isolated exosomes and have confirmed their size, shape and concentration with western blots Nanosight Analysis and electron microscopy. In a preliminary analysis of 8 normotensive term women, we have sequenced the exosomal messenger RNA cargo and used STAR, HT\_Seq and DESeq2 to identify differentially expressed genes in the pregnant mothers compared to 24 hours post-delivery. 79 genes were differentially expressed after FDR correction. The Citrulline Mediated Endocytosis pathway, involved in vesicle-target cell communication, was enriched for upregulated genes. We are using innovative bioinformatics techniques to further analyze this data and the severe pre-eclamptic/gestational age matched control samples. This includes qSVA to correct for bias in RNA expression due to delayed processing and Nonnegative Matrix Factorization to deconstruct the transcription profiles of the exosomal cargo into the contribution from their tissues of origin. Identification of the transcript profiles in these extracellular vesicles will provide insights into the mechanisms severe preeclampsia and lead to new strategies for treatment, prediction and prevention.

**Cause for clinical concern: Genome-wide cfDNA for cases screening positive for trisomy 15.** *E. Soster*, *T. Boomer*. Sequenom/Integrated Genomics, San Diego, CA.

Cell-free DNA (cfDNA) testing has been integrated into routine prenatal care. Expansion of cfDNA technology includes select microdeletions, large copy number variants, and esoteric aneuploidies. Initial data regarding outcomes from a commercial genome-wide cfDNA test has been described.<sup>1,2,3</sup> Based on this commercial laboratory experience, the outcomes observed for cases positive for trisomy 15 (T15) suggest significant risk for complications in these pregnancies. A retrospective analysis was performed on over 40,000 maternal blood samples submitted for genome-wide cfDNA analysis. Samples were subjected to DNA extraction, library preparation, and genome-wide massively parallel sequencing.<sup>4</sup> Sequencing data were analyzed using a novel algorithm to detect trisomies and subchromosomal, genome-wide copy number variants 7Mb and larger.<sup>1</sup> The cases that screened positive for T15 were reviewed. Clinical outcomes were requested from ordering providers as part of routine follow-up of positive cases. There were 18 cases that screened positive for T15. Of those, 3 cases were confirmed by diagnostic testing. An additional 8 cases ended in miscarriage or fetal demise. There were 2 discordant cases with a known co-twin demise and 3 discordant cases with no obvious biological explanation, but raw sequencing data in those cases suggests mosaicism. Two cases were lost to follow-up and outcomes are unknown. Fourteen of 18 cases included maternal age as a reason for referral. Ultimately, 50% (9/18) of cases ended in pregnancy loss. One of the confirmed cases resulted in a fetus with Prader-Willi syndrome (PWS), suggesting a trisomic rescue. T15 is a fairly common cause of pregnancy loss, accounting for 1.68% of all spontaneous abortions and 7.4% of trisomies seen in spontaneous abortions.<sup>5</sup> As T15 is usually an error in maternal meiosis, it follows that many of these cases were referred due to maternal age.<sup>6</sup> The high rate of adverse outcomes can be explained by the frequent meiotic origin of T15, which has been previously described.<sup>6,7</sup> These outcomes are similar to those reported in another cohort of cfDNA cases.<sup>8</sup> Although the sample size is relatively small and unfortunately, most of the losses did not have diagnostic testing, the cause for concern is apparent. Whether caused by full or mosaic T15 in the fetus or placenta, or UPD leading to PWS/Angelman syndrome, a positive cfDNA result for T15 carries significant concern for an adverse outcome, particularly pregnancy loss.

**528F**

**Improved DNA amplification used for human karyomapping to phase single gene defects.** S. Rulli<sup>1</sup>, M. Horňák<sup>2</sup>, A. Janosch<sup>3</sup>, D. Unt<sup>3</sup>, N. Hochstein<sup>3</sup>, R. Kläver<sup>3</sup>. 1) QIAGEN Sciences Inc., 6951 Executive Way, Frederick, MD 21703, US; 2) REPROMEDA BIOLOGY PARK, Studentska 812/6, 62500 Brno, Czech Republic; 3) QIAGEN GmbH, QIAGEN Strasse 1, 40724 Hilden, Germany.

Karyomapping allows to phase single gene defects in embryos and is performed when a couple has a family history of a genetic disorder. In most cases, the method is applied on a single cell or small number of cells from an embryo during preimplantation genetic diagnosis. One obstacle when performing karyomapping on single or few cells is the small amount of sample DNA. Whole genome amplification (WGA) can be used to overcome this limitation. The performance of WGA is essential as the quality of amplified DNA affects karyomapping results. To improve reliability and reproducibility of WGA and subsequent karyomapping experiments we developed an advanced version of the Phi-29 amplification system and added a single cell storage buffer optimized for collecting and storing eukaryotic single cells. In this study, we have validated the performance and robustness of the new WGA components and protocol (REPLI-g Advanced DNA Single Cell Kit, QIAGEN) and its compatibility with subsequent karyomapping experiments. For karyomapping we performed SNP genotyping of 300.000 SNP markers across human genome using the Human KaryoMap-12 SNP array (Illumina) and used the corresponding QC metrics for validation of WGA performance. These QC metrics comprised overall call rate, AB rate, Allelic drop out rate and Miscall rate. We analyzed numerous cases (on average 2 - 9 embryos per case) with family history of different genetic disorders e.g. fragile X syndrome, cystic fibrosis or nephronophthisis. Overall, the QC metrics of all cases displayed good quality of the amplified sample DNA from parental origin as well as from embryo biopsies. In addition, the karyomapping could be used to identify embryos free of chromosomal aneuploidies, which frequently occur in human embryos. Our study confirms that the improved DNA amplification is highly suitable for human karyomapping and gives reliable and reproducible results for phasing of single gene defects.

**Parents' attitude of chromosomally affected child towards carrier screening.** N.N. Kadam<sup>1</sup>, B.B. Ganguly<sup>2</sup>. 1) MGM Medical College & Hospital, Navi Mumbai, Maharashtra, India; 2) MGM New Bombay Hospital, Navi Mumbai, Maharashtra, India.

The information generated from genotype-phenotype correlations has importance in clinical setting. Genetic counseling and screening of blood-linked relatives not only prevents transmission of irreparable genetic alterations to future generations but also help in understanding its impact on future health. We present a 6 days old female child born with choanal atresia and subsequently detected with an abnormal karyotype with an extra recombinant marker chromosome. She also had anteposed anal opening, ASD and developed hyperbilirubinemia. The child cried immediately after birth; however, shortly developed acute respiratory distress. An emergency nasogastric connection had detected bilateral choanal atresia, which had opened the left nostril partly. Conventional karyotyping in peripheral blood detected a constitutional abnormality with 47,XX,+mar pattern. The marker chromosome was confirmed as an acrocentric one from its involvement in acrocentric association, which might have been produced from a balanced translocation present in one of the parents. The father and the elder sibling also complained of some amount of nasal blockade (? unilateral atresia) causing chronic cold and cough. However, the family was reluctant to undergo karyotyping and confirm the source of the recombinant chromosome in their female child. This is the first case of choanal atresia caused by unbalanced chromosomal rearrangement. Carrier screening of the parents was extremely important for identification of the chromosomes involved in the proband, for their elder son and future life of their offspring. Presence of a balanced translocation, if present in one of the parents, had influenced meiotic non-disjunction resulting in aneuploidy in the fertilized gamete.

**Clinical utility of expanded carrier screening: Results-guided actionability and outcomes.** G.A. Lazarin, K. Johansen Taber, K.A. Beauchamp, A. Arjunan, D. Muzzey, K. Wong, J.D. Goldberg. Counsyl, South San Francisco, CA.

**Introduction:** Expanded carrier screening (ECS) facilitates reproductive and pregnancy management, such as in vitro fertilization (IVF) with preimplantation genetic diagnosis (PGD) and prenatal diagnostic testing. However, studies exploring the actions of at-risk couples (ARCs) after receiving ECS results have been limited by small sample sizes. Here, we describe the impact of ECS results on planned and actual pregnancy management in the largest sample of ARCs studied to date. **Methods:** Couples who elected ECS and were found to be at high risk of having a pregnancy (ARCs) affected by at least one of 176 genetic conditions were invited to complete a survey about the impact of ECS results on planned and actual pregnancy management. **Results:** 391 ARCs completed the survey. 77% of ARCs who received results before they were pregnant reported that they altered or were planning to alter pregnancy management to reduce the risk of an affected pregnancy, including IVF with PGD, use of donated gametes, adoption, avoidance of pregnancy altogether, and prenatal diagnosis if/when they became pregnant. 37% of ARCs who received results while they were pregnant elected to undergo prenatal diagnosis. Approximately one-third of pregnancies were found to be affected, and 42% of affected pregnancies were terminated. Among those who received ECS results before they were pregnant, 126 pregnancies occurred. In those who were pregnant when they received ECS results, 40 subsequent pregnancies occurred. This yielded 166 pregnancies in which ARCs knew their ECS results prior to conception. 35% of these pregnancies were achieved through IVF with PGD. Prenatal diagnosis was pursued in approximately 30% of pregnancies, with 29% of these pregnancies found to be affected; 75% of affected pregnancies were terminated. In couples who chose not to pursue prenatal diagnosis, common reasons cited were to avoid the risk of miscarriage, a perception that it was not necessary because the couple had undergone IVF with PGD, a perception that the risk of an affected pregnancy was low, and a perception that a positive result would not have led to pregnancy termination or informed management. **Conclusions:** ECS results impacted couples' reproductive decision-making and led to altered pregnancy management that reduced the risk of an affected pregnancy.

**Mendelian mutations may explain a significant number of unexplained recurrent spontaneous abortions.** H.M. Byers<sup>1</sup>, M.E. Mehaffey<sup>2</sup>, A. LaCroix<sup>2</sup>, R.J. Silver<sup>3</sup>, M.A. Bamshad<sup>2</sup>, I.A. Glass<sup>2</sup>, H.C. Mefford<sup>2</sup>. 1) Pediatrics, Stanford University, Stanford, CA; 2) Pediatrics, University of Washington Medical Center, Seattle, WA; 3) Obstetrics & Gynecology, University of Utah, Salt Lake City, UT.

**BACKGROUND:** Infertility is a global problem with high social, economic, medical and personal costs. Approximately 50%, the evaluation for an etiology is unsuccessful and couples don't receive an explanation, leaving them with few options. We predicted that some couples with recurrent spontaneous abortions may have a Mendelian etiology for the embryonic or fetal loss. If detected, the couple could be offered individualized treatment to support the pregnancy, more precise recurrence recurrence and/or diagnostic testing.

**METHODS:** Couples with idiopathic recurrent pregnancy losses, defined as  $\geq 2$  or more unexplained spontaneous abortions, were enrolled. Medical records were reviewed to ensure recurrent pregnancy losses had no attributable etiology. DNA was extracted from abortus, male and female partner. Chromosomal microarray was performed if chromosomal assessment had not been previously performed on the abortus. Trio exome sequencing with variant analysis was performed. Candidate results were Sanger sequenced for confirmation.

**RESULTS:** Ninety-eight couples (77 trios) met eligibility criteria after medical record review, provided a sample for DNA extraction and consented for enrollment. Chromosomal microarray was performed on the 24 without chromosomal analysis prior to enrollment, 3 were abnormal and excluded. After DNA quantity, DNA quality and fingerprinting were assessed, 84 samples from 26 trios were prepared for exome sequencing. 11 samples failed amplification. 73 samples from 20 trios were successfully sequenced and analyzed. Variants were assessed considering first the fetus, male and female partner as the proband. Of the 20 trios, a candidate diagnostic, Mendelian change was identified in 10 of the 20 trios, for a diagnostic rate of 50%. Of these, 4 were *de novo* variants in the fetus, 1 was inherited from a mosaic father, 2 were changes in mother that were thought to contribute to inability to support the pregnancy and 1 was X-linked. **CONCLUSION:** Trio-exome sequencing is a powerful tool for hypothesis-generation research for conditions predicted to have a significant Mendelian genetic component with limited phenotypic information. Despite limited and heterogeneous phenotypic information, a diagnostic rate of 50% (10/20) was achieved for couples with recurrent pregnancy losses, providing the possibility for targeted treatment in female partner and more precise information about likely recurrence risks. Further study is warranted. .

**Calculating power to detect maternal and fetal effects in genetic association studies.** *G-H. Moen*<sup>1,2</sup>, *N.M. Warrington*<sup>3</sup>, *D.M. Evans*<sup>3,4</sup>. 1) Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, Oslo, Norway; 2) Faculty of Medicine, University of Oslo, Institute of Clinical Medicine, Oslo, Norway; 3) University of Queensland Diamantina Institute, Translational Research Institute, Brisbane, Australia; 4) Medical Research Council Integrative Epidemiology Unit, University of Bristol, Bristol, UK.

**Background:** Perinatal offspring outcomes, such as birthweight, are a function of maternal genetics operating on the intrauterine environment, fetal genetics and environmental factors. Partitioning genetic effects into maternal and fetal components is not straightforward because maternal and child genotypes are correlated. Such partitioning requires genotyped mother-offspring duos or genotyped individuals with phenotypic information on both themselves and their offspring. **Methods:** We derived closed form solutions, performed asymptotic power calculations and data simulations to estimate power to detect maternal and fetal genetic effects after accounting for the correlation between the genotypes. We performed calculations for both a one degree of freedom test where the maternal or fetal effect was constrained to zero and a two degree of freedom test where both parameters were set to zero. We tested the effect of different study designs, missing data and strength of residual correlation between maternal and fetal phenotypes on power. To make our power calculations accessible, we developed an online power calculator, the "Maternal and Fetal Effects Power Calculator", allowing others to conveniently estimate the power to detect these quantities in their own studies. **Results:** 53,000 genotyped mother-offspring duos were required to achieve 80% power to detect a variant exerting a maternal (or fetal) effect that explained 0.1% of the trait variance at genome-wide levels of significance (one degree of freedom test). Genotyped mother-offspring duos were in general the most powerful study design for detecting maternal or fetal effects; however, studies of genotyped individuals with their own and their offspring's phenotype had similar power when the residual correlation between maternal and offspring phenotypes approached 0.5. A two degrees of freedom test to estimate whether the genetic variant had any effect on the outcome (maternal and/or fetal) was considerably more powerful for locus detection purposes compared to a one degree of freedom test estimating either the maternal or fetal component. Studies where genotyped individuals had either their own or their offspring's phenotype (but not both) were the least powerful of the research designs considered. **Conclusion:** Samples sizes required to detect maternal or fetal effects that explain realistic proportions of the trait variance with appreciable power are achievable and within the range of current research consortia.

**When is a disease too rare? A statistical framework for estimating clinical sensitivity for expanded carrier screening panels.** *R. Ben-Shachar*, *A. Svenson*, *D. Muzzey*. Counsyl, South San Francisco, CA.

Current guidelines issued by the American College of Obstetricians and Gynecologists (ACOG) provide criteria for determining if a disease should be included in an expanded carrier screening (ECS) panel. The criteria endeavor to confine screening to diseases that are severe, phenotypically well understood, testable via prenatal diagnosis, early-onset, and common (a carrier rate above 1 in 100). We analyzed de-identified data from 44,483 patients who underwent ECS on a 176-condition panel to evaluate how exclusion of diseases that do not meet certain criteria impacts the rates of detection of both individual carriers and at-risk couples. The criterion that a disease must have a carrier frequency above 1 in 100 can be interpreted in different ways, as carrier frequencies vary widely by ethnicity. Depending on the definition used, this criterion is satisfied by between 12 (7%) and 75 (43%) conditions on the 176-condition panel; restricting the panel only to conditions meeting this criteria would reduce identification of at-risk couples by between 5% and 51% and carriers by between 20% and 83%, respectively. To determine a less ambiguous and more clinically relevant carrier-frequency cutoff, we introduce a statistical framework that models clinical sensitivity, an analysis based on the probability that sufficient reported cases exist in the literature to interpret the pathogenicity of observed variants. We show that the allele-frequency distribution of pathogenic variants for most diseases is well approximated by an exponential distribution, and that estimated clinical sensitivity depends on the value of the exponential decay parameter: Diseases with lower decay parameters have lower estimated clinical sensitivities than diseases with higher decay parameters. Our modeling suggests that a disease with a carrier frequency as low as 1 in 4,000 could still achieve a clinical sensitivity of 50%. In summary, we show that, while disease-inclusion criteria are needed for an ECS panel to be clinically meaningful, the 1-in-100 carrier-frequency threshold is unclear and arbitrary, limiting at-risk couple detection. We suggest that this threshold should be revisited and propose an alternative model to determine when a disease is too rare to include in an ECS panel.

**GenetiSure pre-screen assay for pre-implantation genetic screening by array CGH.** N. Novorodovskaya<sup>1</sup>, S. Basehore<sup>2</sup>, S. Happe<sup>2</sup>. 1) R&D, Agilent Technologies, La Jolla, CA; 2) R&D, Agilent Technologies, Cedar Creek, TX.

Preimplantation genetic testing for aneuploidy (PGT-A) is a technique that is used to screen for chromosomal abnormalities in embryos prior to transfer in an *in vitro* fertilization (IVF) cycle. Next generation sequencing (NGS) and array-based comparative genomic hybridization (aCGH) are two major platforms that have become widely adapted for aneuploidy screening in human embryos with a current detection limit of 5-10 Mb and a turnaround time of at least 12 hours. The aim of this study was to develop a high throughput, cost-effective PGT-A workflow with shorter turnaround time, to avoid the need for embryo cryopreservation and enable embryo transfer in the same IVF cycle, and higher resolution, based on the Agilent aCGH platform. The GenetiSure Pre-Screen assay, that works with two common whole-genome amplification (WGA) methods (multiple displacement amplification (MDA) and PCR-based) was developed. The workflow includes the following steps: WGA, enzymatic labeling, purification of amplified labeled DNA and hybridization to the GenetiSure Pre-Screen microarrays specifically designed for an aneuploidy screening. A single-color array design allows processing of up to 14 test and 2 reference samples per slide, providing high-resolution and cost-effective results in less than 8 hours when using the MDA method. Three single cell data analysis methods implemented in the CytoGenomics software allow detection of: (1) aberrations > 5 Mb; (2) small aberrations > 1 Mb and (3) aberrations > 20 Mb in mosaic samples. Cell lines with known aberrations were used as a model system and biopsied cells from day 3 or day 5 embryos were used to validate the workflow. Using single cell (1-2 cells) and few cell (3-5 cells) samples isolated from cell lines with known aberrations (Coriell), we demonstrated successful detection of copy number (CN) gains and losses > 5 Mb using the Single Cell Recommended analysis method and detection of expected aberrations in 1 Mb range using the Single Cell Small aberration analysis method. Using mixtures of two cell lines to mimic mosaic samples, we demonstrated the detection of a 30 Mb aberration at 20% mosaicism with the Single Cell Long Low analysis method. High correlation of the GenetiSure PreScreen results with other confirmatory methods (NGS, FISH or aCGH) used during assay validation demonstrated high accuracy of the GenetiSure PreScreen assay.

**535W**

**Pre-implantation genetic screening: One year experience at a single center in Northwest fertility clinic in Mexico.** L. Patron<sup>1,2</sup>, H.E. Almanza-Reyes<sup>1</sup>, J.J. Hernández-Ledezma<sup>2</sup>, J.F. Walters-Arballo<sup>2</sup>. 1) Universidad Autonoma de Baja California, Tijuana, CA; 2) Hospital Ángeles Tijuana.

**Objective:** Describe the indications for pre-implantation genetic testing for aneuploidy (PGT-A) cycles in our clinic population. **Desing:** Retrospective cohort study. **Setting:** Private medical reproduction center **Methods:** This is a retrospective cohort study from June 2017 to June 2018 at the Fertilitate Clinic in Tijuana, Baja California, Mexico. The samples were obtained during (75 PGS cycles) undertaken for 57 couples. Indications for PGT-A are such as maternal advanced age, recurrent implantation failure, ectopic pregnancy, male factor infertility, recurrent spontaneous abortion, and others. Biopsy was performed at day 5-7 post-fertilization, approximately 6-10 cells from the trophectoderm layer of blastocyst was analyzed. Next Generation Sequencing (NSG) technology was performed to screen all chromosomes for aneuploidy. This test is limited to screening for aneuploidies greater than 20MB in size.

**Results:** The mean female age (years,±) 38.3±5.3 vs. mean male age 37.2 ± 5.7. 17/57 couples received egg from donors, the mean age in this group was 26.5 ± 1.6. The main indication for the genetic screening was advancing maternal age/low ovary reserve in 38 (66%) couples. Infertility duration was 4.8 ± 2.6. AMH(ng/mL) 3.03±2.9, BMI(kg/m<sup>2</sup>) 30.8±4.7. 231 embryos were analyzed, blastocyst with genetic result 225 (97.4%), blastocyst no result 6(2.5%). Euploid blastocysts: 121 (52.38%) vs. 91 (47.63) aneuploid blastocysts. In the euploid group, 55(45.5%) were female vs. male 66 (54.5%), in the aneuploidy group 48 (52.7%) female embryos vs. 43 (47.5%) male embryos. In this group trisomy was present in 47 (53%) samples, 1 mosaic of trisomy 8, and 46 (51%) cases of monosomy. 9 cases report trisomy and monosomy simultaneously. 12 (5.2%) blastocyst report complex chromosomal abnormalities, 2 (0.8%) were inconclusive and 4 (1.7%) reported low DNA. **Conclusion:** In our study the main indication for IVF/PGT-A was maternal advanced age/low ovary reserve, this differs from other studies, were recurrent spontaneous abortion is more common. It was expected that, the proportion of aneuploid embryos was higher in women above 35 years. In order to measure the impact of the effectiveness of PGT-A we will follow the implantation rates, miscarriage rates and the full term pregnancies. The limitation of our study is that is only 12 months; we will extend this period to analyze this data.

**536T**

**Fetal fraction evaluation in non-invasive prenatal testing.** *M.S. Hestand<sup>1,2,3</sup>, M. Bessem<sup>3</sup>, P. van Rijn<sup>3</sup>, R.X. de Menezes<sup>4</sup>, D. Sie<sup>3</sup>, I. Bakker<sup>3</sup>, E.M.J. Boon<sup>3</sup>, E.A. Sistermans<sup>3</sup>, M.M. Weiss<sup>3</sup>.* 1) Division of Human Genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA; 2) Department of Pediatrics, University of Cincinnati, Cincinnati, OH, USA; 3) Department of Clinical Genetics, VU University Medical Center Amsterdam, Amsterdam, NL; 4) Department of Epidemiology and Biostatistics, VU University Medical Center Amsterdam, Amsterdam, NL.

A sufficient percentage of fetal DNA is required for non-invasive prenatal testing (NIPT) to avoid false negative results. During a six month period, we successfully performed shallow whole-genome sequencing on 14,379 NIPT samples. Technical and biological factors were evaluated for their influence on the percentage of fetal DNA. We found shipping time did not influence the percentage of fetal DNA. However, bioinformatics algorithms had a profound influence on fetal DNA fractions. DEFRAG (Y-chromosome based analysis) performed best on male fetuses while SeqFF (count-based analysis) performed best on female fetuses. Biologically, a negative correlation was found between fetal fraction and an increased weight/BMI. Gestational age of up to 21 weeks and maternal age had no influence on fetal fraction. Finally, though not statistically significant, we did observe a trend for increased fetal fractions in trisomy 21 samples and decreased fetal fractions in trisomy 13 and 18 samples. In the future, individual labs should further optimize detection methods and associations with larger cohorts performed to successfully develop appropriate fetal fraction cut-offs for reliable detection of fetal aneuploidies and smaller copy number variants with NIPT.

**Performance verification of the OnePGT preimplantation genetic testing system: Concurrent detection of aneuploidies, structural rearrangements, and monogenic disorders in single cells from *in vitro* fertilized (IVF) embryos.** *S. Happe<sup>1</sup>, K.O. François<sup>1</sup>, J. Allemeersch<sup>1</sup>, R. Richards<sup>1</sup>, S. Moeyts<sup>1</sup>, J. Theuns<sup>1</sup>, M.Z. Esteki<sup>2,4</sup>, C. Melotte<sup>4</sup>, E. Coonen<sup>2,3</sup>, J. Dreesen<sup>2,3</sup>, A. Paulussen<sup>2</sup>, J. Dumoulin<sup>3</sup>, C. Van Uum<sup>2</sup>, M. Drusedau<sup>2</sup>, J. Engelen<sup>2</sup>, K. Derks<sup>2</sup>, R. Van Golde<sup>3</sup>, E. Dimitriadou<sup>4</sup>, H. Masset<sup>4</sup>, C. De Die-Smulders<sup>2</sup>, J.R. Vermeesch<sup>4</sup>.* 1) Agilent Technologies, Diagnostics and Genomics Group; 2) Department of Clinical Genetics, GROW School for Oncology and Developmental Biology Maastricht University Medical Center+, Maastricht, The Netherlands; 3) Center for Reproductive Medicine, GROW School for Oncology and Developmental Biology, Maastricht University Medical Centre+; 4) Center for Human Genetics, University hospital of Leuven, KU Leuven, Leuven, Belgium.

OnePGT (Agilent Technologies) is a genome-wide next-generation sequencing (NGS) solution for concurrent preimplantation testing for monogenic disorders (PGT-M) structural rearrangements (PGT-SR), and aneuploidies (PGT-A), based on the haplarithmis concept which combines haplotyping and copy-number profiling of DNA from single cells (Zamani Esteki et al, 2015). In collaboration with Maastricht University Medical Center (MUMC) and Catholic University of Leuven (KU Leuven), a total of 213 embryo samples (177 PGT-M; 36 PGT-SR) were tested for concordance with the respective gold standard PGT method (SNP array with haplarithmis (siCHILD) analysis at KU Leuven; STR-PCR for PGT-M, or FISH/array CGH for PGT-SR at MUMC). For the KU Leuven study, left-over whole genome-amplified DNA from the embryo biopsies was processed, while at the MUMC site, a second biopsy was taken and amplified with REPLI-g sc (Qiagen). In addition, a total of 86 cell line samples (36 single cells and 48 few (5-10) cells) originating from 12 Coriell cell lines, of which 10 were aneuploid and 2 were euploid, were tested internally to demonstrate the sensitivity and specificity of the OnePGT solution for PGT-A. NGS libraries were generated using OnePGT library preparation reagents, sequenced on NextSeq500 (Illumina) and data analyzed within the Agilent Alissa OnePGT software suite. For PGT-M analysis, OnePGT demonstrated a 91% call rate (n=161). The 16 embryos which did not receive a conclusion were shown to possess LOH-like regions in the family members (n=10) that precluded haplotyping, or single gene disorder loci that either fell on a recombination breakpoint (n=5) or within uninformative regions of low SNP density (n=1). After excluding samples with chaotic genome-wide copy number profiles or those for which gold standard results were inconclusive, 100% of the 154 remaining samples agreed with the gold standard PGT result. For PGT-SR analysis (n=36), 2 embryos were shown to have additional mitotic aberrations due to an unstable genome; of the remaining 34 embryos, 100% concordance with the reference PGT methods was demonstrated. Of the 84 Coriell cell line samples processed for PGT-A concordance analysis, an observed sensitivity of 98.5% and an observed specificity of 94.7% was demonstrated. In addition, a limit of detection of 5 Mb and 20 Mb for single and few cell sample types respectively was demonstrated. For Research Use Only. Not for use in diagnostic procedures.

**538W**

**Digital karyomapping following genomic autopsy: Implications for preimplantation genetic diagnosis in the genomic era.** T. Hardy<sup>1,2,3</sup>, D. Lawrence<sup>4</sup>, A. Byrne<sup>4</sup>, P. Arts<sup>4</sup>, S. King-Smith<sup>4</sup>, M. Babic<sup>4</sup>, C. Barnett<sup>4</sup>, H. Scott<sup>1,4</sup>. 1) SA Pathology, Adelaide, Australia; 2) Repromed, Adelaide, Australia; 3) Women's and Children's Hospital, Adelaide, Australia; 4) Centre for Cancer Biology, University of South Australia, Australia.

**Background:** Karyomapping identifies informative single nucleotide polymorphism (SNP) profiles in embryos using an array sampling ~300,000 genomic loci. Karyomapping may not be feasible if there are insufficient loci around the gene of interest due to poor SNP coverage or consanguinity. Whole genome sequencing could define all informative variants individualised to a couple; however, the expected resolution of this strategy has not been assessed. **Aim:** To develop an automated method for digital karyomapping feasibility studies using genomic data and compare to standard karyomapping. **Method:** A user-friendly graphical tool for digital karyomapping was built on top of VariantGrid (variantgrid.com), a variant database developed at SA Pathology. WGS data was analysed for two families with an abnormality in a previous pregnancy. Informative variants within a standard karyomapping window of 2Mb of the gene of interest were identified and compared to a virtual SNP array. **Results:** Compound heterozygous mutations were identified in *MDFIC* (Family 1) and *MKS1* (Family 2). Genome-wide analysis demonstrated 97,067 informative variants on SNP array compared to 3,107,644 variants on WGS for Family 1, and 103,682 informative variants on SNP array compared to 3,389,623 informative variants on WGS for Family 2. This represents a 30-fold increase in available informative variants using WGS. In the 2Mb window around the gene of interest, there were 2,968 variants around *MDFIC* and 3,915 variants around *MKS1*. SNP array would have identified only 2% of the available information (61 variants for Family 1 and 87 variants for Family 2). **Conclusion:** Digital karyomapping provides a 30-fold increase in the availability of informative variants for analysis in embryos and may be utilised in cases in which higher resolution is required. Immediate transition to IVF and PGD without further feasibility studies will be possible for couples who have undergone WGS of a rare disorder in a previous pregnancy.

**539T**

**Rapid whole exome sequencing for diagnosis of prenatal phenotypes.** A. Haworth<sup>1</sup>, S. Drury<sup>1</sup>, Y. Patel<sup>1</sup>, R. Dubis<sup>1</sup>, J. Rizvi<sup>1</sup>, N. Lench<sup>1</sup>, J. Short<sup>2</sup>, S. Mansour<sup>3</sup>, T. Homfray<sup>3</sup>. 1) Congenica Ltd, Hinxton, Cambridgeshire, CB10 1DR, UK; 2) South West Thames Regional Genetics Laboratory, St George's Hospital, London, SW17 0QT, UK; 3) Clinical Genetics, St Georges Hospital, London, SW17 0QT, UK.

**Objectives:** i) Development, refinement and implementation of a rapid whole exome sequencing workflow from DNA to report for the diagnosis of fetal abnormalities detected on ultrasound; ii) Expansion of fetal phenotype in a single centre. **Method:** DNA (CVS, amniotic fluid, fetal blood or tissue, parental gDNA) was enriched using the Agilent Sureselect CREv2 and sequenced using Illumina NextSeq 500. Maternal cell contamination exclusion was performed where relevant. HPO terms and pedigree information were loaded into the NextSeq run folder at initiation of the sequencing run. Data from completed runs was automatically collected from the instrument daily, processed using DRAGEN BIO-IT processor and Sapientia™. Gene panels and variant filter settings were preconfigured in Sapientia™ to further expedite analysis. Analysis was stratified by candidate genes, phenotype relevant panels and DDG2P with Exomiser prioritisation as relevant for each case. **Results:** To date 18 cases with a prenatal phenotype have been tested; 13 trios and 5 singletons. 1 case with tested in the NICU. A molecular diagnosis was made in 5/18 (28%), including mutations in *CHD7*, *PIEZO1*, *PTPN11*, *BICD2* and *FGFR2*. DNA to primary result using our current workflow can be reduced to 7 working days. In three cases, the molecular diagnosis was not the suspected clinical diagnosis (*CHD7*, *BICD2*, *FGFR2*). The causative mutation was identified using DDG2P and Exomiser variant prioritisation in 2 cases (*CHD7*, *FGFR2*) and phenotype relevant gene panel (Genomics England PanelApp) in one (*BICD2*). **Conclusion:** Whole exome sequencing for prenatal diagnosis can be challenging due to limited phenotype and requirement for rapid turnaround. The utility of stratifying analysis to candidate genes, followed by extension to phenotype relevant panels is highlighted in this setting. Using streamlined laboratory and data processing workflows we continue to identify areas for improvement to facilitate translation to routine diagnostic use. We are validating a parallel SNP barcoding method to help obviate the need for Sanger confirmation which adds significant time to that reported here. Whole exome sequencing is a valuable tool for furthering gene-prenatal presentation association.

**540F**

**Parental age effects on the incidence of human de novo pathogenic variants.** Y. Cao<sup>1</sup>, P. Stankiewicz<sup>1</sup>, J. Salvo<sup>2</sup>, F. Xia<sup>1,2</sup>, Y. Guan<sup>1,2</sup>, C. Eng<sup>1,2</sup>, P. Liu<sup>1,2</sup>, J. Zhang<sup>1,2</sup>. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, Texas, USA; 2) Baylor Genetics, Houston, Texas, USA.

De novo DNA change(DNC) is the major mechanism causing human monogenic disorders demonstrated by clinical whole-exome studies that nearly 60% of solved cases were caused by dominant disorders and >70% of them were attributed to de novo pathogenic variants. Approximately 80% of de novo germline point variants arise from paternal origin likely due to the DNA replication and repair errors during mitotic spermatogenesis. Advanced paternal age at conception (PAC) is associated with the increased incidence in several dominant diseases including FGFR2- and FGFR3- related disorders. However, for the majority of dominant diseases it is still unclear whether there is a paternal and/or maternal age effect on the occurrence of de novo changes. We retrospectively studied more than 2,000 cases which were referred for whole exome sequencing, diagnostic panel, and non-invasive single gene disorder panel at the Baylor Genetics from November 2012 to April 2018. 1328 patients from 1325 unrelated families were found to carry at least one apparently de novo variant, with a total of 2394 de novo variants on 1984 different genes. A total of 296 genes were found with at least two de novo changes in unrelated patients, including 14 variants arising in more than two times. Paternal age at conception ranged from 17-78 yrs(average age 32.4 yrs with the standard deviation (SD) of 6.9 yrs) while maternal age at conception from 15-46yrs (avg age 29.5 yrs with SD of 5.7 yrs). The average number of DNC in the exome region per case gradually increased from 20-40 years in both maternal and paternal group with similar rate. The increasing trend was persistent for fathers from 40yr to 60yr. Interestingly, the growth rate of DNC accelerated when PAC was older than 40 yrs compared with that in the 20-40 yrs group. Furthermore, after functionally annotating genes, we found that pathogenic de novo variants were clustered in pathways involving in cell growth suggesting that there might be an advantage for gain-of-function mutations during spermatogenesis or fertilization. The average PAC was increased to 34.6 yrs in father (P = 0.01) and 31.1 yrs in mother (p=0.03) of probands with de novo variants associated with RASopathies. In summary, our study provides insights into the effects of advanced parental age on the occurrence of human de novo pathogenic variants as well as how the risks for monogenic diseases associated advanced paternal age can be better calculated for genetic counseling.

## 2787W

**The SureMASTR BRCA Screen assay combined with MASTR Reporter analysis is an accurate and precise workflow for SNV, indel and CNV detection in blood- and FFPE-derived DNA.** K. Bettens<sup>1</sup>, B. Slabbinck<sup>2</sup>, J. Vermeire<sup>1</sup>, M. Vyverman<sup>2</sup>, B. Tegenbos<sup>1</sup>, L. Claes<sup>1</sup>, L. Heyrman<sup>1</sup>, H. Swennen<sup>1</sup>, C. Marques<sup>1</sup>, A. Rotthier<sup>1</sup>, J. De Schrijver<sup>1</sup>, D. Goossens<sup>1</sup>, J. Crappé<sup>2</sup>, J. Del Favero<sup>1</sup>. 1) R&D, Agilent Technologies, Niel, Antwerp, Belgium; 2) R&D, Agilent Technologies, Ghent, Belgium.

**Introduction:** Targeted next-generation sequencing has tremendous potential to steer targeted therapy. Inhibitors of poly-(ADP-ribose) polymerase (PARP) have emerged as a new class of targeted anti-cancer drugs, specifically for tumors showing homologous recombination repair deficiency in ovarian and breast cancers. **Methods:** The SureMASTR BRCA Screen workflow comprises a sample to result solution. The library preparation is a single plex assay enabling mutation analysis of all coding regions of *BRCA1*, *BRCA2*, *PALB2* and *CHEK2*. The assay comprises 355 amplicons ranging in size from 80 to 224 bp. Data quality control as well as variant calling of SNPs, indels and CNVs are performed using MASTR Reporter. The SureMASTR BRCA Screen workflow was extensively examined in house and by 3 external clinical labs using both blood- and FFPE-derived DNA. **Results:** In total, 105 clinical samples were analyzed by three external clinical sites for germline mutation detection during a beta testing study. These samples harbored 114 annotated, mostly pathogenic variants, of which 8 in *CHEK2*, 14 in *PALB2*, 49 in *BRCA1* and 43 in *BRCA2*. The 114 variants included 8 CNV events and 49 indels up to 13 basepairs. All indels and SNVs were correctly called with the BRCA Screen workflow. In addition, all CNV events were correctly observed. The assay is optimized for cost-efficient use of the sequencing capacity obtained by (i) > 99% of the reads mapping to the target region and (ii) > 99.4% of the amplicons having a coverage within 20% of the mean coverage. Testing was performed on Illumina's MiSeq sequencer, and compatibility with Illumina's NextSeq and MiniSeq was demonstrated. FFPE-derived reference samples of Horizon were assessed for the quality of the DNA with the QC Plex assay. Uniformity of amplification remained high, with on average 99.1% of amplicons reaching a coverage of 20% of the mean coverage. A study with clinical FFPE derived samples is initiated to confirm these data. **Conclusions:** The SureMASTR BRCA Screen assay is a single plex assay which significantly reduces the hands-on time, DNA input, required sequencing capacity and in combination with the MASTR Reporter results in an accurate and precise workflow. Using the SureMASTR BRCA Screen workflow, we demonstrated that it can be routinely applied with a LOD down to 5% to detect somatic or germline *BRCA1*, *BRCA2*, *PALB2* and *CHEK2* mutations.

## 2788T

**Molecular genetics study of hereditary colorectal cancer in Algerian patients.** F. Cherbal<sup>1</sup>, F. Khider<sup>1</sup>, L.A Boumehdji<sup>1</sup>, I. Tabet<sup>1</sup>, S. Hamine<sup>1</sup>, K. Layaida<sup>2</sup>, H. Mahfouf<sup>3</sup>, F. Zebboudj<sup>4</sup>, M. Maaoui<sup>5</sup>. 1) Unit of Genetics, LMCB, FBS Université des Sciences et de la Technologie Houari Boumediene, Algiers, Algeria; 2) Gastroenterology service, University Hospital Mustapha Bacha, Algiers, Algeria; 3) Mohamed El Kolli Public Hospital, Academic Medical Oncology Services, School of Medicine, University of Algiers, Rouiba, Algeria; 4) Mohamed El Kolli Public Hospital, Academic General Surgery Services, School of Medicine, University of Algiers, Rouiba, Algeria; 5) Bachir Mentouri Public hospital, Academic General Surgery Services, School of medicine, University of Algiers, Kouba, Algiers, Algeria.

**Background** Colorectal cancer is the second most common cancer in men and women in Algeria. The present study focuses on the two major forms of hereditary colorectal cancer, Familial Adenomatous Polyposis (FAP) and Lynch Syndrome (LS) in Algerian patients. Here, we analyzed by PCR-direct sequencing *APC* gene of 20 FAP patients and *MLH1*, *MSH2*, *MSH6* genes of 20 patients with LS, respectively. **Methods** The patients and their families were referred from 2012 to 2017 through the main medical oncology services and gastroenterology and general surgery services of Public Hospitals of Algiers. We screened by PCR-direct sequencing exon 15 of *APC* gene in 20 patients with a strong family history of FAP. 20 patients with Lynch syndrome who fulfilled Amsterdam criteria were screened by PCR-direct sequencing for germline mutations in the *MMR* genes: *MLH1* (exons 9,10,13,16), *MSH2* (exons 5,6,7,12) and *MSH6* (exon 4). **Results** The analysis of DNA samples of 20 FAP patients revealed that five patients carried pathogenic variants and one patient carried a VUS in *APC* gene. Four distinct pathogenic variants: c.3784delT, c.3905deT, c.3927\_3931delAAAGA, c.4459dupA and the VUS p. Glu1317Gln were identified in *APC* gene. The *APC* c.3784delT and c.4459dupA pathogenic variants have never been reported in LOVD, UMD and ClinVar databases. These new *APC* germline variants could be specific of Algerian FAP patients. All the carriers of pathogenic variants in *APC* gene have developed colorectal carcinoma. Three distinct germline mutations: c.1852\_1854delAAG in exon 16 of *MLH1*, c.1165C>T in exon 7 of *MSH2* and the Newfoundland mutation c.942 +3A>T in exon 5 of *MSH2* were detected in four Lynch syndrome patients. Interestingly, the c.942+3A>T *MSH2* mutation was found in two unrelated Lynch families. Moreover, the *APC* European founder mutation c.3927\_3931delAAAGA has been also detected in two unrelated FAP families. Haplotype analysis of the *APC* mutation c.3927\_3931delAAAGA and the c.942+3A>T *MSH2* mutation will establish if the origin of these two mutations in Algeria is linked to the common history and migration flow of Mediterranean countries. **Conclusion** We report here the first screening of *APC* gene in FAP patients and *MMR* genes in Lynch syndrome patients of Algerian national cohort. The accumulating knowledge about the prevalence and nature of *APC* variants and *MMR* genes variants will contribute in the future to the implementation of genetic testing and counseling for patients and families at risk.

**2789F**

**Comparison of enzymatic fragmentation vs sonication for the production of cfDNA reference standards for liquid biopsy assay validation.** *H. Child, A. Mele, K. Wilczynska, J. Wickenden.* Horizon Discovery, Cambridge, UK, Cambridgeshire, United Kingdom.

**Introduction:** Liquid biopsies hold great promise to revolutionise the field of clinical oncology testing. cfDNA can be extracted from a routine patient blood sample and used to determine the genetic profile of a solid tumour located elsewhere within the body. This facilitates more informative disease management for the clinician, without the need for invasive surgery for the patient. With new cfDNA NGS assays being able to detect variants from as little as 2-10ng DNA, assay validation to ensure sufficient accuracy has never been so critical. Reference materials that closely mimic real cfDNA samples are essential to support this effort. Here we present results from a comparative study into the production of cfDNA reference standards, assessing enzymatic fragmentation compared to fragmentation by sonication, and the benefit of including a size selection step. **Methods:** DNA was extracted from engineered cancer cell lines and fragmented to 160bp using either sonication or enzymatic shearing, as assessed by TapeStation. In addition, a size selection step was included to investigate the ability to purify the fragment peak to a size distribution profile most similar to real cfDNA samples. The presence of mutations was confirmed by ddPCR, allowing for accurate variant allele frequency to be determined. The sample set was tested by NGS on Thermo breast cfDNA assay, and Illumina TST-15 assay, following the manufacturer's instructions. **Results:** Variant detection by ddPCR confirmed the presence of 8 mutations across 4 genes (*EGFR*, *KRAS*, *NRAS* and *PIK3CA*) at either 0.1% or 5% variant allele frequency. TapeStation analysis confirmed that both sonication and enzymatic shearing produced cfDNA with an average fragment size of 160-170bp. A size selection step proved useful to concentrate the amount of DNA within the desired fragment size range. Analysis by NGS confirmed that all variants were detectable at the correct allele frequency as expected. **Conclusion:** Results demonstrate that both sonication and enzymatic shearing can be used to create cfDNA reference material with an average fragment size of 160bp to closely mimic cfDNA from real patient samples. This study has compared the utility of two alternative production methods, highlighting the potential of enzymatic shearing and a size selection step to further improve the commutability of high quality cell-line derived reference material for the validation of liquid biopsy assays.

**The utilization of public population databases for somatic variant classification.** *J.P. De La O, H. Cox, M. Jones, B. Coffee, L. Esterling, S. Manley.* Myriad Genetic Laboratories, Inc., Salt Lake City, UT.

**Background:** The presence of pathogenic variants in genes associated with homologous recombination (HR) may inform treatment decisions for some cancers. For example, the PARP inhibitor olaparib is FDA approved for women with ovarian cancer only if they have a pathogenic variant in *BRCA1* or *BRCA2*. The allele frequency (AF) of a variant in research grade population databases, such as gnomAD, is often used in variant classification by clinical testing laboratories, based on recommendations from ACMG/AMP. Specifically, variants that are present in these databases at an AF higher than the expected gene-associated disease prevalence may be classified as benign. In order to ensure accurate variant classification and appropriate treatment decisions, it is imperative that laboratories apply additional scrutiny to this research grade data. Here, the data quality from gnomAD was analyzed for HR related genes to assess the feasibility of using such data in variant classification.

**Methods:** Data quality from gnomAD was assessed for 6 genes associated with HR to identify high frequency variants that could be classified as benign. Quality metrics, including NGS read frequencies, mapping quality, pseudogene homology, and importantly somatic contamination, were analyzed. Variants of uncertain significance identified in the course of clinical testing were downgraded to benign if their AFs were above the ACMG/AMP recommended population specific AF thresholds ( $\geq 5\%$  or an overall AF of  $\geq 1\%$ ) and the available data passed all quality filters. **Results:** A total of 22 variants were identified in gnomAD that met the ACMG/AMP recommended population specific AF thresholds. Overall, low levels of somatic contamination were identified in the 6 HR genes evaluated here. In total, the gnomAD data for 8/22 (36%) variants failed one or more of our quality parameters. The remaining 14/22 (64%) variants were downgraded to benign. **Conclusions:** Here we found that 36% of variants in HR-associated genes that met ACMG/AMP AF thresholds failed the quality parameters instituted by our laboratory. The use of low quality in data in population databases during variant classification may result in a false-negative result, preventing eligible patients from receiving appropriate treatment. This emphasizes the importance of appropriate laboratory quality filters in variant classification, even when using AF thresholds recommended by society guidelines.

**Puliation screening for BRCA1 and BRCA2 mutations: Results from a feasibility study within a military treatment facility.** *R.E. Ellsworth<sup>1</sup>, L.A. Lovejoy<sup>2</sup>, C.D. Shriver<sup>1,3</sup>*. 1) Clinical Breast Care Project, Murtha Cancer Center, Bethesda, MD; 2) Chan Soon-Shiong Institute of Molecular Medicine at Windber, Windber, PA; 3) Uniformed Services University, Bethesda, MD.

**Background:** Although strategies have been developed to decrease risk of developing breast and ovarian cancer in women with germline mutations in BRCA1 or BRCA2, genetic testing in the United States (US) is offered only to women with a significant family history, thus excluding carriers that do not meet testing criteria. Identification of carriers only after a cancer diagnosis may be considered a failed opportunity for prevention and implementation of a population screening program at or around age 30 has been proposed to identify high-risk women in the US. In this pilot study, we evaluated the yield and utility of population screening within a cohort of women with health-care provided through a military treatment facility. **Methods:** BRCA status was determined for 368 women age 18-40 years who had benign biopsies at Walter Reed National Military Medical Center and who had genomic (blood) DNA available for research purposes. 78% of the women tested did not meet the NCCN guidelines for genetic risk evaluation. BRCA1 and BRCA2 were sequenced using next-generation sequencing technologies and variants were classified as pathogenic, likely pathogenic, variants of uncertain significance (VUS), likely benign or benign, according to ACMG criteria. **Results:** Pathogenic mutations were detected in 2% of women (BRCA1 n=5 and BRCA2 n=3); an additional three and 12 women harbored novel mutations and VUS, respectively. Two of the patients with pathogenic mutations did not have a significant family history and would not have been eligible for genetic testing under current guidelines. **Conclusions:** These data have important clinical. Based on 2010 US Census data, there were 41,141,300 women age 20-39; extrapolation from our pilot data suggests that >800,000 women in that age range harbor BRCA1/2 mutations including 223,000 who would not qualify for testing. Identification of women with germline mutations before the development of breast cancer will allow risk-reduction strategies to be implemented, improving the health of these women while decreasing medical costs. The opinions or assertions contained herein are the private ones of the author/speaker and are not to be construed as official or reflecting the views of the Department of Defense, the Uniformed Services University of the Health Sciences or any other agency of the U.S. Government.

**Searching for variants by whole-exome sequencing in Brazilian women at high-risk for hereditary breast/ovarian cancers, negative for mutations in BRCA1/BRCA2 genes.** *P.S. Felicio<sup>1</sup>, R.S. Grasel<sup>1</sup>, B.D.F. Barros<sup>2</sup>, N. Campacci<sup>1</sup>, H.C.R. Galvão<sup>3</sup>, C.P. Souza<sup>3</sup>, A.F. Evangelista<sup>1</sup>, D.M. Carraro<sup>2</sup>, E.I. Palmero<sup>1</sup>*. 1) Molecular Oncology Research Center, Barretos Cancer Hospital, Barretos, São Paulo, Brazil; 2) Laboratory of Genomics and Molecular Biology, CIPE - A. C. Camargo Cancer Center, São Paulo, Brazil; 3) Department of Oncogenetics, Barretos Cancer Hospital, Barretos, São Paulo, Brazil.

**Background:** BRCA1 and BRCA2 testing is uninformative in approximately 80% of families with clinical features of inherited susceptibility to breast and ovarian cancers. Early identification of high-risk individuals may lead to improvements in screening and prevention strategies, and, potentially, improving overall cancer survival. **Aim:** To identify the missing heredity associated to cancer development in high-risk families, BRCA1/2 WT (BRCAx families), through whole-exome sequencing (WES) of constitutive DNA. **Methods:** We performed WES (Nextera Rapid Capture Exome and Expanded Exome Kit) in 45 BRCA1/2 WT individuals with high-risk for breast/ovarian cancer. The criteria for data analysis were: (i) coverage  $\geq 10x$ , (ii) variants present in less than 15% ( $\leq 7$  samples) and (iii) missense, in-frame and stop loss variants classified as pathogenic by at least three of six *in silico* prediction programs selected. **Results:** For each sample, an average of 122 genetic changes per sample (ranging from five to 196 variants) was identified. In addition, most of the identified variants were of the missense type, followed by the nonsense variants. Among the twenty most commonly altered genes, many of them have already been associated with hereditary predisposition syndromes to cancer, such as: *ATM*, *MLH1*, *MSH6*, *MUTYH* genes. Besides, pathogenic/probably pathogenic alterations were identified in DNA repair genes, such as *ERCC3*, *ERCC4*, *EXO1* and *FAN1* genes were identified. **Conclusion:** Our data show that significant genetic heterogeneity exists in BRCAx families. Large-scale collaborative efforts will be required to attain sufficient power to understand the missing heredity associated with breast/ovarian cancer development in high-risk families.

**2793W**

**Circulating tumor DNA methylation haplotypes in plasma can accurately detect early-stage colorectal cancer and advanced adenomas in a single blinded study.** J. Gole<sup>1</sup>, A. Gore<sup>1</sup>, J. Min<sup>1</sup>, H. Wang<sup>1</sup>, J. Dang<sup>1</sup>, H. Shi<sup>1</sup>, J. Lu<sup>1</sup>, S. Mo<sup>2</sup>, X. Lan<sup>3</sup>, W. Dai<sup>2</sup>, R. Wang<sup>2</sup>, Y. Gao<sup>1</sup>, K. Zhang<sup>1</sup>, L. Liang<sup>3</sup>, G. Cai<sup>2</sup>, R. Liu<sup>1</sup>. 1) Singlera Genomics, La Jolla, CA; 2) Fudan University Shanghai Cancer Center, Shanghai, China; 3) Southern Medical University, Guangzhou, China; 4) University of California - San Diego, La Jolla, CA.

**Background:** Colorectal cancer (CRC) is one of the most common forms of cancer and is responsible for approximately 700,000 deaths per year worldwide. Because of this, colorectal cancer screening is recommended by the USPSTF, but patient compliance can be low due to the invasiveness of screening colonoscopy. While a non-invasive circulating tumor DNA (ctDNA) methylation screening test has been developed using the Septin9 gene, the sensitivity and specificity of the test are inadequate for use as a primary screening tool (especially for early-stage CRC). We set out to develop a highly accurate, non-invasive plasma based screening assay to identify colorectal cancer at an early stage using ctDNA methylation signatures. **Methods:** Blood samples from 88 healthy individuals, 150 individuals diagnosed with advanced adenoma by colonoscopy, and 526 individuals diagnosed with colorectal cancer by colonoscopy were collected in EDTA tubes and immediately separated into plasma. Plasma samples were then processed using the Singlera Genomics ACE assay, a targeted bisulfite sequencing method which identifies methylation haplotype patterns specific to early- and late-stage colorectal cancer. 217 samples were used to train a classification model based on colonoscopy results, and 218 samples were used as a test set to validate the model. An additional 329 samples were held out as a single blinded independent test set to further confirm the model accuracy and robustness. **Results:** In the single blinded independent test set, the ACE assay was able to show a sensitivity of 88.4% in advanced adenoma patients and 93.1% in colorectal cancer patients, with a specificity of 96.5% in healthy patients. **Conclusions:** We have shown that ctDNA methylation can be utilized to non-invasively screen for early-stage colorectal cancer and advanced adenoma with best in class sensitivity, paving the way for a primary blood-based colorectal cancer screening assay.

**2794T**

**Multi-gene panel testing 54 breast cancer predisposition genes.** C. Hata<sup>1</sup>, H. Nakaoka<sup>1</sup>, L. Wei<sup>2</sup>, K. Zheng<sup>3</sup>, H. You<sup>2</sup>, I. Inoue<sup>1</sup>. 1) National Institute of Genetics, Mishima, Japan; 2) Affiliated Cancer Hospital & Institute of Guangzhou Medical University, Guangzhou, China; 3) Department of Endocrine and Breast Surgery, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China.

Breast cancer is the most common noncutaneous malignancy in woman and approximately 10-15% of cases are associated with germline mutations of DNA repair genes. In this study, we scrutinized germline mutations of 54 cancer predisposition genes including *BRCA1/2* in 672 breast cancer patients of Chinese origin. DNA samples, extracted from peripheral blood samples, were subjected to NGS sequencing based on a pool and capture method established by our previous study. After the quality control step, the sequence reads were aligned to the human reference genome (hg19). The aligned reads were processed for removal of PCR duplicated and erroneous reads by Picard tools. The local realignment and base quality recalibration conducted by GATK. Single nucleotide variants (SNVs) and insertions and deletions (indels) were detected with the GATK. Variants were classified according to pathogenicity as follows: First, variants were classified as 'benign' if their frequencies were greater than 1.0% in the public database in the 1000 Genomes or ExAC project. Second, nonsense, splice site mutations, and indels were classified as 'pathogenic'. Third, we explored missense variants with previously established pathogenic or benign effects based on ClinVar. Variants were classified as 'conflicting interpretations of pathogenicity' if reports were conflicted on ClinVar. Finally, variants with 'uncertain significance' were classified as 'VUS'. Variants without reliable information were classified 'NA'. We detected 81 pathogenic mutations (34 nonsense, 37 frameshift indels and 10 splice site mutations) in 672 breast cancer patients, accounting for the 12% causality. Furthermore, 5.5% of the patients harbored *BRCA1/2* mutations (37/672). The remaining 7% of the patients carried pathogenic mutations on 23 genes (44/672). Interestingly, we detected a novel deletion-insertion mutation on *PTENα*, where 69bp of mitochondrial DNA sequence was inserted into 46bp deletion site in the 1<sup>st</sup> exon of *PTENα*. Finally, we identified significant associations between mutation status and clinical variables. Taken together, these results suggest that screening of pathogenic mutations in breast cancer patients based on the multi-gene panel is clinically useful.

**2795F****An analysis of tumor mutation burden in colorectal cancer has revealed signature damage patterns associated with multiple cancer types.** *J. Huang<sup>1</sup>, R. Chaudhary<sup>1</sup>, V. Mittal<sup>2</sup>, W. Tom<sup>1</sup>, F. Shen<sup>1</sup>, J. Au-Young<sup>1</sup>, F. Hyland<sup>1</sup>.*

1) Clinical Next-Generation Sequencing Division, Thermo Fisher Scientific, South San Francisco, CA; 2) Clinical Next-Generation Sequencing Division, Thermo Fisher Scientific, Ann Arbor, MI.

**Introduction:** Tumor mutation burden (TMB) is defined as the rate of somatic mutations within a tumor genome and has been shown in several cancer types to be a promising genomic biomarker that effectively indicates potential for successful immunotherapy. TMB analyses can reveal tumorigenesis signature patterns associated with specific damages through substitution type and context of somatic mutations. **Methods:** We estimated mutation burden (mutation count per Mb) from 50 FFPE tumor research samples of colorectal cancers (CRC), melanoma, and non-small cell lung cancer (NSCLC) with OncoPrint™ Tumor Mutation Load Assay, a PCR-based target enrichment panel that covers 409 cancer-related genes and 1.7 Mb of genomic regions. The workflow requires only 20 ng of input tumor DNA (no matched normal sample required). Sequencing was performed on Ion GeneStudio with ~500x coverage. Germline variants, along with background noise, are removed through application of filters based on variants prevalent in population databases.

**Results:** Initial results for a cohort of CRC FFPE tumors demonstrated that most of the samples had a high TMB and mutations in mismatch repair (MMR) genes. Further analysis revealed a series of signatures of tumorigenesis based on the substitution type and genomic context of somatic mutations. In addition, signatures for FFPE deamination were observed for quality evaluation. Characteristic signature patterns have been observed in multiple tumor types, including deamination of 5-methylcytosine in CRC tumors, tobacco damage in lung tumors, and UV damage in melanoma tumors. The proportion of respective signatures to the total somatic mutations was quantified. In a CRC tumor, 43.6% C>G>T:A mutations were observed at CpG sites representing spontaneous deamination of 5-methylcytosine. In a melanoma tumor, we found two novel signatures: high C:G>T:A at TpC, high C:G > T:A at CpC and CpC sites, totaling 88.6% mutations, consistent with DNA damage signatures of ultraviolet radiation exposure. Finally, lung tumor samples showed 48.3% C:G>A:T mutations consistent with tobacco damage. **Conclusions:** Tumor mutation burden analyses can be used to detect somatic mutations and reveal signature patterns correlating with the genomic damage characteristic of specific tumor types. This analysis will aid in elucidating properties of the tumor corresponding to known mechanisms of tumorigenesis and identify additional variants of different tumor origin.

**2796W****Clinical application of the OncoKids<sup>SM</sup> next generation sequencing platform for detection of germline and somatic alterations in pediatric brain tumors.** *J. Ji<sup>1,2</sup>, K. Kaneva<sup>3,4</sup>, M.H. Hiemenz<sup>1,2</sup>, R.J. Schmidt<sup>1,2</sup>, A. Margol<sup>3,4</sup>, N. Robison<sup>3,4</sup>, G. Dhall<sup>3,4</sup>, D. Tian<sup>1,2</sup>, D. Hawes<sup>1,2</sup>, J.A. Cotter<sup>1,2</sup>, A.R. Judkins<sup>1,2</sup>, J.A. Biegel<sup>1,2</sup>.* 1) Department of Pathology and Laboratory Medicine, Children's Hospital Los Angeles, Los Angeles, CA; 2) Department of Pathology, University of Southern California; 3) Department of Pediatrics, Children's Hospital Los Angeles, Los Angeles, CA; 4) Department of Pediatrics, University of Southern California.

We developed a comprehensive DNA- and RNA-based next generation sequencing (NGS) panel, OncoKids<sup>SM</sup>, to detect diagnostic, prognostic, and therapeutic markers across the spectrum of pediatric malignancies, including leukemias, solid tumors, and brain tumors. To date, 100 pediatric brain tumors have been prospectively analyzed using OncoKids<sup>SM</sup>, including low and high-grade gliomas, choroid plexus tumors, embryonal tumors, and ependymomas. OncoKids<sup>SM</sup> demonstrated pathogenic mutations in 64% (64/100) of cases. A total of 88 SNVs and small InDels of strong clinical significance (Tier I) or potential clinical significance (Tier II) in 29 genes were reported in 53 cases. Diagnostic and prognostic Tier I mutations included mutations in *H3F3A*, *HIST1H3B*, *FGFR1*, *ACVR1*, and *TP53* in high-grade gliomas; *BRAF* V600E, *FGFR1*, and *NF1* mutations in low grade gliomas; *KDM6A*, *PTCH1*, *SMARCA4*, and *TP53* mutations in medulloblastomas; *CTNNB1* exon 3 mutations in craniopharyngiomas; and *SMARCB1* mutations in rhabdoid tumors. A combination of *H3F3A* G34R, *ATRX*, and *TP53* Tier I mutations which characterizes a specific subtype of high-grade glioma was identified in four histologically challenging neuroepithelial tumors. Clinically significant RNA fusions were identified including *KIAA1549-BRAF* in 11 pilocytic astrocytomas, *PTPRZ1-MET* in two high-grade gliomas, *YAP1-MAML2* in one malignant neoplasm of the posterior fossa without further histologic classification, and *FGFR2-SHTN1* in one ganglioglioma. Amplifications of *EGFR*, *MYCN*, *MET*, and *MDM4* were detected in three high-grade gliomas, including one patient with amplification of *EGFR*, *MYC*, and *MDM4*. A high frequency of mutations was observed in two high grade-gliomas, consistent with the high tumor mutation burden that is seen in association with mutations in mismatch repair genes. One patient had a bi-allelic germline mutation in *MSH2* and the other patient had a bi-allelic germline mutation in *MSH6*. Potential targeted therapies with BRAF, FGFR, mTOR, MET, IDH1 or ALK inhibitors, were suggested in 34% (22/64) of cases with at least one Tier 1 variant. OncoKids<sup>SM</sup> analysis also revealed potential germline mutations in cancer predisposition genes for 26% (26/100) of cases, including one patient with possible germline mosaicism for an *FGFR1* mutation. Our results demonstrate significant clinical utility of integrating NGS-based genomic profiling into routine clinical testing for pediatric brain tumors.

**2797T****The Veterans Health Administration's Research Precision Oncology****Project: Integrating real-world data into a learning health system.** *B.R.**Johnson<sup>1,2,4</sup>, D.C. Elbers<sup>1</sup>, E. Pierce<sup>1</sup>, F. Meng<sup>1,3,4,5</sup>, N. Fillmore<sup>1,2,4</sup>, S. Ayandeh<sup>1</sup>, D. Chen<sup>3</sup>, L. Selva<sup>1</sup>, N.B. Begley<sup>1</sup>, A.J. 1) MAVERIC- VA Boston, Boston, MA; 2) University of Buffalo, School of Medicine, Buffalo NY; 3) Boston University School of Medicine, Boston, MA; 4) BD-STEP program, NCI/VA, Washington DC; 5) UCLA, Los Angeles CA.

The Veterans Health Administration's (VHA) "Veterans Integrated Service Network 1" collected targeted molecular diagnostic oncology panel data from multiple vendors as the standard of care. The program yielded 1967 reports from patients with advanced cancer from 2015 to December 2017. Notable among these reports, 785 (40%) of these patients had a lung cancer diagnosis, 140 (7%) had liver cancer and 101 (5%) were determined to have prostate cancer. So far, 113 of these patients have consented to have their data shared under the IRB approved Research Precision Oncology Program (RePOP) protocol. Patients were enrolled from 26 facilities throughout the VHA. Data has been aggregated for visualization from multiple streams, including; molecular diagnostics from multiple vendors and radiology. Over 90% of these consented patients were determined to have at least 1 of 327 unique clinically actionable variants. There were 27 (24%) patients with *KRAS* mutations found in the consented population. The large majority (>95%) of patients with lung cancer within the cohort were diagnosed with Non Small Cell Lung Carcinoma (NSCLC), with an almost even split among adenocarcinoma and squamous histologies. The VHA contains a wide array of data that may be utilized for precision medicine, predictive models and in creating a learning healthcare system. To reach this goal, we are preparing the consented cohort of data derived from REPOP for ingestion into the Precision Oncology Data Repository. This effort is making VHA oncology data more widely available to the research community. Internally, we are analyzing patterns of survival and treatment options to better understand current treatment modalities and outcomes. Additionally, Non-VHA researchers will be able to gain access for the establishment of predictive models and research purposes.

**2798F****Clinicopathological and molecular analysis of 45 cases of mucinous****breast cancer.** *SY. Kang<sup>1</sup>, MS. Ahn<sup>1</sup>, YS. Jung<sup>2</sup>, TJ. Park<sup>3</sup>, SH. Park<sup>4</sup>, JH.**Kim<sup>4</sup>, HE. Yim<sup>4</sup>.* 1) Hematology-Oncology, Ajou University School of Medicine, Suwon, South Korea; 2) Department of Surgery, Ajou University School of Medicine, Suwon, South Korea; 3) Department of Biochemistry and Molecular Biology, Ajou University School of Medicine, Suwon, South Korea; 4) Department of Pathology, Ajou University School of Medicine, Suwon, South Korea.

**Purpose:** Mucinous carcinoma of the breast is characterized by clusters of tumor cells floating in abundant extracellular mucin and can be divided into two main subtypes based on architectural and cytologic features: paucicellular (classic) and hypercellular variant. However, clinicopathological and molecular differences between these two variants has far not been investigated.

**Materials and Methods:** We retrospectively evaluated clinicopathologic features of 45 cases of surgically removed mucinous carcinoma of the breast at Ajou university hospital from April 2011 to April 2017. Among them, 8 cases were microdissected and subjected to whole exome sequencing for molecular analysis. SNPs and Indels were called from every alignment files by using HaplotypeCaller with GVCF mode which covers not only variable sites, and also same with reference genotype, and then all genomic vcf files were merged by using CombineVCF. To compared the allele frequencies between normal individual and the 8 breast cancers, we used Korean Reference Genome Common Variants (KRGCV) of 1,100 Korean people. We further analyzed the differences of the frequencies between two subtypes of mucinous breast cancer. **Results:** Of the 45 patients who underwent surgery, 30 were paucicellular subtypes and 15 were hypercellular subtypes. We found lymph node metastasis in 5 cases of hypercellular subtypes but no in paucicellular subtypes. Hormone receptors were positive in both groups and 2 patients were HER2 positive only in hypercellular subtypes. All patients were alive at the time of analysis and one of the hypercellular subtypes underwent reoperation due to local recurrence. By whole exome sequencing analysis, we found 1,523 SNPs and 812 INDELS significantly different between mucinous breast cancers and reference Genome Data Base (KRGCV). Among them, 133 SNPs were significantly different between two variants of mucinous carcinoma.

**Conclusion:** Our results suggested that hypocellular and hypercellular variant show different patterns of SNPs and hypercellular variant maybe associated with more frequent lymph node metastasis than paucicellular subtypes.

**2799W**

**BRCA1/2 mutations, including large genomic rearrangements, among unselected ovarian cancer patients in Korea.** D. Kim<sup>1</sup>, N. Ryoo<sup>1</sup>, D. Jeon<sup>1</sup>, W. Lee<sup>1</sup>, J. Ha<sup>2</sup>, C. Cho<sup>2</sup>, S. Kwon<sup>3</sup>. 1) Department of Laboratory Medicine, Keimyung University School of Medicine, Daegu, South Korea; 2) Department of Obstetrics and Gynecology, Keimyung University School of Medicine, Daegu, South Korea; 3) Department of Pathology, Keimyung University School of Medicine, Daegu, South Korea.

We performed small-scale mutation and LGR analysis without selection in multiple ovarian cancer subtypes. We also evaluated the usefulness of several mutation carrier prediction algorithms for predicting *BRCA1/2* mutations, including LGRs. Here, we report the results of a comprehensive *BRCA1/2* genetic study that determined the prevalence and the characteristics of mutations among unselected ovarian cancer patients. All ovarian cancer patients who visited a single institution between September 2015 and April 2017 were included. Sanger sequencing, multiplex ligation-dependent probe amplification (MLPA), and long-range polymerase chain reaction (PCR) were performed to comprehensively study *BRCA1/2*. The genetic risk models BRCAPRO, Myriad, and BOADICEA were used to evaluate the mutation analysis. In total, 131 patients were enrolled. Of the 131 patients, Sanger sequencing identified 16 different *BRCA1/2* small-scale mutations in 20 patients (15.3%). Two novel nonsense mutations were detected in two patients with a serous borderline tumor and a large-cell neuroendocrine carcinoma (LCNC). MLPA analysis of *BRCA1/2* in Sanger-negative patients revealed two LGRs. The LGRs accounted for 14.3% of all identified *BRCA1* mutations, and the prevalence of LGRs identified in this study was 1.8% in 111 Sanger-negative patients. The genetic risk models showed statistically significant differences between mutation carriers and non-carriers. These results partially support a previous study that showed a positive correlation between the proportion of mutations due to a LGR and the BRCAPRO score. The two patients with LGRs had at least one blood relative with breast or ovarian cancer. Twenty-two (16.8%) of the unselected ovarian cancer patients had *BRCA1/2* mutations that were detected through comprehensive *BRCA1/2* genetic testing. Patients with ovarian borderline tumors with aggressive characteristics and LCNC of the ovary should be considered for *BRCA1/2* genetic testing. Additionally, an above-average score on the BRCAPRO, Myriad, or BOADICEA assessments may also indicate the need for LGR testing in Sanger-negative patients. Ovarian cancer patients with Sanger-negative results should be considered for LGR detection if they have one blood relative with breast or ovarian cancer. The detection of more *BRCA1/2* mutations in patients is important for efforts to provide targeted therapy to ovarian cancer patients.

**2800T**

**An amplicon panel for BRCA sequencing bundled with a user-friendly bioinformatics solution.** K. Kushiro, A. Sharma, D. Fox, S. Piehl, A. Kothandaraman. Bioo Scientific, a PerkinElmer company, 7050 Burleson Rd Austin, TX 78744.

More and more labs are exploring next-generation sequencing for clinical research applications as adoption is being fueled by the prolific growth of personalized medicine. The identification of mutations in *BRCA1* and *BRCA2* tumor suppressor genes is a staple in many clinical research projects and as such, amplicon panels have proven to be very versatile and economical solutions to understand these genes in human cancers. Panels and bioinformatic pipelines have been designed to construct libraries from fresh and frozen tissues or FFPE samples, both of which are popular sample types for labs. The panel for *BRCA1*, *BRCA2*, *PALB2*, and *CHECK2* using fresh and frozen tissue is composed of 187 amplicons ranging from 92-235bp in size, not including primer regions, and exhibits 98% uniformity at 0.2x coverage and 100% uniformity at 0.1x coverage. The panel for *BRCA1* and *BRCA2* from FFPE tissue is composed of 261 amplicons ranging from 64-129bp in size, not including primer regions, and exhibits 97% uniformity at 0.2x coverage and 100% uniformity at 0.1x coverage. Aside from reliable and optimized library prep at the bench, amplicon panels facilitate a naïve user's transition into adopting next-generation sequencing as it also allows for a much narrower and targeted approach that also minimizes the amount of data generated compared to wider sequencing applications like DNA-Seq or hybrid-capture methods. This poster reviews the workflow, performance and sequencing metrics, and the bioinformatics analysis and output associated with these chemistries for amplicon panels. Research use only. Not for diagnostic procedures.

**2801F**

**Validation of the GeneReader NGS system for BRCA 1 and BRCA 2 genotyping.** E. Lee<sup>1,2</sup>, N. Park<sup>2</sup>, W. Lee<sup>2</sup>, S. Chun<sup>2</sup>, W. Min<sup>2</sup>. 1) Hallym University College of Medicine, Hwaseong-Si, Korea, Republic of; 2) University of Ulsan College of Medicine and Asan Medical Center, Seoul, Korea, Republic of.

**Background:** BRCA1/2 testing with NGS technology offers many advantages over Sanger sequencing, including high throughput, and automated analysis. However, multiple barriers still exist for its broader adoption in clinical laboratory, such as fragmented workflow and complex bioinformatics analysis. GeneReader NGS system includes all sample processing steps starting from nucleic acid extraction to an integrated bioinformatics solution that allows for direct access to real-time updates from clinical knowledge and evidence. We evaluated performance of the GeneReader NGS Platform for BRCA 1 and BRCA 2 genotyping. **Methods:** BRCA1 and BRCA2 sequence determination using GeneReader was performed in a total of 100 patients who were diagnosed breast or ovarian cancer and previously tested BRCA1 and BRCA2 analysis using Sanger sequencing. Libraries (253 amplicons covering 37.5 kb) were prepared using QIAGEN Library Kit. Emulsion PCR and bead enrichment steps were performed using GeneReader QIACube and Clonal Amp Q Kit. All the procedures were performed according to manufacturer's protocols. QCI Analyze software performed read alignment, quality control, variant calling, and clinical report generation. The results generated by GeneReader were compared to those obtained by Sanger sequencing. For reproducibility of variant calling, we performed the process in triplicate using 28 samples and analyzed the results. We reviewed turnaround time (TAT) of total process and its hands on time. **Results:** Greater than 99.9% of the target regions showed read depths >100x and the percentage of reads in on-target regions was 90.5%. Variants generated from GeneReader achieved 100% (13/13) and 98.9% (722/730) concordance with those generated from Sanger sequencing in insertion/deletions (indels) and single nucleotide variations (SNVs), respectively. The annotation of the GeneReader system showed over 99.9% (744/745) concordance with databases in ClinVar. All of 272 SNVs and 7 indel variants showed 100% calling reproducibility. The GeneReader provided a truly integrated workflow and most process was composed of hands off time (3250 min, 87% of total TAT). **Conclusions:** The GeneReader NGS system for BRCA 1 and BRCA 2 genotyping showed great performance and takes much shorter hands on time compared with Sanger sequencing. With a full end-to-end solution with integrated sample preparation to bioinformatics interpretation, the GeneReader NGS System can be useful for clinical laboratory practices.

Clinical Genome Resource (ClinGen) is a National Institutes of Health (NIH)-funded resource dedicated to building an authoritative central resource that defines the clinical relevance of genes and variants for use in precision medicine and research. ClinGen has developed expert panels in different clinical domains to adapt the American College of Medical Genetics and Genomics/Association for Molecular Pathology (ACMG-AMP) guidelines for consistent and accurate variant classification of specific genes and diseases. Eighteen expert panels has been established to date under ClinGen and two of them (Cardiomyopathy and RASopathy) has published their recommendations of disease-specific variant classification rules. A new Myeloid Malignancy Expert Panel has recently started to focus on curating variants in genes associated with inherited risk for myeloid malignancies. This panel consists of expert clinicians, clinical laboratory diagnosticians, and researchers who enlist representatives from community-organized efforts to implement standardized protocols for sequence variant specific annotations of genes related to the specific disease domain. The optimization of the ACMG/AMP guidelines represent disease-/gene-informed specifications or strength adjustments of existing rules, including gene-specific population frequency cutoffs, recommendations for the use of computational/predictive data, functional data, and clinical evidence. Some rules will be deemed not applicable. This expert panel will consider variants in genes that cause life-long thrombocytopenia (e.g., RUNX1, ANKRD26, and ETV6) as well as those associated only with cancer risk (e.g., DDX41 and CEBPA). In summary, ClinGen Myeloid Malignancy Expert Panel provide recommendations to optimize ACMG/AMP criteria using for standardization of variant interpretation practices. This effort will facilitate more knowledgeable utilization of genomic variants in clinical diagnostics and cancer research, and provide a strong foundation for genomic medicine.

**Multi-gene testing of an Indian ovarian cancer cohort: Prevalence of BRCA1/2 and non-BRCA mutations.** A.U. Mannan, J. Singh, S. Deshwal, S. Sur, N. Thota, A.V. Kanthi, P. Preeti, K. Saxena, S. Sankaran, S. Katragadda, V. Veeramachaneni, R. Hariharan. Strand Life Sciences, Bangalore, Karnataka, India.

Ovarian cancer is one of most commonly diagnosed hereditary cancer and leading cause of deaths among gynecologic malignancies in India. This emphasizes on the need for a cost-effective method for early detection and prevention of the cancer. NGS (next-generation sequencing) based tests provide an attractive alternative to the traditionally employed sequential testing strategies as they allow massively parallel sequencing of multiple genes associated with a cancer efficiently and at a significantly lower cost as compared to the traditional methods. We sequenced 519 unrelated patients and families affected with ovarian cancer using the TruSight Cancer panel, which includes 11 genes strongly associated with risk of inherited ovarian cancer. Multi-gene sequencing was done on the Illumina MiSeq/NextSeq platform. Genetic variations were identified using the Strand NGS software and interpreted using the StrandOmics platform. We were able to detect pathogenic mutations in 38.7% (201/519) cases. In familial ovarian cancer cases, the detection rate increased to 52% (117/223) and in sporadic cases, the diagnostic yield was 28.4% (84/296). Overall distribution of mutations showed that 89.6% were detected in the *BRCA1/2* genes and 10.5% were detected in the non-BRCA genes. Among the non-BRCA genes, 2% of mutations were detected in the MMR genes and 3.5% in the *RAD51C/D* genes. We also identified 2 *BRCA1* recurrent mutations (likely to be founder mutations) in 41 cases in our cohort, which accounts for 20.4% of the total mutations. In our cohort, among the 201 mutations detected in ovarian cancer patients, the majority (89.6%) were in the *BRCA1/2* genes and they are likely to benefit from PARP [poly (ADP-ribose) polymerase] inhibitors as targeted therapy for treatment of cancer. Our study suggests that NGS based multi-gene panel increase the sensitivity of mutation detection and help in identifying patients with a high risk of developing cancer as compared to sequential tests of individual genes. Incorporation of such cost-effective and comprehensive test as a first-tier test will be helpful in optimizing resources for screening, prevention, treatment and disease management measures in the clinical practice for hereditary ovarian cancer.

**Pathogenic germline variants in a pediatric cancer cohort and identification of new candidate cancer predisposition genes.** K.E. Miller<sup>1</sup>, D.C. Koboldt<sup>1,2</sup>, B.J. Kelly<sup>1</sup>, P. Brennan<sup>1</sup>, V. Magrini<sup>1,2</sup>, J.M. Gastier-Foster<sup>1,3</sup>, P. White<sup>1,2</sup>, E.A. Varga<sup>1,4</sup>, C.E. Cottrell<sup>1,3</sup>, R.K. Wilson<sup>1,2</sup>, E.R. Mardis<sup>1,2</sup>. 1) Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH, USA; 2) Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH, USA; 3) Department of Pathology and Laboratory Medicine, Nationwide Children's Hospital, Columbus, OH, USA; 4) Division of Hematology/Oncology/Bone Marrow Transplantation, Nationwide Children's Hospital, Columbus, OH, USA.

Previous studies report the frequency of pathogenic germline variants in cancer predisposition genes to be ~8-10% in pediatric cancer populations. Identification of new susceptibility genes is essential, as there are undoubtedly many genes that remain to be recognized as cancer-predisposing. We applied exome sequencing to a pediatric cancer cohort at Nationwide Children's Hospital (Columbus, OH, USA) to search for germline variants in *bona fide* cancer genes and to identify putative cancer predisposition genes. Our cohort (N = 45) included 38 patients with central nervous system (CNS) tumors (e.g., pilocytic astrocytoma, ganglioglioma), 5 patients with non-CNS solid tumors (e.g., osteosarcoma, rhabdomyosarcoma), and 2 patients with hematological cancers. Most patients were pediatric with median age at diagnosis 10.0 years (range: 6 months to 24 years). For each patient, we performed exome sequencing on both tumor (mean depth ~194x) and germline (mean depth ~215x) samples and used SnpEff plus custom in-house scripts to annotate single nucleotide variants (SNVs)/indels with gene, transcript, molecular consequence, population frequency, and damaging prediction scores. SNVs/indels were assessed for pathogenicity using the current ACMG/AMP clinical variant interpretation guidelines. Six patients (13.3%) harbored pathogenic germline variants in well-established cancer predisposition genes *TP53* (3 patients), *NF1* (2 patients), and *PALB2* (1 patient). All 3 patients harboring a *TP53* germline variant had a diagnosis of choroid plexus carcinoma; both patients harboring an *NF1* germline variant had a diagnosis of CNS astrocytoma. For the remaining 39 patients, we examined rare damaging or loss-of-function variants to identify possible predisposition alleles. Four patients harbored rare, likely damaging missense variants in previously implicated cancer genes *PMS2* (1 patient), *SMARCA4* (2 patients), and *ALK* (1 patient). To identify potential novel predisposition genes, we searched for genes in which at least two patients harbored a very rare, damaging or loss-of-function variant, which nominated four new candidate genes involved in chromatin remodeling / DNA repair (*KAT6B* and *POL1*, respectively) or cell signaling (*TXK* and *PTPRF*). Identification of new cancer predisposing genes and detection of germline pathogenic variants may increase our understanding of tumorigenesis, influence clinical management, and prompt further genetic testing for the patient and family members.

**Cancer mutations in healthy admixed elderly: Can we improve pathogenicity interpretation?** M.S. Naslavsky<sup>1,2</sup>, G.L. Yamamoto<sup>1,3</sup>, S.A.M. Ezquina<sup>1</sup>, Y.A.O. Duarte<sup>4,5</sup>, M.R. Passos-Bueno<sup>1</sup>, M. Zatz<sup>1</sup>. 1) Human Genome and Stem Cell Research Center, University of São Paulo, São Paulo, Brazil; 2) Hospital Israelita Albert Einstein, São Paulo, Brazil; 3) Department of Clinical Genetics, Children's Hospital, Medical School, University of São Paulo, São Paulo, Brazil; 4) Department of Epidemiology, Public Health School, University of São Paulo, São Paulo, Brazil; 5) School of Nursing, University of São Paulo, São Paulo, Brazil.

Population-based whole genome sequencing (WGS) initiatives have been taken in different countries and tens to hundreds of thousands of individuals are being studied without a prior clinical indication. While providing insights into novel biological mechanisms, ancestry and evolution, the actionability in public health and patient-oriented measures is still limited. Incidental findings in undiagnosed patients or normal controls impose an important diagnostic challenge particularly in large population-based projects with limited clinical and phenotypic information as well as follow-up and tracking-back obstacles. The American College of Medical Genetics and Genomics (ACMG) recommends reporting back to sequenced individuals pathogenic variants in specific genes with actionability. Among them, *BRCA1* and *BRCA2* germline mutations are the most commonly associated to familial susceptibility to breast-ovarian cancer, and genes involved in mismatch repair (MMR) *MLH1*, *MSH2*, *MSH6* and *PMS2* germ-line mutations associated to Hereditary non-polyposis colorectal cancer (HNPCC), a multisystem tumoral predisposition syndrome. Here we report the variant analyses of these 6 genes from a cohort of elderly (60 and older) from São Paulo, Brazil (n=1324) submitted to WGS. Among the over 12 thousand variants within these genes, 577 have coding or splicing consequences of which 35 potentially result in loss of function. Filtering for pathogenic assertions in ClinVar yielded 9 variants (7 curated) in 10 individuals, with frequencies of less than 0.02% (gnomAD). Among those, six subjects are asymptomatic, including a 93 year old woman with *BRCA1* p.Q563X stopgain carrier without family history of cancer. One subject carrying a *BRCA2* frameshift deletion reported lung cancer and another who carries a *MSH6* frameshift insertion reported intestinal cancer. Two subjects have not provided cancer history. These ten individuals are admixed, 7 are mostly non-European (<70% European ancestry). Our preliminary results suggest that genome and clinical data of elderly individuals are of utmost importance to improve variants pathogenicity interpretation and risks estimates in genetic counseling. Moreover, data on admixed individuals may provide insights to explain reduced penetrance and may lead to the identification of population specific genetic modifiers to known monogenic genes.

**Novel *GREM1* enhancer region duplications and associated phenotypes.** R. O'Connor, J. Van den Akker, S. Kim, G. Mishne, A. Zimmer, A. Leon, J. Ji. Color Genomics, Burlingame, CA.

Hereditary mixed polyposis syndrome (HMPS) is an autosomal dominant inherited cancer syndrome characterized by colorectal polyps of multiple or overlapping histological types. The syndrome is caused by duplications of the upstream regulatory region of the gremlin1 (*GREM1*) gene that include the 3' region of the adjacent *SCG5* gene. A duplication of 40kb was originally described in HMPS families of Ashkenazi Jewish descent (Jaeger 2012). Subsequently, duplications of 16kb (Rohlin 2016), 57kb (Venkatachalam 2011), and 24kb (McKenna 2018) have now also been described in patients with a personal or family history of colorectal cancer. These additional reported cases of *GREM1* duplications have indicated that testing of the 5' regulatory region of *GREM1* beyond the 40kb Ashkenazi founder is necessary to get a full picture of *GREM1*-associated HMPS. Here we report ten novel duplications or triplications of the *GREM1* upstream regulatory region identified in twelve individuals who were tested using a 30-gene panel for hereditary cancer risk at Color Genomics. Details of the duplications and the patient clinical histories will be presented. In summary, (1) duplications that include the 5' regulatory region of *GREM1*, and have both breakpoints located between the *SCG5* start codon and *GREM1* start codon, which have previously been demonstrated to increase the expression of the *GREM1* gene (Jaeger 2012, Rohlin 2016), correlate with strong clinical histories of colorectal cancer; (2) Larger duplications including the 5' regulatory region of *GREM1* with the entire *SCG5* gene and additional genes upstream correlate with weaker clinical histories and/or later onset of cancer; (3) duplications that include the 5' regulatory region and entire coding sequence of *GREM1* display the weakest clinical association. Each of these duplications was identified by NGS read depth analysis. NGS split read analysis revealed the breakpoints of 5 unique tandem duplications, which were confirmed by dedicated PCR and Sanger sequencing across the breakpoints. The remaining duplications were all confirmed by MLPA. This study extends the knowledge of the types of duplications occurring near *GREM1* in individuals of diverse ethnicities and reveals phenotypic variability associated with *GREM1* duplications.

**2807F****Mutation spectrum identified by germline testing of hereditary cancers from 500 healthy Chinese individuals using an accessible 30-gene panel following ACMG guidelines.**

*D. Siu<sup>1</sup>, L. Servais<sup>2</sup>, Y. Okazaki<sup>3</sup>, S. Lam<sup>4</sup>, K. Law<sup>5</sup>, J. Wu<sup>5</sup>, A. Gardner<sup>5</sup>, A. Zhou<sup>2</sup>.* 1) Rainbow Genomics, Hong Kong; 2) Color Genomics, Burlingame, CA; 3) Juntendo University Graduate School of Medicine, Tokyo, Japan; 4) Hong Kong Sanatorium and Hospitals, Hong Kong; 5) HKDNA laboratory, Hong Kong.

Driven by rapid reduction of DNA sequencing cost and increased access to testing, significant progress has been made in the characterization of hereditary cancer variant carriers in the U.S. and European populations. In contrast, relatively few studies have been conducted in the Chinese population, especially regarding asymptomatic carriers of germline pathogenic variants. With physician consultation and genetic counseling support, Hong Kong-based Rainbow Genomics has been providing hereditary cancer testing to both patients with cancer symptoms and healthy individuals, and the testing and reporting process follows current American College of Medical Genetics and Genomics (ACMG) guidelines. Here, we present the results of testing over 500 healthy Chinese individuals by next-generation sequencing using a 30-gene panel, in collaboration with Color Genomics (Color). The 30-gene panel detects pathogenic variants associated with increased risk for hereditary breast, ovarian, uterine/endometrial, colorectal, melanoma, pancreatic, prostate, and stomach cancer (*APC, ATM, BAP1, BARD1, BMPR1A, BRCA1, BRCA2, BRIP1, CDH1, CDK4, CDKN2A (p14ARF and p16INK4a), CHEK2, EPCAM, GREM1, MITF, MLH1, MSH2, MSH6, MUTYH, NBN, PALB2, PMS2, POLD1, POLE, PTEN, RAD51C, RAD51D, SMAD4, STK11, and TP53*). The testing was performed at Color's U.S. laboratory under CLIA and CAP compliance. English and Chinese clinical reports, localized pre-test consultation, and post-test genetic counseling in Mandarin or Cantonese were provided. Initial results indicate pathogenic or likely pathogenic variants were detected in over 8% of these individuals, higher than the 1% - 3% previously reported in the literature for healthy ethnic Chinese. The positive findings were mostly associated with colon and breast cancer variants. A significantly higher number of individuals also received reports with one or more variants of uncertain clinical significance (VUS). In this presentation, we will report the mutation spectrum of pathogenic and likely pathogenic variants, as well as the VUS detected. This Chinese variant distribution will be compared to those from other ethnic groups using data generated from Color's worldwide testing results.

**2808W****Technical validation of EFIRM, a sensitive, plate-based, rapid, inexpensive, liquid biopsy platform for common EGFR variants in non small cell lung cancer.**

*C.M. Strom<sup>1</sup>, F. Wei<sup>1</sup>, J. Cheng<sup>1</sup>, D. Chia<sup>1</sup>, W. Liao<sup>2</sup>, M. Tu<sup>2</sup>, D. Wong<sup>1</sup>.* 1) UCLA Head and Neck Cancer Center, Dental School, Los Angeles, CA., USA; 2) EZLife Bio, Los Angeles, CA.

Liquid Biopsy (LB) is the analysis of circulating tumor DNA (ctDNA) in patients with solid tumors. LB may be particularly useful in non small cell lung cancer (NSCLC) because of the frequent presence of activating mutations that convey sensitivity to particular chemotherapy drugs and the limited access to tumor tissue. The p.L858R and Exon 19 del variants in *EGFR* confer sensitivity to Tyrosine Kinase Inhibitors (TKI) and are found in up to 50% of NSCLC tumors in China and 10% of NSCLC tumors in the USA. Electric Field Induced Release and Measurement (EFIRM) is a novel plate based signal amplification platform that is capable of detecting ctDNA in both direct saliva and unprocessed plasma samples. Only 60 µl of direct plasma or saliva are needed for this assay. Two previous publications demonstrated near perfect correlation between EFIRM LB genotyping results and the tissue samples in patients with advanced NSCLC (stage 3 and 4) for the 2 most common *EGFR* somatic activating mutations, p.L858R and Exon19 del. Preliminary data has expanded this observation to early stage NSCLC patients. The current study presents the data from the technical validation of a qualitative EFIRM assay for 3 variants in *EGFR*, the common activating mutations, p.L858R and Exon19 del and a third variant, p.T790M that is seen when tumors develop resistance to tyrosine kinase inhibitors. We established reference ranges and determined limit of detection, intra and inter assay variability (0%) for each mutation. EFIRM has improved performance when benchmarked against published data from an available IVD for *EGFR* genotyping. The EFIRM assay is capable of detecting as few as 5 copies of mutant DNA and variants with a minor allele frequency of between 0.1% and 1%. Unlike other available LB modalities, EFIRM is capable of detecting fragments of single stranded DNA as small as 30 - 100 base pairs. Subcellular fractionation reveals that EFIRM is preferentially detecting variants in the exosomal fraction. In addition to the lack of sample manipulation, these observations may explain the ability of EFIRM to detect ctDNA using a small volume of plasma or saliva. Potential uses are early detection diagnosis screening, treatment selection, treatment monitoring, and stratification of individuals with indeterminate pulmonary nodules discovered on screening spiral CT scans. Work in underway to validate a quantitative *EGFR* assay for these 3 mutations. .

**2809T**

**Association of lower expression of beta-catenin with pancreatic carcinogenesis and poorer prognosis.** L. Suo<sup>1</sup>, L. Green<sup>1,3</sup>, J. Jiao<sup>2</sup>, S. Lai<sup>1,3</sup>. 1) Dept of Pathology, Baylor College of Medicine, Houston, TX; 2) Dept of Molecular & Cellular Oncology, MD Anderson Cancer Center, Houston, TX; 3) Dept of Pathology, Michael E. DeBakey VA Medical Center, Houston, TX.

**Background:** Pancreatic ductal adenocarcinoma (PDA) is the most common malignancy of the pancreas and the third most common cause of cancer related mortality with a 5-year survival of <5%. Promising cancer treatments depend on identification of biomarkers and targeted therapy. Beta-catenin is a dual function protein with an important role in cell-cell adhesion and gene transcription. It has been reported to contribute to tumor progression. However, its role in pancreatic cancer is yet uncharacterized. The aim of this study is to determine the expression and clinical significance of beta-catenin in relation to tumor progression and survival. **Design:** Tissue microarray samples were retrieved from archives from 2007-2015, including pancreatic tissue: 29 PDA, 16 neuroendocrine tumors (NET), 1 sarcomatoid carcinoma, 8 benign neoplasms (BEN), 24 normal parenchyma (N), and 13 nonpancreatic carcinomas (NPC). Immunohistochemistry was performed using anti-beta-catenin antibody and each section was scored (ranged from 0-300) by the sum of multiplying both intensity (0, 1+, 2+ and 3+) and extension values (0-100%). Related pathologic data and patients' demographic information were also obtained. **Results:** Differential membranous expression of beta-catenin was observed. Beta-catenin scores were similar in normal pancreatic acini and ducts. Beta-catenin scores were significantly lower in cancer groups (PDA, NET and NPC) compared with BEN and N groups. Decreasing trend of beta-catenin score was found in the more clinically aggressive pancreatic adenocarcinomas: N (227.5±19.5), BEN (200.5±24.8) and PDA (114.5±18.4). Importantly, lower beta-catenin expression was correlated with poorer survival in PDA group (p=0.02). **Conclusions:** Our findings support the theories that the low beta-catenin membranous expression is one of the possible mechanisms of pancreatic carcinogenesis and may be a prognostic factor for poor outcome in pancreatic ductal adenocarcinoma.

**2810F**

**Development of SureSelect sequencing panels and algorithms to simultaneously detect mutations, copy number variations and DNA rearrangements in FFPE specimens.** H. Tao, A. Ashutosh, A. Khare, G. Amparo, C. Lecocq, A. Vadapalli, L. Forsmark, L. Niu, J. Jin, J. Ghosh, M. Ruvolo, D. Roberts. Agilent Technologies, Santa Clara, CA., USA.

**Introduction:** We have developed custom SureSelect target enrichment sequencing panels for comprehensive profiling of single nucleotide variations (SNP/INDEL), gene level copy number variations (CNV), and DNA translocations (TL) in a single assay. SureSelect target enrichment baits were designed to cover exons of target genes to detect SNP/INDEL, spanning putative translocation regions to detect TL, or periodically spaced across genes being assessed for CNV. We leverage high sensitivity SureSelect (XTHS) reagents employing molecular barcodes to aid in detection of low frequency mutations. To evaluate detection limit of SNP, CNV and TL, a custom SureSelect cancer panel was utilized in SureSelect target captures on gDNA from cell lines and FFPE samples harboring CNVs (ERBB2 or MET) or fusion genes (ALK or ROS1). Detection limits were assessed by identifying the lowest detectable allele frequency in serial dilutions of 2 genomic DNA samples titrated against one another or tumor DNA titrated with its matched normal DNA. To further assess the sensitivity and accuracy of CNV and TL detection, multiple breast FFPE tumor samples previously determined to be Her2+ by IHC, and multiple lung FFPE tumor samples (ALK positive by FISH), were analyzed with the above SureSelect custom panel. Fusions and CNVs detected by NGS were compared with results from Fluorescence in situ Hybridization (SureFISH). **Results:** For SNP/INDEL, SureSelect panels coupled with our analysis algorithm can detect SNVs down to 1% allele frequency. For CNV, DNA containing 3 copies of ERBB2 or MET genes can be detected at 10% tumor fraction (overall 2.1 copies) in both cell line samples and FFPE samples. For TL, ALK/EML4 or SLC34A2/ROS1 fusion genes can be detected at <=3% tumor fraction. In comparison with FISH, the positive percent agreement (PPA) for ERBB2 CNV detected by the custom cancer panel is 97.5% (40/41) and negative percent agreement (NPA) is 97.5% (40/41). For ALK TL detection in 52 lung FFPE samples, the custom cancer panel successfully identified EML4/ALK or KIF5B/ALK gene fusion in 37 (86%) out of 43 ALK FISH positive samples. **Conclusions:** We demonstrate a customizable SureSelect sequencing platform to detect all types of DNA mutations in FFPE samples with high sensitivity and accuracy. SureSelect target enrichment assays have great potential to be used as alternatives to or pre-screens for traditional FISH assays.

**2811W****Molecular cytogenetic characterization of a case of a mixed myelodysplastic/myeloproliferative neoplasm: Chronic myelomonocytic leukemia-1 (CMML-1) with an abnormal karyotype with an apparent monosomy 7 resulting in rearrangements involving chromosomes 7 and 21. C.A.**

*Tirado*<sup>1,2,3,4</sup>, *D. Chung*<sup>2,5</sup>, *A. Reyes*<sup>2,5</sup>, *A. Nguyen*<sup>2,5</sup>, *K. Cunnien*<sup>1</sup>, *L. Batholomaeus*<sup>1</sup>, *D. Serk*<sup>1</sup>, *J. Ahmad*<sup>1</sup>, *K. Stieglbauer*<sup>1,3</sup>. 1) Cytogenetics, Allina Health Laboratory, Minneapolis, MN; 2) The International Circle of Genetic Studies, Los Angeles, CA; 3) HPA, Minneapolis, MN; 4) The University of Minnesota, Department of Laboratory Medicine and Pathology, Minneapolis, MN; 5) The University of California at Los Angeles, Los Angeles, CA.

We report here a 69 y.o. male with persistent anemia suspicious cells on blood smear review (by clinical history). Renal dysfunction raised the issue of a plasma cell neoplasm. However, on 08/02/2017 the LD, total was 529.00. No recent iron panel data or ferritin determination was seen in the Allina Laboratory database. This patient was then diagnosed with mixed myelodysplastic/myeloproliferative neoplasm: chronic myelomonocytic leukemia-1 (CMML-1). Chromosome analysis revealed an abnormal karyotype with an apparent monosomy 7 and the presence of two marker chromosomes in 19 of the 20 metaphase cells examined. FISH analysis of metaphases from distained G-banded slides revealed translocation of D7S486 to a derivative chromosome 21, and 2 copies of *RUNX1* located on an isoderivative chromosome 7. This karyotype was then reinterpreted as an abnormal male karyotype with rearrangements of chromosomes 7 and 21 [ider(7)(q10)t(7;21)(q11.2;q11.2), der(21)t(7;21)], resulting in loss of 7p and gain of 21q. And it was described as: 46,XY,ider(7)(q10)t(7;21)(q11.2;q11.2),der(21)t(7;21)[19]/46,XY[1]. ish ider(7)(D7Z1+,*RUNX1*++),der(21)(D7S486+).nuc ish(D7Z1,D7S486)x2[200],(*RUNX1*T1x2,*RUNX1*x3)[333/500] Extra copies of *RUNX1* and abnormalities of chromosome 7 are seen in myeloid disorders including MDS/MPN. Complex rearrangements as the ones present in this study suggest genomic instability which is usually associated with a poor prognosis. Clinicopathologic correlation of these results is recommended. This case pinpoints the importance of characterization of complex rearrangements using molecular cytogenetics techniques on metaphases previously G-banded.

**2812T****Reference standards for the validation of myeloid sequencing assays. M. Wang, H. Child, J. Wickenden.** Horizon Discovery, Cambridge, UK, Cambridgeshire, United Kingdom.

**Introduction:** Myeloid neoplasms are diseases of the hematopoietic stem cells. They can be categorised into five primary types based on WHO classification, with Acute Myeloid Leukemia (AML) occurring at the highest incidence. With the advent of more robust sequencing capabilities, pathogenic mutations have now been identified in genes from 5 main groups: signalling pathway proteins (e.g. *CBL*), transcription factors (e.g. *RUNX1*), epigenetic regulators (e.g. *ASXL1*), tumor suppressors (e.g. *TP53*) and components of the spliceosome (e.g. *SF3B1*). A recent influx of new myeloid gene panels for sequencing of these genes requires rigorous validation to ensure sufficient clinical accuracy, as errors can often occur in library prep, sequencing, analysis and interpretation of results. In order to support this effort, Horizon has developed a novel cell-line derived reference standard containing 22 variants across 19 genes involved in all of the main pathway groups, including *CBL*, *RUNX1*, *ASXL1*, *TP53*, *SF3B1*, *JAK2*, *FLT3*, *ABL*, *KRAS* and *DNMT3A*. **Methods:** Engineered cancer lines were single-cell diluted and investigated for their genomic status by Sanger sequencing at key loci identified as relevant to myeloid cancer in the literature. Target variants were then further characterised by ddPCR, to enable the variant allele frequency to be reliably determined. The material was sent to test labs for assessment across a range of mainstream myeloid NGS gene panels and compared to the gold standard ddPCR data. **Results:** Sequencing by both Sanger and ddPCR confirmed the presence of 22 variants across 19 genes relevant to myeloid cancer, at a blended ratio of 5-70% variant allele frequency. Multiple reproducible batches of DNA were tested producing consistent sequencing results. The reference material was found to have good coverage across some of the most commonly used clinical myeloid NGS gene panels, and performance-testing yielded accurate variant calling of the confirmed mutations at the expected allele frequencies as originally verified by ddPCR. **Conclusion:** This is the first fully cell-line derived Myeloid Reference Standard containing 22 relevant mutations across 19 genes implicated in the diagnosis, management and treatment of myeloid cancers. Results show it to be a consistent, commutable and high quality DNA reference standard that closely mimics DNA from real clinical samples to support the genetic testing of myeloid cancer patients.

**2813F**

**Improving patient outcomes: Demonstrating competence in *BRCA1/BRCA2* variant classification for PARPi treatment stratification.** *N. Wolstenholme<sup>1</sup>, F. Khawaja<sup>2</sup>, F. Moon<sup>2</sup>, S. Patton<sup>1</sup>, Z.C. Deans<sup>2</sup>.* 1) EMQN, Manchester, United Kingdom; 2) UK NEQAS/GenQA, Edinburgh, United Kingdom.

**Introduction** The availability of PARP-inhibitor therapy for ovarian cancer patients with *BRCA1/BRCA2* mutations has introduced the requirement for testing laboratories to accurately classify the pathogenicity of variants detected. There is a worldwide approach to the implementation of standardised classifications many using ACMG/AMP guidelines and ENIGMA guidance. However, the success of application is variable and in order to drive standardisation and educate those performing variant classifications a web-based external quality assessment has been provided. **Methods** Using the NEQAS/GenQA online genomics training assessment competency tool (G-TACT) a module was developed to enable individuals to assess 15 *BRCA1/BRCA2* variants (SNVs, exonic deletions/duplications and splicing defects) and submit a classification of pathogenicity for each along with or without recommendation for PARP-inhibitor treatment. The variants ranged from class 1, benign to class 5, pathogenic. The submissions were scored, reported to each participant and a summary report was issued. This detailed the expected variant classifications and provided an overview of all submitted results. Participants were invited to join WebExs which summarised the evidence assessed, the expected variant classifications and addressed participant queries. **Results** Submissions were received from 271 individuals from 59 countries. The majority of classifications were correct with a third +/-1 class. As most participants with discordant classifications did not provide their evidence it is not possible to attribute reasons to these conflicting classifications. However five variants gave variable classifications and these will be discussed. In countries where mutation testing is required for PARP inhibitor treatment, this is recommended for likely pathogenic and pathogenic variants. Overall where participants had correctly classified the variant, the recommendations for PARP inhibition therapy were correct. **Conclusion** Overall there was consistency of variant classifications with most variability between benign or likely benign, and pathogenic or likely pathogenic. However where a variant of uncertain significance (VUS) was reported instead of a likely pathogenic/pathogenic classification this would have an impact on patient management and therefore the need for standardisation has been identified and through education, training and competency assessment this can be achieved.

**Mutation analyses of four Japanese pedigrees with Hereditary Pheochromocytoma/Paraganglioma Syndrome (HPPS): Identification of a novel *SDHB* IVS2-2A>C mutation in two unrelated pedigrees.** *M. Yamanaka<sup>1,3</sup>, K. Shiga<sup>4</sup>, S. Fujiwara<sup>1</sup>, Y. Mizuguchi<sup>1</sup>, S. Yasuda<sup>1,3</sup>, K. Ishizawa<sup>1</sup>, Y. Saiki<sup>1</sup>, K. Higashi<sup>1,2</sup>, T. Ogawa<sup>1,2</sup>, N. Kimura<sup>5</sup>, A. Horii<sup>1</sup>.* 1) Department of Molecular Pathology, Tohoku University School of Medicine, Sendai, Miyagi, Japan; 2) Department of Otolaryngology-Head and Neck Surgery, Tohoku University School of Medicine, Sendai, Miyagi, Japan; 3) Exploring-Germination-and-Growth Program for Young Scientists, Tohoku University, Sendai, Miyagi, Japan; 4) Department of Otolaryngology and Head and Neck Surgery, Iwate Medical University School of Medicine, Morioka, Iwate, Japan; 5) Department of Clinical Research, Pathology Division, National Hospital Organization Hakodate National Hospital, Hakodate, Hokkaido, Japan.

Pheochromocytomas and paragangliomas are neuroendocrine tumors which arise from sympathetic and parasympathetic nerve. Hereditary cases afflicted by both or either pheochromocytomas and paragangliomas have been reported: these are called hereditary pheochromocytoma/paraganglioma syndromes (HPPS). Many cases of HPPS are caused by mutations of one of the *SDHB*, *SDHC*, or *SDHD* genes that encode subunits for the mitochondrial respiratory chain complex II. In this study, we investigated mutations of these genes in six HPPS patients from four Japanese pedigrees using peripheral blood lymphocytes and tumor tissues. Results showed that all of these cases harbored germline mutations in *SDH* genes. In two pedigrees, a novel splice-site mutation in *SDHB* was found, and the tumor RNA of the patient clearly showed frameshift caused by exon skipping. The remaining two pedigrees harbored reported mutations in *SDHB* and *SDHD*, respectively. All these mutations were heterozygous in constitutional DNAs, and two-hit mutations were evident in tumor DNAs. The novel mutation revealed by our study may contribute to improvement of clinical management for patients with HPPS.

**Genetic features in children with acute lymphoblastic leukemia.** *L.T. An, D.Q. Vu, X.H. Nguyen, D.N. Ngo, N.L. Bui, T.H. Le.* Human Genetic Department, National children hospital, Hanoi, Hanoi, Viet Nam.

**Background:** To study chromosome abnormalities and fusion oncogenes caused by chromosomal abnormalities play an important role in acute lymphoblastic leukemia (ALL) especially in children. Detecting the most common fusion oncogenes such as BCR-ABL, MLL-AF4, ETV6-RUNX1 and TCF3-PBX1, will play an important role the assessment of prognosis and indication of treatment regimen. **Methods:** 111 patients were collected in the descriptive study from Feb, 2017 to March, 2018 in the National Children's Hospital, who were recently diagnosed with ALL. Karyotype analysis from bone marrow was performed on all patients. 44/111 patients were done Fluorescence In Situ Hybridization (FISH) to detect the common fusion oncogenes. **Results:** 32/111 (28.83%) patients had been failed karyotype. The frequency of cytogenetic abnormalities, including numerical and structural arrangements was 39.24% (31/79). 16/79 (20.25%) patients had structural chromosomal abnormalities, the most common was t(1;19) in 8.86% (7/79) of the patients. 15/79 (16.46%) patients had hyperdiploid (47-68 chromosomes), five patients complex karyotypes with structural abnormalities. 2/79 (2.53%) patients had hypodiploid, one patient had t(1;19). Complex karyotypes (a finding of three and more chromosomal aberrations in a karyotype) were identified in 5 (6.33%) out of 79 patients. 3 patients had variable chromosome included inv9(p12q13), 9qh+ and 15ps+. Fusion oncogenes were detected in 5 (11.36%) out of 44 patients by FISH, included: 3 patients with ETV6/RUNX1 and 2 patients with MLL/AF4. 17/44 (38.64%) had extra or missed signals (1 to 3 signals) of the oncogenes. **Conclusion:** Applying FISH technique to detect the common fusion oncogenes and bone marrow karyotype analysis at diagnosis should be used to guide treatment decision and prognosis in children with acute lymphoblastic leukemia.

**2816F**

**Recurrent independent cytogenetic characteristics of myelodysplastic syndromes (MDS) and associated IPSS-R risk.** *BaniB. Ganguly.* MGM New Bombay Hospital, Navi Mumbai, Maharashtra, India.

MDS represents heterogeneous clonal pre-malignant condition of hematopoietic stem cells that are typically associated with peripheral blood cytopenia, ineffective hematopoiesis, hypercellular marrow with morphologically defined dysplasia and risk of progression to AML. Conventional cytogenetic anomalies of bone-marrow have been reported in 30% *de novo* MDS and 50% of therapy-related. Del(3q/5q/7q/11q/12p/20q), monosomy 5/7, trisomy 8/19, i(17q), -Y, are frequently detected. A number of anomalies indicate presumptive diagnosis in absence of morphological dysplasia, including del(5q)/-7/del(7q)/del(9q)/-13/del(13q)/del(11q)/t(11q)/del(12p)/t(12p)/-17/del(17p)/i(17q)/+19/t(19)/idic(Xq13); whereas, +8/del(20q)/-Y are not considered as presumptive evidence of MDS because of their global presence in other myeloid neoplasms. Therapeutic response and clinical evolution of chromosomal rearrangements are taken into account for classification and risk-stratification in International Prognostic Scoring System-Revised (IPSS-R). We present cytogenetic data on 314 MDS collected during 2013-2014 of different age groups with prevalence at older group (60-80 years). Conventional cytogenetic investigation was carried out following unstimulated bone-marrow culture. The major observation includes culture failure in 5.4%, and normal and abnormal karyotypes in 48.7% and 45.9% respectively, which is concordant with Schanz et al, 2012 except del(5q), which was detected in all complex aberrations in our study (Table). It has been observed that many of the abnormalities are not considered in IPSS-R classification. Therefore, compilation of cytogenetic data will throw some input in understanding the risk and therapeutic response, and also may propose new cytogenetic risk grouping.

**2817W**

**Cytogenomic characterization of B-Acute Lymphoblastic Leukemia (ALL) with intrachromosomal Amplification of Chromosome 21 (iAMP21) reveals co-existing cytogenetic manifestations and outlines driver alterations that play a role in leukemogenesis.** *R. Garcia, K. Wilson, P. Koduru.* UT Southwestern, Dallas, TX.

B-ALL with iAMP21 is a rare cytogenetic aberration accounting for 2% of cases. It is detected by FISH using the *RUNX1* probe. While amplified *RUNX1* is not considered pathogenic, it is consistently part of the critical region amplified on chromosome 21. In this study, we explored the relationship of other cytogenetic abnormalities underlying evolutionary pathways and identified driver alterations leading to disease progression in this subset of B-ALL. Cytogenetic data from B-ALL patients with iAMP21 from the literature was evaluated for recurring chromosome abnormalities (RCAs), constructed oncogenetic tree to identify evolutionary pathways, identified genes involved in these pathways and in disease progression. Finally oncogenetic signatures and signaling pathways associated with the driver genes were identified. Programs used for the above analyses were tm text analysis in the R environment, TRNCO, PCA, Driver Net Algorithm, and Enrich R. Results from this analysis were applied to classify four institutional cases (3B-ALL one AML) with iAMP21. A total of 412 B-ALLs with iAMP21 were retrieved from the literature; in these karyotypes 31 RCAs were identified. The timed oncogenetic tree analysis of these RCAs revealed seven major and two minor clusters with RCAs 21q-, +X, 20q-, 12p-, 7q-, 11q-, 9p-, +9 and 15q- as entry points, and these were driver alterations. Three other aberrations, 6q-, 13q- and 16q- were determined to be secondary and probably involved in clonal evolution. These driver alterations deregulated DGF-ERK, JAK2, PTEN, HOXA9, KRAS, RAF, MTOR, EGFR, KRAS and E2F1 pathways, and abnormal signaling in JAK-STAT, Toll like receptor and VEGF pathways. CMA data from 4 institutional cases was compared with results from the above analyses. Two cases were assigned to the 21q- pathway. This subset consistently deleted *PCNT* and *DIP2A* and correlated with PDGF-ERK and JAK2 downregulation ( $p = .01$ ). A third case was assigned to the +X category containing *PDK3*, *KDM6A*, *CSF2RA*, *ARHGAP6* and *IL1RAPL1*, all associated in a number of oncogenic pathways including TP53, ATM, NOTCH, KRAS and RAF ( $p > .05$ ). The AML case with iAMP21 was unclassifiable into any of the B-ALL clusters by our data. This analysis suggests B-ALL with iAMP21 is comprised of closely related subset of neoplasms that are characterized by co-existing cytogenetic abnormalities and by functional driver alterations that play a role in tumor progression. Key words: iAMP21, Driver genomic alterations, array.

**Genetic heterogeneity in pediatric alveolar rhabdomyosarcoma tumors.**

*K. Gleditsch<sup>1,2</sup>, J. Penas<sup>2</sup>, D. Mercer<sup>2</sup>, A. Umrigar<sup>2</sup>, M. Stark<sup>2</sup>, F. Tsieng<sup>2</sup>, A. Hollenbach<sup>2</sup>.* 1) Division of Hematology/Oncology, Department of Pediatrics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) Department of Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 3) Department of Pathology, Children's Hospital New Orleans, New Orleans, LA.

In the United States, more than 13,000 cases of soft tissue sarcomas are diagnosed per year, of which over 5,000 are fatal. Rhabdomyosarcoma is the most common pediatric type of soft tissue sarcoma affecting skeletal muscle. The alveolar subtype (ARMS) typically has a more aggressive clinical course and portends a poorer clinical prognosis than the embryonal subtype (ERMS). Therefore distinguishing between the two subtypes is necessary for appropriate treatment. ARMS is genetically characterized by one of three translocation states: the presence of a translocation between chromosomes 2 and 13 [t(2;13)(p35;p14)] leading to the production of the PAX3-FOXO1 fusion protein, the presence of a translocation between chromosomes 1 and 13 [t(1;13)(p35;q14)] leading to the production of the PAX7-FOXO1 fusion protein or a lack of translocation leading to fusion negative status. These oncogenic proteins have the potential to enhance the local invasive capacity of the tumor cells and increase metastatic potential, PAX3-FOXO1 more so than PAX7-FOXO1. Multimodality analyses, such as SNP array and RT-PCR, have previously shown that significant heterogeneity regarding the number of translocations exists within tumor tissue samples from rhabdomyosarcoma patients, leading to a variation in clinical outcome. The aim of this study is to investigate the heterogeneity of pediatric ARMS tumor specimens obtained from patients of the Children's Hospital of New Orleans Hematology/Oncology clinic. We have designed and validated a fluorescence in situ hybridization (FISH) probe in our laboratory that can simultaneously and distinctively identify t(2;13) and t(1;13) translocations. Thirty-six tumor samples from rhabdomyosarcoma patients ranging in age from 6 months to 18 years were analyzed to determine the presence of these clinically significant translocations and the extent of heterogeneity within each sample. In addition to identifying varying numbers of translocation events within nuclei, we also observed a large amount of heterogeneity with respect to the percentage (7-96%) of translocation positive nuclei within tumor samples, along with differences in the extent of aneuploidy within individual cells. Our analysis of the cytogenetic markers for the t(2;13) and t(1;13) demonstrates that these translocations exhibit significant variation within these rhabdomyosarcoma samples providing a potential method to improve diagnostic and prognostic indicators for these tumors.

**Translocation (3;8)(q26.2;q24) in myeloid neoplasm: Report of two new cases and review of the literature.** J. Liu<sup>1</sup>, N. Benvenuto<sup>2</sup>, G. Uppa<sup>3</sup>, S. Nedumakel<sup>1</sup>, D. Foster<sup>1</sup>, E. Johnson<sup>4</sup>, J. Gong<sup>4</sup>, Z. Wang<sup>4</sup>, S. Peiper<sup>5</sup>. 1) Clinical Cytogenomics Laboratory, Department of Pathology, Anatomy, and Cell Biology Thomas Jefferson University, 1025 Walnut Street, Philadelphia, PA 19107; 2) Sidney Kimmel Medical College, Thomas Jefferson University 1025 Walnut Street, Philadelphia, PA 19107; 3) Section of Hematopathology, Hematology and Flow Cytometry, Department of Pathology, Anatomy, and Cell Biology, Sidney Kimmel Medical College, Thomas Jefferson University, 125 South 11th Street, Philadelphia, PA 19107; 4) Molecular & Genomic Pathology Laboratory, Department of Surgery, Pathology, Anatomy, and Cell Biology, Thomas Jefferson University, 1025 Walnut Street, Philadelphia, PA 19107; 5) Department of Pathology, Anatomy, and Cell Biology, Thomas Jefferson University, 1020 Locust Street, Philadelphia, PA 19107.

Translocation (3;8)(q26.2;q24), involving the *MECOM* gene complex (*MDS1* and *EV11* Complex Locus), is an extremely rare chromosomal abnormality in myeloid neoplasms. At present, there are only 23 cases reported in literature, mainly found in AML, MDS, CMML and blastic phase of CML. Patients with t(3;8)(q26.2;q24) demonstrate overlapping features to those with other types of 3q26 abnormalities, such as elevated platelet counts, multilineage dysplasia, monosomy 7 and poor clinical outcomes. The underlying molecular pathological mechanism is not well understood mainly due to the rarity of this entity. Here we report the clinical, morphological, cytogenetics, molecular genetics and prognostic features in two AML cases with t(3;8). Available clinical data was reviewed, including age, gender, presentation, treatment, response and outcomes. Peripheral blood smears, bone marrow aspirate and core biopsy results were assessed. Bone marrow cellularity, blast morphology and percentage, background dysplasia were particularly studied. Immunophenotype by flow cytometry and/or immunohistochemistry and laboratory data were also collected. Patient 1 was a 74-year-old male with a history of CMML. The bone marrow biopsy showed significantly increased blasts (64%) and markedly hyperplastic atypical megakaryocytes. Cytogenetics and FISH studies demonstrated 46,XY,t(3;8)(q26;q24), -7 and three copies of *MECOM* consistent with a rearrangement. Next generation sequencing (NGS) technology based hematological malignancy gene panel test revealed pathogenic mutations in genes *ASXL1*, *FLT3*, *KRAS*, *PTPN11*, *SRSF2* and *TET2*. The patient had persistent poor response to chemotherapy and died four year later after the initial diagnosis. Patient 2 was a 54-year-old male with a history of MDS-RAB. The bone marrow biopsy showed dramatically increased blasts (~90%) and significant megakaryocytic dysplasia. Cytogenetics and FISH studies demonstrated 46,XY,t(3;8)(q26;q24), -7 and a c-MYC gene rearrangement. NGS based molecular test revealed pathogenic mutations in genes *IDH2* and *NRAS*. The patient was lost to follow up later on. In summary, two new cases with t(3;8) were reported, a thorough review of currently published clinical cases were also performed, and possible mechanisms in addition to overexpression of the *MECOM* gene are discussed. This is also believed to be the first time that NGS panel test was included to describe this unique entity.

**2820W**

**Molecular cytogenetic characterization of Rh30 and Rh4 alveolar rhabdomyosarcoma (ARMS) cell lines.** J.A. Peñas<sup>1</sup>, K. Gleditsch<sup>1,2</sup>, D. Mercer<sup>1</sup>, A. Umrigar<sup>1</sup>, Y. Li<sup>3</sup>, T.J. Chen<sup>3</sup>, A. Hollenbach<sup>1</sup>, F. Tsieng<sup>1</sup>. 1) Department of Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) Children's Hospital of New Orleans, New Orleans, LA; 3) Hayward Genetics Center, Tulane School of Medicine, New Orleans, LA.

Rhabdomyosarcoma, the most common soft tissue sarcoma in children, is comprised of two subtypes: alveolar (ARMS) and embryonal (ERMS). ARMS makes up 30% of all rhabdomyosarcoma cases, is typically more aggressive, and has a poorer clinical prognosis. ARMS is characterized by the presence of the t(2;13)(q35;q14) or t(1;13)(p36;q14) translocations, leading to the creation of the PAX3-FOXO1 and PAX7-FOXO1 oncogenic fusion proteins, respectively, with the PAX3-FOXO1 variant being more aggressive. Up until now the only commercially available diagnostic fluorescence *in situ* hybridization (FISH) probe for detecting the presence of the translocation, a FOXO1 breakpoint probe, was not capable of differentiating between these events, making accurate diagnosis difficult. Therefore, we designed novel probes capable of simultaneously differentiating PAX3-FOXO1 and PAX7-FOXO1, allowing for a more accurate diagnosis. We used these probes to address the specific aims of this project, which is to determine the significant large-scale genetic similarities and differences between Rh4 and Rh30 cell lines, two of the most commonly used ARMS cell lines, which derive from pediatric patients clinically diagnosed with ARMS. We utilized G-banding, FISH, spectral karyotyping (SKY), and array comparative genomic hybridization (aCGH), followed by pathway analysis which utilizes bioinformatics to uncover affected cellular processes and networks. Initial FISH results demonstrate that Rh30 had a higher number of PAX3-FOXO1 fusions compared to Rh4 whereas Rh4 had significant amplification of *PAX3*, *PAX7*, and *FOXO1*. Consistent with our FISH results, G-banding demonstrated a significant difference in ploidy between Rh4 and Rh30. Initial SKY analysis of Rh4 shows large scale and highly complex chromosomal rearrangements and aneuploidy throughout the genome. Our aCGH data confirmed large-scale insertions and deletions in gene regions previously associated with ARMS. Bioinformatics analysis of genes present in these regions of insertion and deletion identified genes previously associated with ARMS while also identifying novel DNA markers that could potentially be used for clinical diagnosis and the development of targeted therapies. Therefore, the resulting cytogenetic profile and bioinformatics analysis of these cell lines may potentially be used as a reference for ARMS researchers with our novel probes providing greater specificity for more accurate diagnosis for ARMS patients.

**2821T**

**T(3;8)(q26.2;q24) is commonly associated with therapy-related myeloid neoplasms and involves MECOM/MYC rearrangement.** G. Tang, S. Hu, Z. Tang, G. Toruner, J. Medeiros, W. Xie. Hematopathology, University of Texas MD Anderson Cancer Center, Houston, TX.

**BACKGROUND** T(3;8)(q26.2;q24) is a rare recurrent cytogenetic abnormality and ~20 cases have been reported. Most cases reported were myeloid neoplasms and showed *MECOM* rearrangement. The clinicopathologic, cytogenetic and molecular features of myeloid neoplasm with t(3;8)(q26.2;q24) have not been well characterized. **METHODS** We retrospectively reviewed the cytogenetic archives in our hospital over the past 20 years (1998-2018) and identified 20 patients who had myeloid neoplasm with t(3;8)(q26.2;q24). A detailed chart review was conducted; FISH analysis for *MECOM* and *MYC* rearrangements using break-apart probes was performed in cases with BM material available. **RESULTS** The study group included 12 men and 8 women, with a median age of 61 years (range, 21-79). Eleven patients had therapy-related myelodysplastic syndromes (MDS, n=3) or acute myeloid leukemia (AML, n=8); 7 had blast phase of chronic myeloid leukemia (CML, n=4) or chronic myelomonocytic leukemia (CMML, n=3); 1 had primary MDS and 1 had primary AML. Four patients had t(3;8)(q26.2;q24) as the sole abnormality, 7 had one additional abnormality and 9 had 2 or more additional chromosomal abnormalities; monosomy 7 was detected in 5 patients. *MECOM* rearrangement was confirmed in 13/14 patients and *MYC* rearrangement in 12/14 patients by FISH. *MYC* expression was assessed in 14 patients by immunohistochemistry, all 14 patients had *MYC* expression, ranging from 20% to 70%, and the level was largely correlated with the percentage of blasts in bone marrow. Fourteen patients underwent gene mutation testing, including 6 patients with targeted next generation sequencing, 7 of 14 patients showed at least one gene mutation, including *ASXL1* (2/6), *TET2* (2/6), *SRSF2* (2/6), *NRAS* (2/12), *ABL1* (1/6), *CBFB* (1/6), *BRINP3* (1/6), *GATA2* (1/6), and *RUNX1* (1/6). *FLT3* mutation was not detected in any of 14 patients tested. Fourteen patients were treated with chemotherapy or hypomethylating agents, with or without tyrosine kinase inhibitors. At the last follow-up, 18 patients died and 2 were alive with persistent disease, the median overall survival was 6 months. **CONCLUSION** T(3;8)(q26.2;q24) often leads to *MECOM/MYC* rearrangement and is highly associated with therapy-related myeloid neoplasms and advanced stage of disease. Patients with this chromosomal abnormality often have very poor outcomes.

**2822F**

***ETV6* deletion as a potential biomarker for blastic plasmacytoid dendritic cell neoplasm.** Z. Tang, W. Wang, G. Tang, N. Pemmaraju, S. Hu, C. Yin, M. Konopleva, G.A. Toruner, L.J. Medeiros, J.D. Khoury. University of Texas MD Anderson Cancer Center, Houston, TX.

**Background:** As a rare and aggressive hematologic malignancy with very poor prognosis, over 50% blastic plasmacytoid dendritic cell neoplasm (BPDCN) cases present chromosomal abnormalities detected in bone marrow specimen, approximately 40% of them with an involvement of 12p, mostly a deletion of 12p or other structural abnormalities involving rearrangement of *ETV6* gene located on 12p. In this study, we investigate the potential application of *ETV6* gene as a biomarker for this group of BPDCN cases. **Methods:** Patients with confirmed BPDCN treated at our institution from January 2014 to April 2017 were included in this study. Conventional cytogenetic analysis was routinely performed as a workup and staging of BM specimen in all cases. Fluorescence in situ hybridization (FISH) and array comparative genomic hybridization (CGH) to assess *ETV6* or the 12p locus were performed in selected cases according to the physician's orders. Additional *ETV6* FISH tests were performed on archived BM specimen of 11 cases and skin biopsy specimen of 6 cases respectively. Clinical and laboratory data were collected by electronic medical chart review. **Results:** Twenty-seven men and 5 women, with a median age of 64 years (range, 2 to 84 years) were included in this study. Six out of 12 cases with an abnormal karyotype exhibited an apparent 12p involvement by conventional cytogenetics in the BM specimen. Notably, chromosome 12p aberrations resulting in *ETV6* rearrangement were detected in 2 BM samples without morphologic or immunophenotypic involvement by BPDCN. We then assessed 29 BM samples collected at different time points from 11 BPDCN patients by FISH and identified 3 cases with *ETV6* deletion that were not detectable by karyotype analysis previously. Very interestingly, the detection of *ETV6* deletion was consistent with the clinical course of BPDCN diseases in these patients. Notably, *ETV6* deletion is detected in all 6 skin biopsy specimen involved by BPDCN. **Conclusions:** Chromosomal aberrations involving *ETV6* (including *ETV6* deletion and rearrangement) are highly prevalent in BPDCN. The rate of *ETV6* aberrations seems highest in disease lesions involving the skin, a feature of potential diagnostic utility at presentation. In some instances, aberrations involving the *ETV6* locus may be identified in the BM in the absence of detectable involvement by BPDCN. The *ETV6* can be a potential biomarker for BPDCN.

**Duplication of the band q21q27 on the long arm of chromosome 3 : A rare cytogenetic event in B-Chronic Lymphocytic Leukemia (B-CLL).** D. Zhao<sup>1,2</sup>, K. Liu<sup>1,2</sup>, A. Nguyen<sup>1,2</sup>, D. Chung<sup>1,2</sup>, J. Reinartz<sup>3,4</sup>, D. Serk<sup>2</sup>, J. Ahmad<sup>3</sup>, L. Bartholomaeus<sup>3</sup>, K. Stieglbauer<sup>3,4</sup>, A. Reyes<sup>1,2</sup>, C.A. Tirado<sup>2,3,4,5</sup>. 1) UCLA, Los Angeles, CA; 2) The International Circle of Genetic Studies, Los Angeles, CA; 3) Allina Health, Inc. Minneapolis, MN; 4) HPA, Minneapolis, MN; 5) The University of Minnesota, Department of Laboratory Medicine & Pathology, Minneapolis, MN.

We present the case of an 83-year-old female with a long history of B-CLL followed by observation only. Twelve years after her diagnosis of CLL, routine follow-up chromosome analysis of peripheral blood revealed an abnormal metaphase with a dup(3)(q21q27) in 18 of 20 metaphase cells. To further characterize the abnormal chromosome 3, fluorescence in situ hybridization (FISH) was performed using the Abbott BCL6 probe for 3q27. An additional BCL6 signal was observed in 303 of the 500 interphase nuclei examined. The ISCN was reported as 46,XX,dup(3)(q21q27)[1]/46,XX[2]. nuc ish(5'BCL6, 3'BCL6)x3(5'BCL6 con 3'BCL6x3)[303/500]. This abnormality was seen again in one of three available metaphases in a follow up peripheral blood study 5 years later, consistent with persistent disease. Molecular genetic analysis identified the presence of somatic hypermutation of the immunoglobulin heavy chain gene variable region (IGH-V), which is recognized as an independent favorable prognostic marker in CLL. FISH analysis was negative for loss of SEC63 (6q21), amplification of MYC (8q24), loss of ATM (11q22.3), trisomy 12, loss of D13S319 (13q14.3), loss of TP53 (17p13.1) and CCND1/MYEOV/IGH rearrangement [t(11;14) (q13;q32.30)]. Partial trisomy 3 is a relatively rare event seen in B-CLL, with commonly overrepresented segments including the q21-23 region and the q25-29 region of the long arm of chromosome 3, as well as changes leading to gains of 3q26-q27. The clinical significance of this finding in B-CLL is uncertain; however, our patient remains well and has not required therapy 17 years after her initial diagnosis. .

Friedman<sup>1</sup>, K. Offit<sup>2,3</sup>, J.M. Kalish<sup>4,5</sup>, M. Walsh<sup>1,2,3</sup>. 1) Department of Pediatrics, Memorial Sloan Kettering Cancer Center, New York, NY; 2) Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; 3) Niehaus Center for Inherited Cancer Genomics, Memorial Sloan Kettering Cancer Center, New York, NY; 4) Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 5) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Sixteen thousand children are diagnosed with cancer annually in the US. Recent molecular studies show that approximately 10% of children with cancer are born with a pathogenic mutation in a known cancer predisposition gene, however this is considered a low estimate. Gene discovery efforts and cancer susceptibilities revealed through non-DNA sequencing assays will add to the understanding of predisposition. Wilms tumor represents less than 5% of pediatric cancer. Predisposition to Wilms tumor is reported in 10-15% of patients, and 1% of patients have a family member with a history of Wilms tumor. Overt syndromes, such as Beckwith-Wiedemann Syndrome (BWS; characterized by overgrowth, glucose dysregulation, omphalocele, ear anomalies, etc.), familial Wilms tumor, and isolated cases of Wilms tumor are each reported having underpinning germline susceptibility. Cancer susceptibility resulting from mosaic DNA sequence mutations in cancer predisposition genes such as *TP53* and *RB1* are recognized, however parallel examples resulting from mosaic epigenetic alterations in non-overtly syndromic populations are less appreciated. Here we describe test results for six patients entering our predisposition clinic with a diagnosis of Wilms tumor. Four patients had bilateral tumors (stage V) while two had unilateral (one stage III, one stage IV). Age at diagnosis ranged from 2.1 to 6.5 years. Only two patients had other clinical manifestations of BWS (one with hemihyperplasia, one with mild neonatal hypoglycemia). All six underwent agnostic methylation testing of the BWS locus at 11p15. Genomic DNA extracted from blood was treated with sodium bisulfite followed by quantitative methylation sensitive PCR to measure the degree of methylation at the IC1 and IC2 regions on 11p15. The degree of methylation detected at IC2 ranged from 53.81% - 56.28% (normal range 50.00% +/- 1.54%), consistent with low-level mosaic gain of methylation. These results suggest that more patients are potentially mosaic for imprinting disorders than previously recognized, and routine sequencing currently deployed by many oncologists is insufficient to identify cancer susceptibility in all pediatric cancer patients.

**Assessment of *BAP1* germline alterations in uveal melanoma.** R. Pilarski<sup>1</sup>, M.H. Abdel-Rahman<sup>1,2</sup>, G. Boru<sup>2</sup>, T. Grose<sup>2</sup>, F.H. Davidorf<sup>2</sup>, C.M. Cebulla<sup>2</sup>.

1) Division of Human Genetics, Dept of Internal Medicine, Comprehensive Cancer Center, The Ohio State University, Columbus, OH; 2) Department of Ophthalmology and Visual Science, The Ohio State University.

**Objective:** The aim of this study is to assess the frequency of germline *BAP1* mutation and deletion/duplication in uveal melanoma (UM) patients with strong personal and family histories of cancers. **Methods:** Germline mutations in *BAP1* were assessed in 172 UM patients with moderate to high risk for hereditary cancer predisposition by direct (Sanger) sequencing. Germline large deletions and duplications were assessed by multiplex ligation probe amplification (MLPA) and epigenetic inactivation by pyrosequencing. The expression of *BAP1* was assessed in 17 non-tumor choroids by qRT-PCR. **Results:** We identified 28 patients with one or more germline variants in *BAP1*, 7 of these were deleterious (4 nonsense and 3 frame shift deletions). The remaining 21 patients had benign/likely benign variants. Germline large deletion/duplication was successfully assessed in 140 patients and in one patient a whole gene deletion was detected. The proband with whole gene deletion was diagnosed with UM at age 16 with no personal or family history of other cancers. The highest frequency of pathogenic *BAP1* alterations - 6/17 (35.3%) - was in patients with UM and personal/family history of  $\geq 2$  *BAP1*-related cancers followed by patients with young age of onset 4/21 (19%) and familial UM 6/34 (17.6%). No significant evidence of constitutional promoter hypermethylation was detected in the samples tested. Two out of the 17 non-tumor choroid tissues showed decrease in *BAP1* RNA expression compared to normal controls. No detectable germline genomic alteration or aberrant promoter methylation was identified suggesting other mechanisms for epigenetic *BAP1* inactivation. **Conclusions:** *BAP1* is an important candidate for hereditary predisposition to UM but additional candidate genes exist. Assessment for large deletions should be included in clinical testing. In UM patients a strong personal or family history of cancer associated with *BAP1*, early age of onset and familial UM are each risk factors germline mutations in *BAP1*.

**Differential association of Lynch syndrome genes with colorectal and breast cancer.** A.D. Zimmer, J. van den Akker, C.L. Neben, A.Y. Zhou. Color Genomics, Burlingame, CA.

**Background:** Lynch syndrome (LS) is an inherited condition that greatly increases the risk of multiple cancers, including colorectal, endometrial, and ovarian cancer. Pathogenic variants in *MSH2* and *MLH1* are identified in 70-90% of LS families whereas *MSH6* and *PMS2* are estimated to account for 10-30% and *EPCAM* for 1-3%. The spectrum of cancer risks associated with variants in these genes has been reported to vary by gene, with *MLH1* and *MSH2* conferring a higher risk for colorectal and endometrial cancer and an earlier age of onset. Recent evidence has also suggested that some of these genes differentially increase breast cancer risk. **Methods:** We analyzed a cohort of 546 individuals who received NGS panel testing for hereditary cancer risk from Color Genomics and were identified to have a pathogenic or likely pathogenic (hereafter referred to as pathogenic) variant in *MLH1*, *MSH2*, *MSH6*, *PMS2*, or *EPCAM*. Individuals with more than one pathogenic variant or a homozygous variant were excluded from the analysis. Familial relationships were not assessed. Personal history of cancer was based on information reported by the individual or ordering physician, and phenotype analysis was limited to individuals with sufficient information. **Results:** The pathogenic variants in this cohort were evenly distributed across *MLH1* (101), *MSH2* (137), *MSH6* (156), and *PMS2* (152). Colorectal cancer was more closely associated with *MLH1* (28/73, 38%) and *MSH2* (22/98, 22%) than with *MSH6* (5/132, 4%) and *PMS2* (7/117, 6%) ( $p < 0.01$ ), consistent with previous studies. Similarly, the mean age of colorectal cancer onset was lower for *MLH1* (40.3 $\pm$ 13.0 yrs) and *MSH2* (42.1 $\pm$ 8.3 yrs) than for *MSH6* (50.4 $\pm$ 19.2 yrs) and *PMS2* (49.4 $\pm$ 10.0 yrs,) (*MLH1/MSH2* vs *MSH6/PMS2*,  $p = 0.03$ ). Among females in the cohort, there were no differences in reported personal history of breast cancer in *MSH2* (9/51, 18%), *MSH6* (10/77, 13%), and *PMS2* (12/69, 15%), ( $p = 0.70$ ). Intriguingly, breast cancer was less reported with *MLH1* (2/45, 4%), but did not reach statistical significance ( $p = 0.10$  vs *MSH2/MSH6/PMS2*). The age of breast cancer onset was not different between genes. **Conclusions:** The spectrum of cancers in this cohort supports previous data that *MLH1* and *MSH2* have greater association with colorectal cancer than *MSH6* and *PMS2*. However, we observed that *MSH2*, *MLH6*, and *PMS2* were more associated with breast cancer than *MLH1*, providing evidence for a differentiation of breast cancer risk amongst LS genes.

**2827T****Genotyping ccfDNA in cerebrospinal fluid as a new source of liquid**

**biopsy.** O. Sonmezler<sup>1</sup>, I. Boga<sup>1</sup>, C. Mujde<sup>1</sup>, A. Bisgin<sup>1,2</sup>. 1) Cukurova University AGENTEM (Adana Genetic Disease Diagnosis and Treatment Center), Adana, Turkey; 2) Cukurova University, Faculty of Medicine, Medical Genetics Dept of Balcali Hospital and Clinics, Adana, Turkey.

**Objective:** Central nervous system (CNS) involvement is clinically important and a major challenge in oncology due to high morbidity and mortality rates. Thus, liquid biopsy of cerebrospinal fluid (CSF) derived ccfDNA might be effective in tracking clinically relevant genomic alterations in cancer patients with CNS metastasis. Where in applied next generation sequencing of CSF and peripheral blood derived ccfDNA and compared with the FFPE tissue sample from the primary tumor by a targeted multi-gene panel in a gastric cancer patient. **Method:** FFPE tissue sample from primary localized tumor, liquid biopsy sample from peripheral blood and also CSF were obtained from the patient. gDNA (genomic DNA) isolated from FFPE tissue sample while ccfDNA (circulating cell-free DNA) isolated from both peripheral blood and the cerebrospinal fluid. We measured the concentration of DNA using our usual protocol and each of them compared. Multi-gene panel including *AKT1*, *ALK*, *BRAF*, *DDR*, *ERBB2*, *ESR1*, *KIT*, *KRAS*, *MAP2K1*, *NRAS*, *NTRK*, *PDGFRA*, *PIK3CA*, *PTEN*, *ROS1*, *RICTOR*, *EGFR*, *MET* and *FGFR1* genes and copy number changes in *RICTOR*, *EGFR*, *MET*, *FGFR1* and *ERBB2* genes were sequenced and analyzed via GeneReader NGS System. **Results:** Unique R776H variant in *EGFR* gene which reported as “panitumumab” drug sensitivity for gastric cancer was captured in CSF ccfDNA when compared with plasma and primary tissue. Also *FGFR1* amplification was identified in plasma, while non in FFPE tissue sample. **Conclusion:** Liquid biopsy of CSF for the precise characterization and molecular diagnosis of tumors with CNS metastasis can be used to both complementary and/or more efficiently facilitate diagnosis and prognosis.

**2828F****Clinical relevance of circulating tumor DNA assessed through amplicon-based next-generation sequencing in cancer.** H. Zembutsu<sup>1</sup>, H. Osumi<sup>2</sup>, K. Yamaguchi<sup>2</sup>, E. Shinozaki<sup>2</sup>, M. Ozaka<sup>3</sup>, T. Sasaki<sup>3</sup>, N. Sasahira<sup>3</sup>.

1) Cancer Precision medicine Center, Cancer Institute, TOKYO, JAPAN; 2) Department of Gastroenterological Chemotherapy, Cancer Institute Hospital, Japanese Foundation for Cancer Research, TOKYO, JAPAN; 3) Department of Gastroenterology, Cancer Institute Hospital, Japanese Foundation for Cancer Research, TOKYO, JAPAN.

The development of circulating tumor DNA (ctDNA) panel covering hundreds of mutations is important to establish high sensitive diagnostic system for cancer. We enrolled 101 and 76 patients with metastatic colorectal (CRC) and pancreatic cancer (PC), respectively. The genomic profiling of 14 genes in plasma were performed to evaluate the feasibility of this panel. Somatic mutations were detected in 87.1% and 90.8% of patients with CRC and PC in their plasma, respectively. The Mutations in *TP53*, *KRAS* and *APC* genes were detected in 69.3%, 38.6% and 23.7% in CRC patients, and 64.3%, 60.5%, 13.2% in PC patients. ctDNA level were significantly associated with metastasis (liver,  $P<0.00001$ , lymph node,  $P=0.008$ , number of metastatic organs,  $P<0.0001$ ), tumor markers (CEA and LDH,  $P<0.0001$ , CA19-9,  $P=0.006$ ), and tumor diameter (maximum and sum of diameter,  $P<0.0001$ ). The overall concordance rate of *RAS* status between ctDNA and matched CRC tissue was 77.2%. PC patients with lower ctDNA level showed significantly longer overall survival ( $P=0.00000026$ ). These results suggest that profiling of mutated genes in the panel could be biomarkers to monitor changes in mutational status and tumor burden.

**Rapid detection of genomic rearrangements and gene fusions in human leukemias using Oxford nanopore sequencing.** P. Zuzarte<sup>1</sup>, T. Murphy<sup>2</sup>, K. Garimella<sup>3</sup>, M. Minden<sup>2</sup>, J. Simpson<sup>1,4</sup>. 1) Genome Technologies, Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 2) Princess Margaret Cancer Centre, University Health Network, Toronto, Canada; 3) Li Ka Shing Centre for Health Information and Discovery, University of Oxford, Oxford, UK; 4) Department of Computer Science, University of Toronto, Toronto, Canada.

**Genetic rearrangements are a hallmark of many human hematological disorders. The correct identification of genetic rearrangements plays an important role in the diagnosis and treatment of these disorders. Although cytogenetics and FISH are considered the gold standard for identifying genetic arrangements in human Leukemias, these tests can take several days to complete and often miss small or cryptic genetic rearrangements. The Oxford Nanopore MinION is a small handheld sequencer that is capable of sequencing long fragments of DNA, often in excess of 10kbp, or nascent full-length RNA directly. In this proof of concept study, we show that nanopore sequencing can be used to rapidly detect and identify novel rearrangements in clinical samples from 6 patients who have been diagnosed with various forms of leukemia. Nanopore sequencing detects cryptic chromosomal rearrangements that are below the detectable level of resolution for cytogenetics (5Mb) and is capable of performing real-time basecalling, enabling the the rapid detection of rearrangements, often within 24 hours of initiating a sequencing run. Chromosomal breakpoints that were identified through DNA sequencing were validated by PCR amplification. Single molecule sequencing of full length nascent poly-adenylated RNA was also used for rapid validation of transcribed fusion gene products and may also offer other insight into fusion gene transcription. .**

**2830T**

**Validation of a targeted massively parallel sequencing panel for the clinical diagnostic testing of fusion genes associated with hematological malignancies.** M.R. Avenarius<sup>1</sup>, E. Stonerock<sup>1</sup>, S.C. Reshmi<sup>1,2,3</sup>, R. Pfau<sup>1,2,3</sup>, V. Magrini<sup>1,3</sup>, C.E. Cottrell<sup>1,2,3</sup>, J. Gastier-Foster<sup>1,2,3</sup>, E. Zmuda<sup>1,2,3</sup>. 1) Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH; 2) Department of Pathology, The Ohio State University College of Medicine, Columbus, OH; 3) Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH.

Hematological malignancies are derived from oncogenic mutations in the proliferative, blood-forming cells and include leukemias, lymphomas and myelomas. Recurrent gene fusions drive oncogenesis in a significant proportion of these hematologic diseases and their presence often carries diagnostic, prognostic or therapeutic ramifications. To this end we clinically validated a customized Archer® FusionPlex® Pan-Heme assay that targets 148 genes for the detection of both known and novel fusion events. Through this work we optimized assay performance on a range of Illumina instrumentation, identified strategies to systematically assess assay quality, and developed bioinformatic tools beyond the standard Archer pipeline to ensure robust assessment of clinical results. Experimentation to test assay performance included the establishment of platform sensitivity and specificity, reproducibility and definition of the limits of detection. Through these experiments we also identified inconsistencies in the ability to detect immunoglobulin rearrangements and thus developed improved analytical methods for their detection. After meeting our internal standards for assay performance, a focused version of this assay, limited to genes associated with Acute Lymphoblastic Leukemia rearrangements, was launched. To date, we have completed testing on 93 cases. 54% of these cases were children/young adults (<30) while the remaining were adult patients (46%). Our cohort was primarily comprised of presumed Acute Lymphoblastic Leukemia diagnoses, however, a limited number of other hematological diseases were represented (ie myeloproliferative disorders). Of the 93 cases analyzed, 37.5% (n=35) tested positive for a verified, clinically meaningful fusion event. The majority of fusion positive cases harbored recurrent fusion events with previous associations to hematological malignancies (91.5%), while 8.5% (n=3) harbored novel fusion events. Compared to other fusion detection methods such as RT-PCR or FISH, our validation of the custom FusionPlex® Pan-Heme assay demonstrates the ability to detect novel gene fusion events with increased sensitivity (≥ 10% blast), specificity (100%), and precision (100% of fusions tested reliably detected within/between runs). In addition, the actionable fusions detected by this assay have significant diagnostic, prognostic or therapeutic implications and illustrates the increased clinical utility of this diagnostic test.

**Comprehensive evaluation of data quality in public population databases guides pathogenic allele frequency threshold determination for variant classification downgrades in hereditary cancer genes.** *M. Jones, H. Cox, L. Esterling, J.P. De La O, T. Judkins, S. Manley, K. Bowles, D. Mancini-DiNardo, B. Coffee.* Myriad Genetic Laboratories, Inc., Salt Lake City, UT.

**Background:** Data in research grade population databases, such as gnomAD, are often used by clinical testing laboratories as evidence in variant classification as recommended by ACMG/AMP guidelines. Specifically, a variant allele frequency (AF) higher than the expected disease prevalence associated with pathogenic variants in that gene may be used as evidence that the variant is benign. However, careful evaluation of the data available in such databases is necessary to avoid misclassification of variants. Here we report on a comprehensive quality assessment of gnomAD data for germline variants in 24 cancer-predisposition genes. **Methods:** Quality of the gnomAD data was analyzed for germline variants in 24 genes included on our laboratory's hereditary pan-cancer panel at every genomic position within the laboratory review window. Quality metrics analyzed included coverage, sequence complexity, NGS read frequencies, mapping quality, pseudogene homology, and somatic contamination. Pathogenic AF thresholds for each gene were determined by assessing variants identified by our laboratory in the course of clinical testing of >500,000 patients that are also present in gnomAD, along with estimates on penetrance, allelic and locus heterogeneity. **Results:** Quality issues were identified for germline variants in all 24 genes that would result in inaccurate AFs, including artifacts caused by homopolymer tracts, presence of somatic variants likely due to clonal hematopoiesis, and variants identified in pseudogenes that incorrectly map to the functional gene. As a result of this analysis, gnomAD data were fully excluded as evidence for variant classification for two genes and partially excluded for three genes due to inadequate quality. After assessment of quality, a maximum expected pathogenic AF threshold was determined. These AF thresholds were used to reclassify 40 variants in 12 genes from uncertain clinical significance to benign, impacting over 6,000 patients. **Conclusions:** Although public population databases can be an excellent resource for variant classification in research applications, the data require thorough review prior to integration into clinical applications to avoid potential variant misclassification. Use of vetted data that only includes high quality regions can result in greater accuracy in setting pathogenic AF threshold cutoffs for use in downgrading variants.

**2832W**

**Benefits in the surveillance of the copy number of *RUNX1* in childhood B-ALL patients from targeted gene sequencing.** *M. Wang, P. Cao, Y. Zhang, F. Wang, Y. Zhang, H. Liu, T. Wang, H. Liu.* Pathology & Laboratory Medicine Division, Hebei Yanda Lu Daopei Hospital, Si Pu, Beijing, China.

**Objective** Intrachromosomal amplification of chromosome 21 (iAMP21) defines a distinct cytogenetic subgroup of childhood BCP-ALL and have a dismal outcome when treated as standard risk. It is defined by multiple copies of the *RUNX1* gene (3 or more additional *RUNX1* signals) by FISH and is difficult to be detected by karyotyping. However, many limitations may have led to the underestimated diagnosis of patients with iAMP21. **Methods** We retrospectively analyzed the next generation sequencing data (targeted 58 genes involved in hematological malignancies) of 510 patients with B-ALL by ONCOCNV to calculate the copy number variation of *RUNX1* gene. **Results** A total of 49 (9.6%) cases were identified with *RUNX1* copy number gain. Chromosome karyotyping results are available in 30 cases. Among them 11 cases have duplication of chromosome 21, the remaining 19 cases have chromosome abnormalities not involved in chromosome 21 duplication and the median copy number gain was 3.5 copies (rang 3-5.5 copies). Analysis of the prognosis of the 19 patients found that 9 (47.4%) cases relapsed. Three of 19 cases performed FISH and were diagnosed with iAMP21, the copy number of *RUNX1* gene from sequencing data are concordant with FISH signals for all the three patients. The *RUNX1* copy number gain analyzed from next generation sequencing may suggest the diagnosis of iAMP21 and need to be confirmed by further testing. In addition, it is noteworthy that these patient concomitants with unique spectrum of secondary genetic abnormalities, including chromosomes gains (X, 6q and 10) or deletions (7q and 11q), which may also be used to improve the diagnosis of iAMP21. **Conclusion** In summary, we developed a potential strategy to improve the identification of iAMP21, thus improving the prognosis of patients within this high-risk group. .

Constitutional epimutations are an alternative to genetic mutations in the etiology of genetic diseases. These epimutations can be primary, defined as purely epigenetic events labile in the germline. They can also be secondary, caused by a *cis*-acting genetic defect transmitted following a Mendelian inheritance pattern, with re-establishment of the epigenetic change in the offspring. Constitutional epimutations of *MLH1* have been identified as a rare etiology of Lynch syndrome. Patients with primary *MLH1* epimutations, as well as a few families with secondary *MLH1* epimutations, have been reported. A secondary epimutation is usually suspected when 2 epimutation-carriers are diagnosed within a family and validated when the *cis*-acting genetic cause is identified. This is crucial to determine the risk of transmission in the family and to offer accurate genetic counseling to relatives. We have recently reported a first series of Lynch syndrome patients with a broad spectrum of genetic defects associated with their *MLH1* epimutation (Genetics in Medicine, 2018). We present here these results extended to a second series of patients, representing a total of 28 probands. Various types of variations were found to be associated with *MLH1* secondary epimutations, including single nucleotide variations, copy number variations and other structural variants such as insertion of an *Alu* element. We provide further insight into the complexity of molecular mechanisms leading to secondary epimutations and highlight the need for extensive *MLH1* gene analysis in Lynch syndrome patients with constitutional epimutations.

**Development of a novel, rapid, ultra-sensitive and intraoperative IDH mutation detection method.** T. Avsar<sup>1,2,3</sup>, A. Sursal<sup>2,3</sup>, G. Turan<sup>2,3</sup>, BN. Yigit<sup>2,3</sup>, FA. Mazi<sup>3</sup>, D. Altunsu<sup>2,3</sup>, K. Cantasir<sup>4</sup>, G. Duyu<sup>4</sup>, T. Kilic<sup>5</sup>, M. Acar<sup>1</sup>. 1) Bahcesehir University, School of Medicine, Department of Medical Biology, Istanbul, Turkey; 2) Bahcesehir University, Health Sciences Institute, Neuroscience Program, Istanbul, Turkey; 3) Bahcesehir University, School of Medicine, Neuroscience Research Laboratory Istanbul, Turkey; 4) Bahcesehir University, School of Medicine, Turkey; 5) Bahcesehir University, School of Medicine, Neurosurgery Department, Istanbul, Turkey.

IDH1/2 mutations are indicative of good prognosis upon treatment and they may have intraoperative importance for disease management. Intraoperative diagnosis became a new technical approach in glioma management. If a neurosurgeon would know the mutation status in IDH genes, he/she would change the extent of resection in tumor removal. Because mutated tumors responsive to chemo/radiotherapy. We aimed to conduct a comprehensive IDH mutation analysis by using PCR based methodology during surgery. Our aim is to provide rapid, highly sensitive and specific intraoperative mutation detection system with robust accuracy. To this aim Amplification refractory mutation system (ARMS) was modified and optimized. The novelty of our methodology is adding an extra mismatch to increase specificity. ARMS was used to detect the presence of *IDH1*R132H, *IDH1*R132K and *IDH1*R132L mutation in 236 glioma sample selected from our tumor bank followed by Sanger sequencing. All results were also evaluated by immunohistochemistry (IHC) for IDH1 R132H. We also evaluated the diagnostic and screening potential of the test. By addition of the third mismatch to conventional ARMS we successfully detect IDH1 R132H mutation by 98.22% coherency with Sanger sequencing. Comparison between IHC and 3 mismatch-ARMS showed, 3-mismatch ARMS is superior to IHC in terms of accuracy. Based on our results, frequencies of *IDH1*/2 mutations among different glioma grades are, 6.67%, 69.84%, 65.08% and %8.75 for grade I, II, III and IV respectively. 3-mismatch ARMS is a novel methodology with great potential to be used as an intraoperative diagnostic test. It can detect *IDH* mutations in 67 minutes without the need of sequencing with the ability to be adapted for detection of various mutations through easy primer design.

**Validation of an amplicon-based hematopoietic gene panel to characterize aberrant clonal expansions/clonal hematopoiesis.** D. Castillo, T.P. Slavin, S. Sand, R. Mejia, J. Wang, X. Wu, J. Longmate, T.F. Springer, J. Herzog, B. Nehoray, J.N. Weitzel. City of Hope, Duarte, CA.

**Purpose:** Clonal hematopoiesis (CH) is an aberrant clonal expansion (ACE) in individuals with or without overt hematologic disease (with the latter referred to as CHIP), often marked by a pathogenic variant (PV) in hematopoietic pathway gene(s) at a minor allele frequency (MAF) < than expected for a heterozygous germline finding. The prevalence increases with age, and we recently demonstrated that 20% of commercial lab multigene panel-detected pathogenic *TP53* variants represented ACE, rather than a germline finding. The natural history of this phenomenon, and whether there is concomitant or sequential acquisition of PVs in other hematopoietic pathway genes is unknown, so we created and validated an economical next-generation sequencing (NGS) assay (81 gene QIAseq amplicon based panel) to assess reproducibility of the MAF (test/retest), compared to a standard Agilent targeted capture library. **Methods:** We evaluated DNA from 14 participants with known *TP53* PV-associated ACE. All individuals were consented and enrolled in the Clinical Cancer Genomics Community Research Network prospective registry. Libraries were prepared in triplicate using separate aliquots of DNA from blood and other tissues, and were sequenced on an Illumina HiSeq 2500 (Illumina Inc., San Diego). Unique molecular indexes (UMI) tag fragments in the original sample were used to reduce the chances of annotating amplification error. Variant call format files were produced and annotated using American College of Medical Genetics variant calling guidelines through Ingenuity Variant Analysis version 4 (Qiagen Inc, Alameda, CA). **Results:** All 14 *TP53* PVs were detected; average read depth of 275X; MAF ranged from 10.55%- 45.56%[ST1] [CD2] . Within-subject standard error was 3%, with no significant excess variability ( $P = 0.17$ ). Five of 14 (36%) subjects had additional CH-associated gene PV(s). These included: 1) *TET2* c.1360A>T (MAF=21.11%), 2) *TET2* c.3467delA (1.2%), 3) *ATM* c.8096C>T (3.42%), 4) *TP53* c.669delA (0.95%), 5) *TP53* c.350G>T (14.91%) and 6) *ATM* c.8096C>T (3.42%).[NB3] **Conclusions:** Our assay successfully identified all expected *TP53* PV(s), demonstrated reproducible MAF (minimal intra-case variability), and concurrently identified other CH-associated PV(s). This indicates that our custom panel can reliably detect and quantify ACE as it evolves, at a low per sample cost for future studies. The assay can further be extended in the future to other tissue types. .

**Next generation sequencing of hereditary paraganglioma-pheochromocytoma syndrome.** W. Lee, W. Min, S. Chun, H. Kim, S. Ahn. University of Ulsan College of Medicine, Seoul, Korea, Republic of.

**Introduction** Hereditary paraganglioma-pheochromocytoma(PGL/PCC) syndrome is an inherited condition characterized by the growth of noncancerous tumors in paraganglia. The diagnosis of this syndrome is based on several methods including genetic testing. SDHA, SDHB, SDHC and SDHD are four nuclear genes that closely related to the syndrome. Also SDHAF2, MAX, NF1, RET, TMEM127 and VHL genes are known to be relevant to this condition. In this research, we were trying to detect and validate genetic variants related to PGL/PCC syndrome from the pheochromocytoma patients using the Hereditary Tumor Next Generation Sequencing (NGS) panel which covers 128 genes. **Method** We analyzed the pheochromocytoma patients suspected as inherited nature during 6 monthes, who were referred for Hereditary Tumor NGS analysis in Asan Medical Center. Their diagnosis, variant gene, variant types, and inheritance pattern were investigated. The genetic variants were classified as Pathogenic (P), Likely Pathogenic (LP), and Uncertain significance (US) according to the ACMG STANDARDS AND GUIDELINES (2015). **Result** During the study period, total 30 pheochromocytoma patients were referred. Genetic variants related to the PGL/PCC syndrome were discovered from 16 patients. The genetic variants discovered from the patients were varied across the whole genes related to the PGL/PCC syndrome. A pathogenic variant was found in TP 53, and 8 LP variants were found in ACD, SDHB, TMEM127 and VHL. Four US variant were found in CDKN1B, MSH2, RAD50 and SDHA. Interestingly, pathogenic/likely pathogenic variants were detected in the genes (ACD and TP53), not well known to be related to the PGL/PCC syndrome. **Conclusion** Through this study, we discovered various genetic variations associated to PGL/PCC syndrome. Almost half of the pheochromocytoma patients showed P/LP/US variant, therefore, NGS work which covers many candidate genes for pheochromocytoma patients could be helpful for diagnosis of the disease when compared with the existing single-gene targeting method. NGS can help to find more meaningful genetic variants from possible PGL/PCC syndrome patients. In addition, two P/LP variants were discovered in the genes whose direct relations to PGL/PCC syndrome were not known. Further study with this panel could expand our knowledge on hereditary paraganglioma-pheochromocytoma(PGL/PCC) syndrome.

Sonmezler<sup>1</sup>, A. Bisgin<sup>1,2</sup>. 1) Cukurova University, Adana, Turkey; Cukurova University AGENTEM (Adana Genetic Disease Diagnosis and Treatment Center), Adana, Turkey; 2) Cukurova University, Faculty of Medicine, Medical Genetics Dept of Balcali Hospital and Clinics, Adana, Turkey.

**Objective:** Using Next generation sequencing (NGS) to identify somatic mutations in cancerous tissues has become accepted as routine in molecular diagnostics in the name of "Precision Medicine". To gain insight into the issues of being continually asked to evaluate more genes with limited sample volume. We investigated the success rate of AIT Panel (Qiagen) targeted ("hotspot") cancer NGS test for genomic DNA derived from FFPE tissue across colorectal cancer. **Methods:** FFPE tissue samples were collected and DNA isolations were performed from 100 colorectal cancer patients. Samples with limited tissue or low amount of extracted DNA were still analyzed by NGS due to our institutional optimizations. During the study *KRAS*, *NRAS*, *BRAF*, *PDGFRA*, *KIT*, *PIK3CA*, *EGFR*, *ALK*, *RAF1*, *ESR1*, *ERBB2* and *ERBB3* genes were next generation sequenced via GeneReader NGS system (Qiagen). Bioinformatics' analysis was made accordingly with patients' clinical findings. Then, treatment modalities related to patients' status were determined in terms of genetic alterations related to therapy resistance and/or sensitivity for clinical reporting. **Results:** As a result, total of 77 variants were detected in 57% (n=57) of the patients. Unfortunately, 43% (n=43) patients had no actionable mutations. Our analysis showed that this NGS system with AITP targeted cancer panel have shown high success rate with no needed. We detected all the actionable variants in 8 different genes which are *KRAS*, *NRAS*, *KIT*, *PIK3CA*, *BRAF*, *RAF1*, *EGFR* and *PDGFRA*. Among all these detected variants, 22 (%28.6) were related to the sensitivity to certain therapies, while %32.5 (n=25) were related to drug resistance in literature. Furthermore, 20.8% (n=16) of the variants were reported as related with both drug resistance and sensitivity. Moreover, we detected 6.5% (5) variants of uncertain significance and 4 (5.2%) variants related to an ongoing clinical trial. Rest of the variants (6.4%) indicated disease prognosis. **Conclusion:** Within the context of precision medicine, we reviewed our results on colorectal cancer samples that were not triaged by sample size, type or DNA quantitation prior to NGS for targeted "hotspot" multi-gene panel. By the virtue of NGS, multi-gene panel studies for somatic variant detection become more achievable, and this kind of studies by commercial hotspot panels may facilitate further improvements for targeted personalized therapies.

**Germline reporting in the National Cancer Institute - Children's Oncology Group (NCI-COG) Pediatric MATCH National Precision Oncology Trial.** S.E. Plon<sup>1,2</sup>, S. Scollon<sup>1,2</sup>, S. Joffe<sup>3</sup>, J.A. Biegel<sup>4</sup>, S. Kulkarni<sup>5</sup>, G. Miles<sup>6</sup>, L. Diller<sup>7</sup>, C.V. Fernandez<sup>8</sup>, D. Malkin<sup>7</sup>, J.A. Oberg<sup>8</sup>, M.V. Relling<sup>9</sup>, J.D. Schiffman<sup>10</sup>, L.A. Schwartz<sup>3,11</sup>, D.R. Stewart<sup>12</sup>, N.L. Seibel<sup>13</sup>, D.W. Parsons<sup>1,2</sup>. 1) Baylor College of Medicine, Houston, TX; 2) Texas Children's Hospital, Houston, TX; 3) University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 4) Children's Hospital Los Angeles, Los Angeles, CA; 5) Dana Farber Cancer Institute, Boston, MA; 6) Dalhousie University, Halifax, Nova Scotia, Canada; 7) The Hospital for Sick Children, Toronto, Ontario, Canada; 8) Columbia University Medical Center, New York City, NY; 9) St. Jude Children's Research Hospital, Memphis, TN; 10) Huntsman Cancer Institute at the University of Utah, Salt Lake City, UT; 11) Children's Hospital of Philadelphia, Philadelphia, PA; 12) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 13) Cancer Therapy and Evaluation Program of the National Cancer Institute.

**Background:** Genomic changes identified by tumor testing are increasingly used to inform treatment decisions and determine eligibility for clinical trials. Although at least 10% of cancer patients carry germline cancer susceptibility pathogenic variants, precision oncology trials have generally not incorporated germline reporting. We describe here the development of a process for return of matched germline results during the genomic screening portion of the national COG-NCI Pediatric MATCH trial for children with relapsed tumors. **Design/Method:** A multidisciplinary germline reporting committee and MATCH study leadership developed the germline reporting process. At entry, each subject provides a blood sample in addition to the required tumor sample (expected enrollment n=1000). Tumor and blood genomic analyses are performed on the same Pediatric MATCH Ion Torrent panel but reported independently. The committee selected 43 of 159 genes on the panel with clearly documented adult or pediatric cancer susceptibility for germline reporting. Germline reports are generated for each subject by experienced hereditary cancer genetic testing laboratories and include potential limitations of the germline analysis. Data on each subject are reviewed weekly by the testing laboratory, study leadership, and germline reporting teams. We also provide a genetics resource for the participating COG oncologists including genetic counselors, geneticists and oncologists with surveillance expertise. **Results:** Pediatric MATCH opened in 2017 and is now open at over 100 clinical sites in the U.S. Blood samples for genomic testing have been obtained from >95% of subjects enrolled to date. As expected, many somatic findings in genes like *TP53* were seen in the tumor but not the germline. Germline interpretation scenarios encountered to date represent a diversity of findings: clinically significant germline variants in patients with known genetic diagnoses (e.g. *NF1*, *MLH1*), findings in genes typically associated with adult cancer risk (e.g. *CHEK2*, *BRCA1*), and germline pathogenic variants lost in the tumor (*NF1*, *BRCA1*). **Conclusions:** Coordinated germline and tumor reporting has the potential to maximize the clinical value of genomic testing, including for patients in whom a biomarker for a molecularly-targeted treatment is not identified. The germline reporting process developed for Pediatric MATCH can serve as a model for germline reporting in multi-institutional precision oncology trials.

**NEBNext Direct Custom Ready Panels overcome challenges associated with targeted re-sequencing.** A. Barry<sup>1</sup>, K. Patel<sup>2</sup>, S. Bowman<sup>2</sup>, A. Eberman<sup>2</sup>, S. Adams<sup>2</sup>, B. Desmond<sup>2</sup>, J. Dunn<sup>2</sup>, S. Corbett<sup>2</sup>, C. Elfe<sup>2</sup>, E. Mauceli<sup>2</sup>, E. Dimalanta<sup>1</sup>, F. Stewart<sup>1</sup>, T. Davis<sup>1</sup>, C. Hendrickson<sup>2</sup>. 1) New England Biolabs, Ipswich, MA; 2) Directed Genomics, Ipswich, MA.

Efficient utilization of targeted gene panels for clinical research is challenged by the wide variation in gene constituents specific to a given study. While focused gene panels efficiently provide the necessary depth of coverage for low frequency variant detection, the high costs and design challenges associated with panel design present challenges. Furthermore, inherent issues with amplification-based enrichment include low uniformity of target coverage, and challenges when modifying content of a given panel. NEBNext Direct Custom Ready Panels employ a novel approach to selectively enrich nucleic acid targets ranging from a single gene to several hundred genes, without sacrificing specificity. The approach rapidly hybridizes both strands of genomic DNA with biotinylated probes prior to streptavidin bead capture, enzymatic removal of off-target sequence, and conversion of captured molecules into sequencer-ready libraries. This results in a unique read coverage profile that results in uniform coverage across a given target. Unlike alternative hybridization methods, the approach does not necessitate upfront library preparation, and instead converts the captured molecules into dual-indexed illumina sequencer compatible libraries containing an 8 basepair sample ID and a 12bp Unique Molecule Index (UMI). The result is a 1-day protocol that enables the preparation of sequence-ready libraries from purified genomic DNA specific to the gene content included in the panel. We have designed and optimized baits specific to the full exonic content of >800 genes associated with cancer, neurological disorders, autism, cardiovascular disease, and other conditions. These are designed, balanced, and pooled on a per gene basis, and can be combined into NEBNext Direct Custom Ready Panels, allowing rapid turn-around of specific custom gene subsets. Here, we present the ability to rapidly deploy custom gene panels across a variety of panel sizes and content, while maintaining high specificity, uniformity of coverage across target content, and sensitivity to detect nucleic acid variants from clinically relevant samples.

**Systematic “minor genes” testing in inherited cardiac diseases: Friend or foe?** V. Novelli<sup>1</sup>, F.D. Tiziano<sup>1</sup>, M.C. Russo<sup>1</sup>, G. Pelargonio<sup>2</sup>, F. Crea<sup>2</sup>, P. Zeppilli<sup>3</sup>, M. Genuardi<sup>1</sup>. 1) Institute for Genomic Medicine, Fondazione Policlinico A. Gemelli, Rome, Rome, Italy; 2) Cardiology Department, Fondazione Policlinico A. Gemelli, Rome, Rome, Italy; 3) Sport Unit, Fondazione Policlinico A. Gemelli, Rome, Rome, Italy.

**Introduction:** Genetic testing in inherited cardiac diseases has been revolutionized by NGS technology: the NGS-based panel approach, indeed, has enabled to test a large number of genes simultaneously, differently from the traditional Sanger, limited to the most prevalent and characterized genes. Therefore, recently, so called “minor genes” have been included in diagnostic NGS panels, generating remarkable interpretative problems, mostly related to the high prevalence of variants of unknown significance (VUS). Here, we report our experience with expanded gene panels for genetic testing. **Materials and Methods:** 103 consecutive patients, 26 suspected Hypertrophic Cardiomyopathy (HCM), 33 Arrhythmogenic Cardiomyopathy (ACM), 18 Long QT syndrome (LQTS), 19 Brugada syndrome (BrS) and 7 Idiopathic Ventricular Fibrillation (IVF) patients have been analyzed using 3 different Ion custom sequencing panels, including 11 genes for HCM, 9 for ACM, 12 for LQTS/IVF/BrS. **Results:** Thirty probands carried at least one potentially pathogenic variant (30%) have been identified. According to the ACMG guidelines, the majority of the identified variants (70%) were classified as VUS, while 18% were Likely Pathogenic (LP) and 12% Pathogenic (P). Looking at the VUS, the 24% of these have been identified in minor genes, mostly in genes related to inherited arrhythmias diseases. On the other hand, except for one variants classified as LP, all the other variants reported in minor genes did not reach the pathogenicity due to lack of functional studies or limited data reported in the literature. **Conclusions:** These data showed that the inclusion of minor genes in the genetic screening, even if restricted to a limited number of genes, gives a very limited contribution, increasing the rate of VUS and making the tests clinically irrelevant.

**Enabling high quality hypertrophic cardiomyopathy genetic testing using multiplexed patient-like reference material.** Z.C. Deans<sup>1</sup>, F. Khawaja<sup>1</sup>, F. Moon<sup>1</sup>, D. Brudzewski<sup>2</sup>, C. Huang<sup>2</sup>, R. Santhanam<sup>2</sup>. 1) GenQA/UKNEQAS, Edinburgh, United Kingdom; 2) SeraCare Life Sciences Inc, Milford, MA, USA.

**INTRODUCTION** UK NEQAS for Molecular Genetics promotes high quality accurate genetic testing through external quality assessment (EQA) and educational exercises. UK NEQAS provided participants a multiplexed reference sample (SeraCare) with known pathogenic and non-pathogenic variants associated with hypertrophic cardiomyopathy (HCM) in the genes *MYBPC3*, *MYH7*, *TNNI3*, *TNNT2* and *TPM1*. Participants reported all detected variants as well as the variant classification. **METHODS** Laboratories participating in the UK NEQAS HCM 2017 EQA received the reference sample and applied routine testing strategy and variant classification for HCM. Variant type ranged from substitutions and small insertions to large deletions within repetitive regions. This was an educational exercise and no scores were assigned. Details of the variants present in the reference sample, collation of the submitted results, methodologies performed, and general feedback comments were provided to the participants. **RESULTS** The reference sample was distributed to 17 laboratories from eight countries; the majority from UK (53%), followed by Australia (12%). A next generation sequencing approach was used by all but one which performed Sanger sequencing. There was considerable variation in the number of genes each laboratory analyzed ranging from 4 to 141 genes, all included the five genes supplied with known variants except one laboratory did not test *TPM1*. The standard of variant detection was generally very high with 16/17 laboratories detecting  $\geq 70\%$  of variants included in this reference sample. The large deletion situated within a repetitive region was detected the least, independently of testing methodologies. The laboratories reported expected classifications for most of the variants and these will be discussed. Three laboratories reported additional variants; two of which were confirmed by SeraCare and one variant of uncertain significance in the *PRKAG2* gene which was only reported by a single laboratory. **CONCLUSION** HCM mutation testing is not standardised, with laboratories testing different gene targets and variable limitations of the testing approaches. The use of reference material with known clinically relevant and challenging variants enables laboratories to determine the limitations of the test and review the scope of other tests performed. Such benchmarking exercises demonstrate the benefits of educational elements of external quality control in helping to promote high quality molecular testing.

**A targeted enrichment sequencing assay for inherited cardiac condition genes.** K. Patel<sup>1</sup>, S. Bowman<sup>1</sup>, A. Emerman<sup>1</sup>, C. Hendrickson<sup>1</sup>, S. Adams<sup>1</sup>, B. Desmond<sup>1</sup>, J. Dunn<sup>1</sup>, A. Barry<sup>2</sup>, T. Davis<sup>2</sup>, S. Corbett<sup>1</sup>, C. Elfe<sup>1</sup>, E. Mauceli<sup>1</sup>. 1) Directed Genomics, Ipswich, MA; 2) New England Biolabs, Ipswich, MA.

Genetic information is useful for the diagnosis, prognosis, and management of cardiac disorders. In addition to screening the patient, screening of the patient's family members may help determine whether regular cardiac testing is recommended. To this end, next generation sequencing technologies are rapidly being adopted for the screening of loci that contribute to a variety of inherited cardiac conditions. Target enrichment sequencing assays are ideal for this purpose, as greater coverage of the genomic regions of interest can be achieved for reliable variant detection, with reduced sequencing costs and data analysis burden compared to whole genome/exome sequencing. The NEBNext Direct cardiac disease focused panel was designed to target 87 genes associated with cardiomyopathy, inherited arrhythmia, familial hypercholesterolemia, and pulmonary arterial hypertension. This panel was developed to provide maximum coverage of all protein coding regions (~390 kb) with 10 base pair padding to also enable the detection of splicing variants. Individual baits were designed to capture both strands of the targeted molecules, followed by balancing of the baits by performance to increase or decrease coverage where necessary, resulting in uniform coverage that is superior to that typically seen with amplification based assays. Greater than 95% of the reads mapped to targeted regions and greater than 99.9% of target bases were covered at greater than 20X read depth. The NEBNext Direct target enrichment protocol is a single day, hybridization-based assay that produces a sequencer-ready library with an 8 base pair sample index and a 12 base pair Unique Molecular Identifier (UMI).

**Clinical characterization of hypertrophic cardiomyopathy caused by the ancestral mutation p.Q1233\* in the MYBPC3 gene.** M. Polyak<sup>1</sup>, G. Radghabova<sup>1</sup>, Yu. Surikova<sup>1</sup>, N. Chakova<sup>2</sup>, S. Komissarova<sup>2</sup>, O. Blagova<sup>2</sup>, A. Motreva<sup>3</sup>, O. Kalmykova<sup>3</sup>, M. Bos<sup>4</sup>, M. Ackerman<sup>5</sup>, O. Chumakova<sup>6</sup>, M. Golubenko<sup>7</sup>, J. Ingles<sup>8</sup>, C. Semsarian<sup>9</sup>, S. Dzemeshevich<sup>1</sup>, E. Zaklyazminska-ya<sup>1,9</sup>. 1) Petrovsky National Research Centre of Surgery, Moscow, Russian Federation; 2) Institute of Genetics and Cytology of NAS of Belarus, Minsk, Belarus; 3) Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation; 4) Federal Center for Cardiovascular Surgery, Astrakhan, Russian Federation; 5) Mayo Clinic, Rochester, MN, USA; 6) City Clinical Hospital No 17, Moscow, Russian Federation; 7) Tomsk National Research Medical Center of the Russian Academy of Sciences, Tomsk, Russian Federation; 8) Sydney Medical School, The University of Sydney, Australia; 9) Pirogov Russian National Research Medical University, Moscow, Russian Federation.

**Introduction.** Hypertrophic cardiomyopathy is a genetic-based disorder, characterized by thickening of left ventricular (LV) and interventricular septum, which can't be explained by other cardiac or systemic disease. Mutations in over a dozen genes are found to cause HCM. The clinical spectrum and phenotype-genotype correlations have not been fully investigated. The aim of our study is to characterize a natural history of the HCM caused by ancestral mutation p.Q1233\* in the MYBPC3. **Methods.** Patients with the p.Q1233\* mutation in the MYBPC3 underwent detailed clinical evaluation. Clinical and genetic data were collected from centers in Russia, USA, Australia, and Belarus. Clinical information was collected from 51 mutation carriers (38 probands and 13 relatives; M:F ratio 1:1) aged 1 to 71. Genetic screening included NGS of the 78 genes (25 probands), and Sanger sequencing of the MYBPC3 gene (12 probands). **Results.** Mutation p.Q1233\* was co-inherited with the polymorphism p.R326Q in all the cases. Co-segregation of these two variants and the same haplotype were confirmed by cascade familial screening in familial cases. Twenty-six probands (68%) had self-reported Slavonic origin. This mutation was found in 11% of HCM patients of Slavonic origin in the HCM cohort tested in Petrovsky Russian Research Centre of Surgery (Moscow, Russia). The majority of mutation carriers manifested with cardiac hypertrophy. One proband (47 y.o., female) had LVNC and severe arrhythmias without obvious myocardial hypertrophy, she also carried p.R237W variant in MYH7 previously assigned to be causative for DCM. The remaining 50 mutation carriers were diagnosed with HCM, mainly with sigmoidal hypertrophy of interventricular septum. Five out of 50 (10%) met LVNC criteria. Mean age at the diagnosis was 41 years, and the mean age of manifestation (or typical complains) was 34 y.o. Seventeen out of 50 carriers had a LVOT obstruction, and probability to have an LVOT was increasing with age. Ten patients underwent surgical treatment (extended myectomy or alcohol ablation), and 1 proband was transplanted. Ventricular arrhythmias were noted in 36% of carriers, and SCD occurred in 7 families, at a mean age of SCD of 51 years. **Conclusion.** We suggest the mutation p.Q1233\* had risen on the background of p.R326Q-allele. This mutation is the most common in HCM patients of Slavonic origin, and is highly penetrant. Mutation carriers have a high probability to meet criteria for early surgical treatment.

**Targeted gene pannel screening in sudden cardiac death: Challenges and utilities, to be or not to be?** S.G. Temel<sup>1</sup>, A. Akcay<sup>2</sup>, I. Deniz<sup>3</sup>, B. Turk-genc<sup>4</sup>, M.C. Ergoren<sup>5</sup>, C. Yalciner<sup>6</sup>. 1) Uludag University, Faculty of Medicine, Department of Medical Genetics, Bursa, Turkey; 2) Ministry of Justice, Council of Forensic Medicine, Mortuary Department, Istanbul, Turkey; 3) Nicosia Nalbantoglu Government Hospital, Department of Forensic Medicine, Nicosia, Cyprus; 4) Acubadem University Hospital, Genetic Diagnosis Centre, Istanbul, Turkey; 5) Near East University, Faculty of Medicine, Department of Medical Biology, Nicosia, Cyprus; 6) Acibadem University, Faculty of Sciences & Arts Department of Molecular Biology & Genetics, Istanbul, Turkey.

Sudden cardiac death (SCD) is one of the major causes of mortality worldwide and is responsible for a large proportion of sudden deaths in young individuals. In forensic medicine up to 30% of all sudden death cases remain unexplained after routine postmortem autopsy, with no definite cardiac etiology identified after gross and microscopic inspection of the heart. Two groups of inherited hearth diseases are responsible for SCD: cardiomyopathies and channelopathies. Our research group focuse on cardiac channelopathies, which are characterized by lethal arrhythmias in the structurally normal heart, incomplete penetrance, and variable expressivity. Arrhythmias in these disease group result from pathogenic variants in genes encoding cardiac ion channels or associated proteins. Due to a lack of structural changes in the heart; it can not be detectable during conventional forensic autopsy investigation, channelopathies are often considered as potential causes of death in unexplained forensic autopsies. The asymptomatic nature of channelopathies is cause for concern in family members who may be carrier, making the identification of these genetic factors of significant clinical importance. Targeted sequencing was performed to the forensic SUD cases and family members. Postmortem genetic testing, challenges and utilities of the genetic testing will be discussed with unique SCD cases in our cohort. Molecular autopsy, post-mortem genetic testing and detailed premorbid clinical and family history can survive family members of SCD cases. .

**2845T**

**Molecular dissection of the dilated cardiomyopathy in pediatric patients in Russia.** E. Zaklyazminskaya<sup>a1,2</sup>, A. Bukaeva<sup>a</sup>, M. Polyal<sup>a</sup>, A. Shestak<sup>a</sup>, V. Mikhailov<sup>a</sup>, O. Blagova<sup>a</sup>, Yu. Frolova<sup>a</sup>, I. Povolotskaya<sup>a</sup>, N. Kotlukova<sup>a</sup>, S. Dzemeshkevich<sup>a</sup>. 1) , Russian Federation; 2) Pirogov Russian Research Medical University, Moscow, Russian Federation; 3) Sechenov State Medical University, Moscow, Russian Federation; 4) Centre of Genetics and Reproductive Medicine GENETICO, Moscow, Russian Federation.

**Aim:** To determine mutation spectrum in patients with early manifestation of the dilated cardiomyopathy (DCM), and to propose optimal way of DNA diagnostics in pediatric DCM cohort. **Materials and Methods.** Complete clinical and instrumental examination of the 35 pediatric DCM patients with DCM was performed in expert cardiology departments. Molecular genetic study had included the semiconductor sequencing based on the IonTorrent platform of the coding and adjacent regulatory areas of the 90 genes (for 25 isolated cases); and whole exome sequencing *trios* on the Illumina platform (for 10 family cases). **Results and discussion.** The group included 35 probands diagnosed with DCM before the age of 17, the average age of diagnosis was 6.5 years old. The gender ratio (M: F) was 17: 7. Sporadic cases of DCM were 27, familial cases - 8 (when the diagnosis of DCM was found in at least one parent and/or sibling). Pathogenic and likely pathogenic genetic variants were found in 23 probands (66%). *De novo* origin of mutation was confirmed in 7 probands (20%). Complex genotype (one homozygous mutation or heterozygous compounds were found in 6 probands (17%). Surprisingly, no mutation leading to the premature stop codon, or any other potentially pathogenic substitutions were found in the *TTN* gene. Half of detected mutations were found in the genes encoding sarcomeric proteins. **Conclusion.** The combination of the large target gene panel and whole exome sequencing allows to identify genetic cause of DCM in >60% probands manifested before 18 y.o.. *De novo* mutations and "double-hit" cases accounts significant portion of patients. The results of this study do not allow to consider the *TTN* gene as the first line of DNA diagnostics for DCM in the pediatric group, despite the publication of a high incidence of mutations in this gene in whole DCM cohort. The optimal strategy of the DNA diagnostics is the whole-exome sequencing.

**2846F**

**Validation of targeted next-generation sequencing panel for thoracic aortic aneurysms and aortic dissections.** C. Seo<sup>1,2</sup>, B. Lee<sup>2,3</sup>, H. Yoo<sup>2,3</sup>, S. Cho<sup>2</sup>, C. Park<sup>a</sup>, E. Seo<sup>1,2</sup>. 1) Laboratory Medicine, University of Ulsan College of Medicine and Asan Medical Center, Seoul, South Korea; 2) Pediatrics, University of Ulsan College of Medicine and Asan Medical Center, Seoul, South Korea; 3) Medical Genetics Center, University of Ulsan College of Medicine and Asan Medical Center, Seoul, South Korea.

**Background:** Thoracic aortic aneurysms and aortic dissections (TAAD) are associated with genetic disorders such as Marfan syndrome, Loeys-Dietz syndrome, and other heritable thoracic aortic diseases. We developed and validated amplicon-based targeted next-generation sequencing (NGS) panel for TAAD. **Methods:** The NGS panel comprised 16 genes including ACTA2, COL3A1, FBN1, MAT2A, MYH11, MYLK, NOTCH1, PRKG1, SKI, SLC2A10, SMAD3, SMAD4, TGFB2, TGFB3, TGFB1, and TGFB2 (518 amplicons, 95kb). We used NA12878 as a reference material (Coriell, Camden, NJ, USA) and positive control samples from 5 patients with known variants as follows: FBN1:c.5683T>C, FBN1:c.8165del, FBN1:c.4684\_4697del, FBN1:c.4839\_4840dup, and TGFB2:c.1609C>T. The primary NGS platform was Ion OneTouch and Ion PGM Dx (Thermo Fisher Scientific, Waltham, MA, USA). And we re-validated the panel when the platform was upgraded to Ion Chef and Ion S5 XL (Thermo Fischer Scientific). Bioinformatics tools were Torrent Suite 5.6 and Ion Reporter 5.6 (Thermo Fisher Scientific) and Biomedical Genomics Workbench (BxWB) 5.0.1 (Qiagen, Hilden, Germany). We compared quality control (QC) metrics between Ion PGM Dx and Ion S5 XL. The performance evaluation included accuracy, precision, analytical sensitivity, specificity, reportable range, and reference range. We also performed this panel testing for 8 TAAD patients who was negative for FBN1 Sanger sequencing. **Results:** Ion S5 XL showed better QC metrics compared to Ion PGM Dx, especially for mean read length (208 vs. 169bp), and percent end-to-end reads (89.5 vs. 16.2%). The performance evaluation using NA12878 showed higher accuracy, precision, analytical sensitivity, and specificity in Ion S5 XL compared to Ion PGM Dx. BxWB was complementary to Torrent Suite and Ion Reporter for variant analysis and interpretation. From the test for 8 TAAD patients who was negative for FBN1 sequencing, 4 significant variants were identified: TGFB2:c.1042C>T (LP), TGFB2:c.1322G>A (VUS), FBN1:c.5788+5G>A (P), NOTCH1:c.6557G>T (VUS). **Conclusions:** Ion S5 XL showed better QC metrics and performance characteristics compared to Ion PGM Dx. Method-based validation with reference material provided useful and accurate performance evaluation. It is recommended to use more than one bioinformatics tools for complementary strategy. This panel is expected to provide efficiency and high diagnostic yield for TAAD patients.

**2847W****Identification of mosaic mutations in two Chinese families with MFS/LDS.**

Y.Guo, Zhu<sup>1</sup>, H. Yang<sup>1</sup>, Z.Wei Zhou<sup>1</sup>, Y.Ming Luo<sup>2</sup>, H.Yin Zhang<sup>1</sup>, Z. Zhou<sup>1</sup>. 1) State Key Laboratory of Cardiovascular Disease, Beijing Key Laboratory for Molec, Beijing, China; 2) State Key Laboratory of Cardiovascular Disease, Center of Vascular Surgery, Fuwai Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, 100037, China.

**Background:** Marfan syndrome (MFS) and Loeys-Dietz syndrome (LDS), are two autosomal dominant connective tissue disorders, with many overlapping phenotypic characteristics. Considering their fully penetrance at an early stage, the variant observed in a healthy parent might be downgraded to VUS (variant of uncertain significance) or likely benign/benign, as it can be considered as strong evidence for a benign interpretation. However in that case, mosaicism must be taken into account. **Methods:** A total of 563 patients with suspected MFS or early onset TAAD were referred to our center to take a gene panel testing, involving 15 genes associated with Marfan and its related aortic diseases, including *FBN1*, *TGFBR2* and so on. Then the suspected mutations were verified by Sanger sequencing. Thereinto, 2 rare mutations were identified, which were inherited from their healthy parents, but Sanger sequencing results displayed an unbalanced double peak in the mutation site, suggesting mosaicism might exist. To confirm the mosaicism, a deep sequencing (5000×) on the single amplicon was performed on the DNA sample extracted from whole blood on Life PGM™ instrument. **Results:** Two mosaic mutations were discovered and confirmed in our study. The first mutation *TGFBR2*, R356P was identified in patient AD257, who was a 8 year-old boy presented with aortic pseudo-aneurysm, tortuous bilateral carotid artery, cleft palate, hypertelorism, which strongly suggested LDS. However, his father harbored the same mutation but appeared quite normal except that cardiac ultrasonography revealed reduced left ventricular diastolic function. Finally, the overall quantity 25% of mutated alleles in the father's blood was determined through deep sequencing. The second mutation *FBN1*, C1305F was detected in patient AD700-1, who was a 7 year-old boy with typical MFS features. His father was 30 years old, tall (190cm/100Kg) and myopia, with no other abnormality. After deep sequencing, 10% mutated alleles were detected from the father's blood and confirmed the mosaicism. According to 2015 ACMG criterion, these two variants were both classified as pathogenic. **Conclusions:** Mosaicism could be a more common phenomenon in MFS and its related diseases than it has been realized so far. We should take it into account when no mutation is found in a classic MFS patient, and when a variant is also observed in the atypical/healthy parent. It might help to improve the diagnostic rate.

**2848T****The importance of gene-based knowledge in variant classification: An analysis of *FBN1* missense variant classifications in ClinVar.** L.M. Baudhuin, K.E. Kotzer, M.L. Kluge, S.A. Lagerstedt. Mayo Clinic, Rochester, MN.

**Background:** Genetic variant classification for inherited disorders can be enhanced with gene-specific knowledge. In order to better understand the classification of critical and non-critical region-specific variants by the clinical laboratory community, we analyzed *FBN1* missense variants submitted to the ClinVar database. **Methods:** ClinVar *FBN1* variant data was downloaded and relevant missense variants were binned into 11 different categories based on whether they impacted a previously defined critical residue. ClinVar submitter variant classification and evidence (when available) were analyzed utilizing ACMG 2015 criteria. **Results:** A total of 1405 unique *FBN1* variants with 1963 classifications from 18 different submitters were downloaded. There were 355 unique missense variants (with 418 classifications) that occurred at critical amino acid residues. Overall, 82.3% of critical residue missense variants were classified as likely pathogenic or pathogenic (LP/P). There was a lower percent of LP/P classification for variants that did not impact a cysteine residue [60.1% (79/130)] compared to cysteine variants [92.3% (275/287)]. There were 285 unique missense variants (with 513 classifications) that did not occur at known critical residues. Of these, LP/P and uncertain significance (VUS) variant calls that included evidence were likely overclassified in 56% (24/43) and 30.1% (63/209) of cases, respectively. **Conclusions:** *FBN1* missense variants that occur at critical residues that do not impact cysteine residues or do not occur at known critical residues have a higher likelihood of being misclassified. These results underscore the importance of relying on both gene-based knowledge and applying appropriate ACMG criteria for variant classification, as well as updating classifications as more evidence becomes available.

**Molecular spectrum of PAH gene mutations in the Aegean region of Turkey: Identification of four novel mutations.** F. Ozkinay<sup>1,4</sup>, M. Çoker<sup>2</sup>, T. Atik<sup>1</sup>, E. Isik<sup>1</sup>, E. Er<sup>2</sup>, M. Kose<sup>3</sup>, H. Onay<sup>4</sup>. 1) Pediatric Genetics, Ege University, School of Medicine, Izmir, Turkey; 2) Pediatric Metabolism, Ege University, School of Medicine, Izmir, Turkey; 3) Pediatric Metabolism, Dr. Behcet Uz Training and Research Hospital, Izmir, Turkey; 4) Medical Genetics, Ege University, School of Medicine, Izmir, Turkey.

Phenylketonuria (PKU) is a common autosomal recessive disease caused by mutations in the Phenylalanine Hydroxylase (PAH) gene located at chromosome 12q22-q24.2. The incidence of phenylketonuria is respectively high in Turkey. Mutation spectrum of PAH gene differs among race and ethnicity. The aim of this study is to investigate the molecular spectrum of PAH mutations in the population from Aegean region of Turkey. In the study 124 unrelated patients with PKU and 23 unrelated carriers referred to a reference center for molecular analysis over a 2 year period (from 2016 to 2017) were included. The majority of patients were diagnosed during newborn screening. All 13 coding exons and exon-intron boundaries of the PAH gene were sequenced using next-generation sequencing. Sixty different mutations including 4 novel mutations were detected in 271 phenylketonuria alleles. IVS6+4A/T, K396R, F149S, F55LfsX6 are the novel mutations that have not been reported in the literature. The four most common mutations were IVS10-11G>A (12.4%), A403V (9.56%), A300S (9.22%) and R261Q (9.22%). The present study showed a marked genetic heterogeneity in hyperphenylalaninemia patients from Aegean Region of Turkey. Similar to the most of other Mediterranean populations and populations from other regions of Turkey, IVS10-11G>A is the most frequent mutation in this region. Results of this study will serve as valuable tools for genetic diagnosis and appropriate genetic counseling in the related area.

**IGF1R variants in patients with growth impairment: Four novel variants and genotype-phenotype correlations.** L. Yang, F. Luo, W. Zhou. Children's hospital of Fudan university, shanghai, China.

**Objective:** IGF1R gene mutations have been associated with varying degrees of intrauterine and postnatal growth retardation, as well as microcephaly. Both autosomal dominant and autosomal recessive inheritance patterns have been reported. This study aimed to analyze the IGF1R gene in children with growth impairment using whole exome sequencing (WES) and to assess the clinical features with the autosomal dominant and recessive models. **Methods:** We performed WES in 28 unrelated patients and found 4 children harboring IGF1R gene variants. We compared the clinical findings in our cases carrying IGF1R mutations to those in patients reported in the HGMD database. **Results:** We identified four novel IGF1R gene variations by WES in 3 unrelated patients, including one missense variant (c.3740T>C (p.M1247T)) (Patient 1) inherited from an affected mother, one *de novo* nonsense variant (c.2629C>T, (p.R877X)) (Patient 2), and two compound heterozygous variations (c.2305G>C (p.E769Q); c.2684G>A (p.R895Q)) (Patient 3). To date, twenty-two patients have been described as harboring pathogenic variations in IGF1R in the HGMD database. We found that patients with compound heterozygous or homozygous variations displayed more severe phenotypes that were mainly characterized by developmental and speech delays, as well as mental retardation. **Conclusion:** We identified four novel pathogenic variations in the IGF1R gene, which expanded the known mutation spectrum. Through a comparison among patients with reported IGF1R pathogenic variations, this study determined that an autosomal recessive inheritance model of the IGF1R gene results in a more severe phenotype with developmental and speech delays, as well as mental retardation.

**Screening for mutations in 14 kinds of MODY genes in patients with MODY in Japanese by next generation sequencing.** *N. Iwasaki*<sup>1,2,3,4</sup>, *T. Yamamoto*<sup>2,4</sup>, *H. Akagawa*<sup>2</sup>, *M. Ogata*<sup>2,5</sup>, *M. Tsuchiya*<sup>2</sup>, *K. Saito*<sup>1</sup>. 1) Institute of Geriatrics, Tokyo Women's Medical University, Tokyo, Japan; 2) Institute of Integrated Medical Science, Tokyo Women's Medical University, Tokyo, Japan; 3) Diabetes Center, Tokyo Women's Medical University, Tokyo, Japan; 4) Institute of Medical Genetics, Tokyo Women's Medical University, Tokyo, Japan; 5) Department of Nutrition, Shukutoku University, Chiba, Japan.

[;Aim]; Maturity onset diabetes of the young (MODY) is a subtype of diabetes mellitus characterized by a single gene disorder and a part of MODY (MODY1, 2 and 3) are known to be good targets for personalised medicine. In UK, it is reported that MODY2 and MODY3 comprise 80% of whole MODY. However, the responsible genes in MODY are not fully elucidated in Japan. The aim of the study was to screen mutations in 14 kinds of MODY genes by comprehensive methods using next generation sequencing in Japanese subjects with MODY. [;Methods]; The subjects were clinically diagnosed with MODY and unidentified the causative mutations to date. Inclusion criteria were those diagnosed with diabetes before the age of 30 years old, negative for GAD antibody if tested, and BMI <30. Family history was not considered. Genotyping was performed by using HaloPlex SureDesign system (Agilent Technologies, Santa Clara, CA) that covered whole coding regions in 14 MODY genes and sequenced on an Illumina MiSeq v3(600) (Illumina, San Diego, CA). Identified variants were annotated with 1000 genome, CADD, ClinVer and gnomAD browser. This study was performed under the permission of Ethical Board for the human Genome study in the University. [;Results]; Forty eight patients (M/F: 18/30; age at diagnosis: 16.5±3.9 years, BMI at first visit: 21.5±2.8 m<sup>2</sup>/kg (m±SD) were analyzed. We have found a total of 26 kinds of nonsense or missense variants in 34 subjects. Those variants were found in 10 MODY genes including *HNF4A*, *GCK*, *HNF1A*, *PDX1*, *CEL*, *PAX4*, *INS*, *ABCC8*, *KCNJ11* and *RFX6* genes. Two nonsense mutations, C370X in *GCK/MODY2*, and W324X in *HNF1A/MODY1* were identified. The following 4 variants were seemed to be likely pathogenic (R148G in *PDX1/MODY4*, R121W in *PAX4/MODY9*, G826V in *ABCC8/MODY12* and E140K in *KCNJ11/MODY13*). R121W in *PAX4/MODY9* was found in 5 subjects (10.1%), and remaining was one each. Interestingly, two subjects carry dual mutations; one individual carried R148G in *PDX1* and R121W in *PAX4*, and the other proband carried C370X in *GCK* and R121W in *PAX4*. [;Conclusion]; Overall, 8 in 48 subjects (16.7%) were found to have pathogenic or likely-pathogenic mutations in known MODY genes, including three unreported mutations in Japanese subjects with MODY.

**Personalized medicine in diabetes: Unraveling the disease casualty of *HNF1B* gene coding variants of "unknown clinical significance" in two large Norwegian diabetes registries.** *B.B. Johansson*<sup>1</sup>, *K.A. Mohamed*<sup>1</sup>, *M. Ringdal*<sup>1</sup>, *A. Kaci*<sup>1</sup>, *L. Bjørkhaug*<sup>2</sup>, *P.R. Njølstad*<sup>1,4</sup>, *J. Molnes*<sup>1,3</sup>. 1) KG Jebsen Center for Diabetes Research, Department of Clinical Science, University of Bergen, Norway; 2) Department of Biomedical Laboratory Sciences and Chemical Engineering, Western Norway University of Applied Sciences, Bergen, Norway; 3) Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway; 4) Department of Pediatrics and Adolescents, Haukeland University Hospital, Bergen, Norway.

**Background/aims:** Genetic variants in *HNF1B* encoding the transcription factor hepatocyte nuclear factor-1 beta (HNF-1B) can cause Maturity-Onset Diabetes of the Young type 5 (MODY5; HNF1B-MODY) but is also the most common known monogenic cause of developmental kidney disease. The aim of this study was to investigate possible pathogenic effects of 17 *HNF1B* variants identified in the Norwegian Childhood Diabetes Registry (NCDR) and the Norwegian MODY Registry, using functional protein analyses, and to correlate findings with clinical characteristics of *HNF1B* variant carriers. **Methods:** *HNF1B* variants were classified using a five-tier score system commonly used in clinical diagnostic laboratories. To investigate the effect of HNF1B variants on normal HNF-1B transcriptional activity, we used a Dual-Luciferase assay system in transfected HeLa cells **Results:** 17 *HNF1B* variants were identified in patients of the NCDR (*n*= 5093) and in probands of the Norwegian MODY Registry (*n*=1145). 7 variants were classified as likely pathogenic or pathogenic, 6 variants of unknown significance and 4 variants were interpreted as benign or likely benign. All rare variants were further investigated by functional studies. 8 patients with *HNF1B* variants presented with renal disease, and the commonest renal manifestation in these patients were renal cysts which were present in 5/16 patients. 3/16 patients presented with renal disease without diabetes. Diabetes was present in 12/16, whereof 7 probands presented with early-onset diabetes without reported kidney disease. Extra renal features seen in the patients, in addition to diabetes, were pancreas hypoplasia or atrophy, exocrine deficiency and liver dysfunction. Only 8/16 families met the minimal MODY criteria (families with at least two generations of diabetes with at least one subject diagnosed under the age of 25 years). The effect of the observed *HNF1B* variants on transcriptional activity is now being investigated in HeLa cells. Preliminary results shows reduced transactivation activity in the two variants p.Arg137\_Lys161del and a positive control p.Arg177Ter, which is also supported by others. This also coincides with the available clinical data on the patients. **Conclusion:** Investigation of *HNF1B* variant functional effects should support precision medicine in diabetes clinics and could help to distinguish neutral variants from variants causing HNF1B-disease, in combination with family history and clinical characteristics.

**Prevalence of significant genetic variants in glycogen storage disease via custom NGS panel in a single center hospital based study.** A. Bisgin<sup>1,2</sup>, I. Boga<sup>2</sup>, H.N. Onenli Mungan<sup>3</sup>, D. Kor<sup>2</sup>, S. Tug Bozdogan<sup>1,2</sup>, O. Sonmezler<sup>2</sup>.

1) Cukurova University, Faculty of Medicine, Medical Genetics Dept of Balcali Hospital and Clinics, Adana, Turkey; 2) Cukurova University, AGENTEM (Adana Genetic Diseases Diagnosis and Treatment Center), Adana, Turkey; 3) Cukurova University, Faculty of Medicine, Pediatric Metabolism-Endocrinology Dept. of Balcali Hospital and Clinics, Adana, Turkey.

**Objective:** Glycogen storage diseases (GSDs) are mostly transmitted as autosomal recessive disorders and are therefore more frequent in countries with high consanguinity rates such as in Turkey. This study reports our local experience in the genetic diagnosis of inborn errors of metabolism over the GSDs.

**Methods:** 576 patients recruited for this study were all clinically suspected GSDs and admitted to our genetic diseases diagnosis and treatment center (CU AGENTEM). We have customized a GSD related multi-gene panel including 19 genes (*GAA*, *SLC37A4*, *G6PC*, *GYS2*, *AGL*, *GBE1*, *PHKA2*, *PHKB*, *PHKG2*, *PHKA1*, *PYGM*, *PYGL*, *PFKM*, *PGAM2*, *LDHA*, *ENO3*, *PGM1*, *ALDOA* and *GYG1*) for next generation sequencing (MiSeq, Illumina). **Results:** A significantly high consanguinity rate was observed among parents of affected children. 181 clinically significant variants were reported in 170 (29.5%) out of 576 patients. 69 (40.6%) of them had novel variants which was confirmed by parental testing for the carrier status. The most frequent cases were *AGL* gene related GSD type III, GSD type I with mutations in *G6PC* and *SLC37A4* genes, *PYGM* gene related GSD type V and GSD type IX with mutations in *PHKA2*, *PHKG2* and *PHKB* genes. **Conclusion:** Inborn errors of metabolism are common and it is important to enhance awareness among clinicians and families. Although our results are preliminary still suggests the idea of how it is necessary to do molecular testing fast and accurately for patient management, and genetic counselling.

**2854T**

**Common mutation and hot-spot region of *ATP7B* gene in Vietnamese children with Wilson disease.** H.M.T. Nguyen<sup>1</sup>, H.A.P. Nguyen<sup>2</sup>, M.P.T. Nguyen<sup>1</sup>, N.D. Ngo<sup>1</sup>, T.M. Ngo<sup>1</sup>, N.T. Ngo<sup>1</sup>, D.M. Tran<sup>1,2</sup>, H.T. Le<sup>1,2</sup>. 1) Human genetics Dept, Vietnam National Children's Hospital, Hanoi, Hanoi, Viet Nam, MsC; 2) Hepatology Dept, Vietnam National Children's Hospital, Hanoi, Hanoi, Viet Nam, MD.

**Introduction** The WD gene—*ATP7B*, codes for a copper transporting P-type ATPase, which is expressed mainly in hepatocytes and functions in the transmembrane transport of copper. It is a rare autosomal recessive disorder of copper metabolism, which is characterized by hepatic and neurological disease. The mutation spectrum of *ATP7B* gene is dissimilar between ethnic groups and appears to be population-specific. p.R778L is very common in Asian but p.H1069Q is the most frequent mutation in European. **Aim of study** The goal of this study is to investigate characteristics of *ATP7B* mutation in children with Wilson disease. **Patient and method** Peripheral blood was collected from unrelated 78 WD patients—46 females and 32 males. Direct DNA sequencing for 21 exons and intron boundary was used to identify the mutation in *ATP7B* gene. **Result** A total of 27 different mutations (missense mutations, n= 16; frame shift, n=6; nonsense mutations, n=1; splice site mutations, n=4) were detected in this study, which accounted for 96.8%. Of the 78 Wilson patients, *ATP7B* mutations were identified in both alleles in 38 patients (homozygous; n=26, compound heterozygote; n=49); in only one allele in three patients (n=1); and none of mutation in both alleles in two patients (n=2). Among 47 genotypes, ratio of homozygote and compound heterozygote are 62,8% and 33,3%. p.S105X often found in homozygous patients and present in 37.1% of the 156 alleles studied. Following is five other mutations, including: p.L1148T (7.3%), IVS14-2A>G (6.6%), p.L1371P (6.0%), p.T850I và p.V176SfsX28 (5.3%). Most of mutations in this study occurred in exon 2 (43.0%), exon 16 (9.9%), exon 8 (8.6%), exon 14 and intron 14 (6.6%). Procedure to detect *ATP7B* gene mutation were set up as following: (1) exon 2; (2) 6 exon (8, 16, 14, 15, 18, 20); (3) 5 exon (6, 10-13); (4) the remainings in *ATP7B* gene. **Conclusion** S105X is the most prevalent of Wilson mutation in this study. Exon 2, exon 8, exon 16, exon 14 and intron 14 are considered as hotspot regions in children with Wilson disease in Vietnam. The discovery of the characteristic of *ATP7B* gene in Wilson patients has opened up a new approach in diagnosis for this disease in Vietnam. .

**Genetic testing for patients with exercise intolerance, rhabdomyolysis, or a suspected metabolic myopathy.** M. Kyriass, A. Gruber, F. Xu, Q. Hurshman, J. Weber. PreventionGenetics, Marshfield, WI.

The metabolic myopathies are a heterogeneous group of disorders caused by defects in muscle energy metabolism that cause inadequate production or maintenance of ATP levels (Kahler 2017. *Metabolic Myopathies*. In: *Inherited Metabolic Diseases: A Clinical Approach*). Typical clinical features include slowly progressive muscle weakness with or without hypotonia, premature fatigue, episodic aches, cramps and myalgia, exercise intolerance with or without a "second wind" phenomenon, rhabdomyolysis which may or may not be accompanied by myoglobinuria, high creatine kinase (CK) levels, and acute renal failure (Wortmann 2002. *Reumatologia*. 18: 90-93; Olpin et al. 2015. PubMed ID: 25878327; Kahler 2017). Early recognition of these disorders is important as proper intervention can help prevent morbidity and/or mortality caused by the more severe symptoms (generally rhabdomyolysis and renal failure) (Olpin et al. 2015. PubMed ID: 25878327). In an effort to provide a molecular diagnosis for these patients, PreventionGenetics developed a next-generation sequencing (NGS) panel containing 59 genes associated with known metabolic myopathies or disorders that include exercise intolerance and/or rhabdomyolysis as a main clinical presentation. To date, a clear positive result was found in approximately 6% of cases. The most frequently affected gene was *PYGM*, which is known to be one of the most common causes of metabolic myopathy (Olpin et al. 2015. PubMed ID: 25878327). We have also identified causative variants in genes more rarely associated with these disorders, such as *ANO5* and *HADHB*. In addition to the clearly positive cases, an additional 14% of cases were found to carry a single pathogenic or likely pathogenic variant, and nearly 70% of cases had variants of uncertain significance that could be related to the phenotype. In the majority of cases, deletion/duplication testing was not performed to look for possibly causative copy number variants (CNVs), which may have further clarified test results. In the near future, CNV analysis will be integrated with this test. Overall, these results indicate that NGS-based panel testing for metabolic myopathies, exercise intolerance and/or rhabdomyolysis can aid in the clinical diagnosis of this patient group.

**Detection of GBA missense mutations and other variants using the Oxford Nanopore MinION.** C. Proukakis<sup>1</sup>, M. Leija-Salazar<sup>1</sup>, K. Mokretar<sup>1</sup>, S. Mullin<sup>1</sup>, M. Toffoli<sup>1</sup>, M. Athanasopoulou<sup>1</sup>, A. Donald<sup>2</sup>, R. Sharma<sup>3</sup>, D. Hughes<sup>4</sup>, A.H.V. Schapira<sup>1</sup>, F.J. Sedlazeck<sup>5</sup>. 1) Institute of Neurology, University College London, London, England, United Kingdom; 2) Department of Paediatrics, Royal Manchester Children's Hospital, UK; 3) The Mark Holland Metabolic Unit, Salford Royal Foundation NHS Trust, Salford, UK; 4) Lysosomal Storage Disorders Unit, Royal Free Hospital, London, UK; 5) Human Genome Sequencing Center, Baylor College of Medicine, Houston, USA.

Mutations in *GBA* cause Gaucher disease when biallelic, and are strong risk factors for Parkinson's disease when heterozygous. *GBA* analysis is complicated by the nearby pseudogene. We designed and validated a method for sequencing *GBA* on the Oxford Nanopore MinION. We sequenced an 8.9 kb amplicon from DNA samples of 17 individuals, including patients with Parkinson's and Gaucher disease, on older and current (R9.4) flow cells. These included samples with known mutations, assessed in a blinded fashion on the R9.4 data. We used NanoOK for quality metrics, two different aligners (Graphmap and NGMLR), Nanopolish and Sniffles to call variants, and Whatsp for phasing. We detected all known mutations in these samples in a blinded fashion, including the common p.N409S (N370S) and p.L483P (L444P), and three rarer ones, at the correct zygosity, as well as intronic SNPs. In a sample with the complex RecNcil allele, we detected an additional coding mutation, and a 55-base pair deletion. We confirmed compound heterozygosity where relevant. False positives were easily identified. The Oxford Nanopore MinION can detect missense mutations and an exonic deletion in this difficult gene, with the added advantage of phasing and intronic analysis. It can be used as an efficient diagnostic tool.

**Innate immune gene expression signature in rheumatoid arthritis revealed the key role of *TLR8* and *IL1RN* in discrimination of active and inactive disease.** A. Petrackova<sup>1</sup>, P. Horak<sup>2</sup>, M. Radvansky<sup>2</sup>, R. Fillerova<sup>1</sup>, V. Smotkova-Kraicova<sup>1</sup>, M. Kudelka<sup>3</sup>, F. Mrazek<sup>1</sup>, M. Skacelova<sup>2</sup>, A. Smrzova<sup>2</sup>, M. Schubertova<sup>2</sup>, E. Kriegova<sup>1</sup>. 1) Department of Immunology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic; 2) Department of Internal Medicine III - Nephrology, Rheumatology and Endocrinology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic; 3) Department of Computer Science, Faculty of Electrical Engineering and Computer Science, Technical University of Ostrava, Ostrava, Czech Republic.

**Background:** Innate immunity plays a critical role in the pathogenesis of rheumatoid arthritis (RA). Although many studies have focused on individual mediators of innate immunity, a comprehensive innate gene expression signature associated with RA and particularly with disease activity has not been established. **Methods:** The gene expression profile of 18 innate immunity genes, Toll-like receptors (*TLR*)1-10, and seven members of the interleukin (*IL*)1/*IL1R* family, together with *CXCL8/IL8*, were assessed in peripheral blood mononuclear cells (PBMC) from patients with RA (n=67) treated according to the standard protocol and age-/gender-matched healthy control subjects (n=55) using a high-throughput SmartChip Real-Time-qPCR system (WaferGen). The subgroups of patients were formed on the basis of the disease activity, with a *Disease Activity Score in 28 joints (DAS28)* of  $\geq 3.2$  being taken as the active disease (inactive RA, n=35; active RA, n=32). **Results:** Expression profiling revealed the deregulation of 13 innate immunity genes in patients treated for RA when compared to the healthy controls ( $P_{\text{corr}} < 0.05$ ), with *TLR10* and *IL1RAP* being reported for the first time. In active RA, upregulated expression of *TLR2*, *TLR4*, *TLR6*, and *TLR8* and downregulation of *TLR10* ( $P < 0.04$ ) was observed when compared to inactive RA. Applying artificial neural networks, two gene sets within an eight-activity gene expression signature (*TLR1*, *TLR2*, *TLR3*, *TLR7*, *TLR8*, *CXCL8/IL8*, *IL1RN*, *IL18R1*) were able to discriminate between patients with the active and inactive disease. Multivariate visual network analysis revealed *TLR8* and *IL1RN* as key genes whose expression characterizes active and inactive RA. **Conclusion:** The innate immune gene expression signature revealed the key role of *TLR8* and *IL1RN* in the discrimination of active and inactive RA. Our study further supports the important role of innate immunity in RA and highlights the heterogeneity of active RA. **Funding:** MZ CR VES15-28659A, IGA UP\_2018\_010, IGA UP\_2018\_016, MH CZ – DRO (FNOL, 00098892).

**2858F**

**Comprehensive profiling of chemokine receptors in peripheral blood mononuclear cells obtained in patients with chronic lymphocytic leukemia.** E. Kriegova<sup>1</sup>, V. Smotkova Kraicova<sup>1</sup>, R. Fillerova<sup>1</sup>, G. Manukyan<sup>2</sup>, A. Petrackova<sup>1</sup>, Z. Mikulkova<sup>1</sup>, G. Gabcova<sup>1</sup>, L. Kruzova<sup>2</sup>, R. Urbanova<sup>2</sup>, P. Turcsanyi<sup>2</sup>, P. Ryznerova<sup>2</sup>, T. Papajik<sup>2</sup>. 1) Department of Immunology, Faculty of Medicine and Dentistry, Palacky University Olomouc and University Hospital Olomouc, Olomouc, Czech Republic; 2) Department of Hemato-Oncology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic; 3) Laboratory of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia.

**Background:** Chemokines and their receptors are involved in the regulation of cell recruitment, survival, proliferation, and trafficking, all these processes crucial in the pathogenesis of chronic lymphocytic leukemia (CLL). Comprehensive profiling of chemokine receptors in CLL and its subgroups according prognostic relevance is missing. **Aim:** To characterize the chemokine expression pattern in CLL patients and subgroups according to prognosis and cytogenetic aberrations. **Patients/Methods:** We studied the gene expression pattern of 16 canonical and 4 atypical chemokine receptors in peripheral blood mononuclear cells (PBMC) of CLL patients (n=88) and healthy subjects (n=34) by using SmartChip quantitative RT-PCR (WaferGen Bio-systems). Given the dynamic variability of CD5 expression and its link to the proliferating pool of neoplastic cells, the expression of CXCR3, CXCR4, CXCR5, CXCR7, and CCR7 was confirmed by flow cytometry on CD5<sup>high</sup> and CD5<sup>low</sup> cell subpopulations. **Results:** Among deregulated receptors, 5 receptors (CCR7, CCR10, CXCR3, CXCR4, CXCR5) were up-regulated and 9 receptors (CCR2-CCR6, CCR8, CCRL2, CXCR1, CXCR2) down-regulated in CLL; the expression of others did not differ between CLL and controls ( $P > 0.05$ ). In patients with del(17p) associated with a poor prognosis, higher mRNA levels of CXCR6, CXCR7 and CCR10 was observed comparing to del(13q). On protein level, CD5<sup>high</sup> cell subpopulation expressed higher levels of CXCR3 ( $P < 0.001$ ), CXCR5 ( $P = 0.007$ ), CCR10 ( $P = 0.001$ ), whereas CD5<sup>low</sup> cells expressed higher levels of CXCR4 receptor ( $P < 0.001$ ) in CLL as a whole as well as in subgroups. Moreover, our study revealed distinct differences in CXCR3 expression on both CD5<sup>high</sup> and CD5<sup>low</sup> between IgHV<sup>mut</sup> and IgHV<sup>unmut</sup> subgroups. **Conclusion:** Our results provide a complete picture of expression patterns of chemokine receptors in CLL. Further studies are needed to clarify how chemokine receptor network affects neoplastic development and progression. Grant support: MZ ČR VES16-32339A, IGA\_UP\_2018\_016, MH CZ – DRO (FNOL, 00098892).

**Retrospective analysis of a patient cohort referred for carrier testing for Alpha Thalassemia.** *P.H. Fernandes, A. Kruger, J.P. Tazelaar, J. Zdrodowski, C.A. Holland.* Progenity, Inc., Ann Arbor, MI.

Alpha thalassemia is an autosomal recessive disorder, affecting up to 5% of the world's population. It is most often caused by deletions involving one or both  $\alpha$ -globin genes (*HBA1* and *HBA2*). The alpha thalassemia deletion detection test is intended for carrier testing in adults of reproductive age in accordance with recommendations by ACOG. We performed a retrospective analysis of 75,332 patients referred for alpha thalassemia carrier testing. Testing included Multiplex PCR-based analysis to identify 7 common  $\alpha$ -globin deletions, including  $-\alpha3.7$ ,  $-\alpha4.2$ ,  $--SEA$ ,  $--FIL$ ,  $--MED$ ,  $-\alpha20.5$ , and  $--THAI$ . Of the patients tested, 5191 (6.9%) were positive for at least one  $\alpha$ -globin deletion. Among those that were positive, 4805 (92.6%) were heterozygotes, and 373 (7.2%) were homozygotes, who all had the  $-\alpha3.7/-\alpha3.7$  genotype. We also identified 13 (<1%) compound heterozygotes. These included 7 patients with the  $-\alpha3.7$  and  $-\alpha4.2$  deletions, and 6 patients, whose genotype resulted in defective production of 3 out of 4  $\alpha$ -globins (HbH disease). The highest positivity rate was seen within the African American/Black population (32.4%), followed by the populations of Others/Mixed (7.9%), Asian (7.3%), Native American (5.4%), Hispanic (4.6%), Ashkenazi/Jewish (4.6%), and Caucasian/White (1.6%). To our knowledge, this is the largest and most ethnically diverse population studied in relation to alpha thalassemia carrier status. Analysis of these common  $\alpha$ -globin deletions was successful in identifying silent carriers of alpha thalassemia and those with alpha thalassemia trait as well as those with HbH disease in our patient cohort. In addition, positive carriers were identified at an unexpectedly high frequency in relatively understudied ethnic backgrounds, like Native American and Hispanic populations, giving further impetus to test patients of all ethnicities. This is especially important considering the increasing number of patients with unknown or mixed ancestry.

**2860T**

**Detection of alpha-thalassemia common large deletions by next generation sequencing.** *SH. Rosenthal<sup>1</sup>, A. Gerasimova<sup>2</sup>, R. Owen<sup>1</sup>, J. Catanese<sup>1</sup>, A. Buller-Burckle<sup>3</sup>, F. Lacbawan<sup>1</sup>.* 1) Advanced Diagnostics – Genetics, Genomics and R&D, Quest Diagnostics, San Juan Capistrano, CA; 2) Bioinformatics R&D, Quest Diagnostics, San Juan Capistrano, CA; 3) Molecular Genetics, Quest Diagnostics, San Juan Capistrano, CA.

Alpha-thalassemia is the most common inherited disorder of hemoglobin synthesis, affecting approximately 5% of the world's population. Genomic deletions involving the alpha-globin gene cluster on chromosome 16p13.3 are the main molecular cause of the disease, accounting for approximately 90% of cases. Multiplex gap-PCR and multiplex ligation-dependent probe amplification (MLPA) are frequently used molecular methods for the detection of these deletions. However, those methods are not easily consolidated with newer analytical procedures used for carrier screening of inherited disorders. In this study, a next generation sequencing (NGS) method was developed to detect common alpha-thalassemia deletions including  $-\alpha3.7$ ,  $-\alpha4.2$ ,  $-\alpha20.5$ ,  $--MED$ ,  $--SEA$ ,  $--FIL$ ,  $--THAI$ , as well as the Constant Spring point mutation. To enable efficient sequencing on the Illumina MiSeq platform, a conventional multiplex gap-PCR was performed, followed by nested PCR for each deletion. Using this method, 18 other common inherited diseases including beta thalassemia were consolidated in one assay to create an expanded NGS carrier screening panel. Validation of the consolidated panel using 159 samples showed 100% sensitivity and specificity for all variants tested. Subsequent testing of 3,752 clinical samples using the consolidated panel showed that 7.6% (286/3,752) of cases harbored one or more alpha-thalassemia gene deletions, including 237 cases of  $\alpha\alpha/-\alpha3.7$ , 40 cases of  $-\alpha3.7/-\alpha3.7$ , 7 cases of  $\alpha\alpha/-\alpha4.2$ , 1 case of  $-\alpha3.7/-\alpha4.2$ , and 1 case of  $\alpha\alpha/--MED$ . This demonstrates the implementation of an NGS method to screen common alpha-thalassemia variants as part of a larger comprehensive carrier screening panel.

**2861F****Clonal cell proliferation in paroxysmal nocturnal hemoglobinuria:****Evaluation of *PIGA* mutations and T-cell receptor clonality.** *M. Kim<sup>1,2</sup>, J. Lee<sup>1,2</sup>, J. Park<sup>1,2</sup>, Y. Kim<sup>1,2</sup>, K. Han<sup>1,2</sup>, N.G. Chung<sup>3</sup>, B. Cho<sup>3</sup>, S.E. Lee<sup>4</sup>, J.W. Lee<sup>4</sup>.*

1) Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of; 2) Catholic Genetic Laboratory Center, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of; 3) Department of Pediatrics, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of; 4) Division of Hematology, Department of Internal Medicine, Catholic Blood and Marrow Transplantation Center, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic of.

**Background:** Paroxysmal nocturnal hemoglobinuria (PNH) is an acquired pluripotent hematopoietic stem cell disorder associated with an increase in the number of glycosyl-phosphatidyl inositol (GPI)-deficient blood cells. We investigated the PNH clonal proliferation in each blood cell lineage by analyzing the *PIGA* gene mutation and T-cell receptor (TCR) clonality. **Methods:** Twenty-four PNH patients were enrolled. Flow cytometry was used to measure GPI-deficient fractions in each cell lineage. *PIGA* gene mutation was analyzed by Sanger sequencing in granulocytes and T lymphocytes. TCR clonality assay was carried out in isolated GPI-deficient T lymphocytes. **Results:** The GPI-deficient fraction was the highest in granulocytes followed by red blood cells and T lymphocytes. *PIGA* mutations were detected in both granulocytes and T lymphocytes of 19 patients (79.2%), and the mutant burden was higher in granulocytes. The GPI-deficient fractions of granulocytes and T lymphocytes were significantly correlated with *PIGA* mutant burden of the respective cell lineage. The GPI-AP deficient RBC fraction correlated with reticulocyte count. *PIGA* mutation was more frequently observed in patients with clonal rearrangements in TCR genes ( $P = 0.015$ ). The *PIGA* mutant burden of T lymphocytes was higher in patients showing clonal *TCRB* rearrangement. **Conclusion:** This study demonstrated that PNH clone size varied according to blood cell lineage and the clonal cells may obtain proliferation potential or gain a survival advantage compared with normal cells. **Keywords:** Paroxysmal nocturnal hemoglobinuria; Clonal cell proliferation; *PIGA* mutation; T-cell receptor clonality.

**2862W****Expanded genetic testing for primary immunodeficiencies: Findings from a 207-gene next-generation sequencing panel.** *B. Johnson, P. Nicolosi, C. Hartshorne, S. Martin, K. Ouyang, J. Holle.* Invitae, San Francisco, CA.

**Many primary immunodeficiencies (PIDs) share overlapping presentations, complicating clinical diagnosis. Expanded next-generation sequencing (NGS) panels are valuable in facilitating the diagnosis of patients with PIDs. We performed a retrospective analysis of the clinical utility of a 207-gene PID NGS panel used in a clinical diagnostic laboratory. From April to October 2017, 260 panels were ordered for patients with suspected or known PIDs. Seventy-four pathogenic or likely pathogenic (P/LP) variants were identified in 63 (24.2%) patients. Eight (10.8%) of the P/LP variants were copy number variations (6 deletions, 2 duplications). Fifty-two patients (20%) had 1 P/LP variant, and 11 patients (4.2%) had 2 P/LP variants. Of positive patients, 31.7% ( $n = 20$ ) were heterozygous carriers for autosomal recessive conditions where a second variant was not identified. Twenty-two patients had P/LP heterozygous variants in genes with autosomal recessive and autosomal dominant inheritance patterns, in which the positive findings may or may not explain the patient's phenotype. For example, 13 variants in this category were heterozygous variants in *TNFRSF13B* (*TACI*). Genetic diagnoses were established or likely in 30% of patients with P/LP variants (7.3% of all patients). Five patients were heterozygous for a single P/LP variant and a variant of unknown significance in the same autosomal recessive gene. Four patients in whom a genetic diagnosis was determined were also heterozygous carriers for a second, unrelated condition. One patient was found to have two distinct genetic diagnoses. Variants of uncertain significance (VUS) were identified in most (94.2%) patients. The average turnaround time from test requisition to return of results was 18 days. In total, 63% percent of genetic diagnoses were for conditions that are treatable with hematopoietic cell transplantation. These results illustrate the utility of broad NGS panels for the diagnosis of patients with PIDs..**

**HLA typing using capture-based next-generation sequencing.** S.K. Lai<sup>1</sup>, N.C. Chen<sup>2</sup>, C.S. Chen<sup>3</sup>, P.L. Chen<sup>1,3,4,5</sup>. 1) Graduate Institute of Molecular Medicine, National Taiwan University College of Medicine, Taipei, Taiwan; 2) Graduate Institute of Electronics Engineering, National Taiwan University, Taipei, Taiwan; 3) Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan; 4) Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; 5) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, Taipei, Taiwan.

Human leucocyte antigen (HLA) genes are critical in organ transplantation and immune-related diseases. Traditional HLA typing methods, either by sequence-based typing (SBT) or sequence-specific oligonucleotide (SSO), might report ambiguous typing results, which are caused by the phasing problem or the polymorphic sites outside the sequencing regions. Recent next-generation sequencing (NGS)-based methods rely on long-range PCR, which might suffer from allele drop-out. Using probe capture-based NGS may solve the above-mentioned tackles. In this study, we established a probe capture-based NGS method for HLA typing. Probe sets for Class-I HLA gene (HLA-A, B, C), Class-II HLA gene (DRB1, DPA1, DPB1, DQA1, DQB1, DRB3,4,5) and also MICA covering exon 2 to exon 4 were designed. Ten samples previously known to carry the most common HLA types in Taiwanese were used as the stage one validation for this method. The results were 100% concordant to those from the SBT method. We then proceeded to test the 85 samples from The International HLA Reference Standards from International Histocompatibility Working Group (IHWG). An average of 99% results were consistent with the results from IHWG. The remaining 1% results were inconsistent, including 2 DPA1 alleles, 9 DPB1 alleles, 4 DQA1 alleles, 4 DQB1 alleles and 1 DRB1 allele; we later proved that those results from IHWG were wrong. The ratio of two allele read depth in heterozygous loci were 40%-60% in average. Furthermore, our data showed that this method could resolve ambiguous HLA types due to phasing problems.

**A Blau syndrome family: Mutated *NOD2* allele transmitted from the father with somatic and germline mosaicism.** Y. Lin<sup>1,2</sup>, C. Zeng<sup>1</sup>, X. Chen<sup>1</sup>, T. Li<sup>1</sup>, H. Liu<sup>1</sup>, H. Liu<sup>3</sup>, H. Hu<sup>2</sup>, L. Liu<sup>1</sup>. 1) Department of Genetics and Endocrinology, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong, China; 2) Guangzhou Institute of Pediatrics, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong, China; 3) Department of Radiology, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong, China.

**Objective:** Blau syndrome (BS) is a rare autosomal dominant autoinflammatory disorder caused by *NOD2* gene deficits with a representative feature of granulomatous arthritis, uveitis and dermatitis on the joints, eyes and skin, which is still not well-known. In this study, we sought to ascertain the intrinsic cause of the suspected family. **Methods:** Here we employed a whole exome sequencing (WES) in a familial aggregation of 2 polyarthritis and erythra affected individuals across 2 continuous generations, followed by a confirmatory Sanger sequencing. **Results:** WES revealed a "de novo" heterozygous pathogenic variant, c.1000C>T(p.R334W), in *NOD2* gene of the proband, which was not found in the symptomatic father. A confirmatory of Sanger sequencing showed that the father shared the identical mutation to the proband as a somatic and germline mosaicism. An urgent prenatal diagnosis was further performed for this family due to an approximately 1/5 recurrence risk recommended by the spermatoc mosaic status. **Conclusion:** This is the first case of described *NOD2* mosaicism in Chinese, the most extensive investigation of the mosaic status, and the first case to speculate the timing of mutagenesis in BS. Our study provides precise diagnosis and genetic counseling for the family, and alerts clinicians and geneticists to be cautious about the molecular findings to avoid omissions and prevent an intrafamilial recurrence of the identical genetic abnormalities.

**2865W**

**Prenatal diagnosis of alpha thalassemia in Northern Vietnam.** *N.T.T. Nhung<sup>1</sup>, N.T.P. Mai<sup>1</sup>, A.T. Lan<sup>1</sup>, N.M. Tien<sup>1</sup>, N.T.M. Huong<sup>1</sup>, N.D. Ngoc<sup>1</sup>, L.T. Thuy<sup>2</sup>, L.T. Hai<sup>2</sup>.* 1) National children's Hospital, Hanoi, VietNam; 2) Hanoi Hospital of Obstetrics and Gynecology, Vietnam.

**Background:** Alpha Thalassemia is the most common single-gene disorder in worldwide. There are two severe forms of death: HbH and Bart's Diseases. In this study, we conducted prenatal diagnosis for families with a history of HbH and HbBart's birth from January 2010 to April 2018. **Methods:** We analyzed 226 samples of amniotic fluid from pregnant women at high risk of HbH and HbBart's births. Their family members (pregnancies, their husbands and their children) were identified mutations of *hba* gene. C-ARMS PCR, Multiplex Gap PCR, sequencing and MLPA techniques were accurated for screening all mutations in *hba* gene. **Results:** 54/226 fetuses had no mutations in *hba* gene; 107/226 fetuses had heterozygous of mutations in *hba* gene, 10/226 fetuses had compound heterozygous of 02 mutations and 55/226 fetuses had hommozygous  $\alpha^0$ -thal. **Conclusions:** DNA testing is a basis progress for the diagnosis and preventive treatment before birth. Prenatal diagnosis process is only done on the family who had known mutations. **Keywords:** Alpha Thalassemia, HbBart's, HbH, pregnancy, DNA testing, Vietnam.

**2866T**

**The CFTR MASTR v2 assay combined with MASTR reporter analysis is a fast and precise research solution for SNV, indel, CNV and (TG)m(T)n locus detection.** *A. Rotthier<sup>1</sup>, K. Bettens<sup>1</sup>, B. Verhelst<sup>2</sup>, C. Marques<sup>1</sup>, R. De Smet<sup>2</sup>, B. Slabbinck<sup>2</sup>, J. Crappé<sup>2</sup>, J. Del Favero<sup>1</sup>.* 1) R&D, Agilent Technologies Belgium, Niel, Antwerp, Belgium; 2) R&D, Agilent Technologies Belgium, Ghent, Belgium.

**Introduction:** NGS based complete *CFTR* mutation analysis is the method of choice to diagnose Cystic Fibrosis in patients, neonatals and to perform carrier screening. To further improve the speed and accuracy of mutation analysis the *CFTR* MASTR Dx\* assay was extended to a complete workflow comprising of a sample to result solution for all coding *CFTR* regions, 7 selected deep intronic regions, the (TG)m(T)n heteropolymeric region, and promoter region up to position c.-108. Data quality control to measure, monitor and optimize the complete workflow and data analysis is integrated within the MASTR Reporter. In addition, the MASTR Reporter includes a customizable variant filter for selection of the most relevant variants for any population under study. The *CFTR* NGS workflow was extensively examined in-house using both blood and dry blood spot (DBS) derived DNA. **Methods:** The *CFTR* MASTR v2 with MASTR Reporter (v1.1.0) *CFTR* v2\*\* was verified on 57 blood samples (for 552 SNVs, InDels and (TG)m(T)n reference variants) and on 195 blood samples (for 15 CNVs). The MASTR Reporter *CFTR* v2\*\* achieved 100% sensitivity and specificity for SNVs, InDels and (TG)m(T)n events in blood. The (TG)m(T)n was correctly called by MASTR Reporter in all samples. For CNV, the MASTR Reporter *CFTR* v2\*\* showed 100% sensitivity and 98.45% specificity. In addition, *CFTR* MASTR Dx with MASTR Reporter *CFTR* Dx\* was validated on 50 DBS (64 SNVs and InDels) and on 116 blood samples (431 SNVs, InDels and (TG)m(T)n). Sensitivity, specificity and accuracy\* were all 100% for both SNVs on DBS as for (TG)m(T)n repeats, SNVs and Indels in blood. Noteworthy, MASTR Reporter identified the combined *CFTR* heterozygous I507del and F508del mutations. **Conclusion:** The *CFTR* MASTR v2 assay combined with MASTR Reporter\*\* results in a fast and precise research solution for identification of SNVs, InDels, CNVs and (TG)m(T)n. The development of an advanced PCR stutter correction algorithm in MASTR Reporter (v1.1.0) also represents a major advantage for quality control and accurate (TG)m(T)n calling. Since the *CFTR* MASTR Dx with MASTR Reporter\* validation study called SNVs (on DBS), and SNVs, Indels and (TG)m(T)n (on blood) with 100% accuracy, the complete workflow allows for routine diagnostic testing for all *CFTR* mutations. \*The MASTR *CFTR* Dx workflow is available as CE-IVD product in EU only. \*\*For Research Use Only. Not for use in diagnostic procedures.

**2867F**

**Differential cytokine pattern associated with a osteolysis predisposing allele TNF-238\*A in patients with/without severe osteolysis around total hip arthroplasty.** R. Fillerova<sup>1</sup>, T. Dyskova<sup>1</sup>, P. Schneiderova<sup>1</sup>, V. Smotkova-Kraiczova<sup>1</sup>, J. Gallo<sup>2</sup>, E. Kriegova<sup>1</sup>. 1) Department of Immunology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic; 2) Department of Orthopedy, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic.

**Introduction:** Individual susceptibility to periprosthetic osteolysis (PPOL) around total hip arthroplasty (THA) is associated with genetic variations in cytokine genes. Thus, cytokine pattern may differ in THA patients with mild and severe PPOL and in patients carrying a risk allele TNF-238\*A, associated with severe osteolysis. **Methods:** Peripheral blood mononuclear cells (PBMCs) obtained from 31 THA patients with severe (n=23) and mild (n=8) osteolysis carrying (n=12)/non-carrying (n=19) a TNF-238\*A risk allele were stimulated by lipopolysaccharide (LPS). Conditioned media were collected and protein concentrations of cytokines IL-2, IL-5, IL-10, IFN- $\gamma$ , TNF- $\alpha$ , VEGF, and RANKL were measured by Luminex and ELISA. **Results:** Elevated expression of IL-2, IL-5, VEGF, and RANKL ( $P < 0.05$ ) was observed in supernatants from patients with severe comparing to mild osteolysis, irrespective of TNF-238 genotype. Patients with TNF-238 GG genotype with severe osteolysis showed up-regulated expression of all studied cytokines, except IL-10 and VEGF, comparing to those with mild osteolysis. In severe osteolysis, the carriers of rare TNF-238\*A allele showed lower expression of IL-2, IFN- $\gamma$ , TNF- $\alpha$ , and RANKL ( $P < 0.05$ ) when comparing to non-carriers. **Conclusion:** Alteration in cytokine-expression pattern in LPS-stimulated PBMCs from THA patients with mild and severe osteolysis and differing by TNF-238\*A genotype was observed. Molecular mechanisms by which TNF-238\*A allele increases a risk of severe osteolysis should be further investigated. **Grant support:** MZ CR VES16-31852A, MZ ČR VES15-27726A, IGA UP\_2018\_016, MH CZ – DRO (FNOL, 00098892).

**Detecting *FLT3-ITD* and *NPM1* mutations in adult patients with acute myeloid leukemia in the Mongolia.** S. Oyunbileg<sup>1,2</sup>, D. Batbayar<sup>2</sup>, S. Tungalag<sup>1</sup>, Kh. Batsukh<sup>1</sup>, M. Sukhbaatar<sup>1</sup>, E. Elbegjargal<sup>1</sup>, A. Boldbaatar<sup>1</sup>, O. Norov<sup>1</sup>, S. Baasabjav<sup>2</sup>. 1) Hematology and Bone Marrow Transplantation Center of Mongolia, Ulaanbaatar, Mongolia; 2) Mongolian National University of Medical science, Department of Physiology.

**Objective:** *FLT3* is a cytokine receptor that is expressed on leukemic blasts in most cases of acute myeloid leukemia. The *FLT3* gene encodes a tyrosine kinase receptor that plays a key role in controlling survival, proliferation and differentiation of hematopoietic cells. *FLT3* mutations have emerged as important targets for molecular therapy.[1] Although *FLT3* internal tandem duplication (ITD) mutations in acute myeloid leukemia (AML) confer an adverse prognosis, co-occurrence with a nucleophosphomin (*NPM1*) mutation partially improves response and survival outcomes. Our study aims to establish a conventional detection method for *FLT3/ITD* and *NPM1* mutations in adult patients with acute myeloid leukemia in the Mongolia. **Materials and methods:** Genomic DNA was extracted from peripheral blood of 24 patients newly diagnosed and was diagnosed with acute myeloid leukemia. Primers were designed to distinguish between wild-type *FLT3* and *FLT3/ITD* variants. Methods using a polymerase chain reaction (PCR), PCR-ABI 3100 Genetic Analyzer (ROX-500 size standard), and PCR – agarose gel electrophoresis were compared. **Result:** *FLT3/ITD* mutations were found in 12.5% (3) of patients. *FLT3/ITD* was associated with clinical characteristics including higher white blood cell count than acute myeloid leukemia patients without *FLT3/ITD* mutation. By the Kaplan- Meyer method, over 40% of the Adult patients with acute myeloid leukemia overall survival was more than 400 days. In the group of *FLT3-ITD* mutation overall survival was less than 100 days. Of the 24 diagnosed AML samples whose cells were available to us, we successfully screened 2 samples for *NPM1* mutation. **Conclusion:** The average age of AML morbidity in adult Mongolia is 35 years, and this type of cancer is relatively young. The overall survival rate is over 40% longer than 400 days, which is longer than the previous years. It is concluded that the treatment of this leukemia is improved. In our study, *FLT3/ITD* was detected 12%. But *NPM1* was detected 8% (2 samples). This type of mutation was low in Mongolia. It is statistically significant to the number of blood cells in diagnosis compared to uneven prevalence groups, the same as in other researchers.

**2869T**

**Intragenic large deletions of *F8* gene in Hemophilia A: Lessons from DNA sequencing analysis.** T. Atik<sup>1</sup>, E. Isik<sup>1</sup>, B. Akgun<sup>2</sup>, K. Kavaklı<sup>2</sup>, M. Sezgin-Evim<sup>3</sup>, T. Tahtakeser<sup>4</sup>, G. Tuysuz<sup>5</sup>, F. Sahin<sup>6</sup>, H. Onay<sup>7</sup>, F. Ozkinay<sup>7</sup>. 1) Pediatric Genetics, Ege University, School of Medicine, Izmir, Turkey; 2) Pediatric Hematology, Ege University, School of Medicine, Izmir, Turkey; 3) Pediatric Hematology, Uludag University, School of Medicine, Bursa, Turkey; 4) Pediatric Hematology, Kanuni Sultan Suleyman Training and Research Hospital, Istanbul, Turkey; 5) Pediatric Hematology, Akdeniz University, School of Medicine, Antalya, Turkey; 6) Hematology, Internal Medicine, Ege University, School of Medicine, Izmir, Turkey; 7) Medical Genetics, Ege University, School of Medicine, Izmir, Turkey.

Hemophilia A (HA) is an X-linked bleeding disorder caused by mutations in the *F8* gene. The most frequent mutations in *F8* are intron 22 (Inv22) and intron 1 (Inv1) inversions, which occur in approximately 40-50% and 1,5-3% of patients, respectively. However, different kinds of mutations such as point mutations, small and large deletions may cause HA with a clinical feature changing from mild to severe. In this study, molecular analysis results of 253 male HA patients referred to our molecular genetic laboratory for *F8* molecular analysis were retrospectively evaluated. Firstly, patients were analyzed for Inv22 and Inv1. Subsequently, sequencing using next-generation sequencing (NGS) platform was performed in Inv22 and Inv1 mutations negative patients. Of 253 HA patients, 111 (43,8%) were found to have Inv22 (n=108; 42,6%) or Inv1 (n=3; 1,2%), 122 (48,2%) point mutations or small deletions or insertions. In 20 patients, no mutations were detected with inversion analysis and sequencing analysis. When NGS results of these patients were reevaluated, in 8 of them (3,2%), amplification failures were detected in one or more exonic regions (del ex1, del ex2-9, del ex7-13, del ex9, del ex11-12, del ex14, del ex15-22 and del ex26) and it was considered that large deletions involving these unamplified regions are present. In 12 patients, no diagnostic results were obtained with techniques used. MLPA analysis has been planned to confirm these deletions and to reveal other CNVs in these 8 patients and remaining 12 patients. As a conclusion, regarding mutation types, in Turkish HA patients mutation distribution is similar to other populations and careful examination of NGS results may reveal large intragenic deletions in *F8* gene. .

**2870F**

**Hyper IgE syndrome, recurrent infection and sex reversal: A new recessive disorder diagnosed by serendipity.** K. Mandal, P. Srivastava, A. Aggarwal, S. Phadke, D. Saxena. Sanjay Gandhi Post-Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India.

**Introduction:** Autosomal recessive hyper-IgE recurrent infection syndrome (OMIM 243700) is caused by homozygous or compound heterozygous mutations in the *DOCK8* gene (OMIM 611432). We are presenting a family with a new disorder: Hyper IgE syndrome, recurrent infection and sex reversal where the proband had a 470 Kb homozygous deletion on chromosome 9p24.3 involving *DOCK8*. The homozygous deletion in *DOCK8* gene was chance detection, by sub-telomeric Multiplex Ligation-dependent Probe Amplification (MLPA). **Clinical details:** The proband was a 10 month old female born to consanguineous parents. She had skin rash, recurrent respiratory infections and diarrhoea. In view of very high IgE levels (675.4 IU/ml) and eosinophilia (46%) she was diagnosed to have hyper IgE syndrome. She had normal developmental milestones till 15 months of age when she had herpes encephalitis. **Investigation results:** Clinical exome sequencing by NGS was done to look for various putative sequence variations causing hyper IgE syndrome. No significant sequence variation was detected. However, it revealed that the sample was that of a male. Ultrasound of abdomen revealed normal female internal genitalia. To obtain fast results about the sex of the child, we did MLPA using SALSA MLPA P070 subtelomeres probemix (MRC Holland). It revealed Y fragments. This probe set contains a probe at exon 24 of *DOCK8* at 9p24.3. To our surprise, there was homozygous deletion at this point. Later on both parents were found to be heterozygous for the deletion. Karyotype (GTG banding) of the proband also confirmed male sex. Array CGH, performed, using Kit 750 K (Affymetrix, Santa Clara, CA, USA) identified 470Kb homozygous deletion on chromosome 9p24.3 (arr[hg19] 9p24.3(208,454-678,837)x0). This region included 2 important genes; *DOCK8* and *KANK1*. **Discussion:** 46,XY sex reversal is reported in some of the individuals with heterozygous deletion at 9p24.3. Since, in most 9p deletion cases (OMIM 158170) sex reversal was not observed, Hoo et al. (1989) postulated that there might be a recessive gene on 9p24 important for the development of testes. The DMRT cluster, located at 9p24.3, has been shown to be the strongest candidate for sex reversal. In our patient, the homozygous deletion involving *DOCK8* and *KANK1* genes, distal to the DMRT cluster, refuted the *DMRT* haploinsufficiency as the cause of sex reversal and points towards a still unknown testis determining factor at 9p24.3.

**2871W****Diagnosis X-linked agammaglobulinemia disease by molecular testing.**

T.M. Ngo, M.T.P. Nguyen, N.D. Ngo, A.T.V. Nguyen, H.T. Le, H.M.T. Le. Vietnam National Children's hospital Hanoi, Vietnam.

**Background:** X-linked agammaglobulinemia (XLA) is a primary immunodeficiency characterized by a failure to generate immunoglobulins of all isotypes due to the absence of mature B cells and plasma cells. Mutations of the Bruton's tyrosine kinase (BTK) gene are responsible for most of the X-linked agammaglobulinemia. **Materials and methods:** In this study, we investigated 4 male patients with XLA-compatible phenotype from 4 unrelated Vietnam families by sequencing and MLPA technique. **Results:** We identified 4 different mutations, one of which were a large deletion mutation from exon 2 to exon 5 of *BTK* gene. Three mutations had been reported previously including one missense mutation (c.862C>T) and two non-sense mutations (c.843G>A and c.753G>A). DNA samples from 3 of 4 of the mothers of males with disease and found mutations in *BTK* gene were positive for the mutation found in their son and one mother was not found a non-sense mutation (c.843G>A) in her son. **Conclusion:** The sequencing and MPLA technique were an important tool for early confirmed diagnosis of XLA disease and detective accurate the carrier. It supports for clinicians to provide genetic counseling and prenatal diagnosis in the future. **Keywords:** X-linked disease, XLA, *BTK* gene.

**2872T****The gene expression profile in the acute leukemia with minor *BCR/ABL1* fusion.**

J. Lee<sup>1,2</sup>, M. Kim<sup>1,2</sup>, S. Hong<sup>3</sup>, Y. Kim<sup>1,2</sup>. 1) Department of Laboratory Medicine, College of Medicine, The Catholic University of Korea, Seoul, Seoul, Korea, Republic of; 2) Catholic Genetic Laboratory Center, College of Medicine, The Catholic University of Korea, Seoul, Seoul, Korea, Republic of; 3) NGS Division2, TheragenETEX Co. LTD, Suwon, Korea, Republic of.

**Background:** It is interesting that minor *BCR/ABL1* is accompanied in acute lymphoblastic leukemia (ALL), acute myeloid leukemia (AML) and mixed phenotype acute leukemia (MPAL). Morphology and immunophenotyping are commonly used to diagnose the disease, however, it has not been well established how the same genetic aberration cause three different disease category. In this study, we tried to find specific gene expression profile according to disease category to clarify differences. **Methods:** Twelve patients with minor *BCR/ABL1* were enrolled; ALL (N=5), AML (N=3), MPAL (N=4) who were diagnosed in Seoul St. Mary's hospital. RNA was extracted from bone marrow specimen and gene expression analysis was performed using using the TruSeq RNA sample prep Kit and Illumina HiSeq2500 sequencer (Illumina, CA). Filtered reads were then mapped to the human reference genome and fusion genes were detected using three different tools. Differentially expressed genes were analyzed using Gene Set Enrichment Analysis and Gene Ontology. **Results:** Gene expression values were compared according to disease category. All minor *BCR/ABL1* were identified and an additional fusion was found which was confirmed by Sanger sequencing. Grouping with gene expression profile excellently reflected phenotypic characters of three disease category. We developed experimental simulation model using scoring the selected specific genes showing significantly overexpressed in each disease category; 251 genes in AML, 117 genes in ALL group. **Conclusions:** RNA sequencing detected fusion genes reliably. Gene expression profiles were significantly different in AML, ALL and MPAL even though they shared same driver genetic aberration. Therefore, gene expression profile made it possible to group acute leukemia because it reflected disease specific phenotypic characters. Through the model developed in this study, a gene expression profile can be used to diagnose acute leukemia by disease specific profile as well as fusion gene detection especially in case showing ambiguous phenotype. **Key Words:** minor *BCR/ABL1* fusion, Mixed Phenotype Acute Leukemia, Gene expression, RNAseq.

**2873F****Segmental maternal uniparental disomy 14 (UPD14) identified by clinical exome sequencing in a patient with parathyroid adenoma and diverticulosis.** S.-H.L. Kang<sup>1</sup>, M. Mulatino<sup>1</sup>, J. Kianmahd<sup>2</sup>, A. Chan<sup>3</sup>, J.A. Martinez-Agosto<sup>2,4,5</sup>, J. Yeh<sup>3</sup>, H. Lee<sup>1</sup>, UCLA Clinical Genomics Center. 1)

Department of Pathology and Laboratory Medicine, University of California, Los Angeles, Los Angeles, CA; 2) Department of Pediatrics, Division of Medical Genetics, University of California, Los Angeles, Los Angeles, CA; 3) Department of Pediatrics, Division of Pediatric Gastroenterology, University of California, Los Angeles, Los Angeles, CA; 4) Department of Human Genetics, University of California, Los Angeles, Los Angeles, CA; 5) Department of Psychiatry, University of California, Los Angeles, Los Angeles, CA.

Chromosome 14 harbors imprinted genes subject to differential expression dependent on the parental origin. The *MEG3* and *MEG8* genes in the chromosome 14q32 region are maternally imprinted. Maternal uniparental disomy 14 [UPD(14)mat] results in loss of paternally expressed genes and overexpression of the maternally expressed genes in the imprinted domain. The cardinal clinical features associated with UPD(14)mat include low birth weight, hypotonia, feeding problems early in life, motor delay, short stature, early puberty, dysmorphic features such as broad forehead and wide nasal tip, and small hands and feet. Utilization of clinical testing methodologies that screen for regions of homozygosity have increased detection and diagnosis of patients with imprinting disorders. Here we report a 15 year-old male with minor dysmorphic features, short stature, precocious puberty, elevated BMI, mild learning disabilities, asthma, hypercalcemia and hyperparathyroidism secondary to parathyroid adenoma, and chronic intermittent constipation/diarrhea. His clinical history includes prematurity at 29 weeks gestation due to IUGR, history of prolonged NICU course, and hypotonia. At the age of 15, he was hospitalized due to intestinal perforation and found to have diverticulitis. Clinical exome sequencing (CES) was requested to identify variants in genes associated with intellectual disability and cancer predisposition. Trio CES analysis identified no clinically significant variants; however, a 6.5 Mb region of homozygosity (ROH) was detected on chromosome 14 involving the 14q32.2->14q32.33 region. The sequencing data from the trio was consistent with all variants in this ROH region being only inherited from the mother with no evidence of a paternal deletion. These findings were confirmed using a PCR-based clinical UPD test. Although many of the patient's clinical features are consistent with UPD(14)mat; his GI history and parathyroid adenoma are not part of the clinical phenotype for this disorder and have not yet been reported in UPD(14)mat patients. To our knowledge, the clinical presentation of diverticulosis and parathyroid adenoma observed in this patient adds to the phenotypic spectrum of UPD(14)mat. Furthermore, the *MEG3* and *MEG8* genes are likely candidates for the majority of this syndrome's clinical spectrum.

**2874W****Using linked-read sequencing to resolve pathogenic mutations and overcome pseudogene interference in *PKD1* for autosomal dominant polycystic kidney disease testing.** C. Kao<sup>1</sup>, M. Gonzalez<sup>2</sup>, K. Wang<sup>3</sup>, R. Pellegri<sup>1</sup>, W.M. Zhang<sup>3</sup>, J. Garifallou<sup>1</sup>, C. Kaminski<sup>1</sup>, J. Smiler<sup>1</sup>, J.D. Blumenfeld<sup>3</sup>, H. Renner<sup>2</sup>, H. Hakonarson<sup>1,4</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Weill Cornell Medical College, New York, NY; 3) The Rogosin Institute, New York, NY; 4) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

Autosomal dominant polycystic kidney disease (ADPKD) is an adult-onset disorder arising from a constitutional mutation of either the *PKD1* or *PKD2* genes. Mutations in *PKD1* account for ~85% of cases and typically are associated with a more severe disease compared to *PKD2* mutations. ADPKD is typically an adult onset disorder, although cysts in the kidney are often present from birth or childhood. These cysts originate from cells that lose the remaining functional copy of *PKD1* or *PKD2* and slowly begin to grow replacing most of the normal mass of the kidney. By age 60, about half of those with ADPKD will experience kidney failure, requiring dialysis or kidney transplantation. These cysts can also develop in liver and pancreas, and complications can also occur in heart valves, abdominal walls, and blood vessels. Genetic testing of ADPKD is challenging. While sequencing of *PKD2* is relatively straightforward, the *PKD1* locus is difficult to resolve using target capture-based next generation sequencing (NGS) approaches reliant on short reads due to the gene's large size and the presence of six *PKD1*-like pseudogenes (*PKD1P1-P6*) located on chromosome 16p13.1, ~13-16Mb centromeric to *PKD1*, that have on average ~97.7% homology. Current diagnostic methods are laborious and expensive, relying on long-range PCR followed by Sanger sequencing. We demonstrate here how linked read sequencing can be applied to resolve/map *PKD1* reads accurately and unambiguously within a standard target capture based NGS framework. The input DNA is partitioned into gel-beads in emulsion (GEMs) using the Chromium instrument (10x Genomics, Inc.), and NGS-compatible mini-libraries are created within each GEM tagged with a unique 16mer barcode. All mini-libraries are pooled together and undergo whole-exome target enrichment with SureSelect baits (Agilent, Inc.), then sequenced on HiSeq2500 (Illumina, Inc). The GEM barcodes provide positional information linking short reads to the original input DNA fragments captured by a specific GEM, thus enabling us to map short, homologous reads that belong to *PKD1* from those originating from the pseudogenes. We apply linked read whole exome NGS on a number of "truth" samples with known pathogenic mutations in *PKD1* and provide a framework for designing a more targeted panel that can be developed for use in ADPKD genetic testing.

**2875T**

**Infant with ARC syndrome caused by novel homozygous deletion in the *VIPAS39* gene.** V. Adir<sup>1</sup>, L. Sagi-Dain<sup>1</sup>, C. Hartman<sup>2</sup>, Y. Elenberg<sup>2</sup>, A. Rotschild<sup>3</sup>, J. Haddad-Halloun<sup>1</sup>, O. Sadeh<sup>1</sup>, A. Peleg<sup>1</sup>. 1) The Institute of Human Genetics, Carmel Medical Center, Haifa, Israel; 2) Pediatric Gastroenterology and Nutrition Unit, Carmel Medical Center, Haifa, Israel; 3) Department of Neonatology, Carmel Medical Center, Haifa, Israel.

Arthrogryposis renal dysfunction and cholestasis syndrome (ARC) is a severe autosomal recessive disorder, associated with liver and kidney dysfunction and congenital joint contractures. In most patients the disease is associated with mutations in the *VPS33b* gene, while in the minority of cases it is caused by *VIPAS39* gene mutations. *VIPAS39* protein forms a complex with the *VPS33B* protein, which functions in regulation of cell apical-basolateral polarity during hepatic and renal development, and in the sorting of lysosomal proteins. We report a female newborn, the firstborn child to first-degree Arab Muslim cousins. The infant was referred to our clinic due to facial dysmorphism, microcephaly, cleft palate, bilateral club foot, limb shortening, hypoplastic kidneys with echogenic cortex, thin corpus callosum, anteriorly displaced anus, abnormal renal and hepatic functioning and failure to thrive. Next-generation sequencing showed no sequence signals for exons 13-17 of the *VIPAS39* gene. This result was confirmed by PCR reaction and gel electrophoresis of these exons. Further PCR reactions and Sanger sequencing revealed the deletion breakpoints, defining the mutation as *14:g.77,899,605\_77,904,634del5029*. This finding enabled us to develop a PCR test that would enable easy identification of carriers. The severity of ARC syndrome highlights the importance of prenatal diagnosis and carrier screening in the extended family.

**Genotype and phenotype of Vietnamese patients with 11 $\beta$ -hydroxylase deficiency.** M.T.P. Nguyen<sup>1,2</sup>, C.D. Vu<sup>1</sup>, T.H. Nguyen<sup>2</sup>, T.M.H. Nguyen<sup>1</sup>, T.T.N. Ngo<sup>1</sup>, M.T. Ngo<sup>1</sup>, D.N. Ngo<sup>1</sup>, V.H. Nong<sup>2</sup>, T.H. Le<sup>1</sup>, H.H. Nguyen<sup>2</sup>. 1) Human genetics department, National Children Hospital, Hanoi, Hanoi, Viet Nam; 2) Institute of Genome Research, Vietnam Academy of Science and Technology.

Congenital adrenal hyperplasia (CAH) is an autosomal recessive disease which is characterized by a deficiency of one of the enzyme activities for the synthesis of cortisol from cholesterol by the adrenal cortex. More than 90% cases of CAH are due to 21-hydroxylase deficiency (21OHD), whereas 5-8% arises from 11 $\beta$ -hydroxylase deficiency. CAH due to 11 $\beta$ -hydroxylase deficiency is frequently associated with hypertension. Mutations in *CYP11B1* gene are the cause of the lack of 11 $\beta$ -hydroxylase activity. In this study, we applied PCR and sequencing techniques to screen mutations in *CYP11B1* gene for 15 patients with 11 $\beta$ -hydroxylase deficiency. Results showed that 8/15 patients had heterozygous mutation p.R43Q (06 boys and 02 girls): 05/06 male patients had classical simple virilization CAH; 01/06 male patient had classical salt wasting CAH; 01 female patient had classical simple virilization CAH and 01 female patient had non-classical CAH. There are 2/15 male patients had homozygous mutation p.R43Q but had difference phenotypes: one patient had hypertension and classical simple virilization CAH; the other had classical salt wasting CAH. This study also found 05 novel mutations in 06 patients, which is p.R51K, p.E147D, p.N152K, IVS6+5G>T and p.Y395X. All of six patients had classical simple virilization CAH. This studies also identified the effects of novel mutations (p. R51K, p. E147D, p.N152K) on the level of expression of the 11 $\beta$ -hydroxylase enzyme. All three mutations affect the expression level of the enzyme. In particular, p.R51K reduced the activity of 11 $\beta$ -hydroxylase to about 29% compared to control. p.E147D mutation decreased to 48% and p.N152K reduced to 36% compared to control. The mutations p.R51K, p.E147D, p.N152K affected the structure of the *CYP11B1* enzyme by altering the hydrogen bonding with adjacent amino acids. We also predicted of mutation in IVS6+5G>T gene are likely to affect mRNA synthesis using MaxEntScan software (Yeo and Burge, 2004-<http://gens.mit.edu/burgelab/maxent/5ss>). Understanding of *CYP11B1* genotype and phenotype is the basis for genetic counseling and prenatal diagnosis in the future.

**2877W**

**A novel next generation sequencing based genetic test platform for congenital adrenal hyperplasia due to CYP21A2 defects.** Q. Lao<sup>1</sup>, Y. Zhao<sup>2</sup>, M. Mehta<sup>2</sup>, B. Tran<sup>2</sup>, D. Merke<sup>1,3</sup>. 1) National Institutes of Health Clinical Center, Bethesda, MD; 2) Frederick National Laboratory for Cancer Research, Frederick, MD; 3) Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD.

Congenital Adrenal Hyperplasia (CAH) due to *CYP21A2* defects is an autosomal recessive disease of steroidogenesis and affects approximately 1 in 15,000 in the severe classic form. Mandatory neonatal CAH screening relies on a sometimes ambiguous hormonal test plagued by false positives and false negatives rather than *CYP21A2* genotyping, which has been historically challenging. *CYP21A2* is located in a low copy repeat named *RCCX* module composed of “*STK19-C4A-CYP21A2P-TNXA-STK19P-C4B-CYP21A2-TNXB*”, 4 pairs of highly homologous genes in tandem in the chromosome 6 major histocompatibility complex region. Most of the *CYP21A2* mutations are due to gene conversions from *CYP21A2P*, which also presents a major obstacle of pseudogene interference in the mapping procedure of standard NGS approaches. Commonly existing copy number variations (1-4 copies in haploid) due to unequal crossovers throughout the *RCCX* module lead to further chaos in mapping, especially for the commonly found CAH alleles with 30-kb deletion or duplications. We aimed to develop a novel NGS based CAH genetic test platform that can 1) overcome the mapping interference by pseudogenes and copy number variations; 2) determine the haplotype/phase of detected mutations without the requirement of parental genotyping; 3) also cover *TNXB* since about 10% of the CAH alleles have contiguous deletions extending into *TNXB* causing Ehlers-Danlos Syndrome in autosomal dominant manner. We applied a 10X GENOMICS CHROMIUM partitioning and molecular barcoding system followed by Illumina MiSeq based standard targeted sequencing on two index gDNA samples of typical CAH genotypes: sample A has bi-modular *RCCX* in both alleles while sample B has one bi-modular allele and one mono-modular allele with a *TNXA/TNXB* chimera. Standard 10X GENOMICS software mapped and phased sample A successfully but failed on sample B, likely due to the interference by regional copy number variations. Still utilizing the linked reads generated by the 10X genomics system, we developed a novel *in silico* approach to overcome the interference by homologous pseudogene reads and regional copy number variations. Our preliminary results suggest that the incorporation of 10X genomics, Illumina NGS and our *in silico* analysis meets our goals and poses to be the most accurate and informatic high throughput genetic test platform for CAH.

**2878T**

**Transaldolase deficiency (TALDO-D) as a mimic of gestational alloimmune liver disease (GALD).** H. Yen<sup>1</sup>, B. Mendelsohn<sup>2</sup>, J. Vargas<sup>1</sup>, J. Carmichael<sup>1</sup>, L. Judge<sup>2</sup>, N. Weiss<sup>2</sup>, S. Winter<sup>2</sup>, H. Gao<sup>1</sup>. 1) Fulgent Genetics, Temple City, CA; 2) Department of Pediatrics, University of California, San Francisco, San Francisco, CA; 3) Medical Genetics and Metabolism, Valley Children's Hospital, Madera, CA.

Transaldolase deficiency (TALDO-D) is caused by mutations in the *TALDO1* gene. Transaldolase is the rate-limiting enzyme for the non-oxidative branch of the pentose phosphate pathway, a glucose metabolic pathway that generates NADPH and pentoses. TALDO-D is a rare inborn autosomal recessive disease that presents with a wide range of phenotypes, from IUGR, hepatosplenomegaly, congenital heart defect, to thrombocytopenia. The first patient with TALDO-D was described in 2001. Since then, no more than 40 cases have been reported in literature. Here we present two severe cases in a family resulting in early infant deaths. The older sister (SF) died at the age of 4 weeks and the younger brother (BB) died at the age of 6 weeks. Patient BB was initially suspected to have GALD due to severe neonatal hemochromatosis observed at autopsy in the older sister. Therefore, the mother was treated with intravenous immunoglobulin for the subsequent pregnancy, and patient BB received an exchange transfusion. Nevertheless, patient BB developed lethal liver disease. Both siblings had IUGR, neonatal hemochromatosis, cholestasis, splenomegaly, coagulopathy, thrombocytopenia, intracranial hemorrhage, and hypertrophic cardiomyopathy. Liver failure was the major diagnosis established at autopsy for both siblings. Subsequently, a whole exome trio analysis was performed on samples from BB and the parents. The analysis identified two different missense variants in the *TALDO1* gene. The first, a paternally-inherited heterozygous variant, NM\_006755.1:c.574C>T (p.Arg192Cys), has previously been reported in multiple patients with TALDO-D in the homozygous state. The second, a maternally-inherited heterozygous variant, NM\_006755.1:c.715C>T (p.Arg239Cys), has not been previously reported in literature. This variant is located in the highly conserved putative phosphate binding site, which is required for transaldolase activity. Upon clinical suspicion of TALDO-D in BB, a targeted mutation test was performed on the affected sister, resulting in the detection of both missense mutations. This study strongly supports the pathogenicity of the novel variant, p.Arg239Cys, in the *TALDO1* gene. TALDO-D can mimic GALD and should be considered in cases of GALD, as recurrence risk differs between the two disorders. Genetic or polyol testing should be considered in cases of suspected GALD to address the possibility of TALDO-D.

**Mapping of FAH mutations in hepatorenal tyrosinemia type 1 in consanguineous families.** *M. Zahoor<sup>1</sup>, S. Ijaz<sup>1</sup>, K. Ramzan<sup>2</sup>, H. Cheema<sup>3</sup>.* 1) Institute of Biochemistry & Biotechnology, Faculty of Biosciences, University of Veterinary & Animal Sciences, Lahore, Punjab, Pakistan; 2) Department of Genetics, King Faisal Specialist Hospital and Research Centre, Riyadh, Saudi Arabia; 3) 3Department of Pediatric Gastroenterology and Hepatology, The Children's Hospital & The Institute for Child Health, Lahore, Pakistan.

Hepatorenal tyrosinemia type 1 (HT1) is a rare inborn error of tyrosine catabolism with a worldwide prevalence of 1 out of 100,000 live births affecting in infancy. HT1 is clinically characterized by hepatic and renal dysfunction resulting from the deficiency of fumarylacetoacetate hydrolase (FAH) enzyme, caused by recessive mutations in the *FAH* gene. Seven Pakistani families, having affected child with HT1, were enrolled over a period of 6 years. All regions of the *FAH* gene spanning exons and splicing sites were PCR amplified and mutation analysis was carried out by direct sequencing. Results of sequencing were confirmed by PCR-RFLP analysis. Evolutionary analysis of the *FAH* has also been performed along with mutation spectrum for treatment strategy. Four different *FAH* mutations were found to co-segregate with the disease phenotype. Two of these *FAH* mutations (c.192G>T and c.974C>T) and one novel (c.67T>C; p.S23P) were mapped in one family each while (c.1062+5G>A [IVS12+5G>A]) found in four families. Five of the affected children has been died from during course of time as they were presented late with acute form segregating (c.1062+5G>A [IVS12+5G>A] and c.192G>T) mutations. Most of the children do not survive due to delayed diagnosis followed by untimely treatment. The mutation spectrum in the disease is different on severity and prognosis of the disease. This tragic condition advocates the establishment of expanded newborn and carrier screening program for HT1 in affected families and sporadic cases specially with mutations having high severity and founder affect.

**2880W**

**Compound heterozygous missense variants in the *ADAM17* gene cause neonatal inflammatory skin and bowel disease 1.** *I. Imoto<sup>1,2</sup>, M. Saito<sup>2</sup>, K. Suga<sup>2</sup>, T. Naruto<sup>2</sup>, T. Kohmoto<sup>2</sup>, M. Otsu<sup>2</sup>, K. Horiuchi<sup>3</sup>, H. Nakayama<sup>4</sup>, S. Higashiyama<sup>4</sup>, R. Nakagawa<sup>2</sup>, S. Tange<sup>2</sup>, K. Masuda<sup>2</sup>, S. Kagami<sup>2</sup>.* 1) Aichi Cancer Center, Nagoya, Aichi, Japan; 2) Tokushima University, Tokushima, Japan; 3) Keio University School of Medicine, Tokyo, Japan; 4) Ehime University Graduate School of Medicine, Toon, Ehime, Japan.

A disintegrin and metalloprotease 17 (ADAM17), also called TNF $\alpha$  converting enzyme (TACE), is the major sheddase for various proteins including TNF $\alpha$  and EGFR ligands. The genetic deficiency with null mutations of ADAM17 has been linked to neonatal inflammatory skin and bowel disease 1 (NISBD1). We identified the compound heterozygous missense variants in *ADAM17* in the infant with erythroderma with exudate in whole body, recurrent skin infection and sepsis, and prolonged diarrhea through targeted exome sequencing. *ADAM17* was transcribed equally from both alleles and translated. Both missense variants locate outside of the catalytic domain. To determine the activity of two ADAM17 mutants, we constructed plasmids expressing ADAM17 with those mutations (ADAM17-Mut1 and Mut2), and transfected these mutant plasmids, plasmid expressing wild type ADAM17 (ADAM17-WT), or empty vector into ADAM17/ADAM10 double knockout mouse embryonic fibroblasts (ADAM10,17<sup>-/-</sup>mEFs). ADAM17-WT, Mut1, and Mut2 proteins were expressed at similar levels on the plasma membrane of transfected cells. However, impaired basal and phorbol myristate acetate (PMA)-stimulated TACE activities were observed in both ADAM17-Mut1 and Mut2 compared with ADAM17-WT in in vitro TACE assay using cell lysates from transfected cells. In addition, PMA-inducible shedding activity for alkaline phosphatase (AP)-tagged TNF $\alpha$ , TGF $\alpha$ , or HB-EGF was strongly reduced in both ADAM17 mutants compared with ADAM17-WT in transfected cells. Because clinical features of the patient seem to be explained by the defect of ADAM17 activity, compound heterozygous missense variants detected in *ADAM17* may lead to the development of NISBD1.

**Implementation of three-tier sequencing algorithm improves cystic fibrosis newborn screening.** D.M. Kay<sup>1</sup>, M. Berdella<sup>2</sup>, J. Boyer<sup>3</sup>, J. DeCelle-Germana<sup>4</sup>, A. Dozor<sup>5</sup>, C.N. Fortner<sup>6</sup>, R. Giusti<sup>6</sup>, D.M. Goetz<sup>7</sup>, L. Guida<sup>8</sup>, E. Hughes<sup>1</sup>, R. Kaslovsky<sup>9</sup>, C. Kier<sup>10</sup>, L. Krein<sup>11</sup>, E. Langfelder-Schwind<sup>2</sup>, A. Laterza-Ozrowski<sup>9</sup>, L. Martin<sup>11</sup>, C.A. Saavedra-Matiz<sup>1</sup>, H. Sadeghi<sup>12</sup>, Z. Soutan<sup>2</sup>, A. Ting<sup>13</sup>, C. Stevens<sup>1</sup>, M. Caggana<sup>1</sup>, New York State Cystic Fibrosis Newborn Screening Consortium. 1) Wadsworth Center, New York State Department of Health, Albany, NY; 2) Mount Sinai Beth Israel, New York, NY; 3) Westchester Medical Center, Valhalla, NY; 4) Cohen Children's Medical Center, New Hyde Park, NY; 5) Upstate Medical University, Syracuse, NY; 6) NYU Langone, New York, NY; 7) Children's Hospital of Buffalo, Buffalo, NY; 8) Good Samaritan Hospital, West Islip, NY; 9) Albany Medical Center, Albany, NY; 10) Stony Brook University, Stony Brook, NY; 11) University of Rochester Medical Center, Rochester, NY; 12) Columbia University Medical Center, New York, NY; 13) Mount Sinai Medical Center, New York, NY.

Cystic Fibrosis (CF) newborn screening (NBS) began in NY using an IRT-DNA algorithm in 2002. Despite several improvements, a high false positive rate and low positive predictive value (PPV=3.7%) prompted implementation of a three-tier IRT-DNA-SEQ algorithm on 12/1/2017. Infants with high immunoreactive trypsinogen (IRT; top 5%) were screened for a panel of 39 variants. Those with one variant or ultra-high IRT (top 0.1%) were comprehensively sequenced using Illumina's MiSeqDx CF Clinical Sequencing Assay with supplemental testing to target specific deletions. Variants were confirmed via Sanger sequencing. Infants with two *CFTR* variants were referred to Specialty Care Centers for diagnostic testing, and the primary care provider and hospital of birth were issued reports for all screen negatives, with recommendation for genetic counseling of carriers. Benign/likely benign variants were not reported. During the first four months, 38 infants with two variants were referred. Forty-four *CFTR* alleles were known CF-causing/pathogenic, 19 were varying clinical consequence (VCC), and 13 were uncertain significance (VOUS). Sequencing identified 161 as carriers and 65 with no clinically significant variants. With the original IRT-DNA algorithm, 264 infants would have been referred. The average number of referrals decreased from 73 to 9 per month. Median age at first sweat test was 24 days (range 10–72). Nine infants had confirmed CF, one is classified as possible CF and diagnosis is pending for two (PPV=27.8%; 10/36). Twenty-six infants with two variants and intermediate/low sweat chloride levels are classified as CF-Related Metabolic Syndrome (CRMS)/CF Screen Positive, Inconclusive Diagnosis (CFSPID) and will be followed. The CRMS/CFSPID to CF ratio increased from 0.9 to 2.6, and 25/26 CRMS/CFSPID cases carried at least one VCC or VOUS. Implementation of IRT-DNA-SEQ resulted in 85.6% reduction in referrals and 7-fold increase in PPV. We project 110 infants will be referred annually, and 650 infants will be reported as negative after comprehensive genetic analysis. Additional testing increases lab workload, turnaround times and cost, but is balanced by reduction in follow-up by NBS staff and Care Centers, and an overall reduction in healthcare costs due to elimination of most false positives. Identification of asymptomatic infants with two *CFTR* variants and intermediate/negative sweat results poses new clinical and practical challenges for care teams and families.

**2882F**

**Clinical and molecular features of X-linked hypophosphatemic rickets patients in a cohort of 32 unrelated Han families in Southern China.** L. Liu, Y. Lin, M. Wu, X. Li, J. Cheng, Y. Huang, C. Zeng, X. Mao, Z. Zhou, W. Zhang, C. Li, H. Sheng, Y. Cai, Y. Shao, X. Su, Z. Liu, M. Peng, M. Jiang. Department of Genetics and Endocrinology, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong, China.

**Objectives:** X-linked hypophosphatemic rickets (XLHR) is the most common HR caused by deleterious mutations within *PHEX* gene with a representative feature of hypophosphatemia, skeletal deformities and growth retardation. As XLHR is not well-known and affected individuals are frequently diagnosed as vitamin D deficiency, our study aimed to provide accurate diagnosis and avoid mistreatment. Moreover, the clinical, radiological, biochemical and mutational spectrum of XLHR patients in Southern China were also investigated in this study. **Methods:** A cohort comprised 44 pediatric HR patients and 57 relatives from 40 unrelated families were recruited for genetic analysis with a combined strategy of DNA sequencing and qPCR assay. The clinical features, radiological findings, and serum biochemical parameters of probands were enrolled and further scored for phenotypic correlation analysis. **Results:** 29 diverse mutations were identified in 36 probands (81.82%) along with the *PHEX* gene, and 15 of them were novel. 2 high-frequent single nucleotide replacement mutations, c.1601C>T (p.P534L) and c.2239C>T (p.R747X), were found in 3 unrelated families. Physical examinations, radiological inspections, biochemical tests and genetic analyses revealed typical features of XLHR, and the degree of phenotype might be potentially correlated to mutation type, as the more detrimental mutation would trigger more severe skeletal impairment.

**Conclusions:** Our study extends the mutational spectrum of *PHEX* gene, contributes to accurate diagnosis, and provides evidence for potential hotspots and predictor of disease severity. Our study also addresses *PHEX* gene as the most common but extremely unstable causative gene for HR, which indicates the priority to survey *PHEX* gene when a patient was suspected to suffer from HR. In addition, a supplementary qPCR or MLPA assay is suggested to remedy the weakness of classical sequencing method in the field of gross insertion/deletion.

**2883W****Genetic study of 20 Egyptian patients with Dyggve-Melchoir Clausen syndrome and identification of 5 novel mutations.** G.A. Otaify<sup>1</sup>, M.S. Aglan<sup>1</sup>, N. Patel<sup>2</sup>, S. Ismail<sup>1</sup>, M.S. Zaki<sup>1</sup>, G.M.H. Abdel-Salam<sup>1</sup>, K. Amr<sup>3</sup>, G. Hosny<sup>4</sup>, F.S. Alkuraya<sup>2,5,6</sup>, S.A. Temtamy<sup>1</sup>.

**Abstract** Dyggve–Melchior–Clausen (DMC) syndrome is a rare, autosomal recessive disorder characterized by severe progressive spondyloepimetaphyseal dysplasia leading to disproportionate short stature with short trunk, in addition to microcephaly, facial dysmorphism, and intellectual disability. The disease is caused by mutation in the *DYM* gene which encodes Dymeclin protein. We report in this study 20 patients from 12 families with DMC of variable clinical severity representing the largest reported cohort from the same ethnic background. Sequencing of all coding regions of *DYM* gene revealed identification of 7 mutations; among them 5 novel (nonsense and splice site) mutations and 2 previously reported (nonsense and deletion) mutations. All mutations were homozygous except for one patient who had compound heterozygous mutation. Genotype/phenotype correlation was investigated and we found that patients with nonsense mutations attained more severe phenotype. This study highlights the possibility of variable evolution of the genotype spectrum of patients with identical phenotype. The study added 5 novel mutations to the 28 previously reported ones expanding the spectrum of the molecular background of these disorders. **Key words:** Dyggve–Melchior–Clausen- dysplasia- Dymeclin- novel- mutation- spondyloepimetaphyseal.

**2884T****The endothelial nitric oxide synthase gene variants as a possible predisposing factor for ankylosing spondylitis in a Turkish population.** K. Ozdilli<sup>1</sup>, A.F. Nursal<sup>2</sup>, S. Gursoy<sup>3</sup>, M. Pehlivan<sup>4</sup>, M.S. Akaltun<sup>3</sup>, S. Pehlivan<sup>5</sup>.

1) Pediatric Bone Marrow Unit, Medipol University, Medipol University Hospital, Istanbul, Turkey; 2) Department of Medical Genetics, Faculty of Medicine, Hitit University, Corum, Turkey; 3) Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Gaziantep University, Gaziantep, Turkey; 4) Department of Hematology, Faculty of Medicine, Gaziantep University, Istanbul, Turkey; 5) Department of Medical Biology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Ankylosing spondylitis (AS) is a chronic inflammatory arthritis that mainly affects the sacroiliac joints and spinal joints. Nitric oxide (NO), a signaling molecule, is constitutively produced from L-arginine by the enzyme endothelial nitric oxide synthase (eNOS). NO is considered as a pro-inflammatory mediator that induces inflammation. Several polymorphisms of the *eNOS* gene have been identified, and their association with various diseases has been explored. *eNOS* variants might have a functional potential to affect the bioavailability of *eNOS*. *eNOS* 894G/T (a guanine/ thymine substitution at position 894 on exon 7) variant leads a change from glutamate to aspartate at position 298 (rs1799983). Other variant of the *eNOS* is intron 4 a variable number of tandem repeats (VNTR) polymorphism which causes basal NO production. It was suggested that the *eNOS* gene variants have been associated with different autoimmune diseases. The aim of this study was to investigate the influence of the *eNOS* gene (894G/T) and (intron 4 VNTR) variants on susceptibility to AS in a Turkish population. The study included 78 AS patients and 100 healthy controls. All patients fulfilled the New York criteria for AS. The *eNOS* gene variants were genotyped by Polymerase Chain Reaction (PCR) and/or PCR based-Restriction Fragment Length Polymorphism (RFLP) technique. Odds ratio (OR) with 95% confidence interval (95%CI) were calculated using the  $\chi^2$  test. We found statistically significant difference in the TT genotype distribution of the *eNOS* (894G/T) variant in patients and control groups. ***eNOS* (894G/T) TT genotype was more frequent in the patients compared to the healthy control group ( $p=0.001$ ).** There was no significant difference in the frequency of *eNOS* (intron 4 VNTR) genotypes and alleles between patients and healthy controls. There was no significant difference between *eNOS* variants genotype distributions and clinical features including HLA-B27, Bath Ankylosing spondylitis disease activity index (BASDAI), Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Function Index (BASFI), Bath Ankylosing Spondylitis Radiology Index (BASRI), and assessing quality of life (AS-QoL). *In conclusion, we have demonstrated that the eNOS gene (894G/T) variant may represent susceptible factor for AS in Turkish population, but further studies including larger sample sizes are needed to confirm this results.*

*The autosomic alteration due to a ring formation is a rare aberration of either chromosome 13 and 18 which is in relation with phenotypic malformations, neurologic problems and genital abnormalities. Two clinical polymalformed cases with skull treboliform dismorphies with early seizures and malformed genitals with micropenis is presented from four of the total patients found in this study. Among chromosomal alterations, the ring of autosomic chromosome 13 and 18 are not frequent, the main phenotypical alterations in this study are in relation to neurological, genital and craniofacial malformations. Taking in consideration that mutations or chromosome aberrations are alterations in the chromosome number or structure. They are mainly considered due to gametogenesis inborn error (meiosis) or during the zygote first cellular divisions. All these alterations might be observed during metaphase from the cellular cycle, where DNA loses are seen due to DNA repair processes deficiency or total absence, among others. 4617 chromosomal studies were performed at Hospital Para El Niño Poblano (Pediatric Hospital) in Mexico (from 1992 to 2011) were 34.6% (1596 patients) showed different chromosomal alterations and only two patients showed ring chromosome aberrations. These chromosome changes are classified as structural alterations. Both pediatric patients with these genetic diseases are described in this study analyzing their clinical characteristics, medical or surgical treatments according to the phenotypic alterations..*

**A 235 Kb deletion at 17q21.33 encompassing the COL1A1 gene, and two additional secondary copy number variants in an infant with type I osteogenesis imperfecta: A rare case report.** *N. Numbere<sup>1</sup>, D.R. Weber<sup>2</sup>, M.A. Iqbal<sup>1</sup>.* 1) Department of Pathology and Laboratory Medicine, University of Rochester Medical Center, Rochester, NY; 2) Pediatric Endocrinology, Department of Medicine, University of Rochester Medical Center, Rochester, NY.

Osteogenesis imperfecta (OI) is a rare genetic disorder characterized by increased susceptibility to fractures due to increased bone fragility. It is most commonly inherited in an autosomal dominant fashion, but recessive OI has also been reported. At least nine types (types I-IX OI) have been described based on clinical, radiologic and genetic features. About 90% of cases are due to mutations in COL1A1 (17q21.33) or COL1A2 (7q21.3) that result in quantitative or qualitative defects in type 1 collagen, a key structural constituent of the extracellular matrix of bone. In contrast to mutations, deletion of the entire COL1A1 gene is a rare cause of OI (Van Dijk et al. 2010; Bardai et al. 2016). We present a case of type I OI in a Caucasian female referred at 10 months of age for investigation of multiple fractures with minimal or no known trauma, small stature and blue sclerae. The patient had a suspected left femur fracture and bowing of left femur detected at prenatal ultrasound. Array comparative genomic hybridization revealed a previously unreported 235 kilobase (kb) pathogenic deletion at 17q21.33 encompassing COL1A1, ITGA3, PDK2, SGCA3, HILS1 genes and other RefSeq genes. Additionally, a 283 kb gain at 8p21.3 from 19375578 to 19658401 base pairs encompassing the CSGALN-ACT1 gene and a 163 kb loss at 10q21.3 from 68395508 to 68558659 base pairs encompassing CTNNA3 gene were found. At her most recent follow up at 21 months of age, she had suffered multiple lifetime fractures including fractures of the right ulna, right fibula, and multiple ribs. Her father has 4-5 lifetime fractures, blue sclera and normal stature. High-density targeted array done at another laboratory revealed him to be a carrier of a heterozygous 14.5 kb deletion of the entire COL1A1 gene. Together with previously reported cases of deletions, it is recommended that the presence of such large deletions and secondary copy number variations be considered for identification of common clinical features which may establish as yet unknown variations in OI.

**2887T****Targeted-NGS on skeletal dysplasias: Evaluating the diagnostic yield.**

K.C. Silveira, T.Y. Kanazawa, C. Silveira, C.A. Moreno, M.D.J. Lacarubba-Flores, D.P. Cavalcanti. Skeletal Dysplasia Group, Department of Medical Genetics, University of Campinas (UNICAMP), Campinas, São Paulo, Brazil.

Skeletal dysplasias (SD) represent a diagnostic challenge due to the great clinical-etiological heterogeneity. Currently, NGS methodologies are the best tools to reach the final diagnosis. Here, we present the preliminary results of a big Brazilian cohort of patients with SD studied by targeted-NGS. Two custom NGS panel (TruSeq Custom Amplicon and Nextera - Illumina), with selected genes according to the previous radiological diagnosis, were used. The sequencing of 119 patients was performed on a MiSeq machine. The Sanger sequencing (SS) was also used for confirmation of the pathogenic variants, as well as to investigate the insufficiently covered regions. Patients were previously classified into 19 different groups according to the Nosology of the Genetic Skeletal Disorders [AJMG, 2015; 167A:2869]. However, for the analysis the patients were also sorted into two group: group 1- assured diagnosis (N=84), and group 2- probable diagnosis (N=35). The current results include 97 patients since 22 patients are still under analysis. Pathogenic variants were found in 75/97 (77.3%) of patients. However, the diagnostic yield was higher in patients of the group 1 - 88.2% (N= 67/76), or perhaps even higher, if it takes in account that eight among the negative patients are still under SS for investigation of bad coverage regions. As presumed, the positivity rate was lower in patients of the group 2 - 38.1% (N=8/21). For the remainder 14 negative patients, six were submitted to the WES. All patients classified in the following groups, TRPV4, Slender bones, Cleidocranial D., MED-PseudoAch, Perlecan, COL11, were positive. Other groups with very good diagnostic yields were as follows: ciliopathies (83.3%), OI (76.9%), and COL2A1 (70.8%). In conclusion, these results confirm the targeted-NGS as a good strategy for molecular diagnosis of SD and show that the diagnostic yield is a consequence of the previous diagnosis, being better among those with an assured radiological diagnosis. Finally, regions insufficiently covered by NGS are still a hurdle to be overcome. Financial Support: CNPq #590148/2011-7 / Faepex #402/15 / FAPESP # 98/16006-6; 2015/22145-6.

**2888F**

**Novel *CARD14* mutation in pityriasis rubra pilaris type V.** T. Miyauchi<sup>1</sup>, T. Nomura<sup>1</sup>, S. Suzuki<sup>1</sup>, M. Takeda<sup>1</sup>, K. Natsuga<sup>1</sup>, H. Hata<sup>1</sup>, Y. Fujita<sup>1</sup>, K. Arita<sup>1</sup>, W. Nishie<sup>1</sup>, M. Akiyama<sup>2</sup>, H. Shimizu<sup>1</sup>. 1) Hokkaido University, Sapporo, Hokkaido, Japan; 2) Nagoya University, Nagoya, Aichi, Japan.

Pityriasis rubra pilaris (PRP) is a group of rare chronic inflammatory skin disorders, clinically characterized by keratotic follicular papules, well-demarcated scaly erythematous plaques interspersed with distinct islands of uninvolved skin, and palmoplantar keratoderma. Up to 6.5% of all PRP patients have a family history. The autosomal dominant subtype, which is classified as PRP type V (PRPV), is associated with gain-of-function mutations in *CARD14*, encoding caspase recruitment domain containing protein 14 (*CARD14*) that activates the noncanonical nuclear factor-kappa B (NF-κB) pathway. Because only 12 families with *CARD14* mutations have been reported in the literature, the clinical features of PRPV remain unsatisfactorily understood. In this study, we analyzed a 60-year old Japanese male with erythroderma, palmoplantar keratoderma, and ectropion all of which had appeared since his birth. Joint contractures of the fingers were also noted. Notably, he has experienced multiple skin tumors including malignant melanoma, squamous cell carcinoma, seborrheic keratosis, and pyogenic granuloma. Histopathological findings showed hyperkeratosis with parakeratosis, acanthosis, and perivascular inflammatory infiltration in the upper dermis. Based on these observations, the patient was initially diagnosed with congenital ichthyosiform erythroderma (CIE), an autosomal recessive genodermatosis. To confirm the diagnosis, we performed whole-exome and Sanger sequencing using genomic DNA extracted from his peripheral blood cells. Unexpectedly, these tests identified a novel heterozygous mutation c.356T>C (p.Met119Thr) in *CARD14*, whereas neither homozygous nor compound heterozygous pathogenic mutations were detected in any of the 12 known causative genes for CIE: *ABCA12*, *TGM1*, *ALOXE3*, *ALOX12B*, *CYP4F22*, *NIPAL4*, *PNPLA1*, *LIPN*, *CERS3*, *SDR9C7*, *ST14*, and *SULT2B1*. This *de novo* mutation was absent in available databases. Furthermore, NF-κB luciferase reporter assay revealed that mutant *CARD14* resulting from the c.356T>C allele showed 2-fold increase in NF-κB activity compared with wild-type, suggesting the pathogenicity of the mutation. These findings finally led us to diagnose the patient as having PRPV. In summary, this study further expands our understanding of clinical and genetic features of PRPV. Multiple occurrence of skin tumors in our patient may suggest potential tumorigenesis associated with the disease, although further studies are needed to assess this hypothesis.

**2889W**

**Exome based genetic testing for skeletal conditions: One lab's experience in ending the diagnostic odyssey.** J. Dong, M. Kyriass, R. Vanneste, R. Steiner, J. Weber. PreventionGenetics, Marshfield, WI.

Skeletal disorders are a clinically and genetically heterogeneous group of diseases that impair skeletal or joint function. The diagnosis of these patients is based on clinical presentation, ultrasound or X-ray findings, and genetic testing. The diagnostic process for these challenging disorders can take up to 7 years (Velasco and Morales. 2017. PubMed ID: 29158687). Genetic skeletal disorders can be divided into 436 conditions based on the 2015 Revision of the Nosology and Classification of Genetic Skeletal Disorders and more than 300 genes have been implicated in these disorders. Recently, PreventionGenetics developed a unique Skeletal Disorders and Joint Problems Sequencing Panel with Copy Number Variation (CNV) detection based on whole exome capture and sequencing. This panel includes 258 genes associated with a variety of genetic skeletal conditions mainly selected from the article "Nosology and Classification of Genetic Skeletal Disorders –2010 Revision". These include genes related to achondroplasia/thanatophoric dysplasia, osteogenesis imperfecta, short-rib thoracic dysplasia, hypophosphatemic rickets, polydactyly/brachydactyly/syndactyly, and Ellis-van Creveld syndrome. Of the cases reported to date, approximately 40% of all test orders have been prenatal requests due to abnormal ultrasound findings. We have identified at least one pathogenic or likely pathogenic variant in 39% of these samples. For examples, a pathogenic variant in the *FGFR3* gene was found in a fetus with shortened long bones with bowing, frontal bossing, very small chest circumference, suspicious for a cloverleaf skull, large head circumferences and protuberant abdomen on 21 week's ultrasound findings. In another prenatal case with short long bones, polyhydramnios, polydactyly on 31 week's ultrasound findings, a hemizygous truncating variant in the *EVC2* gene and a large heterozygous deletion encompassing two exons of the *EVC2* gene were detected, emphasizing the added value of CNV detection. In summary, exome based panel testing is an effective method to help formulate accurate diagnosis for skeletal conditions, ending the diagnostic odyssey for patients and their families. Since this test is performed using exome capture probes, reflex to whole exome testing is available for negative or indeterminate cases.

**2890T**

**Complex mutation landscape of pseudoxanthoma elasticum revealed by multigene next-generation sequencing panel.** A. Saeidian<sup>1</sup>, E. Ryu<sup>1</sup>, L. Youssefian<sup>1</sup>, A. Touati<sup>1</sup>, D. Li<sup>1</sup>, H. Vahidnezhad<sup>1</sup>, E. Duval<sup>2</sup>, E. Oliphant<sup>2</sup>, SF. Terry<sup>2</sup>, A. Ertel<sup>1</sup>, P. Fortina<sup>1</sup>, J. Uitto<sup>1</sup>, Q. Li<sup>1</sup>. 1) Thomas Jefferson University, Philadelphia, PA; 2) PXE International, Inc., Washington, DC, USA.

Pseudoxanthoma elasticum (PXE) is characterized by calcium hydroxyapatite deposition in the skin, eyes and the cardiovascular system. The majority of cases are caused by mutations in the *ABCC6* gene in an autosomal recessive inheritance pattern. Attesting to the genetic heterogeneity are recent demonstrations of mutations in the *ENPP1* and *GGCX* genes in patients with PXE-like phenotypes. Increasing evidence suggests the presence of predisposing genetic factors that modify the PXE phenotype, and deep phenotyping has revealed inter- and intra-familial phenotypic heterogeneity among PXE patients. In order to find causative genes or potential modifiers with significant roles in the severity of the phenotype, we developed a disease-specific, gene-targeted next-generation sequencing panel with the Illumina platform. The panel contains 29 genes, including *ABCC6*, all of which are associated with disorders of calcification. Pathogenic variants were identified by variant calling using databases including dbSNP, 1000 Genomes Project and ExAC, and pathogenicity was analyzed by prediction softwares. Among 401 probands, 130 distinct variants were identified in *ABCC6* consisting of 81 missense (62%), 22 indel (17%), 15 nonsense (12%), and 12 splicing (9%). There were biallelic *ABCC6* mutations in 301 cases, 98 of which had associated potential modifier gene mutations that may be contributing to disease severity. Moreover, 36 cases had monoallelic *ABCC6* mutations without candidate for digenic inheritance and 30 cases had monoallelic *ABCC6* mutations with candidate for digenic inheritance. No variants in *ABCC6* were found in 34 cases. Therefore, our total detection rate for *ABCC6* was 91.5%. Of the 401 confirmed cases, 281 had complete Phenodex scores available characterizing phenotypic severity. Preliminary analysis has not established clear-cut genotype-phenotype correlations. In conclusion, additional *ABCC6* mutations were identified that expand the existing database with implications for genetic counseling, prenatal genetic testing and development of allele specific personalized treatments for PXE. The identification of modifier genes for PXE will help to explain clinical variability beyond allelic mutations in the known primary disease-causing gene *ABCC6* and allow new pathways in ectopic mineralization to be discovered.

**Using the SNP array evaluation tool to optimize the use of resources and guide genetic testing leading to the diagnosis of Netherton Syndrome-A case report.** P. Gupta, J. Valdez-Camacho, L. Fried, L. Tambini-King, A. Gomez. St Joseph's Children's Hospital, Paterson, NJ.

**Introduction:** Netherton syndrome is a rare autosomal recessive skin disorder characterized by congenital erythroderma, hair-shaft abnormality and atopic manifestations with high IgE levels. Some infants with Netherton syndrome develop progressive hypernatremic dehydration, failure to thrive, and enteropathy which can be fatal. The disorder is associated with mutations in the *SPINK5* gene, which encodes the serine protease inhibitor LETK1. Diagnosis would often be delayed till the appearance of the characteristic hair-shaft finding of Trichorrhexis Invaginata or bamboo hair. In the era of molecular genetics, sequencing of the *SPINK5* gene can confirm the diagnosis of Netherton syndrome prior to the appearance of characteristic clinical findings. **Case Presentation:** A full-term male infant was born to a 22 year old G2P1 mother at 37 weeks via vacuum assisted C-section for transverse lie, maternal fever and fetal tachycardia. Thick meconium stained fluid was noted. BW was 7lbs 5oz and length 19 inches. Placenta was positive for candida. Patient presented with generalized epidermal desquamation, underlying erythema, alopecia, and foul-smelling skin. Family history was significant for consanguinity. Genetics consult was requested due to above findings and failure to thrive. Chromosome analysis with reflex to SNP microarray revealed a normal male chromosome complement and multiple regions of homozygosity. The patient subsequently had UTI with *E. cloaca*, two episodes of *Staphylococcus aureus* bacteremia, *Influenza*, and *Para-Influenza* infections suggestive of a primary immunodeficiency. He also had significantly elevated IgE, IgA and eosinophils. We used The Genomic Oligoarray and SNP array evaluation tool to look for autosomal recessive genes in the regions of homozygosity using the clinical features of our patient and *SPINK5* was one of the candidate genes. Sequencing of *SPINK5* revealed a homozygous variant, resulting in premature protein termination reported as causative for Netherton syndrome. **Discussion:** Erythroderma is not an uncommon presentation of primary immunodeficiency in early infancy with a broad differential where genetic confirmation can be an expensive process. In the appropriate clinical setting the SNP array evaluation tool can help predict the candidate gene thereby supporting single gene sequencing which is less expensive than large panel testing or whole exome sequencing.

**2892W**

**A unified PCR/CE carrier screening workflow for CFTR, SMN1, and FMR1 variants that consolidates the detection of SNVs, Indels, CNVs, and triplet repeat expansions.** L. Chen, S. Gokul, E. Hallmark, B. Haynes, G. Latham. Asuragen Inc, 2150 Woodward St, Austin, TX. 78744.

**Introduction:** About 5% of Western populations are genetic carriers for one of three disorders: Fragile X Syndrome (FXS), Spinal Muscular Atrophy (SMA), or Cystic Fibrosis (CF). Reliable identification of the underlying pathogenic elements for these disorders require that molecular assays accommodate multiple classes of sequence variants, namely CGG repeat expansion in *FMR1* (FXS), CNVs in *SMN1* (SMA), and SNVs and Indels in CF (*CFTR*). These variants are each technically challenging to resolve, and current screening assays often rely on distinct technologies, platforms and workflows. We describe a simple and accessible multiplex PCR approach that can report genetic variants in *FMR1*, *SMN1*, and *CFTR* by capillary electrophoresis (CE) in a single workstream. **Methods:** Multiplex primers for *FMR1*, *SMN1*, and *CFTR* PCR assays were derived using a novel pipeline and designs that allowed detection of proximal variants. AmpliDeX<sup>®</sup> PCR/CE *FMR1*\* reagents and prototype *SMN1* reagents (Asuragen) were used to genotype the corresponding targets. A prototype PCR/CE assay was developed to detect and discriminate multiple actionable SNV and Indels in the *CFTR* gene. All PCR assays were designed with dye- and mobility-tags to permit co-detection of >100 variants across the three genes using a single CE injection on a 3500 Genetic Analyzer (Thermo Fisher). Analyses were performed using AmpliDeX<sup>®</sup> Reporter software with assay-specific plug-in modules (Asuragen). **Results:** We developed a variation of multiplex allele-specific PCR (AS-PCR) to resolve different disease-associated SNVs and Indels in *CFTR*. In preliminary studies, different classes of these variants in heterozygous samples could be readily discriminated in a single-tube PCR, including multiple mutations clustered in complex regions that can incapacitate standard AS-PCR. Further, *CFTR* amplicons could be combined with *FMR1* and *SMN1* amplicons to resolve multifarious combinations of SNVs, Indels, CNVs (0-3 *SMN1* copies), and repeat expansions (*FMR1* premutations and full mutations) in a single PCR/CE workflow. **Conclusions:** Our results demonstrate feasibility for a streamlined, single-platform, PCR-based assay that can unify the detection of *FMR1*, *SMN1*, and *CFTR* variants. This technology has the potential to address carrier screening in decentralized laboratory settings using standardized reagents, existing instrumentation, and fit-for-purpose analysis software. \*Research Use Only. Not intended for diagnostic use.

**2893T**

**Utility and diagnostic rates of genetic testing for ataxia-related disorders in patients over 50.** M. Stosser, J. Scuffins, F. Millan, A. Lindy. GeneDx, Gaithersburg, MD.

Identifying the etiology of a heterogeneous disorder, such as ataxia, can be challenging, especially for older patients. Although many forms of adult-onset ataxia are caused by repeat expansions in a subset of genes, multiple forms have been associated with other types of pathogenic variants and exome sequencing (ES) allows for the screening of these variants. The objective of this study was to review the diagnostic outcomes of ES for patients with ataxia, focusing on patients >50 years of age at the time of testing and comparing these results with patients <21 years. In a review of 2135 patients with ataxia tested by ES, 16% (330/2135) were >50 when referred for genetic testing compared to 69% (1477/2135) that were <21. Patients >50 had a positive diagnostic rate (PDR) of 11% (35/330), 50% (166/330) had a non-diagnostic finding, and 39% (129/330) were negative. Patients <21 had a higher PDR (35%; 510/1477) and were more often submitted for trio-analysis (concurrent sequencing/analysis of parental samples; 72%; 1063/1477). In contrast, only 5% (16/330) of patients >50 were submitted as a trio. Trio testing was associated with a higher PDR in both groups of patients. For patients >50, 19% (3/16) of trio cases were positive compared to 12% (29/245) of proband-only cases. For patients <21, 36% (386/1063) of trio cases were positive compared to 25% (44/175) of proband-only cases. Patients typically presented with additional features including structural cerebellar abnormalities, neuropathy, extrapyramidal signs, seizures, and/or white matter disease. Clinical features most commonly observed in patients >50 included structural cerebellar abnormalities (37%; 123/330) and neuropathy (23%; 77/330), whereas seizures (30%; 438/1477) and structural cerebellar abnormalities (18%; 270/1477) were common comorbidities for patients <21. Patients >50 with cerebellar abnormalities had a higher PDR (16%; 20/123) than those with neuropathy (8%; 6/77). Although genetic testing for patients >50 years of age yielded a lower PDR compared to patients <21, 11-19% of older patients are expected to receive a positive result, with improved outcomes observed for trio analysis and patients with cerebellar abnormalities. The appreciable PDR for sequence analysis of ataxia-related genes indicates that sequencing is a valuable tool for diagnosis, even in older patients. A molecular diagnosis can aid in prognosis and treatment for affected individuals and risk assessment for families.

**Characterization of recessive myopathy/ataxia syndrome due to *MSTO1* variants.** J. Woods, H. Lee, R. Signer, J. Wan, J. Martinez, C. Palmer, S. Nelson, Undiagnosed Diseases Network Members. University of California Los Angeles, Los Angeles, CA.

Mitochondrial myopathy and ataxia (MIM: 617675) is a rare disease caused by pathogenic variants in the nuclear gene *MSTO1*. Previous publications reported five patients from four families with an autosomal recessive disease form and four patients from the same family with an autosomal dominant disease form. The University of California Los Angeles Undiagnosed Diseases Network (UCLA UDN) recently identified two additional patients with autosomal recessive *MSTO1* associated disease. Cerebellar hypoplasia and myopathy are phenotypically definitive in individual with autosomal recessive forms of *MSTO1* associated disease. Individuals with autosomal recessive disease were compound heterozygous for rare pathogenic variants in *MSTO1*. Individuals with autosomal dominant disease forms have a less severe phenotype with ataxia and neurocognitive impairment. The gene product of *MSTO1* has not yet been well characterized though it is a cytosolic protein with tubulin and tubulin-like domains that localizes to the outer mitochondrial membrane. *MSTO1* plays a key role in maintaining a functional mitochondrial network. Mitochondrial network functionality is contingent upon the balance between fusion events that repair damaged mitochondria and fission events that redistribute the mitochondria. Previous staining with MitoTracker™ in fibroblasts derived from patients with pathogenic variants in *MSTO1* demonstrated fragmented mitochondrial networks. Previous functional assays with mitochondrial photoactivatable-GFP also demonstrated decreased mitochondrial fusion events. These experimental findings were reproduced utilizing fibroblasts from an individual compound heterozygous for pathogenic variants in *MSTO1* identified by the UCLA UDN. Pathogenic variants in *MSTO1* may also lead to mitochondrial DNA depletion, as mitochondrial fusion events are necessary to repair damaged mitochondrial DNA. Presently the UCLA UDN is analyzing mtDNA to determine if mtDNA depletion is a characteristic of *MSTO1* associated disease. Future studies will also focus upon mechanistically defining the role that *MSTO1* plays in mitochondrial fusion by exploring interactions with other mitochondrial fusion genes.

**Novel HSP candidate gene, HSP1-V2 regulates neurite outgrowth via JNK/c-Jun activation.** J. Min<sup>1,2</sup>, M. Choi<sup>1,3</sup>, D. Kim<sup>1,2</sup>, J. Yoon<sup>1,2</sup>, J. Lee<sup>1,2</sup>, J. Lee<sup>1,2,3</sup>, K. Chung<sup>1,2,3</sup>, D. Halder<sup>1</sup>, S. Jun<sup>1,3</sup>, H. Cho<sup>1,2,3</sup>, N. Kim<sup>1,2,3</sup>. 1) Rare Disease Division, KRIBB, Daejeon, Republic of Korea; 2) Genome Research Center, KRIBB, Daejeon, Republic of Korea; 3) Department of Functional Genomics, Korea University of Science and Technology, Daejeon, Republic of Korea.

Hereditary spastic paraplegia (HSP) are a group of neurodegenerative disorders that are progressive spasticity and weakness of the lower limbs by damaging of the longest neuronal fibers of corticospinal tract. In this study, we demonstrated that HSP1-V2 loci plays an important role as a novel regulator in HSP. Single nucleotide variant of HSP1-V2 (c.883G>T, p.D295Y) was identified from whole exome data of 60 HSP families using bioinformatics analysis. Reduction of HSP1-V2 decreased axon and neurite outgrowth which were recovered with overexpression of HSP1-V2. Overexpression of HSP1-V2 decreased epidermal growth factor receptor (EGFR) via phosphorylation of EGFR and increased nerve growth factor receptor (NGFR) via activation of JNK/c-Jun. The activation of JNK signal cascades was mediated by direct binding between HSP1-V2 and JNK. Intriguingly, the D295Y mutation of HSP1-V2 led to decreases of neurite outgrowth by decrease of interaction between HSP1-V2 and JNK. Overall, these results suggest that HSP1-V2 is a novel causative gene of HSP and mediates between proliferation status and differentiation of neuronal cells during neural development.

**Genetics of epileptic encephalopathy.** M.Y. Issa<sup>1</sup>, G.M.H Abdel-Salam<sup>1</sup>, M.S. Abdel-Hamid<sup>2</sup>, J.G. Gleeson<sup>3</sup>, M.S Zaki<sup>1</sup>. 1) Clinical Genetics Human Genetics and Genome Research Division, National Research Centre, Cairo, Cairo-Egypt, Egypt; 2) Medical Molecular Genetics Department, Human Genetics and Genome Research Division, National Research Centre, Cairo, Egypt; 3) Laboratory for Pediatric Brain Disease, Howard Hughes Medical Institute, University of California, San Diego, San Diego, CA 92093, USA.

**Abstract:** Early infantile epileptic encephalopathy is a heterogeneous group of a severe form of epilepsy, which was first reported by Ohtahara et al. (1976). It is characterized by frequent tonic seizures or spasms which starts in early infancy life with a specific EEG finding of suppression-burst patterns, characterized by high-voltage bursts alternating with almost flat suppression phases. The seizures are resistant to control with AEDs. Nearly 75% of "Early infantile Epileptic Encephalopathy" EIEE patients may progress to 'West syndrome,' which is characterized by tonic spasms with clustering, arrest of psychomotor development, and hypsarrhythmia on EEG (Kato et al., 2007). To date 65 causative genes are described as a causative gene for EIEE of which 28 are AR, 29 are AD and 8 causative genes are X-linked after searching OMIM <https://www.omim.org/>. Herein, we describe 46 cases from 30 non-related Egyptian families with EIEE. Whole Exome sequencing (WES) was done for patients with suspected genetic cause of epilepsy. Results: 12 different genes were revealed. The most common genes described were WWOX in 13/46 cases from 10 unrelated families, AARS in 8/46 from 4 unrelated families and PNKP 7/46 from 4 unrelated families. Other genes found are STZ2 in 5/46 patients from 3 families, SLC25A12, SLC25A22, UBA5, AP3B2, ITPA, CACNA1A, ALS35A2 and CDKL5 Conclusion: WES is a crucial tool for genetic diagnosis of EIEE to elucidate the cause and early initiation of treatment, hence proper genetic counseling. Next generation sequencing technologies have increased the speed of gene discovery tremendously. The prevalence of AR disorder is due to high consanguinity among the studied population. References: Kato, M., Saitoh, S., Kamei, A., Shiraishi, H., Ueda, Y., Akasaka, M., Tohyama, J., Akasaka, N., Hayasaka, K. A longer polyalanine expansion mutation in the ARX gene causes early infantile epileptic encephalopathy with suppression-burst pattern (Ohtahara syndrome). *Am. J. Hum. Genet.* 81: 361-366, 2007. **Hereditary neuropathies and differential diagnoses: Experiences from more than 300 cases of next-generation sequencing based genetic panel diagnosis.** *K. Eggermann<sup>1</sup>, L. Soellner<sup>2</sup>, M. Begemann<sup>3</sup>, B. Gess<sup>4</sup>, M. Haerussler<sup>3</sup>, J. Weis<sup>4</sup>, I. Kurth<sup>1</sup>.* 1) Institute of Human Genetics, University Hospital RWTH Aachen, Aachen, Germany; 2) Department of Neurology, University Hospital, RWTH Aachen, Aachen, Germany; 3) Department of Pediatrics, University Hospital, RWTH Aachen, Aachen, Germany; 4) Institute of Neuropathology, University Hospital RWTH Aachen, Aachen, Germany.

Peripheral neuropathies or polyneuropathies (PNP) are a heterogeneous group of disorders of the peripheral motor, sensory and autonomic nerves with an estimated prevalence of 5-8% in the general population and with a higher prevalence among the elderly. PNPs can have a multitude of etiologies and present with overlapping phenotypes; hereditary forms include Charcot-Marie-Tooth disease/hereditary motor sensory neuropathy (CMT or HMSN), hereditary motor sensory and autonomic neuropathies (HSAN or HSN), hereditary motor neuropathies (HMN) and small fiber neuropathies (SFN). Mutations in more than 100 different genes have been described so far and more are yet to be discovered; hereditary neuropathies may follow all different patterns of inheritance. In some instances, mutations in neuropathy-associated genes may also be responsible for other clinical entities such as spastic paraplegia (HSP) or myopathy. Using next generation sequencing (NGS), diagnostics has become easier, more straightforward and less time-consuming in recent years. Although in the majority of cases no causal treatment is yet available, knowing the cause of the disorder provides relief for patients and it allows conclusions regarding possible risks for offspring, siblings or other family members. Learning about the underlying pathology might also provide options for treatment in the near future. Based on our experiences from more than 300 cases of genetic panel diagnostics, we suggest an algorithm for molecular diagnostic work-up and present a summary of the results. As a first step, probes are analyzed for copy number variants of PMP22, followed by GJB1 sequencing in families with a clear X-chromosomal inheritance. Among the mutation-negative probes then analyzed by NGS, approximately 15% showed a pathogenic sequence variant; in approximately the same proportion of patients one or more variants of unknown significance (class III) were detected which prompted us to ask for further clinical (and/or molecular) investigations, segregation analyses or functional analyses. Some unexpected results will be discussed.

**Identification of causative variations in cases with microcephaly using cytogenetic microarray and next generation sequencing.** *S. Masih, P. Srivastava, K. Mandal, S.R. Phadke.* Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India.

Microcephaly is a genetically heterogeneous neurodevelopmental disorder. It may be an isolated trait or in combination with other major birth defects or malformations. Despite of remarkable advances in genetic testing, the molecular diagnosis remains unknown in about 40% of cases of microcephaly. We present the clinical features including associated malformations and neurological abnormalities along with the results of copy number variations (CNVs) identified by microarray and sequence variations identified by whole exome sequencing. Cytogenetic microarray was done using Affymetrix 750K in 34 patients (4 consanguineous and 30 non-consanguineous) and identified pathogenic/likely pathogenic CNVs in 7 cases. Homozygosity mapping was done in 4 consanguineous patients and candidate gene was identified in one case. Exome sequencing was done in 24 patients (11 consanguineous and 13 non-consanguineous). Pathogenic/likely pathogenic sequence variations were identified in 10 patients out of which 5 were born to consanguineous parents. Homozygous variations were identified in CIT, ANKLE2, ORC1, SLC13A5 and CENPF genes. Two were reported previously while 3 are novel. The siblings with likely pathogenic variations in CENPF had severe short stature (height -3.5SD) and microcephaly (head circumference -8SD) without ophthalmological abnormalities as reported in cases of Stromme syndrome. Causative sequence variations were identified in 5 patients born to non-consanguineous parents. One patient had novel heterozygous likely pathogenic sequence variation in CTNBN1 and two other had reported pathogenic sequence variations (heterozygous in MECP2 and hemizygous deletion in PQBP1 gene). One novel likely pathogenic homozygous sequence variation was identified in a patient with similarly affected siblings (non-consanguineous) in DCPS gene. The phenotype of this case was prenatally detected cerebellar hypoplasia and severe congenital microcephaly and convulsions since neonatal period. An interesting finding in one patient showed heterozygous likely pathogenic sequence variations two genes, namely; MCPH1 and ASPM genes. The two variations were inherited from asymptomatic parents (one from each) indicating the possibility of digenic inheritance. These novel findings of double heterozygosity, likely pathogenic variations in CENPF and DCPS genes in cases with novel phenotypes need further functional studies. The detailed phenotypes and data of sequence variants will be presented. .

**ARX gene polyalanine repeat expansions are not common cause of intellectual disability or epilepsy.** E. Nikkola, C-Y. Lee, J.D. Vargas, A. Zhong, S. Lau, H. Gao, S.P. Strom. Fulgent Genetics, Temple City, CA, US.

**Background:** The pathogenic mutations in *ARX* have been shown to cause X-linked West syndrome, Ohtara syndrome, infantile spasms, intellectual disability (ID), and syndromic epilepsy in males. Affected females have also been reported, typically presenting with milder symptoms. The best described pathogenic variants in *ARX* gene are short tandem repeat expansions of polyalanine tracts in exons 2 and 4. As widely used short read NGS methods cannot reliably detect the larger repeat expansions, PCR with Sanger sequencing has been used to evaluate these tracts in our clinical lab. Our aim is to evaluate the clinical utility of this complementary testing. **Methods:** We systematically performed Sanger-based polyalanine tract testing for all clinical cases involving intellectual disability and/or epilepsy. We estimated the detection rates for both polyalanine repeat expansions in exons 2 and 4, and also for other pathogenic variants in *ARX* gene identified by NGS. **Results:** We evaluated total of 2,476 clinical cases; 1,351 were from intellectual disability panels, 593 from epilepsy panels, and 532 from others (autism, Rett Syndrome, etc.). We did not detect any pathogenic polyalanine repeat expansions. For sequence variant analysis, we identified 4 pathogenic variants and 17 variants of unknown significance. When we include both the pathogenic variants and the variants of unknown significance, the detection rates were still small; 0.4 % for ID panel, 1% for epilepsy, and 0.3% to 4.5% for other panels with smaller sample sizes. The highest detection rate was for Rett-Angelman gene panel, suggesting that when the symptoms are well refined, the genetic defect is potentially easier to identify. **Conclusions:** Based on over 2,476 cases analyzed, we conclude that *ARX* polyalanine repeat expansions are not as common cause for ID or Epilepsy as had been originally indicated. As 1433 (58%) of these cases are male, we can rule out allele drop-out as a significant source of false negatives. We recognize that our study population is highly heterogeneous and some of the individuals tested have milder symptoms, therefore assaying *ARX* gene repeat expansions may be warranted when ID presents with infantile epilepsy/movement disorder or brain and genital malformations.

**SMN1 and SMN2 copy number assays universally perform on five different thermocyclers.** Z. Kabir, Y. Machida, S. Paquerault, L. Jiang, J. Huuskonen. Canon US Life Sciences, Inc., Rockville, MD.

**Introduction** Spinal muscular atrophy (SMA), an autosomal recessive disorder, causes a spectrum of muscle weakness and atrophy that affects newborns and young adults. SMA is largely caused by *SMN1* gene deletion, the gene that codes for the survival motor neuron (SMN). Disease severity is modulated by the low-level expression of SMN from the 99% identical *SMN2* gene. Here, we determine the assay performance of the Novallele copy number assays for *SMN1* and *SMN2* on five thermocyclers capable of high-resolution melting (HRM). **Methods** Using cell-line genomic DNA and genomic DNA isolated from blood with four different, commercially available DNA extraction kits, the copy number of each uncharacterized sample was determined using the Novallele copy number assays and confirmed with a comparable method, either multiplex ligation-dependent probe amplification (MLPA) or digital PCR. Using the DNA samples, the Novallele copy number assays were individually evaluated on five different, commercially available HRM-enabled thermocyclers. Reaction chemistry and DNA amount as well as PCR and melt protocols were uniform for all of the thermocyclers. All Novallele copy number assay data were analyzed using the Novallele HRM Analyzer. Both accuracy and repeatability studies were completed. The accuracy testing compared the copy number determined to the known copy number or the result of the comparable method, as applicable. The repeatability study was conducted on each of the five thermocyclers and comprised three replicate plates containing 48 or 96 samples depending on the thermocycler plate format allowed. **Results** Both assays correctly determined the *SMN1* or *SMN2* copy number of all DNA samples as compared to the commercially available technology. The results were 100% accurate for all HRM-enabled thermocyclers and DNA extraction kits. We analyzed 1060 data points for the repeatability study. Four of the thermocyclers had 100% consistent results for all data points. One thermocycler had 95.4% (95% confidence interval: 89.4–100.0%) repeatability. Four of the thermocyclers were able to provide results within one hour; the other thermocycler provided results within 90 minutes due to slower melt conditions. **Conclusions** The Novallele copy number assays can reliably determine copy number using multiple thermocyclers and DNA extraction kits without changing PCR protocols or reaction chemistry. The Novallele copy number assays are for Research Use Only. Not for use in diagnostic procedures.

**2901W**

**A novel partial *de novo* duplication of *JARID2* in a patient sharing phenotypic features with deletion patients.** K. Kiiski<sup>1</sup>, K. Avela<sup>2</sup>, L. Viitasalo<sup>2</sup>.

1) HUSLAB, Laboratory of Genetics, Helsinki University Hospital, Helsinki, Finland; 2) Department of Clinical Genetics, Helsinki University Hospital, Helsinki, Finland.

We present a novel partial *de novo* duplication of the *JARID2* gene (OMIM\*601594) in a patient sharing phenotypic features with previously characterized patients with *JARID2* deletions. The duplication was detected using a 180k whole genome chromosomal microarray showing that the 309 kb duplication in chromosomal region 6p23p22.3 covers at least exons 1-6 of the *JARID2* gene. The MLPA method revealed that exons 1-7 of *JARID2* are duplicated (NM\_004973.3). A FISH study was consistent with a tandem duplication but the orientation of the duplication remained unelucidated. The identified duplication is located in a known 6p22 microdeletion syndrome region, however, a microduplication syndrome has not been characterized. According to literature, partial duplications of *JARID2* are rare. In DECIPHER, there are five patients listed with a partial *JARID2* duplication, the size of which varies between 270-2,060 kb. One of the deletions is known to be *de novo* and one inherited from an unaffected parent. In all the cases the clinical significance remains unknown. To date, the identified duplication in *JARID2* is the largest partial duplication to be characterized. Deletions of *JARID2* have been identified in patients with intellectual disability, behavioral abnormalities, gait disturbances and dysmorphic features such as prominent supraorbital ridges, deep set eyes, midface hypoplasia and infraorbital dark circles. It has been suggested that *JARID2* is likely a dosage sensitive gene. Our patient is a 12-year-old boy, the second child to nonconsanguineous Finnish parents. The pregnancy and delivery were uneventful. He was born at term with birth measurements within normal range. He started walking at the age of one year. However, since the first years of life he has had problems with coordination and clumsiness. At 3.5 years of age, he was referred to a phoniatrist due to language delay and unclear speech. He attended a normal curriculum at school but needed extra support since he had problems with behavior and attention. The patient also has difficulties with social contacts and daily activities. He has markedly dark infraorbital circles and slightly prominent supraorbital ridges. Currently, RNA studies of *JARID2* are ongoing in order to identify the sequence as well as expression level of the mutated allele. We suggest that partial duplications of *JARID2* may cause a similar phenotype that is associated with deletions of *JARID2*.

**Detection of copy number variations in patients with neurodevelopmental disorders.** A.R. Pate<sup>1,2</sup>, S.S. Chettiar<sup>2</sup>, D.D. Jhala<sup>2</sup>. 1) B.J. Medical College, Civil Hospital Campus, Ahmedabad, Gujarat, India; 2) GeneXplore Diagnostics and Research Center Pvt. Ltd., Ellis Bridge, Ahmedabad, Gujarat, India; 3) Department of Zoology, Biomedical technology and Human Genetics, Gujarat University, Ahmedabad, Gujarat, India.

Detection of copy number variants (CNVs) by chromosomal microarray analysis (CMA) is now well accepted as genetic diagnostic test for the complex neurodevelopmental disorders like Developmental delay (DD), Intellectual disabilities (ID) and Autism spectrum Disorders (ASD). Chromosomal microarray (CMA) offers high resolution scan of whole genome which, significantly contribute to understand the etiology of these complex neurodevelopment impairments. Considering the detection efficiency and impact on medical management of CMA, it is first-choice of test for in-depth analysis of children with these disorders. In the present study, 110 children (68 Males and 42 Females; Age ranges from: 2yrs. to 17yrs.) diagnosed with DD, ASD or ID were recruited for precise genetic analysis. The microarray platform utilized in this study was specifically designed to increase detection of CNVs in genomic regions of demonstrated relevance to DD/ID/ASD. Array CGH was performed on oligonucleotide microarray platform (G2565CA, Agilent, USA). Data of the array was analyzed using cytogenomics software (Agilent technologies). Results of CMA showed total 36 patients (32.72%) with a total 47 Copy number variants (CNVs) and from these findings 29 (61.70%) represented a known diagnostic CNVs contributing to the clinical representation and 18 represented non-diagnostic CNVs i.e. variants of unknown significance (VOUS). Nine patients (25%) with developmental delay (DD) showed 12 CNVs, Fifteen patients (42%) with Intellectual disabilities (ID) showed 21 CNVs and Twelve patients (33%) with Autism spectrum Disorders (ASD) showed 14 CNVs. Chromosomal imbalances of chromosome 2, 15 and 22 were most common. CNVs were detected more in males than females. The likelihood of an abnormal microarray result increased with the number of clinical abnormalities. CMA has demonstrated great value in clinical assessment of neurodevelopmental disorders. Present study concludes that optimized CMA platform can increase diagnostic yield. Pathogenic findings give insights into the etiology of patients, neurodevelopmental conditions, and in many cases impact medical management. The development of novel and accurate methods to interpret the potential pathogenicity of VOUS will further enable patients and clinicians to identify maximum benefits of genetic testing for clinical care.

**2903F**

**A possible new epilepsy locus: Chromosome 4q28.1q28.3 deletion encompassing *PCDH10* segregating in a family with a history of epilepsy and intellectual disabilities.** G.H. Scharer<sup>1</sup>, S. Offord<sup>2</sup>, L. Weik<sup>2</sup>, E. Virlee<sup>1</sup>, N. Zemlicka<sup>1</sup>, P. Aggarwal<sup>1</sup>, R. Lorier<sup>1</sup>, U. Broeckel<sup>1,3</sup>. 1) Advanced Genomics Laboratory, Medical College of Wisconsin, Milwaukee, WI, 53226, USA; 2) Genetics Center, Children's Hospital of Wisconsin, Dept of Pediatrics, Milwaukee, WI, 53226, USA; 3) Department of Pediatrics, Medical College of Wisconsin, WI, 53226, USA.

Copy number variations (CNVs) are causally linked to a significant percentage of diagnoses of monogenic epilepsy. The prevalence is even higher in patients presenting with generalized epilepsy and intellectual disability. We present the case of a 6 year old female with a history of early developmental delays (speech, gross motor), absence spells and gait ataxia, who was diagnosed with generalized epilepsy based on EEG at 4 years of age. Brain MRI did not show structural abnormalities and patient responded well to ethosuximide (20mg/kg/day). Family history was significant for one full sibling with seizures, another full sibling with psychiatric disorder and cognitive disability, as well as a maternal half-sibling with seizures. The biological mother is reported with intellectual disabilities; and additional maternal relatives are reported with unspecified seizures indicating a dominant genetic disorder. Initial genetic work-up included normal metabolic screening studies and CMA (CytoScanHD™ microarray), which revealed an approximately 9Mb interstitial deletion at chromosome 4q28.1q28.3 (chr4:127,068,548-136,111,450; hg37). The deletion interval includes 40 genes, 8 of these have entries in OMIM; however, none of them have an obvious association with epilepsy to date. Further investigation of affected family members confirmed the deletion in the mother and one of the affected siblings, additional segregation studies are ongoing; although initial observations do support the CNV as a likely cause of the shared phenotype in this family. Upon further review of the haplo-insufficient genes in the deleted region in this case we focused more attention on the *PCDH10* gene, which encodes a protein of calcium-dependent cell-cell adhesion molecules in the cadherin superfamily. Protocadherin-10 belongs to a subclass of protocadherins (PCDH 8/10/18/19) that share a highly conserved 17-amino acid cytoplasmic motif. Of those *PCDH19* is a well-known disease gene because early infantile epileptic encephalopathy-9 (EIEE9), also known as epilepsy and mental retardation restricted to females (EFMR), is caused by mutation in *PCDH19*. Deletion in *PCDH10* was previously implicated in association studies (homozygosity mapping) as possibly linked to autism spectrum disorders. Further investigation, including screening a large sequencing database of epilepsy patients for point mutations in *PCDH10*, is needed to confirm *PCDH10* as a possible new epilepsy locus.

**Clinical next-generation sequencing: A retrospective study of the diagnostic rate in pediatric epilepsy patients.** M. Cadieux-Dion<sup>1,2</sup>, I. Thiffault<sup>1,2,3</sup>, S. Smith<sup>1</sup>, D. Lyalin<sup>1</sup>, R. Caylor<sup>1</sup>, E. Farrow<sup>1,3,4</sup>, C. Saunders<sup>1,2,3</sup>. 1) Center for Pediatric Genomic Medicine, Children's Mercy Hospital; 2) Department of Pathology and Laboratory Medicine, Children's Mercy Hospital; 3) University of Missouri-Kansas City School of Medicine; 4) Department of Pediatrics, Children's Mercy Hospital.

Epilepsy affects 1-3% of the population and is caused by abnormal electrical discharges in the brain (seizures). Currently, the International League Against Epilepsy recommends characterizing the type and the etiology of the seizures as well as the electroclinical syndrome to establish a diagnosis. Although the genetic basis of monogenic syndromic epilepsy is well known (TSC, NF, Rett syndrome), they represent a small proportion of genetic epilepsies. Considering phenotypic and locus heterogeneity, with seizures presenting alone or with other comorbidities such as intellectual disability, autism spectrum disorder, attention-deficit hyperactivity disorder, molecular diagnosis remains challenging. We conducted a retrospective review of patients with epilepsy who received symptom-driven whole exome or genome sequencing (WES/WGS) at our institution. Phenotypes of patient undergoing WES or WGS are recorded as HPO terms in an internal database, which was interrogated for the parent term "seizures." A total of 221 probands (WES n=213, WGS n=8) were identified, including 127 parent-child trios, 46 parent-proband duos, and 48 singletons. The majority of the cohort (76%, 167/221) had comorbidities, with epilepsy in addition to congenital anomalies and/or neurological features. A diagnostic genotype was identified in 19% (42/221), including dominant (32), recessive (7) and X-linked (3) variants. Among cases with a dominant inheritance, 53% (17/32) were explained by a *de novo* variant. The majority of those diagnosed had complex phenotypes (76%, 32/42) compared to seizures only. The most common diagnoses were established based on pathogenic variants in *SCN1A* (3), *CHD2* (2), *PRRT2* (2) and *SYNGAP1* (2). Although pathogenic variants in genes encoding ion channels are well known causes of epilepsy, they are underrepresented in our diagnostic cohort (16%, 7/42). We hypothesize that a significant number of variants of unknown clinical significance would be diagnostic if proven *de novo* since 42.5% of analyses lacked one or both parental samples. In addition, novel gene-disease associations for epilepsy will increase future diagnostic rates. Our data emphasize the need of gene curation, phenotyping and data sharing in pediatric disorders to increase the diagnostic rate of NGS in individuals with epilepsy. .

**2905T**

**Utility of comprehensive next-generation sequencing panel for neuromuscular diseases in Korean patients.** *D. Jang<sup>1</sup>, J.S. Ryu<sup>2</sup>.* 1) Department of Rehabilitation, Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea; 2) Department of Rehabilitation Medicine, Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

**Background:** Neuromuscular disease is a very broad term that encompasses many diseases that affect the neuromuscular system. Genetic and clinical heterogeneity, unspecific clinical features, unidentified genes and the implication of large genes give challenges in routine molecular diagnosis, increasing turn-around time and effort to make molecular validation of the diagnosis. Recently, multigene disease-specific panels have been emerging as a molecular diagnostic tool, which is a part of next generation sequencing (NGS) technique. The purpose of the present study was to assess the utility of a comprehensive neuromuscular diseases NGS panel. **Methods:** We designed a NGS panel targeting 293 genes (version 1) and 410 genes (version 2) associated with comprehensive hereditary neuromuscular diseases. A total 91 patients were enrolled. All patients were analyzed by a targeted NGS panel of comprehensive hereditary neuromuscular diseases (Version 1 was used from June 2016 to September 2017, and version 2 was used from October 2017 to May 2018), chromosomal microarray and karyotyping. **Results:** A genetic diagnosis was possible in 36 of 91 patients (39.5%). Thirty-four patients were diagnosed through the comprehensive neuromuscular diseases NGS panel and two were confirmed by chromosome microarray test. Four of 55 patients who were not diagnosed were performed additionally a whole exome sequencing test and one of them was diagnosed. A diagnostic yield of version 2 was higher than version 1. Total 37 definitive causative variants and 10 possible causative variants were identified, of which 17 were novel variants. **Conclusions:** Comprehensive neuromuscular diseases NGS panel can improve the genetic diagnosis efficiency. Due to the rapid discovery of new disease causing genes, an update of gene panel is required.

**2906F**

**Novel compound heterozygous *EPG5* mutations consisted with a missense mutation and a microduplication in the exon 1 region identified in a Japanese patient with Vici syndrome.** *S. Shimada<sup>1</sup>, H. Hirasawa<sup>1</sup>, T. Takeshita<sup>1</sup>, N. Nakatsukasa<sup>1</sup>, S. Shimojima<sup>2,3</sup>, N. Nagata<sup>1</sup>, Y. Yamamoto<sup>2,3</sup>.* 1) Tokyo Women's Medical University, Department of Pediatrics, Tokyo, Japan; 2) Tokyo Women's Medical University, Institute of Medical Genetics, Tokyo, Japan; 3) Institute of Medical Genetics, Tokyo Women's University, Tokyo, Japan.

Vici syndrome is a rare, autosomal recessive, multisystem disorder, characterized by agenesis of the corpus callosum, cataracts, psychomotor delay, cardiomyopathy, hypopigmentation, and recurrent infections. Mutations in the ectopic P-granules autophagy protein 5 homolog gene (*EPG5*), which encodes a key autophagy regulator, are responsible for this syndrome. A 3-year-old Japanese girl manifesting similar symptoms to those found in patients with Vici syndrome showed intractable diarrhea, rather than immunodeficiency. Whole exome sequencing identified only a heterozygous variant in *EPG5*, MN=020964.2(*EPG5*):c.3389A>C(p.His1130Pro), which was inherited from her mother. Sequencing analyses of the *EPG5* mRNA showed only an altered nucleotide "C" at position, c.3389, indicating decreased expression of the wild type allele. Microarray-based comparative genomic hybridization revealed a *de novo* microduplication in the exon 1 region. This was considered the cause of the decreased expression of the wild type allele. In conclusion, we successfully identified novel compound heterozygous mutations in *EPG5* in a patient who was clinically considered to have Vici syndrome.

## 2907W

**Dynamic approach to genetic testing for childhood-onset epilepsy.** J. Balciuniene<sup>1</sup>, E.T. Dechene<sup>1</sup>, G. Akgumus<sup>1</sup>, E.J. Romasko<sup>1</sup>, K. Cao<sup>1</sup>, M. Sarmady<sup>1,2</sup>, N.B. Spinner<sup>1,2</sup>, L.K. Conlin<sup>1,2</sup>, I. Helbig<sup>3,4</sup>, A. Abou Tayoun<sup>1,2,5</sup>. 1) Division of Genomic Diagnostics, Department of Pathology and Laboratory Medicine, The Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Pathology and Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 3) Division of Neurology, The Children's Hospital of Philadelphia, Philadelphia, PA; 4) Department of Neurology, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 5) Al Jalila Children's Specialty Hospital, Dubai, UAE.

The genetic landscape of epilepsy has been rapidly changing through continuous discovery of new disease genes. This is necessitating more dynamic genetic testing approaches to keep up with an evolving gene repertoire and achieve the highest possible clinical sensitivity. We developed an exome-sequencing based panel for idiopathic childhood epilepsy. The test focuses on an initial proband-only comprehensive analysis for sequence and copy number changes in 100 thoroughly curated epilepsy genes, with additional genetic testing options being offered afterwards. Our cohort includes 151 individuals referred for seizures, with and without additional findings. The panel analysis established molecular diagnoses in 16 probands (11%), while the majority of cases were inconclusive (N=87, 57%) or negative (N=48, 32%). Parental testing was available for 15 of the patients with inconclusive findings and led to molecular diagnoses for 7 of them (46%), increasing the overall diagnostic yield to 15.2%. Ten probands with inconclusive or negative findings were reflexed to whole exome testing, and 4 were diagnostic (40%) in genes not included in our panel. This raised the overall diagnostic yield of the study to 17.9% (27/151). For the 27 positive cases, disease causing genes/loci were: *SCNA1* (4x), *STXBP1* (2x), *del16p11.2* (2x), *IQSEC2* (2x), *ATP1A2*, *ATP1A3*, *CACNA1*, *GABRA1*, *KCNQ2*, *KCNT1*, *PRRT2*, *SCN2A*, *SCN8A*, *del of DEPDC5*, *TPP1*, *PCDH19* and *UBE3A*, which were on the curated panel, and *SMC1A*, *SETBP1*, *NR2F1* and *TRIT1* which were identified by the exome test. Of note, probands with epilepsy onset in infancy (N=44) (between 1 and 12 months of age) had the highest diagnostic rate (36%). For the remaining 124 non-diagnostic cases, analysis was expanded to 13 additional genes implicated in epilepsy since the launch of our panel in 2016. While promising findings were identified in at least 4 cases, supporting variant information is still needed to reclassify these cases. We show that an exome-based panel is an efficient testing option that enables rapid analysis of a pre-selected set of genes while retaining unprecedented flexibility in gene content. We argue epilepsy testing benefits from a dynamic strategy with parental samples readily available for follow up analysis of inconclusive findings, and whole exome trio for the remaining non-diagnostic cases. Periodic reanalysis, to capture information in newly identified genes, is expected to further increase the diagnostic yield.

## 2908T

**Clinical exome testing as an effective diagnostic tool for epilepsy/seizure disorders.** F. Xia<sup>1,2</sup>, L. Meng<sup>1,2</sup>, W. Bi<sup>1,2</sup>, P. Liu<sup>1,2</sup>, X. Wang<sup>1,2</sup>, R. Xiao<sup>1,2</sup>, A.A. Braxton<sup>1,2</sup>, P.A. Ward<sup>1,2</sup>, W. He<sup>2</sup>, F. Vetrini<sup>2</sup>, J. Dong<sup>2</sup>, H. Cheng<sup>1,2</sup>, D.M. Muzny<sup>2</sup>, R.A. Gibbs<sup>2</sup>, C.M. Eng<sup>1,2</sup>, Y. Yang<sup>1,2</sup>. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Baylor Genetics Laboratories, Houston, TX; 3) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX.

**Background:** In the United States, about 3 million adults and 0.5 million children suffer active seizure disorders each year, which account for 1.2% of the population. Clinical whole exome sequencing (WES) has been proven as a powerful tool for evaluation of genetic disorders, however, the effectiveness of WES on heterogeneous neurological disorders, such as epilepsy/seizures, has not been thoroughly evaluated. **Method:** We retrospectively analyzed clinical WES cases consecutively tested in our clinical laboratory. Of those individuals, 3,026 had an indication of active epilepsy or history of seizure disorders. Single nucleotide variants and small insertions/deletions were detected by WES analysis and chromosomal microarrays, cSNP arrays and other techniques were employed to confirm large copy number variation (CNV) and other types of mutations. Variant classifications were based upon modified ACMG guidelines. Clinical correlations were determined by a 3-level review system. **Results:** The overall diagnostic rate was 34.5% (1,056/3,026) within this cohort. In addition, 17% cases carried variants of unknown significance that warrant further study. Among patients younger than 18 years-old, the yield was 35.1% (978/ 2,785), while 32.5% (78/241) of adults were diagnosed. There are contributing defects in more than 800 genes. Among them, *SCN1A*, *STXBP1*, *MECP2*, *KCNT1*, *CDKL5*, *DYRK1A*, *SMC1A*, *WDR45*, *KCNQ2*, *PURA*, *SCN8A*, *SYNGAP1*, *SCN2A*, *ARID1B*, *PCDH19*, and *TBC1D24* together account for ~ 24% of the 1,056 diagnosed cases. Ninety genes encoding membrane-bound transporters and channels comprised the largest group by contributing ~25% of the diagnosed cases. More than 500 genes only had contributing variant(s) in a single case and ~6% of diagnoses were made by identification of large CNVs or chromosomal changes. **Conclusion and discussion:** Clinical WES diagnosed an overall ~1/3 of a diversified epilepsy/seizures cohort, and suggested follow-up work for more than 1/2 of the diagnosed cases. Several genetic mechanisms underlie epilepsy pathology, including: 1) Ionic changes; 2) Alteration of neuron transmitters and their receptors; 3) Metabolic dysregulation; 4) Immunity deficiency; 5) Structural developmental defects; and 6) Tumorigenesis – and each can require distinctive therapies. Clinical WES can distinguish these causes and therefore is a cost-effective platform that should be considered for all epilepsy/seizure related disorders.

**Background:** Korean undiagnosed rare disease program (KUDP) was launched on January 2017 as one year pilot project with global increasing interest of undiagnosed patients in rare diseases. We would summarize this project and reinforce the unmet needs in undiagnosed rare diseases. **Results:** The patient enrollment, assessment, and diagnostic process were decided by the clinical expert consortium. Patients followed the diagnostic workflow, after being categorized into four groups: I) insufficient clinical information or lack of standard diagnostic processes, II) clinical diagnosis and its targeted confirmatory test being concluded at initial expert consortium meeting, III) clinical diagnosis made at initial meeting but next generation sequencing being required due to its genetic heterogeneity, and IV) no definite clinical diagnosis with heterogeneous and nonspecific clinical presentations. Ninety-seven patients were enrolled in this project, which included 10 patients with category II, 67 with category III, and 20 with category IV. Of those 85 patients (87.6%) were children (<15 years old), 59 (60.8%) were males, and 79 (81.4%) had neurologic symptom as their main problem. For 1 year, 72 patients completed the diagnostic assessment with clinical, biochemical, pathological and molecular genetic analysis. Of those, 28 patients (28/72 38.8%) were reached the diagnosis. Thirteen patients were diagnosed based on the traditional tests such as biochemical assay, single or targeted genetic analysis, and chromosomal microarray. We performed whole exome sequencing in 53 patients, of which 15 (28.3%, 15/53) were reached the final diagnosis. One new disorders were discovered with international collaboration and 3 other candidate genes were on functional validation or waiting for further research. **Conclusions:** KUDP pilot project through efficient clinical diagnostic workflow showed fair diagnostic yield rate with further possibility of additional diagnosis and new scientific discovery in complex rare diseases. KUDP also showed the unmet need in complex and multisystem disorders and utility of emerging genomic technology and further research in rare conditions, still remained undiagnosed.

**2910W****De novo missense variants in the alternative exon 5 of SCN2A are a rare cause of neurodevelopmental disorders with or without seizures.**

D.N. Shinde<sup>1</sup>, L. Rohena<sup>2,3</sup>, S. Weatherspoon<sup>4</sup>, K.L. Helbig<sup>5</sup>, C. Antolik<sup>1</sup>, D.R. Hamlin<sup>2</sup>, J.M. Berg<sup>2</sup>, C. Schultz<sup>1</sup>, Z. Powis<sup>1</sup>, S. Tang<sup>1</sup>, K. Radtke<sup>1</sup>. 1) Amby Genetics, Aliso Viejo, CA; 2) Department of Pediatrics, Division of Medical Genetics, San Antonio Military Medical Center, San Antonio, TX; 3) Department of Pediatrics, Division of Medical Genetics, University of Texas Health Science Center at San Antonio, San Antonio, TX; 4) Department of Pediatric Neurology, Le Bonheur Children's Hospital, University of Tennessee Health Science Center, Memphis, TN; 5) Division of Neurology, Children's Hospital of Philadelphia, Philadelphia, PA.

SCN2A encodes Na<sub>v</sub>1.2, the alpha subunit of the neuronal voltage-gated sodium channel that is responsible for generation and propagation of action potentials. Heterozygous mutations in SCN2A cause a spectrum of neurodevelopmental disorders including benign familial infantile seizures and early infantile epileptic encephalopathy, with or without autism spectrum disorders and intellectual disability. Na<sub>v</sub>1.2 has two developmentally regulated isoforms (neonatal [N] and adult [A]) that use alternatively spliced coding exons 5N and 5A, respectively. During early brain development, the N isoform is more abundantly expressed than the A isoform, but its relative proportion decreases as it is replaced by the A isoform during postnatal development. N channels are less excitable than A channels, and mutations in SCN2A that increase neuronal excitability of the N channels to the level of the A channels, are thought to increase susceptibility to seizures in the neonatal period. Although most mutations in SCN2A are found in both the isoforms, to date, there is only one report of a likely pathogenic variant, c.634A>G (p.N212D), found exclusively in the N isoform in an infant with Ohtahara syndrome. Here, we report two additional unrelated affected individuals with *de novo* missense variants in exon 5N of SCN2A, c.647T>A (p.L216H) and c.668G>T (p.R223I), that were identified using trio-based whole exome sequencing. Both the affected individuals presented with global developmental delay and abnormal brain MRI findings. Additionally, infantile spasms were observed in one of the affected individuals, while the other presented with intellectual disability and autistic behaviors. Both altered amino acids are located in the voltage-sensor S4 transmembrane helix of Na<sub>v</sub>1.2, and structural analysis indicates that the alterations impact channel function by disrupting charge gating. Functional studies to determine impact on channel activity are ongoing, and identification of additional affected individuals may help to elucidate the phenotypic spectrum of variants in exon 5N of SCN2A. Our results highlight the clinical utility of reporting variants in alternative isoforms of genes with clinically well-characterized primary isoforms.

**Whole exome sequencing and rhPCR accurately resolve copy number variation in highly homologous *SMN1* and *SMN2* genes.** J. Sistonen, M. Valori, H. Junnila, A. Korppoo, L. Koskinen, E. Salminen, T.P. Alastalo, S. Myllykangas, J.W. Koskenvuo, P. Salmenperä. Blueprint Genetics, Helsinki, Finland.

Spinal muscular atrophy (SMA) is a neuromuscular disorder characterized by progressive degeneration of spinal cord motor neurons, atrophy of skeletal muscles, and generalized weakness. The clinical phenotype ranges from a severe infantile form with a limited life expectancy to an adult-onset mild form of the disease. In the majority of cases, the disease is caused by a homozygous absence of the survival motor neuron 1 (*SMN1*) gene. Highly homologous *SMN2* gene that differs from *SMN1* only by a single coding nucleotide resulting in a splicing defect and low *SMN2* function can also modify the disease severity. Patients with a higher *SMN2* copy number usually manifest a milder clinical phenotype. To address the clinical importance of accurate and efficient *SMN1* and *SMN2* copy number analysis, we developed a custom bioinformatic analysis based on whole exome sequencing data combined with a novel RNase H2-dependent PCR (rhPCR) for confirmation analysis. The bioinformatic method utilizes next-generation sequencing (NGS) reads at four loci differing between the genes while the rhPCR assays target two of the loci with RNA-modified primers and activating RNase H2 enzyme improving the assay specificity and sensitivity compared to traditional quantitative PCR-based methods. We validated the methods using a set of commercially available samples and patient DNA samples extracted from blood and saliva. Both methods showed 100% sensitivity and specificity. Additionally, we applied the bioinformatic analysis to test 2196 de-identified patient samples and observed heterozygous *SMN1* deletion in 2.6% of the samples, which is in agreement with frequencies reported earlier. In conclusion, we have established an accurate and high-throughput approach to test for *SMN1* and *SMN2* copy numbers enabling diagnostics of SMA and application of novel therapeutic strategies.

**2912F**

**Development, validation and application of next-generation sequencing assay for carrier screening of spinal muscular atrophy.** X. Meng, C. Ye. WuXi NextCODE, Shanghai, China.

Spinal muscular atrophy (SMA [MIM 253300]) is caused by biallelic mutations in the survival motor neuron 1 (*SMN1*) gene, whereas *SMN2* copy number may modify disease severity. The identification of SMA carrier status in large populations is necessary for congenital defects prevention. Traditional methods such as ddPCR and MLPA are expensive and low throughput in large scale carrier screening, and incapable of detecting novel variants. Recently, NGS-based carrier screening assays show increased efficacy in CNV detection than conventional methods in a high throughput mode for a large number of genes. We developed a capture-based NGS assay and its analysis tool to detect copy numbers of *SMN1/2*. Our algorithm first quantified the normalized unique reads on exon 7. Then, the unsupervised Gaussian Mixture Model (GMM) was trained for carrier status classification. In total, 2058 samples were used to setup baselines for each copy number mode. For validation, another 1170 samples were used with MLPA/ddPCR confirmations. The sensitivities (and positive predictive values, PPVs) for *SMN1* with 0, 1 and  $\geq 2$  copy numbers on exon 7 were 100% (94.7%), 98.4% (72.1%) and 97.7% (99.9%), respectively. Furthermore, the sensitivities (and PPVs) for *SMN2* were 100% (97.2%), 99.5% (96.6%) and 98.3% (99.9%), respectively. The specificities for *SMN1* and *SMN2* were 97.7% and 98.3%, respectively. With demonstrated high sensitivity and specificity, the developed NGS assay was applied in front-line carrier screening. To further reduce false positive and false negative in clinical practice, NGS identified high confident positive/carrier samples and low confident results were all confirmed by MLPA. To date, 828 samples were included in the prospective study. According to NGS results: 1) 19 samples were SMA carriers (10 high confident and 9 low confident results); 2) 7 samples were low confident negatives; 3) the rest 802 samples were high confident negatives. According to confirmations by MLPA, 1) the sensitivity is 100%; 2) the PPV is 68.4% (6 low confident "carriers" were later found as negatives); 3) 7 low confident negatives were all identified as negatives. The total SMA carrier frequency as a result is 1.57% (13/828). In conclusion, we have developed, validated and applied an effective patented NGS assay for SMA carrier screening with reduced cost and improved performances. It could be easily incorporated into other extensive screening panels for better congenital defects prevention.

**2913W****Clinical approach of Angelman syndrome: A study of 23 cases. I.O.**

*Focsa*<sup>1</sup>, *L.C. Bohiltea*<sup>1</sup>, *D. Craiu*<sup>1,2</sup>, *C. Iliescu*<sup>1,2</sup>, *D. Birca*<sup>1,2</sup>, *A.C. Tutulan-Cunita*<sup>3</sup>, *S.M. Papuc*<sup>3</sup>, *A. Arghir*<sup>3</sup>, *M. Budisteanu*<sup>2,3,4</sup>. 1) C.Davila University of Medicine and Pharmacy, Bucharest, Romania; 2) Prof. Dr. A. Obregia Clinical Hospital of Psychiatry, Bucharest; 3) V. Babes National Institute of Pathology, Bucharest; 4) University of Medicine Titu Maiorescu, Bucharest.

**Introduction:** Angelman syndrome (AS) is a genetic disorder characterized by a severe phenotype including: global developmental delay, a happy disposition and other behavior problems, movement disorder or ataxia and by a recognizable facial dysmorphism. Epileptic seizures, microcephaly and hypo-pigmentation are reported in many patients. Several genetic mechanisms have been associated with AS: deletions of 15q11-q13, paternal uniparental disomy, imprinting defects or mutations in *UBE3A* gene. **Aim:** In this paper we will present our experience regarding the diagnosis and the management of Angelman syndrome. **Material and methods:** Our study included 23 children (7 boys and 16 girls) with a putative diagnosis of AS, of ages ranging from 6 months to 12 years. The clinical diagnosis was established due to the presence of typical features included in consensus criteria (Williams 2006). In order to confirm the diagnosis, we performed genetic tests – FISH, methylation PCR, sequencing. For each patient, a personalized management plan was established. **Results:** The genetic tests certified the diagnosis in all 23 children: in 21 cases, the 15q11-15q13 deletion was identified, whereas a mutation in *UBE3A* gene was found in 2 patients. All patients showed severe intellectual disability, ataxic gait, sleep disturbances and happy disposition. The impairment of language was severe: only 2 patients were able to say a few words. Microcephaly was noted in 18 cases. 22 children had epileptic seizures. The most frequent seizures were partial seizures (12 children), followed by tonic-clonic generalized seizures, hypotonic seizures, and infantile spasms. The EEG exhibited the characteristic AS pattern in all patients. Valproate was the anticonvulsant of choice, alone, or in combination with other antiepileptic drugs. A good control of seizures was obtained in 20 children. Physical therapy and cognitive stimulation were performed in all children, leading to improvement of the motor delay, but with very little progress in cognitive functions. **Conclusions:** Angelman syndrome is a severe disorder, with complex clinical picture, imposing a multidisciplinary approach. An early diagnosis is tremendously important in order to develop the efficiency of the personalized management plan.

**2914T****Behind the Seizure™: A no-cost, 125-gene epilepsy panel for pediatric seizure onset between 2 and 4 years. S. Aradhya<sup>1</sup>, M. Bailey<sup>2</sup>, J. Cohen-Pfeffer<sup>3</sup>, S. Koh<sup>3</sup>, J.J. Millichap<sup>4</sup>, R. Truty<sup>5</sup>, E.C. Wirrell<sup>5</sup>, N. Miller<sup>5</sup>.**

1) Invitae, San Francisco, CA; 2) BioMarin Pharmaceutical Inc., Novato, CA; 3) Emory University School of Medicine, Atlanta, GA; 4) Lurie Children's Hospital, Chicago, IL; 5) Mayo Clinic, Rochester, MN.

**Objectives:** CLN2 disease, a form of neuronal ceroid lipofuscinosis (NCL), commonly presents ~3 years-of-age with seizures and history of language delay. Average diagnosis occurs ~5 years: two years after symptom onset and after neurodegeneration marked by loss of ambulation and speaking ability. Our objective is to understand the molecular diagnostic yield of a US-based, targeted, no-cost epilepsy gene panel program, Behind the Seizure™ (BTS), and determine if this can decrease the age of diagnosis in CLN2 disease. **Methods:** BTS eligibility criteria: (I) age at test order ≥24 months to <60 months, (II) unprovoked seizure onset at ≥24 months. Physician-reported clinical history and suspicion of seizure etiology was collected. Average test turnaround time is 10-14 days (Invitae Epilepsy Panel). **Results:** Non-BTS epilepsy gene panel testing (all ages, age of seizure onset) resulted in a 17.1% molecular diagnostic yield (n=277/1620) and 0.12% for *TPP1* (CLN2 disease). For BTS testing, the yield for CLN2 disease was 2.3% (n=4/176), a 19-fold improvement. Age-at-diagnosis of CLN2 disease was earlier than average (3-4 years versus 5 years). From BTS, 3 of 4 molecular diagnoses in *TPP1*, CLN2 disease was unsuspected. Other genes with molecular diagnoses: *MECP2*, *CHD2*, *SYNGAP1*, *SCN1A*, *GPHN*, *GRIN2A*. **Conclusions:** Behind the Seizure™ facilitated CLN2 disease identification earlier than average and in cases which CLN2 was not suspected. While there is no direct comparator for the BTS group, these findings may indicate that broad epilepsy gene panel tests implemented with clinical criteria can increase diagnostic yield for CLN2 disease and simultaneously identify other genetic causes of epilepsy. .

**2915F**

**Molecular basis of CLN2 disease: A review and classification of *TPP1* gene variants reported world wide.** N. Miller<sup>1</sup>, E. Gardner<sup>2</sup>, A. Schulz<sup>3</sup>, M. Aristonera<sup>4</sup>, M. Bailey<sup>1</sup>, W.W. Xin<sup>1</sup>, S.E. Mole<sup>2</sup>. 1) BioMarin Pharmaceutical Inc, Novato, CA; 2) University College London, London, UK; 3) University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 4) Massachusetts General Hospital, Boston, MA, USA.

**BACKGROUND:** CLN2 disease is caused by autosomal recessive inheritance of 2 pathogenic variants *in trans* in the *TPP1* gene, leading to deficient activity of the lysosomal enzyme tripeptidyl peptidase I (TPP1). A subtype of neuronal ceroid lipofuscinosis, CLN2 disease is diagnosed through clinical findings, TPP1 enzyme deficiency, and/or molecular findings in *TPP1*. CLN2 disease classically presents with seizures at 2-4 years of age and a history of early language delay, followed by rapid psychomotor decline and death in the second decade. A form of juvenile onset disease was initially described as autosomal recessive spinocerebellar ataxia 7 (SCAR7) before being attributed to TPP1 enzyme deficiency. **METHODS:** We collected individuals reported to have TPP1 enzyme deficiency from literature review, public databases and laboratory communication. Previously unrecorded individuals collected were added to the University College London *TPP1*-specific database. **RESULTS:** We present an update on the spectrum of *TPP1* gene variants associated with CLN2 disease including 178 unique variants and 405 individuals reported to have TPP1 enzyme deficiency (739 alleles). Two known pathogenic variants, c.509-1G>C and c.622C>T (p.Arg208Ter), collectively occur in 54% of affected individuals collected; at least 91 variants are private to single families. Homozygosity occurs in 43% of individuals where both alleles are known (84% of reported individuals). Atypical CLN2 disease represents 17% of individuals recorded with associated phenotype. Increased use and early adoption of diagnostic testing for a genetic basis of epilepsy is aided by description of *TPP1* variants in association with clinical and laboratory findings. NCBI ClinVar currently holds records for only 23% of variants collected from literature. **DISCUSSION:** Effective CLN2 disease management requires timely diagnosis; however, irreversible neurodegeneration occurs before diagnosis is typically reached at age 5. Timely classification and public reporting of *TPP1* variants is essential as molecular testing increases in use as a first-line diagnostic test for pediatric-onset neurological disease.

**Searching for blood biomarkers to improve the diagnosis and the management of patients with epilepsy.** M. Martin<sup>1</sup>, S.H. Avansini<sup>1</sup>, A.S. Vieira<sup>1</sup>, R. Secolin<sup>1</sup>, M.L. Santos<sup>1</sup>, F.R. Torres<sup>1</sup>, F. Rogério<sup>2</sup>, A.C. Coan<sup>2</sup>, M.K.M. Alvim<sup>2</sup>, M.E. Morita<sup>2</sup>, C.L. Yasuda<sup>2</sup>, R. Barbosa<sup>2</sup>, F. Cendes<sup>2</sup>, I. Lopes-Cendes<sup>2</sup>. 1) Medical Genetics Dept., University of Campinas (UNICAMP), Campinas, Brazil; 2) Neurology and Anatomical Pathology School of Medical Sciences, University of Campinas (UNICAMP), Campinas, Brazil.

**Introduction and Hypothesis:** It is estimated that the misdiagnosis of epilepsy occurs in 25% of patients and 1/3 of these do not respond to clinical treatment. Thus, the search for biomarkers for the diagnosis and the prediction of response to antiepileptic drugs (AEDs) is urgently needed. Potential candidates are circulating microRNAs, present and stable in body fluids and are already associated with the diagnosis and staging of various diseases. **Objective:** This study aims to determine whether robust and non-invasive molecular signatures of circulating microRNAs could help to improve diagnosis and or management of patients with epilepsy, and to identify and validate whether these molecular signatures could also be associated with response to AEDs. **Methods:** The study is divided into two phases: an initial discovery phase with 10 patients with mesial temporal lobe epilepsy (MTLE) who are responsive to AED treatment, 10 patients with MTLE who are AED resistant, 10 patients with focal cortical dysplasia (FCD), 10 patients with genetic generalized epilepsy and 10 control individuals. These will be used to quantify plasma levels of microRNAs by microRNA-sequencing. In the second phase, we enrolled an additional independent cohort of 100 patients with MTLE using the same diagnostic criteria as previously described and we will assay the most significant microRNAs found in phase 1 using RT-qPCR. We also recruited an additional 200 healthy individuals without epilepsy as a control group. **Results/Discussion:** To date, we have completed the recruitment of patients for both phases of the study and the main phenotypic characteristics of our cohort are as follows. We found that patients with MTLE who are AED responsive have fewer seizures than patients who are AED resistant (*p-value* = 0.0017). Patients with MTLE are older than patients with FCD (*p-value* < 0.05). Patients with AED resistant MTLE have seizure onset earlier (*p* < 0.05) and use a high number of AEDs than patients with AED responsive MTLE (*p* = 0.0029). **Conclusion:** We have successfully recruited and characterized clinically a cohort of patients who are being currently studied for the discovery of circulating biomarkers for epilepsy and response to treatment. When completed our study will likely to have a relevant impact in the way clinicians manage patients with different types of epilepsy. **Supported by:** FAPESP, SP, Brazil.

**2917T**

**PIK3CA mutations in fibrolipomatous hamartomas of nerve.** *P.R. Blackburn<sup>1</sup>, D. Milosevic<sup>1</sup>, B.M. Howe<sup>2</sup>, A.L. Folpe<sup>1</sup>, R.J. Spinner<sup>3</sup>, J.M. Carter<sup>1</sup>.* 1) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 2) Department of Radiology, Mayo Clinic, Rochester, MN; 3) Department of Neurologic Surgery, Mayo Clinic, Rochester, MN.

Fibrolipomatous hamartoma (FLH)/lipomatosis of nerve is a rare developmental malformation characterized by an aberrant lipomatous proliferation within peripheral nerve fascicles. FLH most frequently involves the median nerve, and can manifest clinically as a peripheral neuropathy. However, a significant subset of FLH is associated with proliferation of bone and/or soft tissue in the affected nerve's territory, manifesting clinically as tissue overgrowth. The molecular genetic profile of FLH, including anatomically and phenotypically-distinct variants, and its association with tissue overgrowth disorders, is not well understood. Seven FLH (from 4 females and 3 males, median age at presentation: 10 years; range: 0-33 years) involving the median (N=4), sciatic, ulnar, or peroneal nerves (N=1 each) were analyzed by whole-exome sequencing. Five patients had FLH nerve territory overgrowth (N=3 median nerve, N=1 each for sciatic and ulnar nerves). *PIK3CA* missense mutations were identified in 6 of 7 cases. The two FLH without clinically apparent overgrowth (peroneal nerve FLH and one median nerve FLH) both had the c.3140A>T, p.H1047L variant (mutant allele frequency range: 6 to 17%). Four of 5 FLH with overgrowth had the more common c.3140A>G, p.H1047R variant (mutant allele frequency range: 14 to 26%). No detectable *PIK3CA* mutations were found in the sole ulnar FLH. The *PIK3CA*-related overgrowth spectrum of disorders is characterized by post-zygotic *PIK3CA* mutations with tissue mosaicism. Within this spectrum, somatic missense mutations at the H1047 residue in the kinase domain of *PIK3CA* are frequently seen in fibroadipose overgrowth, hemihyperplasia with multiple lipomatosis, and isolated macrodactyly, with or without median nerve FLH. Our data demonstrate that *PIK3CA* p.H1047 mutations are frequent events in FLH, irrespective of anatomic site or overgrowth phenotype. While the small case number limits genotypic-phenotypic correlation, both mutant allele frequency and *PIK3CA* mutational subtype may determine the extent and distribution of tissue overgrowth. Regardless, as FLH are defined by aberrant lipomatous overgrowth within nerve, these lesions likely belong to the *PIK3CA*-related overgrowth spectrum. .

**2918F**

**Overcoming challenges in validation of potentially mosaic variants.** *C.M. Grochowski<sup>1</sup>, R.T. Gonçalves<sup>2,3,4</sup>, Z.H.C. Akdemir<sup>1</sup>, S.R. Lalani<sup>1</sup>, J.R. Lupskij<sup>1,5,6,7</sup>, C.M.B. Carvalho<sup>1</sup>.* 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Universidade Federal de Minas Gerais (UFMG); 3) Sociedade Brasileira de Genética Médica (SBGM); 4) Faculdade da Saúde e Ecologia Humana (FASEH); 5) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 6) Department of Pediatrics, Baylor College of Medicine, Houston, TX; 7) Texas Children's Hospital, Houston, TX.

Increasingly sensitive sequencing methodologies have led to the discovery of variants present in a mosaic state. The identification of mosaic variants has a profound impact not only on genetic counseling for recurrence risk when found in a parent, but also on patient care as mutation mosaicism can have an effect on disease burden and outcome. As mosaic mutations are found in potentially 1% of exomes analyzed, orthogonal validation methods are needed. We present two cases in which ddPCR was used to validate a mosaic variant discovered in WES. The first case involving an individual with Wolf-Parkinson-White Syndrome (MIM 194200) and a missense variant in the gene *RHBDF1* which presented with a low variant read to total read ratio (32/217 14.7%) leading to the suspicion of mosaicism. A TaqMan assay was designed with two different fluorescent probes that would bind with either the mutant or reference allele. The proband showed a ratio of positive droplets for the mutant allele versus wildtype allele of 13.3% (2415/18105), corroborating the low variant count originally found in the WES data. A second case involved a diagnosis of epileptic encephalopathy (MIM 607208) and a missense variant in *SCN1A* in which the proband showed a variant read to total count of 39% (47/119) and the father (who reported epilepsy as a child that resolved with age) presented with a low variant read to total ratio of 12.7% (15/118), again raising suspicion of mosaicism. A TaqMan assay was designed but the mutant and wildtype both amplified the same region due to the length of the probe (24bp). As probes >18bp are better at discriminating these changes, we sought to lower the length through the use of LNA bases, though this approach also failed. A third attempt was performed using allele specific primers and EvaGreen. Forward primers were designed with a single bp difference in the 3' end denoting the G>A change with a destabilizing mismatch placed in the penultimate nucleotide. Using a common reverse primer, the ratio of positive droplets for the mutant allele versus wildtype was 42% (1871/4378) in the proband and 17% (1083/6217) in the father, closely matching the WES call. As NGS becomes more widely utilized, the discovery of variants in a mosaic state will increase. Overcoming the challenges to validate these variants is critical in providing parents the true nature of their recurrence risk and providing patients with a deeper understanding and subsequent care for their disease.

**2919W**

**Low-level parental mosaicism is a characteristic of holoprosencephaly pathogenic variants previously described as de novo.** A.F. Martinez, P. Hu, P.S. Kruszka, E. Roessler, M. Muenke. National Institutes of Health, Bethesda, MD.

Holoprosencephaly (HPE) is the most common forebrain malformation of the developing embryo. We developed a novel high-coverage targeted capture panel of 150 potential HPE genes to determine the inheritance pattern of disease-causing mutations and selected *de novo* variants (DNV) for analysis of possible parental mosaicism. We identified 28 high-confidence DNVs that were confirmed by family studies, exome data and droplet digital polymerase chain reaction. Most of the DNVs were identified among four known HPE genes (20/28) and were consistently pathogenic (95%) and exclusively exonic. Randomly distributed singleton DNVs of uncertain significance constituted the remaining detections. Analysis of the sequence alignment (BAM) files revealed variable degrees of parental somato-gonadal mosaicism in 26% of cases. In addition, evidence for likely post-zygotic *de novo* events in probands were exclusively detected in 4/8 (50%) of targets (one in an HPE gene and three without previous HPE association). Our results indicate that high-coverage sequencing is essential to providing an accurate assessment of recurrence risk of HPE in mutation-positive families. Detection and confirmation of low-level mosaicism needs to be offered to all at-risk families.

**Detection of spinal muscular atrophy-associated loss of SMN1 in a clinical whole genome sequencing test.** A.L. Halpern<sup>1</sup>, A. Chawla<sup>1</sup>, S.S. Ajay<sup>1</sup>, R.T. Hagelstrom<sup>1</sup>, C.M. Brown<sup>1</sup>, A. Buchanan<sup>1</sup>, A.J. Connell<sup>2</sup>, M.E.R. Butchbach<sup>2</sup>, J. McEachern<sup>1</sup>, D.L. Perry<sup>1</sup>, M.A. Eberle<sup>1</sup>, R.J. Taft<sup>1</sup>. 1) Illumina, Inc, San Diego, CA; 2) Nemours Biomedical Research, Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE.

Spinal Muscular Atrophy (SMA) is an early-onset neurogenetic disorder caused by loss of motor neurons in the spinal cord and brain stem, leading to generalized muscle weakness, atrophy and death. SMA is caused by biallelic loss of function of the *SMN1* (*survival motor neuron 1*) gene. Approximately 95% of affected individuals have a complete loss of *SMN1* with the remaining 5% of affected individuals having other pathogenic *SMN1* variants on the same or, rarely, both haplotypes. The *SMN1* gene has a paralogous gene known as *SMN2*, whose copy number can modify disease severity. *SMN1* and *SMN2* are nearly identical except for a few nucleotide differences, the most notable being c.840C>T (transcript: NM\_000344.3). This nucleotide transition within exon 7 causes the vast majority of *SMN2*-derived transcripts to lack exon 7 and, as a result, produce a truncated, unstable protein. Variants in *SMN1* and copy numbers of *SMN1* and *SMN2* are routinely assessed by polymerase chain reaction (PCR) coupled with restriction fragment length polymorphism analysis, and quantitative PCR, multiplex ligation-dependent probe amplification or digital droplet PCR, respectively. These techniques are often performed in addition to other molecular investigations, adding to cost and complexity of clinical care. The high homology between *SMN1* and *SMN2* creates challenges for standard variant calling pipelines, which typically produce poor quality variant calls in most of *SMN1*, including the c.840C position. To address this, we have developed a SMA caller that reports allele depths for both 'C'- and 'T'-supporting reads derived from either *SMN1* or *SMN2*. A finding of SMA-positive is reported if the read support for c.840C is consistent with no functional copies of *SMN1*. The SMA caller was tested on 40 samples with known SMA status. Sensitivity to accurately detect the c.840C>T variant in the samples was assessed to be 95.83%, with a specificity of 100%. Future aims include detection of other variants in *SMN1*, estimating paralog-specific copy number and identification of gene conversion between *SMN1* and *SMN2*.

**Targeted re-sequencing system in inherited muscular diseases.** A. Iida<sup>1</sup>, M. Okubo<sup>2</sup>, M. Inoue<sup>2</sup>, A. Ishiyama<sup>2</sup>, Y. Saito<sup>2</sup>, I. Nonaka<sup>2</sup>, S. Hayashi<sup>2</sup>, S. Noguchi<sup>2</sup>, I. Nishino<sup>1,2</sup>. 1) Medical Genome Center, National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan; 2) National Institute of Neuroscience, National Center of Neurology and Psychiatry, Kodaira, Tokyo, Japan.

Inherited skeletal muscle diseases are clinically and genetically heterogeneous rare disorders characterized by muscle weakness and degeneration. However, the pathogenesis remains largely unknown. National Center of Neurology and Psychiatry (NCNP) is a referral center for neuromuscular diseases in Japan. Since 1978, we have served the diagnosis service for muscle diseases all over Japan. Now, more than 70% of biopsied samples were gathered in NCNP. We have screened approximately 18,000 biopsied samples based on clinical and pathological information. Recently, we also established the molecular diagnostic system with four targeted gene panels containing 180 muscular genes to diagnose the etiology of muscle diseases, including muscular dystrophy (MD), congenital myopathy/congenital myasthenic syndrome (CMP), myopathy with protein aggregations/rimmed vacuoles (MFM), and metabolic myopathy (MM). To elucidate the patients with muscle diseases, we performed mutation analysis in 1,567 patients by Ion PGM sequencer coupled with the targeted gene panels. The diagnostic yield of MD panel was 55%, CMP panel was 36%, MFM panel was 39% and MM panel was 56%. Total diagnostic yield was 46%. Furthermore, novel mutations in five causative genes in five muscular diseases are detected; *VCP* in multisystem proteinopathy, *DYSF* in MD, limb-girdle type 2B, *LMNA* in CMP, *POMGNT2* in dystroglycanopathy, and *MTM1* in X-linked myotubular myopathy. The mutations in inherited muscular diseases will serve as an additional resource for analyzing correlation between mutations and phenotypes and future clinical sequencing.

**A diagnostic odyssey: Multiple platforms fail to detect this *MECP2* deletion.** S. Ceulemans<sup>1</sup>, M.C. Jones<sup>1,2</sup>, R. Haas<sup>1,2</sup>. 1) Rady Children's Hospital, San Diego, CA; 2) University of California - San Diego, San Diego, CA.

We describe a Rett syndrome case that highlights the difficulty caused by differences in laboratory assays resulting in failure to identify intragenic copy number variants (CNVs). Our patient is a four year old female who was noted to have reduced fetal movement but otherwise had an uncomplicated pregnancy and delivery. She had feeding difficulties but met milestones until age six months, when she was hospitalized for silent aspiration identified during a swallow study. Clinical exam showed gross hypotonia, obstructive sleep apnea, with mild dysmorphic features. She developed seizures around 15 months, which have proven to be intractable. The EEG showed abundant generalized slow spike and wave complexes in awake and sleep states, indicating severe epileptic encephalopathy. In the course of her thorough and complicated work-up, she underwent muscle and skin biopsies, lumbar punctures, biochemical testing, and six molecular genetic tests at five laboratories, one of which identified a deletion of 345 base-pairs within the fourth exon of *MECP2*. Table 1 outlines each result and whether the inability to detect the deletion was due to a technical limitation or a lab error. CNVs of approximately one to two exons are difficult to identify using NGS or oligo-SNP microarray, and single-exon array appears to have better yield. Laboratory differences impact the length of the diagnostic odyssey, possible treatment interventions and prognosis, and the relationship between patient and care team.

Genetic Test	Results	What happened?
Lab A - Oligo-SNP microarray	Duplication of PMP22, consistent with family history	Technical limitation: No probes within exon 4, CNV not big enough
Lab B - "Clinical exome" with NGS, revised to include "100% coverage of <i>MECP2</i> "	Carrier for Gaucher, 7 VUSs	Technical limitation: CNVs between 25bp-2 exons not consistently detected
Lab C - Research exome trio, NGS	Negative	Technical limitation: not designed for CNVs
Lab A - <i>MECP2</i> del/dup, qPCR	Negative	MISS, semi-quantitative approach
Lab D - Research genome trio, NGS	Suggestive of <i>MECP2</i> deletion	Needed confirmation
Lab E - <i>MECP2</i> del/dup with exon-level array, confirmed with MLPA	Partial deletion of <i>MECP2</i> exon 4	"Full coverage" is >3 probes, and 7 probes were on exon 4 alone

**2923T**

**Bi-allelic *ATAD3A* and *ATAD3B* deletions in two siblings with multiple congenital defects including severe pontocerebellar hypoplasia, resulting in neonatal death.** *F.AT. de Vries<sup>1</sup>, L.S. Smit<sup>2</sup>, A. Go<sup>3</sup>, M.M. Veghel Van – Plandsoen<sup>1</sup>, C.F.B. Labrijn – Marks<sup>1</sup>, M. Wilke<sup>1</sup>, G.M.S. Mancini<sup>1</sup>.* 1) Dept. Clinical Genetics, Erasmus Medical Centre, Rotterdam, The Netherlands; 2) Dept. Neurology, division Pediatric Neurology, and Dept. Pediatrics, division Neonatology, Erasmus Medical Centre, Rotterdam, The Netherlands; 3) Dept. Gynecology and Obstetrics, Erasmus Medical Centre, Rotterdam, The Netherlands.

In the second pregnancy of an healthy female, ultrasonography revealed polyhydramnion and talipes equinovarus. A male was born at 33 5/7 weeks gestational age and died 5 days after birth due to respiratory insufficiency. Postnatal examination showed severe pontocerebellar hypoplasia, optic atrophy, macula dystrophy, corneal oedema and congenital arthrogryposis. Routine SNP array analysis and whole exome sequencing (panel for intellectual disability, CRE-exome) did not reveal any pathogenic abnormalities. Triggered by described distinct clinical findings in patients with bi-allelic *ATAD3* gene cluster mutations<sup>4</sup>, additional SNP array analysis and a region specific long range PCR<sup>5</sup> were performed. A ~36 kb homozygous deletion (minimal region: chr1:g.1415790\_1452101 in hg19) including exon 5-16 of the *ATAD3B* gene and exon 1-2 of the *ATAD3A* gene was detected. At the time of the genetic confirmation, the woman was pregnant again and advanced sonography revealed bilateral talipes equinovarus, arthrogryposis, lissencephaly and pontocerebellar hypoplasia. Prenatal testing of the *ATAD3* gene cluster in amniotic fluid showed a similar ~36 kb homozygous deletion of exon 5-16 of *ATAD3B* and exon 1-2 of *ATAD3A*. A girl was born at 38 weeks of gestation and died within 1 hour after birth due to respiratory insufficiency. The above described techniques were used to demonstrate the carrier status of the parents and confirmed the presence of a heterozygous deletion in the *ATAD3* gene cluster in both parents. <sup>4</sup> Harel et al., 2016, *Am J Hum Genet* 99:831-845 <sup>5</sup> Desai et al., 2017, *Brain* 140:1595-1610.

**Comprehensive genetic analyses implicate highly heterogeneous etiology of idiopathic cerebral palsy spectrum disorders.** *H. Hu.* Guangzhou Women and Children's Medical Center, Guangzhou, China.

Cerebral palsy (CP) is an umbrella concept spanning a range of symptoms albeit with the common feature, i.e., an inborn disturbance of human movement and posture. CP is observed with consistent prevalence regardless of the socioeconomic advancement, and familial CP cases were reported. Seminal studies have confirmed the involvement of genetic changes, in the forms of copy number variant (CNV), insertion and deletion (Indel), and single-nucleotide variant (SNV). As a major children's medical center in China, we recruited a CP cohort of >500 individuals with multiple subtypes and severity. To elucidate the genetic causality, we initiated a pilot study of 120 idiopathic CP patients with their parents and siblings, with a comprehensive genomic assessment. We considered possible etiologic mechanisms from chromosomes to genes, via multiple high-throughput platforms. We found that up to 45% of CP cases could be due to detrimental mutations. Inherited causative mutations were comparable in prevalence with de novo ones, and post-zygotic mutations (PZM) took a nonnegligible portion. Major fractions of the causal mutations were SNVs and indels in nuclear genome, while mitochondrial genome harbored several putative mutations, and large segmental alterations accounted for 8% of CP cases. Strikingly, besides the conventional nonsynonymous and splicing-site mutations, we observed by whole-genome sequencing a host of mutations residing in the regulatory regions which might serve as culprit for disease. Our work is of critical significance to reveal the underlying reasons of CP, which is among the major causes for children referred to the neuropediatric departments and rehabilitation institutions.

**2925W**

**A rapid, high-throughput multiplex PCR/CE assay that reliably quantifies *SMN1* copy number.** J.N. Milligan, W. Laosinchai-Wolf, K. Jefferson, I. Beldorth, K. Nicholson, B. Printy, S. Filipovic-Sadic, J. Ashton. Asuragen, Austin, TX.

**Introduction:** Spinal Muscular Atrophy (SMA), an autosomal neuromuscular disease caused by loss of *SMN1* gene function, is the primary genetic cause of infant death with an incidence of ~1/10,000 and a carrier rate of ~1/50. In 95% of patients, both genomic copies of *SMN1* are absent, typically measured by detection of exon 7 which has a single coding nucleotide that distinguishes it from the highly homologous *SMN2* gene. Current ACOG carrier screening guidelines recommend offering SMA carrier screening to all women who are pregnant or are considering pregnancy. This broad recommendation requires rapid, accurate, and high-throughput *SMN1* copy number determination. Herein we report the preliminary performance of the AmpliDeX® PCR/CE *SMN1* Kit\*, a quantitative PCR/Capillary Electrophoresis (CE) assay that quantifies *SMN1* copy number. **Methods:** The optimized and multiplexed PCR simultaneously amplified *SMN1* and an endogenous control (EC) gene and reported results within 5 hours from sample-to-answer. PCR products were separated and quantified via CE (3500 Genetic Analyzer, Thermo Fisher). The copy number of *SMN1* was calculated as the peak area ratio of target gene and EC normalized to a calibrator that was included with the kit along with a positive control. Fifteen previously characterized human cell-line samples and >230 human genomic DNA samples derived from blood or buccal samples were used to characterize the assay. All sample measurements were compared to an independent reference method. **Results:** The assay was compatible with 20-80 ng of blood or buccal genomic DNA purified using common methods. Quantitative results were automatically calculated from raw instrument data using AmpliDeX® PCR/CE Reporter 2.0\* software, which outputted genotypes as 0, 1, 2, 3, or >3 genomic *SMN1* copies with high sensitivity and specificity. Across 236 clinical samples tested, the overall percent agreement between the prototype kit and reference method was 97% for *SMN1* copy numbers. Additionally, positive percent agreement for independently annotated single-copy *SMN1* samples was 100%, while the negative percent agreement was 99.6%. **Conclusion:** AmpliDeX® PCR/CE *SMN1* Kit and companion software accurately quantified *SMN1* copy numbers in <6 hours with a simple reaction setup and robust analytical performance. This rapid method can overcome operational and data analysis limitations of other methods. \*This product is in development; Future availability and performance cannot be ensured.

**Developing custom targeted disease research using optimized assays for next-generation sequencing: An automated system from disease to annotated variants.** F. Hyland, L. Na, A. Ewing, Y. Zhu, A. Broomer, M. Andersen, S. Roman. Thermo Fisher Scientific, South San Francisco, CA.

Targeted multiplex DNA enrichment panels enable sequencing and investigation of one or many genes. Identifying all important genes for a disease of interest, developing optimized and robust assays, and implementing accurate, reproducible and simple analysis pipelines can be challenging. We present methods to enable genetic disease research by automating the development and analysis of assays. Our Disease Research Database is a comprehensive knowledgebase and discovery tool for human genes and genetic disorders. The database has two key novel attributes. First, it integrates data from multiple databases into one system. Second, it provides an unbiased scoring algorithm to rank gene-disease association at any level of the disease ontology hierarchy. Optimized gene panels can be developed narrowly targeted to specific diseases, or larger gene panels can be developed for broader phenotypes. Disease categories include early onset neonatal phenotypes such as metabolic disorders, Severe Combined Immunodeficiency, heme disorders, developmental disabilities; and late onset phenotypes such as cardiovascular disorders. We developed optimized AmpliSeq assays for 5000 disease research genes; we developed a custom assay design algorithm, and all amplicons were carefully performance screened, with each gene being screened in multiple panels. We performed multiple rounds of assay designs, testing, and redesign especially for the ACMG 59 genes, and we cover a comprehensive list of newborn screening genes. From a simple web interface, scientists can select any combination of diseases, and see all the relevant genes. Any of these genes (plus additional genes), can be combined into a panel, and expected coverage for each gene can be visualized. A custom Ion AmpliSeq gene panel can be created containing any combination of these optimized assays. We created panels for neonatal screening, lung diseases, kidney diseases, rheumatoid arthritis, ACMG 59, among others. The panel size ranged from 17 to 300 genes. We tested on a variety of sample types including frozen samples, cheek swabs, and dried blood spots. We saw very consistent coverage > 97%, using 20ng of input DNA. SNP sensitivity on NA12878 was > 99%, and PPV was > 98%. Simple data analysis is available for both single sample and parent-child trios, with optimized variant calling followed by reporting of amino acid change, protein prediction, and detailed annotation of variants and genes from ClinVar, dbSNP, ExAC, OMIM.

**2927F**

**Diagnostic yields of genetic testing for an unselected ALS cohort from a clinical lab.** A.S. Lindy, A. Decker, J. Scuffins, D.A. McKnight. Neurogenetics, GeneDx, Gaithersburg, MD.

Amyotrophic Lateral Sclerosis (ALS) is a progressive neurodegenerative disease that involves both upper and lower motor neurons. ALS is clinically related to frontotemporal dementia (FTD), as pathogenic variants in the associated genes can manifest as both disorders in one individual or as separate disorders in members of a single family. To date, 100+ genes have been reported in association with ALS, but very few have been established as high yield; namely *SOD1*, *TARDBP*, *FUS*, *C9ORF72*. We evaluated a cohort of 376 individuals (average age 59 yrs; range 18-88) with a clinical suspicion of ALS, FTD, or both, to determine the diagnostic rates for *C9ORF72* repeat expansion (RE) analysis and sequencing of 24 other genes. The positive yield for *C9ORF72* RE analysis was 18% (55/313) and the average age at molecular diagnosis was 56 yrs (range 21-74). Family history was provided for 48 positive cases; 58% (28/48) had a family history of ALS/FTD. Of the 258 negative *C9ORF72* RE analyses, 35% (90/258) of individuals pursued sequencing analysis of an additional 24 genes and 3% (3/90) had a subsequent positive result. An additional 72 individuals did not have *C9ORF72* RE analysis, to our knowledge, but pursued multi-gene sequencing. Collectively, 7% (12/162) of all sequencing tests were positive and the average age at molecular diagnosis was 53 yrs. Family history was provided for all 12 individuals with a positive result: 83% (10/12) had a family history of ALS/FTD. Diagnostic results were reported in 7/24 genes sequenced: *SOD1*, *TARDBP*, *VCP*, *FUS*, *MAPT*, *OPTN*, and *SQSTM1*. By far, *C9ORF72* had the highest positive yield (18%) of all genes analyzed and a positive *C9ORF72* result was only associated with a positive family history in 58% of cases; suggesting that this analysis be considered regardless of family history. Family history appeared to be more predictive of a positive result for the other genes evaluated and was observed in 83% of positive cases. This could be due to the smaller sample size, lower overall positive rate or later age of onset associated with these genes, or preferential referral of individuals with a family history. In summary, *C9ORF72* RE analysis has a high diagnostic yield (18%) for individuals with ALS/FTD regardless of family history, but sequence analysis also has utility in the diagnosis of these individuals regardless of family history (7% positive; 17% positive without family history) and should be completed after negative *C9ORF72* RE analysis.

**Precision medicine for stress disorders: Diagnostic biomarkers and repurposed drugs.** A. Niculescu<sup>1,2,3</sup>, H. Le-Niculescu<sup>1</sup>, K. Roseberry<sup>1</sup>, D. Levey<sup>1</sup>, J. Rogers<sup>1</sup>, K. Koasary<sup>1</sup>, S. Prabha<sup>1</sup>, T. Jones<sup>3</sup>, S. Judd<sup>1</sup>, M. McCormick<sup>1</sup>, A. Wessel<sup>1</sup>, A. Williams<sup>2</sup>, P. Phalen<sup>1</sup>, F. Mamdani<sup>1</sup>, A. Sequeira<sup>1</sup>, S. Kurian<sup>5</sup>. 1) Indiana University School of Medicine, Indianapolis, IN; 2) Stark Neuroscience Research Institute, Indiana University School of Medicine, Indianapolis, IN; 3) Indianapolis VA Medical Center, Indianapolis, IN; 4) Department of Psychiatry and Human Behavior, UC Irvine, Irvine, CA; 5) Department of Molecular and Experimental Medicine, The Scripps Research Institute, La Jolla, CA.

The biological fingerprint of environmental adversity may be key to understanding health and disease, as it encompasses the damage induced as well as the compensatory reactions of the organism. Metabolic and hormonal changes may be an informative but incomplete window into the underlying biology. We endeavored to identify objective blood gene expression biomarkers for psychological stress, a subjective sensation with biological roots. To quantify the stress perception at a particular moment in time, we used a simple visual analogue scale for life stress in psychiatric patients, a high risk group. Then, using a stepwise discovery, prioritization, validation, and testing in independent cohorts design, we were successful in identifying gene expression biomarkers that were predictive of high stress states, and of future psychiatric hospitalizations related to stress, more so when personalized by gender and diagnosis. Some of these biomarkers are increased in expression in high stress states (being putative risk genes), and others are decreased in expression (being putative protective/resilience genes). One of the top biomarkers that survived discovery, prioritization, validation and testing was FKBP5, a well-known gene involved in stress response, which serves as a de facto reassuring positive control. We also compared our biomarker findings with telomere length (TL), another well-established biological marker of psychological stress, and show that newly identified predictive biomarkers are comparable or better state or trait predictors of stress than TL or FKBP5. Over half of the top predictive biomarkers for stress also had prior evidence of involvement in suicide, and the majority of them had evidence in other psychiatric disorders, providing a molecular underpinning for the effects of stress in those disorders. Some of the biomarkers are targets of existing drugs, of potential utility in patient stratification and pharmacogenomics approaches. Moreover, the biomarkers gene expression signatures yielded new drug candidates and natural compounds upon bioinformatics drug repurposing analyses. Our work may lead to improved diagnosis and treatment for stress disorders such as PTSD, that result in decreased quality of life and adverse outcomes including addictions, violence and suicide.

**Maternally inherited 8q11.23 microduplication identified in 5 affected children with ASD from two unrelated multiplex families.** *M.E.S. Lewis<sup>1</sup>, Y. Qiao<sup>1</sup>, K. Calli<sup>1</sup>, S. Redmond<sup>1</sup>, S. Martell<sup>1</sup>, C. Chijiwa<sup>1</sup>, E. Rajcan-Separovic<sup>2</sup>.* 1) Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada; 2) Pathology and Laboratory Medicine, University of British Columbia, Vancouver, British Columbia, Canada.

We have recruited >700 families with simplex and multiplex ASD and are performing chromosome microarray and whole genome sequencing studies as part of the iTARGET Autism project (<http://www.itargetautism.ca/>), open-access genomic database for autism research. In this cohort, we identified 5 affected subjects from 2 unrelated families who have ASD and a maternally inherited microduplication at 8q11.23 involving *RB1CC1*. Microduplications involving this gene have been reported in 30 cases in DECIPHER Database with variable neurodevelopmental phenotypes, as de novo or inherited (maternal or paternal). Their clinical significance, therefore remains uncertain. The mother in Family 1 has a past history of depression. The father in Family 2 has many Asperger-like features. None of the affected 5 children have outward dysmorphic features. Genetically, the 5 children with ASD were found to carry a similar maternal 8q11.23 duplication (maximum range: 53413457-53827622bp, hg19) involving 3 genes (*RB1CC1*, *ALKAL1*, and *NPBWR1*) with the first two genes shared by both families. Family 2 also contains gene *NPBWR1*. *RB1CC1* is a DNA-binding transcription factor involved in the regulation of multiple cell processes including neuronal homeostasis. Duplication of this gene has been reported to be associated with schizophrenia. Animal models have shown deletion of this gene leads to cerebellar degeneration. Somatic mutations in *RB1CC1* are more frequently observed in cancers, including breast cancers. From published papers, none of the 3 genes have been reported to be related to autism. Our two families therefore expand the phenotypic spectrum of this copy number variant which may be yet another locus for neurodevelopmental abnormalities with variable penetrance. On-going whole genome analysis may uncover additional genetic factors causing ASD.

**2930F**

**Application of the ClinGen gene-disease clinical validity process to assess the strength of evidence for genes implicated in autism and intellectual disability.** *B. Bostwick<sup>1</sup>, C. Barry<sup>2</sup>, A. Behlmann<sup>3</sup>, C. Chen<sup>1</sup>, C. Collins<sup>4</sup>, A. Grant<sup>5</sup>, E. Riggs<sup>6</sup>, A. Ronza<sup>7</sup>, R. Siegert<sup>8</sup>, T. Sneddon<sup>9</sup>, C. Thaxton<sup>7</sup>, M. Tokita<sup>8</sup>, J. Yin<sup>10</sup>, X. Zhou<sup>10</sup>, D. Miller<sup>11</sup>, C. Schaaf<sup>12</sup>.* *ClinGen Intellectual Disability/Autism Gene Curation Expert Panel.* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA; 2) Autism & Developmental Medicine Institute, Geisinger Health System, Lewisburg, PA, USA; 3) Department of Human Genetics, Emory University School of Medicine, Atlanta, GA, USA; 4) Perkin Elmer Genomics, Branford, CT, USA; 5) Laboratory for Molecular Medicine, Partners Healthcare Personalized Medicine, Cambridge, MA, USA; 6) Department of Clinical Genomics, Stanford School of Medicine, Stanford, CA, USA; 7) Department of Genetics, The University of North Carolina, Chapel Hill, NC, USA; 8) Institute for Genomic Medicine, Rady Children's Hospital-San Diego, San Diego, CA, USA; 9) Department of Neurology, University of California Los Angeles, Los Angeles, CA, USA; 10) The Institute for Precision Medicine, University of Pittsburgh Medical Center, Pittsburgh, PA, USA; 11) Division of Genetics & Genomics, Children's Hospital Boston & Harvard Medical School, Boston, MA, USA; 12) Institute of Human Genetics, University Hospital Cologne, Köln, Germany.

**OBJECTIVE:** As part of the NIH-funded Clinical Genome Resource (ClinGen) effort, the Intellectual Disability and Autism Gene Curation Expert Panel evaluates clinical, basic science, and population data to determine the strength of evidence that a gene contributes to the phenotypic spectrum of autism and intellectual disability. This collaborative workgroup of clinicians, researchers, biocurators, and molecular diagnosticians aim to annotate and share the strength of gene-disease relationships for the benefit of those in the medical genetics field and the public. **METHODS:** We used an evidence-based standardized framework to evaluate genetic and experimental evidence supporting or refuting a gene's role in a given disease. Genes implicated with ID/autism were categorized as Definitive, Strong, Moderate, or Limited using a systemized scoring rubric to assess strength of evidence based on data in published clinical reports, basic research articles, and population databases. We generated a prioritized gene list to review by selecting genes appearing in 25% or more of commercially available ID/autism sequencing or microarray panels in the Genetic Testing Registry that had not previously been evaluated by SFARI or the Geisinger Developmental Brain Disorders Database. **RESULTS:** To date, the ClinGen ID/Autism Gene Curation Expert Panel has evaluated and classified 30 gene-disease pairs. Of the 30 genes curated thus far, 22 (76%) have Definitive evidence to support an ID/autism gene-disease relationship. Surprisingly, five of the curated genes (17%) were found to have only Limited evidence for an ID/autism gene-disease relationship despite inclusion on several commercial genetic testing panels. The curation results are available on [clinicalgenome.org](http://clinicalgenome.org). **CONCLUSIONS:** The ID/Autism Gene Curation Expert Panel's curated information on genes and diseases is publicly available. This information can be utilized in a variety of clinical and research applications, including building evidence-based clinical genetic testing panels, resolving discrepancies in variant interpretation, and improving patient care through an evidence-based medicine approach. Diagnostic laboratories should consider the strength of the evidence for gene-disease relationship prior to including a gene in a diagnostic panel.

**2931W**

**Genetic test results for 523 patients with ASD/ID: The diagnostic yield of multigene analysis (Autism/ID Xpanded test) is higher than conventional first-tier tests, such as FMR1 repeat analysis and chromosomal microarray.** A. Shanmugham, D. McKnight, J. Scuffins, T. Brandt. GeneDx Inc., Gaithersburg, MD.

Established guidelines for evaluating children with autism spectrum disorder (ASD), global developmental delay (GDD) and/or intellectual disability (ID) recommend FMR1 repeat analysis and chromosome microarray (CMA) as first-tier tests. However, FMR1 analysis as a first-tier test is being re-examined as studies show a low diagnostic yield for individuals without a clinical suspicion of Fragile X syndrome. We performed a retrospective study to evaluate the diagnostic yield of currently recommended first-tier tests (FMR1 and CMA) compared to a second-tier test, the Autism/ID Xpanded panel (sequencing of >2300 genes associated with ASD/ID). The patient cohort was unselected and included 523 individuals (145 females; 378 males) with ASD/GDD/ID referred to our laboratory for genetic testing. The overall positive diagnostic rate for first-tier genetic testing (FMR1 analysis and CMA) was 6.1% (32/523). Positive FMR1 full expansions were identified in only 0.6% (3/523) of cases, corresponding to 0.8% (3/378) of males. The three males were reported to have either GDD, developmental regression and ASD or ID. CMA testing identified causative copy number variants (CNVs) in 5.5% (29/523) of cases. Seventy-two percent of all individuals (375/523) proceeded to second-tier testing using the Autism/ID Xpanded panel, and almost 10% (36/375) of those had a diagnostic result. Of note, five positive CMA cases continued on with an Autism/ID Xpanded panel. In only one of these cases were other causative variants identified by sequencing. In summary, our results demonstrate that the diagnostic yield of FMR1 testing in general is low and, despite its relatively low cost, this test is not an effective first-tier test, particularly for affected females. CMA yielded a higher diagnostic rate than FMR1 analysis, similar to what is reported in the literature. The Autism/ID Xpanded panel had the highest diagnostic yield in this study. While ordering a CMA as a first-tier test is more cost effective today, technology advances improving detection of CNVs from NGS data will soon allow detection of sequence and copy number variants with a single test at reasonable cost; therefore, guidelines for evaluating children with ASD, GDD and/or ID may change in the future.

**2932T**

**Clinical symptoms of Fragile X syndrome patients depends on mosaicism in CGG repeat length and FMR1 promoter methylation.** D.V. Yudkin<sup>1</sup>, I.V. Grishchenko<sup>1</sup>, Y.V. Maksimova<sup>2</sup>, A.R. Shorina<sup>3</sup>. 1) SRC VB VECTOR, Novosibirsk Region, Koltsovo, Russian Federation; 2) Novosibirsk State Medical University, Novosibirsk, Russian Federation; 3) Novosibirsk City Clinical Hospital No. 1, Novosibirsk, Russian Federation.

Fragile X syndrome is a most common reason of inherited intellectual disability in human. Mechanism of the syndrome development is due to CGG repeat expansion in 5' UTR of FMR1 gene located in chromosome X. Normally the gene contains no more than 50 triplets. When repeat size became more than 200 triplets – full mutation – the syndrome develops. Repeat expansion leads to methylation and heterochromatinization of FMR1 promoter region followed by gene silencing. Absence of FMRP encoded by FMR1 is cause of abnormal neurons development and intellectual disability. CGG repeat size in patients can vary from 200 to 2000 triplets and more. Additionally patients can have somatic mosaicism and somatic repeat expansion. Woman carriers have two chromosomes X and two alleles of FMR1 gene and somatic mosaicism. Methylation of FMR1 promoter can be presented not in each cell and some patients with full mutation can save some level of FMR1 expression. All above is influence to degree of intellectual disability and clinical cases are vary. Samples of peripheral venous blood were collected in Novosibirsk City Hospital No. 1 according to international standards, which include the awareness of the subject, his or her consent to participating in the study in its entirety, and guarantees of confidentiality. All of the studies conformed to ethical standards developed in accordance with the Helsinki Declaration of the World Medical Association as amended in 2000. In addition, the studies were supervised by the Institutional Review Board. DNA was purified and analyzed by GC-rich PCR followed by fragment analysis. Study of methylation level in FMR1 5' UTR was carried out using methyl dependent restriction endonuclease followed by PCR. Clinical study was obtained from psychiatric counseling for every patient. As a result, we have investigated the severity of symptoms in dependence of repeat size, methylation level and somatic mosaicism in repeat size and methylation level. The high level of mosaicism was shown. Acuity of symptoms decreases in presence of premutant and normal alleles in mosaic form. Additionally short repeat even in full mutation leads to decreasing of chromosome fragility. This study is supported by the Russian Science Foundation (grant 18-15-00099).

**Myelin redundancy: A brain biomarker for “aging” versus Alzheimer’s disease in Down syndrome.** A. Van Hoek<sup>1</sup>, L. Dai<sup>2</sup>, J.R. Korenberg<sup>2</sup>. 1) Neurology, University of Utah, Salt Lake City, UT; 2) Pediatrics, Medical Genetics, University of Utah, Salt Lake City, UT.

A major challenge for accelerating therapeutics of Alzheimer’s Disease (AD) and “normal” Aging is the identification of dynamic neuronal and glial biomarkers that distinguishes AD from normal Aging. Down syndrome (DS) is considered an ideal model given that the pathology of aging involves degenerative neuronal and myelin features with genetic causes like AD, which characterize 100% with DS by age 35 as forerunners of dementia affecting ~70%. However, DS-AD dementia merges with signs of accelerated aging seen in DS with three copies of the HS Chr 21 gene APP encoding the amyloid plaque protein, but without biomarkers for the age-related waning of capacities not related to AD. We examined the architecture of myelin in 22 cervical spinal cord samples obtained from the NIH NeuroBioBank (NBB) and our NIH DS study, with diagnoses of DS (41-76y), AD (54-60y) or normal control (50-74y) by genetic (confocal microscopy) and morphological (transmission electron microscopy) analyses of 11 single donor glutaraldehyde (GA) and formalin (F) fixed tissues. The results thus far indicate that DS myelin (n=6, F and GA fixed tissues) exhibited striking age-related redundancy and exaggerated ballooning aberrant sheaths connecting neighboring normal and degenerated axons and concentric sheaths separated by apparent oligodendrocytic cytoplasmic contents. In contrast, myelin in AD (n=4; 54, 60y) was ballooned, non-redundant with interlaminae dark globular electron dense and extra-axonal fibrillary material. Myelin of aged controls (52-58y) was even less ballooned and more compact. Chloroform extraction eliminated ballooned myelin laminae resulting in large empty regions in DS retaining compacted myelin and structures reflecting helical formation. These results indicate that aged and less so young DS but not AD is associated with redundant myelin sheaths that are readily extracted in contrast to normal myelin. This biomarker of normal aging in DS may suggest a linear decrease in conduction velocity with decreased effective sheath thickness and consequent cognitive loss in DS and more subtly in non-DS, non-AD aging. Although its severity may result from aberrant repair by the Chr 21 encoded gene OLIG2, the redundancy biomarker may reflect physiologic and modifiable *in vivo* dysfunction that constitutes a therapeutic target for non-AD aging, whether or not related to Alzheimer’s neuropathology.

**Whole-genome sequencing is more effective than whole-exome sequencing for detecting structural variants.** F. Mafra<sup>1</sup>, D. Li<sup>1</sup>, E. Bhoj<sup>1</sup>, M. Harr<sup>1</sup>, R. Pellegrino<sup>1</sup>, B. Keena<sup>2</sup>, E. Zacka<sup>2</sup>, H. Hakonarson<sup>1,3</sup>. 1) Center for Applied Genomics, The Children’s Hospital of Philadelphia, Philadelphia, PA; 2) Division of Human Genetics, The Children’s Hospital of Philadelphia, Philadelphia, PA; 3) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

**Introduction:** Whole exome sequencing (WES) and whole genome sequencing (WGS), are increasingly used in diagnostic and research laboratories to identify rare and common genetic variants in humans; these approaches are known as next-generation sequencing. WES focuses on the protein coding sequences, usually being the first method of choice due to the lower cost since less overall sequence is needed. Although currently more expensive, WGS is more powerful than WES for detecting potential disease-causing mutations within the exome, particularly structural variants, variants in GC-rich regions, and variants in regulatory regions. **Methods:** We compared the two NGS techniques, performing WES with the Agilent Sure Select Human All Exon kit v5 and WGS with the Illumina TruSeq DNA PCR-Free sample preparation kit on a blood sample from a 5 years old Caucasian patient with a history of epilepsy, micrognathia, microcephaly, optic nerve hypoplasia, short stature, developmental delay and febrile seizures. The findings were validated by Sanger sequencing. **Results:** No candidate genes were elucidated using WES, while the WGS revealed a *de novo* 5 kb single-exon deletion in the gene *DYRK1A* (chr21:38,853,731-38,859,397; hg19). Based on the autosomal dominant inheritance pattern associated with the disease linked to the gene, phenotypic match, published literature and population frequency databases checking (such as internal cohort, ClinGen, DECIPHER, and DGV), this variant was classified as pathogenic and was considered as the potential cause of the patient’s phenotype. The libraries showed differences in depth, read length and PCR amplification in addition to exome capture. WGS gave superior variant calls where its longer reads gave better mappability, the coverage was more uniform in total depth and in distribution of the position of a variant within a read. **Conclusions:** This case demonstrated the utility of WGS for the detection of structural variants (SV), particularly small deletions. This is due to a higher uniformity of coverage achieved with WGS and the fact that this SV was not covered by WES because of the poor probe density at the breakpoints region. The main factors underlying the heterogeneous coverage of WES are related to the hybridization/capture and PCR-amplification steps required for the preparation of sequencing libraries for WES. **Acknowledgments:** WGS funded by the Roberts Collaborative Study.

**Benign-Ex & DISCRIMINATOR: Assigning pathogenicity classifications to CNVs.** A. Hahn<sup>1,2</sup>, M. Parida<sup>3</sup>, H. Major<sup>1</sup>, J. Manak<sup>2,4</sup>, B. Darbro<sup>1,2</sup>. 1) Stead Family Department of Pediatrics, Roy J. and Lucille A. Carver College of Medicine, University of Iowa, Iowa City, IA, United States; 2) Interdisciplinary Program in Genetics, University of Iowa, Iowa City, IA, United States; 3) Biochemistry, University of Iowa, Iowa City, IA, United States; 4) Biology, University of Iowa, Iowa City, IA, United States.

Developmental disabilities affect nearly 15% of children and 10-20% of cases are attributable to copy number variants (CNVs). While over a hundred microdeletion/microduplication syndromes (MMS) have been described, several thousand CNVs have been characterized as variants of unknown significance (VUS) and genetic heterogeneity has been identified in several known MMS including DiGeorge/Velocardiofacial Syndrome, Pitt-Hopkins Syndrome, and Rhatt Syndrome. The overall goal of our research laboratory is to determine if any VUS represent novel genetic causes of known MMS. To accomplish this goal, we use a combination of computational tools to identify the underlying genetic burden imposed by CNVs. We have developed and tested two such tools (Benign-Ex & DISCRIMINATOR) on chromosomal microarray data from pediatric patients referred for clinical testing (N=3416). Developmental delay was the most prevalent phenotype followed by dysmorphic features and autism. CNV data was collected over a ten-year period and utilized three different CMA platforms: NimbleGen 385K (n=417; 12%), NimbleGen 720K (n=655; 19%), and Affymetrix CytoScanHD (n=2344; 69%). Benign-Ex utilizes DGV and ClinGen to identify regions of the human genome which are copy number variable without phenotypic consequence (benign), while DISCRIMINATOR annotates CNVs as benign, primary (a known pathogenic MMS CNV), or secondary (VUS). Here we present results from the training of Benign-Ex using data from OMIM, DECIPHER, ClinGen, and a manually curated list of all known MMS associated with developmental disabilities. These training lists were used to balance and optimize the performance of Benign-Ex to reduce identifying pathogenic regions as benign. When optimized, Benign-Ex designated more of the genome as copy number variable compared to previous analyses using DGV alone. DISCRIMINATOR utilizes the output of Benign-Ex as well as a list of known MMS to assign pathogenicity classifications to the CNV datasets (primary, secondary, or benign). In our dataset we discovered >350 primary CNVs, >15,000 secondary CNVs, and that >75% of all CNVs were classified as benign. Additionally, consistent with their prevalence rates, 22q11.2, 15q11.2, and 16p11.2 primary CNVs were the most common MMS detected by DISCRIMINATOR. Identified non-benign CNVs will be used in downstream analyses to explore the genetic heterogeneity of known MMS and identify genes and/or networks which are important to the MMS's clinical phenotype.

The ClinGen Dosage Sensitivity (DS) Working Group systematically evaluates genes and genomic regions for DS in an effort to facilitate the process of genomic content evaluation and promote interpretation consistency among clinical laboratories. Neurodevelopmental disorders (NDDs), such as autism and intellectual disability, are a frequent reason for referral for clinical genetic testing, including multi-gene panel testing, whole exome sequencing, and cytogenomic microarrays. Understanding which genes cause NDDs through haploinsufficiency (HI) or triplosensitivity (TS) mechanisms can help clinical laboratories interpret loss of function (LOF) and/or whole gene duplication events involving these genes. Given the relative importance of this clinical domain, we are focusing on evaluating DS of candidate NDD genes identified through various sources. Our first source is the Geisinger Developmental Brain Disorder Genes Database - an online, curated resource cataloging variants identified in published literature in the context of NDDs. As of 9/2017, 95 genes were identified in the Geisinger database as being "Tier 1," or high confidence candidate genes based on the number of de novo, pathogenic, LOF variants reported. We evaluated each of these genes for evidence of HI and/or TS. Seventy-seven genes (81.1%) were classified as having "sufficient" evidence for HI; LOF variants identified within these genes could be considered likely pathogenic (LP) or pathogenic (P) when observed in a clinical setting. Six genes (6.31%) were classified as having "emerging" evidence for HI, 3 genes (3.2%) had "little" evidence, and 1 gene (1.1%) was classified as "gene associated with autosomal recessive condition." While 1 gene (*MECP2*) had "sufficient" evidence for both HI and TS, most of the 95 genes had either "little" (7.4%) or no evidence (91.5%) for TS, indicating that there is not enough evidence to consider single, whole gene duplications of these particular genes LP or P at this time. We will continue to evaluate genes associated with NDDs in order to provide a comprehensive resource of DS information to the genomics community.

**Novel first tier DNA methylation-based diagnostic platform for neurodevelopmental disorders.** S. Choufani<sup>1</sup>, K. Garg<sup>1</sup>, C. Cytrynbaum<sup>2</sup>, S. Cyrus<sup>3</sup>, B. Chung<sup>4</sup>, W.T. Gibson<sup>3</sup>, R. Weksberg<sup>1,2</sup>. 1) Program in Genetics and Genome Biology, The Hospital for Sick Children, Toronto, Canada; 2) Div Clin and Metabolic Gen, Hosp Sick Children, Toronto, ON, Canada; 3) Child and Family Research Institute, Vancouver, BC, Canada; 4) Dept of Paediatrics and Adolescent Med, Li Ka Shing Faculty of Medicine, Hong Kong.

Diagnostic genetic testing has evolved dramatically in the last decade with the introduction of next generation sequencing (NGS). While significantly improving diagnostic yield, NGS have magnified some of the challenges of DNA sequence-based testing in clinical genomics, most notably the interpretation of variants of unknown significance (VUS), incomplete coverage of certain genomic regions and detection of small deletions/duplications. Our previous work showed that pathogenic mutations in epigenes (genes involved in epigenetic regulation), such as *NSD1*, *CHD7*, *KMT2D*, *KDM5C*, are associated with epigene-specific genome-wide DNA methylation (DNAm) signatures as well as the utility of these signatures to serve as functional tools for VUS classification. In the current work, we tested the utility of these DNAm signatures for first tier diagnosis of cases with undiagnosed neurodevelopmental syndromes. We compared the profiles of 2000 methylomes (1600 from the Illumina 450k array and 400 from the Illumina EPIC array) generated in our lab from blood samples of cases with known pathogenic mutations, VUS, undiagnosed cases and controls. We tested each sample against the different epigene-specific DNAm signatures associated with the clinical phenotypes of Sotos (*NSD1*), Weaver (PRC2 complex genes: *EZH2*, *EED*, *SUZ12*), Kabuki (*KMT2D*) and susceptibility to Autism (*CHD8*) syndromes. Using principal component analyses as well as unsupervised hierarchical clustering; genome-wide DNAm data for each case were compared to the disease-specific reference (derived from n=5-10 cases with pathogenic mutations) and a control reference (n=15). This approach allowed us to classify two undiagnosed samples with the *NSD1*-specific DNAm signature. Research-based NGS analyses on these 2 samples identified pathogenic variants in *NSD1*, thereby validating the first tier diagnosis of Sotos using the DNAm signature. A review of the phenotype of these two patients demonstrated macrocephaly, developmental delay and other characteristic features of Sotos syndrome. Similarly, we were able to predict mutations in PRC2 complex genes (n=2), *KMT2D* (n=1) and *CHD8* (n=1); these diagnoses were confirmed by NGS and post hoc clinical review of these cases. These data highlight the potential utility of gene-specific DNAm signatures not only in functionally classifying VUS as pathogenic or benign but also in categorizing individuals by syndromic diagnosis, thereby serving as a first tier diagnostic platform.

The ClinGen Dosage Sensitivity (DS) Curation workgroup uses an established evidenced-based review process to evaluate genes/genomic regions for haploinsufficiency and triplosensitivity, assigning a numerical score corresponding to strength of evidence associated with each dosage mechanism. While this process has been effective for evaluating individual genes in a standardized manner, the evaluation of multigenic regions, particularly recurrent copy number variants (CNVs), has been challenging. For example, regions such as 15q11.2 (BP1-BP2) or 16p12.2 exhibit incomplete penetrance and variable expressivity; and segregation data, along with statistics for population-level frequency can be challenging to interpret clinically without well-defined syndromic features. While our current framework incorporates levels of knowledge of penetrance and expressivity into gene and region scoring, more refined criteria are necessary to define "well documented" associations between phenotype and incomplete penetrance and/or variable expressivity, including strength of statistical data and segregation patterns. Moreover, literature describing recurrent CNVs often presents conflicting evidence depending on the type of study (e.g., case-control vs. cohort only). In order to effectively and consistently account for these factors, a subgroup composed of professionals with expertise on recurrent CNV interpretation is currently working to revise the criteria for dosage sensitivity scoring of recurrent CNVs. We propose incorporating additional variables into our original framework, including the number of unrelated probands, number of independent peer-reviewed studies, study type, phenotypic specificity and variability, segregation/inheritance data, population-level statistics, and conflicting data; these revisions include weighting types of evidence and study types. For example, statistically significant enrichment in cases in a case-control study will be weighted more than lack of such enrichment or case-only studies. Likewise, specific phenotypes will be weighted more than non-specific phenotypes. This new framework will provide objectivity to scoring, result in better alignment with other more quantitative ClinGen efforts with respect to variant evaluation, and aid in clinical interpretation and reporting of recurrent CNVs.

**Population prevalence and inheritance pattern of recurrent CNVs associated with neurodevelopmental disorders. A study of 7986 newborns from the Norwegian Mother and Child Cohort.** S. Johansson<sup>1,2</sup>, K. Lavrichenko<sup>1,3</sup>, D. Smajlagic<sup>1,2</sup>, O. Helgeland<sup>1,4</sup>, S. Berland<sup>1,2</sup>, G.P. Knudsen<sup>4</sup>, P.M. Knappskog<sup>1,2</sup>, J. Haavik<sup>5</sup>, M. Vaudel<sup>1,2</sup>, G. Houge<sup>1,2</sup>, P.R. Njølstad<sup>1</sup>, T. Zayats<sup>5</sup>. 1) Department of Clinical Science, University of Bergen, Bergen, Norway; 2) Department of Medical Genetics, Haukeland University Hospital, Bergen, Norway; 3) Computational Biology Unit, Department of Informatics, University of Bergen, Bergen, Norway; 4) Department of Genetics and Bioinformatics Norwegian Institute of Public Health, Oslo, Norway; 5) Department of Biomedicine, University of Bergen, Bergen, Norway.

**Introduction.** Rare recurrent CNVs are common causes of neurodevelopmental disorders and risk factors for psychiatric traits. A number of regions prone to recurrent duplications and deletions have been extensively studied in various disease cohorts, however less is known about the true prevalence and inheritance pattern in the general population. Here we present an interim analysis using SNP-array-based CNV calling of the first 7986 child-mother-father trios genotyped in the Norwegian Mother and Child Cohort (MoBa). **Materials and methods.** 7986 trios of Norwegian ancestry from the MoBa cohort were genotyped using the Illumina HumanCoreExome chip and passed stringent quality control for CNV-analysis. CNVs were first called using PennCNV and PennCNVtrio. We developed a set of tools specific for trio analyses post- PennCNV trio calling, to further improve and refine the CNV calls and their inheritance pattern. All putative de novo calls were visually inspected for accuracy. **Results.** As of June 2018, a total of 7986 complete trios have been CNV genotyped and passed strict QC. We found a total of 106 children with bona fide de novo CNVs > 100 kb, corresponding to a minimal prevalence of 1.3 % large de novos per generation. As previously described, more de novo CNVs were of paternal origin (~ 60%). We next analysed a list of regions known to harbour recurrent CNVs implicated in neurodevelopmental disorders (NDD) and psychiatric traits. We found 22 de novo and 161 inherited rare deletions and duplication >100 kb intersecting the known NDD regions. For example the known recurrent chr16p11.2 microdeletion was seen in 6 newborns (4 being de novo) corresponding to a prevalence of 7.5 per 10 000 newborns with 66% being de novo. The reciprocal microduplication was found in 7 children (all inherited). Corresponding numbers for the large 2 Mb microdeletion/duplication at the chr15q13.3 locus were 4 deletions (all inherited) and 5 duplications (1 de novo), corresponding to prevalences of approximately 5-6 events per 10 000 live born children each for duplications and deletions. **Conclusion/Discussion.** Our interim analysis of an unselected and representative population of newborns and their parents provide a clearer picture of the rate of recurrent microduplication/deletions implicated in developmental delay. Further 6000 trios will be included in the final analyses providing a unique opportunity to study the phenotypic consequences using MoBa data from birth to 8 years of age.

**2940W**

**Analysis of copy number variations in 400 patients with mental retardation or developmental delay using aCGH.** B. Wu, R. Liu, W. Lu, H. Wang, W. Zhou. Children's Hospital Fudan University, Shanghai, China.

**Objective:** Using Array Comparative Genomic Hybridization (aCGH) to detect genomic imbalances in patients with unexplained mental retardation or developmental delay (MR/DD) and to evaluate the effectiveness of aCGH in molecular diagnosis of children with unexplained MR/DD in China. **Methods:** Children with unexplained MR/DD were enrolled in this study. DNA was extracted from whole blood of the patients by standard procedures. aCGH was performed using the Agilent 4\*180 CGH-SNP chip (Boston Children's Hospital custom designed). Data analysis was performed using Agilent Cytogenomics software. Genomic positions refer to the Human Genome February 2009 assembly (GRCh37/hg19). Copy number variations (CNVs) were interpreted and classified according to phenotypic features of the patient, and records in the Database of Genomic Variants (DGV), Online Mendelian Inheritance in Man (OMIM), Clinical Genome Resource (ClinGen), Database of Genomic Variation and Phenotype in Humans using Ensembl Resources (DECIPHER), in-house databases et al. **Results:** A total of 400 patients with unexplained MR/DD with or without dysmorphisms, multiple congenital anomalies, learning difficulties and autism spectrum disorders (ASD) were recruited, in which 234 cases were male. The age ranged from 15 days to 15 years. Of all samples completed the aCGH tests, 92 cases had pathogenic CNVs, including 37 known syndromes. The size of pathogenic copy number variants ranged from 40 Kb to 38 Mb. 77 cases had detected CNVs of unknown significance, including 32 deletions and 45 duplications, accounting for 19% of the total test sample. 24 cases had detected absence of heterozygosity (AOH) greater than 9Mb, of which 4 cases had more than 3 AOH regions on the chromosome, indicating consanguinity relationship between the parents. Another 2 cases had detected 151Kb and 6.8Mb likely pathogenic microdeletions, containing autosomal recessive gene match to the phenotype of the patients in the deletion area. Sanger sequencing of the candidate gene was done after that, and another pathogenic point mutation was found in the gene. QPCR and Sanger confirmation tests using parents' samples showed that one parent carried the deletion and the other carried the pathogenic point mutation. **Conclusion:** Genome imbalance contribute up to 25% genetic etiology to patients with unexplained MR/DD. aCGH is an effective method in molecular diagnosis of children with unexplained MR/DD in China.

**Introduction** During the past decade, extensive use of next generation sequencing in the field of developmental disorders has increased substantially our understanding of these entities. Deciphering Developmental Disorders study has reached a diagnostic yield of 23% considering only coding *de novo* mutations (DNM), but their statistical modeling predicted that up to 41.8% of cases could be explained by a pathogenic DNM detected by trio exome sequencing. These results highlight the long way to go to in the delineation of new genotype-phenotype correlations. Notably, diseases caused by specific missense variants in a modification-of-function mechanism are more challenging to model than loss-of-function variants and their identification will require innovative strategies and large scale data sharing. **Material and methods** We present an easy approach based on the publicly available denovo-db data, a large collection of *de novo* mutations from various trio cohort studies. We used denovo-db to retrospectively flag variants from our 1,200 solo exomes database, with the idea that mutational recurrence in at least two unrelated individuals with a developmental disorder (one from denovo-db and one from our local cohort), would be a powerful approach to identify strong candidate variants. **Results** This approach identified a limited set of 51 variants, from which 32 variants showed high evidence for pathogenicity, including variants already known as pathogenic in our team, but also several new diagnoses. Mutational recurrence highly relied on CpG transitions, but other mechanisms such as 'selfish spermatogonial selection' did appear clearly from our data. We identified *FEM1B* as a new gene for syndromic developmental disorder including global developmental delay, auto-aggressively, facial dysmorphic features, deafness and heart defects. We also confirmed the implication of *ACTL6B* as responsible for a neurodevelopmental disorder. **Discussion** We propose that the prospective and retrospective annotation of local variants with de-novo db could be an easy and effective strategy for detecting rare variants associated with developmental disorders. We hypothesize that this kind of approach based on mutational recurrence will be essential for the identification of several new diseases caused by specific missense variants, in the process of getting closer to the high estimated yields brought by whole exome sequencing.

**2942F**

**Whole-exome trio sequencing in 51 patients with intellectual disability/ developmental delay.** Y. Dincer<sup>1,2</sup>, J. Schulz<sup>1</sup>, C.M. Wilke<sup>1</sup>, M.Y. Cohen<sup>1,3</sup>, D. Wahl<sup>1,4</sup>, S. Wilson<sup>1</sup>, S.H. Eck<sup>1</sup>, V. Mall<sup>2,3</sup>, I. Rost<sup>1</sup>, H.G. Klein<sup>1</sup>. 1) Center for Human Genetics and Laboratory Diagnostics, Martinsried, Germany; 2) Chair of Social Pediatrics, Technical University of Munich, Munich, Germany; 3) kbo Children's Center Munich, Munich, Germany; 4) Practice for Genetic Counseling and Psychotherapy, Augsburg, Germany.

**Introduction:** Due to extensive clinical and genetic heterogeneity, the causes of intellectual disability/ developmental delay (ID/DD) remain largely unknown. Whole-Exome Sequencing (WES) was shown to be an effective diagnostic strategy in patients with rare monogenic disorders. However, broad Next Generation Sequencing (NGS) approaches are still limited by time-consuming manual data interpretation. The Multiple Integration and Data Annotation Study (MIDAS) aims to accelerate NGS data analysis and to enhance the validity of the results by computer-based variant prioritization using patient's phenotype data. For this purpose, a central software system for data integration will be developed within MIDAS. **Methods:** By now, 51 patients (29 males, 22 females) with unexplained ID/DD and their unaffected parents (trios) were enrolled. All patients were evaluated by a clinical geneticist and phenotypic features were recorded in a standardized way using the Human Phenotype Ontology (HPO). Before enrollment, the patients had undergone extensive diagnostic testing (karyotyping, array-CGH, Fragile-X analysis), but none of these tests had led to a diagnosis. We performed trio WES and evaluated the identified variants using data from population (dbSNP, ExAC, gnomAD) and disease (HGMD, OMIM, ClinVar, Orphanet) databases. The remaining variants were examined by scientists and clinicians in the context of patients' clinical presentation. **Results:** By WES trio analysis, we were able to identify a causative variant in 23 of 32 yet analyzed ID/DD patients (diagnostic yield: 72%). In 19 of the 23 patients with positive WES, we identified a *de novo* variant in heterozygous state (9 loss-of-function and 10 missense variants). Additionally, we identified one homozygous missense variant each in two patients from different consanguineous families as well as one compound heterozygous variant and one homozygous nonsense variant in unrelated families. **Discussion:** WES is an effective diagnostic strategy for patients with ID/DD. Nonetheless, more than a quarter of our patients did not receive a diagnosis by WES although there is strong evidence for a genetic cause of their condition. For these patients, we will now perform a Copy Number Variation analysis based on their WES data and potentially Whole-Genome Sequencing analysis. NGS approaches, such as WES or WGS, lead to a rising amount of genetic data in diagnostics and necessitates powerful computational algorithms for improved data analysis.

**2943W**

**Exome sequencing identified a *de novo* mutation of *PURA* gene in a patient with familial Xp22.31 microduplication.** E. Rajcan-Separovic<sup>1</sup>, Y. Qiao<sup>1</sup>, H. Bagheri<sup>2</sup>, F. Tang<sup>1</sup>, C. Harvard<sup>3</sup>, S. Martell<sup>4</sup>, M.E.S. Lewis<sup>5</sup>, W. Robinson<sup>6</sup>, M. Connolly<sup>6</sup>, L. Arbour<sup>6</sup>. 1) Pathology and Laboratory Medicine, Children's and Women's Hospital of BC, Vancouver, Canada; 2) Dana-Farber Cancer Institute, Boston, USA; 3) Advanced Diagnostics Molecular Lab, University Health Network, Toronto; 4) Department of Medical Genetics, UBC, Vancouver, BC, Canada; 5) Division of Pediatric Neurology, Department of Pediatrics, UBC and BC Children's Hospital, Vancouver; 6) Department of Medical Genetics, University of Victoria, Victoria.

The clinical significance of Xp22.31 microduplication is controversial as it is reported in subjects with developmental delay (DD), their unaffected relatives and unrelated controls. We performed multifaceted studies in a family of a boy with hypotonia, dysmorphic features and DD who carried a 600 Kb Xp22.31 microduplication (7515787-8123310bp, hg19) containing two genes, *VCX* and *PNPLA4*. The duplication was transmitted from his cognitively normal maternal grandfather. We found no evidence of the duplication causing the proband's DD and congenital anomalies based on unaltered expression of *PNPLA4* in the proband and his mother in comparison to controls and preferential activation of the paternal chromosome X with Xp22.31 duplication in proband's mother. However, a *de novo*, previously reported (Tanaka et al, 2015, PMID 27148565) deleterious, missense mutation in Pur-alpha gene (*PURA*) (5q31.2), with a role in neuronal differentiation was detected in the proband by exome sequencing (NM\_005859:c.563T>C; p.(Ile188Thr)). Phenotypically, the two cases shared many common features including severe developmental delay (speech and motor delay), ID, hypotonia, feeding difficulties, and facial dysmorphism such as dolicocephaly, hypertelorism and highly arched palate. We propose that the variability in the phenotype in carriers of Xp22.31 microduplication can be due to a second and more deleterious genetic mutation in more severely affected carriers. Widespread use of whole genome next generation sequencing in families with Xp22.31 CNV could help identify such cases.

**Introduction:** Clinical whole exome sequencing (cWES) is thought to be the first-tier molecular test in heterogeneous rare diseases with suspected genetic etiology. Its diagnostic yield ranges from 30% to 50% depending on the applied strategy (singleton versus trio) and the investigated disorders. Laboratories performing cWES have to deploy smart strategies to identify causative variants in patients with negative exome results, taking into account economic and human resources issues. We present our last 6 years' experience in multi-step WES strategies applied to patients presenting with congenital anomalies and intellectual disability (MCA/ID) for a cost-effective reduction of the diagnostic odyssey. **Methods and results:** Initially, a group of 816 patients underwent OMIM-based singleton cWES analysis, which resulted in a positive molecular diagnosis in 239 cases (29.2%). Annual research reanalysis in 156 non-positive patients allowed additional diagnosis in 24 cases and the identification of 9 new genes involved in human disease. Knowing the burden of *de novo* variants in developmental delay disorders, we interrogated the denovo-db and DECIPHER databases seeking for evidences that could help us to reclassify the variants of unknown significance identified in our dataset. This complementary strategy permitted to identify 3 new candidate genes, which after reverse-phenotyping resulted in 3 additional diagnoses. Finally, we deployed trio cWES analysis in 63 syndromic patients with negative solo cWES, which resulted in the identification of 23 new candidate genes. International Matchmaker Exchange systems, allowed us to confirm the pathogenic role of the candidate variants in 15/63 patients (24%). Overall, these combined strategies led to the identification of 23 new genes responsible for MCA/ID. Our estimation is that trio analysis would lead a theoretical maximal diagnostic yield of 49%. **Conclusions and Perspectives:** The sequential deployment of singleton cWES, re-analysis and trio-based strategy represents an efficient strategy for diagnosing and deciphering molecular bases of MCA/ID. Annual re-analysis had a significant impact on the overall diagnostic yield, yet trio-based analysis greatly improved the selection of candidate variants while saving time. We plan to enhance such approaches through: i) introduction of a trio-like WES approach involving pooled parental DNA; ii) deployment of WGS coupled with RNA-seq to answer unexplained negative trio-like WES.

**Trio Exome Sequencing of a patient with neurodevelopmental disorder and neonatal death identified a pathogenic variant in *CLPB* gene causing 3-methylglutaconic-aciduria type VII.** C.M. Wilke<sup>1</sup>, Y. Dincer<sup>1,2</sup>, J. Schulz<sup>1</sup>, M.Y. Cohen<sup>1,3</sup>, S. Eilitz<sup>1</sup>, S. Lippert<sup>1</sup>, S.H. Eck<sup>1</sup>, V. Mall<sup>2,3</sup>, I. Rost<sup>1</sup>, H.G. Klein<sup>1</sup>.

1) Center for Human Genetics and Laboratory Diagnostics, Martinsried, Germany; 2) Chair of Social Pediatrics, Technical University Munich, Munich, Germany; 3) kbo Children's Center Munich, Munich, Germany.

**Phenotype:** Here we are presenting the case of a boy, who died on day seven of life exhibiting a variety of neurological and dysmorphological symptoms including developmental delay (DD), hypomyelination of the brain, seizures, muscular hypertonia, microcephaly, decreased body weight, short stature and craniofacial dysmorphism. Basic genetic testing (karyotyping, array-CGH, FISH) was negative. **Methods:** As part of the Multiple Integration and Data Annotation Study (MIDAS), we performed whole exome sequencing (WES) of the index patient and his healthy, unrelated parents (trio). The detected variants were evaluated using data from population (dbSNP, ExAC, gnomAD) and disease (HGMD, OMIM, ClinVar, Orphanet) databases. **Results:** By WES trio analysis, we identified a homozygous pathogenic variant in the gene *CLPB* (NM\_030813.4:c.1249C/T, p.(Arg417\*)), which was inherited in an autosomal-recessive pattern. This nonsense variant results in the introduction of a premature stop codon and truncation of the corresponding protein. *CLPB* is a mitochondrial protein that belongs to the ATPase superfamily. Variants in the *CLPB* gene are known to cause 3-Methylglutaconic-Aciduria Type VII, with cataracts, neurologic involvement and neutropenia (MEGCANN) syndrome, which is primarily characterized by increased levels of 3-methylglutaconic acid with neonatal or prenatal onset. The phenotype is highly variable, characterized by intellectual disability (ID), DD, progressive cerebral atrophy, seizures, movement abnormalities, microcephaly and neutropenia. As consequence of the progressive neurological symptoms, patients with severe phenotype died within the first months of life. Due to the rapid deteriorating health status of the newborn, different diagnostic tests were initiated simultaneously. WES led to the diagnosis MEGCANN, besides also metabolic testing revealed increased levels of 3-methylglutaconic acid. **Discussion:** Genetic and clinical heterogeneity in ID/DD represent a diagnostic challenge and many patients remain undiagnosed. Our data strongly support the value of WES as an effective diagnostic tool in patients with rare monogenic disorders. Over 70% of the MIDAS patient cohort received a diagnosis by WES, which is important for clarifying genetic risk factors for the affected families and for clinical management. In conclusion, the high diagnostic yield and the impact on therapeutic treatment qualifies WES as a standard set-up in diagnostics of complex genetic syndromes.

**Genomic sequencing in a primarily trio-based cohort of 572 probands with developmental delay and intellectual disability.** M.L. Thompson<sup>1</sup>, K.M. Bowling<sup>1</sup>, C.R. Finnila<sup>1</sup>, S.M. Hiatt<sup>1</sup>, M.D. Amaral<sup>1</sup>, K.B. Brothers<sup>1</sup>, K.M. East<sup>1</sup>, W.V. Kelley<sup>1</sup>, D.E. Gray<sup>1</sup>, J.M.J. Lawlor<sup>1</sup>, M.B. Neu<sup>1</sup>, E.J. Lose<sup>3</sup>, C.A. Rich<sup>2</sup>, S. Simmons<sup>2</sup>, J. Krefting<sup>2</sup>, C. Holden<sup>3</sup>, R.M. Myers<sup>1</sup>, G.S. Barsh<sup>1</sup>, E.M. Bebin<sup>2</sup>, G.M. Cooper<sup>1</sup>. 1) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 2) University of Louisville, Louisville, KY; 3) University of Alabama at Birmingham, Birmingham, AL.

Over the past five years, the Clinical Sequencing Exploratory Research (CSER) project at the HudsonAlpha Institute for Biotechnology has focused on finding molecular diagnoses for children with unexplained developmental delay, intellectual disability, and related conditions (DD/ID). While we have previously published portions of this study, here we present an updated, comprehensive overview of data from 572 DD/ID-affected probands, 455 of which were sequenced as part of proband-parent trios. 80% of enrolled affected probands had received previous genetic testing, typically cytogenetic and/or microarray-based, and in many cases had also undergone extensive additional diagnostic testing. Overall, we generated exome data for 127 probands (365 total individuals) and genome sequencing data for 445 probands (1,115 total individuals). Pathogenic/likely pathogenic (P/LP) variants (SNVs, CNVs) were found in 29% of affected probands and variants of uncertain significance (VUS) were found in an additional 14%. Several measures have been taken to improve diagnostic yield. Systematic reanalysis of all data over the course of the study increased the P/LP rate from 23% to 29%. Furthermore, 77 genes harboring VUSs have been submitted to GeneMatcher. Thus far, 6% of these submissions led to publications describing new disease associations, including for variation in *EBF3*, *MYT1L*, *FGF12*, and *NTRK2*, and ongoing collaborations exist for an additional 18% of submitted genes. This study also assessed secondary findings within the 908 enrolled parent participants. 1.5% of parents who opted to receive secondary results harbored variation within one of the ACMG SFv2.0 genes and 1.8% harbored dominant P/LP variation in a non-ACMG gene. 70% of these participants self-reported family history or symptoms that are likely related to their genetic findings. The data underlying the results described here have been shared via ClinVar, GeneMatcher, and dbGAP. We find that WGS, especially when coupled to data sharing, is an effective first-choice diagnostic tool that advances clinical and research progress associated with pediatric neurological diseases.

**2947T**

**A new case of “KAT6A Syndrome” in a 2-year-old Japanese female with intellectual disability and multiple minor anomalies.** Y. Watanabe<sup>1,2</sup>, M. Kinoshita<sup>1</sup>, K. Fukui<sup>1</sup>, H. Mishima<sup>3</sup>, A. Kinoshita<sup>3</sup>, K. Yoshiura<sup>3</sup>, Y. Yamashita<sup>1</sup>.

1) Pediatrics and Child Health, Kurume University, Kurume, Japan; 2) Res Institute of Medical MS, Kurume University School of Medicine, Kurume, Japan; 3) Dept. Human Genetics, Nagasaki University, Graduate School of Biomedical Sciences, Nagasaki, Japan.

**Introduction:** The *KAT6A* gene encodes a lysine acetyltransferase, a member of the MYST family of histone acetyltransferases (HATs). *KAT6A* is involved in gene-specific H3 acetylation regulating developmental gene expression and in p53 acetylation and signaling, both of which have been known to control a wide range of processes including DNA repair and replication and metabolism. Since whole-exome sequencing (WES) has been introduced, mutations in *KAT6A* have been identified in individuals with intellectual disability (ID) of unknown etiology. Facial characteristics including broad nasal tip, large/low set posteriorly rotated ears, thin upper lip, down-turned corners mouth, and bitemporal narrowing are reported in the individuals, which may suggest that “KAT6A syndrome” is clinically recognizable. **Case Study:** The proband was a 2 1/2-year-old Japanese female born to a 24-year-old mother and a non-consanguineous 20 year-old father, both of whom were in good health. She was a full term (37w) and her height, weight, and OFC were 39cm (-3.6SD), 1670g (-3.2SD), and 28.2cm (-3.3SD), respectively. Epicanthal folds, hypertelorism, broad nasal tip, thin upper lip, low set/posteriorly rotated anomalous ears, and micrognathia were noted as an infant. She was kept in the NICU for 60 days for persistent pulmonary hypertension, respiratory distress, and feeding difficulty requiring a tube feeding for 30 months. A VP shunt was placed at age 4 months for hydrocephaly. Renal ultrasound study at age X months showed the left polycystic dysplastic kidney. Her developmental milestones are: head control at 3 Mo, rolls over at 10 Mo, sits without support at 12 Mo, crawls at 18Mo, cruises at 20 Mo, and walks at 29 Mo. She does not have a single word. The Trio WES (propositus and her parents) showed a de novo variant, c.3070C>T (p.R1024X) in *KAT6A* in the proband, confirming the diagnosis. **Discussion:** Since Arboleda et.al. and Tham et. al. independently reported individuals with intellectual disability with *KAT6A* mutations in 2015, there have been at least 20 cases reported to date. Three Japanese siblings (Sato et.al.) and one patient of unknown ethnicity (Arboleda et.al.) had the identical *KAT6A* mutation found in the propositus. Neither the CNS cystic lesions nor polycystic dysplastic kidney were reported in the those individuals. Owing to lacking specific clinical and laboratory findings, WES may be the most practical tool in making a diagnosis of “KAT6A syndrome”.

**Diagnostic flow-chart to improve the detection rate and to uncover the genetic heterogeneity in Pitt-Hopkins syndrome: Experience on 61 subjects.** M. Zollino<sup>1</sup>, S. Frangella<sup>1</sup>, S. Ricciardi<sup>1</sup>, D. Orteschi<sup>1</sup>, C. Pantaleoni<sup>2</sup>, P. Bonanni<sup>3</sup>, M. Macchiaiolo<sup>4</sup>, M. Murdolo<sup>1</sup>, P. Doronzio<sup>1</sup>, S. Lattante<sup>1</sup>, G. Maranghi<sup>1</sup>. 1) Institute of Genomic Medicine, Catholic University, Rome, Rome, Italy; 2) Developmental Neurology Unit, C. Besta Neurological Institute Foundation, Milan, Italy; 3) Epilepsy and Neurophysiology Unit, Scientific Institute, IRCCS Eugenio Medea, Treviso, Italy; 4) Rare Diseases and Medical Genetics, Bambino Gesù Children's Hospital Rome, Italy.

Pitt-Hopkins syndrome (PTHS, OMIM #610954) is a neurodevelopmental disorder caused by the haploinsufficiency of the *TCF4* gene. It is clinically defined by the association of severe intellectual disability, severe speech impairment, postnatal microcephaly, a typical facial gestalt, breathing abnormalities, subtle brain MRI alterations, and typical behavioral features. The PTHS phenotype overlaps with different conditions, mainly including Angelman (AS), but also Mowat-Wilson, Christianson and Rett syndromes. In the past nine years, a total of 158 subjects were analyzed both clinically and genetically because of clinical suspicion of PTHS. The diagnostic procedure included the following steps: 1) clinical evaluation of patients' phenotypes; 2) direct sequencing and MLPA analysis of *TCF4*; 3) MS-MLPA for 15q11q13 (AS region); 4) NGS analysis of a panel of genes responsible for diseases included in the differential diagnosis with PTHS (*TCF4*, *CNTNAP2*, *NRXN1*, *UBE3A*, *SLC9A6*, *MECP2*, *CDKL5*, *FOXG1*, *MEF2C*, *ZEB2*, *ATRX*); 5) whole exome sequencing (in a total of 12 patients); 6) standard karyotyping or FISH analysis. The genetic diagnosis was obtained in 61 subjects. The identified variants were: *TCF4* intragenic variants (36); large 18q21 deletions (2); partial *TCF4* deletion (2); balanced de novo translocations (2); *MECP2* variants (6); *UBE3A* variants (4); *ZEB2* variants (2); *FOXG1* variants (3); *EHMT1* variant (1), and *SZT2* variant (1). We could also define a preliminary intragenic phenotypical map of the *TCF4*, allowing for the prediction of the functional consequences of variants causing the selective dysfunction of specific protein domains. Based on our results, clinical implications and diagnostic strategies will be discussed.

**Dissecting TSC2-mutated renal and hepatic angiomyolipomas in an individual with ARID1B-associated intellectual disability.** C. Zweier<sup>1</sup>, A. Agaimy<sup>2</sup>, C. Kraus<sup>1</sup>, K.X. Knaup<sup>3</sup>, A.B. Ekici<sup>1</sup>, S. Uebe<sup>1</sup>, A. Reis<sup>1</sup>, M. Wiesener<sup>3</sup>, B. Popp<sup>1</sup>. 1) Institute of Human Genetics, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany; 2) Institute of Pathology, University Hospital Erlangen, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany; 3) Department of Nephrology and Hypertension, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Erlangen, Germany.

Several subunits of the SWI/SNF chromatin remodeling complex are implicated in both cancer and neurodevelopmental disorders (NDD). Though there is no clinical evidence for an increased tumor risk in individuals with NDDs due to germline variants in most of these genes so far, this has been repeatedly proposed and discussed. A young woman with NDD due to a *de novo* variant in *ARID1B* now presented with a large renal (>19 cm in diameter) and multiple hepatic angiomyolipomas (AMLs) but no other signs of tuberous sclerosis. We analyzed tumor and healthy tissue samples with exome and panel sequencing. Additionally to the previously known, germline *ARID1B* variant we identified a post-zygotic truncating *TSC2* variant in both renal and hepatic AMLs but not in any of the healthy tissues. We did not detect any further, obvious tumor driver events. The identification of a passenger variant in *SIPA1L3* in both AMLs points to a common clonal origin. Metastasis of the renal AML into the liver is unlikely on the basis of discordant histopathological features. Our findings therefore point to very low-grade mosaicism for the *TSC2* variant, possibly in a yet unknown mesenchymal precursor cell that expanded clonally during tumor development. A possible contribution of the germline *ARID1B* variant to the tumorigenesis remains unclear but cannot be excluded given the absence of any other evident tumor drivers in the AMLs. This unique case highlights the blurred line between tumor genetics and post-zygotic events that can complicate exact molecular diagnoses in patients with rare manifestations. It also demonstrates the relevance of multiple disorders in a single individual, the challenges of detecting low-grade mosaicisms, and the importance of proper diagnosis for treatment and surveillance.

**Diagnostic utility of genotype data from SNP arrays in neurodevelopmental disorders.** J.K. Nicholl<sup>1</sup>, C. Barnett<sup>2</sup>, J. Liebell<sup>2</sup>, A. Correll<sup>1</sup>, S.L. Kang<sup>1</sup>, Y. Hull<sup>1</sup>, A. Attwood<sup>1</sup>, S. Smith<sup>1</sup>, T. Hardy<sup>1</sup>, S. Yu<sup>1</sup>. 1) Genetics and Molecular Pathology, SA Pathology, North Adelaide, South Australia, Australia; 2) Paediatric and Reproductive Genetics, South Australian Clinical Genetic Service, Women's and Children's Hospital, North Adelaide, South Australia, Australia.

Since 2015, 6,500 patients with neurodevelopmental disorders have been tested using one of two Illumina CytoSNP array platforms: the 300K 12 BeadChip or the Infinium -850K BeadChip. Both platforms detect not only copy number variations but also genotype data. We have reviewed the clinical utility of copy number neutral loss of heterozygosity (LOH) in this cohort. From a total of 21 cases, further molecular investigation has led to a genetic diagnosis in nine cases so far. **Regions of LOH led to the diagnosis of an autosomal recessive (AR) disorder.** 7 cases were flagged for molecular follow up. For two cases, the clinical diagnosis of an autosomal recessive disorder was established with a candidate gene located in a region of LOH. Further DNA sequencing of the candidate gene identified a homozygous pathogenic mutation: a missense mutation in the *LPL* gene in a patient with lipoprotein impairment; a mutation of the *NPHS1* gene in a patient with nephrotic syndrome. No causative mutation was identified in one case. Investigations of four cases are in progress. **Regions of LOH led to the diagnosis of various types of Uniparental isodisomy (UPD) or an AR disorder.** Two cases showed UPD involving an entire chromosome. Methylation MLPA confirmed UPD15 of paternal origin, consistent with the clinical diagnosis of Angelman syndrome in the first case. In a second patient the diagnosis of Retinitis pigmentosa was confirmed following the finding of an homozygous mutation involving the *TULP1* gene on chromosome 6. Two cases showed mosaic segmental isodisomy of chromosome 11 involving the Beckwith Wiedemann syndrome (BWS) region. Molecular analysis confirmed that the segmental UPD11 is paternal in origin, consistent with BWS. Ten cases with a single or multiple LOH involving a single chromosome were detected. In two cases, microsatellite analysis of the trio showed iso-heterodisomy of chromosome 7 consistent with Silver-Russell syndrome. Maternal hetero-isodisomy of chromosome 4 was seen in a patient with a homozygous mutation in the *IDUA* gene supporting the clinical diagnosis of Hurler syndrome. For one patient with a 37Mb LOH on chromosome 20, which was shown to be identity by descent (IBD), the *GNAS* gene was in a region of bi-parental inheritance. Three patients showed bi-parental inheritance outside of the region of LOH. Three are in progress. This review demonstrates the clinical utility of SNP arrays to detect autosomal recessive and imprinting disorders.

**2951F**

**High resolution microarray testing in 420 individuals with developmental disorders in the south of Brazil.** M. Ocampos<sup>1,10</sup>, T.F. Chaves<sup>2,11</sup>, I.T. Barbatto<sup>3,10</sup>, L.F. Oliveira<sup>4,11</sup>, G.R. De Luca<sup>5,12</sup>, J.H. Barbato Filho<sup>6,12</sup>, L.L.C. Pinto<sup>7,12</sup>, P. Bernardi<sup>8,13</sup>, A.F. Maris<sup>9,11</sup>. 1) Biologist, PhD in Biotechnology and Molecular Biology; 2) Biologist and doctoral student in cell biology and development; 3) Biologist and Master of Chemical Engineering; 4) biomedic and doctoral student in cell biology and development; 5) Medical geneticist and PhD in Child and Adolescent; 6) Medical geneticist and pediatrician; 7) Medical Neuropediatricist, Children's Hospital Joana de Gusmão, Florianópolis, Santa Catarina, Brazil; 8) Medical geneticist; 9) Biologist, PhD in molecular biology and genetics, university professor in the department of cell biology, embryology and genetics; 10) Neurogene Laboratory, Florianópolis, Santa Catarina, Brazil; 11) Federal University of Santa Catarina, Florianópolis, Santa Catarina, Brazil; 12) Children's Hospital Joana de Gusmão, Florianópolis, Santa Catarina, Brazil; 13) University Hospital Professor Polydoro Ernani de São Thiago, Florianópolis, Santa Catarina, Brazil.

**Introduction:** Currently, chromosomal microarrays are recommended as first tier in the evaluation of copy number variations (CNVs) in individuals with neurodevelopmental disorders (NDD). However, in developing countries such as Brazil, classical cytogenetic tests are still the most used in clinical practice as well as in academic research, as reflected by the scarcity of publications of microarray investigation in larger cohorts. We report here the diagnostic yield of microarrays in a cohort of 420 individuals with NDDs from the south of Brazil and investigate which phenotypes relate to a higher diagnostic answer. **Methods:** The microarrays were carried out from 2013 to 2016 through the clinical diagnostic laboratory Neurogene, Florianópolis, SC Brazil. The platforms used were the Affymetrix chip CytoScan HD (75%) and 750 K (25%). The analysis was performed on ChAS software (Affymetrix®) and with information gathered from public and private databases. The collection of clinical data of the participants was through a semi-structured questionnaire to the referring physicians. The study was approved by the ethics committee of the Joana de Gusmão Children's Hospital. **Results:** Of the 420 participants, 62% were male, 38% female, mean age of 9.5 years. A total of 96 pathogenic CNVs were found in 18% of the participants; 12% presented as the main finding variants of uncertain clinical significance and 70% showed no relevant CNVs. The main reasons for referral for the test were developmental delay (DD), intellectual disability (ID), facial dysmorphism and autism spectrum disorder (ASD). Of the participants, 67% presented DD, 41% have ID (many of which also had DD), together accounting for 80% of the participants with DD and/or ID; 52% had facial dysmorphism and 32% presented ASD. According to univariate analysis, some phenotypes in this population are predictive of higher diagnostic yield, as follows: obesity ( $p$ -value= 0.006, OR= 0.20), short stature ( $p$ -value= 0.032, OR= 0.44), abnormalities and genitourinary malformations (AGM) ( $p$ -value= 0.032, OR= 0.63) and ASD ( $p$ -value= 0.039, OR= 1.94). **Conclusion:** The diagnostic rate in this study was 18%, within the range reported in the literature (15-20%). In NDD cohorts, ASD and less frequent phenotypes such as obesity, short stature and AGM could be predictive phenotypes with higher diagnostic yield. However, for more reliable results on phenotypic data, a standardized reevaluation and a larger sample are advisable.

**2952W**

**Experience and challenges of variant classification of the DMD gene.** H. Cheng<sup>1,2</sup>, J. Dong<sup>2</sup>, C. Gijavanekar<sup>2</sup>, E. Schmitt<sup>1,2</sup>, S. Peacock<sup>1,2</sup>, S. Wen<sup>1,2</sup>, J. Scull<sup>1,2</sup>, Z. Chen<sup>1,2</sup>, F. Xia<sup>1,2</sup>, L. Meng<sup>1,2</sup>. 1) Department of Molecular and Human Genetics, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030; 2) Baylor Genetics, 2450 Holcombe Blvd, Houston, TX 77021.

**Background:** DMD gene is involved in a wide spectrum of diseases, ranging from severe Duchenne/Becker muscular dystrophy, to X-linked dilated cardiomyopathy and intellectual impairment. Interpretation of DMD variants can be facilitated by clinical presentations, family history and functional studies. However, rules for classifying variants identified in asymptomatic females through reproductive risk screening has not been well-established. **Method:** Following ACMG variant classification guideline, we established evidence-based gene-specific guidelines for DMD variants classification. Key factors include: 1) variant type, 2) previously reported patients and their clinical presentations, and 3) frequencies in the general population. Furthermore, special rules were applied for DMD copy number variants (CNVs), including: 4) reading frames, 5) protein domain and the expected impact on DMD function, 6) similar or adjacent CNVs previously reported, and 7) exon skipping. We applied more stringent criteria to DMD exon duplications due to the uncertainty of their genomic location. **Results:** A total of 82 unique CNVs were detected in female individuals seeking DMD carrier testing, including 50 exonic deletions, 31 exonic duplications and 1 complex rearrangement. Comparing to deletions (74.0% pathogenic, 20.0% likely pathogenic, and 6.0% variant of unknown significance (VUS)), smaller portion of duplications were considered clinical significant (32.2% likely pathogenic, 67.8% VUS). A total of 116 individuals were determined to be carrier of a likely pathogenic or pathogenic DMD variant. Deletions were detected in 78 individuals (67.2%), with exon 45 to 51 being hotspots. Duplications were detected in 8 cases (6.9%), SNVs including truncating variants, splicing variants and rare missense variants were detected in 29 cases (25%); a complex arrangement was detected in 1 individuals (0.9%). **Conclusion and Discussion:** We developed gene-specific guidelines for interpreting DMD variants, and successfully applied them in clinical testing of general population carrier screening. DMD variant interpretation remains challenging for several reasons, such as unknown breakpoints, limited CNV control data, and significant frequency of private variants. Detailed and extensive collection of clinical evaluation, family segregation analysis, and functional studies in families with DMD variants are highly desirable to further address the more complicated variants.

**2953T**

**Redefining and refining neuromuscular disease diagnostics: Implications for molecular diagnosis and treatment.** A. Ankala<sup>1,2</sup>, J. Alexander<sup>1,2</sup>, J. Xie<sup>1,2</sup>, H. Askree<sup>1,2</sup>, M. Hegde<sup>1,3</sup>, R. Nallamilli<sup>2</sup>, A. Kesari<sup>2</sup>, L. Bean<sup>1,2</sup>. 1) Emory University, Atlanta, GA; 2) EGL Genetics LLC, Tucker, GA; 3) Perkin Elmer Genomics, GA.

With the advent of next generation sequencing (NGS) the traditional gene-by-gene approach for molecular diagnosis for some of the highly heterogeneous disorders like neuromuscular diseases (NMDs) has become a rarity. Today, NGS panel testing has become the first-tier testing for molecular diagnosis of NMDs; thereby eliminating the diagnostic odyssey for many individuals and families and allowing for faster and cost-effective diagnosis. While research based NGS testing has facilitated identification of new disease-causing genes, clinical diagnostic testing has uncovered new dimensions and previously unrecognized modalities of disease causation for some of the long known and well-studied genes. One classic example is that of the *DMD* gene where a complete spectrum of clinical presentation ranging from 'classic' Duchenne phenotype in a male to an early onset muscular dystrophy in a female has been observed. Having reported over 10,000 NMD sequencing cases EGL Genetics has identified atypical clinical presentations and diagnostic findings. Utilizing genotype-phenotype correlation and collective analysis of multiple unrelated case-cohorts, we have been able to identify and establish new disease causing variants including in-frame deletion variants in *CAPN3* causing a newly recognized autosomal dominant calpainopathy, mosaic loss-of-function variants in *DMD* causing an unusual milder phenotype and several 'leaky' variants predicted or shown to result in reduced protein expression and consequently a milder and later onset diseases. These data, in conjunction with other recently published reports, demonstrate the variability of clinical features that define NMDs - from congenital muscular dystrophies to early onset DMD and from adult onset LGMD and to some of the very late onset muscular dystrophies. In addition, our large-scale analysis brings into question the evidence for some previously reported genes and diseases, such as *SYNE1* and *SYNE2* that have been associated with an autosomal dominant muscular dystrophy. In this era of clinical therapeutics, where several clinical trials and therapies are emerging for genes such as *DMD*, finding the causative gene and genotype in a timely manner is often critical for enrollment of patients into relevant clinical studies. In conclusion, our data show how single genes like *DMD* and *COL6A2* can present with a spectrum of clinical phenotype and underlines why NGS based testing should be the first-tier test for NMDs.

Facioscapulohumeral muscular dystrophy (FSHD) has a prevalence of 1:7,000-20,000 in the general population and is recognized as one of the most common forms of neuromuscular disorders. FSHD is primarily (95% of cases) caused by a deletion of the D4Z4 macrosatellite repeats (each unit 3.3 kb long) on chromosome 4p35, resulting in 1-10 D4Z4 repeats (healthy range 11-100). The D4Z4 region in healthy individuals has been shown to be transcriptionally repressed. This is evident by the epigenetic marks associated with heterochromatin and DNA hypermethylation in the region. Studies have shown the region becomes transcriptionally de-repressed and DNA demethylated when the number of D4Z4 repeats is shortened to 10 units or less. Current standard genetic testing for FSHD is to detect contracted D4Z4 array using Pulsed-Field Gel Electrophoresis (PFGE) in combination with Southern Blotting, which is time consuming, labor intensive and not precise. Here, we used a novel approach, optical mapping, to identify the copy number of D4Z4 repeats as well as the methylation state of the D4Z4 array region. Optical mapping captures a pattern of fluorescent labels in native-state, megabase size DNA molecules in nanochannel arrays for *de novo* genome assembly and SV calling. This technology offers substantial advantages over the current clinical diagnostic practice as it has been successfully used for identification of SVs in Duchenne muscular dystrophy. We incorporated dual high molecular weight DNA labeling for genome assembly and epigenetic methylome profiling for FSHD diagnosis. First, long DNA molecules were nicked/labeled with *BssSI* endonuclease and red fluorescent nucleotides, respectively. Second, the same DNA molecules were treated with *M. TaqI* methyltransferase that attached green fluorescent cofactor onto non-methylated CpGs. Imaging and analysis of the sample library revealed the methylation pattern as well as the number of D4Z4 repeat units. We successfully identified the molecular diagnosis in our sample cohort and show that optical mapping enhances the clinical diagnostic workflow for FSHD patients.

**Detection of mitochondrial heteroplasmic variants in a single clinical whole genome sequencing assay.** A. Chawla<sup>1</sup>, E. Dolzhenko<sup>1</sup>, B. Lajoie<sup>1</sup>, R.T. Hagelstrom<sup>1</sup>, V. Rajan<sup>1</sup>, A. Warren<sup>1</sup>, F. Mullen<sup>1</sup>, K. Bluske<sup>1</sup>, A. Islip<sup>1</sup>, J. Le<sup>1</sup>, S.S. Ajay<sup>1</sup>, A. Pizzino<sup>2</sup>, O. Sherbin<sup>2</sup>, A. Vanderver<sup>2</sup>, D.L. Perry<sup>1</sup>, J.W. Belmont<sup>1</sup>, D.R. Bentley<sup>1</sup>, R.J. Taft<sup>1</sup>. 1) Illumina, Inc, San Diego, CA; 2) Children's Hospital of Philadelphia, PA.

Mitochondrial variants are routinely assessed by Sanger sequencing, quantitative PCR and long-range PCR followed by massively parallel sequencing (LR-PCR/MPS). These techniques are often performed in addition to other molecular investigations, adding complexity to test cadence and clinical care. The TruGenome Undiagnosed Disease Test offered by the Illumina Clinical Services Laboratory (ICSL) is intended to identify the underlying cause of a genetic condition through a single clinical whole genome sequencing (cWGS) assay. The current test definition targets single nucleotide variants (SNVs), small insertions and deletions, and copy number variants (CNVs) greater than 10 kb in the nuclear genome. We have extended the test definition to include detection of SNVs across the mitochondrial genome at a complete range (0-100%) of heteroplasmic frequencies. To validate mitochondrial variants, we first used DNA from four Coriell cell lines. Libraries were prepared using the Illumina TruSeq PCR-free kit and sequenced on the Illumina HiSeq X instrument with an average autosomal coverage of 30x and mitochondrial coverage of ~9000x. We employed two approaches to confirm the accuracy of alignment, variant detection and heteroplasmy estimation: 1) an orthogonal confirmation performed by an external laboratory using the LR-PCR/MPS assay and 2) a serial dilution series performed within ICSL. With the first approach, cWGS and LR-PCR/MPS detected a total of 104 mitochondrial SNVs in the four Coriell cell lines including the four known pathogenic variants. All SNVs had a maximum variant read fraction (VRF) difference of 5% between the two assays. In the mixture experiments, we performed serial dilutions using two of the Coriell cell lines to generate heteroplasmic variants with a wide range of VRFs. All VRFs across all variants and all dilutions were found to lie within 5% of their expected value. The first clinically significant mitochondrial variant detected by our cWGS pipeline, m.3243A>G, is a known pathogenic variant, detected in a 19-year-old female showing symptoms of mitochondrial leukoencephalopathy. The proband was estimated to carry the variant at 44% heteroplasmy, whereas the unaffected mother carried the same variant at only 16% heteroplasmy, compared to the population mean VRF of approximately 0.01%.

**Clinical utility of Dual Genome NGS panel for mitochondrial disorder: Towards comprehensive understanding about disease etiology.** H. Dai<sup>1</sup>, Y.M. Feng<sup>2</sup>, Y.J. Jiang<sup>2</sup>, E. Gorman<sup>2</sup>, H. Yu<sup>2</sup>, L.S. Toon<sup>2</sup>, S. Chen<sup>2</sup>, J.L. Zhang<sup>1,2</sup>, X. Wang<sup>1,2</sup>, Z. Chen<sup>1,2</sup>, H. Mei<sup>1,2</sup>, C. Eng<sup>1,2</sup>, L.J. Wong<sup>1,2</sup>, Y. Wang<sup>1,2</sup>. 1) Baylor College of Medicine, Houston, TX 77030, United States; 2) Baylor Genetics, Houston, TX 77021, United States.

Dual genome NGS panel targeting both mitochondrial and nuclear genes simultaneously is a critical approach for full molecular diagnosis of mitochondrial disorders due to the wide variability of clinical presentations linked with genetic heterogeneity throughout both the nuclear and mitochondrial genomes. Since we launched the first dual genome NGS panel in 2012, we have accumulated over 1,500 cases both diagnosed and unsolved; in the process, we have witnessed variant re-classifications, panel expansion, sensitivity improvement for detecting variants in the mitochondrial genome, and many unexpected findings requiring in-depth analysis. Through our experiences, we have found three points of great interest: Firstly, the number of solved cases seems to be evenly matched between mitochondrial and nuclear etiology, suggesting that disregarding nuclear genes when diagnosing suspected mitochondrial diseases risks missing some 50% of diagnoses. Secondly, in addition to the genes previously reported to be highly prevalent in mitochondrial disorders, we also report a high diagnostic rate from defects in the FBXL4 gene, which is an important finding as it is a relatively new gene. Finally, the vast improvements in NGS sensitivity to mutation load in mitochondrial genes makes diagnosis of mitochondrial diseases involving heteroplasmy possible by NGS panel analysis. In conclusion, the dual-genome NGS panel approach provides a comprehensive tool for diagnosis of mitochondrial diseases.

**Analysis of mtDNA mutations in Serbian patients with Leber's hereditary optic neuropathy.** P.G.A. Dawod<sup>1,2</sup>, B. Rovacanin<sup>2</sup>, M. Brankovic<sup>2,3</sup>, A. Marjanovic<sup>2,3</sup>, M. Jankovic<sup>2,3</sup>, I. Novakovic<sup>2,3</sup>, F.I. Abdel Motaleb<sup>1</sup>, J. Janic<sup>2,4</sup>, V. Kostic<sup>2,3</sup>. 1) Medical Biochemistry and Molecular Biology, Faculty of Medicine, Ain Shams University, Cairo, Egypt; 2) Faculty of Medicine, University of Belgrade; 3) Neurology Clinic, Clinical Center of Serbia; 4) Child and Adolescent Neurology and Psychiatry Clinic, Belgrade, Serbia.

**Introduction:** Leber hereditary optic neuropathy (LHON) is a mitochondrial inherited degeneration of of retinal ganglion cells (RGCs) leading to severe visual impairment or even blindness. Besides primary mtDNA mutations number of secondary changes affect phenotype. Aim of this study was to investigate the presence of mutations in mtDNA among Serbian patients affected with LHON. **Material and Methods:** Individuals included in this study were recruited from the Child and Adolescent Neurology and Psychiatry Clinic and from Neurology Clinic CCS, Belgrade, Serbia. All examined individuals for 17 unrelated families had characteristic clinical presentation suggesting the presence of LHON. Multiple segmental PCR amplicons of mtDNA have been sequenced by Sanger's method and the obtained results were compared with the referent mtDNA sequence. **Results:** Substitutions mt.3460 G>A in ND1, mt.11778 G>A in ND4, and mt.14484 T>C in ND6, were found as primary mutations in 6/17, 10/17 and 1/17 families, respectively. The most frequent primary mutations mt.3460 G>A and 11778 G>A were associated with secondary mutations (4216C/ND1-10398G/ND3-13708A/ND5-15257A/CYB-MT-15812A/CYB-MT). These changes has been well established in European haplogroup J that increase penetrance of LHON. Many other mutations were found in various parts of mitochondrial genome. **Conclusion:** This study of spectrum of mutations in mtDNA in Serbian LHON patients assists understanding of their role in etiopathogenesis and progression of disease.

**Plasma derived cell-free mitochondrial DNA (cf-mtDNA): A novel and non-invasive method to identify the mitochondrial DNA haplogroup.** C. Newell<sup>1</sup>, S. Hume<sup>2</sup>, S.C. Greenway<sup>3,5</sup>, L. Podemski<sup>2</sup>, J. Shearer<sup>3</sup>, A. Khan<sup>1,5</sup>. 1) Department of Medical Genetics, Cumming School of Medicine, University of Calgary, Alberta, Canada; 2) Department of Medical Genetics, University of Alberta, Alberta, Canada; 3) Department of Cardiac Sciences, Libin Cardiovascular Institute of Alberta, University of Calgary, Calgary, Alberta, Canada; 4) Faculty of Kinesiology, University of Calgary, Alberta, Canada; 5) Department of Pediatrics, Alberta Children's Hospital Research Institute, Cumming School of Medicine, University of Calgary, Alberta, Canada.

**Background:** Mitochondrial disease comprises a heterogeneous group of diseases affecting 1:5000 people and can be caused by gene mutations in either nuclear or mitochondrial DNA (mtDNA). Less-invasive methods to obtain mtDNA have involved collection from peripheral blood leukocytes, urine sediment and buccal swab. However, these tissues contain low levels of mitochondria and may not adequately represent commonly affected tissues such as the brain and skeletal muscle. Recently, research suggests that cellular apoptosis and cellular turnover release small 150-200 base pair fragments of DNA from hematopoietic and non-hematopoietic cell types, which can be extracted from plasma as cell-free DNA (cfDNA). Entire mtDNA has not been successfully identified from the cell free fraction previously. As we suspect that the circular nature of mtDNA is protective, our objective was to develop a methodology to identify entire cf-mtDNA from plasma. **Methods:** Blood samples from patients with mitochondrial disease diagnosed from skeletal muscle biopsy (n=7) and healthy controls (n=7) were collected and their cfDNA isolated. To demonstrate the presence of the mitochondrial genome within these samples, we amplified the isolated DNA using custom PCR primers specific to overlapping fragments of mtDNA. cfDNA samples were then sequenced using the Illumina MiSeq sequencing platform. **Results:** We confirmed the presence of mtDNA, demonstrating that the full mitochondrial genome is in fact present within the cell-free plasma fraction. Furthermore, sequencing of the cfDNA identified a mitochondrial haplogroup match with the tissue specimen for all patients. **Conclusion:** We report a successful method showing positive identification of mtDNA by haplogroup analysis from cell-free plasma. This technique has clinical application to diagnose mitochondrial disease, evaluate mtDNA haplogroup variants and response to future transplantation or mitochondrial therapies.

Mitochondrial diseases pose a diagnostic challenge due to clinical and genetic heterogeneity, propelling unbiased whole exome sequencing (WES) into the early diagnostic setting. Over 300 disease-associated genes implicated in mitochondrial energy metabolism are currently recognised, and this number continues to grow. Through global collaboration, initiated by the European network for mitochondrial diseases, GENOMIT, we assimilate data from patients investigated by WES under clinical and/or biochemical suspicion of mitochondrial disease. Systematic analysis of WES data from 1500 paediatric and adult patients established a genetic diagnosis in 735 (49%). Furthermore, this endeavour, and subsequent follow-up studies, resulted in molecular diagnosis of over 1000 patients and included discovery of 40 novel disease genes. Pathogenic variant(s) in 459 (31%) patients harboured within 138 mitochondrial disease-associated genes, with defects in *ACAD9*, *ECHS1*, *FBXL4* and *MT-ATP6* occurring most frequently. To date, over 40 cofactor metabolism defects have been discovered, leading to impaired mitochondrial energy metabolism amendable to specific cofactor supplementation. And indeed, 92 of the solved exome cases fall into this category. However, effective defect-targeted treatments for the majority of mitochondrial diseases are missing. Thus, genotyping is fast becoming the prerequisite for efficacious treatment and clinical trial inclusion. Remarkably, 33 patients with molecularly-verified mitochondrial disease demonstrated normal respiratory chain complex activity, highlighting difficulty in disease definition. This is further reflected by 276 patients harbouring disease-causing variant(s) in non-primarily mitochondrial disease-associated genes (179 genes including *TANGO2*, *CAD*, *IARS*, *SLC52A2*) and 64 patients with unsuspected but genetically-proven mitochondrial disease diagnosed in the same time-period. This study exemplifies the value of international collaboration in the rare disease setting. By coupling exomes to clinical, biochemical and experimental data, we further elucidate the heterogeneous genetic architecture of mitochondrial disease. Prompting careful consideration of diagnostic criteria, by emphasising discrepancies between clinical, biochemical and genetic means of diagnosis and demonstrating the need to consider this entire body of evidence in aggregate. GENOMIT is hence establishing a valuable global registry for both clinical and genomic data.

Mitochondrial cytopathies can be caused by mitochondrial DNA (mtDNA) anomalies such as point variants or large-scale single deletions. In addition to these causative anomalies, multiple deletions of mtDNA can arise due to pathogenic variants in nuclear genes involved in the maintenance of mtDNA. These 3 types of anomalies (point variants, single and multiple deletions) are investigated for diagnostic purpose thanks to amplification of mtDNA by 2 long-range PCR, and sequencing by NGS short reads technology. However, the use of short reads does not allow to easily and accurately identify the deletion breakpoints at the nucleotide level. In order to determine if long read sequencing technologies overcome this limitation, we perform mtDNA sequencing of controls and patients with single or multiple deletions on Oxford Nanopore MinION. This technology allowed an accurate identification at the nucleotide level of the breakpoints of the deletions, even in the case of complex multiple deletions. These breakpoints have been confirmed by Sanger sequencing. This determination is useful for family testing in the case of single deletion. Furthermore, studies could also take advantage of this method to decipher the mechanisms of occurrence and to track the accumulation of mtDNA multiple deletions in mitochondrial or degenerative diseases, but also during normal aging. In addition, despite a higher per base error rate in comparison with other NGS technologies, the accuracy of Oxford Nanopore MinION sequencing is sufficient to correctly determine the mitochondrial haplogroup of each patient. Due to the portability of MinION, it raises the possibility of in-the-field sequencing experiments for population genetics studies.

**Targeted next-generation sequencing facilitates genetic diagnosis and provides novel pathogenetic insights into deafness with enlarged vestibular aqueduct.** C-C. Wu<sup>1,2</sup>, Y-H. Lin<sup>1,3</sup>, Y-H. Lin<sup>1</sup>, C-S. Chen<sup>2</sup>, T-C. Liu<sup>1</sup>, C-J. Hsu<sup>1</sup>, P-L. Chen<sup>2,3</sup>. 1) Department of Otolaryngology, National Taiwan University Hospital, 7 Chung-Shan South Road, Taipei, Taiwan; 2) Department of Medical Genetics, National Taiwan University Hospital, 7 Chung-Shan South Road, Taipei, Taiwan; 3) Graduate Institute of Medical Genomics and Proteomics, National Taiwan University College of Medicine, 1 Jen-Ai Road Sec.1, Taipei, Taiwan.

Enlarged vestibular aqueduct (EVA) is an inner ear malformation associated with sensorineural hearing impairment. The majority of EVA are associated with Pendred syndrome (PS) and non-syndromic DFNB4, two autosomal recessive disorders caused by mutations in *SLC26A4*. However, a significant percentage of EVA patients cannot have confirmed diagnosis by screening common *SLC26A4* mutations, constituting an enigma in genetic diagnosis. To enable comprehensive genetic examination and explore the etiologies of EVA, we designed a next-generation sequencing (NGS) panel targeting the entire length of three PS/DFNB4 genes (*SLC26A4*, *FOX11* and *KCNJ10*) and exons of ten other genes related to EVA, and performed genetic testing in 50 EVA families without confirmative results on screening for *SLC26A4* hotspots (c.919-2A>G and p.H723R). We identified bi-allelic *SLC26A4* mutations in 34 families and *EYA1* mutations in two families, yielding a diagnostic rate of 72% (36/50). In addition, we identified two variants in *KCNJ10* and *FOX11*, but our findings did not support previous hypothesis that mutations in these two genes are probable contributors to EVA through recessive inheritance or digenic inheritance with *SLC26A4*. Of note, a large *SLC26A4* deletion was confirmed in one step using our panel. Our results demonstrate the utility of NGS-based panel in addressing EVA families by identifying various types of gene mutations with satisfactory diagnostic yields, and provide novel insights into the pathogenesis of EVA.

**2962T**

**Detection of stereocilin (*STRC*) gene deletions by multiplex digital droplet PCR.** R.L. Margraf<sup>1</sup>, R. Mao<sup>1,2</sup>. 1) ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT; 2) Department of Pathology, University of Utah, Salt Lake City, UT.

Stereocilin gene (*STRC* [MIM 606440]) mutations are a common cause of moderate autosomal recessive hearing loss (MIM 603720). 11% of all individuals with isolated non-syndromic hearing loss have a large *STRC* deletion, which can encompass the entire gene. The *STRC* gene is 98% homologous with its pseudogene (*pSTRC*), which includes a 100% homologous section from exons 1 to 15. *STRC* deletions cannot be accurately detected using NGS, microarray, or MLPA due to the *pSTRC* pseudogene homology. To specifically detect large *STRC* deletions, digital droplet PCR (ddPCR) assays were developed on the Bio-Rad QX200™ Droplet Digital™ PCR system. Four target assays were designed to three locations within *STRC* (Exon 19, near Exon 23, and Intron 25) and one area within the nearby *CATSPER2* gene (MIM 607249). These assays were designed to avoid common polymorphisms, and to be specific to *STRC* by covering bases that are divergent between *STRC* and *pSTRC*. Also, a stable two copy gene was used as a reference assay for calculating *STRC* copy number. Wild type (WT) sample with two *STRC* copies was tested to choose the pre-ddPCR DNA fragmentation method, and had copy number values ranging from 1.2-1.9 for sonication versus 1.9-2.1 for enzyme digestion. The restriction enzyme digestion was chosen over sonication due more precise copy number values. To test multiplexing, two target assays were combined in various ratios, along with the reference, in one reaction. Multiplexing results were very sensitive to the mixing ratios of the two target assays, since droplet data points can start to overlap at some ratios. At the chosen optimal mixing ratio, the multiplexed assays had a WT copy number average of 1.94 +/- 0.05 copies and heterozygous for deletion samples had 0.99 +/- 0.03 copies. WT and heterozygous samples correctly genotyped at a range of DNA input (7.5ng - 75ng/reaction). Samples with known and suspected homozygous *STRC* deletions amplified for the reference assay, but did not amplify for the target assays even at 2-4x higher than the recommended 37.5ng DNA input, indicating the ddPCR assays were specific to *STRC* versus *pSTRC*. The ddPCR assays were successfully multiplexed in sets of two target assays with one reference assay, and generated the expected copy number for the known genotyped samples. The addition of this *STRC* ddPCR assay will increase the clinical sensitivity of the NGS hearing loss panel test by allowing for the detection of large deleterious *STRC* deletions.

**2963F**

**Identification of novel CNV in *PTPRQ* associated with autosomal recessive hearing loss by target exome sequencing.** Z. Wei<sup>1</sup>, F. Chang<sup>1</sup>, Y. Pan<sup>1</sup>, J. Li<sup>1</sup>, X. Tian<sup>1</sup>, F. Mu<sup>1</sup>, S. Xu<sup>1</sup>, Y. Li<sup>1</sup>, P. Fang<sup>1</sup>, Y. Yuan<sup>2</sup>. 1) WuXi NextCode Genomics (Shanghai) Co., Ltd; 2) Department of Otolaryngology, Head and Neck Surgery, PLA General Hospital, Beijing, P. R. China.

Next generation sequencing is widely used in the diagnosis of inherited disease. However, the detection of copy number variants (CNV) is not implemented in most next-generation sequencing pipelines. To detect single nucleotide variants (SNV), indels and CNV simultaneously, we designed a target exome sequencing based-panel, which contains 139 genes related with hereditary hearing loss. Using this panel, three variants in *PTPRQ* in a non-syndromic sensorineural hearing loss patient are identified, including one novel large deletion. *PTPRQ* is recognized as a receptor-like phosphatase to be active against phosphatidylinositol phosphates, which is involved in the cell regulation, proliferation. Pathogenic variants in *PTPRQ* will cause progressive moderate-to-profound sensorineural hearing impairment and vestibular dysfunction (DFNB84), however, no CNV of this gene has been reported before. We here first identified a paternally inherited large deletion spanning exon 42 of *PTPRQ* (NM\_001145026.1), which was called by HMM pipeline of NextGNEe and then validated by long range PCR. Sequencing of PCR product further confirmed the breakpoint of deletion (c.6453+131\_6602+90delinsTTTGT). This indel is located in the phosphatase domain and predicted to cause a single exon loss of *PTPRQ*. Loss of function is considered as a known mechanism of pathogenicity for *PTPRQ*, and null variant has been reported previously in the same region, thus the CNV is regarded as a pathogenic variant. We also identified another two maternally inherited SNVs in this patient including one missense (c. 1124C>T) and one splicing variant (c.6603-3T>G). Both of them are very rare in normal population without healthy homozygote reported before. The missense is predicted to have no impact on gene product, whereas the splicing variant is predicted to affect mRNA splicing. However, more evidences are required to evaluate the pathogenicity of these two SNVs. In conclusion, CNV is an important cause of *PTPRQ* related hearing loss, which must be included in the genetic testing; compared with other methods, such as array-CGH, target exome sequencing is a cost effective, time saving and high resolution approach for CNV detection in clinical diagnosis.

**2964W**

**Homozygous non-coding sequence change of the *OCA2* causing oculocutaneous albinism in a child.** A. Maher<sup>1,2</sup>, A. Tsa<sup>1,2</sup>. 1) University of Colorado Denver, Aurora, CO; 2) Children's hospital Colorado.

Oculocutaneous albinism type 2 (*OCA2*) is characterized by hypopigmentation of the skin and hair and the characteristic ocular changes found in all types of albinism, including nystagmus; reduced iris pigment with iris translucency; reduced retinal pigment with visualization of the choroidal blood vessels on ophthalmoscopic examination; foveal hypoplasia associated with reduction in visual acuity; and misrouting of the optic nerve fiber radiations at the chiasm, associated with strabismus, reduced stereoscopic vision, and altered visual evoked potentials (VEP). Most non-Africans with *OCA2* are compound heterozygotes. Approximately one third of the reported non-African individuals have only one pathogenic variant detectable by sequence analysis of the coding region, the intron-exon boundaries, and several hundred bases of the 5' promoter region and 3' untranslated region of *OCA2* [Oetting & King 1999, King et al 2001a, King et al 2001b, Gargiulo et al 2011]. To date, no pathogenic variant has been reported beyond 20 bp into the intron region of an exon/intron boundary. Approximately 20% of all individuals who have complete sequencing of the entire coding sequences and the flanking intron sequences have shown only one pathogenic variant. Cryptic splice sites or variants in regulatory regions could affect transcriptional regulation [King et al 2001a]. We herein report a case of a 6 month old with no family history of albinism who presented with the characteristic symptoms of *OCA2* including hypopigmentation of the skin and the hair. Eye examination revealed transillumination defects 360 bilaterally, with foveal hypoplasia and blonde fundus bilaterally. With normal extraocular muscles movement without strabismus or other refractive errors. In addition to nystagmus secondary to foveal hypoplasia. NGS Pigmentation panel, testing for 30 genes including the *OCA1*, *OCA2*, *HPS* genes, *PAX3* and *SOX10* didn't reveal any variants in the genes of the pigmentation panel. By using TaqMan qPCR that identified a homozygous non coding sequence change of the *OCA2* gene that was identified by the lab as likely pathogenic. Both parents had lighter pigmentation and sun sensitivity. Additional study on the mechanism of this non-coding region change is underway.

**Introduction** Congenital cataracts demonstrate marked clinical and genetic heterogeneity, often with additional ocular and extraocular features. We have previously obtained a genetic diagnosis in a high proportion of patients utilising an NGS-based panel or whole exome sequencing (WES) approach and CGH microarray, finding answers in over 70% (33/46) of congenital cataract patients. **Methods** In this study we applied whole genome sequencing (WGS) to assist with 13 congenital cataract cases unsolved after CGH microarray, and panel or WES. WGS utilized the Illumina HiSeq X Ten and a bioinformatics structural variant analysis pipeline, ClinSV, which allows confident detection of rare structural- and copy number variants, using evidence from split-reads, discordant pairs and depth-of-coverage. **Results** A causative variant was found in 2/13 patients, who harboured deletions too small to be seen on conventional microarray or capture-based sequencing. A novel 3.2kb deletion in the *MIP* gene was found in a patient with congenital cataracts and microphthalmia. A 4kb deletion in the X-linked syndromal gene *NHS* was found in a male with congenital cataracts and coloboma. Subsequent study with high-resolution chromosomal microarray was able to confirm the presence of both these deletions. **Discussion** This study demonstrates an increased yield of genetic diagnoses in a cohort of patients. While the yield of CGH microarray combined with panel/exome based testing is significant, WGS analysis revealed additional diagnoses of structural variants, providing new diagnostic and management information.

**2966F**

**NGS surprise: Pathogenic haplotypes.** I.T. Perva<sup>1,2</sup>, A. Chirita-Emandi<sup>1,2</sup>, M. Puiu<sup>1,2</sup>. 1) Medical Genetics, Center of Genomic Medicine, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; 2) Medical Genetics Compartment, Louis Turcanu Emergency Hospital for Children, Timisoara, Romania.

**Aim.** To present a rare next generation sequencing interpretation approach and raise awareness to evaluate also the haplotype level of a VCF document. **Materials and methods.** Ophthalmologic evaluation of a 7 years old boy revealed severe bilateral hypermetropia (+7 diopter) and discromia. Maternal uncle presents the same eye phenotype. NGS analysis WES was performed for index and using the online databases the variants were called (Genome Aggregation Database (gnomAD), Exome Sequencing Project (ESP), 1000Genome project (1000G), Online Mendelian Inheritance in Man (OMIM) and CentoMD). **Results.** The following relevant variants were detected, in the third exon of the *OPN1LW* gene: c.457A>C p.(Met153Leu); c.511\_513delinsATT p.(Val171Ile); c.532A>G p.(Ile178Val). Individually these have no clinical relevance, but combined, the three define a toxic opsin haplotype and subsequently determine the X linked Bornholm eye disease (OMIM®: 300843). The same haplotype was found in the maternal uncle, by WES analysis. **Discussions.** The defining positions are 153, 171, 174, 178 and 180, and the haplotype name is given by the amino acid letter code corresponding to these coordinates. The LIAVA variant combination was previously reported with third exon skipping and lack of opsin mRNA, thus interpreted as pathogenic significance. **Conclusion.** Current NGS interpretation pipelines do not, generally, include haplotype variant interpretation, doing so various diseases can be overlooked in diagnosis. By the presentation of this case, we hope that at least in the face of unsolved cases, some specialists, will evaluate a combined variant option. **Clinical and molecular characterization of hereditary retinal degeneration in Portugal.** V. Peter<sup>1</sup>, L. Paris<sup>2</sup>, M. Quinodoz<sup>1</sup>, K. Cisarova<sup>1</sup>, A. Veiga<sup>2</sup>, S. Meira<sup>2</sup>, O. Afonso<sup>2</sup>, AB. Sousa<sup>3</sup>, R. Rodrigues<sup>3</sup>, LC. Santos<sup>3</sup>, C. Rivolta<sup>1,4</sup>.

1) Department of Computational Biology, Unit of Medical Genetics, University of Lausanne, Lausanne, Switzerland; 2) Instituto de Oftalmologia Dr. Gama Pinto, Lisbon, Portugal; 3) (1)Medical Genetics of the Paediatrics' Department, Hospital de Santa Maria/ Centro Hospitalar Lisboa Norte – Lisbon – Portugal; 4) Department of Genetics and Genome Biology, University of Leicester, Leicester, United Kingdom.

Hereditary retinal degenerations (HRDs) represent a class of diseases leading to the progressive degeneration of the retina and, in the end, to loss of vision and blindness. HRDs are genetically highly heterogeneous and missing heritability accounts for ~40% of all clinically-diagnosed cases. Most importantly, the mutational spectrum of HRDs can vary widely depending on the population studied, and be highly dependent on the degree of genetic homogeneity of the cohort analyzed. Since there are currently no comprehensive data concerning either the spectrum of HRD mutations or the presence of population-specific disease genes in the Portuguese, we performed a cross-sectional study combining clinical and molecular assessment of 83 families from this country, affected by a variety of HRD diagnostic classes. SNP-chip genotyping of selected subjects from 57 families enabled the detection of at least one known HRD gene as most probable cause of the disease in 28 cases (49%). In 20 cases (35%) we identified regions of homozygosity that may harbor new genetic associations and are currently performing WES analyses to detect the actual pathological mutations. We also found that the degree of autozygosity in 57 unrelated subjects from our cohort (median=88 Mb) is significantly higher than in 361 Portuguese controls (median=9 Mb; p-value = $1.9 \times 10^{-17}$ ), which is itself higher than in 3,797 subjects from 6 European countries (Switzerland, Italy, France, Spain, Germany, Belgium; median=4 Mb; p-value = $4.15 \times 10^{-9}$ ). Moreover, we identified a haplotype of 9.5 Mb shared by 4 patients and harboring a deletion in the *EYS* gene, representing 10% of cases with autosomal recessive retinitis pigmentosa (n=39) in our cohort. To our knowledge, this is the first study assessing the cross-sectional genotype-phenotype landscape of HRDs in the Portuguese population. Our preliminary data reveal an unexpected level of cryptic consanguinity as one of the main contributors to the molecular pathology of these diseases, as well as the presence of at least one prevalent and population-specific mutational event for this part of Europe.

**Elevated incidence of microphthalmia in Chuuk, FSM – a mystery solved?**

A.S. Schneider<sup>1</sup>, A.A. Yomai<sup>2</sup>, A.V. Levin<sup>3</sup>, D. McNear<sup>4</sup>, S. Kopinsky<sup>1</sup>, J. Capasso<sup>5</sup>, J. Chaing<sup>7</sup>, M. Hegde<sup>6</sup>, S. Shankar<sup>6</sup>, T.M. Glaser<sup>2</sup>. 1) Genetics, Einstein Medical Center Philadelphia, Philadelphia, PA; 2) University of California, Davis, Davis, CA; 3) Wills Eye Hospital, Philadelphia, PA; 4) Department of Health Services, Chuuk, FSM; 5) Independent Educational Consultant, Cambridge, MN; 6) Perkin Elmer Genetics, Pittsburgh, PA; 7) Molecular Vision Laboratory, Hillsboro, OR.

Microphthalmia, anophthalmia and coloboma (A/M) are rare ocular birth defects with a complex genetic basis and environmental risk factors. The incidence of A/M is elevated 4-5 fold in Chuuk state, Federated States of Micronesia, affecting 14 per 10,000 births (Yomai *et al.* 2010) compared to the worldwide average of 3 per 10,000 (Shah *et al.* 2011). This remote archipelago in the western Pacific contains 42 inhabited islands, which were peopled 1000-3000 years ago. The population is dispersed, but most residents live in a ring of barrier islands surrounding the Chuuk lagoon. The elevated incidence of A/M and population structure in Chuuk are consistent with a genetic founder effect. Moreover, Vitamin A deficiency (VAD), a known maternal risk factor for A/M disease, is endemic in Chuuk, suggesting a potential gene x environment interaction. To investigate the clinical features and etiology of A/M disease in this population, we held clinics in Chuuk during April 2017. We performed eye and medical exams, and obtained family history data and genomic DNA from 25 probands with suspected A/M and their parents from 7 different islands. Five probands from one island were found to have LCA (Leber's congenital amaurosis) with enophthalmos (recessed eye globes) and a homozygous inactivating mutation in *CRB1* (c.3134delT). The remaining 20 probands (8M, 12F) were determined to have colobomatous microphthalmia. Some exhibited poor growth and microcephaly, but were not dysmorphic, and most have normal intellect. The majority of mothers with affected children reported night-blindness during pregnancy, consistent with VAD, and we found that serum retinol and RBP levels were moderately or severely reduced in 78% (14 of 18 mothers tested). The segregation ratio for the A/M trait in 22 affected sibships was 21% (24/117), consistent with autosomal recessive or digenic inheritance. To identify gene mutations, we performed high resolution SNP analysis on all samples and whole genome sequencing (WGS) on 5 probands. Although several pathogenic sequence variants were discovered, no solitary region of homozygosity >5Mb was identified that is shared among all probands. These data exclude a single recessive founder mutation and suggest a polygenic basis for A/M disease in Chuuk, with maternal VAD as a likely contributing factor.

**Cytogenomic findings in Brazilian patients with OAVS.** P.A.S. Abu Hana<sup>1,2</sup>, H. Sakata<sup>1</sup>, C.P. Oliveira<sup>3</sup>, R.S. Bonadio<sup>1</sup>, I. Ferrari<sup>1</sup>, H.P.N. Safatle<sup>1</sup>, M.S. Cordoba<sup>1</sup>, M.T.A.S. Rosa<sup>3</sup>, C. Rosenberg<sup>4</sup>, E.L. Freitas<sup>4</sup>, R.E. Pogue<sup>5</sup>, A.C. Acevedo-Poppe<sup>1</sup>, A. Pic-Taylor<sup>1</sup>, S.F. Oliveira<sup>1</sup>, J.F. Mazzeu<sup>1</sup>. 1) University of Brasilia, Brasilia, Brazil; 2) Health Sciences University of Alagoas, Maceio, Alagoas, Brazil; 3) Health Department of the Federal District, Brasilia, Brazil; 4) Department of Genetics and Evolutionary Biology, Institute of Biosciences, University of Sao Paulo, SP, Brazil; 5) Catholic University of Brasilia, Brazil.

Oculoauriculovertebral spectrum (OAVS) (OMIM 164210) is a developmental defect involving the first and second branchial arch derivatives and intervening first pharyngeal pouch and branchial cleft, in particular the ear, mouth, mandible, eye and cervical spine. We present a genomic screening for copy number variations (CNVs) in OAVS Brazilian patients, referred to the Clinical Genetics Service – University of Brasilia, aiming to identify genomic regions and genes potentially involved in this disease pathogenesis. For this purpose, genomic DNA from venous blood samples from these patients was extracted, followed by Chromosomal microarray analysis (CMA) with Affymetrix or Agilent platforms. The study included 24 isolated and six familial cases of OAVS. CMA detected copy-number variants in 12/30 (40%) patients including four deletions (33.3%), five duplications (41.6%), two segments of absence of heterozygosity (AOH) (16.6%) and one complex rearrangement involving a deleted and a duplicated region, both “*de novo*”, in the 2p23.3-p25.3 region. Three alterations were considered pathogenic including a partial deletion at 22q11.2 (including *TBX1*), a microdeletion at 12q24.21, involving *TBX3* and a microduplication at 20p12.3-p12.2 with partial duplication of *PLCB4*. Nine CNVs were classified as VOUS. These results confirm the heterogeneity of the syndrome and show that chromosome imbalances are an important cause of OAVS.

**Genomics and clinical association study in duplication of 5p.** L.A.R. Bicu-do<sup>1</sup>, M.V.P.F. Santos<sup>1</sup>, R.M.O.F. Curado<sup>1</sup>, S.J. Sestari<sup>1</sup>, G.F. Vasconcelos<sup>1</sup>, S.S. Coelho<sup>2</sup>, N.A. Bergamo<sup>1</sup>, B.F. Gamba<sup>1</sup>. 1) Federal University of Goias, Goiania, GO; 2) University of Sacred Heart, Bauru, SP.

Duplication of 5p (5p trisomy) is a rare genetic condition associated, or no, with complex rearrangements involving other chromosomes. Phenotype expression in patients with trisomy 5p is highly variable and the clinical condition as well as its severity depend on the size and location of the duplication. In the present work we report a chromosome 5p duplication case as well as an association between chromosomal 5p breakpoints and clinical annotation based on 16 cases from literature. Chromosome 5p region, ensemble about 46 Mb of DNA which involves 241 genes (110 OMIM ® genes). Wide phenotype variability, totalizing 88 shared clinical findings in all patients were annotated. The data collected were added in Gephi software to establish relationship between patients, 5p breakpoint and clinical finding. We call this analysis as intuitive analysis. According to the wide phenotypic variability and different breakpoints in the 5p chromosome region found in the present group, our intuitive analysis showed a remarkable genetic-clinical interface in four groups of individuals. Clinical findings such as facial dimorphism, hypertelorism, low ears, broad nasal bridge, microretrognathia, global developmental delay, hypotonia, language delay, ocular anomalies, respiratory difficulties, dolichocephalic, macrocephaly, arachnodactyly, crooked feet were the most shared clinical signs among all patients. This result evidences the existing phenotypic variability when we studied several cases with a chromosomal region alteration. As we observed wide phenotypic variability, broad genetic heterogeneity was also observed, but some duplicate genes are potentially responsible for the clinical findings in trisomy 5p, like *CLPTM1L*, *SLC1A3*, *NIPBL* and *GDNF* genes. These genes are present in duplicated region identified in the patient and may be responsible for the observed phenotype. We conclude that genotype-phenotype correlation it's still difficult challenge to geneticists, but the use of computational tools can be useful in this type of strategy and potentiate the analyzes. Our results point to four groups of patients that share a larger number of data (genetic and clinical), which may direct future analysis and allow better understanding of the 5p chromosomal region.

**Evaluation of copy number variation (CNV) in deceased patients with previously unknown molecular etiology.** C. Chung<sup>1</sup>, K. Stumm<sup>1</sup>, D. Watson<sup>1</sup>, M. Harr<sup>1</sup>, M. Khan<sup>1</sup>, J. Glessner<sup>1</sup>, H. Hakonarson<sup>1,2,3</sup>, A. Santanji<sup>1,4</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 3) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4) Department of Pathology, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

**Background.** Recently, posthumous genetic testing has begun to shed light on the cases of patients who had unexplained deaths. The aim of this study is to analyze copy number variation (CNV) of individuals in our pediatric cohort with unknown molecular etiology and to analyze the potential relationship between the genetic testing results and the patients' phenotype and cause of death. **Methods.** Patients for this study were previously enrolled in a research biorepository at the Center for Applied Genomics at Children's Hospital of Philadelphia. Subjects were selected by a search of their medical records with ICD-9/10 codes for sudden infant death syndrome (SIDS; ICD-9: 798.0) and unknown cause of mortality (ICD-10: R99), excluding those with cancer diagnoses (ICD-10: C00-D09). Fifty-four deceased patients were identified for this study (61.1% male, 38.9% female). Thirty-one patients had ante-mortem whole genome microarrays and microarray studies were subsequently performed on an additional twenty-three cases. A custom analysis pipeline was used to call, annotate and analyze the CNV data. Results from the arrays were then compared to the clinical features of each patient in order to analyze a possible association. **Results.** The average age of the patients' death was 6.2 years (ranged from 1 hour of life to 23 years); their phenotypes included multiple congenital anomalies (68.5%), neurodevelopmental disorders (42.6%), craniofacial disorders (11.1%) and skeletal dysplasia (1.8%); some presented overlapping features. Autopsy was performed in 35.2%. Family history that increased suspicion for a genetic etiology was reported in 14.8%. Pathogenic or VUS CNVs were identified in 26% of the 54 patients. Clinical correlation was performed by a clinician and in total, five CNVs were determined to be potentially related to the cause of death. **Conclusion.** Genome analysis can help to elucidate causes of death that originally had an unknown etiology and to provide important information to the family members, such as a potential diagnosis and recurrence risk. This data further supports the utility of genome analysis in deceased patients with molecularly undiagnosed genetic conditions, therefore comprehensive molecular testing should be recommended on all patients with SIDS or unexplained cause of mortality.

**9q34.11 deletion, including *DNM1* and *SPTAN1* but lacking *STXBP1*, causes a distinctive phenotype with intellectual disability, speech delay, and dysmorphic facial features.** K. Kurosawa<sup>1</sup>, N. Harada<sup>1</sup>, T. Saito<sup>1</sup>, Y. Enomoto<sup>1</sup>, Y. Tsurusaki<sup>1</sup>, H. Murakami<sup>1</sup>, Y. Kuroda<sup>1</sup>, M. Masuno<sup>2</sup>. 1) Division of Medical Genetics, Kanagawa Children's Medical Center, Yokohama, Japan; 2) Genetic Counseling Program, Kawasaki University of Medical Welfare, Kurashiki, Japan.

9q34.11 deletion syndrome is a newly recognized syndrome characterized by epileptic encephalopathy, hereditary hemorrhagic telangiectasia, and variable degree of intellectual disability (Campbell et al., 2012). These phenotypes are caused by haploinsufficiency of the combinatory of the dosage sensitive genes including *ENG*, *STXBP1*, *SPTAN1*, and *TOR1A*. Large deletion encompassing the 9q34.11 provides a typical phenotype including severe intellectual disability, early infantile spasm. However, genotype-phenotype correlation of each gene in the region is poorly understood. Here we report a patient with severe intellectual disability, dysmorphic facial features, but no seizure episode by the age of 8 years. Microarray revealed 2.0 Mb deletion including the 10 OMIM genes from *DNM1* to *TOR1A*. Among the deleted genes, only the *DNM1* and *SPTAN1* show high score (1.0) of loss of function intolerance (pLI). For *SPTAN1* mutation, hemizyosity has been suggested to result in hypomyelination, although dominant negative effect causes early onset infantile spasm. For *DNM1* mutation, effect of hemizyosity is unknown, although dominant negative effect causes epileptic encephalopathy. Further, mutation in the PH domain of *DNM1* has been suggested to cause non-epileptic phenotype with dysmorphic facial features and developmental delay. These results indicate that the deletion of 9q34.11, including *DNM1* and *SPTAN1* but lacking *STXBP1*, causes a distinctive phenotype including dysmorphic facial appearance and ID.

**2973W**

**Detection of pericentric inversion of Y chromosome in an infant with Pierre Robin syndrome: A case report.** R. Pattarkine, C. Kumar. Westchester medical center, valhalla, NY.

Sox 9 (SRY box-9) is a protein coding gene located on chromosome 17; It acts during chondrocyte differentiation and regulates transcription of the anti-Muellerian hormone (AMH) gene. Deficiencies lead to the skeletal malformation syndrome Campomelic dysplasia, Pierre robin syndrome and frequently with sex reversal. Here we present a case of a male baby born to a mother with phenylketonuria at 38 weeks of gestation with multiple dysmorphic features and Pierre robin syndrome. Upon further evaluation multiple abnormalities like anemia, low fibrinogen, elevated PT/PTT, LDH, liver enzymes and bilirubin were identified. Because of the phenotypic abnormalities, the chromosomal microarray and the cytogenetic investigations were indicated. The microarray analysis performed on peripheral blood did not identify any clinically relevant copy number changes or regions with absence of heterogeneity. Chromosome analysis performed on GTG banded metaphases prepared from cultured lymphocytes shows baby's karyotype as 46,X,inv(Y)(p11.2q?11.23~q12). The Fluorescence in situ hybridization (FISH) test was performed to characterize the inversion breakpoints of inv(Y) chromosome. FISH analysis using Y-chromosome specific probes (alpha satellite (DYZ3)/satellite III (DYZ1) and LSI SRY probes) revealed that one copy of sex determining region (SRY) probe was in the expected position, one copy of centromeric probe in the metacentric position whereas two copies of the Y-heterochromatin probe, one at the expected Yq region and the other at the short arm of the Y chromosome confirming the pericentric inversion of Y chromosome with breakpoints on the short arm at p11.2 and on the long arm at the proximal heterochromatin region of q12. Paternal blood chromosome analysis could not be performed to confirm if this rearrangement is familial or de novo in origin. The pericentric inversion of Y chromosome is a heritable normal variant and may be associated with any phenotypic manifestations or fertility problems. In some rare cases, reduced fertility or phenotypic abnormalities related to sex determination are associated with deletion or disruption of genes located in the inverted area. The FISH results confirmed that the baby had a pericentric inversion characterized as 46,X,inv(Y)(p11.2q12). Finally, our question, whether specific inversion breakpoints are indicative for impaired fertility, remains open as no clear genotype-phenotype correlation has been shown up till now.

**2974T**

**Cerebral white matter abnormalities in 6p25 deletion syndrome.** I.M.

Bader<sup>1</sup>, I. Reindl<sup>2</sup>, G. Sander<sup>1</sup>, G. Kronberger<sup>1</sup>, C. Rauscher<sup>2</sup>, J. Koch<sup>2</sup>, J. Atzwanger<sup>2</sup>, O. Rittinger<sup>1</sup>, E. Haschke-Becher<sup>2</sup>, W. Sperl<sup>2</sup>. 1) Division for Clinical Genetics, Paracelsus Medical University Salzburg, Austria; 2) Department of Pediatrics; Paracelsus Medical University, Salzburg, Austria; 3) University Institute of Medical and Chemical Laboratory Diagnostics, Salzburg, Austria.

We report the phenotype and genotype of a 4 years and 11 months old boy who was transferred to hospital after an accident. CT-scan and cMRI showed a cranial fracture as a result of the accident and two incidental findings: 1) large bifronto-temporal arachnoidal cysts and 2) multifocal white-matter-lesions involving the periventricular, deep, and subcortical cerebral white matter. The clinical phenotype of the boy included mild developmental delay, strabismus, slightly dysmorphic features and mild hearing impairment. Molecular karyotype from a blood sample detected a ~ 3,9 Mb heterozygous microdeletion in 6p25.3 - 6p25.2 deleting 34 genes, 18 of which were OMIM annotated including the transcription factor *FOXC1*. Microdeletions in 6p25 are thought to be associated with a distinctive clinical phenotype – the 6p subtelomeric deletion syndrome – that includes sensorineural hearing loss, anterior chamber eye defects, cardiac defects, developmental delay and other developmental and behavioral abnormalities, hypotonia, hip dysplasia, cerebellar abnormalities and a characteristic facial appearance. Few reports exist that describe multifocal T2-weighted and FLAIR abnormalities involving the periventricular, deep, and subcortical cerebral white matter associated with the 6p25 deletion in young children and in adults. From our case and from the review of the literature we conclude that a microdeletion in 6p25 should be considered as the cause for unclear multifocal cerebral white matter abnormalities in patients that in addition have dysmorphic features and multiple congenital anomalies even when intellectual abilities are within the normal range (Vernon et al. 2013).

**2975F**

**Consecutive medical exome analysis at a tertiary center: Diagnostic and health-economic outcomes.** R. Kosaki<sup>1</sup>, M. Kubota<sup>2</sup>, T. Uehara<sup>3</sup>, H. Suzuki<sup>3</sup>, T. Takenouchi<sup>3</sup>, K. Kosaki<sup>3</sup>. 1) Divisions of Medical Genetics, National Center for Child Health and Development, Tokyo, Japan; 2) Divisions of Neuology, National Center for Child Health and Development, Tokyo, Japan; 3) Center for Medical Genetics, and Department of Pediatrics, Keio University School of Medicine, Tokyo, Japan.

**Background:** The utility of whole exome analysis has been extensively demonstrated in research settings, but its clinical utility as a first-tier genetic test has not been well documented from diagnostic and health economic standpoints in real-life clinical settings. Both pediatricians and health policy makers are in need of such data. **Methods:** We performed medical exome analyses focusing on a clinically interpretable portion of the genome (4813 genes) as a first-tier genetic test for 360 consecutive patients visiting a genetics clinic at a tertiary children's hospital in Tokyo, Japan, over a 3-year period. Bioinformatics analyses were conducted using standard software including BWA, GATK, and SnpEff. **Results:** A molecular diagnosis was made in 171 patients (47.5%) involving a total of 107 causative genes. Among these 107 causative genes, 57 genes (53%) were classified as genes with potential organ-specific interventions and management strategies. Hence, clinically relevant results were obtained in approximately a quarter of the patients (92 out of 360). The estimated cost for a singleton medical exome analysis per patient was comparable to the average cost of brain magnetic resonance imaging (MRI) scans and G-band chromosome analyses spent prior to participation in this study, even though these analyses were non-contributory to the diagnosis.

**2976W**

**Genetic testing in pediatric dentistry: A new way of thinking about oral health care.** E. Severin<sup>1</sup>, R. Baltag<sup>2</sup>. 1) Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2) Profildent, Bucharest, Romania.

**Background.** By definition, genetic testing is a type of medical test that identifies changes in genes, chromosomes, or proteins. The results of a genetic test can confirm or rule out a suspected genetic condition or help determine a person's chance of developing or passing on a genetic disorder. Understanding variability between individuals allows for more targeted or personalized health-care based on genetic differences. Literature review provided many examples of gene mutations that cause isolated inherited dental anomalies, mutations with pleiotropic effects and of genetic testing for oral cancer susceptibility and presymptomatic diagnosis of periodontal disease. The great majority of dental health specialists recognize the importance and potential of genetics and genomics in the future, but little has been done to incorporate genetic testing extensively in clinical practice. **Objective.** In this paper, we discuss the current status of genetic testing properly applied in pediatric patients with oral health problems. We highlight successful strategies for gene identification into our dental clinical practice. **Methods and Patients.** Children with syndromic oro-dental anomalies were investigated. Clinical and radiographical assessments were performed, followed by detailed investigation into the personal and family medical history of the patients with cherubism, cleidocranial dysplasia, osteogenesis imperfecta and Fabry disease. Molecular tests were performed as well. **Results.** The research focused on four rare monogenic disorders caused by mutations in SH3BP2, RUNX2, COL1A2, and GLA genes. The selected monogenic diseases are known to involve oral and dental anomalies in permanent dentition. Different severity of oro-dental phenotypes were found. Micrognathia was associated with dental anomalies and malocclusion. Tooth number anomalies were noticed in two forms, agenesis and multiple supernumerary teeth. Enamel hypoplasia, premature and delayed eruption, and dental size anomalies were noticed as well. The patterns of oral and dental anomalies revealed previously described features, but also individual findings. **Conclusion:** Genetics has the potential to shape the dental education and practice. In the context of precision medicine, the dentists have to integrate the tools of genetics in their dental practice for prediction, prevention and personalized dental therapy. .

**2977T**

**An amplicon panel for the detection of Noonan syndrome (NS).** *M. Shafiekhani, R. Hrdlickova, J. Nehyba, D. Fox, R. Blidner.* Bioo Scientific, a PerkinElmer Company, Austin, TX.

A class of human genetic syndromes, RASopathies, is caused by germline mutations in genes of the Ras/mitogen activated protein kinase (MAPK) pathway. This pathway plays an important role in the regulation of the cell cycle, differentiation, and growth; therefore, it is at the center of many clinical research activities. Noonan syndrome (NS), one form of RASopathy, is an autosomal dominant disorder that prevents normal development in various parts of the body. It is typically characterized by unusual facial characteristics, short stature, congenital heart defects, blood clotting deficiency, developmental delays, and malformations of the bones of the rib cage. Individuals with NS also have an increased risk of cancer. The incidence of NS is approximately 1/1000 to 1/2500 newborns. At present, the most common genes associated with NS are *PTPN11*, *KRAS*, *SOS1*, and *RAF1*. We developed a panel with 90 amplicons to cover all of the coding exons of all isoforms of *PTPN11*, *KRAS*, *SOS1*, and *RAF1* genes with a 25 bp of buffer at the exon-intron boundaries. Amplicon sizes are between 92- 237 bp. The prepared libraries were validated with GIAB (Genome in a Bottle) on the Illumina® MiSeq® instrument. All targeted regions were successfully sequenced with 100% uniformity at  $\geq 0.1\times$  mean coverage, and  $\geq 99.3\%$  of the reads mapped to the targeted regions. The primer designs and library preparation method are platform-agnostic, with the exception of the instrument-specific adapters, and would easily allow compatibility with the Ion Torrent™ platform. The poster will also review the assay's ability to detect previously described mutations in *PTPN11*, *KRAS*, *SOS1*, and *RAF1* genes in other reference samples. The Noonan Syndrome Panel covers a 15.5 kb region and allows for the detection and differentiation of critical mutations associated with NS in a clinical research setting. This panel could serve as a base for larger panels that would also detect other, less frequent forms of RASopathy. Research use only. Not for diagnostic use.

**2978F**

**L1CAM partial deletion in a Polish family with X-linked hydrocephalus: Clinical and molecular characterization.** *M. Mlynek, A. Cie&scute;likowska, D. Wicher, M. Krajewska-Walasek, K. Chrzanoska.* Department of Medical Genetics, Children's Memorial Health Institute, Warsaw, Poland.

L1 syndrome describes a group of overlapping X-linked disorders caused by mutations in *L1CAM* located at Xq28. Clinical phenotypes within L1 syndrome include X-linked hydrocephalus with stenosis of the aqueduct of Sylvius (HSAS); mental retardation, adducted thumbs, shuffling gait, and aphasia (MASA) syndrome; spastic paraplegia type 1; and agenesis of the corpus callosum. Hundreds of mutations in *L1CAM* have been reported, however, only a few large gene deletions have been documented. Here we report on the clinical and molecular characterization of a four-generation Polish family in which six of the nine male members suffer from congenital hydrocephalus, short stature, microcephaly, strabismus, scoliosis, adducted thumbs, clubfoot, intellectual disability, aphasia, shuffling gait, and spasticity. Based on clinical and medical history (consistent with X-linked inheritance) a diagnosis of MASA syndrome was made. Additional features observed in the affected members include generalized seizures, cryptorchidism, intestinal obstruction or Hirschprung's disease. Initial failure of *L1CAM* gene sequencing suggested the possibility of a large rearrangement. Further whole-genome oligonucleotide microarray analysis revealed a 3.777-base pair hemizygous deletion within Xq28. The deleted region encompasses exons 3–5 of *L1CAM* with genomic coordinates chrX:153136766-153140542; GRCh37. This is the first report of array CGH used to diagnose partial *L1CAM* deletion. Given our results and other reported individuals with entire or partial *L1CAM* deletion, it appears that large gene rearrangements cause a more severe phenotypic expression of L1 syndrome. In this family, array CGH analysis was performed to detect asymptomatic female carriers. The identification of *L1CAM* deletion in family members with MASA syndrome will give them an opportunity for DNA-based counseling and precise prenatal diagnosis for all future pregnancies in this family, where appropriate. This study was supported by CMHI Grant No M23/17.

**2979W**

**Molecular characterization of complex ring chromosome 11 in an infant with multiple congenital anomalies.** R.S. Ebrahim<sup>1,2</sup>, B. Kettinger<sup>2</sup>, M. Hankered<sup>2</sup>, M. Kristofice<sup>2</sup>, A.I. Ahmed<sup>1,2</sup>. 1) Wayne State University school of Medicine, Detroit, MI, USA; 2) Detroit Medical Center University Laboratories, Cytogenetic, Detroit, MI USA.

Ring chromosome 11 is an uncommon chromosomal abnormality reported in at least 20 cases in the literature. We report on the cytogenetic and molecular characterization of a rare, atypical, and complex ring chromosome 11 with deletions and duplications affecting both arms in an infant with multiple congenital anomalies. The infant was born at 40 weeks gestation to a 20 year old G2P1 mother. The pregnancy was complicated by gestational diabetes that was identified within the last three weeks of pregnancy. The infant presented with hypotonia, hypoglycemia, respiratory distress, dysmorphic features, cardiac defects, and was found to have a ring chromosome 11 on routine chromosome analysis shortly after birth. Follow-up array-CGH testing revealed two interstitial duplications and two terminal deletions, one at either end of the ring chromosome 11: 46,XX,r(11)(p15.5q25).arr[GRCh37]11p15.5(205827\_766624)x1,11p15.5p15.4(873973\_8011711)x3,11q24.3q25(130341685\_131845433)x3,11q25(131855948\_134928849)x1. The deletion at 11q25 overlaps the Jacobsen syndrome region and includes the *JAM3* gene implicated in congenital heart defects as well as, the *OPCML* and *NTM* genes associated with intellectual disability. The duplication at the 11p15.5-p15.4 overlaps with the Beckwith-Weidemann syndrome (BWS)/Silver-Russell syndrome (SRS) critical region. This is the first case report of a ring chromosome 11 with deletions and duplications overlapping the Jacobsen syndrome and the BWS/SRS critical region. This case demonstrates the effective use of array CGH for the diagnosis of ring chromosome 11 and the characterization of a complex phenotype for clinical management.

**Beckwith-Wiedemann syndrome and Jacobsen syndrome caused by 11p duplication and 11q deletion inherited from paternal pericentric inversion.** S. Lim<sup>1</sup>, E. Seo<sup>1,2</sup>, H. Yoo<sup>1,3</sup>, B. Lee<sup>1,3</sup>, C. Seol<sup>1,2</sup>, J. Lee<sup>1</sup>, J. Lee<sup>4</sup>. 1) Medical Genetics & Genomics Center, Asan Medical Center; 2) Department of Laboratory Medicine, Asan Medical Center; 3) Department of Pediatrics, Asan Medical Center; 4) Asan Institute for Life Sciences, Asan Medical Center.

We report on a female infant with a paternally derived recombinant chromosome 11 of 11p duplication and 11q deletion. This infant showed lung hypoplasia, generalized skin edema, polyhydramnios, club foot, DORV and VSD in prenatal ultrasound. At birth, the infant had respiratory problem. The conventional karyotype was 46,XX,rec(11)dup(11p)inv(11)(p15.1q24.2). Methylation-specific MLPA (MS-MLPA) result of genes located on 11p showed duplication of *H19* and *KCNQ1* alleles, and normal level of *KCNQ1* alleles and an increased level of *H19* alleles in methylation status, suggesting duplication of paternal alleles. The karyotype of the father showed the pericentric inversion of chromosome 11. In addition, array-CGH was performed in order to define the copy number changes more precisely and to rule out other chromosomal rearrangements. We identified an 11p15.5p14.3 duplication of 23.6 Mb and an 11q23.3q25 deletion of 13.8Mb. This finding is associated with Beckwith-Wiedemann syndrome (BWS) and Jacobsen syndrome (JBS). This patient presented with craniofacial features consistent with JBS: microcephaly, down slant palpebral fissure, webbed neck, low set ears. The others manifestations were thrombocytopenia, neutropenia, infection and double-outlet right ventricle (DORV) with VSD, interruption of central pulmonary artery. Meanwhile the clinical findings of BWS were polyhydramnios, macrosomia, splenomegaly, and renal abnormality with several cysts. Chromosome analysis, molecular test and array-CGH analysis for the diagnosis of syndromes will provide us with integrated insight into these complex rearrangements and the underlying mechanisms.

**2981F**

**Brazilian experience of 22q11.2 deletion syndrome: Clinical variability and immunodeficiency.** M.M. Montenegro<sup>1</sup>, E.A. Zanardo<sup>1</sup>, J. Damasceno<sup>1</sup>, D.C.Q. Soares<sup>2</sup>, G.M. Novo-Filho<sup>1</sup>, A. Nascimento<sup>1</sup>, L. Liro<sup>1</sup>, Y. Gasparini<sup>1</sup>, A.T. Dias<sup>1</sup>, S.N. Chehimi<sup>1</sup>, F.A.R. Madia<sup>1</sup>, O.S. Akli<sup>1</sup>, C.A. Kim<sup>2</sup>, M.M.S. Sampaio<sup>3</sup>, L.D. Kulikowski<sup>1</sup>. 1) Laboratório de Citogenômica, Departamento de Patologia, Faculdade de Medicina FM, São Paulo, Brazil; 2) Unidade de Genética, Departamento de Pediatria, Instituto da Criança, Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, São Paulo, SP, BR; 3) Departamento de Pediatria, Instituto da Criança, Hospital das Clínicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo, São Paulo, SP, BR.

The 22q11.2 deletion syndrome (22q11.2DS) is the most common microdeletion syndrome estimated in approximately 1 in 4,000 births. The spectrum of 22q11.2DS DiGeorge syndrome, also include Velocardiofacial, Cayler's Cardiofacial Syndrome and conotruncal face anomalies. Classical clinical manifestations of a deletion in 22q11.2 include congenital cardiac anomalies, typical facies with prominent ears and enlarged nasal bridge and immune deficiency such as T cell lymphopenia. The variability of clinical manifestations encompassing altered genomic between 0.7 to 3 million Mb. We studied 63 Brazilian patients followed in the Genetics Unit of the Instituto da Criança HCFMUSP (Brazil). Cytogenomic study of the microdeletion was performed by MLPA using P064, P356 and P250 kits and array technique with CytoSNP-850K BeadChip. Clinical manifestations were collected in collaboration of Medical Geneticists and Immunogeneticist. To assess immunocompetence, tests with specific panel of antibodies were performed. Breakpoint size of del 22q11.2 was mapping in all patients. Typical deletions were found in 54 patients (3Mb) and atypical deletions in nine patients (2.3 Mb). The most prominent clinical characteristic observed both in patients with typical and in atypical deletions was neuropsychomotor development delay (NPDD - 22/63), High palate (14/63), tetralogy of Fallot (11/63), Repeat Infections (11/63), short stature (11/63) and others. The immunological analysis demonstrated alteration in the NK cells with elevated relative values of NK cells and NK CD161+ cells and low levels of NK CD4+ and NK CD8+ cells when compared to healthy controls. Clinical features of varying degree of expression occur in all patients, however all present NPDD and tetralogy of Fallot. The size of the deletion suggest that the variability is due to the loss of important genes that participate in the biological process of tissue and organ formation. In addition, such structural alteration may cause changes in chromatin conformation or impairing the function of other genes, affecting the expression of other genes involved in the pathogenesis of the 22qdel11.2. Lastly, the immunodeficiency observed in our patients with 22q11.2DS could be associated with B-cell defects and also NK-cell abnormalities. A multidisciplinary approach including cytogenomics and accurate immunological studies can improve the management of these patients and a better understanding of complexities in 22q11.2DS.

**Integrated genomic and epigenomic analysis of CNVs involving the *NFIX* locus.** M.L. Duque Lasio<sup>1</sup>, I. Amarillo<sup>2</sup>. 1) Department of Pediatrics, Washington University School of Medicine, St. Louis, MO; 2) Cytogenetics and Molecular Pathology Laboratory, Division of Laboratory Medicine, Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, MO.

**Introduction:** *NFIX* (nuclear factor I/X, MIM #164005) encodes for a highly conserved protein that has an N-terminal DNA binding domain and a C-terminal activation/repression domain. Sequence variations and microdeletions in *NFIX* are associated with allelic disorders Sotos syndrome 2 (Sotos 2) (aka Malan syndrome) and Marshall-Smith syndrome. Recently, a 19p13 microduplication including *NFIX* was reported in patients with phenotypic features described to be reciprocal to Sotos 2. This study aims to identify small deletions and duplications (<200 kb) involving *NFIX*, further characterize the genomic and epigenomic features of such CNVs, and correlate with the phenotypic findings. **Methods:** We performed a retrospective study using CMA data from patients referred to our clinical laboratory from 2008 to 2017 (n=4,700). Using the Affymetrix Chromosome Analysis Suite analysis software, a 1 kb/1 probe CMA filter was used to capture CNVs involving the *NFIX* locus (19p13.12 in hg19). Small CNVs were verified by qPCR. We aligned CNVs from published reports and DECIPHER database with those from our patient set. We performed genotype-epigenotype-phenotype analysis on small CNVs with breakpoints within *NFIX* and on CNVs encompassing the entire gene using the UCSC Genome and the WashU EpiGenome browsers. **Results:** We identified four duplications, two deletions and one concurrent deletion/duplication within our data set. Patients with deletions had phenotypic findings consistent with Sotos 2 syndrome. All duplications occurred in exon 1, and associated phenotypic findings were not consistent with the recently described 19p13 duplication syndrome. Alu-rich regions in exons 6 and 7 of *NFIX* have been implicated as hotspots for CNVs. Our study revealed Alu-repeats at recurrent breakpoints within introns 1, 2 and 9, suggestive of potential novel hotspots for CNVs. These small intervals also revealed significant genomic and epigenomic marks distributed across *NFIX* that are involved in spatiotemporal regulation, e.g. multiple CpG islands, repeat elements such as Alu SINEs, DNA and histone methylation, and enhancer/repressor regions. **Conclusion:** Our retrospective high-resolution CMA integrated with salient genomics and epigenomics data may improve the diagnostic yield and enhance the clinical management of patients with *NFIX*-related disorders.

**Clinical interpretation of regions of homozygosity identified by SNP arrays in consanguineous families.** J. Levy<sup>1,2</sup>, C. Dupont<sup>1</sup>, M. Rachid<sup>1</sup>, B. Benzacken<sup>1,2</sup>, Y. Capri<sup>1</sup>, S. Drunat<sup>1</sup>, F. Guimiot<sup>1,2</sup>, P. Gressens<sup>2</sup>, S. Grotto<sup>1</sup>, D. Haye<sup>1</sup>, S. Passemard<sup>1,2</sup>, L. Perrin<sup>1</sup>, A. Maruan<sup>3,4</sup>, F. Renaldo<sup>5</sup>, M. Schiff<sup>6</sup>, M-A. Thaly<sup>1</sup>, A. Verloes<sup>1,2</sup>, E. Pipiras<sup>1,2</sup>, A-C. Tabet<sup>1,4</sup>. 1) Department of Genetics, AP-HP, Robert-Debre University Hospital, Paris, France; 2) INSERM UMR1141, Robert-Debre University Hospital, Paris Diderot University, AP-HP, Paris, France; 3) Department of Child and Adolescent Psychiatry, Robert Debré University Hospital, AP-HP, Paris, France; 4) Human Genetics and Cognitive Functions, Pasteur Institute, Paris, France; 5) Department of Child Neurology, Robert Debré University Hospital, AP-HP, Paris, France; 6) Reference Center for Inborn Errors of Metabolism, Robert Debré University Hospital, AP-HP, Paris, France.

Inbreeding is a common cultural practice in many parts of the world. Children born in these families have regions of homozygosity (ROHs) and an increased risk of autosomal recessive disease. SNP array allows whole genome analysis to identify both copy number variants (CNVs) and ROHs. These ROHs indicate ancestral homozygosity, uniparental disomy, or parental consanguinity depending on the size, the location and the chromosome(s) involved. In the context of several genetic disorder in children of consanguineous parents, the identification of the causal gene can be difficult given the great genetic and clinical heterogeneity. In these families, the mutated gene in the homozygous state is frequently found in a ROH. When SNP array revealed no genomic imbalances, we performed a clinical interpretation of ROHs in 213 patients with a broad range of clinical indications including intellectual disability, developmental delay, multiple congenital anomalies, or autism spectrum disorder. We analyzed these regions in order to identify genes that could be implicated in recessive pathology concordant with patients' phenotype. The analysis of ROH using the software "SNP array evaluation tool v3.0" found the mutated gene in 26/213 patients (12,2%). We further analyzed 30 multiplex families in which both affected and unaffected siblings were recruited. We studied common ROHs shared by affected patients, excluding ROHs present in unaffected siblings. Based on key words describing our patients' phenotype, we searched for OMIM genes implicated in recessive diseases concordant with the phenotype and selected candidate genes. ROHs analysis successfully lead to a diagnosis in 8/30 families (26,7%) in 15 patients. Finally, we performed whole exome sequencing in 7 selected multiplex families in which the ROH analysis was non-contributory and identified the causal gene in two out of three families analyzed. We identified two novel pathogenic variants in *ERBB3* reported to cause lethal congenital contractural syndrome 2 (MIM # 607598). The analysis of the remaining 4 families is currently ongoing. The diagnosis of genetic and chromosomal disorder in a context of consanguinity, ROH analysis must be considered in order to sequence the gene of interest, or to target WES analysis. Our strategy improves the efficiency of genetic diagnosis in a more targeted and cost-effective way.

**Using array-based comparative genomic hybridization to diagnose Pallister-Killian syndrome: Are we there yet?** I. Marcussi, C.M. Lourenco, J. Peral, K. Romanin, M.C. Silva. CENTRO UNIVERSITARIO ESTACIO DE RIBEIRAO PRETO, Ribeirao Preto, Sao Paulo, Brazil.

**Introduction** Pallister-Killian syndrome (PKS) is a rare genetic disorder characterized by craniofacial dysmorphisms including a prominent forehead with sparse frontotemporal hair and a wide range of developmental delays, intellectual disability, hypotonia, seizures, skin pigmentation, and other systemic anomalies **Material/Results** Here we describe two unrelated patients with PKS whose array CGH results pointed out to different results, maybe reflecting the degree of mosaicism that could be foreseen by skin pigmentation features **Discussion** Analysis of skin fibroblasts or buccal smears has been proposed as a diagnostic gold standard, but this notion is still controversial. To many experts, a skin biopsy sample should continue to be the diagnostic gold standard for PKS because of the variable and insufficient quality of buccal smears. Nonetheless, more and more it has been showed that in patients with suspected PKS, array CGH or FISH analysis of buccal smear cells seems to be the first diagnostic choice because these two methods are reliable, rapid, and noninvasive. So, skin biopsy should only be performed if buccal-smear analysis cannot detect i(12p) **Conclusion** PKS is a rare multisystem disorder that is difficult to diagnose prenatally and in early infancy. Suspicion of PKS can be made by physical examination if characteristic dysmorphic features and global developmental delay are present. Array CGH can be used to diagnose PKS in early infancy and during the prenatal period. Clinicians can also employ FISH analysis to diagnose this disorder in patients with visible PKS features. Subsequently and only if buccal smear analysis fails to produce results, then a skin biopsy is warranted.

**2985W**

**Genotyping by NGS of 1200 known pathogenic mutations for extensive carrier screening of 228 monogenic recessive diseases helps avoid reporting VUS.** *D. Bercovich<sup>1</sup>, S. Horn-Saban<sup>2</sup>, R. Gershoni<sup>2</sup>.* 1) Human Molecular Genetics, Tel Hai Colleleg, Tel Hai, Israel; 2) Galile Genetic Analysis lab, Kazarin, Israel.

Full sequencing of genes related to monogenic recessive diseases revealed lots of VUS (variants of unknown significance) per individual which there are diabetes if they should be reported or not as there clinical significance is unclear. To avoid this problem, we generated a genotyping method using NGS of about 1200 known pathogenic mutations which are known to be related to the 228 most common monogenic recessive diseases in the Israeli and European populations. More than 80% of mutations are known rare mutations which are not screened by genetics labs on regular basis. As all the clinical information on these 1200 mutations is fully known, the TAT of summery letters is reduce to half the time, in comparison to full genes sequencing, as there is no need to address VUS and analyze their clinical significance. In screening several hundred healthy individuals and couples it was found that the carrier rates amounted to 1 to 2 mutations per DNA sample with an average of 1.3 mutations. To increase the genetic test sensitivity we added the SMA, FRAX (only women) and 6 most common microdeletions in the CFTR, GJB6, MCOLN, NEB, GALT & PAH genes as well. It was found that about 0.001% of couples were both carriers of different mutations in the same gene which can lead to approximately  $7.5 \times 10^{-5}$  offsprings with genetic diseases out of all births per year in Israel. These results indicate the importance of extensive genetic panel for common monogenic diseases for the detection of known recessive mutations in the general population and prevention of sick babies being born. We advise that such extensive genetic mutations panel will be applied as routine pre-conceptual screening, and should be followed by genetic counseling.

**2986T**

**Distribution of MYCN pathogenic variants in Feingold syndrome 1.** *S.M. Kirwin<sup>1</sup>, K.M.B. Vinette<sup>1</sup>, S.E. Mora<sup>1,2</sup>, K.M. Robbins<sup>1</sup>, K.W. Gripp<sup>1,2</sup>, V.L. Funanage<sup>1</sup>.* 1) Molecular Diagnostics Laboratory, Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE; 2) Division of Medical Genetics, Nemours/Alfred I. duPont Hospital for Children, Wilmington, DE.

*MYCN* is a proto-oncogene and member of the MYC family. Located on chromosome 2p23-2p24, it encodes a transcription factor with a basic helix-loop-helix region. Somatic variants within *MYCN* are primarily known to cause neuroblastoma and retinoblastoma. Feingold syndrome 1 (FGLDS1; OMIM 164280) is an autosomal dominant disorder associated with heterozygous germline variants or deletions in *MYCN* leading to haploinsufficiency of the protein. These variants in *MYCN* have been identified in patients with microcephaly; short stature; short palpebral fissures; digital anomalies (thumb hypoplasia; brachymesophalangy 2 and 5; toe syndactyly 2-3 or 4-5); variable intellectual disability (spectrum from normal intelligence through mild-moderate disability); and 20-40% of patients may also present with esophageal atresia or tracheal esophageal fistula, cardiac or renal anomalies. We present a review of novel and previously reported variants found in an extensive cohort of FGLDS1 patients in our diagnostic laboratory including eight probands and two symptomatic parents. The preponderance of mutations are located within exon 3, as previously reported, and all variants found in exon 2 create an early termination of the protein due to a stop codon or frameshift variant. FGLDS1 is reported to have variable expressivity and further examination of family members found two parents with *MYCN* mutations, leaving 80% of this cohort predicted to be *de novo* in nature. Sequence analysis of *MYCN* is indicated in individuals with a phenotype suggestive of Feingold syndrome.

**The utility of a next generation sequencing panel in severe pediatric onset inherited diseases.** *E. Isik<sup>1</sup>, H. Onay<sup>2</sup>, T. Atik<sup>1</sup>, E. Canda<sup>3</sup>, O. Cogulu<sup>1,2</sup>, F. Ozkinay<sup>1,2</sup>.* 1) Subdivision of Pediatric Genetics, Department of Pediatrics, Faculty of Medicine, Ege University, Izmir, Turkey; 2) Department of Medical Genetics, Faculty of Medicine, Ege University, Izmir, Turkey; 3) Subdivision of Pediatric Metabolism, Department of Pediatrics, Faculty of Medicine, Ege University, Izmir, Turkey.

**Aim:** Mendelian diseases are very rare, with many of them are genetically heterogeneous. Despite this however, they collectively account for about 20% of infant mortalities and about 18% of pediatric hospitalizations. Targeted next generation sequencing provides simultaneous sequencing of many genes, and is therefore able to play; it has an important role in the genetic diagnosis of Mendelian disorders. The aim of this study is to evaluate the diagnostic rate of a targeted next generation panel in severe pediatric onset and genetically heterogeneous autosomal recessive diseases. **Material and Methods:** In this study, molecularly analyzed cases between March 2015 and November 2017 were evaluated retrospectively. All cases had originally been diagnosed using a next generation sequencing panel (TruSight Inherited Disease® Panel) on Illumina MiSeq platform. **Results:** A hundred and eighty five cases (175 affected, 10 carrier) were analyzed using TruSight Inherited Disease® Panel. Referral reasons for molecular analysis of the cases were: Inborn errors of metabolism (47.6%), genetic syndrome (23.9%), neurological disorder (7%), mental retardation / multiple congenital anomalies (5.9%) and others (15.6%). The molecular diagnostic rate of the next generation sequencing panel in all cases was 40%. The highest diagnostic rate was achieved in neurological disorders (69.2%). In the cases not having a clinical diagnosis prior to molecular analysis no pathogenic variant was found Fifty four mutations in 39 different genes, defined in 37 cases, were novel. **Conclusion:** This is the first study to evaluate the diagnostic effectiveness of on inherited disease panel (TruSight Inherited Disease® Panel). This targeted next generation panel achieved a high molecular diagnostic rate which provides the opportunity for advanced genetic counseling in severe pediatric onset and genetically heterogeneous autosomal recessive diseases. Comprehensive clinical examination is recommended to achieve specific clinical diagnosis for more efficient molecular analysis.

**Copy number variation analysis for newborn screening using genome-wide SNP array and its application study on Korean population.** *J.S. Bae<sup>1</sup>, J. Joo<sup>1</sup>, B.R. Park<sup>1</sup>, H.J. Kwon<sup>1</sup>, J. Kim<sup>1</sup>, H. Kim<sup>1</sup>, H. Im<sup>1</sup>, R.P. Mohanty<sup>1</sup>, A. Goyal<sup>1</sup>, S. Lee<sup>1</sup>, M.J. Kim<sup>2</sup>, M.S. Lee<sup>1,2,3</sup>.* 1) Eone-Diagnomics Genome Center, Inc., Incheon, Republic of Korea; 2) Diagnostics, Inc., 5775 Kearny Villa Rd., San Diego, CA 92123, USA; 3) Incheon National University, 119 Academy-ro Yeonsu-gu, Incheon, 22012, Republic of Korea.

Copy number variation (CNV) is the major cause of structural variation in the human genome, involving both duplications and deletions of sequences leading to several disorders. Analysis of neonatal CNV is crucial in managing CNV-related chromosomal disorders. In this study, we have developed and validated a newborn screening test for genomic abnormalities in 138 CNV-related chromosomal disorders. We used customized Illumina Infinium Global Screening Array (GSA) BeadChip (version 1), which includes 680,960 single nucleotide polymorphism (SNP) makers, and CNVs surveyed in 4507 Korean subjects. For CNV data analysis, we used our own analytical pipeline. To confirm the analytical performance, we analyzed genomic DNA from 22 human cell lines with CNV and successfully detected all corresponding CNV regions using our analysis pipeline. In total, 4507 newborn screenings were conducted with this developed test. The CNVs related to genetic disorders were identified in 69 cases (1.53%) with 27 disorders. The most frequently detected region for microdeletions were 2q13 Joubert syndrome-4, and the 15q11.2 deletion syndrome, corresponding to 11 out of 69 cases (0.244%) in each region. The next most frequently detected CNV region was 22q11.2 duplication syndrome in 7 cases (0.155%). CNVs in the CNV regions of 1q21.1 microdeletion syndrome, 16p11.2 duplication syndrome, 17q12 duplication syndrome, 17p13.3 microduplication syndrome, downsyndrome, triple X syndrome, and Klinefelter syndrome corresponds to 3 cases (0.067%) in each. The CNV regions related with 15 other syndromes were found in one case each (0.022%). In conclusion, genome-wide SNP array is useful and powerful method for detecting the neonatal CNV, by accurate screening and subsequently identifying the risk of the disease in advance, thereby discovering new etiologies.

**2989T**

**Copy Number Variations (CNVs) data from Brazilian patients with neuropsychomotor developmental delay and congenital malformations obtained through SNP array methodology.** L.P.G. Bertollo, E.A. Zanardo, C. Ae Kim, A.T. Dias, L.D. Kulikowski. Faculdade de Medicina da Universidade de São Paulo, Av. Dr. Arnaldo, 455, São Paulo, Brazil.

**Introduction and objectives:** neuropsychomotor developmental delay (NDD) associated with congenital malformations (CM) is a frequent condition in clinical practice that often remains undiagnosed. We investigated undiagnosed NDD/CM patients using the SNP array methodology, aiming to search for Copy Number Variations (CNVs) relevant to clinical phenotype, as well as describing the CNVs characteristics in this cohort of Brazilian patients. **Methods:** we studied SNP array and clinical data from 60 patients referred from a high complexity genetic outpatient clinic. The results were analyzed according to the American College of Medical Genetics guidelines using independent tests and were compared with the following databanks of CNVs: the Database of Genomic Variants, the Database of Chromosomal Imbalance and Phenotype in Humans Using Ensemble Resources and the UCSC Genome Bioinformatics database. The genomic positions are reported according to their mapping on the GRCh37/hg19 genome build. The CNVs were then classified as benign, pathogenic or VUS (variants of uncertain clinical significance) and a qualitative frequency analysis was performed. **Results:** in 27 patients (45%), at least one pathogenic CNV was found. In 19 patients (31.7%), only benign CNVs were found. In 4 patients, no pathogenic variants were found, but there was at least one VUS. In 10 patients, no CNVs were found. The chromosomes which presented a higher frequency of pathogenic CNVs were chr.4 (7 pathogenic CNVs, especially involving the 4q35 and 4p16 regions), chr.5 (6 pathogenic CNVs, specially involving the 5q35 and 5p15.33 regions), chr.9 (4 pathogenic CNVs, 3 in the 9p24 region) and chr.X (4 pathogenic CNVs, 3 in the Xq28 region). 44% of the pathogenic CNVs represented deletions. **Conclusions:** SNP array is an extremely useful tool for investigating patients with NDD/CM, providing a higher diagnostic conclusion rate for our patients compared to CGH Array (around 10-14% according to the literature). The accurate assessment of the CNVs in these patients consist of an important database with representative information from Brazilian people. **Funding Agency:** FAPESP - process 2017 / 21659-1.

**Precise breakpoint detection of balanced and unbalanced structural variation in whole genome sequencing data using haplotype blocks created by linked-reads.** J. Knijnenburg<sup>1</sup>, M. Kriek<sup>1</sup>, H.A. van Duyvenvoorde<sup>1</sup>, N. Pappas<sup>2</sup>, Y. Ariyurek<sup>3</sup>, H.P.J. Buermans<sup>3</sup>, K.M.L. Hertoghs<sup>1</sup>, M.E.Y. Laurensse-Bik<sup>1</sup>, K. Kuipers-Heijboer<sup>1</sup>, F. Baas<sup>1</sup>. 1) Clinical Genetics, LUMC, Leiden, Netherlands; 2) Biomedical Data Sciences, LUMC, Leiden, the Netherlands; 3) Human Genetics, LUMC, Leiden, the Netherlands; 4) GenomeScan, Leiden, the Netherlands.

**Introduction:** Routine diagnostics of genome wide balanced and unbalanced structural variation is still dependent on classical techniques such as karyotyping and (SNP-)array. Both techniques result in a rough breakpoint detection where especially karyotyping can result in significant misinterpretation of chromosomal breakpoints. New sequencing technologies such as long range haplotyping by mapping linked-reads to generate haplotype blocks (Chromium Genome Solution, 10x Genomics, San Francisco USA) are expected to overcome this problem, although repeat sequence elements at breakpoints in the genome may occasionally interfere with a precise detection. **Materials and Methods:** To test whether this NGS based approach with linked-reads is suitable for routine diagnostics, a small series of patients, including one with a de novo balanced translocation (8;17) and one with a duplication detected with SNP-array, were analysed. **Results:** The expected structural variants based on previous knowledge were identified and in both patients precise breakpoints of these variants could be detected. In the translocation patient, the breakpoint differed at least 15 Mb from the estimated breakpoint and proved SOX9 to be causative for the phenotype of the patient. In the second patient the orientation of the duplication fragment could be defined to be in tandem, making a gene disruption to be causal for the phenotype unlikely. **Conclusions:** Structural variant analysis using WGS with linked-reads promises to be a feasible technique for detection of balanced and unbalanced structural variants in the genome and may be a next step in replacing classical cytogenetic techniques for genome wide screening.

**2991W**

**FISH is still the most reliable diagnostic tool for Pallister-Killian syndrome: A case based review.** S. Tug Bozdogan<sup>1,2</sup>, A. Bisgin<sup>1,2</sup>, G. Ceylaner<sup>2</sup>, I. Boga<sup>2</sup>, S. Ozer<sup>2</sup>. 1) Cukurova University, Faculty of Medicine, Medical Genetics Dept of Balcali Hospital and Clinics, Adana, Turkey; 2) Cukurova University AGENTEM (Adana Genetic Disease Diagnosis and Treatment Center), Adana, Turkey; 3) Intergen Genetic Diagnosis Center, Ankara, Turkey.

**Objective:** Pallister-Killian syndrome is a rare sporadic genetic syndrome with distinctive dysmorphic features caused by chromosomal mosaicism of chromosome 12p tetrasomy. Estimated prevalence of disease is 5.1 per million in live birth with the 50% mortality rate during the first year of their lives. Clinical heterogeneity with short life time and tissue limited mosaicism make the diagnosis difficult. However, cytogenetic testing is the only methodology for genetic diagnosis. Though, due to the mosaicism cytogenetic analysis from leukocyte may not capture the abnormality. Therefore, proper clinical genetic evaluation is substantial for diagnosis with proper diagnostics. Within this case based presentation the diagnostic algorithm for a Pallister-Killian syndrome was reviewed from cytogenetics to far distant but misused of a whole exome sequencing. **Methods:** We report a 5-years old female patient who referred to our clinical genetics policlinics with dysmorphological features of overgrowth, macrocephaly and coarse face with intellectual impairment and developmental delay. Cytogenetics, molecular cytogenetics and whole exome sequencing was performed to the patient. **Results:** Firstly cytogenetic investigations from peripheral blood was performed with normal karyotype (46,XX). However as a next step diagnostics, whole exome sequencing was applied in another out patient clinics with no genetics specialist. During the follow up we performed the cytogenetics from skin biopsy. Finally, patient had a diagnosis with Pallister-Killian syndrome due to mosaic tetrasomy in chromosome 12p according to skin biopsy cytogenetic investigation and the result was confirmed with metaphase FISH on cultured skin fibroblasts (46,XX [18] / 47,XX, +i(12)(p10)[12], nuch ish (AMLx2) (ETOx4) [40/100]). **Conclusion:** Whole exome sequencing might be easily misused by non-experienced clinicians as a final solution for diagnosis. However, such cases as in Pallister-Killian syndrome, cytogenetic testing or FISH analysis are still the most reliable ones within the hands of medical/clinical geneticists.

Urofacial syndrome (UFS) or Ochoa syndrome (OMIM : 236730) is characterized by infantile onset of urinary bladder voiding dysfunction, abnormal facial movement with expression. A peculiar facial dysmorphism is related to an unusual inversion of facial expression that occurs when the child smiles or cries. Bladder voiding dysfunction increases the risk for urinary incontinence, megacystis, vesicoureteric reflux, hydroureteronephrosis, urosepsis, and progressive renal impairment. We applied whole exome sequencing technology to a 7 year old moroccan boy, born from consanguineous parents, presenting severe voiding dysfunction and a characteristic facial expression of UFS. By using a trio whole exome sequencing, we identified a homozygous nonsense mutation, c.1414C>T (p. Arg472\*) in exon 10 of *HPSE2* (which encode the protein Heparinase 2). The same variant has previously described like pathogenic by Saly et al. in one Turkish family. This mutation has been observed to lead to nonsense mediated decay of the transcript and absent protein. The gene is normally expressed in both the central nervous system and the bladder. The parents were both confirmed as heterozygotes for the mutation. We describe the second family in our knowledge with the homozygous nonsense mutation c.1414C>T in *HPSE2* causing Urofacial syndrome.

**Novel pathogenic mutation of *ST3GAL5* gene identified in Moroccan family with Salt and Pepper syndrome.** G. Egéa<sup>1</sup>, A. Zrhidri<sup>2</sup>, I. Cherkaoui Jaouad<sup>2,3</sup>, J. Lyahyai<sup>2</sup>, MC. Ferreira<sup>1</sup>, S. Kemeny<sup>1</sup>, P. Pugnieri<sup>1</sup>, E. Page<sup>1</sup>, P. Lochu<sup>1</sup>, A. Seffiani<sup>2,3</sup>. 1) Department of Medical Genetics, IMAGENOME, GEN-BIO Laboratory, Clermont-Ferrand, France; 2) Center of Human genomic, Medical and pharmacy faculty, Mohammed V University, Rabat, Morocco; 3) Department of Medical Genetics, National Institute of Health, Rabat, Morocco.

We identified an autosomal recessive Salt and Pepper syndrome characterized by severe intellectual disability, epilepsy with absence of speech, decreased eye contact, irritability and choreoathetosis in three siblings observed on consanguineous family, two brothers and one sister. In our study, whole exome sequencing was performed on one brother and sister affected and the parents unaffected. The analysis revealed a novel, homozygous missense mutation (c. 674C>T) in exon 5 of the *ST3GAL5* gene, resulting from p.Ala225Val (NM\_003896.3). Whole exome sequencing data was further validated using Sanger sequencing by designing the primers of the identified mutation. Moreover this mutation was found homozygous for the other brother affected. The *ST3GAL5* gene (OMIM : 609056) encodes for a sialyltransferase (also known as GM3 synthase) that synthesizes ganglioside GM3, a glycosphingolipid enriched in neural tissue. The gene might then have a role for normal brain function. Our report presents the results of the quartet exome data of both unaffected parents and their affected son and daughter with the phenotype describing the salt and Pepper syndrome. A homozygous missense variant in the *ST3GAL5* gene was identified as a candidate causal variant for the clinical phenotype in this family. The complementary investigation in analytical chemistry is ongoing in order to measure the plasma GM3, and its downstream metabolites, GD3 gangliosides. This case expanded the clinical and genetic spectrum of ultra-rare disease, Salt and Pepper Syndrome with *ST3GAL5* mutation.

**A pitfall in the molecular diagnostics of Kabuki syndrome: Functional redundancy of exon 15 in *KDM6A*.** S.K. Fiordaliso<sup>1</sup>, A. Otsubo<sup>1</sup>, A.L. Ritter<sup>1</sup>, L. Lulis<sup>2</sup>, S. Baker<sup>2</sup>, K. Helbig<sup>3</sup>, I. Helbig<sup>3</sup>, M. Dulik<sup>2</sup>, K. Izumi<sup>1,2</sup>. 1) Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Genomic Diagnostics, Children's Hospital of Philadelphia, Philadelphia, PA; 3) Division of Pediatric Neurology, Children's Hospital of Philadelphia, Philadelphia, PA.

The *KDM6A* gene encodes a histone demethylase and pathogenic variants in this gene are found in around 5-8% of individuals with Kabuki syndrome. Although *KDM6A* resides on the X-chromosome, it escapes X-inactivation, allowing Kabuki syndrome to occur in both female and male patients. While the introduction of comprehensive NGS-based genetic diagnostic testing has revealed a wider phenotypic spectrum for Kabuki syndrome, its phenotypic spectrum has yet to be defined. Occasionally, a genetic testing finding not consistent with the clinical findings creates a diagnostic dilemma. Here, we report a 12-year-old girl with developmental delay, moderate intellectual disability, short stature, autistic features, expressive speech and language disorder, and focal seizures beginning at age 4 years. Clinical trio exome sequencing identified a heterozygous, likely pathogenic *KDM6A* nonsense variant (NM\_021140.3, c.1519C>T; p.Gln507\*) that was paternally inherited and predicted to create a premature stop codon in the 15th of 29 coding exons, occurring upstream (5') of previously reported loss-of-function, disease-causing variants. Although this molecular finding was highly suggestive of Kabuki syndrome, neither the proband nor her father had any physical features suggestive of Kabuki syndrome. A lymphoblastoid cell line was established from the hemizygous father, and although quantitative RT-PCR revealed a lack of exon 15 transcript, exon 14 and exon 16 transcripts were still present, suggesting that *KDM6A* transcripts lacking exon 15 can compensate for the function of exon 15-containing isoforms. Therefore, we concluded that exon 15 of *KDM6A* is functionally redundant, and our patient's nonsense variant does not cause Kabuki syndrome nor explain her clinical findings. Despite evidence implicating *KDM6A* as a dosage-sensitive gene in humans, our findings suggest that exon 15 of *KDM6A* is functionally redundant, and that a variant introducing a premature stop codon in exon 15 does not cause Kabuki syndrome. From a molecular diagnostics standpoint, it is important to recognize that variants which seemingly result in loss-of-function may only affect a subset of gene isoforms and not critically affect a gene's overall function. As molecular diagnostic tools become more widespread, our finding emphasizes the importance of functional analysis and clinical correlation.

**Repeat expansion disorders in patients evaluated by clinical whole exome sequencing.** S. Gu<sup>1,2</sup>, J. Scull<sup>1,2</sup>, B. Yuan<sup>1,2</sup>, C. Shaw<sup>1,2</sup>, J. Zhang<sup>1,2</sup>, C. Eng<sup>1,2</sup>, Y. Yang<sup>1,2</sup>, P. Liu<sup>1,2</sup>. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, US; 2) Baylor Genetics, Houston, TX, US.

Clinical whole exome sequencing (WES) has been demonstrated to improve diagnosis and alter patient management by numerous large cohort studies. It has become a routine genetic testing approach, with a diagnostic yield of 25-45% based on different studies. One category of genetic diseases that may escape detection by WES is the repeat expansion disorder (RED). We retrospectively reviewed ~10,000 consecutive clinical WES patients analyzed between November 2011 and April 2018, and identified 446 patients who also underwent testing for potential REDs in our diagnostic laboratory. This included 9 patients tested for spinocerebellar ataxia type 1 (SCA1), 9 for SCA10, 31 for Friedreich ataxia (FRDA), 116 for myotonic dystrophy type 1 (DM1), 6 for dentatorubral-pallidoluysian atrophy (DRPLA), 257 for Fragile X syndrome (FMR1), 5 for Kennedy Disease (KD), and 13 for Huntington Disease (HD). Among these patients with a positive RED result, three had concurrent WES and RED testing due to suspected genetic disorders with a non-specific clinical presentation, including two patients with expansions on both alleles for FRDA and one patient with an expansion for DM1. Three patients had molecular diagnoses of REDs before being tested for WES, and WES was ordered due to additional phenotypes unexplained by their RED diagnosis. This included one patient with an expansion for SCA10, one patient with an expansion for FMR1, and one unusual patient with expansions on both alleles for DM1. One particular patient had DM1 testing after a non-diagnostic WES due to atypical DM1 presentation, yet she was found to have an allele with approximately 1350 repeats. Additionally, six patients had mutable/premutation/intermediate alleles for autosomal dominant/X-linked REDs, while two other patients were FRDA carriers, informing disease risk estimates for individual families. Our analysis demonstrated the importance of concurrent WES and REDs testing in a substantial proportion of patients. Recent advancement in computational algorithms demonstrated successful estimation of repeat numbers based on short-read whole genome sequencing (WGS) data (Dolzhenko E. *et al.*, Genome Res. 2017). Therefore, for patients with non-specific phenotypes that are not typical of well-characterized disorders, it is promising to identify the underlying various types genetic abnormalities, e.g. small nucleotide changes (SNVs), structural variations, copy-number variants and REDs, simultaneously by clinical WGS.

**2996F**

**Rapid turnaround whole exome sequencing for critically ill neonates.** C.S. Gubbels<sup>1,2,3,4</sup>, G.E. VanNoy<sup>2</sup>, D. Copenheaver<sup>5</sup>, S. Yang<sup>6</sup>, M. Wojcik<sup>1,2,3,6</sup>, N.B. Gold<sup>1,2</sup>, C. Genetti<sup>1,4</sup>, J. Stoler<sup>1,2</sup>, A.H. Beggs<sup>1,2,4</sup>, O. Bodamer<sup>1,2,3</sup>, J. Juusola<sup>5</sup>, P.B. Agrawal<sup>1,2,4,6</sup>, T.W. Yu<sup>1,2,3,4</sup>. 1) Division of Genetics and Genomics, Boston Children's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Broad Institute of MIT and Harvard, Cambridge, MA; 4) The Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston MA; 5) GeneDx, Inc., Gaithersburg, MD; 6) Division of Newborn Medicine, Boston Children's Hospital, Boston, MA.

In this study, we investigate the impact of applying rapid-turnaround trio-based WES in a cohort of critically ill neonates. Key inclusion criteria include corrected age <6 months, and one or more of the following clinical features: hypotonia, seizures, multiple congenital anomalies and/or a complex metabolic phenotype. Clinically relevant genomic variants (diagnostic of the phenotype, or otherwise relevant to the current hospitalization) are returned within seven days; no incidental findings are reported. Additional mitochondrial DNA (mtDNA) analysis is performed in cases when clinical suspicion warrants. 21 of 25 approached families decided to enroll. Families that declined cited reasons related to timing and privacy concerns surrounding genomics. One family withdrew after enrollment. To date, twenty WES and four additional mtDNA analyses have been performed. Sixteen out of these twenty cases (80%) received a definitive molecular diagnosis. In one additional case a variant contributing to the phenotype was found, and in another patient a strong candidate gene was identified. Fifteen of the diagnoses were found on rapid WES; the sixteenth arose from mtDNA analysis. Our patients were diagnosed earlier than cases of these disorders reported in the literature, and they had phenotypes on the severe side of the spectrum, especially for the metabolic and neuromuscular disorders. Outcome analyses demonstrate that in all cases the rapid result inspired one or more changes in management and/or had consequences for parents or other family members. Knowledge about the diagnosis and its prognosis prompted a shift to comfort care in half of the patients. Also, additional specialists were involved in the patients' care anticipating future needs. Other effects included medication changes, such as a switch in anti-epileptic drug leading to reduced seizure frequency in one patient, and the consideration of new experimental therapies in two others. For families with an inherited variant, consequences were mostly related to reproductive options for future pregnancies. In one family, mutation carriers were referred to cardiology for evaluation. This algorithm-driven approach identified candidate patients with a high likelihood of a diagnosis for rapid WES. These results suggest that rapid turnaround WES can lead to faster and more accurate diagnoses in neonates in the ICU setting, reduce unnecessary testing and procedures, and impact the course of medical care.

**Biallelic HDAC3 mutations in a patient with developmental delay, hypotonia and seizures.** A. Otsubo<sup>1</sup>, S. Yum<sup>2</sup>, L. Medne<sup>1</sup>, J. Balciuniene<sup>3</sup>, B. Krock<sup>2</sup>, K. Izumi<sup>1,3</sup>. 1) Division of Human Genetics, Children's hospital of Philadelphia, Philadelphia, PA; 2) Division of Pediatric Neurology, Children's hospital of Philadelphia, Philadelphia, PA; 3) Division of Genomic Diagnostics, Children's hospital of Philadelphia, Philadelphia, PA.

Gene regulation is a biological process essential to all organisms. Many neurodevelopmental disorders are associated with abnormalities in gene regulation. Histone deacetylase 3 (HDAC3) is one of the enzymes that controls gene expression by deacetylating histone proteins, leading to chromatin in transcriptionally inactive state. Previously, one individual with a primary seizure disorder was reported to have a *de novo* HDAC3 missense mutation. However, the association between HDAC3 mutation and genetic diagnosis has not been established yet. Here we report a patient with a severe epileptic encephalopathy with biallelic HDAC3 mutations. The proband is a 10 year-old female with severe and global developmental delays, hypotonia, periventricular heterotopias and intractable seizures. She developed infantile spasms at ~8 months of age that progressed to intractable myoclonic epilepsy. Brain MRI demonstrated subependymal gray matter heterotopias. Her initial presentation included hand-wringing and hand-mouthing behaviors, but she developed dyskinesia with choreoathetoid movements by ~18 months of age. Her length and weight have been below the 5th centile, although her head circumference measurements are in the normal range. Clinically, she was suspected of having a Rett syndrome, however, *MECP2*, *CDKL5*, *ARX*, and *FOXP1* sequencing was unremarkable. Exome sequencing revealed biallelic novel missense mutations (c.64C>G; p.H22D and c.317G>T; p.R106L) in *HDAC3* in the proband. Neither of these variants has been reported in healthy controls (ExAC or gnomAD). *In silico* prediction programs indicate that both missense variants are likely pathogenic. Although the proband here demonstrates some clinical overlap with the previously reported individual, her clinical symptoms are more severe. In our case, a heterozygous HDAC3 variant is seen in each of her healthy parents; therefore, the pathogenic mechanism of mutations may be different between the two cases. Interestingly, this proband was suspected of having Rett syndrome clinically, which is mainly caused by *MECP2* mutations. HDAC3 interacts with *MECP2*, and its genomic localization is compromised in Rett syndrome patient-derived cell lines. Therefore, biallelic mutations of *HDAC3* may have caused similar effects to those of *MECP2* mutations seen in Rett syndrome. In summary, we propose that the biallelic HDAC3 mutations may cause a novel neurodevelopmental disorder characterized by developmental delay, hypotonia and seizures. .

**The VetSeq study: A pilot study of expanded exome sequencing in the Veterans Health Administration.** J.L. Vassy<sup>1,2,3</sup>, L.E. Hull<sup>1</sup>, M.H. Crawley<sup>1</sup>, A. Muirhead Oza<sup>1</sup>, S. Amr<sup>1</sup>, P. Pomianowski<sup>1</sup>. 1) VA Boston Healthcare System, Boston, MA; 2) Department of Medicine, Harvard Medical School, Boston, MA; 3) Division of General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA; 4) Laboratory for Molecular Medicine, Partners HealthCare.

**Background** Whole exome sequencing (WES) is increasingly demonstrating utility in a range of clinical contexts. We conducted a pilot study of WES at VA Boston Healthcare System (VABHS), returning both indication-based and secondary results. **Methods** VABHS providers refer patients for indication-based WES via a research protocol. Patients complete baseline surveys and interviews, using validated instruments to measure genetic literacy, quality of life, and trust in the healthcare system. WES is performed at a CLIA-certified lab, and the WES report includes results related to the indication for testing, secondary pathogenic or likely pathogenic (P/LP) variants in >4600 genes associated with monogenic disease risk, carrier status variants, and pharmacogenomic results for 20 medications. The referring provider discusses the results with the patient and documents medical decision-making in the medical record. Patients complete follow-up interviews 3 months after receiving results. **Results** Two patients have enrolled to date. P1 is a 72-year-old man with a long history of sensory neuropathy and myalgias treated with chronic opioid therapy. In his interview, he hoped that WES would identify a diagnosis and possible treatment for his children and grandchildren, who suffer similar symptoms. WES identified a pathogenic p.Arg298Cys variant in *LMNA* associated with Charcot-Marie-Tooth hereditary neuropathy type 2. Although other *LMNA* variants are associated with dominantly inherited neuromuscular disease, the patient's variant was inconclusive for his symptoms because it is typically associated with autosomal recessive inheritance. He had no P/LP variants in any of the 59 actionable ACMG genes, but secondary heterozygous frameshift variants were identified in *KIAA0586* (Joubert syndrome 23) and *NPHP1* (nephronophthisis 1) and are awaiting assessment and Sanger confirmation. P2 is a 33-year-old woman with a history of severe thrombocytopenia in her and 1 of 2 sons. In her interview, she endorsed hope that WES would suggest a treatment to stabilize their platelet counts. WES identified a variant of uncertain significance in a conserved DNA-binding domain of *ETV6*, a gene that is often rearranged or fused with other genes in certain leukemias. Testing of family members to assess segregation is pending for both patients. Both endorsed high trust in VABHS. **Conclusions** It is feasible to use WES in clinical care at VABHS and study its impact on patient care and outcomes.

**FISH following aCGH analysis identifies unexpected results: Further support for FISH characterization of copy number changes.** S.G. Sulpizio<sup>1</sup>, S.A. Morton<sup>1</sup>, D.A. VanGundy<sup>1</sup>, V.M. Cawich<sup>1</sup>, K.A. Leiser<sup>1</sup>, A.J. Flage<sup>1</sup>, C. Burson<sup>2</sup>, K. Fry<sup>3</sup>, L.A. Bailey<sup>4</sup>, K.K. Bachmann<sup>3</sup>, L. Bailey<sup>3</sup>, L. Escobar<sup>3</sup>, K. Tsuchiya<sup>5</sup>, G. Bellus<sup>3</sup>, A. Seeley<sup>6</sup>, B. Salbert<sup>6</sup>, B. Torchia<sup>1</sup>. 1) Allele Diagnostics, Spokane, WA; 2) Rocky Mountain Hospital for Children at Presbyterian/St Luke's, Denver, CO; 3) Pediatric Genetics, Geisinger Medical Center, Danville, PA; 4) Genomic Medicine Institute/Maternal Fetal Medicine, Geisinger Health System, Danville, PA; 5) Medical Genetics & Neurodevelopmental Center, St. Vincent Hospital & Health Services, Indianapolis, IN; 6) Seattle Children's Hospital, Seattle, WA.

Array CGH (aCGH) analysis provides information regarding the size and gene content of copy number changes, but aCGH results are not always informative as to the chromosomal structure of the alteration. Our laboratory routinely employs fluorescence *in situ* hybridization (FISH) analysis to visualize alterations detected by aCGH. Samples from 416 unique probands with copy number changes identified by aCGH and specimens that could be cultured were analyzed using FISH with BAC probes to visualize chromosomal structure. Many copy number changes, such as recurrent deletions/duplications arising via non-allelic homologous recombination (NAHR), had predictable underlying chromosome structure; however, we identified unexpected complexities in 16 (3.8%) cases. In nine cases, FISH analysis revealed unexpected findings including insertions, cryptic translocations, and super-numerary marker chromosomes, after aCGH detected copy number changes of clinical significance or unclear clinical significance. In the additional seven cases, FISH analysis revealed cryptic insertions or translocations after aCGH detected copy gains that were expected to be benign based on gene content. Although the gene content of the inserted material remains not clinically relevant, these rearrangements may cause gene expression changes at or near the breakpoint sites. Our data is consistent with previously published reports which indicate that up to 3% of copy gains identified by aCGH represent insertions or other unbalanced rearrangements. Clarifying the structure of the aberration by FISH is helpful in determining the most appropriate parental follow-up testing and providing the most accurate genetic counseling, including estimating recurrence risk. This data provides additional evidence to support the importance of FISH to assess cryptic structural changes, which can contribute to abnormal phenotypes.

**3000W**

**Genome sequencing for NICU newborns across the south.** K.M. Bowling<sup>1</sup>, S.M. Hiatt<sup>1</sup>, C.R. Finnilla<sup>1</sup>, M.L. Thompson<sup>1</sup>, M.D. Amaral<sup>1</sup>, W.V. Kelley<sup>1</sup>, K.M. East<sup>1</sup>, D.E. Gray<sup>1</sup>, J.M. Lawlor<sup>1</sup>, L.G. Hendon<sup>2</sup>, H. Wienpahl<sup>1</sup>, B.M. Shaw<sup>2</sup>, A.C. Hurst<sup>3</sup>, R. Savich<sup>3</sup>, G.S. Barsh<sup>1</sup>, B.R. Korff<sup>2</sup>, G.M. Cooper<sup>1</sup>. 1) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 2) University of Alabama at Birmingham, Birmingham, AL; 3) University of Mississippi Medical Center, Jackson, MS; 4) Woman's Hospital, Baton Rouge, LA.

We here describe SouthSeq, a Clinical Sequencing Evidence-Generating Research (CSER2) effort to perform whole genome sequencing (WGS) for infants in neonatal intensive care units (NICUs) at hospitals in Alabama, Mississippi, and Louisiana. SouthSeq aims to sequence 1,500 newborn babies presenting with multiple congenital anomalies, or other signs of a genetic disorder. The primary goals of SouthSeq are to provide early diagnoses for conditions that might otherwise lead to diagnostic odysseys and demonstrate the utility of WGS as a frontline test with potential to improve intermediate and long-term clinical outcomes. SouthSeq also aims to ensure that genomic testing is applied across diverse communities. Recruitment efforts will focus on patients from rural and minority populations that have been historically under-represented in both medicine and genomics research. Sequencing and analysis for SouthSeq is being conducted at the HudsonAlpha Institute for Biotechnology in Huntsville, Alabama. Newborns with signs of genetic disease will be enrolled at three different clinical sites, including NICUs at the University of Alabama at Birmingham, the University of Mississippi Medical Center in Jackson, Mississippi, and Woman's Hospital in Baton Rouge, Louisiana. Both biological parents will be enrolled when available so that follow-up testing can be performed to determine inheritance. Further, patient families may choose to opt-into return of secondary findings, which focus on pathogenic and likely pathogenic variation identified within ACMG SFv2.0 genes. Seventeen newborns have thus far been enrolled, seven of which have undergone sequencing and analysis. For one patient, *de novo* pathogenic variation was identified in *GATA6*, associated with pancreatic agenesis and congenital heart defects; *de novo* likely pathogenic variation in *PPP2R1A*, associated with intellectual disability, was identified in another. A third individual harbored a maternally inherited variant of uncertain significance in *TPM3*, which has been linked to congenital myopathy. These three individuals all exhibit phenotypes that overlap those that have been previously associated with the given gene. Enrollment has recently started at one NICU, and in June 2018 the two other sites will begin, with an expectation of enrollment of 5-10 infants per week. Preliminary results suggest that we are likely to identify dozens of medically relevant variants in the coming months, and hundreds in the coming years.

Children with medical complexity have at least one chronic condition, technology dependence, multiple subspecialist involvement, and high healthcare utilization. We hypothesized that whole-genome sequencing (WGS) has the potential to effectively establish genetic diagnoses for children with medical complexity, and that cohorts of children with medical complexity are enriched for novel genetic disorders. Screening the medical records of 545 children with medical complexity from a tertiary-care based Complex Care Program yielded 106 children (19%) suspected of having a genetic condition despite negative prior genetic testing. Eligible participants were evaluated through a clinical genetic assessment; WGS was performed in parallel with any outstanding conventional genetic testing (including whole-exome sequencing, when appropriate). We used our previously published WGS methods, including bioinformatics pipeline, for clinical genome annotation. Of the first 21 probands with WGS data (including 13 trios, 2 dyad, and 6 singletons), 11 have reportable primary diagnostic variants. Seven pathogenic/likely pathogenic variants in known disease genes were identified, including one intronic variant predicted to affect splicing, one small structural variant missed by targeted clinical testing, and one mosaic variant. There also was a promising variant of uncertain significance. Additionally, *de novo* missense variants were identified in three genes without published disease associations: *FBXW7*, *H3F3B*, and *RAC3*. We addressed the N of 1 issue for these candidate disease genes by using public databases (DECIPHER, GeneMatcher, and ClinVar) to rapidly identify similarly affected individuals around the globe. Collaborations have been established and manuscripts are being drafted that will shortly present our combined evidence for disease causality for these three genes (See 2018 ASHG abstract by Chitayat, et al.) Our initial experience applying WGS to children with medical complexity suggests that trio-based genome-wide sequencing is a high yield testing strategy for this patient population, even when prior genetic testing has been negative. Interestingly, this population appears to be enriched for *de novo* mutations and novel genetic disorders. Future work includes analysing unsolved cases using RNA sequencing, in order to identify and evaluate candidate non-exonic variants present in the WGS data.

**3002F****Highly-sensitive quantitative testing enhances molecular diagnosis of mosaic Beckwith-Wiedemann syndrome.**

*S.W. Baker<sup>1</sup>, J. Kelly<sup>1</sup>, J. Richards-Yutz<sup>1</sup>, M. Hernandez-Meadows<sup>1</sup>, K.A. Duffy<sup>2</sup>, M.A. Deardorff<sup>2</sup>, J.M. Kalish<sup>2</sup>, A. Ganguly<sup>1</sup>. 1) University of Pennsylvania, Philadelphia, PA; 2) Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Beckwith-Wiedemann Syndrome (BWS) is a multisystem overgrowth disorder caused by genetic and epigenetic alterations of imprinting control regions (ICR) on chromosome 11p15.5. Though great phenotypic diversity is observed, cardinal features of Beckwith-Wiedemann Spectrum (BWSp) include macroglossia, omphalocele, lateralized overgrowth, hyperinsulinism, and embryonal tumor predisposition. We present the results of high-sensitivity molecular diagnostic testing of a large series of BWS patients. Methods: Molecular diagnosis of BWS was made using a testing strategy that included methylation-specific quantitative real-time PCR (MS-PCR) of bisulfite-treated DNA to evaluate methylation levels at the paternally methylated ICR1 and maternally methylated ICR2, identification of ICR copy number changes using array comparative genomic hybridization, and Sanger sequencing of the *CDKN1C* gene. BWS molecular diagnostic testing for 968 patients was performed by our laboratory. Blood samples from all patients and tissue samples from 66 patients were tested. Results: We confirmed a molecular diagnosis for 293 of 968 patients tested, representing a 30.3% diagnostic yield. Evaluation of the clinical features based on indications for testing demonstrated that this testing cohort represents patients from across the BWSp. Among patients with a molecular diagnosis, 46.1% exhibited loss of methylation at ICR2, 21.5% had gain of methylation at ICR1, 25.9% had paternal uniparental disomy, and 4% of patients exhibited copy number changes of ICR1 or ICR2 or a pathogenic variant in *CDKN1C*. About 20% of patients with methylation defects exhibited evidence of low-level mosaic disease, defined as differential methylation of <10% at ICR1 and/or ICR2. We demonstrate that our assay is highly sensitive and is capable of detecting methylation defects of as low as 3% at ICR1 and ICR2. Additionally, we report a 22.7% increase in diagnostic yield enabled through testing of affected tissue samples from patients whose blood testing was negative. Discussion: Our results demonstrate that MS-PCR has an increased sensitivity for mosaicism detection in BWSp (down to 3%) compared to methylation sensitive multiplex ligation probe amplification (MS-MLPA), a technique used by most diagnostic laboratories (sensitivity of 10-15%). In addition, this study highlights the increased sensitivity of BWSp diagnostic testing enabled by identification of low-level mosaicism in blood and tissue.

TRAF7 is a multi-functional protein involved in diverse signaling pathways and cellular processes. The phenotypic consequence of germline TRAF7 variants remains unclear. Here we report missense variants in TRAF7 in seven unrelated individuals referred for clinical exome sequencing. The seven individuals share substantial phenotypic overlap with developmental delay, congenital heart defects, limb and digital anomalies, and dysmorphic features emerging as key unifying features. The identified variants are *de novo* in six individuals and comprise four distinct missense changes, including a c.1964G>A (p.Arg655Gln) variant that is recurrent in four individuals. These variants affect evolutionarily conserved amino acids and are located in key functional domains. Gene-specific mutation rate analysis showed that the occurrence of the *de novo* variants in TRAF7 ( $P=2.6 \times 10^{-3}$ ) and the recurrent *de novo* c.1964G>A (p.Arg655Gln) variant ( $P=1.9 \times 10^{-9}$ ) in our exome cohort was unlikely to have occurred by chance. *In vitro* analyses of the observed TRAF7 mutations showed reduced ERK1/2 phosphorylation. Our findings suggest that missense mutations in TRAF7 are associated with a multisystem disorder and provide evidence of a role for TRAF7 in human development.

## 3004T

**Mosaic Somatic KRAS mutation is responsible for Oculo-cerebro-cutaneous syndrome (Delleman-Oorthuys syndrome): A seventh patient report.** A. De Leener<sup>1</sup>, V. De Keuleneer<sup>2</sup>, A-F. Dekairelle<sup>1</sup>, P. De Potter<sup>3</sup>, P. Clapuyt<sup>4</sup>, Y. Sznajer<sup>1</sup>. 1) Centre de Génétique Humaine, Cliniques Universitaires St Luc, Brussels, Belgium; 2) Dermatology, Cliniques Universitaires St Luc, Brussels, Belgium; 3) Ophthalmology, Cliniques Universitaires St Luc, Brussels, Belgium; 4) Radiology, Cliniques Universitaires St Luc, Brussels, Belgium.

**Background:** Oculo-cerebro-cutaneous syndrome (Delleman-Oorthuys syndrome) represents a multisystemic condition with skin (aplasia cutis congenita, lipomatosis on subcutaneous regions located from any subcutaneous regions), ophthalmic (choristome and epibulbar cyst), intra medullary and brain lesions. Non ossifying fibromas may develop during the first decade on jaw and throughout life on long bones. Follow-up should guarantee precise diagnosis and prompt management. DNA extracted from femoral fibroma compared to blood DNA, applying whole genome shotgun sequencing, allowed to select variants in 2 genes and KRAS was selected since found in other tissues and absent in unaffected relatives. These findings were confirmed in the second available report so far on 4 patients : this last underlines absence of germline mutation, various degrees of mosaicism and hot spot mutations at codon 13,19,146. Expressivity is highly variable, prognosis factors are not defined so far. **Patient Report and Result:** We report the natural history of girl second child born from unrelated healthy parents. From birth were noted: aplasia cutis on left parieto-occipital region, epibulbar dermoid kyst of left conjunctiva and a subcutaneous mass on nuchal region. At the age of 18 months, milestones were normal, she has no seizure and no behavior problem. Ophthalmic lesion as lipoma's and aplasia cutis are not creating morbidity so far. Standard array CGH was normal. Ultrasound at the posterior cervical mass identified lipomatous tissue. Extracted DNA from lipoma and targeted KRAS gene sequencing identified presence of the c.38G>A (p.Gly13Asp) in 47% of these cells. This mutation is one of the 3 (hotspot) reported so far. **Conclusion:** Present patient is the 7th patient with OCCS identified carrier of somatic mutation in KRAS gene. Clinical diagnosis together with histology and molecular studies enabled appropriate genetic counselling. Precise gain-of-function effect of the missense change in the RAS pathway related to phenotype and indication for mTOR inhibitor therapy remain to be evaluate. **References:** Moog U. et al. **Rare mosaic variant caller allows for low level variant detection in unmatched mosaic overgrowth samples: Results from thirty-five individuals.** J.J. Johnston, J.N. Dudley, M.J. Lindhurst, J.C. Sapp, K.M. Keppler-Noreuil, L.G. Biesecker. Medical Genomics and Metabolic Genetics Branch, National Institutes of Health, Bethesda, MD.

Somatic activating mutations in the phosphatidylinositol-3-kinase (PI3K)/AKT signaling pathway have been implicated in a number of overgrowth disorders including Proteus syndrome and the *PIK3CA*-related overgrowth spectrum (PROS). Detection of these variants is complicated by the mosaic nature of the alterations, often resulting in low levels of the pathogenic variant in samples available for testing. As well, an increasing number of genes connected to these disorders adds to the diagnostic complexity. We have designed a next-generation sequencing panel to detect variants in 11 pathway genes with the ability to expand the panel as necessary. The initial panel targeted exons in *AKT1*, *FGFR1*, *GNAQ*, *KRAS*, *PHLPP1*, *PIK3CA*, *PIK3R1*, *PIK3R2*, *PDGFRB*, *RASA1*, and *TEK*. Libraries were constructed with dual index adapters and run on the Illumina MiSeq with 300 cycles of V2 chemistry on nano flow cells with an average read depth over the targeted exons of 271 reads. Samples without likely pathogenic variants identified at this read depth were rerun on a standard flow cell to achieve an average read depth of 1,735 reads. Using in-house sequence data from a control cohort, statistically significant single nucleotide variation (SNV) was differentiated from position specific background using Fisher's exact test with multiple testing correction. Analysis was restricted to variants with an alternate read count greater than 1. The use of data from a control cohort eliminated the need to use matched samples. LoFreq was employed to detect mosaic insertion-deletion variants in *PIK3CA*. Thirty-five cases with mosaic overgrowth were analyzed. From the nano flow cell data, a total of 6,957 SNVs passed initial filters and 38 variants showed significance that survived multiple testing correction. Of these 38 variants, 16 were in *PIK3CA* with variant allele frequencies (VAF) between 1.8% and 47.4%. Four individuals had variants in *AKT1* with VAF between 7.4% and 30.7%. Variants in *RASA1* (2) and *PIK3R1* (1) were considered likely to be pathogenic. A single *PIK3CA* variant was detected upon rerunning negative samples on standard flow cells, and had a VAF of 0.7%. LoFreq detected two indel variants in *PIK3CA* considered likely to be pathogenic. In total, variants were detected in 26 individuals for a detection rate of 74%, with the majority of individuals having variants in either *PIK3CA* (19) or *AKT1* (4).

**Landscape of chromosomal aberrations among pesticides exposed agriculture workers of Punjab, India.** M. Ahluwalia, A. Kaur. Department of human genetics, Guru Nanak Dev University, Amritsar, Punjab, India.

Punjab is an agrarian state of India and in order to mitigate the crop damage caused by pests, use of pesticides is done extensively. Farmers are occupationally exposed to pesticides thus, are more prone to genotoxicity and oxidative stress. In human system, glutathione-S-transferases are important detoxification enzymes involved in the pesticide metabolism. Due to inherited genetic variation, individuals have different metabolic capacity. Literature suggests that polymorphism in *GSTT1*, *GSTM1*, *GSTP1*, and *GSTA1* lead to loss of metabolic function in individual. So, the present study was aimed towards analysis of chromosomal aberrations (CAs), oxidative stress, and distribution of *GST* polymorphisms among agricultural workers. A total of 200 subjects were enrolled in the study which included agricultural workers (n=100) and non-exposed controls (n=100) from Punjab. CAs were analyzed using peripheral lymphocyte culturing technique. Calorimetric techniques were used to analyze the oxidative stress by estimation of malondialdehyde (MDA), reduced glutathione (GSH) levels and superoxide dismutase (SOD) activity. Null *GSTT1* and *GSTM1* distribution was analysed through multiplex-PCR method. For *GSTP1* (rs1695) and *GSTA1* (rs3957356), PCR-based restriction fragment length polymorphism was done. Increased frequency of total aberrant metaphases (TAM) were observed in exposed subjects;  $15.2 \pm 10.6$  (mean $\pm$ SD) as compared to non exposed controls ( $3.7 \pm 3.9$ );  $p < 0.0001$ . Significant increase in frequency of metaphases with aneuploidy as well as structural aberrations were observed among exposed subjects ( $6.98 \pm 6.7$ ;  $7.1 \pm 6.2$ ) in comparison to controls ( $1.2 \pm 2.2$ ;  $2.1 \pm 2.8$ ). Also, increased number of clonal and non clonal CAs were observed among exposed subjects. Higher oxidative stress was confirmed in exposed group by significantly higher MDA levels ( $p < 0.05$ ) and lower GSH levels ( $p < 0.01$ ). Complete gene deletion in either of *GSTT1* or *GSTM1* was strongly associated with an increased risk (OR=2.01; 95%CI=1.1–3.6;  $p < 0.05$ ) of genetic damage. Increased frequency of TAMs was observed irrespective of *GST* genotypes except combined null genotype of *GSTT1* and *GSTM1* and homozygous mutant (rs3957356) genotype. Thus, a positive association of pesticide exposure with CA frequency and oxidative stress was observed. Due to health effects of genetic damage and oxidative stress on reproduction, progression of cancer, and other disorders, preventive measures on usage and strict regulations are recommended.

**Non-invasive preimplantation genetic testing for monogenic diseases and aneuploidies using cell free embryonic DNA.** S. Madjunkova<sup>1</sup>, V. Kuznyetsov<sup>1</sup>, R. Antes<sup>1</sup>, R. Abramov<sup>1</sup>, S. Chen<sup>1</sup>, Z. Ibarrientos<sup>1</sup>, G. Motamedi<sup>1</sup>, K. Glass<sup>1,2</sup>, A. Baratz<sup>1,2</sup>, C. Librach<sup>1,2,3,4,5</sup>. 1) Reproductive Genetics, CReATe Fertility Centre, Toronto, Ontario, Canada; 2) Department of Obstetrics and Gynecology, University of Toronto, Toronto, Canada; 3) Institute of Medical Sciences, University of Toronto, Toronto, Canada; 4) Department of Physiology, University of Toronto, Toronto, Canada; 5) Department of Gynecology, Women's College Hospital, Toronto, Canada.

**Introduction:** Advances in preimplantation genetic testing (PGT) of human embryos has improved outcomes of assisted reproduction with euploid embryo transfers and selection of embryos free of monogenetic disorders. Along, the limitations of PGT were clearly identified, mainly linked to mosaicism, sampling bias of trophectoderm (TE) biopsy and safety of the procedure. We have showed that using cell free embryonic DNA (cfeDNA) for non-invasive PGT for aneuploidies (NIPGT-A) released into blastocyst culture conditioned medium and blastocoel fluid (BCCM+BF) has the potential to overcome the limitations mentioned above. Our aim was to develop an approach for NIPGT-M and -A screening of embryos from couples at risk and identify the areas to be improved. **Methods:** PGT-A and PGT-M on TE biopsies using NGS (VeriSeq, Illumina), SNP-Karyomapping (Illumina) and direct mutation analysis was performed in four couples at risk for: Fabry disease (*GLA c.1000-2A>G*) (6 embryos), familial exudative vitreoretinopathy (*TSPAN12 del Ex8*) (4 embryos), breast cancer (*BRCA1 c.68\_69delAG*) (2 embryos) and Neu-Laxova Sy (*PHGDH c.488G>A*) (4 embryos). We collected cfeDNA from BCCM+BF from 16 embryos (released within 24-48 hours of culture after d4) under strict aseptic and clean room conditions and blank media cultured on the same dish as a negative control. For PGT-M using TE biopsy Repli-G (QIAGEN) was used for whole genome amplification (WGA) of embryonic DNA. NIPGT samples were amplified with Repli-G WGA (n=4) and SurePlex (Illumina) (n=12). Same assays for mutation detection were used for PGT-M and NIPGT-M. Concordance rates for ploidy between NIPGT-A and mutation detection of NIPGT-M to corresponding TE biopsy samples results were evaluated. **Results:** All NIPGT samples had cfeDNA amplified (23.3±5ng/ul). PGT-A results from TE biopsy showed 11 euploid, 3 aneuploid and 3 mosaic embryos. NIPGT-A results were obtained only for samples amplified with SurePlex at 100% concordance. Samples amplified with RepliG didn't give interpretable NGS results. Full concordance of mutation analysis was present for PGT and NIPGT for *PHGDH* (4/4) and *TSPAN12* (4/4) assays and partial for *GLA* (2/6) and *BRCA1* (1/2) NIPGT-M assays, due to maternal contamination. **Conclusion:** NIPGT-M and NIPGT-A using cfeDNA from BCCM+BF are feasible approach for selection of euploid/unaffected embryos for transfer. WGA systems and sample collection need improvement to reduce maternal contamination and increase sensitivity of NIPGT.

**Semi-automated variant prioritization pipeline for retinal dystrophy diagnostics.** B. Guan, D.M. McGaughey, M.J. Reeves, E. Ullah, W.M. Zein, K. Wetherby, D. Blain, A. Turriff, B.P. Brooks, S.J. Tumminia, R.B. Hufnagel, eyeGENE® Working Group. NEI/NIH, Bethesda, MD.

Over 300 genes contribute to various forms of inherited retinal degenerations (IRDs). A major limitation in NGS diagnostics is bioinformatic analyses to sort pathogenic variants from those of benign or uncertain significance. Here, we developed a reliable semi-automated pipeline featuring filtering and prioritization of single nucleotide variants (SNV) and small insertions-deletions (indels) in exonic and intronic regions. We also incorporated tools for structural variants, copy number variation (CNV), sex determination, and sample switch or contamination control. 147 IRD genes were custom-captured using the Nimblegen SeqCap EZ choice from 100 IRD samples from the eyeGENE® program. The sequences were processed for SNV and indel calling following GATK best practices. Variants were annotated, filtered using a custom script incorporating ANNOVAR/InterVar and Variant Effect Predictor/Gemini. Panel sequencing provided 98% of 2374 targeted exons with average depth of >500x. There were 794 rare variants with allele frequency less than 1% in ExAC per sample on average. Semi-automated variant filtering and prioritization produced 0 to 7 variants (median: 3) per sample for manual variant classification based on 2015 ACMG/CAP guidelines. There was 92% of agreement between ClinVar-annotated variants and the pipeline. Correlated genotype to pre-test diagnosis was found in nearly half of patients, in line with previous published reports in literature. Manual examination of all rare variants did not identify additional pathogenic or likely pathogenic variants, suggesting that our automated pipeline did not overlook those. Intronic and exonic variants not in canonical splicing sites but predicted to affect splicing were found in 15% of cases, offering additional potentially significant variants for consideration. Large CNVs were detected in 11% of cases and provided direct evidence for molecular diagnosis in an additional 8% of cases, which includes a previously reported 353bp *Alu* insertion in the *MAK* gene and a 36.4 kb deletion in the *TRPM1* gene. Lesser allele fraction quality control identified one sample contamination and another sample with likely mosaic chrX deletion. Our pipeline improves efficiency of clinical variant interpretation without sacrificing sensitivity of detecting reportable variants. Pathogenic or likely-pathogenic CNVs and splicing variants are also present in a significant number of samples.

**A reliable and robust DNA library preparation chemistry in an automated workflow for improved sequencing performance.** A. Kothandaraman, S. Eun, M. Carter, S. Piehl, K. Kushiro. Bioo Scientific, a PerkinElmer company, 7050 Burleson Rd. Austin, TX 78744.

For many clinical research labs, next-generation sequencing is a staple in many of its applications and projects. For this indispensable molecular technique, many researchers rely on commercial DNA library preparation kits for convenience, ease of use, and consistency in performance, which can greatly affect the quality of a researcher's data. Many would be quick to agree that though library preparation may seem theoretically simple for all its steps of end-repair of fragmented DNA, ligation of adapters, and amplification, each process must be carefully tuned to avoid bias, which would result in an uneven representation of some segments of the starting materials. Thus, efforts are made to increase efficiency and minimize bias throughout each step in the library preparation protocol. These reagents and workflow give library yields at 102 nM from 250 ng and 125 nM from 1 ng input of fragmented human male DNA. Using *E. Coli* DNA, the resulting library yield was at 84 nM and 126 nM from 1 ng inputs. Genome coverage ranged from 96% to 94% using bacterial DNA with differing GC-content at a 1x coverage and maintained a robust coverage ranging from 89% to 93.5% at a 10x coverage, which was comparatively higher than another commercial reagent on market. The robustness of PCR-free workflows was also investigated. On top of robust performance of the reagent chemistry, the additional benefit of automation for a complex process prone to error that can come from pipetting, mastermix setup, among other processes is more and more visible in the clinical research application field. This poster reviews the specifications of the library prep chemistry in regards to yield, mapping rate, coverage, and GC-bias mitigation and its optimization on an automated platform.

**Mate pair sequencing: Ushering cytogenetics into the era of personalized medicine.** N. Hoppman<sup>1</sup>, B. Pitel<sup>1</sup>, S. Smoley<sup>1</sup>, S. Johnson<sup>2</sup>, J. Smadbeck<sup>2</sup>, M. Webley<sup>1</sup>, S. Koon<sup>1</sup>, L. Baughn<sup>1</sup>, G. Vasmatzis<sup>2</sup>, E. Thorland<sup>1</sup>, H. Kearney<sup>1</sup>. 1) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 2) Center for Individualized Medicine, Mayo Clinic, Rochester, MN.

For many decades chromosome studies were the gold standard of care for patients with abnormal congenital phenotypes. Chromosomal microarray has replaced karyotype as a first-tier test for these patients; however, chromosome studies are still utilized to some degree, particularly following a normal microarray study. Chromosome studies will detect apparently balanced rearrangements such as translocations, but without a molecular understanding of the breakpoints of the rearrangement, those findings most often have uncertain clinical significance. Similarly, chromosomal microarrays often detect copy number gains that may or may not disrupt genes at the breakpoints associated with a phenotype resulting from haploinsufficiency. Parental testing to establish inheritance is recommended in such situations; however, patients are still frequently left with unclear results and no additional clinical testing available to further characterize and classify the abnormality. The Mayo Clinic Genomics Laboratory recently launched a novel clinical test, mate pair sequencing (MPseq), to help clarify uncertain results obtained from chromosome or microarray studies. This assay couples whole genome MPseq with patient-specific, customized analysis to clarify findings detected by other assays in order to provide more clear and molecularly precise results to the patient. In addition to our extensive research and development experience, we have now performed MPseq clinically on nine patients with uncertain karyotype (n=8) or microarray (n=1) findings. MPseq was able to identify and further characterize the abnormality of interest in all nine cases. Of these, four (one translocation and three inversions) were re-classified as pathogenic or likely pathogenic, one (a translocation) was re-classified as likely benign, and four (two translocations, one inversion, and one duplication) remained classified as uncertain. In one case, the rearrangement of interest (a paracentric inversion involving chromosome 5) was significantly more complex than originally appreciated. This summary of our clinical experience with MPseq thus far highlights the unique ability of this novel assay to clarify uncertain results obtained by other cytogenetic methods. Based on this experience, our laboratory has developed algorithms that will be shared for performing MPseq as a follow-up assay for cytogenetic results of uncertain clinical significance in a constitutional setting.

**Telomeric association involving chromosomes Y and 19 in a patient with premature ovarian insufficiency.** B. Kar<sup>1</sup>, B. Linda<sup>1</sup>, P. Aishwarya<sup>2</sup>, S. Kundavil<sup>2</sup>. 1) Center for Genetic Studies & Research, The Madras Medical Mission, Chennai, India, Asia.; 2) Institute of Reproductive Medicine & Women's Health, The Madras Medical Mission, Chennai, India, Asia.

**Background:** Premature ovarian insufficiency (POI) affects about 1% of women below the age of 40 and these patients have a lower chance of getting pregnant. POI has been observed in association with X chromosome abnormalities and with Turner syndrome wherein the patients have a high rate of follicle atresia leading to the termination of ovarian function. Here we present a case of telomeric association between chromosomes Y and 19 observed in a 24-year-old patient with primary amenorrhoea and POI. To the best of our knowledge, this is the first case report of tas(Y;19) that has been associated with POI. **Case description:** The patient visited The Madras Medical Mission after being diagnosed with POI with the hope of conceiving through fertility treatment after 1.5 years of infertility. Clinical evaluation performed on the patient showed webbed neck, high arched palate and a short stature of 145 cm. No axillary hair was present and she had a breast development of Tanner IV stage. Hormone level of AMH was low whereas LH and FSH were high. Clinical pelvic examination revealed a small uterus with an infantile cervix. Ultrasonography also confirmed the presence of a small uterus and ovaries were not visualized. MRI was done for further evaluation and this showed a septate uterus, streak gonads and no evidence of ovotestis. Laparoscopy performed showed streak gonads and histopathology of the gonads confirmed the presence of an ovotestis. The patient was referred for genetic analysis and family history was collected. She had two unmarried sisters who had regular menstruation. Cytogenetic analysis showed mos 46,X,tas(Y;19)(p11.3;q13.4)[20]/45,X[10] karyotype with the short arm of the Y chromosome attached to the end of the long arm of chromosome 19. C banding was done and this showed that the derivative chromosome 19 had two centromeres. FISH for SRY gene (Yp11.32) showed its presence on the derivative chromosome. AZFa, AZFb and AZFc regions that are usually located at Yq were present on the derivative chromosome with no deletion. **Conclusion:** Features of Turner syndrome and the presence of an ovotestis in the patient can be attributed to her mosaic karyotype. Gonadectomy was performed to avoid future risk of gonadoblastoma. This case highlights the need for genetic diagnosis in patients with POI to help in coming up with a proper management of infertility.

**How does DNA break form of three-way translocations?** T. Kato<sup>1</sup>, H. Inagaki<sup>1</sup>, Y. Shinkai<sup>1</sup>, A. Kato<sup>1</sup>, R. Kawamura<sup>1</sup>, M. Tsutsumi<sup>1</sup>, M. Taniguchi-Ikeda<sup>1</sup>, S. Mizuno<sup>2</sup>, Y. Makita<sup>2</sup>, N. Saito<sup>4</sup>, N. Ochi<sup>5</sup>, H. Kurahashi<sup>1</sup>. 1) Fujita Health University, Toyoake, Japan, Select a Country; 2) Department of Pediatrics, Central Hospital, Aichi Human Service Center, Aichi, Japan; 3) Education Center, Asahikawa Medical University, Hokkaido, Japan; 4) Shin-Koga Hospital, Fukuoka, Japan; 5) Aichi Prefectural Mikawa Aitori Medical and Rehabilitation Center for Developmental Disabilities, Aichi, Japan.

Complex chromosomal rearrangements (CCRs) are defined as rearrangements involving three or more chromosomes with three or more breaks. CCRs can be classified into three groups based on the number of breakpoints and type of arrangement: (i) three-way rearrangements, (ii) double two-way translocations and (iii) exceptional CCRs involving multiple chromosomes and breakpoints. Three-way rearrangements involving terminal exchanges with one breakpoint per derivative chromosome have been thought to be the most common category of CCRs. However, recent advance in molecular methodology has greatly improved the characterization of CCRs, with high-density SNP array and next generation sequencing uncovering more complexity among some simple three-way translocations than previously reported. In this study, we identified six individuals with three-way translocations originally identified using standard chromosome banding and fluorescence in situ hybridization. To characterize the breakpoint junctions of three-way translocations, we applied whole genome mate-pair sequencing. None of the six cases carried a simple structural aberration mediated by three breakages and three repairs. Breakpoint fragments of one or two derivative chromosomes consisted of multiple genomic segments arranged in a disorderly array. On the other hand, the remaining derivative chromosomes had simple, single breakpoint rearrangements. The mechanisms underlying these CCRs may be associated with a chromothripsis-like event. Pulverized chromosomes might be then translocated into another chromosome, resulting in the establishment of a derivative chromosome with complex rearrangements. Unrepaired segment of translocated chromosome might be shifted to different chromosomes with simple rearrangements. Therefore, these previously simple three-way rearrangement cases are more consistent with exceptional CCRs, and suggest this type of highly complex arrangements is more common than previously recognized.

**Sodium acetate induces superoxide dismutase activity change and human chromosome aberrations in lymphocyte.** *M. Pongsavee*. Department of Medical Technology, Faculty of Allied Health Sciences, Thammasat University, Patumthani, Thailand.

Sodium acetate is the food additive which can prevent bacterial cultivation in a wide range of acidic region. It is often used to give potato chips a salt and vinegar flavor. Study the effects of sodium acetate on superoxide dismutase activity and human chromosome aberrations in lymphocyte were performed. Four human lymphocyte samples from Thai volunteers were treated with sodium acetate at concentration of 0.04, 0.08, 0.16 and 0.32 mg/ml for 24 and 48 hours. Superoxide dismutase activity assay and standard chromosome culture technique were studied about superoxide dismutase activity and chromosome aberrations. The results showed that 0.08, 0.16 and 0.32 mg/ml of sodium acetate were significantly affected superoxide dismutase activity change on human lymphocyte at 24 and 48 hours ( $P < 0.05$ ). Sodium acetate at concentration of 0.16 and 0.32 mg/ml at 24 and 48 hours caused chromosome aberrations ( $P < 0.05$ ). Sodium acetate significantly effects superoxide dismutase activity change and chromosome aberrations in lymphocyte. Type of food additives, the concentration and the incubation time affect enzyme activity and chromosome aberrations in human.

**Molecular cytogenetic characterization of a female patient with a dicentric X chromosome at breakpoints Xq27.** *R.M. Diaz<sup>1,7</sup>, D. Chung<sup>2</sup>, A. Nguyen<sup>3</sup>, D. Palencia<sup>2</sup>, D. Trejo<sup>2</sup>, L. Villalba<sup>2</sup>, A. Lopez<sup>2</sup>, A. Duarte<sup>2</sup>, W. Herrera<sup>1,7</sup>, C.A. Tirado<sup>1,3,4,5,6</sup>*. 1) The International Circle of Genetic Studies, Chapter Lambayeque, Chiclayo, Peru; 2) Laboratorio de Citogenética, CARPER-MOR – Laboratorio de referencia internacional, México; 3) The International Circle of Genetic Studies, Chapter Los Angeles, USA; 4) HPA, Minneapolis, MN, USA; 5) Allina Health, Inc. Minneapolis, MN; 6) University of Minnesota, Minneapolis, MN, USA; 7) Universidad Nacional PEDRO RUIZ GALLO, Lambayeque, PERU.

A dicentric X chromosomes with breakpoints at Xq are rare. We report a 16-year-old female patient, who presented at the clinics for a very mild intellectual disability. Cytogenetic studies of peripheral blood (GTG banding) showed one normal copy of the X chromosome. The second copy of the X chromosome was characterized as a dicentric X chromosome. To confirm this abnormality, FISH (In Situ Fluorescence Hybridization) using the centromeric probes CEPX (DXZ1), CEPY (DYZ3) on interphase nuclei and metaphases was performed. FISH results showed three CEPX (DXZ1) signals (centromere). The abnormal X was described as 46, X, dic (X; X) (q27; q27). ish dic (X; X) (q27; q27) (DXZ1 ++). This patient behaves as a Triple X Syndrome (XXX Syndrome). The probability of this patient having offspring with Klinefelter syndrome is 50% if the fetus is male and segregates the dicentric X chromosome, and 50% Triple X Syndrome (XXX Syndrome) if the fetus is female. Genetic counseling and chromosome studies of the mother were recommended.

**3015W**

**Prevalence of ACMG 59 associated conditions for 1,031,941 patients in a large rural hospital system.** L. Baas<sup>1</sup>, C. Hajek<sup>1</sup>, J. Smith<sup>2</sup>, G. Frost<sup>1</sup>, K. Ragoth<sup>1</sup>, M. Moore<sup>1</sup>, C.F. Boerkoel<sup>1,2</sup>, M. Sincan<sup>1,2</sup>. 1) Sanford Health, Sioux Falls, SD; 2) Sanford Research, Sioux Falls, SD; 3) Sanford EDA, Sioux Falls, SD.

**Background:** The American College of Medical Genetics and Genomics (ACMG) recommends that laboratories conducting clinical exome or genome sequencing report secondary findings from a "minimum list" of 59 genes associated with 27 rare conditions known to be highly penetrant yet clinically actionable. Multiple studies have investigated the frequency at which these secondary genetic findings occur, reporting figures ranging from 0.5 - 20%. However, a scarcity of literature exists regarding the prevalence of the associated conditions in the general population. Clarifying the prevalence of ACMG 59 associated conditions is useful not only for establishing an evidentiary threshold fully to support the ACMG recommendations, but also for assessing the resources necessary for responding to secondary genetic findings in a clinical setting. To this end, we used International Classification of Disease version 10 (ICD-10) data from the electronic medical record (EMR) to approximate the prevalence of ACMG 59 associated conditions in a population of patients in a large rural hospital system. **Hypothesis:** We expect that our approximation will reflect discordance between the frequency of secondary findings reported in genetic testing and the rate at which the associated conditions are documented in the EMR. **Methods:** We developed a text-matching algorithm linking ACMG 59 associated conditions with ICD-10 codes recorded in the EMR. We estimated prevalence from the number of occurrences of ICD-10 codes matched to ACMG 59 associated conditions. **Results:** We evaluated 10,208,234 total ICD-10 diagnoses for 1,031,941 adult patients seen at a rural healthcare system between July 2016 - July 2017. We identified 4,222 diagnoses corresponding to ACMG 59 associated conditions. These data suggest that ACMG 59 associated conditions occur in approximately 0.4% of individuals in our reference sample. **Conclusion:** Our results are consistent with the expectation that secondary genetic findings are reported during genetic testing at higher frequencies than ACMG 59 associated conditions are recorded in the EMR. We conclude that genetic data must be evaluated in combination with clinical reports in order to comprehend the full disease burden imposed by these conditions. .

**3016T**

**Rapid exome-based testing for disorders of neonatal or infantile onset.** K. Bliven, M. Kyriss, R. Steiner, D. Allingham-Hawkins, G. Londre, R. Van-neste, F. Xu, J. Weber. PreventionGenetics, Marshfield, WI.

In the United States, monogenic disorders resulting in severe neonatal or infantile illness account for ~20% of infant deaths and ~18% of pediatric hospitalizations (Kingsmore. 2012. PubMed ID: 22872815; Saunders et al. 2012. PubMed ID: 23035047). Several studies have shown that genetic testing in such patients can be a very beneficial first-line test, as the results may provide a molecular diagnosis that allows for early intervention for the patient, proper genetic counseling of the family, and may reduce the time spent in the diagnostic odyssey (Kingsmore. 2012. PubMed ID: 22872815; Saunders et al. 2012. PubMed ID: 23035047; Ceyhan-Birsoy et al. 2017. PubMed ID: 28079900). In an effort to provide a molecular diagnostic test for these individuals, PreventionGenetics developed a Neonatal Crisis Sequencing Panel with Copy Number Variation (CNV) detection via Next Generation Sequencing (NGS). This panel includes 1,155 genes that have been linked to disorders with severe neonatal or infantile onset, and is indicated for patients who present with symptoms such as respiratory distress, hypotonia, gastrointestinal distress, difficulty feeding, failure to thrive, lethargy, seizures, encephalopathy, cardiac defects, organomegaly, unusual facial features, abnormal odor, and/or metabolic disturbances. To date, ~22% of cases had a clear positive result. A possible or contributory genetic cause, such as at least one plausible causative variant of uncertain significance in a gene relevant to the patient phenotype, was identified in another ~56% of cases. Of the positive cases, one proband harbored a *de novo* likely pathogenic variant in *TBX5*, a gene associated with Holt-Oram syndrome. Additionally, we identified an indication of maternal UPD15 in one proband who presented with Prader-Willi syndrome as a neonate. ~22% of submitted samples have been for ongoing pregnancies or fetal demise, demonstrating the value of this diagnostic test to aid in delivery management of fetuses presenting with multiple anomalies. Thus far, the positive yield for this panel is comparable to our whole exome sequencing (WES) rate (26%). Coupled with a shorter turnaround time (<21 days) compared to WES (~6 weeks), this panel is ideal for patients in the neonatal or pediatric intensive care unit who present with a suspicion of a rare genetic disease. If desired (i.e., when a negative or indeterminate report is issued), clients also have the potential to reflex to whole exome sequencing.

**3017F**

**Pipeline improvements enable fast genome sequencing and clinical services.** Y. Ding, S. Chowdhury, L.V.D. Kraan, L. Puckett, C. Yamada, S. White, R. Hovey, S. Batalov, N. Veeraraghavan, J. Maria, J. Braun, D. Oh, P. Mulrooney, M. Tokita, K. Ellsworth, J. Cakici, S. Breeding, W. Benson, M. Lurie, S. Cox, D. Dimmock, S. Nahas, S. Kingsmore. Rady Children's Institute for Genomic Medicine, San Diego, CA.

Rapid, clinical Whole Genome Sequencing (rWGS) at Rady Children's Institute for Genomic Medicine (RCIGM) was recently enhanced by implementation of multiple improvements: *In toto*, these enabled achievement of a Guinness World Record for fastest genetic diagnosis by rWGS (~19.5 hours from specimen receipt to provisional diagnosis). As part of this effort, we evaluated the analytic performance of the Novaseq 6000 utilizing various library construction kits and flowcells, for single nucleotide variant (SNV), small insertion and deletion (indel), and larger structure variant (SV) genotypes. Artificial Intelligence (AI) was employed to accelerate the analysis of variants of interest by integration of phenotype and genotype data. At an average coverage of >40X, rWGS provided  $\geq 10X$  coverage for 100% coding domain nucleotides in >95% of OMIM genes. The sensitivity of SNV and Indel calls was 99.5-99.9% and 96.1-99.3%, respectively; precision was 99.99%. To date, we have completed rWGS in ~950 individuals, yielding molecular diagnoses in ~35%. Among diagnoses, 72% were determined to have changed medical management. Further pipeline developments will focus on achieving scalability through sample preparation by liquid handling robots, and integration of an end-to-end laboratory informatics management system (LIMS), with a centralized database of sequences and metadata. These improvements will provide a Turnaround Time (TAT) of rWGS in a routine clinical setting, including in house confirmatory tests, such as Multiplex ligation-dependent probe amplification (MLPA) for detection of deletion and insertion variants, of <1 week. In addition, to meet the needs of on-going clinical trials and research, rapid Whole Exome Sequencing (WES) with spike-in of the Mitochondrial Genome and RNAseq are in development. RCIGM is increasingly providing rWGS for diagnosis of infants in neonatal and pediatric intensive care units at hospitals in the Sanford consortium and other children's hospitals nationwide empowered by these approaches. Ongoing improvements in clinical rWGS instrumentation, sample preparation, AI and pipelines are improving diagnostic yield, shortening time to diagnosis, and decreasing testing cost.

**3018W**

**Assessment of the utility of functional studies in variant classification.** I. Thibodeau, E. Kaseniit, B. Mar-Heyming. Counsyl, South San Francisco, CA.

Proper interpretation of genetic variants is crucial for devising appropriate patient and health management strategies. According to ACMG guidelines, experimental evidence describing the impact of a variant on protein function can contribute to either benign or pathogenic classifications. However, the clinical relevance of functional studies is not well-established. Laboratories weigh experimental evidence differently, leading to discrepancies in variant classifications that may result in uncertainty in patient and health management. Therefore, a more standardized approach to assessing the clinical relevance of functional studies is needed. Focusing on GJB2 (non-syndromic hearing loss) and ATP7B (Wilson's disease), we devised a methodology to interrogate the clinical relevance of experimental assays. We identified variants classified as pathogenic or benign based on their allele frequencies in patients and controls but, critically, independent of functional studies. Next, the reported functional impacts of these variants were retrieved from the literature and analyzed. For GJB2, localization to gap junctions, lucifer yellow (LY) transfer, and junctional conductance (JC) assays were interrogated. For ATP7B, complementation studies, localization to the Golgi apparatus, and Cu uptake assays were analyzed. For both genes, the outcomes of localization studies showed the highest concordance with pathogenic classifications. For GJB2, the results of LY and JC assays exhibited significant variations between laboratories and experimental systems for the same variant. Additionally, at least two benign variants were shown to have activities similar to variants that are classified as pathogenic, challenging the strength of the predictive value of these assays. Moreover, several pathogenic variants showed activities similar to the wild type protein in various assays regardless of the gene studied, suggesting that a neutral functional impact in an assay may not be strong evidence of non-pathogenicity. In summary, we devised a strategy to interrogate the utility of functional studies for variant interpretation and tested it on two genes. We found several study-specific caveats that indicate a need for careful and comprehensive assessment of experimental assays. We suggest that the performance of functional studies be evaluated in a gene-by-gene and study-by-study basis prior to weighing the results in the variant classification process.

**3019T**

**Detection rates of postnatal chromosomal microarray testing based on clinical indication.** T. Guo<sup>1,2</sup>, M. Shafiq<sup>1,2</sup>, R. Singh<sup>1,2</sup>, Y. Mito<sup>1,2</sup>, A. Babu<sup>1,2</sup>, L. J. Edelmann<sup>1,2</sup>, S. A. Scott<sup>1,2</sup>, L. Shi<sup>1,2</sup>. 1) Icahn School of Medicine at Mount Sinai, NY, NY; 2) Sema4, a Mount Sinai venture, Stamford, CT 06902.

Chromosomal microarray (CMA) is a first-tier test for patients with multiple congenital anomalies (MCA), developmental delay/intellectual disability (DD/ID), and autism spectrum disorders (ASD); however, the detection rates of CMA across indications is currently unclear. To determine postnatal CMA detection rates based on clinical indication, deidentified data from 12,589 CMA tests from 2013 to 2017 were assessed. Among these samples, 8,014 (63.7%) were prenatal and 4,575 (36.3%) were postnatal, including 849 (18.6%) with MCA, 1,206 (26.4%) with DD/ID, 669 (14.6%) with ASD, and 1,851 (40.5%) with heterogeneous other indications. All identified copy number variants (CNVs) were classified based on American College of Medical Genetics and Genomics (ACMG) guidelines. CMA testing evolved over time with respect to analytical reporting criteria and included three microarray designs: 44K, 105K, and 180K CGH+SNP (Agilent Technologies). Interestingly, the overall detection rate for variant of uncertain clinical significance-likely pathogenic (VOUS-LP) and pathogenic CNVs was consistent across CMA designs (11.3% for 44K/105K vs. 10.0% of 180K); however, the frequencies of VOUS CNVs significantly increased using the 180K CGH+SNP array (9.4% for 44K/105K vs. 14.8% of 180K). The increased VOUS rate using the higher resolution microarray was due, in part, to the additional reporting of absence of heterozygosity (AOH) that was enabled by the 180K CGH+SNP microarray. Importantly, the detection rates also varied across clinical indications, with VOUS-LP and pathogenic CNVs being reported for MCA, DD/ID, ASD, and other indications being 11.2%, 10.1%, 3.4%, and 11.3%, respectively. In addition, ASD also had the lowest detection rate of AOH (9.0% MCA, 7.1% DD/ID, 4.8% ASD, and 10.0% other), as defined by a single region greater than 10 Mb or when the total autosomal AOH proportion is greater than 3%. However, the overall VOUS rates were similar across the four clinical indications (13.7% MCA, 14.0% DD/ID, 16.0% ASD, and 15.5% other). Taken together, our results indicate that overall postnatal detection rates using CMA platforms designed for clinical cytogenomic testing are ~10%; however, higher resolution platforms also result in an increased VOUS rate. In addition, these data also underscore the genetic heterogeneity between different indications, in particular highlighting the need for higher resolution exon-level CMA and/or gene panel sequencing among individuals with ASD.

**3020F**

**Detection of clinically relevant copy number variation in whole exome sequencing data.** F. Xu, C. Glodosky, M. Benzschawel, D. Allingham-Hawkins, J. Weber. PreventionGenetics, Marshfield, WI.

Next-generation sequencing (NGS) approaches such as whole exome sequencing (WES) have been widely used as a standard tool for detecting disease causing single nucleotide variants or small insertions/deletions (indels). However, copy-number variants (CNVs) including large cytogenetic events and exon level deletions and duplications, although a common genetic cause of disease, have not routinely been identified from NGS data in clinical laboratories. In present study, CNV analysis using Golden Helix's VarSeq CNV caller (VS-CNV) was first validated to establish its performance compared to microarray for 109 rare CNVs and LOH events. These positive CNV/LOH controls have a diverse type of clinically relevant CNVs, including triploidy, trisomy, interstitial and terminal deletions and duplications, recurrent microdeletions and microduplications, mosaic chromosomal deletions, unbalanced chromosomal translocations, loss of heterozygosity, and exon level deletions and duplications. The detection rate was 97% for all CNVs detected by chromosomal microarray (CMA) and 77% for exon level CNVs (ranging from single exon to whole gene deletion/duplication) detected by high density aCGH. This approach allowed the detection of expected deletions and duplications of varying sizes, ranging from 196 bp to whole genome duplication, with the highest sensitivity for the detection of CNVs greater than 50 Kb in length. We then applied the VS-CNV algorithm to WES tests for 170 patients affected by a range of genetic disorders and successfully identified five clinically relevant CNVs including two *de novo* CNVs and one sex chromosome aneuploidy (47,XXY). Our results demonstrate that the CNV calling algorithm is capable of detecting a diverse type and size of CNVs based on high quality WES data. The high sensitivity of our WES CNV data supports its utility for CNV detection in clinical settings, although the specificity is expected to be low due to the greater variability in depth of coverage across an exome. Our experience in a clinical diagnostic laboratory supports the importance of the integration of CNV detection with routine WES and shows this strategy results in an increase in diagnostic yield with reduced turnaround time (TAT) but without additional testing and cost.

**3021W****The clinical impact and analytical validity of copy number variation**

**calling in rapid genomic sequencing.** S. Chowdhury, S. Batalov, Y. Ding, R. Hovey, S. Nahas, M. Bainbridge, M. Wright, K. Ellsworth, M. Tokita, T. Wong, N. Veeraraghavan, D. Dimmock, S. Kingsmore, *RCIGM Investigators*. Rady Children's Institute for Genomic Medicine, San Diego, CA.

Introduction: Implementation of rapid whole genome sequencing (rWGS) has been shown to result in improved diagnostic rates and improved outcomes. A benefit of using rWGS is the potential to simultaneously identify multiple types of genetic variation. The added impact of the inclusion of copy number variation (CNV) within a pediatric patient cohort was assessed. Methods: After consent, blood samples were collected and rWGS was performed via Illumina SBS chemistry to an average genome-wide coverage of 40x. Small variant calling was performed via the Edico DRAGEN, and CNVs were detected using a combination of the CNVnator and Manta callers. Union of the CNV calls generated and custom filtering was applied to ease interpretation burden. The pipeline was optimized to complete alignment and variant calling for small and large genetic variation within 3.5 hours. All reported CNV calls were validated via microarray, Q-PCR, or MLPA. Results: Using a custom filtering workflow, the average number of CNVs to interpret was six per analysis. To date, 443 patients that underwent rWGS resulted in 150 diagnoses for a diagnostic rate of 33%. Of these diagnoses, 24 of the 150 involved CNVs (16%). CNV pathogenic variation ranged from 1.7 kB to whole chromosome abnormalities. All identified variants were orthogonally confirmed with no false positive calls. Seven of the events were less than 50 kB, and thus potentially below the standard resolution and interpretation of microarrays. Three cases involved integrated reporting of a CNV and SNV within the same gene. Conclusion: This study outlines the impact CNV calling has on a rWGS cohort. The ability to rapidly detect multiple types of genetic variation via rWGS will allow greater diagnostic rates, fewer genetic test orders, and faster genetic results, which has been shown to have a significant impact on the clinical utility of genetic testing.

**Enzyme activity determination and DNA extraction obtained from a single 3.2 mm DBS punch.** S.S. Dallaire, C. Gutierrez-Mateo. Molecular Diagnostics R&D, PerkinElmer, Waltham, MA.

The challenge for laboratories to decide which assays to implement is ever-present with the continual advances in science. With more options available than most laboratories have resources, there is a demand to make testing even more efficient than previously required. In newborn screening, testing can be readily performed using a punch from a dried blood spot (DBS) made from a newborn heel stick. Traditionally, each assay performed in the lab needs an individual punch from the DBS card. There is a limited number of times that a DBS card can be punched; thus capping the number of tests than can be done on that specimen. A common way to maximize the number of analytes than can be tested in a single DBS punch is to favor a multiplex assay over a single-plex test, which also decreases the cost per analyte. A new approach, presented here, is the ability to perform two multiplex assays on the same DBS punch, which will allow obtaining adequate results while reducing the required sample material by half. This study demonstrates how a single DBS punch can be exposed to the assay conditions necessary to measure certain enzyme activities via mass spectrometry followed by immediate processing to extract and measure the DNA by PCR amplification. This new sequential elution method allows one to obtain multiple results on two separate platforms using a single 3.2 mm punch.

**Improving continuity of care and reducing healthcare costs by focusing on how CYP2C19 and other pharmacogenetic tests are ordered.** *M. Moore, B. Tucker, A. Mroch, L. Mullineaux, C. Flom, A. Aifaoui, A. Schultz, J. Reiner, R. Pyatt.* Imagenetics, Sanford Health, Sioux Falls, SD.

Electronic medical record (EMR) systems are designed to improve efficiency and safety by creating automatic responses to specific situations. These responses include grouping certain tests together for specific clinical situations and discontinuation of open test orders when a patient's status changes, such as being transferred or discharged. Although the intention of the automatic response is to reduce decision-making time and the number of outstanding orders in the system; unfortunately, the response can actually increase costs and the patient's time involved. Redundant charges arise from standing orders that include testing that has already been performed and automatically cancelled orders may include testing still relevant to clinical care. Sanford Health's genomic medicine program, Imagenetics, has created an inclusive team of medical doctors, molecular laboratory directors, laboratory genetic counselors (lab GCs), laboratory compliance and quality specialists, the laboratory technicians, and pharmacists. The team has devised methods to evaluate specific pharmacogenetic orders to improve overall quality assurance, continuity of care, and reduce healthcare system redundancies. These implementations have already demonstrated increased quality assurance. Data from the first quarter of implementation noted 308 CYP2C19 tests, which included 14 duplicate orders (4.5%), 14 automatically cancelled orders (4.5%), and one changed order (0.3%). Of the automatically cancelled orders due to patient discharge, all but 2 had the testing either reordered (n=7; 50%) or had already been performed (n=5; 35.7%). Through discussions with the hospital clinical informatics operations team, this process has started additional in-patient unit interventions to reduce the number of relevant orders being cancelled. Expanding this process to include other genetic testing performed in our laboratory is also being considered.

**3024W**

**Phenotype clustering and exome reanalysis approach to aid identification of gene-disease associations: A pilot study using genes in the RNA exosome pathway.** *R. Ghosh<sup>1,2</sup>, B. Yuan<sup>1,2</sup>, J. Salvo<sup>2</sup>, F. Xia<sup>1,2</sup>, C. Shaw<sup>1,2</sup>, C. Eng<sup>1,2</sup>, Y. Yang<sup>1,2</sup>, P. Liu<sup>1,2</sup>.* 1) Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX 77030, USA; 2) Baylor Genetics, Houston, TX 77021, USA.

The current overall diagnostic rate for clinical exome analysis is around 30%. To potentially improve the diagnostic rate, we performed a retrospective analysis of exomes of patients referred for clinical exome sequencing who shared similar clinical features. As a pilot study, we focused our analysis on the genes in the RNA exosome pathway. The RNA exosome pathway is a multiprotein complex that is essential for proper RNA metabolism. It is composed of nine core subunits, catalytic components with exoribonuclease activity and other associated proteins. Of these, four of the genes in the core subunit have been associated with disease. We annotated 223 patients with variants in the exosome pathway genes with HPO terms corresponding to their clinical features. We also included HPO term annotated phenotype profiles of previously published patients with causative variants in the exosome core genes in our analyses. We next performed cluster analysis to identify groups of patients with similar clinical features and then analyzed the exomes of groups of individuals that shared phenotype profiles. Patients harboring variants in the EXOSC2 gene have been reported to have distinct clinical features compared to patients with variants in the other exosome core genes. Consistent with these published results, we identified patients reported in the literature harboring EXOSC2 pathogenic variants in a different cluster from the published patients with pathogenic variants in the other exosome core components. We identified three patients in our cohort in the same cluster with overlapping features as the published patients with variants in EXOSC3 including motor and speech delay, cerebellar atrophy, joint contractures and hypotonia. Two of these patients harbored the known homozygous pathogenic c.395A>C (p.D132A) variant in the EXOSC3 gene and the other patient harbored a homozygous rare variant in the EXOSC3 gene. We also identified deleterious variants in genes not currently associated with core exosome components in individuals whose clinical features significantly overlapped with clinical features of patients with pathogenic variants in known exosome genes implicated in human disease. Using a phenotype clustering method, our pilot study show that this approach helps identify cohorts with unique combinations of clinical features on which exome reanalysis could be conducted to identify novel disease genes and/or reclassify previously existing variant assertions.

**3025T****Report of five families with autosomal recessive bestrophinopathies**

**(ARB).** *I. Habibi<sup>1</sup>, Y. Falfoul<sup>1</sup>, M.G. Todorova<sup>2</sup>, S. Wyrsch<sup>3</sup>, M. Helfenstein<sup>3</sup>, D.F. Schorderet<sup>4</sup>, L. El Matri<sup>1</sup>.* 1) Hedi Rais Institute of Ophthalmology (Department B), LR14SP01, Tunis, Tunisia; 2) Department of Ophthalmology, University of Basel, Basel, Switzerland; 3) Eye Clinic, Lucerne Cantonal Hospital, Lucerne, Switzerland; 4) Institute for Research in Ophthalmology, Sion, Switzerland.

Mutations in *BEST1* cause several phenotypes including autosomal dominant (AD) Best vitelliform macular dystrophy type 2 (BVMD), AD vitreoretinopathy (ADVIRC), and retinitis pigmentosa-50 (RP50). These retinopathies are characterized by vitelliform dystrophy for which ophthalmologists like to describe 5 stages, going from pre-vitelliform to the atrophic final stages. A rare subtype of bestrophinopathy exists with biallelic mutations in *BEST1*. Its frequency is estimated to be 1/1'000'000 individuals. We report 5 cases and establish a phenotype-genotype correlation. All patients were referred because of reduced best-corrected visual acuity, ranging from 0.1/10 to 3/10. All patients showed vitelliform lesions present at the macula, sometimes extending into the midperiphery and along the vessels and optic disc. Onset of the disease varied from the age of three to 25 years. Electrooculogram (EOG) revealed reduction in the EOG light rise in all patients. Molecular analysis revealed the previously reported mutations p.[R141H];[A195V], p.[E35K];[E35K], and p.[R202W];[R202W]. Two families showed novel mutations: p.[Q220\*];[Q220\*] and p.[L31M];[L31M]. All mutations were heterozygous in the parents. In one family, heterozygous children showed various reduction in the EOG light rise and autofluorescent deposits. ARB, also rare, can be recognized by its phenotype and should be validated by molecular analysis. Phenotype-genotype correlations are hard to establish and will have to wait for more cases.

**3026F**

**Expanding the options of secondary findings in whole exome sequencing.** *J. Machado, D. Allingham-Hawkins, B. Dorshorst, G. Fischer, R. Steiner, R. Vanneste, J. Weber.* PreventionGenetics, Marshfield, WI.

Individuals undergoing whole exome sequencing (WES) often have complex clinical presentations or disorders with significant genetic and phenotypic heterogeneity. At the same time, they are often asked to decide whether they would like to be informed of secondary findings (SF), medically important discoveries unrelated to the reason for testing. The most common option for SF is the American College of Medical Genetics and Genomics' (ACMG) recommended list of 59 genes for disorders that have established interventions for reducing morbidity and mortality. Outside of these 59 genes, however, there are many other disorders that may have current and potential medical management. Moreover, individuals may also harbor variants for recessive disorders, which may have implications for future family planning. In our PreventionGenetics' PGxome® WES analysis, patients may opt-in for variants in the ACMG 59 genes, and options for assessing variants causing other Mendelian predisposition disorders, and recessive diseases for clinically relevant disorders (e.g. OMIM, HGMD). In the PGxome® analysis, 69%, 40%, and 39% of individuals consented to the assessment of ACMG 59 gene variants, predisposition to other Mendelian disorders, and carrier status for recessive diseases, respectively. Likely pathogenic or pathogenic (LP/P) variants were identified in 2%, 24%, and 90% of cases, respectively. Examples of SF for genes in predisposition disorders include *NOTCH3* (CADASIL), *CHEK2* (Breast cancer), *VWF* (von Willebrand disease), *COL5A1* (Ehlers-Danlos syndrome), and *FLG* (Ichthyosis vulgaris). Additional genes beyond the ACMG 59 genes may alert the patient and healthcare provider to future disease risk, which there may or may not be a treatment for healthcare, and for personal management. For recessive disorders, individuals who opted-in to these SF were, on average, carriers of 3 LP/P recessive variants (range 1-8). One trio analysis detected a heterozygous  $\Delta F508$  *CFTR* variant in the proband and both parents. The parents were previously unaware of their carrier status, and this knowledge provided additional family planning considerations for them. The option of additional SF beyond the ACMG 59 genes empowers individuals and their families by giving them more information for potential future health care decisions.

**3027W**

**24 hours rapid diagnosis for critically ill infants through trio whole exome sequencing.** Y. Qian, B. Wu, Q. Qin, Y. Lu, P. Zhang, H. Wang, W. Zhou. Children Hospital of Fudan University, Shanghai, Shanghai, China.

**Objective:** Genetic diseases in childhood, especially in neonatal period are difficult to receive clearly diagnosis from clinical information. Some disease require distinctive treatments in a timely manner. Therefore, a rapid and precise molecular diagnosis is necessity for patients under intensive care. We aimed to establish a pipeline, from receiving blood sample to oral report within 24 hours through trio-whole exome analysis (Trio-WES). **Study designs:** The rapid WES pipeline was set up by sequencing of the standard DNA sample of NA12878 on IonTorrent S5 XL platform, and thirty-four patients from Pediatric Intensive Care Units (PICU)/Neonate Intensive Care Units (NICU) with rapid progression without definitive diagnosis were enrolled. The samples were sequenced in parallel with the rapid and the routine WES test pipeline. **Result:** Using the standard DNA, we found the precision was 88.08%, and sensitivity was 81.33%, when compare with the golden standard variants in GIAB for single nucleotide variants (SNVs). Then, we successfully completed thirty-four Trio-WES, the mean sequence depth is 70x. Among the thirty-four seriously illness infants under test, definitive diagnosis was made in twenty-three cases, which including immunodeficiency, inherited metabolic diseases, early infantile epileptic encephalopathy and multi-malformation syndrome. The oral reports were sent to clinicians within 24 hours, Sanger sequencing for variants confirmation as fast as nine hours and routine genetic reports will return within 21 days. Clinical treatment strategies were immediately adjusted according to the rapid genetic diagnosis. There are three cases missed the diagnosis from the rapid pipeline due to insufficient coverage or mismatch mapping, which were detected the pathogenic mutations by routine pipeline. So the diagnosis ratio of the infants was 67.6% (23/34), and the false negative ratio was 8.8% (3/34). **Conclusion:** Using the 24 hours rapid Trio-WES, we successfully diagnosed twenty-three out of thirty-four critically ill infants stayed in ICU. Thus, this rapid genetic diagnosis method can serve as a rapid response genetic diagnosis tool, which can guide clinical decision-making in urgent cases.

**3028T**

**Development and validation of a 30 gene pharmacogenetic genotyping panel: Comprehensive allele and copy number detection.** S.A. Scott<sup>1,2</sup>, E.R. Scott<sup>1,2</sup>, A.J. Chen<sup>1</sup>, Y. Seki<sup>1</sup>, M.R. Botton<sup>1,2</sup>, R. Wallsten<sup>1</sup>, A. Owusu Obeng<sup>2,3</sup>, G. Zhao<sup>1</sup>, Y. Yang<sup>1,2</sup>, P. Nicoletti<sup>1,2</sup>, H. Shi<sup>1</sup>, P. Brake<sup>1</sup>, M. Delio<sup>1</sup>, L. Shi<sup>1,2</sup>, R. Kornreich<sup>1,2</sup>, E.E. Schadt<sup>1,2</sup>, L. Edelmann<sup>1,2</sup>. 1) Sema4, a Mount Sinai venture, Stamford, CT; 2) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 3) Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai, New York, NY.

Increasing enthusiasm for implementing clinical pharmacogenetic testing is evidenced by the recent availability of clinical practice guidelines and personalized medicine programs that pre-emptively genotype pharmacogenetic variants. However, there are inconsistencies in content among the available clinical pharmacogenetic panels and some genes and variants implicated in drug response variability are challenging to interrogate due to sequence homology. To develop a novel and clinically relevant pharmacogenetic genotyping panel, a multidisciplinary team evaluated the available evidence and identified 138 common and rare sequence (n=131) and copy number (n=7) variants with clinical validity for drug response testing. These functional variants intersected 30 genes and gene regions, including 11 Clinical Pharmacogenetics Implementation Consortium (CPIC) guideline genes, which together inform on 160 medications. Targeted genotyping and copy number interrogation were accomplished by multiplex single-base extension using the MassARRAY<sup>®</sup> system and multiplex ligation-dependent probe amplification (MLPA), respectively. Analytical validation was accomplished by testing 122 unique DNA samples, which included sequence and copy number variant accuracy (n=119), reproducibility (n=24), and specimen (n=8) controls. Among the accuracy controls were 32 Coriell samples from the 1000 Genomes Project that were selected based on their enrichment of variants included in the pharmacogenetic panel. Coupled with publicly available GeT-RM pharmacogenetic controls, these accuracy samples enabled reference validation material for the majority of interrogated variant alleles, including complex *CYP2D6* structural alleles. Accuracy and reproducibility were both determined to be >99%, indicating that the optimized panel platforms were precise and robust. Importantly, multi-ethnic allele frequencies of the interrogated variants indicate that the vast majority of the general population carries at least one of these clinically relevant variants, supporting the use of this panel for pharmacogenetic research and/or clinical testing programs.

**A rapid and scalable platform for direct modeling of human developmental disorders in mice using CRISPR/Cas9 genome editing.** S.A. Murray<sup>1</sup>, K.A. Peterson<sup>1</sup>, C.S. Heffner<sup>1</sup>, C.N. Baker<sup>1</sup>, X. Liu<sup>2</sup>, R.J. Manak<sup>3</sup>, C. Lo<sup>2</sup>. 1) The Jackson Laboratory, Bar Harbor, ME; 2) University of Pittsburgh School of Medicine, Pittsburgh, PA; 3) University of Iowa, Iowa City, IA.

The pace of discovery of the genetic basis of human disease continues to accelerate. However, ascribing causality to a given gene variant is often challenging and thus many cases remain unsolved. Animal models provide powerful tools to both support gene discovery and to serve as research platforms for mechanistic investigation with the mouse providing the ideal mammalian system to model developmental disorders. While CRISPR/Cas9 genome editing has simplified and accelerated pipelines for mouse model creation, timelines are often incompatible with the needs of human gene discovery programs. To address this issue and to support human disease discovery efforts, we have developed a rapid, scalable platform to directly evaluate the causality of novel genes/variants for developmental disorders, taking advantage of the high-throughput mouse embryo phenotyping platform built for the KOMP2/IMPC program. We demonstrate the feasibility of direct phenotypic analysis of F0 ("founder") mouse embryos generated by CRISPR/Cas9 reducing the time required to model a mutation from over a year to a matter of weeks. In proof-of-principle studies, we show that we can efficiently generate and definitively identify expected morphological phenotypes in a mosaic population of edited embryos. Our platform can generate both knockout (null) and precision knock-in (missense) alleles in a single experiment, creating an allelic series to support our understanding of variant function. High-throughput sequencing methods allow us to quantitate the degree of mosaicism in individual specimens, permitting genotype-phenotype associations. Finally, we apply our platform in support of multiple human disease gene discovery efforts, helping solve these cases, and demonstrating the value of our approach. Together with current experiments to increase the efficiency in generation of precision alleles, our platform has the potential to improve the speed and utility of the mouse as a tool to validate and model novel variants for human disease.

Since the advent of whole exome sequencing (WES) and whole genome sequencing (WGS), the identification of the genetic bases of disease has improved. Although the clinical utility of WES and WGS has been highly debated, several studies have shown that for individuals with complex medical presentation and extensive clinical work-ups, WES/WGS allows clinicians to circumvent the step-wise targeted single-gene or gene panel tests in favour of a more cost- and time-effective diagnostic tool. Advances in WES/WGS platforms and bioinformatic pipelines have greatly improved scientists' ability to conduct WES/WGS, understand human genetic variation associated with disease, as well as improve the ability to provide molecular diagnoses for individuals with complex medical presentations. In Ontario, the Ministry of Health and Long-Term Care (MOHLTC) lacks eligibility criteria for publicly-funded WES/WGS in adults. Therefore, adults with suspected hereditary conditions are often denied coverage. This lack of access has significant clinical implications. In the adult genetics clinic in Toronto, which services over 1,600 patients/year, <30% reach a diagnosis despite extensive diagnostic investigations. As a result, providing guidance for prognosis, appropriate clinical management and treatment, and recurrence risk for patients and families remains an enormous challenge. In response, our research initiative provides WES/WGS for adult patients that were denied funding by the MOHLTC but for whom standard testing was uninformative. We currently recruit from three Mount Sinai Hospital-affiliated clinics and have enrolled 87 families (155 individuals) presenting with breast and gastrointestinal cancer, cardiovascular, neurological, musculoskeletal, or renal disorders. To date, 42 families (71 individuals) have undergone WES or WGS analysis and have been counselled by genetic professionals on their results. Here, we report a diagnosis yield of 23.8% using WES or WGS, a figure that is consistent with the 20-25% diagnostic yield of ES reported in other comparative studies using only pediatric neurodevelopmental or adult cardiac cohorts. Furthermore, this study addresses the importance of both disease type and analytical context (singleton vs. trios) to develop recommendations for improving analysis of WES/WGS. These findings will not only help to generate guidelines for appropriate use in adults, but will strengthen justifications for using WES/WGS as a first tier clinical test.

**The impact of depth of coverage from sample quality in whole genome sequencing.** *K. Park, H. Kwon, S. Lee, M. Roh, D. Seo.* Macrogen Corp., Rockville, MD.

The depth of coverage in sequencing data is one of the important factors to determine whether the data are suitable for scientific researches and clinical studies. As a sequencing service provider, we investigated the depth of coverage using more than 5,000 samples from whole genome sequencing (WGS). Many samples had passed, but some had failed from our QC criteria, called the DOC, measuring difference from Poisson distribution, interquartile range, and mode of depth of coverage. One of the factors that caused DOC failure was the percentage of G and C bases (GC%) in sequencing data, which should be about 41% in the human genome. Among the samples with DOC failure, the percentages of GC in most samples had increased, ranging up to 50% in sequencing data. To identify the cause of GC% alteration, we measured the quality of samples using KAPA hgDNA Quantification and QC kit (Roche, CA, USA), and we observed a negative correlation between Q ratio from this kit and GC%, which indicated that lower quality samples were more likely to have a higher percentage of GC contents. In conclusion, it is challenging, but maintaining a high quality of sample can guarantee to obtain a high quality of sequencing data. .

**Improving quality, cost and turnaround time using the Illumina NovaSeq 6000 System for rapid whole genome sequencing.** *L. Van Der Kraan, L. Puckett, C. Yamada, S. White, R. Hovey, S. Batalov, J. Braun, P. Mulrooney, M. Janes, N. Veeraraghavan, M. Tokita, K. Ellsworth, S. Chowdhury, S. Nahas, Z. Bezares-Orin, Y. Ding, S. Kingsmore.* Rady Children's Institute for Genomic Medicine, 7910 Frost St, San Diego, CA, 92123.

The Clinical Genome Center (CGC) at Rady Children's Institute for Genomic Medicine (RCIGM) is a CAP and CLIA certified clinical laboratory specializing in rapid whole genome sequencing (rWGS) for acutely ill infants and children with suspected genetic conditions. Historically, for diagnostic laboratories, delivering sequencing data in a timely manner while maintaining sequencing performance at a low cost has been challenging. At RCIGM's inception, initial instrumentation included Illumina's HiSeq 2500 (Rapid Mode) and 4000 sequencing platforms. Early last year, Illumina introduced the NovaSeq series to the genetic community. At RCIGM we sought to compare the performance of the NovaSeq 6000 to the standard Illumina sequencing platforms, the HiSeq 2500 and 4000. We validated the NovaSeq 6000 for clinical laboratory use and implemented it for routine rWGS testing. Validation of the NovaSeq 6000 was performed using the same methods as used for the HiSeq 2500 and 4000 with Coriell gold standard (CEPH and AJ) trios, in addition, to previously-tested research-consented patient samples reported from the CGC. Library preparations were completed using either the Illumina TruSeq PCR-Free or KAPA Hyper Prep (Roche) kits. Sequencing on the NovaSeq 6000 was performed using the S2 flowcell with a 6-plexed, single indexed 13.5 nM library loaded on one side with 2x10<sup>1</sup> cycles. Metrics following sequencing on the NovaSeq 6000 produced an average yield of 932 gigabases (Gb) per flow cell, >78% clusters passing filter and >93% Q30. These metrics were comparable and better than that following clinical validation and performance of the HiSeq 2500 and 4000 systems. In particular, with regards to sequencing run time and cost, the average sequencing run time for rWGS on the NovaSeq 6000 is ~24 hours for 6 genomes, on the HiSeq 2500 ~26 hours for 1 genome and on the HiSeq 4000 ~40 hours for 6 genomes. The cost savings per genome on the NovaSeq 6000 is 66.8% when compared to the HiSeq 2500 and 5.6% when compared to the HiSeq 4000. Thus, the NovaSeq 6000 system decreases run time and cost per genome while maintaining and improving the quality of its sequencing data; moreover, it dramatically advances our rWGS approach in the neonatal (NICU) and pediatric intensive care (PICU) units by providing us with faster, higher throughput and better quality sequencing data in a more economical way.

**Solving the mystery of rare genetic disorders: An integrated approach to accelerate diagnosis of rare diseases, facilitate gene discovery and improve management.** X. Wang<sup>1</sup>, M. Harr<sup>1</sup>, D. Watson<sup>1</sup>, F. Mafra<sup>1</sup>, C. Chung<sup>1</sup>, E. Bhoj<sup>1</sup>, K. Stumm<sup>1</sup>, A. Wenocur<sup>1</sup>, L. Tian<sup>1</sup>, M. March<sup>1</sup>, D. Li<sup>1</sup>, C. Hour<sup>1</sup>, R. Pellegrino<sup>1</sup>, P. Sleiman<sup>1,2,3</sup>, H. Hakonarson<sup>1,2,3</sup>, A. Santani<sup>1,4</sup>. 1) Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Department of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; 3) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4) Department of Pathology, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

To benefit patients with rare genetic disorders, it is increasingly critical to create an infrastructure where genome analysis is integrated with functional analysis of novel genes and variants. Integration of sequence data with comprehensive clinical evaluations and advanced machine learning-based algorithms are needed to facilitate rapid and efficient analysis of genomic data. Candidate gene and variants subsequently require further evaluations to demonstrate an impact on protein function. To address these challenges, we have established an infrastructure that integrates a biorepository, a sequencing and microarray facility, an informatics and analysis team, a clinical team and a translational research laboratory. The workflow includes: 1) sample preparation and sequencing; 2) a genomics pipeline including sequence mapping, alignment, variant calling, variant annotation and filtration, 3) A custom-developed phenotype-driven genome analysis algorithm and 4) infrastructure to facilitate in vitro cell studies and functional assays in model systems. The sequencing and informatics workflow was validated by detection of known variants in reference samples with an analytical sensitivity and specificity for SNVs and indels of >99%. The analysis of genomic data primarily relies on leveraging the clinical presentation of the patient. Our analysis strategy utilized our custom variant prioritization algorithm and was validated by performing blinded exome analysis on 32 randomly selected probands who had previously undergone diagnostic exome sequencing by reference laboratories. The causal variant was correctly detected in all cases, and ranked at No.1 for 29/32 cases and in the top 3 for the remaining 3 cases. We report substantially reduced turn-around times with identification of high priority variants within 2 hours after sequencing. This system accelerates the comprehensive analysis of patients with unsolved rare disorders and, coupled with translational follow-through on variants and novel candidate genes, supports identification of novel therapeutics. Using specific case vignettes, we will describe how this infrastructure enabled the diagnosis and understanding of rare genetic disorders. We will highlight successful strategies that other programs can use to facilitate disease diagnosis, impact clinical management and advance medical research.

**Genotype-phenotype analysis of 523 pediatric patients referred for genetics evaluation who underwent whole exome sequencing.** M.N. Ziats<sup>1</sup>, A. Ahmad<sup>2</sup>, E. Ames<sup>2</sup>, J.A. Bernat<sup>3</sup>, R. Fisher<sup>2</sup>, M. Glassford<sup>2</sup>, M. Hannibal<sup>2</sup>, J. Jacher<sup>2</sup>, C.E. Keegan<sup>2,4</sup>, K. Lee<sup>2</sup>, T. Marzulla<sup>4</sup>, B.C. O'Connor<sup>2</sup>, S.C. Quinonez<sup>1,2</sup>, L. Seemann<sup>4</sup>, L. Turner<sup>4</sup>, S. Bielas<sup>4</sup>, N.L. Harris<sup>5</sup>, J.W. Innis<sup>1,2,4</sup>, D.M. Martin<sup>2,4</sup>. 1) Department of Internal Medicine, University of Michigan; 2) Division of Pediatric Genetics, Metabolism, and Genomic Medicine, Department of Pediatrics and Communicable Diseases, University of Michigan; 3) Division of Medical Genetics, Stead Family Department of Pediatrics, University of Iowa; 4) Department of Human Genetics, University of Michigan; 5) Children's Clinical Trial Support Unit, University of Michigan.

Clinical whole exome sequencing (WES) has high potential for uncovering phenotype-genotype relationships that guide discovery and clinical care. Here we present WES genotypes and clinical phenotypes from 523 patients referred to the Pediatric Genetics clinic at Michigan Medicine. Patients were systematically phenotyped by presence or absence of abnormalities for 13 body/organ systems, including autism spectrum disorder (ASD), developmental delay/intellectual disability, cancer, multiple congenital anomalies, dysmorphic features, and behavioral phenotypes. Overall, 30% of patients who underwent clinical WES had an identified pathogenic variant. Notably, 67% of patients had a variant of uncertain significance (VUS; n = 244) or gene of uncertain significance (GUS; n = 116), and 23% had no pathogenic or uncertain variants identified. The most common clinical phenotypes among patients with a pathogenic variant were developmental delay (83%) and neuromuscular system abnormalities (81%); 20% had ASD and 42% had multiple congenital anomalies. The average number of body systems affected for patients with a pathogenic variant was 5.89, vs 6.0 for patients with VUS only and 6.12 for patients with GUS only. For patients with no identifiable variant, this average was 4.6, a significant difference when compared to patients with a pathogenic variant (one-way ANOVA P<0.00001). Among patients with ASD and a pathogenic variant (N=31), 42% had a variant in a gene involved in transcriptional regulation, whereas 23% of patients had a variant involved in synaptic functioning, 16% were involved in ion channels, and 6% were involved in another pathway. In patients with ASD, we analyzed the relationship between implicated molecular pathway and severity of clinical phenotype as inferred from the number of body systems affected. Interestingly, ASD patients with a pathogenic variant in a gene involved in transcription had a higher number of systems affected than those with a gene involved only in synaptic functioning or ion channels (7.4, 4.9, and 5.2, respectively), although this difference did not reach statistical significance (p=.12) perhaps owing to small sample size. In summary, our cohort of 523 pediatric patients with WES exhibits clinical features that are enriched for multiple organ system involvement. Variants identified in this cohort of patients can be leveraged to inform mechanistic understanding of individual disorders with a genetic component.

**3035F**

**The use of multi-mode reader for the quantification of libraries for next generation sequencing systems.** *J. Adigun, C. Nolan, F. Davis, J. Kennedy, W. Lowe, S. Ayres, J. Hatton, S. Hofherr.* GENEDX, Gaithersburg, MD.

Next generation sequencing continues to be an important tool in the determination of causative variants in the pathology of many genetic disorders. The accurate quantification of completed libraries for sequencing on next generation sequencing systems is an important factor in the successful and cost-efficient generation of sequencing data. While the cost of data for generation for massive parallel sequencing has fallen considerably in recent years, inaccurate quantification of libraries continues to lead to costly repeat of the sequencing process. Over the years, many technology and processes have been implemented by laboratories to achieve accurate quantification of libraries. Such include the use of Real-time (quantitative) polymerase chain reaction process, QPCR and/or the use of instrumentations such as the Bioanalyzer and TapeStation systems. More often than not, these processes are cumbersome, not amenable to high throughput laboratories, time consuming and may lead to high recurring cost in the laboratory. Here we describe the use of a reasonably priced microplate reader, the Synergy HTX Multi-Mode reader, with fluorescence-based dye, that is amenable to high throughput laboratories for accurate and dependable quantification of libraries. This workflow is very quick, accurate and cost-efficient in the clinical as well as research laboratories.

**3036W**

**Genome-wide SNP array analysis reveals contribution of mosaicism and chimerism in pediatric genomic diagnostics.** *B. Weckselblatt<sup>1</sup>, L.K. Conlin<sup>1</sup>, J. Fan<sup>1</sup>, E. Zackaj<sup>2</sup>, M. Dulik<sup>1</sup>, N.B. Spinner<sup>1</sup>, M. Luo<sup>1</sup>.* 1) Division of Genomic Diagnostics, Department of Pathology and Laboratory Medicine, Children's Hospital of Philadelphia, Philadelphia, PA; 2) Division of Human Genetics, Department of Pediatrics, Children's Hospital of Philadelphia, Philadelphia, PA.

The chromosomal microarray is a first-tier diagnostic test for patients with congenital anomalies, neurodevelopmental disorders, and/or other clinical phenotypes. We have previously validated a SNP-based array to detect mosaicism and chimerism in at least 5% of cells, and to interpret the timing of these events as pre-zygotic or post-zygotic in origin. In this retrospective analysis, we reviewed the SNP array data from patients received by our clinical laboratory to investigate the contribution of mosaicism to pediatric genomic diagnostics. Since May 2008, we have performed SNP array analysis for 14,078 samples from 13,816 patients. Mosaic changes were detected in ~1.8% (N=251) of cases, accounting for ~15% (N=206) of abnormal reports, while ~18% of the mosaic findings have uncertain clinical significance at this time. When possible, cytogenetic studies confirmed array results and resolved variants that were associated with structural rearrangements. The most common mosaic finding was chromosomal aneuploidy, with the sex chromosomes being most frequently involved, followed by autosomal trisomies involving 13 different chromosomes. Whole genome mosaicism consistent with fertilization errors, including mosaic triploidy and several types of chimerism, were detected in multiple tissues from 10 individuals, with mosaic whole genome paternal isodisomy (androgenetic chimerism) as the most frequently observed genome-wide finding. The remaining results involved supernumerary marker chromosomes, interstitial deletions and duplications, unbalanced translocations, uniparental isodisomy (entire chromosome or segmental), as well as more complex patterns that do not fit known rearrangement models. For 13 individuals, the array had sufficient sensitivity to detect a large abnormality of the B allele frequency present in less than 5% of the cell population, though this level is too low to detect a significant change in the LogR ratio, thus we could not determine whether the region denotes a copy number change or loss of heterozygosity. This review of the last ten years of SNP array testing demonstrates that mosaicism is a significant contributor to the diagnostic yield of SNP arrays, and provides insights into the mechanisms and origins of chromosomal abnormalities.

**3037T**

**The potential significance of Alu elements in genetic diseases as assessed through identification of rare insertion events via whole genome sequencing in a cohort of pediatric patients.** *M.S. Wright, D.G. Tamang, S. Chowdhury, D.P. Dimmock, S.F. Kingsmore, M.N. Bainbridge.* Rady Children's Institute for Genomic Medicine, San Diego, CA.

Alu elements are abundant in the human genome, but it is estimated that less than 0.5% of insertion sites are polymorphic. The current estimate is that de novo Alu insertion events arise in 1:20 births. Alu elements have been implicated in multiple monogenic diseases and cancer development when inserted into new chromosomal locations. We therefore sought to address the potential clinical significance of Alu elements in pediatric disease using genome wide surveys of whole genome sequence data from a cohort of 309 families sequenced through Rady Children's Institute for Genomic Medicine. This included 702 individual genomes comprising 178 trios, 32 proband/parent duos, 94 proband only, and 5 matched germline-somatic samples. We developed a computational pipeline that utilizes a split-read mapping approach to detect Alu insertions. For paired reads in which one read maps to an Alu sequence, the chromosomal location for the other read was identified. To minimize mapping artifacts and remove common polymorphic Alu sites, count data for each insertion site in each individual genome was normalized to population-wide counts, where only locations that exceeded greater than 2 standard deviations above the normalized population counts were retained. This enabled us detect rare events. Using this approach we detected >16,000 rare intergenic Alu insertions in our cohort, as well as >2000 intragenic sites in 2008 genes. Strikingly, we detected Alu insertions in 313 OMIM disease genes, many of which were in UTR sequences. The availability of WGS data from trios allowed us to further estimate de novo retrotransposition rates and the potential contribution of de novo events to genetic diseases. Our results highlight that Alu insertions may play a larger role in the genetic disease burden than previously estimated in pediatric populations, as well as demonstrates the role Alu elements play in genome diversification.

**3038F**

**A simplified, rapid approach to targeted resequencing of dried blood spot samples.** *D. Mandelman, S. Rozenzhak, A. Kraltcheva, C. Van Loy, A. Harris.* Thermofisher Scientific, 5781 Van Allen Way, Carlsbad, CA . 92008.

Dried blood punches (BPs) are a common sample type in hospitals - especially for newborns – and in remote field studies. We present a simplified protocol for preparing libraries from dried blood punches for analysis on next-generation sequencing (NGS) platforms using Ion AmpliSeq™ chemistry. AmpliSeq™ is a PCR-based NGS library prep method that uses targeted primer panels to amplify DNA or RNA regions of interest for most any research application, including inherited and infectious disease. Current BP protocols require laborious, time consuming sample purification from the BP followed by sample quantification. This problem is only exacerbated as sample number increases. Our protocol enables direct use of BPs in PCR. To verify the efficacy of our method, a variety of AmpliSeq™ panels were tested on BPs using the new protocol. When compared to traditionally purified, quantified samples, no differences in sequencing read quality or variant calling were observed between the BPs and purified genomic DNA. Simplified sample prep methods like this will facilitate the uptake of NGS in settings where BPs are a common sample type. *For Research use only. Not for use in diagnostic procedures.*

**3039W**

**Identification of novel CYP2D6 haplotypes that interfere with TaqMan copy number analysis.** A. Turner<sup>1,2</sup>, P. Aggarwal<sup>1,2</sup>, E. Boone<sup>3</sup>, C. Haidar<sup>4</sup>, M. Relling<sup>4</sup>, U. Broeckel<sup>1,2</sup>, A. Gaedigk<sup>3</sup>. 1) The Medical College of Wisconsin, Milwaukee, WI; 2) RPRD Diagnostics, Wauwatosa, WI; 3) The Children's Mercy Hospital, Children's Research Institute, Kansas City, MO; 4) St. Jude Children's Research Hospital, Memphis, TN.

Cytochrome P450 2D6 (*CYP2D6*) is a highly polymorphic gene encoding an enzyme critical in the metabolism of up to 25% of commonly prescribed drugs. There are over 100 described star allele (\*) haplotypes, including frequent gene conversions, deletions, duplications and gene-fusions (D6/D7 hybrid), many of which have altered enzyme activity. Accurate copy number (CN) calling is critical in determining patient drug response. TaqMan CNV assays are a commonly used methodology for CN analysis, utilizing specific primers and labeled probes to evaluate the CN state of a genomic region of interest. Polymorphisms within the primer or probe target sequence can generate a false positive for a CN loss. Currently three *CYP2D6* intra-gene regions can be tested using commercially available TaqMan assays: intron 2, intron 6 and exon 9. Gene-fusions or conversions present as discrepant CN calling between the three regions. During clinical testing, we identified samples with CNV inconsistent with known haplotypes. To characterize the haplotypes that lead to these CNV results, we performed long range PCR, Next-Gen sequencing and allele-specific Sanger sequencing. Sequence analysis of 20 patients identified six novel sub-alleles containing polymorphisms within the TaqMan assay probe binding sites, causing a false-positive copy number loss. In total, four novel haplotypes (sub-alleles) with SNPs within the intron 2 and 6 probes were identified (\*1 sub-allele 1: rs770138443, rs78854695; sub-allele 2: rs781257354, rs37522240. \*2 sub-allele 1: rs180847475, rs186133763; sub-allele 2: rs370010370). Analysis of samples which showed CN loss in only exon 9, identified new \*10 and \*17 sub-allele haplotypes. Two additional samples with exon 9 CNV contained hybrid/deletion arrangements within the probe region that affected CN analysis. In summary, performance of widely used TaqMan CNV assays is affected by the presence of sequence variation within the probe target regions. The identification of these haplotypes and further characterization of these structural variations will be important for clinical interpretation and could directly impact patient care.

**3040T**

**Evolution of dihydropyrimidine dehydrogenase (DPD) diagnostics in a single center in a time-period of eight years.** B.J.C. van den Bosch<sup>1</sup>, A.D.C. Paulussen<sup>1</sup>, M. Breuer<sup>1</sup>, M. Lindhout<sup>1</sup>, D.C.J. Tserpelis<sup>1</sup>, A. Steyls<sup>1</sup>, J. Bierau<sup>1</sup>, M.J.H. Coenen<sup>2</sup>. 1) Department of Clinical Genetics, MUMC+, Maastricht, The Netherlands; 2) Radboud university medical center, Radboud Institute for Health Sciences, Department of Human Genetics, Nijmegen, The Netherlands.

**Background:** Treatment with fluoropyrimidines, the main chemotherapeutic agents used in many types of cancer, is not well tolerated in a subgroup of patients. The enzyme responsible for degradation of fluoropyrimidines is dihydropyrimidine dehydrogenase (DPD), the first and rate-limiting enzyme of the pyrimidine degradation pathway. DPD dysfunction leads to an increased exposure of active metabolites, which can result in severe or even fatal toxicity. **Objective:** Fluoropyrimidine treatment can be optimized based on DPD activity.

**Design:** We provide an overview of eight years DPD diagnostics (n=1194). In this time-frame the test has evolved from a single enzyme measurement using Ultra-High Performance Liquid chromatography (UHPLC) in peripheral blood mononuclear cells (PBMCs) to a combined enzymatic and genetic test of four variants in the *DPYD* gene (*DPYD\*2A*, *DPYD\*13*, c.2846A>T and 1129-5923C>G). **Results:** In the group tested for four variants (n=814), patients with either one variant have a lower enzyme activity than the overall patient group. The majority of patients with the *DPYD\*2A* variant (83%) consistently showed a decreased enzyme activity. Only 24 (25.3%) of the 95 patients with a low enzyme activity (tested for four variants) carried a variant. Complete *DPYD* sequencing in a subgroup with low enzyme activity and without *DPYD\*2A* variant (n=47) revealed 10 genetic variants, of which four have not been described previously. In summary we show that there is a weak correlation between DPD enzyme activity and the presence of the variants tested. With respect to this correlation we observed a sensitivity of 0.25 (24/[24+71]) and a specificity of 0.93 (667/[667 + 52]), i.e. most patients do not carry a variant as expected and all these patients have a normal DPD enzyme activity (high specificity). **Conclusions:** We did not observe a strong link between *DPYD* genotype and enzyme activity. There is no doubt that DPD status should be determined before treatment with fluoropyrimidines to save patients' lives and prevent unnecessary side effects. Our study in combination with literature shows that there is a discrepancy between the DPD enzyme activity and the presence of clinically relevant SNPs. Therefore at this moment a combination of a genetic and enzymatic test is preferable for diagnostic testing.

**A novel NGS solution for combined PGT-M and PGT-A: Analysis for  $\beta$ -thalassemia.** *M. Brockman, K. Warren, M.J. Jasper.* RHS Ltd, Thebarton, South Australia, Australia.

Thalassemia, caused by mutations within genes involved in haemoglobin production, including the haemoglobin subunit beta gene (*HBB*), has become one of the most prevalent blood disorders around the world and is a frequent target for Preimplantation Genetic Testing for Monogenic disorders (PGT-M). The ability to combine aneuploidy detection (PGT-A) and PGT-M, by adding gene-specific PCR primers to a Whole Genome Amplification (WGA), maximises the screening opportunity for a single embryo biopsy. The aim of this study was to demonstrate the application of a novel Target Sequence Enrichment (TSE) protocol using the DOPlify® kit (RHS Ltd) for combined PGT-M for  $\beta$ -thalassemia and PGT-A by Next Generation Sequencing (NGS). Manually sorted 5-cell aneuploid samples (Coriell Institute) modelling a trophectoderm biopsy were subjected to either standard WGA (no enrichment) or WGA using the DOPlify® TSE protocol (WGA+TSE) with *HBB*-specific PCR primer sets targeting exons 1-3. Successful sequence enrichment was determined by performing a *HBB*-specific PCR, and further enrichment of *HBB* sequence was achieved by pooling *HBB*-specific PCR products with the WGA+TSE prior to library preparation and NGS. All samples were sequenced according to the standard PG-Seq™ kit protocol (RHS Ltd) for 48 samples using a MiSeq® instrument (Illumina). Correct aneuploidy diagnoses were achieved for all samples. The NGS protocol used was typical for PGT-A, but was not expected to yield the depth of reads required for PGT-M in the absence of enrichment. As expected, <1x depth of coverage and <10% breadth of coverage was achieved for *HBB* with no enrichment. In contrast, WGA+TSE achieved 5x depth of coverage with 80% breadth of coverage, while further enrichment achieved a depth of coverage of 200x with 100% breadth of coverage. The targeted and concurrent enrichment of *HBB* sequence during WGA provided a suitable depth of coverage for PGT-M without compromising PGT-A results. RHS' TSE protocol provides a unique opportunity to develop a multiplex panel targeting the most common disorders tested by PGT-M.

**3042W**

**A simple NGS method for detection of sequence variants causing alpha and beta thalassemia.** *F. Oliv, M. Uzunel.* Devyser AB, Stockholm, Sweden.

**AIM:** To develop a simple NGS method for detection of mutations causing alpha and beta Thalassemia. **BACKGROUND:** Thalassemias are inherited blood disorders characterized by abnormal hemoglobin production. Depending on the type and number of mutations, the symptoms can vary from none to severe forms where stem cell transplantation is the only curative treatment. Today, many different methods are available for mutation analysis of thalassemia patients. These include ARMS-PCR, restriction-enzyme PCR, GAP-PCR, Sanger sequencing, LIPA and MLPA. The use of different methods may be time-consuming and expensive, especially when analyzing less common deletions. **METHOD:** We have developed an amplicon based NGS method using only ONE oligo-mix to detect virtually all known mutations for alpha and beta Thalassemia. The method includes sequencing of the *HBB*, *HBA1* and *HBA2* genes. We have also included primers for direct detection of the most common deletions in alpha and beta Thalassemia ("Gap-PCR"). In addition, we amplify regions upstream and downstream of the above-mentioned genes to find less common deletions using copy number variation (CNV) analysis. The upstream regions also include regulatory sequences, i.e. HS-40 (*HBA*) and LCRB (*HBB*). The protocol is user-friendly, requires less than one hour of hands-on time and only 10 ng of DNA is needed. **RESULTS:** Libraries have 100% uniformity at  $\geq 0.3x$  mean coverage. We have analyzed 125 clinical samples with known mutations. All mutations were also detected with the Devyser Thalassemia kit. Interestingly, we could find additional mutations in 15% of the samples; mutations not previously detected or tested by the clinical laboratory. CNV analysis could successfully detect deletions and triplications (anti-3.7 triplication). **SUMMARY:** The Devyser Thalassemia kit is simple, user-friendly and efficiently detects mutations causing Thalassemia.

**CNVs inherited from insertion carriers are rare in a large cohort.** *R.D. Burnside<sup>1</sup>, M.K. Rudd<sup>1</sup>, J. Schleede<sup>1</sup>, I. Gadi<sup>1</sup>, P. Papenhausen<sup>1</sup>, K. Phillips<sup>1</sup>, V.R. Potluri<sup>2</sup>, H. Risheg<sup>2</sup>, J.H. Tepperberg<sup>1</sup>, J. Wiley<sup>1</sup>, S. Schwartz<sup>1</sup>. 1) Laboratory Corporation of America, Research Triangle Park, NC; 2) Laboratory Corporation of America, Houston, TX; 3) Laboratory Corporation of America, Seattle, WA.*

Familial follow-up studies to CNVs are important for interpreting the pathogenicity of some CNVs and for proper assessment of recurrence risk. qPCR as a follow up assay has been adopted in many labs due to faster turn-around-time and significant cost savings over FISH. One limitation to qPCR is that this assay cannot determine whether an apparently de novo CNV is actually inherited from a parent with a balanced structural rearrangement, nor can it determine the location of copy number gains. The goal of this project was to ascertain how many parents with follow-up studies carried a structural rearrangement, either balanced or unbalanced, to determine appropriate FISH usage in the context of qPCR as a primary follow up methodology. The current study includes 25,696 CNVs in 21,473 families reported from 111,362 postnatal arrays performed from August 2008 to September 2016. Follow up studies were performed by FISH, chromosomes, or microarray, and in April 2015 qPCR was added as the primary follow-up methodology except for instances of clearly pathogenic CNVs, microscopically visible CNVs, complex abnormalities, or CNVs for which a commercial FISH probe was available. Of those families, 6,634 individuals (31%) either had follow-up studies or were presumed to have obligate parental carriers if CNVs were found in siblings. We identified 18 families (~1:370) in which CNVs resulted from balanced parental insertions, with slightly less than half being microscopically visible. There were five additional families (~1:1,300) in which a parent carried the same unbalanced insertion; consistent with a benign CNV. None of the insertions involved recurrent LCR-flanked CNVs. Microscopically visible CNVs are typically followed up with chromosome analysis, although the resolution of CNVs in the 5-10 Mb range may benefit from molecular techniques. Taken together, 23/6,634 probands (~1:280) with follow up studies have CNVs related to unbalanced structural rearrangements. Given the rarity of balanced insertion carriers, we propose that additional FISH follow up may be reserved for future prenatal studies in families with apparently de novo qPCR CNVs that are not LCR-flanked.

**3044F**

**Cytogenetically detected inversions are rarely formed by ectopic recombination between inverted repeats.** *C. Carvalho<sup>1</sup>, M. Pettersson<sup>2</sup>, J. Eisfeldt<sup>3</sup>, J. Wincent<sup>2,6</sup>, J.R. Lupski<sup>1,4,5</sup>, E.S. Lundberg<sup>2,6</sup>, D. Nilsson<sup>2,3,6</sup>, A. Lindstrand<sup>2,6</sup>.* 1) Dept. of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX; 2) Department of Molecular Medicine and Surgery, Center for Molecular Medicine, Karolinska Institutet, Stockholm, Sweden; 3) Science for Life Laboratory, Karolinska Institutet Science Park, Solna, Sweden; 4) Human Genome Sequencing Center, BCM, Houston, TX; 5) Texas Children's Hospital, Houston, TX; 6) Department of Clinical Genetics, Karolinska University Hospital, Stockholm, Sweden.

The relevance of inversions for disease causation, speciation and adaptation, is broadly recognized. Cytogenetically detected pericentric and paracentric inversions are the hallmark of copy number neutral inversions (INVcnNs), which, in humans, are associated with congenital anomalies in ~9.6% of carriers. Yet, despite biological relevance, inversions are generally assumed to be copy number and phenotypically neutral events. The major mechanism of formation of INVcnNs is proposed to be non-allelic homologous recombination (NAHR) between inverted repeats in which large blocks of sequencing homology is estimated to contribute to the formation of 67% of INVcnNs, whereas shorter repeat sequences underlie formation of the remaining. We performed whole genome sequencing (WGS) with the Illumina 30X paired-end protocol of 15 large inversions detected by classical karyotyping in 14 carriers who were referred to the Karolinska University Hospital diagnostic laboratory with various clinical phenotypes. Data were analyzed using FindSV, a pipeline that combines CNVnator and TIDDIT. Using this approach, we obtained the breakpoint junctions of 9 out of 15 INVcnNs. Contrary to expectations, data analyses revealed that the vast majority (8/9) of the resolved inversions were not mediated by inverted repeats, except for one *Alu-Alu* case. Instead, the majority of those inversions form simple breakpoint junctions, except in 1 case with a 4 kb deletion and a few kb duplication located on each side of an apparently reciprocal inversion. Importantly, in 4 out of 9 (44%) inversions, there was disruption of genes associated with diseases which may potentially contribute to that individual clinical phenotype. The gene disruption frequency is similar to the frequency obtained for balanced translocations (48%), some of which contribute to the carrier phenotype. In summary, our study indicates that: 1. high-coverage, short-read WGS can detect ~60% of the INVcnNs and resolve breakpoint junctions at the nucleotide level; 2. NAHR is not the major mechanism underlying formation of inversions as previously proposed; 3. Inversions are likely relevant contributors to Mendelian diseases. Inversions are considered balanced and clinically neutral genomic rearrangements but our study challenges this historic view, shows that gene disruption occur in almost half of the cases, and provides evidence that molecular mechanisms other than ectopic recombination are prominent contributors.

**3045W****Whole-genome sequencing analysis of copy-number variation (CNV) using low-coverage and paired-end strategies is efficient and outperforms array-based CNV analysis.**

*B. Zhou<sup>1</sup>, S.S. Ho<sup>1</sup>, X. Zhang<sup>1</sup>, R. Pattni<sup>1</sup>, R.R. Haraksingh<sup>1,2</sup>, A.E. Urban<sup>1,3</sup>.* 1) Department of Psychiatry and Behavioral Sciences, Department of Genetics, Stanford University School of Medicine, Stanford, CA; 2) Department of Life Sciences, The University of the West Indies, Saint Augustine, Trinidad and Tobago; 3) Program on Genetics of Brain Function, Stanford Center for Genomics and Personalized Medicine, Tasha and John Morgridge Faculty Scholar, Stanford Child Health Research Institute, Stanford University, Stanford, CA.

**Background:** CNV analysis is an integral component to the study of human genomes in both research and clinical settings. Array-based CNV analysis is the current first-tier approach in clinical cytogenetics. Decreasing costs in high-throughput sequencing and cloud computing have opened doors for the development of sequencing-based CNV analysis pipelines with fast turn-around times. We carry out a systematic and quantitative comparative analysis for several low-coverage whole-genome sequencing (WGS) strategies to detect CNV in the human genome. **Methods:** We compared the CNV detection capabilities of WGS strategies (short-insert, 3kb-, and 5kb-insert mate-pair) each at 1x, 3x, and 5x coverages relative to each other and to 17 currently used high-density oligonucleotide arrays. For benchmarking, we used a set of Gold Standard (GS) CNVs generated for the 1000-Genomes-Project CEU subject NA12878. **Results:** Overall, low-coverage WGS strategies detect drastically more GS CNVs compared to arrays and are accompanied with smaller percentages of CNV calls without validation. Furthermore, we show that WGS (at  $\geq 1x$  coverage) is able to detect all seven GS deletion-CNVs >100 kb in NA12878 whereas only one is detected by most arrays. Lastly, we show that the much larger 15 Mbp Cri-du-chat deletion can be readily detected with short-insert paired-end WGS at even just 1x coverage. **Conclusions:** CNV analysis using low-coverage WGS is efficient and outperforms the array-based analysis that is currently used for clinical cytogenetics.

Sharing data in ClinVar provides open access to variant classifications from many clinical laboratories. While most classifications are consistent across laboratories, classification differences exist. By aggregated submitted classifications, ClinVar provides an opportunity for submitters to collaborate on deriving the most accurate conclusions. A pilot project from ClinGen's Sequence Variant Inter-Laboratory Discrepancy Resolution team focusing on four clinical labs found that 53% of classification differences were resolved by either updating ClinVar with current internal classifications or reassessment of an older classification with current classification criteria (PMID: 28301460). With these findings in mind, our working group prioritized variants that reach a majority consensus ( $\geq 2/3$  of submitters agree) with an outlier classification and expanded the scope to include more clinical labs. The first round compared classifications from 41 clinical labs and identified 24,445 variants classified by  $\geq 2$  clinical labs (April 2017). The majority of classifications were concordant (84.6%; 20,677 variants) and only 2.7% (650 variants) of variants were medically significant differences (MSDs) with potential to impact medical management. Labs with outlier classifications were sent a custom report and encouraged to reassess. Labs have returned results for 204 variants, of which 62.3% (127 variants) were resolved. A second round of this expanded effort including classifications from all clinical labs submitting to ClinVar (108 submitters; April 2018) is underway and preliminary data shows 54.3% (150/276) resolution rate. In total, 67.7% (488/721) of reassessed variants have been resolved through these rounds of discrepancy resolution and 22 clinical labs are now actively involved in this process. By comparison, within one year, 24.3% (106/437) of variants that previously had MSDs but did not reach a majority consensus are now concordant, showing that a subset of differences will be resolved over time by routine reassessment; however, notification of outlier classifications can serve as a prompt for reassessment and accelerate resolution. In conclusion, this process capitalizes on the value of data sharing within ClinVar and will help the community move toward more consistent variant classifications.

**Analytical validation of qPCR detection of CYP2D6 copy number variation.** J.M. Lubieniecka<sup>1,2,3</sup>, K.P. Lubieniecki<sup>1,2,3</sup>, A.L. Mohror<sup>1</sup>, M.M. Soe<sup>1</sup>, J. Reiner<sup>1</sup>, D. Lyalin<sup>1,3</sup>, K. Rageth<sup>1</sup>, M. Mboob<sup>1</sup>, L. Mullineaux<sup>1</sup>, C.F. Boerkoel<sup>1</sup>, R. Pyatt<sup>1,2,3</sup>, L. Carmichael<sup>1</sup>, P. Cherukuri<sup>1,2,3</sup>. 1) Imagenetics, Sanford Health, Sioux Falls, SD; 2) Sanford School of Medicine, University of South Dakota, Sioux Falls, SD; 3) Sanford Research Center, Sioux Falls, SD.

**Background:** CYP2D6 copy number variation (CNV) is a commonly assessed pharmacogenetic variant. Reported variation includes 0, 1, 2, 3 and 4 copies. Frequently this variation is determined by qPCR; however, qPCR has difficulty resolving less than 2-fold differences in DNA copy number, although the resolution can be improved by increasing the number of sample replicates in a qPCR assay. CYP2D6 CNV falls short of the 2 fold difference at higher CNVs raising questions as to whether the commonly recommended 4 replicates per sample is sufficient. **Hypothesis:** More than four sample replicates are needed to detect higher CYP2D6 CNV robustly. **Methods:** Using a TaqMan probe for exon 9 of CYP2D6 and a QuantStudio 12K Flex Real-Time PCR system, we generated qPCR results for 12 replicates of each member of a set of Coriell samples and calculated relative copy number (RCN) as described by Weaver, et al. [1]. To determine the number of replicates needed for confident copy number calls, we used two different approaches: (a) random sub-sampling of 12 replicate data, and (b) median data point approach to minimize the effect of outliers. We also compare varying approaches to reliably determine CYP2D6 CNV. **Results:** This analysis finds that, in order to detect 3 copies of CYP2D6 gene within a 99% CI by qPCR, a minimum of 10 replicates are required. To ensure high accuracy alternative methods of copy number quantification may be necessary. **Conclusions:** The variability of qPCR data confounds detection of higher CYP2D6 CNV indicating that more than four replicates are needed for analytical validity. 1. Weaver, S., et al., *Taking qPCR to a higher level: Analysis of CNV reveals the power of high throughput qPCR to enhance quantitative resolution.* *Methods*, 2010. **50**(4): p. 271-6.

**3048W**

**A retrospective analysis of clinical whole genome sequencing results after non-diagnostic microarray or whole exome sequencing.** A. Scocchia, M. Rajan, M. Bennett, E. Thorpe, C.M. Brown, D.L. Perry, R.J. Taft. Illumina Inc., San Diego, CA.

Patients with a rare and undiagnosed genetic disease (RUGD) often undergo years of serial testing, commonly referred to as the “diagnostic odyssey”. Often, clinicians must navigate the patient’s health insurance policy and choose whether to investigate copy number variation (CNVs) using microarray (CMA) or target single nucleotide variants (SNVs)/indels using whole exome sequencing (WES). The use of clinical whole genome sequencing (cWGS) may provide simultaneous interrogation of the genome for both gene dosage and small base-pair changes, combining detection of SNVs, indels, CNVs, aneuploidy, and other chromosomal changes in a single clinical test. Here, we provide a case series of probands who underwent cWGS testing through the Illumina Clinical Services Laboratory from 2015-2018, in whom cWGS identified molecular findings with clinical congruence to the reported phenotype following prior non-diagnostic CMA or WES. As part of routine cWGS RUGD case analysis for 262 probands, details about prior genetic testing were collected from test requisition forms and medical notes submitted by ordering clinicians to the laboratory. At least 64% (n=167) of these probands were reported to have pursued at least one genetic test prior to cWGS, including CMA (n=104) and WES (n=17). Over half of these probands (57%; n=96) received two or more genetic tests, including nine probands who received both CMA and WES. After cWGS analysis, new information was reported for 62.5% (n=65) of probands who had received prior CMA and 53% (n=9) who received prior WES. Of these cases where new information was provided, most probands received pathogenic or likely pathogenic findings (66%, n=49). Most often, a SNV or indel was identified by cWGS after non-diagnostic CMA (n=36). In five cases, CNVs >100 bp but <87kb were identified by cWGS that were not reported to have been detected on CMA. In two cases, CNVs were detected after non-diagnostic WES. In five cases, new gene-disease relationships had emerged in the literature since last testing. Importantly, a compound heterozygous SNV/CNV pair was detected by cWGS in one case, which may not have been detected until a multi-platform approach was pursued. This case series highlights the added value of simultaneous detection of multiple variant types by cWGS over the serial or reflexive target-capture molecular testing approach often employed to investigate genetically heterogeneous differential diagnoses.

**Implementation of copy number variant detection from existing exome and genome samples.** *E. Farrow*<sup>1,2,3</sup>, *I. Thiffault*<sup>1,2,3</sup>, *M. Cadieux-Dion*<sup>1</sup>, *G. Twist*<sup>1</sup>, *B. Yoo*<sup>1</sup>, *N. Miller*<sup>1</sup>, *T. Pastinen*<sup>1,3</sup>, *C. Saunders*<sup>1,2,3</sup>. 1) Center for Pediatric Genomic Medicine Children's Mercy - Kansas City, Kansas City, Missouri; 2) School of Medicine, University of Missouri-Kansas City, Kansas City, Missouri; 3) Department of Pathology, Children's Mercy - Kansas City, Kansas City, Missouri.

Copy number variant (CNV) detection from next generation sequencing data has been a long standing promise of the technology. Indeed, numerous publications have demonstrated the ability to detect CNVs, ranging from small indels to aneuploidy. However, many of the studies utilize whole genome sequencing (WGS), which remains limited in clinical testing, or small panels. Additionally, there is no consensus on a standard bioinformatics approach. In order to be fully implemented into clinical testing, CNV detection ideally would be applied to both WES and WGS, and would not require modifications to established laboratory workflows. To test advances in CNV detection, with the goal of clinical implementation, we evaluated NxClinical (BioDiscovery), Dragen (Edico), and GATK (Broad Institute) with a validation set of 16 samples with clinically confirmed CNV; including those with existing NGS data and a subset prepared with Sciclone automation for library and enrichment. An initial assessment of these platforms performed surprisingly well: NxClinical detected 13/16, Dragen 12/16, and GATK 13/16 known CNVs, 9 of which were consistent between all three platforms. No CNV was missed by all, indicating that a combined approach may have some benefit. Deletions ranged from 20bp to 14Mbp, and duplications from 195bp to 1.7Mbp. Both Dragen and GATK are amenable to bioinformatic automation, but require custom analysis software for filtering of CNVs. In contrast, NxClinical has a graphical user interface, but is less amenable to automation. To further test CNV detection, an analyst blinded to the results was provided phenotypic information for each sample and recapitulated the diagnosis using NxClinical in 9/12 samples. Evaluation of an additional validation set resulted in a similar 'diagnostic' rate. Small exonic CNV in WES remained challenging for accurate detection, dependent on the amount of neighboring sequence. We therefore analyzed WGS for the WES samples with missed CNV calls. As expected, WGS offered increased resolution of CNV breakpoints; however 2 small exonic CNVs in *STK11* and *PLOD1* remained undetected. Additional testing to validate assay sensitivity and specificity is underway. In sum, CNV detection using existing laboratory workflows and commercially available software can provide accurate detection from both WES and WGS. What is becoming increasingly clear is that integration of CNV detection during clinical NGS testing is an alternative to exome-array. .

**Supporting DNA variant interpretation: The global variome shared LOVDatabases.** *J.T. den Dunnen*<sup>1,2,3</sup>, *J.A.L.H. Lopez Hernandez*<sup>1</sup>, *I.F.A.C. Fokkema*<sup>1</sup>. 1) Human Genetics, Leiden University Medical Center, Leiden, Netherlands; 2) Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands; 3) Global Variome, Newcastle upon Tyne, United Kingdom.

The simplest and cheapest answer to the possible consequences of a variant found in a genome is history. Has the variant been seen before and, when yes, where and what were the associated consequences in relation to the health of the individual? The Global Variome shared LOVDatabases build on a >20 year history of collecting and sharing such material. The databases contain a wealth of information on Individuals (patients), Phenotypes (disease/traits), Screenings and the Variants found, which can be queried in many ways. While the databases do contain information from published literature, most information has not yet been published but was submitted directly (functionality incl. automated data submission). When performing DNA diagnostics it is essential to check LOVD, preventing easily available information to be missed. Facilities supported by LOVD include variant queries (through the website or the API) across all public database installations, containing information from >3.6 million unique variants linked to >450,000 individuals. For genes with active curators (incl. BRCA, colon cancer, CFTR, etc.) specific "Summary records" resume all supporting information towards the conclusion whether the variant is or is not associated with a disease (pathogenicity). "Classification records" show the evaluation (classification) regarding variant pathogenicity as shared by diagnostic labs. Records labelled "In vitro (cloned)" show the results of assays performed to analyse the functional consequences of variants. Where available LOVD shows the parental origin of a variant linked to haplotype information. The RNA field, not available in most other databases, shows whether the consequences of a variant have been analysed on RNA level and what these consequences were. This adds essential evidence to the predicted consequences at the protein level, critical information for the diagnosis in diseases like Duchenne/Becker muscular dystrophy. Based on some examples we will show how the LOVD functionality can be used best to retrieve variant or phenotype information. The Global Variome shared LOVD is a community driven initiative operating under the auspices of Global Variome, a UK charity. Per gene, gene variant home pages link to other resources and data views in the major genome browsers. The data is shared with several public repositories incl. UCSC, EBI and ClinVar, and copies can be download from the gene home pages. Urls: [databases.LOVD.nl/shared](http://databases.LOVD.nl/shared), [www.LOVD.nl/3.0/search](http://www.LOVD.nl/3.0/search).

**New approaches in the cystic fibrosis diagnosis: use of high-throughput sequencing technologies and *in silico* tools to identify and predict pathogenic variants.** S.V.N. Pereira<sup>1</sup>, F.A.L. Marson<sup>1,2,3</sup>, J.D. Ribeiro<sup>2,3</sup>, C.S. Bertuzzo<sup>1</sup>.

1) Department of Medical Genetics, School of Medical Sciences, University of Campinas, Campinas, São Paulo, Brazil; 2) Department of Pediatrics, School of Medical Sciences, University of Campinas, Campinas, São Paulo, Brazil; 3) Laboratory of Pulmonary Physiology, Center for Pediatrics Investigation, School of Medical Sciences, University of Campinas, Campinas, São Paulo, Brazil.

**Introduction:** Cystic fibrosis (CF [MIM 219700]) is caused by *CFTR* mutations (~400 pathogenic). Allelic heterogeneity challenges the molecular diagnosis and precision medicine approaches in CF. **Purpose:** To identify *CFTR* variants by high-throughput sequencing (HTS) and predict the pathogenicity of the new variants by *in silico* tools. **Methods:** 169 CF patients had genomic DNA submitted to a Targeted Gene Sequencing with custom panel. Results were obtained from Basespace® and the alignment from TruSeq® Amplicon by Smith-Waterman algorithm. The variants annotation was made in VariantStudio® and confirmed in the Integrative Genomics Viewer. American College of Medical Genetics and Genomics and the Association for Molecular Pathology recommendations (2015) were applied to deduce the pathogenicity using six *in silico* tools: MutationTaster, MutPred-2, MutPred-LOF, MutPred-Splice, PolyPhen-2, Human Splice Finder. **Results:** A total of 62 variants were identified in 169 CF patients (3 patients had 3 variants). The most frequent alleles were: c.1521\_1523delCTT, p.Phe508del (n=192; 56.30%), c.1624G>T p.Gly542X (n=26; 7.62%), c.3909C>G, p.Asn1303Lys (n=11; 3.23%), c.3484C>T, p.Arg1162X and c.1000C>T, p.Arg334Trp (both n=9; 2.64%). Among identified mutations: 41 were pathogenic, according to the literature [classified as: (I) n=23 (56.09%); (II) n=6 (14.63%); (III) n=1 (2.43%); (IV) n=6 (14.63%); (IV and V) n=1 (2.43%); (VI) n=4 (9.75%)]; 14 had uncertain significance (9 being pathogenicity in all predictors and 5 being discordant); and 7 new mutations were identified, evaluated and, based on the theoretical type of change + prediction analysis, we suggested the classification of c.(580+1\_581-1)\_(2615+1\_2616-1)dup, c.1936G>T, p.Gly646X and c.3557\_3557delA, p.Pro1186Leufs as class I. There was concordance of the predictors as "likely pathogenic" for c.\*1233T>A, c.2804T>A, p.Leu935Gln, and c.4281C>T, p.Ile1427=. Also, c.974A>T, p.Tyr325Phe presented 1 discordant result among the predictors. Compared with the CFF data, among the mutations described, 7 are not in the registry and, among the potentially pathogenic ones, 4 were described. **Conclusion:** HTS plays a major progress in CF molecular diagnosis and was effective to detect rare and new variants. The use of *in silico* tools are an important step to classify the pathogenicity. HTS and *in silico* analysis can identify *CFTR* mutations and to give the opportunity to include the precision medicine into daily practice in a near future.

### 3052T

**Advances in targeted NGS: Towards robust ultralow mutation detection in small and large DNA panels.** E. Lader, R. Samara, Z. Wu, J. Ning, Y. Wang, J. Dicarolo, Q. Peng, D. Kim, C. Xu, Y. Wang. QIAGEN, Frederick, MD.

The quest for higher sensitivity and lower false positive rates are constant motivators in clinical NGS development. While computational optimization can be made to improve one or the other of these objectives, in general improving one metric requires compromise in the other. One tactic currently in use is to optimize detection for a narrowly focused panel, sometimes only a dozen or so clinically important sites, at the expense of (and essentially ignoring) any false positives elsewhere in the read set. We have performed a systematic evaluation of the errors caused by library construction and sequencing methodology with the goal of identifying and minimizing physical and computational errors in our targeted NGS libraries. The combination of these advances allow us to reliably call mutations at levels far below the typical 1% limit, not just for a small select group of sites, but over much larger regions, such as the complete CDS of clinically relevant genes. Critically, false positives are kept at exceptionally low levels through a combination of the enzymology used in library construction, the use of advanced molecular indices, single primer extension (SPE) technology, and the application of a computational model for enzyme induced errors.

**3053F**

**The accuracy of computer-based diagnostic tools for the identification of concurrent genetic disorders.** *D.Y. Park<sup>1</sup>, R.R. Wadhwa<sup>1</sup>, M.R. Natowicz<sup>2</sup>.*

1) Cleveland Clinic Lerner College of Medicine, Case Western Reserve University, Cleveland, OH; 2) Pathology and Laboratory Medicine, and Genomic Medicine Institutes, Cleveland Clinic, Cleveland, OH.

The increasing use of next-generation sequencing, especially clinical whole exome sequencing, has revealed that individuals having two co-existing genetic conditions are not uncommon occurrences. This pilot study evaluates the efficacy of two methodologically distinct, publicly available computational differential diagnosis generating tools – FindZebra and SimulConsult - in identifying multiple genetic conditions in a single patient. Clinical query terms were generated for each of 15 monogenic disorders that were effective in resulting in the top ten list of differential diagnoses for each of the 15 monogenic conditions when entered into these bioinformatics tools. Then, the terms of over 125 pairings of these conditions were entered using each tool and the resulting list of diagnoses evaluated to determine how often both diagnoses of a pair were represented in that list. Neither tool was successful in identifying both members of a pair of conditions in greater than 40% of test cases. SimulConsult, when used in its 'incidence' mode, outperformed FindZebra and SimulConsult in its non-incidence mode in detecting pairs of monogenic conditions. Disorder detection sensitivity was not homogeneous within a tool, with each tool favoring the identification of a subset of genetic conditions. In view of recent whole exome sequencing data showing an unexpectedly high prevalence of co-existent monogenic conditions, the results from this pilot study highlight a need for the development of computational tools designed to effectively generate differential diagnoses with consideration of the possibility of co-existing conditions.

**Experience with rapid exome sequencing of critically ill children: One year milestone.** *K.M. Abbott, B. Sikkema-Raddatz, A.H. van der Hout, Y.J. Vos, H. Lemmink, J.B.G.M. Verheij, I.M. van Langen, M.J. de Groot, H.H.J.*

*Drok, R. Kinds, G. Beunders, E. Zonneveld-Huijssoon, J.C. Herkert, F. Vansenne, J.S. Klein Wassink-Ruiter, E. Gerkes, K.J. van der Velde, M.A. Swertz, R.J. Sinke, W.S. Kerstjens-Frederikse, C.C. van Diemen.* Genetics, University Medical Center Groningen, Groningen, Groningen, Netherlands.

**Introduction** After successfully exploring whole-genome sequencing in critically ill newborns, we implemented rapid exome sequencing for similarly ill children (under the age of 16 years) in routine diagnostics. The advantages of switching to exome sequencing are: better integration into current diagnostic workflow, ability to simultaneously incorporate sequencing data of parents to help interpret and confirm results. Here we present the outcome after one year of implementation regarding diagnostic yield, incidental findings and turnaround time. **Materials and Methods** Forty-seven critically ill or deceased patients under the age of 16 years were included between April 2017 and April 2018. Trio (child-mother-father) exome sequencing was performed using Agilent SureSelect XT exome v6 capturing. After filtering using a virtual gene-panel of 3850 monogenic disease genes and inheritance-mode, we further selected variants based on population frequency, inheritance patterns and prioritization using in-house developed tools (GAVIN). The final variants were discussed in a multidisciplinary team. Pathogenic or likely pathogenic variants matching the patients' phenotype were reported. Variants in genes not matching the patient's phenotype but considered as actionable, were reported as incidental findings. **Results** Turnaround time was less than 14 days in most samples. Pathogenic or likely pathogenic mutations explaining the phenotypes were detected in 10 of the 47 children (21%) and involved the *CHD7*, *CRLF1*, *KCNQ2*, *KCNT1*, *MAP3K7*, *MTM1*, *PDHA1*, *PTPN11*, *SMARCA4* and *TBCK* genes. Incidental findings with clinical consequences were found and communicated in seven families. **Conclusions** Rapid exome sequencing is feasible and has a high yield (21%), allowing more critically ill children to be diagnosed. Trio-based analysis facilitates variant interpretation and confirmation, saving time which is crucial for decision management of both parents and health professionals.

**Comparative quality of whole exome sequencing among commercial laboratories for patients in the Undiagnosed Diseases Network.** D.R. Murdock, H. Smith, S. Chen, B. Dawson, L. Burrage, J. Rosenfeld, B. Lee, *Undiagnosed Diseases Network Members*. Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

The Undiagnosed Diseases Network (UDN) uses diagnostic tools including whole exome sequencing (WES) to solve complex medical cases. Many patients have now already undergone clinical WES through commercial laboratories prior to enrollment in the UDN. We aim to compare quality metrics among three major commercial labs by utilizing raw sequencing data available for these UDN patients. For patients accepted to the Baylor College of Medicine UDN clinical site, we obtained and reprocessed exome binary alignment map (BAM) files from three major commercial labs. A consensus exome design was used based on RefSeq gene transcripts since the proprietary exome designs from each lab were not available. We generated coverage and uniformity statistics for the exome, Online Mendelian Inheritance in Man (OMIM) disease genes, and American College of Medical Genetics Secondary Findings (SF) genes. We also analyzed the first coding exons, intron-exon boundaries, and coverage progressively deeper into introns. As no major commercial lab offers whole genome sequencing (WGS), we also analyzed data from the UDN WGS sequencing core. Importantly, we addressed the quality of the sequencing only, not clinical analysis pipeline or interpretation for clinical reporting. A total of 66 exomes sequenced between 2013 and 2017 were analyzed (Lab A: 39, Lab B: 9, Lab C: 18) along with 20 genomes. There was a small but significant difference ( $p < 0.05$ ) in average coverage for the exome between labs (mean 122X, range 61-204X). This difference was greater ( $p < 0.0001$ ) for OMIM disease and ACMG SF genes, indicating an enrichment for these clinically-relevant genes in some exome designs. Uniformity of coverage differed; some commercial labs provided better homogeneity of sequencing overall or in specific genes or regions (e.g., first exons). There was also a trend for better overall performance in more recent years. WGS provided lower average coverage (~50X) as expected but superior uniformity across all genes and regions, which may result in fewer false negative calls compared to WES at minimum 20X coverage. Clinical WES is an important tool in the diagnosis of patients with complex genetic cases. Our analysis suggests there are notable differences in the sequencing quality provided by different commercial labs, though this analysis does not address the potential impact on clinical utility. At the same time, WGS should be increasingly considered in the context of gene discovery and investigation.

**A diagnostic odyssey ended via detection of CNV from whole-exome sequencing data.** M. Wang<sup>1</sup>, Y. Zou<sup>2</sup>, F. Geng<sup>1</sup>, J. Bai<sup>1</sup>, N. Li<sup>1</sup>, J. Guo<sup>1</sup>, S. Shams<sup>3</sup>, Y. Jiang<sup>4</sup>. 1) Be Creative Lab, Beijing, China; 2) Clinical Cytogenetic Laboratory & Clinical Molecular Laboratory, University of Maryland, Baltimore, MD, USA; 3) BioDiscovery, Inc., El Segundo, CA, USA; 4) Peking Union Medical College Hospital, Beijing, China.

Detection of copy number variation (CNV) plays an important role in the diagnosis of patients with unexplained developmental delay/intellectual disability (DD/ID), autism spectrum disorders (ASD), and multiple congenital anomalies (MCA). To date, chromosomal microarray analysis (CMA) has been viewed as the "gold standard" for CNV detection and is recommended by ACMG as first line test for many constitutional abnormalities. However, the ability to detect CNVs using microarrays is limited by number of probes and non-uniform probe distributions. With the development of whole-exome sequencing (WES), such limitations are being overcome. We used WES to reliably call rare exonic CNVs using the MultiScale Reference (MSR) algorithm embedded in N.Clinical software. By using validation by molecular methods, we confirmed that small CNVs can be reliably called from whole-exome data. This report presents a 6-yr-old girl with intellectual disability, delayed language development, hypotonia, seizures, and autism spectrum disorders. The patient DNA was first analyzed using the Thermo Fisher CytoScan™ 750K SNP microarray which resulted in no unusual findings. The patient and her family were then screened using WES for any small structural variants (e.g. SNVs, In/Dels, etc.). Again, no obvious variant was detected that could explain the phenotype. The WES data was then processed through the MSR algorithm to detect CNVs of arbitrary size. The approach uses a dynamic binning algorithm that can detect small variants in areas of high coverage and larger variants in areas of lower coverage. This means small CNVs overlapping exons should be detected with good confidence. Using this method, we observed a rare deletion in the 12.288Kb range (Xq28(153,283,851-153,296,138)x1) overlapping a small portion of *MECP2*, all of *MIR718* and most of *IRAK1* genes. The left precise fracture point of this deletion is located in the 4<sup>th</sup> exon of *MECP2*, causing C-terminal domain (CTD) inactivation. The NxClinical software identified this as a de novo variant and the discordant mappings of the pair-end reads allowed us to visually detect the exact base pair location of the deletion. We used qPCR methods to confirm this small deletion. *MECP2*-related disorders in females include classic Rett syndrome, variant Rett syndrome, and mild learning disabilities which match the patient phenotype closely.

**Up-to-date literature mining increases the clinical utility of whole exome sequencing.** *W. He, J.S. Salvo, F. Vetrini, R. Xiao, P. Liu, X. Wang, L. Meng, Y. Yang, F. Xia.* Baylor Genetics Laboratory, Houston, TX.

Genetic changes underlie the majority of rare human diseases, especially early onset and severe Mendelian inherited developmental disorders. However, diagnosis of such disorders pose a big challenge for clinicians, largely due to the inherent genetic and phenotypical heterogeneity. The utilization of whole exome sequencing (WES) or whole genome sequence (WGS) has significantly expanded our ability to detect disease-causing mutations by testing all 22,000+ protein-coding genes. Using these techniques, many genes previously unknown to be the root cause of inherited developmental disorders have been discovered and published in the last decade. However, in clinical lab settings, the validity of genotype-phenotype correlation relies heavily on information from databases such as the Online Mendelian Inheritance in Man (OMIM), an online catalog of human genes and genetic disorders and Human Gene Mutation Database (HGMD). Yet information in these databases takes time to curate and doesn't include the most recently published literature. To keep up with newly published disease genes, we have developed a strategy of combining WES data with a list of recently discovered gene phenotype associations during case analysis so that any newly published disease genes will not be missed (So far we have accrued 1280 papers covering 1080 new disease genes in the list). Furthermore, we are able to reanalyze previous undiagnosed cases using these new gene disease associations, providing improved diagnoses years after initial testing. As we continue to accumulate more WES cases, access to the latest available gene disease associations has provided valuable patient insight, and will allow us to improve our diagnostic rate even further.

**Double or multiple hits of CNV could be etiological factors for genetic disorders.** *K. Wittig<sup>1,2</sup>, X. Wang<sup>2</sup>, H. Wang<sup>2</sup>, Y.M. Kim<sup>2</sup>, L. Su<sup>2,3</sup>, S. Lu<sup>2,4</sup>, Z. Wen<sup>2,5</sup>, W. Li<sup>2</sup>, D. Taylor<sup>2</sup>, X. Wang<sup>2</sup>, S. Li<sup>2</sup>.*

1) Department of Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, OK; 2) Department of Pediatrics, University of Oklahoma Health Sciences Center, Oklahoma City, OK; 3) Department of Pediatrics, Yanbian Medical University, Jilin, China; 4) Internal Medicine, Lishui Medical College, Zhejiang, China; 5) Internal Medicine, First Hospital of Jilin University, Jilin, China.

Much is still unknown of copy number variants (CNVs) detected in clinical diagnostic settings with each CNV being unique in size, genomic content, and location in the genome. CNVs are present throughout everyone's genome although many are not causal of genetic disorders with the majority of these being familial. Currently, some pediatric patients with non-syndromic genetic disorders see multiple specialists and undergo multiple different tests, including array comparative genomic hybridization (aCGH) and whole exome sequencing, with less than 40% receiving a causal diagnosis though there are also other factors to consider such as epigenetics, imprinting, and the environment. Previously, Girirajan et al. suggested a two-hit model regarding phenotypic heterogeneity – a second hit compounds with the first to produce a more severe phenotype. Often a variant found in a child also found in a parental sample is evidence for calling it benign. Here, we propose double or multiple CNV hits could be etiological factors for genetic disorders and a compound of two or more parental variants could in part be causative in the child by acting together in physiological networks to alter normal function. To prove this hypothesis, we conducted a pilot study. Our in-house database was mined for aCGH samples from 2015-2018 in two groups: pre-natal amniocentesis (n=29) and older children ages 7-13 years old (n=42). Pre-natal samples are referred to our lab due to advanced maternal age and suspected Down syndrome. A negative finding results in a normal report. Samples with a pathogenic finding or no clinical background provided were excluded. Testing was performed on Agilent 2x400K arrays V.1.0 and analyzed with Agilent CytoGenomics software. All CNV calls were made from the raw data with no size restrictions of three consistent probes within genomic content with a log ratio greater than  $\pm 0.45$  and confirmed by two reviewers. From our two groups, we observe older children having a significantly higher amount total CNVs ( $p=0.01$ ) than the pre-natal samples with no significant sex or age bias. This data provides support that there may be complex genetic interactions responsible for the phenotypes presented in these children with an increased number of genetic events. Altered cellular characteristics may include multi-systemic signaling pathways, flank sequence integrity, transcription factories, chromosome territories, and mitotic pairing.

**3059F**

**How to measure loss of chromosome Y (LOY).** *M. Danielsson<sup>1,2</sup>, J. Halvardsson<sup>1,2</sup>, J. Mattisson<sup>1,2</sup>, B. Torabi Moghadam<sup>1,2</sup>, H. Davies<sup>1,2</sup>, J. Dumanski<sup>1,2</sup>, L. Forsberg<sup>1,2,3</sup>.* 1) Immunology, Genetics and Pathology, IGP, Uppsala University, Uppsala, Sweden; 2) Science for Life Laboratory, Uppsala University, Uppsala, Sweden; 3) Beijer Laboratory of Genome Research.

Recent discoveries show that mosaic loss of chromosome Y (LOY) in leukocytes is associated with increased risks of cancer, Alzheimer's and cardiovascular disease. More than 15% of men older than 70 show some degree of LOY and these men survive on average only half as long as men without LOY. But how is LOY measured today and what would be the best method for the future? Genome wide SNP-Arrays are most commonly used in LOY-studies, but other methods have also been used: whole genome sequencing (WGS), gene targeted qPCR or droplet digital PCR (ddPCR). We have compared, evaluated and made the most of SNP-Arrays, WGS and ddPCR targeting a homologous gene located on the X and Y chromosome for LOY-studies. The cheap and easy ddPCR method gives very similar results as the expensive and precise WGS, when using whole blood for detecting LOY. However, the sensitivity of all these methods are limited, leaving low frequencies of LOY undetected. These methods require high amounts of DNA input from hundreds of thousands of cells, but LOY is a binary event on the single cell level. The clonal expansion of rare LOY cells could have important clinical implications. Therefore, we aim to combine LOY and cell type detection in a clinically applicable single cell assay. The challenge of identifying LOY-cells could be approached by targeting LOY-specific upregulated surface proteins. Amplifying low signals with rolling circle amplification increases the number of targets to choose from and high throughput detection improves the sensitivity of the method. Using this method in the clinic would benefit both individual patients as well as the health care system and the society at large.

**3060W**

**Application of ACMG criteria to classify variants in the human gene mutation database.** *H.Q. Qu<sup>1</sup>, X. Wang<sup>1</sup>, L. Tian<sup>1</sup>, Q. Li<sup>2,3</sup>, H. Hakonarson<sup>4,5</sup>.* 1) The Center for Applied Genomics, Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 2) Faculty of Medicine, Memorial University of Newfoundland(MUN), Canada; 3) Princess Margaret Cancer Centre Research Institute, University Health Network(UHN), University of Toronto, Canada; 4) Department of Pediatrics, The Perelman School of Medicine, University of Pennsylvania, Philadelphia, Pennsylvania, USA; 5) Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, 19104, USA.

Precision medicine based on personal genomics information has become the direction of future medicine. To apply genetic information in medicine, a critical but complicated step is to interpret the functional effects of the genetic variants. The American College of Medical Genetics and Genomics (ACMG) and the Association for Molecular Pathology (AMP) developed a set of standards and guidelines for this topic. The InterVar software enables automated interpretation of variants according to these guidelines, and in this study, it allows for a quantitative assessment of contradictory evidence in variant classification. The Human Gene Mutation Database (HGMD) professional dataset 2014 release was assessed using InterVar. This earlier version of HGMD dataset before the publication of the ACMG guidelines was used as a relatively independent database from the impact of ACMG. Among 139,541 HGMD variants, 42.93% were classified as pathogenic or likely pathogenic, and 6.07% were classified as benign or likely benign. Contradictory evidence was identified in both groups of variations. Evidence for benign classification, BP6 (0.69%, reputable source recently reports variant as benign), BS2 (0.36%, observed in a healthy adult individual), and BP1 (0.23%, missense variant in a gene for which primarily truncating variants are known to cause disease), was identified among variants classified as pathogenic. For likely pathogenic variations, BP1 (3.45%) and BS2 (0.35%) were identified. For the most commonly observed contradictory BP1, this type of pathogenic variants are commonly reported in the literature. Although initial interest in the analysis of some Mendelian diseases focused on finding truncated variants, missense variants are more commonly found to be disease causing. Pathogenic evidence is also observed among benign variations. PM1 (well-established functional domain) is commonly observed among variants classified as benign (24.65%), while PM2 (absent from controls) and PM1 are commonly identified among variants classified as likely benign (49.55% and 42.98%, respectively). Therefore, PM2 and PM1 should not be used as an effective evidence for pathogenicity unless supported by additional data. Taken together, these observations may not only help researchers and clinicians to better understand the coexistence of contradictory evidence in variant classification, but suggests there may be need for potential revisions and improvements of the current ACMG guidelines.

### 3061T

**How to be atypically consistent: Clinical classification of atypical canonical splice variants.** *J.D. Murdoch, Y. Xue.* Fulgent Genetics, Atlanta, GA.

A significant proportion (1-2%, PMID:11058137) of canonical  $\pm 1-2$  splice sites are not in the prevailing GT donor-AG acceptor classes. Mutations at GC donor sites are reported in ichthyosis, spastic paraplegia, etc. (PMID:28403545, 24704789). ACMG guidelines (PMID:25741868) state that canonical  $\pm 1-2$  splice variants are very strong evidence (PVS1) when null variants are a known mechanism of pathogenicity. However, they do not cover atypical canonical splice site variants. Current predictive tools for atypical canonical splice site variants also struggle with non-GT-AG splice variants - in Alamut, only 1 of 5 algorithms gives non-GT-AG predictions. Given short conserved sequences around sites, a genome-wide search for possible atypical splice sites is prohibitive. These shortcomings are a notable gap in current interpretation of potentially actionable splicing variants; e.g. the same clinical lab has called two  $\pm 1$  variants in the *SCN8A* gene VUS and P - despite the P variant being atypical and the VUS being typical (and predicted to abolish all splicing), even while stating for the VUS that loss of function is not a known disease mechanism (at odds with HGMD and ClinVar for LoF *SCN8A* variants, some from that lab). Other labs just call all atypical splice variants VUS. To better report these variants while consistently applying proper criteria, we propose utilizing all available tools: clinical literature, allele frequency databases, reviewed mutation databases, and previously reported internal data. Lacking predictive models, the interpretive framework is necessarily more restrictive than for typical canonical splice variants. We suggest a prudent approach of treating previously unreported atypical canonical site variants as VUS, given no further information or inconsistent allele frequencies, and previously reported variants in cases as LP, given no inconsistent allele frequencies or conflicting literature. Notably, one family, the voltage-gated sodium channel A genes, may constitute a possible special subclass. Half (15/30) of all atypical splice sites encountered in database/literature searches occurred in this family, and of 12 in ClinVar, 11 were reported P/LP, 8 based on literature. Of 83  $\pm 1-2$  splice site SNV entries in ClinVar for this family, 77 were P/LP and only 1 was B/LB (even as a typical site - again in *SCN8A*). We propose that  $\pm 1-2$  disruptions to splice sites in this family, typical and atypical, may be treated as LP even without prior reporting.

### 3062F

**Capture of sample identification SNPs in NEBNext Direct target enrichment panels.** *A.B. Emerman<sup>1</sup>, K.M. Patel<sup>1</sup>, S.K. Bowman<sup>1</sup>, S.M. Adams<sup>1</sup>, B.S. Desmond<sup>1</sup>, J.S. Dunn<sup>1</sup>, A. Barry<sup>2</sup>, T. Davis<sup>2</sup>, S.E. Corbett<sup>1</sup>, C.D. Elfe<sup>1</sup>, E. Mauceli<sup>1</sup>, C.L. Hendrickson<sup>1</sup>.* 1) Directed Genomics, Ipswich, MA; 2) New England Biolabs, Ipswich, MA.

Target-enrichment for next-generation sequencing is a powerful approach that focuses sequencing data on selected genomic regions of interest and is widely used for genetic screening and clinical diagnostics. When used in the clinic, robust tracking of DNA samples is critical to maintain sample and data integrity and to prevent false reporting of results to a patient. A reliable method to track patient samples from sample preparation through data analysis and reporting is to monitor single nucleotide polymorphisms (SNPs) in the patient's DNA. Work from others used whole exome sequencing data from diverse populations to identify 24 SNPs that have a high discriminatory power among individuals. Here we demonstrate that these 24 SNPs can be targeted with hybridization-based target enrichment panels that can be spiked into a primary panel or can be used as a stand-alone assay. Baits targeting the 24 sample identification SNPs were designed for use with the NEBNext Direct target enrichment protocol. After an initial screening of the baits to assess performance, the concentrations of the baits were adjusted to result in uniform coverage of the SNPs, with a final normalized coverage of the targets between 0.4-1.7. The resulting panel had greater than 95% of the reads mapping to the targeted regions. The ability of the panel to distinguish sample identity was validated on 16 HapMap samples from Coriell Institute. Additionally, by titrating the SNP panel into a larger, cancer-focused panel, we could control the reads dedicated to the hereditary SNPs such that we obtained sufficient coverage of the SNPs for sample identification while maintaining the deep coverage of the primary targets that is necessary for low-level variant detection. This work shows that baits targeting sample identification SNPs can be incorporated into NEBNext Direct target enrichment panels or may be used as a secondary screen to confirm sample identity and maintain data integrity. As the NEBNext Direct technology converts samples into sequencer-ready libraries within one day, this method offers a fast and convenient approach to track patient identity in high-throughput sequencing workflows.

**Acceptability of incorporating genetics in risk prediction of cognitive impairment in hematologic cancer survivors treated with blood or marrow transplantation (BMT).** *N. Sharafeldin, E. Matsuda, P. Singh, K. Battles, K. Triebel, V.G. Wadley, S. Bhatia.* University of Alabama at Birmingham, Birmingham, AL.

**Background:** Cognitive impairment is prevalent post-BMT with inter-individual variability in risk suggesting a role for genetic susceptibility. Gene-based personalized interventions carry the potential to induce changes in outcome compared to conventional interventions, however, clear evidence is lacking on patient acceptability of communication of their individual genetic risk and whether that would lead to enhanced intervention acceptability. **Methods:** This is a preliminary report from the Cognitive Training and Attitudes towards Genetics (cTAG) study on a survey of BMT survivors assessing (i) knowledge and understanding of genetics using a 16-item survey (Jallinoja and Aro, 1999), (ii) attitudes towards receiving personal genetic information, and (iii) acceptability of incorporating genetics in risk prediction to inform cognitive interventions in a hypothetical scenario. **Results:** To date 50 BMT survivors have completed the survey: mean±SD age was 50±14.4y; 80% self-identified as white and 20% as black; 62% were males; and 44% had a college degree or higher. The median total score on the 16-item knowledge survey was 62% (IQR: 50-75%); higher education was associated with increased knowledge of genetics ( $p=0.04$ ). Participants tended to score higher on questions pertaining to inherited causes of disease (median score=62.5%) compared to factual questions on genes, chromosomes, and cells (median score=56%). The higher score on inheritance and disease related genetic knowledge was associated with higher education and white race ( $p=0.005$  and  $p=0.05$ , respectively). Fifty percent considered receiving tests of genetic testing before BMT somewhat or extremely important, 26% were neutral, and 24% considered it not important. Participants presented with a hypothetical scenario of a high risk of cognitive problems based on genetic testing were more likely to consider cognitive interventions (61.5%) as compared with those presented with a scenario of a low risk of cognitive problems based on genetic testing (38%). Overall, 86% of participants were confident they understood the questions, and 80% considered it not hard to use genetic information to make intervention decisions. **Conclusion:** These preliminary findings show potential utility of incorporating genetics in predicting risk of cognitive impairment among BMT recipients. Findings from this survey will inform the development of targeted interventions for those identified to be at high risk of cognitive impairment.

**542F**

**Rates of HPV infection in patients of health institutions in the district of David, province of Chiriqui, Panama.** *O.I. Batista<sup>1,2</sup>.* 1) Human Genetics, Centro Gendiagnostik, S.A., David, Chiriqui, Panama; 2) Centro Especializado de Genética/UNACHI, David, Chiriqui, Panama.

Infection with the human papillomavirus (HPV) is a public health problem worldwide. These viruses are a heterogeneous group, which have been associated with the etiology of a number of benign, precancerous and cancerous lesions on the skin, mucosa, and respiratory tract. Although several factors may contribute to the development of cancer of the uterus, epidemiological studies have suggested that the definitive event responsible for uterine cancer is the infection of the cervix by some types of HPV. The objective of this study was to determine the prevalence of HPV infection in patients attending health institutions in the district of David, Province of Chiriqui, Panama. A total of 102 samples were collected by obstetricians, gynecologists, or urologists using swabs. Patient samples consisted of 45 cervico-vaginal samples from women who visited public healthcare institutions. The second group consisted of 43 cervico-vaginal samples and 14 urethral mucosa samples from women and men, respectively, collected in private healthcare facilities. Both sexes showed characteristic signs of sexually transmitted diseases, including genital warts. DNA was extracted from the swabs and was amplified using PCR with the degenerate oligonucleotide primers MY09 and MY011, primers that target the L1 region of the HPV genome. The prevalence of HPV infection in the entire population sample was 66%. 65% of women tested positive for HPV whereas 71% of men tested positive. The prevalence of HPV infection among patients at public or private healthcare institutions was 84% and 51%, respectively. An additional screening test for HPV 16 and 18, the main causative agents of cervical cancer and performed on most of the positive patients in group 2, showed that one patient presented infection by type 16. These results indicate the high prevalence of HPV in the region and the need to offer and improve genetic diagnostics, possibly by genotyping and / or DNA sequencing, using capillary electrophoresis, which are very sensitive technologies and with greater discriminatory power. Besides a methodology based in hybridization will be also performed for comparative analysis. The application of multiple methodologies would allow the unambiguous typing of the viruses present in our environment, a better monitoring of the risk of cancer of the uterus and a more targeted attention to both sexes, frequently afflicted by this infectious disease.

**543T**

**How Canadian general practitioners perceive their roles and information needs in a context of genetic susceptibility to breast and ovarian cancer in a rural area.** *M. Bezeau<sup>1</sup>, R. Drouin<sup>2,3</sup>, C. Bouffard<sup>1</sup>.* 1) Université de Sherbrooke, Sherbrooke, Québec, Canada; 2) Université Laval, Québec, Québec, Canada; 3) Université du Québec à Montréal, Montréal, Québec, Canada.

Many genetic tests make it possible to identify people who are at higher risk of developing breast or ovarian cancer and to estimate their risks of presenting one. They allow doctors to propose preventive approaches that can significantly reduce the mortality rate among people at risk. However, some measures, such as prophylactic mastectomy, are not universally accepted because of their major psychological and physical repercussions. Despite differences of opinion, there is a consensus on the importance of informing patients following the identification of a mutation in a gene associated with breast and ovarian cancer so that they can make informed decisions about their health. It is even more important that general practitioners (GPs) provide adequate and equitable medical care regardless of their practice setting. Yet, the literature indicates many gaps regarding: a) organization and delivery of services; b) levels of knowledge and training of health professionals; c) the type of information they need regarding genetic testing and clinical management in case of increased risk. Finally, the literature shows that the management of patients with a *BRCA1/BRCA2* mutation is far from optimal and may even make access to preventive interventions inequitable. Research interest: 1) What are the perceptions of Canadian GPs regarding the role they believe they should play in the follow-up of patients with a *BRCA1 / BRCA2* mutation? 2) What are their needs for support, resources and training on genetic testing and patient management? Methodology: An exploratory qualitative approach has generated in-depth data on a little-explored topic among the people directly involved. For the first phase of this project, we conducted interviews with 13 GPs in Bas-Saint-Laurent (BSL), a rural region of Canada with some of the highest rates of *BRCA1/BRCA2*-related breast cancer. Results: Participants feel that they do not have enough genetic training to adequately monitor their patients. GPs who wish to become more involved have different training and support needs from those who prefer to leave this follow-up to specialists. Some GPs report that genetics is a hard-to-reach specialty for patients living in remote areas of major centers. Conclusion: The needs of GPs vary depending on the role they want to play. Training and support strategies must evolve with these needs, which are also changing with the arrival of new tests and genes panels.

**544F**

**The other genes: A qualitative look into experiences of patients with a genetic risk for breast cancer in genes other than *BRCA 1/2*.** *K. Cliff<sup>1</sup>, S. Macklin<sup>2</sup>, S. Hines<sup>3</sup>.* 1) Center for Individualized Medicine, Mayo Clinic, Jacksonville, FL., USA; 2) Department of Clinical Genomics, Mayo Clinic, Jacksonville, FL., USA; 3) Center for Breast Health, Mayo Clinic, Jacksonville, FL., USA.

Since the 1990s, genetic testing has been offered to individuals at high risk of carrying a pathogenic variant in the *BRCA1/2* genes. Strong evidence has been gathered on how pathogenic variants in these two genes affect health and thorough, well-researched management guidelines exist. However, pathogenic changes in *BRCA1/2* do not account for all cases of hereditary breast cancer, and additional genes have since been associated with increased cancer risk. Many of these more newly discovered genes are now included on hereditary cancer syndrome gene panels. Exact cancer risks are not available for many of these genes, and many of these genes appear to convey a moderately increased risk for breast cancer compared with the high risk associated with *BRCA1/2*. Also, while association with increased breast cancer risk may be apparent, often, it is not entirely clear which other organs may have increased risk. This ambiguity can make it difficult to decide whether interventions, like increased surveillance, prophylactic surgery and/or pharmacologic risk reductions, should be initiated and when. We are conducting qualitative interviews to explore the personal and healthcare experiences of men and women with pathogenic variants in these "other" genes in order to compare their experiences to those with *BRCA1/2* variants. So far we have found that information available to patients is lacking and patients often find themselves educating their physicians about the meaning of their results. Some participants have stated that they feel they have been "brushed off" by their healthcare professionals because these genes are even less well understood outside of the genetics community. Despite recent rapid growth in the genetic industry, public knowledge and physician knowledge remain lacking. Future research will be required to fully understand the significance and proper management of these more recently discovered hereditary breast cancer genes. In the meantime, to improve patient care, further evaluation of patient and provider education needs should be at the forefront of the conversation. While this study focuses on genes related to hereditary cancer, this topic will be important across numerous indications.

**545T****Increased breast cancer screening and prevention in *ATM*, *CHEK2*, and *PALB2* mutation carriers identified by hereditary cancer panel testing.**

J.O. Culver<sup>1</sup>, C. Hong<sup>1</sup>, C.N. Ricker<sup>1</sup>, D. Sturgeon<sup>1</sup>, P. Levonian<sup>2</sup>, R. Koff<sup>2</sup>, C. Rowe-Teeter<sup>2</sup>, K. Lara-Otero<sup>2</sup>, K.E. Kingham<sup>2</sup>, N.M. Chun<sup>2</sup>, A.P. Lebensohn<sup>2</sup>, K. Lowstuter<sup>1</sup>, K. Partynski<sup>1</sup>, M.A. Mills<sup>2</sup>, I. Petrovich<sup>2</sup>, A. Hartman<sup>2</sup>, B. Allen<sup>2</sup>, K. Brown<sup>2</sup>, K.J. McDonnell<sup>1</sup>, U. Ladabaum<sup>2</sup>, J.M. Ford<sup>2</sup>, S.B. Gruber<sup>1</sup>, A.W. Kurian<sup>2</sup>, G.E. Idos<sup>1</sup>. 1) USC Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA; 2) Stanford Cancer Institute, Stanford University School of Medicine, Stanford, CA; 3) Myriad Genetics, Salt Lake City, UT.

Since the widespread use of hereditary cancer panels, three breast cancer susceptibility genes, *ATM*, *CHEK2*, and *PALB2*, have emerged as clinically useful for risk assessment and screening. The National Comprehensive Cancer Network recommends annual breast MRI screening for female *PALB2* mutation carriers over age 30 and female *ATM* and *CHEK2* mutation carriers over age 40. The aim of this analysis was to determine whether identifying mutations in these genes has influenced clinical decisions among mutation carriers or testing decisions among their relatives. Two thousand patients had a 25- or 28-gene panel test as part of a prospective study. Patients completed a baseline questionnaire to determine pre-test screening practices and were sent 3-, 6-, and 12-month follow-up questionnaires to determine post-test screening behaviors and whether relatives had testing. Chart reviews were used to determine screening behavior for non-respondents. Study participants had a median age of 51 years and were 81% female, 73% with cancer history, 35% non-native English speaking, and 30% with a high school education or less. The distribution of race/ethnicity was 40% White (non-Hispanic), 39% Hispanic, 12% Asian, 4% Black, 5% Other. Among the 2000 tested, 41 (2.1%) carried a mutation in *ATM* (N=15), *CHEK2* (n=17), or *PALB2* (n=9). Responses to at least one follow-up survey were received for 34/41 patients (83%). Among the 21 females eligible for breast MRI screening after testing, 3/21 (14%) had planned annual breast MRI prior to genetic testing. By twelve months after receiving genetic test results, 15/21 (71%) indicated that genetic evaluation influenced breast screening or surgery decisions; 15/21 (71%) had undergone breast MRI and 6/21 (29%) had undergone risk-reducing mastectomy (RRM). A total of 17/21 (81%) had undergone an MRI and/or RRM. Five of six participants who underwent RRM had a unilateral diagnosis of breast cancer or DCIS. Among the 31 respondents to family genetic testing questions, 26/31 (84%) had encouraged family members to undergo testing, and 14/31 (45%) reported that a family member had undergone testing. Findings indicate that for most female mutation carriers eligible for screening and risk reduction, the identification of *ATM*, *CHEK2*, and *PALB2* mutations led to an increase in preventive behaviors within 12 months. Future analysis in this and other populations will help elucidate whether patients continue to comply with screening recommendations.

**546F****Ovarian and breast cancer genetic risk assessment in a community education program setting.** K. Dhillon, H. Malakoff, K. Driscoll. Rivkin Center for Ovarian Cancer, Seattle, WA.

Individuals with mutations in BRCA1, BRCA2 and other DNA repair genes are at higher risk for ovarian, breast and other cancers, and can take advantage of prophylactic surgery and other preventative interventions. Increased awareness and access to genetic testing has led to increased numbers of individuals who do genetic testing for cancer susceptibility genes. This increase has predominately been in individuals without family or personal history of either cancer, while testing is underused by those who may be at high risk and be carriers of cancer-associated mutations. Community health education is an impactful approach to reach high risk individuals. Here we report the progress and impact of the first year of the Rivkin Center's CanCan education program—a joint ovarian and breast cancer education program with a focus on the genetic and family history risks for both cancers. Program goals are to help identify high risk individuals and to educate diverse populations on risk factors, signs, symptoms, prevention options, and screening guidelines for both cancers. A trained instructor and an ovarian or breast cancer survivor teach the one-hour free, interactive workshops. Attendees receive a two-step risk assessment worksheet to (1) document their family cancer history, and (2) complete a risk assessment checklist to determine if they should seek genetic counseling. Workshops take place in diverse community settings, including low income housing developments, religious orgs, corporate offices, and hospitals in Washington State, and in the campus setting for younger women at all PAC-12 universities. Focus on outreach to the Ashkenazi Jewish, minority, immigrant, and LGBTQ communities ensures that the program reaches high risk and underserved communities. Since June 2017, CanCan has conducted 190 workshops, with over 10,000 individuals educated. Post-workshop surveys returned by 563 attendees show that 95% will talk to their family about health history, 99% will seek a healthcare provider for a medical concern, 91% had an excellent or good understanding of the signs, symptoms, and screening guidelines for both cancers, and 96% will share what they learned with others. In summary, the first year of the CanCan ovarian and breast education program has been very successful, with attendees reporting increased awareness and intent to assess their risk. Future goals of the program are to increase program reach in the community and through digital education.

**A pipeline for identification and confirmation of potentially actionable germline mutations in tumor only genomic sequencing.** *D. Farengo Clark<sup>1</sup>, J. Powers<sup>1</sup>, K.L. Nathanson<sup>2</sup>, D.B. Lieberman<sup>2</sup>, J.J.D. Morrisette<sup>3</sup>, K.N. Maxwell<sup>4</sup>, S.M. Domchek<sup>4</sup>.* 1) Department of Hematology-Oncology, University of Pennsylvania, Philadelphia, PA; 2) Division of Translational Medicine and Human Genetics, Department of Medicine, Perelman School of Medicine at the University of Pennsylvania; 3) Department of Pathology and Laboratory Medicine, Perelman School of Medicine at the University of Pennsylvania, Philadelphia; 4) Division of Hematology-Oncology, Department of Medicine, Perelman School of Medicine at the University of Pennsylvania.

**Background:** A published concern of next-generation sequencing for tumor DNA profiling (tNGS) is the identification of potential germline findings. For both the patient and their family, it is critical to develop referral and testing pathways to address potentially actionable germline findings. We describe a novel algorithm for referral of patients for germline testing after tNGS and results of initial implementation. **Methods:** A multidisciplinary team was assembled to determine: (1) criteria to analyze somatic variants for germline actionability; (2) pathogenic variants (PV) triggering "automatic referrals" for germline testing; and (3) a protocol for clinical genetics referral. Data analyzed included gene-specific germline: somatic mutation ratio, genotype-phenotype associations and clinical utility. **Results:** 1695 patients underwent tNGS from 2016-2018 with 111/1695 identified by automatic referral criteria. The criteria to refer germline confirmation included: (1) all PV in *BRCA1/2*, *BRIP1*, *PALB2*, *RAD51C/D*, and mismatch repair genes (75%); (2) PV in patients with classic phenotype for associated cancer susceptibility syndrome (e.g. *TP53* in personal/family suggesting Li Fraumeni syndrome) (23%) and (3) known germline founder PV (2%). The oncologist was asked to discuss findings with the patient prior to the genetic counselor (GC) making contact. The GC facilitated germline testing and reporting (if patient agreeable). Forty-eight (43%) patients underwent germline testing and 28/48 (58%) had confirmed germline PV. Forty-six percent of confirmed germline PV were in genes associated with the tumor type. All *BRCA1/2* PV were referred and 72% (13/18) were confirmed as germline. Eight patients with germline *BRCA1/2* PV had classic HBOC associated cancers [pancreatic (6), prostate (2), breast (1)], while four were identified in tumors not classically associated with HBOC (glioblastoma (2), gallbladder and colon). No germline testing was performed in 63/111 (56%) of patients due to lack of referral (39%), poor patient health or death (24%), and patient refusal (30%). **Conclusions:** 6.5% of patients had somatic findings triggering referral. Of these, 48 (43%) underwent genetic testing, 28 were positive, of which, 10/28 (36%) may not have been referred by personal or family history of cancer alone. Continued research is critically needed to address the challenges of implementation of this algorithm and capture of potentially actionable germline findings found by tNGS.

**548F**

**Effects of nicotinamide on primary cervical cancer cells (fibroblasts): A new therapeutic modality.** *R.N. Hassan, H.L. Luo.* Genetics, Sun Yat-Sen University, Guangzhou, Guangdong, China.

**Background:** Cervical cancer is a spectrum from pre-malignant condition to aggressive disease. Unfortunately, drug resistance is inevitable in this cancer. Alternative therapeutic strategies are urgently needed to improve outcomes and to reduce the cost of treatment. Nicotinamide is a known amide of niacin that plays major role in critical cellular processes. Whether nicotinamide can be used as an anti-cancer agent is still unclear. **Methods:** Fibroblasts derived from primary cervical cancer patients were treated with nicotinamide and the cell viability were assessed using the CCK-8 assay. We used flow cytometry to measure the reactive oxygen species (ROS) and glutathione peroxidation. Cellular morphology were studied post-treatment by DAPI staining. Annexin V assay was conducted to assess apoptosis. We conducted western blot to demonstrate caspase cleavage. Finally, quantitative reverse transcriptase polymerase chain reaction was used to measure redox gene expression in the treated cervical cancer cells. All experiments were performed in triplicates and a p-value of <0.05 were considered significant. **Results:** Nicotinamide was able to inhibit the cellular proliferation of cancer cell fibroblasts in a dose dependent and time-dependent manner. It decreased the GSH content in the cells, while increasing the ROS. Induction of apoptosis was observed in nicotinamide treated cells. **Significance:** We demonstrated that nicotinamide could induce apoptosis and gross inhibition of cervical cancer cells through increased oxidative stress. This new evidence suggests that nicotinamide is a promising anti-cancer agent. **Key words:** nicotinamide, cervical cancer, fibroblast, apoptosis.

**549T**

**The influence of Malay cultural beliefs on breast cancer screening and genetic testing: A focus group study.** *T. Shaw<sup>1</sup>, D. Ishak<sup>1</sup>, D. Lie<sup>2</sup>, S. Me-non<sup>1</sup>, E. Courtney<sup>1</sup>, S-T. Li<sup>1</sup>, J. Ngeow<sup>1,3,4,5</sup>.* 1) Cancer Genetics Service, Division of Medical Oncology, National Cancer Centre Singapore, 169610; 2) Office of Clinical Sciences, Duke-NUS Medical School, Singapore 169856; 3) Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore 308232; 4) Oncology Academic Clinical Program, Duke-NUS Medical School, Singapore 169857; 5) Institute of Molecular and Cell Biology, Agency for Science Technology and Research (A\*Star), Singapore 138673.

**Objective:** Malays comprise an Asian cultural group reported to have low breast cancer screening uptake rates and poor cancer outcomes. Little is known about Malay cultural factors influencing beliefs and practice of cancer screening and genetic testing. Our study aims to explore health beliefs of Malay women around breast cancer screening and genetic testing. **Methods:** We conducted focus groups among healthy English-speaking Malay women in Singapore, aged 40 to 69 years, using a structured guide developed through literature review, expertise input and participant refinement. Thematic analysis was conducted to extract dominant themes representing key motivators and barriers to screening and genetic testing. We used grounded theory to interpret results and derive a framework of understanding, with implications for improving uptake of services. **Results:** Five focus groups (four to six participants per group) comprising 27 women were conducted to theme saturation. Major themes were 1) spiritual and religious beliefs act as barriers towards uptake of screening and genetic testing, 2) preference for traditional medicine competes with Western medicine recommendations, 3) family and community influence health-related decisions, complexed by differences in intergenerational beliefs creating contrasting attitudes toward screening and prevention. **Conclusion:** Decisions to participate in breast cancer screening and genetic testing are mediated by cultural, traditional, spiritual/religious and intergenerational beliefs. Strategies to increase uptake should include acknowledgement and integration of these beliefs into counseling and education and collaboration with key influential Malay stakeholders and leaders.

**550F**

**Cervical screening for cancer and other cytologies: Role of repair genes P53 and hMLH1 methylation status.** *S. Thumojur<sup>1</sup>, YR. Ahuja<sup>1</sup>, M. Vasavi<sup>1,2</sup>.* 1) Genetics and Molecular Medicine, Vasavi Medical and Research Centre, Hyderabad, India; 2) Genetics, Hansgene Cancer Foundation, Hyderabad, India.

**Introduction:** Cervical Cancer is preventable. The main obstacle for the success of screening efforts in women is the stigma about the screening procedure both in rural and urban population. Tissue changes, fueled by DNA damage and repair errors, alter the genome to produce instability that drives tumorigenesis. hMLH1 repair gene is known to be hypermethylated in a variety of tumors. A common polymorphism of *P53* (Pro to Arg) at codon 72, affects the susceptibility of *P53* to E6-mediated degradation in vivo. The association of this polymorphism with different cytologies and cervical cancer cases was studied. **Methods:** Creating awareness, training para-medical staff, involving local voluntary bodies for conducting Pap testing and HPV subtyping in health-camps gave us optimal leads to manage these patients. A total of 315 screened subjects and 148 histologically confirmed cervical cancers were recruited for the hMLH1 methylation study. A total of 482 subjects, out of which 121 normal pap cytology, 213 abnormal cytology and 148 cervix cancers were recruited for *P53* genetic variant study by PCR analysis (rs1042522) *P53* (exon4) primers. **Results:** A total of 530 women (general population) were screened; 1.88% showed high risk HPV subtypes. Initial poor compliance was improved drastically after we changed our approach with pre-camp, general awareness talks and one-to-one counselling of women on importance of testing to avoid future risk for cancer. hMLH1 promoter methylation was significantly higher in inflammation, infection, RCC, ASCUS, SCC cases whereas atrophy, LSIL and surprisingly HSIL did not show any significant change compared to controls. The *P53* (Pro to Arg) residue at codon 72 significantly showed an association of the variant amino acid Arginine with carcinoma of uterine cervix in comparison to cases with normal cervical cytology. **Conclusion:** Conducting national screening programs along with counselling for awareness can reduce the burden of this cancer in developing countries. There is a need to screen women for high risk HPV sub-types for successful application of any future vaccinations programs. Promoter methylation of hMLH1 gene may be associated with increased risk of pathology in the cervical tissue; this could also be enhanced by Hr-HPV infection. Genotyping of *P53* (Pro to Arg) at codon 2 in patients with abnormal pap cytology may be useful in identifying individuals at a high risk of worsening of cervical health and in developing cancer.

**551T**

**Digital direct engagement is an effective method for communicating updated test results.** S. Topper, C.L. Neben, C. Lai, C. Heydrich, A.Y. Zhou. Color Genomics, Burlingame, CA., Select a Country.

The duty to recontact patients with new information that may meaningfully alter medical care was first established in 1999. The issue has grown in urgency since then, and ACMG, ASHG, and ESHG have all issued updated statements re-examining and re-affirming this duty. Despite the ethical framework and the increasing urgency, little has been published about the methods or effectiveness of recontacting. Color Genomics, a clinical laboratory, utilizes electronic communications to maintain active interactions with clients, regardless of their physical location. Here we present data on the effectiveness of providing updated information to 417 clients who received genetic testing ordered by their personal healthcare provider (traditional) or ordered by an open-access, independent healthcare provider (independent). We first assessed whether clients viewed their genetic testing reports after they were made available. A total of 83.7% (170) in the traditional cohort (72.9% within 7 days) accessed their results compared to 96.7% (202) of the independent cohort (93.3% within 7 days). The decreased uptake in the traditional cohort could be attributed to clients directly discussing reports with their personal healthcare providers. At a subsequent date, all of these individuals (and their providers) were notified by email of a revised report based on new genetic or clinical information including variant reclassification, new health history, or updated risk. When looking at the access rates for revised results, a total of 45.4% (93) of the traditional cohort accessed their updated results (43.4% within 7 days) compared to 69.8% (148) in the independent cohort (67.5% within 7 days). We next examined whether the type of new information in the revised reports affected access rates. Clients with updated screening guidelines or recommendations (due to updates in professional society recommendations) accessed revised reports most frequently (87.5%, 14), followed by new health history (56.1%, 125) and variant reclassification (57.3%, 102). In conclusion, to our knowledge, this is the first report on the effectiveness of providing updated information in a clinical laboratory. Taken together, the data presented here demonstrate that digital direct communication mediated by a clinical laboratory is effective for communicating updated test results to clients.

**552F**

**Genetic testing for breast cancer survivors.** J. Wiggins<sup>1</sup>, A. George<sup>1,2</sup>, Z. Kemp<sup>1,2</sup>. 1) Cancer Genetics Unit, Royal Marsden Hospital, Sutton, United Kingdom; 2) Institute of Cancer Research, 15 Cotswold Road, Sutton, United Kingdom.

**Introduction** Knowledge of germline *BRCA1/2* status increasingly influences the management of early breast cancer. However, many breast cancer survivors have not benefited from genetic testing because it may not have been offered, testing criteria may have subsequently broadened or family history may have emerged since initial treatment. Others may not have felt ready to consider testing at diagnosis. The identification of *BRCA1/2* mutations remains important during survivorship both in terms of management of future cancer risk and cascade testing amongst family members. It is anticipated that there will be 2 million breast cancer survivors in the UK by 2040. In the US ACS/ASCO breast cancer survivorship care guidelines (2015) recommend doctors revisit genetic assessment for breast cancer survivors. There are no such recommendations in the UK. Here we describe a collaboration between the genetic and breast cancer teams at the Royal Marsden Hospital to identify patients eligible for genetic review prior to discharge from the breast service. **Method** Early breast cancer patients are routinely reviewed at a virtual MDT (VMMDT) 5 years post diagnosis to determine long term cancer surveillance and endocrine requirements. A Senior Genetic Counsellor joined the VMMDT to highlight patients eligible for genetic referral. Genetics appointments were offered in writing. **Results** Between May 2015 and December 2016 935 patients were discussed at the VMMDT. One third (309/935) were eligible for genetic assessment +/- testing based on their personal +/- reported family history. Less than half of eligible patients had been referred to genetics in the period of breast cancer follow up. Of the patients offered genetic assessment one third declined the appointment or did not attend. Of the 117 patients who attended the genetics clinic, 88 were offered genetic testing and 9 *BRCA* mutation carriers were identified (10.2% detection rate). When taking into account those who had been offered testing before, 3.4% (32/935) of the follow up population were identified as mutation carriers compared with 2.4% (23/935) prior to this intervention. **Conclusion** A significant number of *BRCA1/2* mutation carriers are not identified during their breast cancer treatment pathway. Breast cancer survivors and their families can benefit from routine genetic assessment in the same way issues such as endocrine treatment and surveillance are currently considered.

**553T**

**Findings of a universal screening program for Lynch syndrome in an integrated healthcare system.** *J.E. Hunter, L. Jenkins, E. Shuster, J. Zepp, T. Kauffman, S. Gille, K.A.B. Goddard.* Center for Health Research, Kaiser Permanente Northwest, Portland, OR.

Lynch syndrome (LS) is associated with an increased risk of cancer, most commonly colorectal (CRC) and endometrial (EC) cancers. A diagnosis of LS has a significant impact on clinical management of patients and their at-risk family members. Universal tumor screening (UTS) of all patients newly diagnosed with CRC and EC is recommended to increase identification of cases of LS and reduce morbidity and mortality compared to selective screening based on risk factors such as age and family history. Currently, there is limited data regarding outcomes of screening programs in community healthcare settings, including uptake of follow-up testing in patients who screen positive for LS. Kaiser Permanente Northwest (KPNW) is an integrated healthcare system that serves northwest Oregon and southwest Washington. KPNW implemented a UTS program for LS among cases of CRC in January 2016 and EC in November 2016. Screening includes immunohistochemistry (IHC) of the four mismatch repair proteins associated with LS (MLH1, MSH2, MSH6, and PMS2) followed by reflex to testing for the *BRAF* V600E variant (CRC only) and *MLH1* hypermethylation (CRC and EC), when appropriate, to rule out likely sporadic cases. As of March 2018, 278 cases of CRC and 70 cases of EC had been screened for LS. Overall, ~15% of patients had an abnormal IHC, consistent with the percentage reported in prior studies. Eleven patients (9 CRC, 2 EC) received an abnormal screen result in the absence of signs of sporadic cancer and were offered genetic counseling and genetic testing. Of these, 10 patients (8 CRC, 2 EC) underwent genetic testing. Six (5 CRC, 1 EC) patients were found to have a pathogenic or likely pathogenic variant in one of the LS genes: 1 *MLH1*, 1 *MSH2*, 1 *MSH6*, and 3 *PMS2*. Of those with a diagnosis of LS, age at onset of cancer ranged from 32 to 81 years. Two additional patients with CRC received results for a variant of uncertain significance (VUS): one patient with a VUS in *MLH1* and a second patient with 2 VUSs in *MLH1* and *MSH6*. Genetic testing was negative in three patients. The typical time following surgery for a patient to be contacted by the genetics department for follow-up was roughly 2 weeks. However, 91% of patients who received an abnormal screening result for LS followed up with genetic counseling and testing, indicating that the timing of receiving tumor testing results (i.e., soon after surgery for CRC) is not a significant barrier for follow-up.

**554F**

**Implementing personalized cancer medicine into primary care: Challenges and solutions.** *J.C. Carroll<sup>1,2</sup>, T. Makuwaza<sup>1,2</sup>, D.P. Manca<sup>3</sup>, N. Sopcak<sup>3</sup>, M.A. O'Brien<sup>4</sup>, J.A. Permaul<sup>5</sup>, R. Heisey<sup>1,4</sup>, R. Urquhart<sup>5,6</sup>, C. Sawka<sup>7</sup>, S. Pruthi<sup>8</sup>, N. Schneider<sup>9</sup>, E. Grunfeld<sup>1,10</sup>* On behalf of CanIMPACT. 1) Department of Family and Community Medicine, University of Toronto, Toronto, Ontario, Canada; 2) Ray D Wolfe Department of Family Medicine, Sinai Health System, Toronto, Ontario, Canada; 3) Department of Family Medicine, University of Alberta, Edmonton, Alberta, Canada; 4) Department of Family and Community Medicine, Women's College Hospital, Toronto, Ontario, Canada; 5) Beatrice Hunter Cancer Research Institute, Halifax, Nova Scotia, Canada; 6) Department of Surgery, Dalhousie University, Halifax, Nova Scotia, Canada; 7) Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, Ontario, Canada; 8) General Internal Medicine, Mayo Clinic, Rochester, Minnesota, US; 9) Independent, St. Walburg, Saskatchewan, Canada; 10) Ontario Institute for Cancer Research, Toronto, Ontario, Canada.

**Objective:** To realize the benefits of personalized medicine (PM), it must be integrated into primary care (PC). Previous work identified increased knowledge, connection to genetics specialists and point-of-care (POC) resources as important for successful implementation. Our objective was to explore an implementation strategy using a PM cancer toolkit. **Design:** A mixed methods implementation study including focus groups (FG) and pre/post questionnaires. **Setting and Participants:** PC providers in Canadian team practices (Ontario 2, Alberta 1). **Intervention:** After incorporating PC feedback, we developed a toolkit including POC risk assessment and management tools for hereditary breast and colorectal cancers, introduced at FG1. Using the Consolidated Framework for Implementation Research, we explored implementation strategies with practices through FGs at 2 and 4 months, with evaluation at 6 months. **Methods:** We used semi-structured, framework-informed interview guides and descriptive thematic analysis of transcripts by site and across time. Pre/post questionnaires assessed confidence in PM competencies using Fisher's Exact tests. **Findings:** 19 PC providers participated. Implementation strategies included integrating POC tools into the Electronic Health Record (EHR), modifying workflow to collect family history (FH), and bookmarking the GECKO genetics education website ([www.geneticseducation.ca](http://www.geneticseducation.ca)). Participants described how having few patients with significant cancer FH made it challenging to keep PM top of mind and see the need for practice change. They recognized FH as key to PM and wanted electronic tools for collection and interpretation; additional PM POC EHR tools with routinized reminders; and seamless fit to clinic flow. Local champions were valued for advocating use of PM tools. At 6 months, there was a significant increase in PC providers' confidence regarding hereditary cancer (pre 12%, post 54%,  $p=0.02$ ), deciding who to offer genetics referral (pre 29%, post 75%  $p=0.025$ ), and knowing where to obtain PM information (pre 0%, post 50%,  $p=0.005$ ). **Conclusions:** PM continues to be an implementation challenge in PC. Successful strategies must address both knowledge gaps and practice issues.

**555T**

**Maternally inherited *SDHD*: Management challenges.** *J. Vengoechea, C. Tallo, D. Davis.* Department of Human Genetics, Emory University, Atlanta, GA.

Paragangliomas and pheochromocytomas (PGL/PCC) are rare tumors that develop in neuroendocrine tissue, can secrete hormones leading to high morbidity and may be malignant. Approximately 40% of PGL/PCC cases are hereditary and about 30% of these are caused by a paternally inherited mutation in *SDHD*. Maternally inherited *SDHD*-related PGL/PCC has been reported (Yeap et al, 2009; Bayley et al, 2014; Burnichon et al, 2017), which is plausible due to two independent somatic events: 1) a mitotic recombination resulting in two recombined copies of chromosome 11 and 2) loss of the recombined chromosome containing a paternal 11q23 region and maternal 11p15 region. We describe a case of maternally inherited *SDHD*-related PGL/PCC and highlight the management and genetic counseling challenges for these families. The proband is a 53 year-old woman who was diagnosed with bilateral carotid body tumors and a right glomus vagale tumor, the right sided tumors were removed and confirmed to be paragangliomas. She is undergoing radiation therapy for the left sided tumor. Her family history was notable for a sister who died at 39 from metastatic PGL and a daughter diagnosed with a PCC at age 29 who had tested negative for mutations in *RET*. Clinical testing revealed a pathogenic variant, c.242C>T in *SDHD*. The affected daughter an unaffected 36 year old daughter then tested positive for the variant. There is no consensus on the screening method and frequency for identification of PGL/PCC in presymptomatic individuals with a predisposing germline mutation. We have developed a biochemical and imaging screening protocol, the latter can be costly and time consuming, and often reveals incidental findings that require extensive follow-up. The decision of initiating this protocol in a case of maternally derived *SDHD* should not be taken lightly. In this family, we were able to demonstrate that a maternally inherited *SDHD* variant was penetrant. There is yet to be a consensus about whether this can only be caused by a somatic translocation event. Until there is further clarification on the mechanisms behind penetrance of a maternally inherited *SDHD*-related PGL/PCC, we ordered baseline CT, MRI and MIBG tests. Genetic counseling about how this represented an exception to the general rule of parent-of-origin effect in *SDHD* proved to be challenging. A better understanding of the causes for maternal transmission of *SDHD* will help provide appropriate genetic counseling and management recommendations.

**556F**

**Incidental identification of a moderate penetrant germline *RET* mutation in a patient with advanced epithelial ovarian cancer: A significant benefit of a multidisciplinary molecular tumor board.** *T.A. DeMarco<sup>1</sup>, R. Moore<sup>2</sup>, K. Matthijssen<sup>1</sup>, A. Schott<sup>1</sup>, D. Alaeddin<sup>1</sup>, T. Cannon<sup>3</sup>, L. Knopp<sup>3</sup>, N. Hauser<sup>1</sup>, J. Deeken<sup>1</sup>.* 1) Inova Translational Medicine Institute, Fairfax, VA; 2) Taussig Cancer Center, Cleveland, OH; 3) Inova Schar Cancer Center, Fairfax, VA.

The primary purpose of a molecular tumor board (MTB) is to convene a group of experts to review patients with refractory cancers and to make potential recommendations for targeted therapy based on their somatic tumor profiling. Another potential benefit of an MTB is the identification of somatic tumor results which may have potential germline implications for patients. We present the case of an Asian female diagnosed with advanced metastatic epithelial ovarian cancer at the age of 65. In July of 2016 the patient underwent a multi-gene pan-cancer genetic testing panel composed of 32 genes and no mutations were identified. In November of 2016 somatic tumor profiling was performed indicating several positive alterations, including the identification of the *RET* p.V804M mutation. A genetic counselor present at MTB noted the *RET* mutation as possibly being germline. Since the patient's previous panel testing did not include the *RET* gene, the counselor recommended that the patient receive additional genetic counseling with the option of germline genetic testing for this particular mutation. The patient underwent additional single-site germline genetic testing and her results were positive for the *RET* p.V804M mutation. Mutations in the *RET* gene are associated with MEN2A and an increased risk for the development of medullary thyroid cancer, hyperparathyroidism and also pheochromocytoma. The patient's personal and family history was non-contributory for any of these particular findings; and given that p.V804M is a moderate penetrant *RET* mutation, this is not uncommon. However, this particular *RET* mutation may also increase the risk for the development of papillary thyroid cancer. Interestingly, the patient's daughter had a history of papillary thyroid cancer; but, she tested negative for the familial *RET* mutation. The identification of the *RET* mutation provided information about further cancer risks for the patient and the opportunity for cascade testing in her relatives. Given the lack of suggestive personal and/or family history, had this patient not been presented at MTB attended by a genetic counselor, it is much less likely that the *RET* germline mutation would have been identified. This case illustrates the importance of a multidisciplinary MTB utilizing genetic counselors to identify and discuss somatic tumor findings that may have significant germline implications for patients and their relatives.

**BRCA1 and BRCA2 variant reclassifications from Mount Sinai Hospital, Toronto.** J. Lerner-Ellis<sup>1,3</sup>, C. Mighton<sup>1,2</sup>, M. Wang<sup>1,3</sup>, S. Shickh<sup>1,2</sup>, N. Watkins<sup>1,3</sup>, K.R. Zakoor<sup>3</sup>, A. Wong<sup>3</sup>, Y. Bombard<sup>1,2</sup>. 1) University of Toronto, Toronto, ON; 2) Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON; 3) Laboratory Medicine and Pathobiology, Sinai Health System, Toronto, ON.

**Background:** Accurate interpretations of genetic variants are essential for diagnosis, management and counselling of patients with inherited disorders. Periodic variant reassessment can ensure that classifications reflect current evidence and best practices. Even variants in well-characterized genes such as *BRCA1* and *BRCA2* are prone to inter-laboratory discordance and may be reclassified over time as new evidence is generated. The Advanced Molecular Diagnostics Laboratory (AMDL) provides *BRCA1/2* testing for patients who meet provincial eligibility criteria. Here we report on *BRCA1/2* variant reclassification between 2012 and 2017. **Methods:** Variants were assessed using a standardized variant assessment tool based on ACMG guidelines and tracked in an in-house database. Variants were classified to one of five levels, based on ACMG criteria: benign, likely benign, variant of uncertain significance (VUS), likely pathogenic, and pathogenic. Variants were shared through the Canadian Open Genetics Repository and submitted to ClinVar. **Results:** Between January 1, 2012 and August 18, 2017, 1213 *BRCA1/2* variants were reported. In total, 33.1% (402/1213) were reassessed and 12.5% (152/1213) reclassified. Of the 152 reclassified variants, 63.2% were reclassified to benign, 21.0% to likely benign, 9.9% to variant of unknown significance, 2.0% to likely pathogenic, and 3.9% to pathogenic. In 17.1% of cases, the variant was reclassified more than once, and 8.6% of variants were reclassified back to their initial classification through multiple reclassification events. **Conclusions:** Variants may be reclassified over time, highlighting the importance of periodic reassessment to help ensure that patients receive the most appropriate care based on their genetic test results. It is also important that laboratories engage in data sharing, to advance collective knowledge of variant pathogenicity. In some cases, variant reclassification could impact patients' management. For instance, reclassification of a *BRCA1/2* variant to pathogenic could inform surgeries, increased screening, and predictive testing for family members. Variant reclassification presents ethical and practical challenges related to patient recontact, and suggests a need for research and professional guidance on recontacting patients.

**BRCA in China: Two common founder mutations of BRCA1 in Chinese population.** A. Li, Y. Zi, T. Zhou, Y. Wu, Y. Deng, J. Luo, Y. Shi. TopGene Tech Co., Ltd. Guangzhou, Guangdong Province, P.R.China.

Tumour suppressor genes, *BRCA1* and *BRCA2*, confer a high risk of breast cancer, ovarian cancer and associated hereditary breast and ovarian cancer syndrome (HBOC). Its genetic testing has thrived on next-generation sequencing (NGS) and strong indication for precision medical management. Several recurrent mutations were considered to result from founder effects in previous Chinese *BRCA* researches. To overcome geographical restriction and limited number of carriers (which have previously caused difficulties in verifying presumed founder mutations), we screened a large Chinese nationwide cohort of 5537 samples comprising 630 carriers, in which 196 women (31.1%) and 2 men (0.3%) were diagnosed with breast cancer, 327 (51.9%) with ovarian cancer, 63 (5%) with breast and ovarian cancer, and 36 (5.7%) without cancer. Thirty hot-spot mutations were identified with multiple occurrences (occurred in  $\geq 4$  unrelated patients). *BRCA1*: c.5470\_5477delATTGGGCA was identified from 59 individuals out of 50 unrelated families, and *BRCA1*: c.4801A>T from 7 individuals out of 6 independent families. More importantly, our preliminary bioinformatic analysis indicated that the estimated age of c.5470\_5477delATTGGGCA is 125 generations (with the help of haplotype reconstruction: case vs. control, p-value = 0.01). For unrelated carriers, their family members (without mutations) and normal Chinese control, further comparison of SNPs and STRs (within linkage disequilibrium region) was performed. The results supported that the occurrences of c.5470\_5477delATTGGGCA and c.4801A>T have resulted from the same ancestry, whereas *BRCA1*: c.981\_982delAT, *BRCA1*: c.3770\_3771delAG and *BRCA2*: c.3109C>T is likely to be caused by independent mutational events. The identification of founder mutations would greatly reduce the cost for genetic screening of HBOC in China. Furthermore, to address the lack of public and comprehensive *BRCA1/2* database in China, we have built an online website for researchers to acquire Chinese spectrum of *BRCA1/2* mutations, linking to our developed computational tool for variant interpretation using artificial intelligent technology (submitted). We also observed enrichment at exon 10 of *BRCA1* (density=0.5, p<0.05) and exon 13 of *BRCA2* (density=0.03, p<0.05) in ovarian cancer. For breast cancer, concentrated regions were observed in exon 10 of *BRCA1* (density=0.3, p<0.05) and exon 23 of *BRCA2* (density=0.03, p<0.05).

**559T**

**Identification of pharmacogenetic markers in cancer supportive care.** Z. Gu, M. Wei. Admera Health, South Plainfield, NJ.

**Background:** Precision medicine has become increasingly critical in cancer supportive care, with implications for treatment selection, medication dosing, and side effect prediction. The presence of clinically actionable germline variants brought the hope that accurate prediction of drug efficacy and toxicity would be in the future. This will greatly improve the comprehensive oncology care, where supportive care treatment options can be subjective and personalized. **Methods:** The changes in drug effect and toxicity caused by genetic variations were characterized in 4287 patients submitted for clinical pharmacogenetics testing using a gene panel including key pharmacokinetic and pharmacodynamic genes. For each patient, the need to select an alternate medication and adjust medication dose was determined for the treatment of pain (*CYP2D6*, *CYP1A2*, *OPRM1*), nausea/vomiting (*CYP2D6*), antifungal prophylaxis (*CYP2C19*) and depression (*CYP2D6*, *CYP2C19*). It is recognized that there are many other factors playing in the variations of the response and toxicity to these classes of medications. **Results:** Of the 4287 patients, 964 (22%) would have a recommendation to choose alternatives of oxycodone, codeine, or tramadol therapy and 3394 patients (79%) for a non-standard dosage. A change in certain antiemetics such as ondansetron would be suggested for 171 patients (4%). If voriconazole antifungal prophylaxis was clinical required, 1228 (29%) would need a dose increase, while 133 (3%) should be switched to a different regimen. 2727 patients (64%) should avoid or adjust dosage on some of the commonly used agents for depression due to reduced efficacy or heightened risk of toxicity. **Conclusions:** Pharmacogenetics markers associated with reduced drug efficacy and higher rate of ADRs were commonly observed for medications used in cancer supportive care. Identification of these markers would help clinicians achieve optimal treatment outcome with manageable time and cost. This provides great opportunities to apply precision medicine principles to cancer patient management.

**560F**

**Precision medicine in clinical cardiovascular care: Implementation of a multidisciplinary cardiogenetics clinic.** L.D. Hellwig<sup>1,2,3</sup>, C.E. Turner<sup>2,3</sup>, A. Mains<sup>2</sup>, A. Krokosky<sup>2</sup>, J. May<sup>2</sup>, D. Shanta<sup>2</sup>, C. Dobson<sup>2</sup>, M. Haigney<sup>2,3</sup>. 1) Henry M Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD; 2) Uniformed Services University of the Health Sciences, Bethesda, MD; 3) Walter Reed National Military Medical Center, Bethesda, MD.

**Background:** Cardiac diagnosis and follow-up for families can take great coordination across multiple specialties. The Walter Reed Cardiogenetics Clinic was designed as a multidisciplinary approach that centers on elevated quality of personalized and family-centered care. The Cardiogenetics Clinic includes providers from Adult Cardiology, Pediatric Cardiology, and Genetics, allowing optimization of proper diagnosis, medical management, and follow up care using combined expertise in one clinic visit, as opposed to separate visits for each specialty. We hypothesized that this multidisciplinary approach would increase efficiency of evaluation of Service Members and their families and unify medical management plans for the family. **Methods:** In a single Cardiogenetics visit, patients and their family members receive a thorough cardiac evaluation, physical examination, genetic counseling, and coordinated genetic testing (if indicated and patient-elected). The impact of this clinic was determined by calculating the total number of separate specialty visits the clinic saved since it began on 09 March 2017 and through qualitative assessments by providers. **Results:** Between 01 March 2017 and 1 Feb 2018, a total of 97 patients were evaluated in Cardiogenetics Clinic. Prior to the Cardiogenetics Clinic, these 53 family units would have had to make 188 separate trips spanning Pediatric Cardiology, Adult Cardiology, and Genetics. This indicates a savings of 72% of all visits by employing a multi-disciplinary approach and seeing the family units together in one visit. In addition, cross-disciplinary communication in patient care and clinical decision making has qualitatively improved the quality of care. **Conclusions:** The Cardiogenetics Clinic significantly reduced the number of separate visits each family needed to attend for their medical management. In addition to the time saved for families, this multidisciplinary approach allows for a variety of experts to provide elevated quality of care for these families. Intentions to further this multi-disciplinary approach to precision-medicine and family-centered care include future efforts to expand the current referral network, incorporate telemedicine initiatives to broaden access to this service, institute new research endeavors, and initiate extramural collaborations with other national leaders in the field.

**561T**

**Clinical outcomes of the TTR V122I mutation in a brother-sister pair.** *J. Liu, JY. Liu, A. Sara, J. Fan, J. Wang.* UCLA Ronald Reagan Medical Center, Los Angeles, CA, USA.

Approximately 4% of the African-American population possess a valine-to-isoleucine substitution within the transthyretin protein that results in a tendency for a normally tetrameric protein to dissociate into misfolded, monomeric subunits. These misfolded proteins can then accumulate pathologically and cause an autosomal dominant amyloid cardiomyopathy. Homozygous patients are infrequently documented in case reports, and though there are larger studies among heterozygous patients, there is a lack of studies or reports comparing disease within a family. Here, we report a 65-year-old African-American woman with a history of recurrent supraventricular tachycardia requiring radiofrequency ablation and recurrent chest pain and elevated troponin despite no evidence of coronary artery disease. Our patient was found to be homozygous for the TTR V122I mutation with evidence of infiltrative process on cardiac MRI, diagnosed shortly after her 61-year-old brother died of related cardiac amyloidosis while awaiting orthotopic heart transplantation. Here, we compare the clinical course and imaging data for the aforementioned brother-sister pair in the context of the amyloidogenic V122I transthyretin gene variant. Through this familial report, we aim to highlight variations in expression within a family and emphasize the importance of genetic testing of families at risk for this specific variant within the African-American community.

**562F**

**Type 2 diabetes: More likely in eveningness chronotype than morningness chronotype.** *Q. Naz<sup>1,2,3,4</sup>, N. Verma<sup>2</sup>, K. Usman<sup>4</sup>, A.A. Mahdi<sup>3</sup>.* 1) Physiology, Biochemistry & Medicine, King George's Medical University, Lucknow, India; 2) Dept. of Physiology, King George's Medical University, Lucknow, India; 3) Dept. of Biochemistry, King George's Medical University, Lucknow, India; 4) Dept. of Medicine, King George's Medical University, Lucknow, India.

**Background:** Humans living in modern industrialized societies have easier access to light and are often forced to be awake by social norms against their preferred times independent of the master circadian rhythm. These environmental stimuli eventually lead to the disruption of the circadian system. Thus, both genetic variations in clock genes and environmental elements affect the distribution of chronotype. **Aim:** The aim of this study is to investigate the mRNA expression of circadian clock genes (related to metabolic homeostasis) RevErb alpha and ROR alpha in Type 2 diabetic T2DM patients with Morningness, Eveningness and mixed chronotype. **Methodology:** A total of 135 subjects (morningness n=55, mixed n=55 & eveningness n=25 age 18 to 16 years were recruited in Clinical OPD of General Medicine, KGMU. The subjects we enrolled were mainly treated their diabetes & life style related disease including diabetes & other metabolic disorders. 1 µg of total RNA was reverse transcribed into cDNA using Mol Bio™ reverse transcriptase. RT-PCR analysis was performed by the AB Applied Biosystems in 96 well plates using the SYBR GREEN. Primers were designed with the help of NCBI. GAPDH was used as an internal control. The relative quantification of mRNA expression was calculated as a ratio of target gene to GAPDH. **Results:** When we compared these 3 groups, Significant Different was found in various parameters like FBG (P = 0.01) Postprandial (P = 0.03) HbA1c (P = 0.001) TG (P = 0.001), Total Cholesterol (P = 0.01) & VLDL (P = 0.005). Serum leptin (15.01 ± 14.70) also reduced in eveningness when compared to morningness type, which may increase appetite & reduce energy expenditure leading in turn to the development of obesity & deterioration of metabolism. It also shows the complete inversion of the cortisol level (171.55± 77.70). ROR α expression was reduced in eveningness (p= 0.071) and mixed chronotype (p= 0.025) when compared with morningness chronotype (p= 0.091). Also comparison of REV ERB α expression was reduced in eveningness (p= 0.039) & mixed chronotype (0.047) when compared with morningness type or early eaters. **Conclusion:** Clock gene (REV ERB α & ROR α) mRNA expression is significantly altered in morningness and mixed chronotype as compared to morningness type in T2DM Patients. RT-PCR determination of this specific clock gene may be helpful for earlier detection of T2DM in patients with altered feeding habit & unbalanced lifestyle.

**Identification of pathogenic variants associated with primary immunodeficiency (PID) in Jordanian patients using next generation sequencing (NGS).** M.M. Abu-Halaweh<sup>1</sup>, R. Alzyoud<sup>2</sup>, M. Abu-Shukair<sup>2</sup>, KH. Al-Qaoud<sup>3</sup>, J.R. Lemke<sup>4</sup>, R. Abou Jamra<sup>4</sup>, H. Tawamie<sup>4</sup>. 1) Biotechnology and Genetics Engineering, Philadelphia university, Amman , Amman, Jordan; 2) Queen Rania Al Abdullah Hospital for Children, King Abdallah St. - Medical City, Amman, Jordan; 3) Department of Biological Sciences, Yarmouk University-Irbid 21163-Jordan; 4) Institute of Human Genetics, University Medical Center Leipzig, 04103 Leipzig, Germany.

Primary immunodeficiencies (PIDs) represent a heterogeneous group of monogenic disorders including more than 300 genetically defined diseases that influence the development and functions of innate and adaptive immunity. The extreme heterogeneous phenotypes of PIDs can make the diagnosis workup challenging and time consuming. Thus, accurate identification of causative variants and immunological pathways is crucial as it provides the opportunity for timely treatment to prevent life-threatening infections and irreversible organ damage. Whole exome sequencing (WES) has revolutionized the diagnosis of genetic diseases by providing an increasingly cost-efficient diagnostic tool. In this study we applied whole exome sequencing (WES) in patients from two families of Jordan descent. Homozygous candidate variants that may be relevant for the patients phenotype in *IL21R* (c.563del, p.Leu188Argfs\*43), *CD40LG* (c.418T>C, p.Trp140Arg) have been identified. The validation and segregation of the identified variants were performed by Sanger Sequencing. Our findings indicated that WES is a useful approach for the identification of pathogenic variants associated with PIDs. More studies still necessary to confirm the genotype-phenotype correlation at the functional level.

**Anti-cyclic citrullinated peptide (CCP) in rheumatoid arthritis. Does it have any role in early onset of the disease?** A. Niraula<sup>1</sup>, S. Sapkota<sup>2</sup>, K. Dahal<sup>3</sup>, S. Kunwar<sup>4</sup>, NP. Shah<sup>5</sup>. 1) Senior Resident, Biochemistry, B.P. Koirala Institute of Health Sciences, Dharan, 1, Nepal; 2) Medical Biochemist, Lumbini Zonal Hospital, Butwal, Nepal; 3) DM Resident (Nephrology), National Academy of Medical Sciences (NAMS), Bir Hospital, Kathmandu, Nepal; 4) Lecturer, Department of Biochemistry, Modern Technical College, Sanepa, Lalitpur; 5) Medical Technologist, Nepal Public Health Laboratory, Teku, Kathmandu, Nepal.

**Background:** Rheumatoid arthritis (RA) is the most frequent systemic autoimmune disease affecting approximately 1% of the human population. Rheumatoid arthritis is manifested with the chronic inflammation of small joints, becoming gradually even more destructive in the course of time. The cause for the disease is attributed to various environmental, microbial and genetic factors. The definite diagnosis is based on clinical features and serological tests like Rheumatoid factor (RF), erythrocyte sedimentation rate (ESR) and C-reactive protein. Although, no any marker has been in practice to assess the course of the disease from beginning. Markers like Anti-CCP has been shown to assess the disease at an early period and have shown to have high sensitivity and specificity. **Material and Methods:** This is a hospital based comparative cross-sectional study conducted in patients with RA and healthy controls. Patient was recruited from study Star Hospital Private Limited, Lalitpur, Nepal. Fifty patients with Rheumatoid Arthritis who met at least four criteria and 25 healthy patients who served as control were included in the study. It was done with an aim to predict the prognosis of RA at an early period by Anti-CCP comparing it with the traditional markers of RA like CRP, ESR and RA factor. **Results:** The findings from the study depict that the mean age of the patients with RA in the present study is  $39.88 \pm 9.07$ . Among the study participants majority were female (68%). Biochemical analysis shows median Anti-CCP level 21.05 (6.35, 30.58), Mean ESR level to be  $20.88 \pm 14.44$  and median CRP level 1.20 (0.43, 3.02) and 46% positivity for Rheumatoid factor in RA patients respectively. On comparing Anti-CCP level between cases and control, a significantly increased concentration of Anti-CCP level was anticipated in patients ( $27.87 \pm 14.10$  versus  $4.44 \pm 2.18$ ). Receiver Operating Characteristics (ROC) curve demonstrates the diagnostic efficacy of Anti-CCP for the diagnosis of Rheumatoid Arthritis. The curve depicts that at the cut-off value for Anti-CCP of 8.12 sensitivity of 92.4% and specificity 96.2% was obtained. **Conclusion:** Thus, Anti-CCP can be considered as a novel marker to predict the prognosis and treatment outcome in patients with Rheumatoid Arthritis.

**565T**

**A rare case of familial hyperoxaluria and male infertility.** *R. Frikha<sup>1</sup>, MA. Msedd<sup>2</sup>*. 1) Department of Medical genetics , University teaching hospital of Sfax, Sfax, Tunisia; 2) Department of Urology , University teaching hospital of Sfax, Sfax, Tunisia.

**Introduction:** Hyperoxaluria is an autosomal-recessive disorder of endogenous oxalate synthesis characterized by an accumulation of calcium oxalate primarily in the kidney, and leads to nephrocalcinosis and end-stage renal disease. A wide spectrum of associated anomalies may be present and there are three forms of primary hyperoxaluria in which the underlying defects and clinical onset and severity have been identified. **Case:** It's about a 48-years-old Tunisian man presented with primary infertility since 11 years for who oligo-astheno-azoospermia was related to testicular microlithiasis. Evaluation of primary infertility was performed by assessment of personal and familial medical history, physical exam, ultrasound exam, hormonal and infectious testing. **Results:** The patient had a personal history of recurrent urolithiasis and familial history of similar recurrent lithiasis in his mother (urolithiasis) and brothers (nephrolithiasis) who was infertile. Lithiasis was composed of calcium oxalate monohydrate. Physical exam was normal, FSH level was high and testicular ultrasound showed varicocele as well as bilateral hypotrophy. Never infection was detected. **Conclusion:** To our knowledge; this is the first case of familial hyperoxaluria; especially type III a rare, late and middle entity with a mitochondrial transmission, which is associated with male infertility. .

**Effects of oral eliglustat on bone in adults with Gaucher disease type 1: Long-term results from four clinical trials.** *J. Charrow<sup>1</sup>, T.M. Cox<sup>2</sup>, E. Lukina<sup>3</sup>, P. Mistry<sup>4</sup>, T. Marinakis<sup>5</sup>, M. Foster<sup>6</sup>, S.J.M. Gaemers<sup>6</sup>, M.J. Peterschmitt<sup>6</sup>*. 1) Northwestern University Feinberg School of Medicine, Ann and Robert H. Lurie Children's Hospital of Chicago, Chicago, IL; 2) University of Cambridge, Addenbrooke's Hospital, Cambridge, UK; 3) National Research Center for Hematology, Moscow, Russia; 4) Yale University, New Haven, CT; 5) General Hospital of Athens "G. Gennimatas", Athens, Greece; 6) Sanofi Genzyme, Cambridge, MA.

**Background:** Gaucher disease type 1 (GD1) is a multi-system disorder resulting from deficient activity of lysosomal acid  $\beta$ -glucosidase. Patients with GD1 are at risk of debilitating bone complications that impair quality of life. Eliglustat, an oral substrate-reduction therapy, is a first-line treatment for adults with GD1 who have extensive, intermediate, or poor CYP2D6 metabolizer phenotypes (>90% of patients). Unlike enzyme replacement therapy (ERT), the historic standard of care for GD1, which augments acid  $\beta$ -glucosidase activity in mononuclear phagocytes and is administered by intravenous infusions, eliglustat reduces glucosylceramide accumulation by partially inhibiting glucosylceramide synthase. **Methods:** We analyzed bone mineral density determinations in 4 clinical trials sponsored by Sanofi Genzyme that involved 393 GD1 patients treated with eliglustat for 4–8 years: Phase 2/NCT00358150, ENGAGE/NCT00891202, ENCORE/NCT00943111, EDGE/NCT01074944. Healthy reference scores are >-1 for T-scores and >-2 for Z-scores. **Results:** In treatment-naïve patients (Phase 2, N=26; ENGAGE, N=40), mean spine T-scores moved from the osteopenic range (>-2.5 to  $\leq$  -1) at baseline to the healthy reference range after 2 years of eliglustat with continued improvement thereafter. Mean $\pm$ SEM spine T-score increased from -1.55 $\pm$ 0.28 to -0.59 $\pm$ 0.34 (n=14; mean increase from baseline: 0.96 $\pm$ 0.32), after 8 years in Phase 2, and increased to -0.53 $\pm$ 0.27 in ENGAGE patients with bone data at 4.5 years (n=9; mean increase from baseline: 0.53 $\pm$ 0.16). Femur T-scores improved over time in both trials, as did spine and femur Z-scores. In the ENCORE trial of patients stabilized after a mean of 10 years of ERT (N=157), T- and Z-scores (spine and femur) remained in the reference range for up to 4 years; least square mean spine Z-scores improved by 0.29 ( $P<0.0001$ ). In EDGE (N=170, mostly ERT switch), patients stabilized on eliglustat during a 6- to 18-month lead-in period maintained normal T- and Z-scores (spine and femur). Eliglustat was well-tolerated throughout. Most adverse events were mild/moderate (97%) and considered unrelated to eliglustat (86%); 2% of patients withdrew due to adverse events considered drug-related. **Conclusion:** Long-term eliglustat treatment induced continued improvement in bone parameters in treatment-naïve patients; these parameters remained stable and within healthy reference ranges in trials involving patients who had been previously treated.

**567T**

**Living with xeroderma pigmentosum in Guatemala: Yulmacap village experience.** C.L. Carranza<sup>1,2</sup>, N. Marroquín<sup>1</sup>, N. Escobar<sup>1</sup>, M. Herrera<sup>1</sup>, C. Osorio<sup>1</sup>, M. Guerra<sup>1</sup>, V. Zamora<sup>1</sup>, J. Ortiz<sup>1</sup>, L. Alvarez<sup>1,2</sup>. 1) Institute for the Research in Human Genetic and Metabolic Diseases -INVEGEM-, Guatemala; 2) Istmo University, Guatemala.

Xeroderma Pigmentosum (XP) is a rare autosomal recessive disorder characterized by DNA repair defects that cause photophobia, sunlight-induced cancers, and neurodegeneration. Many of the genes related to Xeroderma Pigmentosum are part of a DNA-repair process known as nucleotide excision repair (NER), and are named as *XPA*, *XPB*, *XPC*, *XPD*, *XPE*, among others. Yulmacap is a village located in Guatemala containing many patients with XP. This is due to the high grade of consanguinity found in this community. The mutation found in these people was first described by Cleaver J in 2006, and is a stop codon in exon 8 in *XPC* gene. It's has been difficult to explain to these people the effects of sun exposure in the affected children. So the majority of the children have severe non-melanoma skin cancer. Their tumors are advanced, with necrosis and infection and they don't use any sun protection. The main goal for the present study was to improve the quality of life of the affected children and to prevent the transmission of the XP disease to another people. We performed a molecular testing for the mutation detection to establish the affected children and the XP family carriers. For doing this, we extracted blood samples and DNA extraction to the affected families. And then performed a polymerase reaction chain followed by enzyme restriction for the mutation detection. We found 9 children affected with the disease and 27 people that are carrier of the mutation. This village is very isolated from the majority of Guatemalan population, they only speak a Mayan language and their education level is extremely low. We developed a special suit that is made from special clothes that prevent the UV light exposure. And we designed the architectural plans for the construction of a day care building, which prevents that UV light penetrates the walls and windows. On the other hand, our team gave a genetic counselling to the mutation carriers, explaining the risk of disease transmission. In conclusion, several institutions collaborate to improve the quality of life of children living with XP. The activities that we performed were the genetic characterization of XPC mutation and genetic counselling, the special suits for affected children, architectural planning of the day care center and the performing skin tumor surgeries.

**Academic performance variability amount adults with Asperger's syndrome: A clinical cohort study.** P. DeSanto. American University of Antigua, Manhattan, NY.

Background:Asperger's syndrome in adulthood is frequently associated with difficulties in social interaction, however few studies have explored the possible association between academic performance variability among those diagnosed. Our goal was to assess this prevalence in a clinical cohort of patients in the US. Method:A clinical retrospective cohort study was performed in patients diagnosed with Asperger's syndrome by analyzing survey data collected at an outpatient clinic between April 1st, 2011 and June 1st, 2018. Patients successfully completed a clinical assessment questionnaire assessing education level, current career, employment status and specific hardships faced during their education along with other self-reported measures of traits. We compared the levels of education along with academic performance during times of schooling with the general population and other clinical groups. Findings: 872 adults (587 men and 285 women) were diagnosed with Asperger's syndrome in the specific study period. All patients selected for this study had attended a learning institution at one point in their lives. 260 respondents have at least a 4th grade education level while 612 respondents received a high school diploma, 284 of those respondents has received a bachelor's degree. 328 respondents received a Master's degree or higher. 375 respondents had received a grade point average of over 3.5/4.0 scale, while 170 had an average between 3.0-3.5 and the remaining 67 were below 3.0. 97% of patients complained of anxiety and increased difficulty surrounding school exams and projects. 80% reported performing below average on multiple exams and disciplines during their education. 35% reported difficulty performing projects in groups or with others. 20% reported difficulty with attendance and punctuality. Compared with the general population, people with Asperger's syndrome are more likely to have higher income careers with a specific focus more commonly around technology, science and medicine. Conclusion:Our finding lend support to reports of increased variable academic performance among patients with Asperger's syndrome. Our study has found that most patients with Asperger's have higher grade point averages, and advanced degrees despite a large number reporting academic difficulties and hardships during their education.

**569T**

**A rare case of Jacobsen syndrome with global diffuse hypomyelination of brain.** *G. Mainali, A. Kumar, G. Raymond.* Penn State Hershey Medical Center, Hershey, PA.

Introduction: Jacobsen syndrome (JS) is a genetic disorder caused by terminal deletion of the long arm of chromosome 11. First report by Jacobsen et al in 1973, more than 200 people have been described. Along with neurocognitive delay, patients may demonstrate malformations involving gastrointestinal, genitourinary, cardiovascular, platelet dysfunction with bleeding and central nervous systems. The deletion ranges from 7 to 20 Mb with a breakpoint at 11q23.3 in 70–80% of cases and often includes HEPACAM associated with megalencephalic leukoencephalopathy with subcortical cysts type 2 (MLC2). Around 65% of JS have a structural abnormality of the brain, issues with myelination have only been rarely reported. We describe a child with severe diffuse hypomyelination mimicking a leukodystrophy. Case presentation: An 8 month old presented with developmental delay and hypotonia. His medical issues included hypoplastic left heart syndrome, undescended testes, neonatal thrombocytopenia and unusual facies. Neurological exam showed, truncal as well as appendicular hypotonia with intact reflexes. Chromosome microarray was sent which showed deletion 11q23-11q24, consistent with JS. Head MRI done initially at 18 months showed severe diffuse hypomyelination of cerebral as well as deep white matter felt to be consistent with leukodystrophy. Basic metabolic work up was unremarkable. Repeat MRI at 3yr showed less extensive lesions consistent with hypomyelination. Discussion: The estimated incidence of Jacobsen syndrome is 1 in 100,000 newborns, with a 2:1 female-to-male ratio. Affected patients have a wide phenotypic spectrum, but ~65% of JS have some CNS structural abnormality including enlarged ventricles; brain atrophy; agenesis of corpus callosum; or pachygyria. While delayed myelination has been reported, there are only a few reports of neuroimages. Our patient had diffuse hypomyelination and was initially suspected of having a progressive destructive process of myelin, but improved with time. Awareness of the MRI presentation of JS is crucial to prevent unnecessary evaluation in this condition. .

**Identifying and counseling patients amenable to mutation-specific therapies in Duchenne muscular dystrophy: Knowledge of resources will fuel genetic counselors' impact.** *A. Ferlini<sup>1</sup>, E. O'Rourke<sup>2</sup>, M. Pastore<sup>3</sup>, A. Martin<sup>4</sup>.* 1) University of Ferrara, Ferrara, Ferrara, Italy; 2) Sarepta Therapeutics, Inc., Cambridge, MA; 3) Nationwide Children's Hospital, Columbus, OH; 4) Parent Project Muscular Dystrophy, Hackensack, NJ.

Introduction: Mutation-specific therapies for Duchenne muscular dystrophy (DMD) are in clinical trials worldwide. More than 60% of DMD patients have *DMD* gene mutations amenable to two current approaches: stop codon read-through and single exon skipping. Methods: We identified gaps in DMD genotyping and examined potential solutions for genetic counselors to help overcome barriers in determining patient eligibility for mutation-specific therapies. Results: Access to genetic testing is one barrier. A survey of 27 physicians who managed more than 2,000 DMD patients showed substantial variability in genotyped patients (~25%-100%). In Europe, multiplex ligation-dependent probe amplification is widely adopted, while availability of sequencing procedures is nonhomogenous, especially in Eastern countries. Awareness of financially viable genetic testing options is essential (eg, International DMD, University of Ferrara [Europe]; Decode Duchenne [USA, Canada]). Accurate, unequivocal mutation interpretation presents a second barrier. While nonsense mutations are amenable to stop codon read-through, other *DMD* deletion mutations vary in amenability to exon skipping, depending on the exons involved. To direct patients to appropriate therapy, clinicians must discern if a mutation is appropriate for exon skipping and amenable to a particular exon-skipping therapeutic. This pinpoints the importance of correct genotyping and genetic counselor involvement in mutation interpretation. Conclusions: Access to interpretation tools and guidance is paramount for genetic counselors to advise both patients and their providers. We will review the *DMD* gene exon map, Leiden DMD database, and Decode Duchenne mutation-specific resource as tools to help genetic counselors determine DMD patients' eligibility for exon skipping trials, with the goal of increasing the number of genotyped patients.

**571T**

**Return of genetic results: Social and cultural challenges in an African population.** G. Landouré<sup>1,2,3</sup>, S. Coulibaly<sup>2,4</sup>, H.A. Sango<sup>2</sup>, L. Cissé<sup>1</sup>, S.P. Coulibaly<sup>2,4</sup>, T. Coulibaly<sup>1,2</sup>, A. Bocoum<sup>1</sup>, M.E. Dembélé<sup>1</sup>, S. Diarra<sup>2</sup>, A. Maiga<sup>2</sup>, A. Taméga<sup>2</sup>, A. Yalcouyé<sup>2</sup>, S.H. Diallo<sup>2,5</sup>, S. Diallo<sup>5</sup>, K.G. Meilleur<sup>6</sup>, C.O. Guinto<sup>1,2</sup>, *The H3Africa Consortium.* 1) Service de Neurologie, CHU du Point G, Bamako, Mali; 2) Faculté de Médecine et d'Odontostomatologie, USTTB, Bamako, Mali; 3) Neurogenetics Branch, NINDS, NIH, Bethesda, MD; 4) Service de Psychiatrie, CHU du Point G, Bamako, Mali; 5) Service de Neurologie, CHU de Gabriel Touré, Bamako, Mali; 6) Neuromuscular Symptoms Unit, NINR, NIH, Bethesda, MD.

**Introduction:** Hereditary neurological disorders (HND) are incurable and debilitating. Low literacy in a population leads to stigmatization of patients and families with genetic disease. While genetic medicine has become standard practice in developed countries, Africa has been exposed to it more recently. One key element of genetic studies is returning results to patients, especially in diseases with strong evidence of causation. In Africa, family and community leaders have an important influence in the decision-making over others in all aspects of their lives. This may negatively impact research and clinical care, if not well managed. **Objective:** To gather difficulties encountered during genetic counseling in an African setting and to share this experience, with the ultimate goal of developing recommendations or guidelines for scientists working on populations of similar cultural backgrounds. **Methods:** Patients with HND and relatives went through a consent process. The goals of the study were stated with a special emphasis on the voluntariness of participation. They were informed that results could show incurable disease and were asked if they wanted to receive the results back. Genetic counseling sessions were recorded. **Results:** Findings from 44 families were available, and 27 were returned. Three patients and the father of a minor had emotional shock upon hearing the result and the implications. Only two patients, a retired teacher and a businessman, showed denial. While the first sought care with other physicians, the second just did not believe the genetic defect was the cause of his disease. In six cases, patients were minors and only one parent was present during genetic counseling. Three patients were mentally inapt adults and were accompanied by relatives other than living spouses. Feedback of findings with extended family members was done in three cases, upon requests by patients and a head of the family with no reluctance. Two heads of family have asked the return of results be postponed due to ongoing issues in the family. The remaining families were not reachable. **Conclusion:** Returning results is an important aspect of the medical practice, especially in genetic medicine where findings have implications for patients and family members. There is no optimal way to ensure standardized return of result process across populations. It is advisable to take into account cultural specificities without undermining the voluntariness and individual preferences.

**572F**

**Parental postzygotic de novo mutation causes different clinical manifestations of COL4A1-related disorder in one Chinese family.** J. Wang, X.D. Wang. CIPHER Gene, Beijing, China.

Mutations in COL4A1 inherited in an autosomal dominant manner cause a wide spectrum of disorders, including porencephaly, schizencephaly, small vessel disease, etc. The proportion of cases caused by a de novo pathogenic variant is estimated to be at least 27%. We studied one family in which the proband (a girl, 8 months old) had a clinical diagnosis of global development delay and microcephaly with brain MRI characteristics (bilateral forehead, top, occipital lobe hemorrhage, right lateral ventricle with old lesions), and her mother had seizures. A de novo pathogenic heterozygote variant in COL4A1 (c.2843G>A, p.Gly948Asp) in proband was initially identified by routine trio-whole exome sequencing (WES). MRI findings confirmed the COL4A1-related small vessel disease. However, the result could not explain mother's clinical symptom. Further investigation found that mother with seizures was a very low-frequency mosaic (Gly948Asp, 9.1%), which might be gonosomal mosaicism (a combination of germ-line and somatic mosaicism). Clinically, small-vessel brain disease manifests as infantile hemiparesis, seizures, single or recurrent hemorrhagic stroke, ischemic stroke, and isolated migraine with aura. Mother with low-ratio mosaic variant suffered from moderate clinical characteristics of seizures. Parental mosaicism of the mutation increases the risk of recurrence and should be fully considered during genetic counseling.

**573T**

**Epigenetic, serological and self-report examinations of adolescent substance use demonstrates that sex abuse results in the initiation and acceleration of smoking: Implications for public policy and clinical practice.** R.A. Philibert<sup>1</sup>, M. Gerrard<sup>2</sup>, K. Vercande<sup>1</sup>, E. Papworth<sup>1</sup>, R. Gibbons<sup>2</sup>, M. Fleischli<sup>2</sup>, A. Becker<sup>3</sup>, C. Wadler<sup>1</sup>, S. McElroy<sup>1</sup>, W. Philibert<sup>1</sup>, M. Grieve<sup>1</sup>, H. El Manaway<sup>1</sup>, K. Dawes<sup>1</sup>, N. Beyer<sup>1</sup>, A. Todorov<sup>2</sup>, J. Long<sup>1</sup>, J. Mills<sup>1</sup>, S. Kuperman<sup>1</sup>, A. Andersen<sup>1</sup>. 1) University of Iowa, Iowa City, IA; 2) University of Connecticut, Storrs, CT; 3) Washington University of St. Louis, St. Louis, MO.

There is a strong relationship between a history of childhood sexual abuse and the subsequent presence of depression and substance use in young adults. However, questions exist about the primacy of the relation of sexual abuse to the onset of drug use and depression. Specifically, “does substance use initiation precede or follow abuse?” This is an important question because it affects how clinicians and policy makers approach substance use prevention and how clinicians approach the treatment of victims of sexual abuse. In part, this uncertainty about the primacy of these two disorders is secondary to the lack of informative longitudinal cohorts with objective measures of substance use and depression contemporaneous with the timing of the abuse. In this longitudinal study of 448 high school sophomores, we analyse the relationship between self-report of unwanted sexual contact (USC), depression, and substance consumption using self-reported, serologic, and newly developed DNA methylation assays of smoking and marijuana use. We show that USC is both common (9%) and is strongly associated with current depressive symptoms and self-reported initiation of smoking, drinking, and cannabis use. USC is also moderately associated with serological measures of cannabis use, and strongly associated with quantitative epigenetic assessments of smoking. Finally, consistent with the consumption measures, we demonstrate that students disclosing USC also report strong willingness to smoke cigarettes and use marijuana, and have favourable images of smokers and marijuana users, all strong predictors of future cigarette and cannabis use during adolescence. But they do not report differential inclination to consume alcohol, nor perceive those peers who consume alcohol favourably. We conclude that USC among American high school students is frequent, and is strongly associated with early initiation of cigarette and marijuana use that appears to result as a consequence of sexual abuse. We further conclude that: 1) detection of smoking or predisposition to smoke in adolescents by objective or subjective means could be an indicator of prior sexual abuse and 2) that victims of sexual abuse should be prioritized for substance use prevention and treatment interventions.

**574F**

**Psychiatric pharmacogenomics: Panacea or predicament?** E. Huang<sup>1,2</sup>, J.K. Wagner<sup>2</sup>, R. Pulk<sup>2</sup>. 1) Lafayette College, Easton, PA; 2) Geisinger, Danville, PA.

**Introduction:** Pharmacogenomics (PGx), which involves the utilization of one’s genotype to predict drug response, is an attractive panacea for the field of psychiatry, in which most medications used to treat mental illness are ineffective or have low adherence rates due to adverse side-effects. However, psychiatric PGx testing is controversial, in part because the mechanisms through which genetic factors influence treatment response are not well-understood. Examining tests marketed by private PGx testing companies can provide valuable insights on public perceptions and expectations of psychiatric PGx. **Methods:** Relying on online information from corporate websites, the psychiatric gene and/or medications panels offered by six pharmacogenomic companies were examined. Advertising strategy used (i.e., targeting clinicians, jointly targeting patients and clinicians, and targeting consumers) was noted. For each gene on all publicly available psychiatric gene panels, PharmGKB clinical annotations on variants associated with psychiatric drugs were reviewed. The psychiatric drugs for which each of these genes had clinical annotations were recorded and compared against each company’s stated panel of medications used to make their drug recommendations. Each company’s panel of medications was also compared against the list of psychiatric drugs with FDA labels that include pharmacogenomic information. **Results:** Less than half of medications for which these pharmacogenomic companies provide recommendations have the potential to be strongly influenced by the genetic information collected. Over a third of the drugs on each of the medications panels published online did not overlap with the list of psychiatric drugs with FDA labels that include pharmacogenomic information. **Conclusion:** Our findings underscore concerns that current pharmacogenomic screening panels are not yet adequately substantiated. Future research on how patient-consumers and clinicians are interpreting test reports can help inform the design of effective educational tools for dispelling confusion generated by test results. Health systems’ offering of PGx screening (coverage with evidence development) for all patients might help set a “gold standard” for how these tests ought to be handled and interpreted. If precision health is the goal, mental health parity must be part of the approach. We must work together to ensure that the field of psychiatry shares in the advances of pharmacogenomics.

**575T**

**Utilization and impact of a psychiatric pharmacogenetic panel in the Department of Veterans Affairs.** L.E. Hull<sup>1</sup>, S. Tuteja<sup>2</sup>, C. Chanfreau-Coffinier<sup>3</sup>, O. Efimova<sup>3</sup>, G. Coronado<sup>3</sup>, D.W. Oslin<sup>2,4</sup>, S.L. DuVall<sup>2</sup>, J.A. Lynch<sup>2</sup>. 1) VA Boston Healthcare System, Boston, MA; 2) University of Pennsylvania, Philadelphia, PA; 3) VA Salt Lake City, Salt Lake City, UT; 4) Philadelphia VA Medical Center, Philadelphia, PA.

**Background:** In 2014, the Department of Veterans Affairs (VA) and, subsequently, Medicare started covering the GeneSight<sup>®</sup> Psychotropic Panel (Assurex Health, Mason, OH), a pharmacogenetic (PGx) panel used to guide psychotropic medication selection. This test assesses potential gene-drug interactions for up to 55 medications and categorizes these medications in color bins: Green ("Use as Directed"), Yellow ("Moderate Gene-Drug Interaction"), or Red ("Significant Gene-Drug Interaction"). In 2017, the VA initiated the Precision Medicine in Mental Health Care (PRIME) study to assess the utility of pharmacogenetics in mental health treatment. This analysis summarizes test use outside of the prospective study. **Objectives:** 1. Identify patient and provider characteristics associated with test orders 2. Describe the impact of the PGx panel on providers' prescribing behaviors **Material and Methods:** Using the VA's electronic health record and patient-level laboratory test data, we conducted a retrospective cohort study. We described demographic and clinical characteristics of patients tested. We assessed whether providers who ordered tests made a medication change based on the results. We analyzed how the PGx panel reported specific genetic variants and potential for adverse reactions. **Results:** There were 221 Veterans tested between 10/6/14 and 2/1/2018. We excluded 40 Veterans from analyses due to inadequate data. Our final study population included 181 Veterans with a mean age of 45.9 years. They were: 84% male, 75% White, and had a mean of 2 mental health diagnoses and 2 psychotropic medication prescriptions at baseline. The majority of providers (25/38) ordered the panel once. After testing, there was a net increase in the number of prescriptions that were classified in the patient's Green bin (+37) and a net decrease in the number of medications prescribed that were classified as Yellow (-25) or Red (-15). Desvenlafaxine was always in the Green bin and was associated with the largest increase in prescriptions (+14). The test report contained data about several genetic variants, although the implications of this information were not always clearly stated. **Conclusions:** A handful of early-adopter VA providers have used this panel to guide prescribing decisions. We are assessing whether this test has resulted in improvements in patient centered outcomes. The reports contain information about several genetic variants that could inform other aspects of care and should be studied.

**576F**

**What do the mothers of patients with ATR-X syndrome consider their carrier risk?** Y. Sato<sup>1</sup>, T. Wada<sup>1</sup>, M. Matsukawa<sup>1</sup>, S. Honda<sup>1</sup>, M. Torisima<sup>2</sup>, S. Kosugi<sup>1</sup>. 1) Medical Ethics and Medical Genetics, Kyoto University Graduate School, Kyoto, Japan; 2) Clinical Genetics Unit, Kyoto University Hospital.

[Background and Objective] Among hereditary diseases, X-linked diseases develop in males, whereas their mothers and female siblings are healthy, but can be carriers. For this reason, it is suggested that X-linked diseases place a greater psychological burden than other genetic disorders. However, studies on the psychological, cultural, and social problems of female carriers of X-linked diseases are rarely performed in Japan. This study aimed to explore the psychological, cultural, and social backgrounds of mothers who carry X-linked diseases. [Method] This was an exploratory qualitative study based on a self-administered questionnaire. We asked the mothers of patients with alpha thalassemia X-linked intellectual disability (ATR-X) syndrome to complete a questionnaire in cooperation with ATR-X syndrome Network Japan between November and December 2017. The frequency distributions of the responses to multiple-choice questions were examined. In addition, free description responses were sectioned by meaning, and then inductive content analysis and theoretical generation were performed. [Results] Of the 25 patients who responded, 16 had daughters. Among them, 5 had been confirmed to be carriers by carrier testing. Regarding the diagnosis itself, most of the respondents had recovered from the uneasiness they felt before the diagnosis was made and were able to understand their children's disease. In addition, it became possible for the subjects to connect with families with the same disorder and increase their sense of security and vision. On the other hand, some subjects experienced anxiety/dissatisfaction with the fact that the disease is rare and anxiety/guilt due to it being hereditary. As for carrier risks, when the subjects learned about them many felt guilty and became worried/uneasy about their daughters' carrier risk. Moreover, some respondents became reluctant about future pregnancies. Some subjects stated, "I hated my parents". However, there were also respondents who said that, "I did not think anything". [Conclusion] This an exploratory qualitative study focused the mothers of patients with ATR-X syndrome. Many respondents found that obtaining a diagnosis allowed them to plan for the future with their children. On the other hand, the respondents learned that their children had a rare disease and genetic disorder, which caused them various psychological consequences. .

**DMD Open-access Variant Explorer (DOVE): A scalable, open-access, web-based tool to aid in clinical interpretation of genetic variants in the DMD gene.** M. Bailey, N. Miller. BioMarin Pharmaceutical Inc., Novato, CA.

**Purpose:** Duchenne muscular dystrophy (Duchenne) is caused by pathogenic variants in the *DMD* gene. Antisense oligonucleotides (AONs) are one emerging precision-medicine treatment for Duchenne. *DMD* molecular genetic testing results guide precision-therapy molecular eligibility, requiring health-care providers to perform analyses currently uncommon in clinical laboratory and medical practices. Clear *DMD* variant notation and interpretation are key components of clinical care with the availability of precision medicine. **Methods:** The *DMD* Open-access Variant Explorer (DOVE) is a web-based aid for *DMD* variant interpretation which additionally reports variant-specific predicted molecular eligibility for therapy. DOVE was developed in Python and adapted to the Django framework, integrates existing open-access tools, and operates independently from any previous variant report/classification. **Results:** DOVE ([www.dnd.nl/DOVE](http://www.dnd.nl/DOVE)) interprets colloquial and HGMD inputs of *DMD* variants to output HGMD variant nomenclature, theoretical molecular eligibility for therapy, and any predicted deleterious molecular consequences of therapy. DOVE relies on holistic *in silico* prediction of molecular eligibility for therapy in lieu of reference to an empirically-defined, "variant-eligible" list. Examples illustrate the advantage and necessity for holistic variant interpretation. **Conclusions:** DOVE may prove useful for variant interpretation both at patient-level and in large-scale programs such as newborn screening and has broad application in concept to molecular genetic test result interpretation.

**578F**

**Regulation of mitochondrial replacement therapy: A literature review analysis of where Canada, the US, the UK, and Mexico stand.** F. Noohi<sup>1,2</sup>, A. Caulfield<sup>2</sup>, Y. Joly<sup>1,2</sup>. 1) Department of Human Genetics, McGill University, Montreal, Quebec, Canada; 2) Centre of Genomics and Policy, Montreal, Quebec, Canada.

Mitochondrial Replacement Therapy (MRT) is a new type of *in vitro* fertilization that aims to prevent the transmission of mitochondrial diseases (matrilineal transmission) by replacing mutated mitochondrial DNA in unfertilized oocytes or zygotes with normal mitochondria from a healthy donor. Since as a result of MRT, permanent changes are made to the germline that would be transmitted through generations, this controversially so-called "three-parent IVF" can be considered as a means of genetic modification. Besides the UK, which became the first country to approve MRT in 2015, only a few countries have addressed this controversial technique through public policy. Whether MRT should be considered genetic modification has been the center of controversy in debating the legitimacy of MRT among relevant stakeholders. In order to explore how the interdependence of ethics, policy, and public views can address questions that arise from new reproductive technologies and analyze the influence of socio-cultural factors upon stakeholders' motives for using MRT, we conducted a systematic literature review of relevant academic sources which characterized the socio-ethical issues and scientific advancements of MRT according to Oxford's Bodleian Libraries review guidelines. Next, we reviewed and assessed pertinent legislation, policies, and ethical guidelines, in both the research and clinical contexts, in Canada, the US, the UK, and Mexico whose approaches in governing the controversial technique ranged from strict bans with serious consequences to an absence of policy. The major themes identified in our review included, concerns over safety and efficacy, slippery slope of germline modification, issues of identity, risk for future generations, equity of access, available resources, and beneficence. Next, the interdisciplinary knowledge produced as a result of this research will be used to analyze perceptions and expectations of relevant stakeholders (clinicians, policymakers, couples with affected children, at risk couples who wish to have biological children, and egg donors—potential so-called third parents—with regard to MRT in the aforementioned countries.

**579T**

**Genetic counseling for 397 deaf-mute couples directed by genetic testing.** *M. Han, P. Dai.* Department of Otolaryngology-Head and Neck Surgery, Chinese PLA General Hospital, Beijing, 100853, China.

**Objective:** To analyze the molecular pathogenesis of deaf-mute couples by genetic testing and provide genetic counseling with different etiology based upon results of genetic testing. **Methods:** 397 deaf-mute couples joined in this study from 2005 to 2017. Each subject is with moderate to profound hearing loss. Genomic and mitochondrial DNA of each subject was extracted from whole blood. Genetic testing including *GJB2*, *SLC26A4* and *mtDNA 12S rRNA* was offered to each subject. And then the genetic counseling was followed. **Results:** There were 119 deaf couples (30.0%, 119/397) with high recurrence risk from 25% to 100%. It is 100% in 88 deaf couples, as each pair were caused by the same deaf genes (*GJB2* or *SLC26A4*); 18 couples had already had deaf offsprings before taking genetic testing; 2 couple got pregnant by means of artificial insemination with the sperm from the local Human Sperm Bank and had normal hearing babes confirmed by prenatal diagnosis; 2 couples got pregnancy and gave deaf babies to birth who were taken cochlear implantation and received the satisfied rehabilitation result. In 26 deaf couples, the recurrence risk is 50%: 20 of them were the one caused by homozygous/compound *SLC26A4* or *GJB2* mutations and the other with a single *SLC26A4* or *GJB2* mutation; 4 of them were the one diagnosed with Warrdenburg's syndrom; 2 of them were the one carried a single *GJB2* mutation which is dominant inheritance. The recurrence risk of 5 couples was 25%: 3 of them were both *SLC26A4* carriers and the other 2 were both *GJB2* carriers. 8 of these 31 couples had normal hearing babies assisted by prenatal diagnosis. In 3 couples, the wives were *mtDNA* A1555G mutation carriers; the instruction for them is that their offsprings must strictly avoid the administration of amino glycoside antibiotics. The rest of 278 couples (70.0%, 278/397) were with low recurrence risk ( $1\sim 3\%$ ). 54 couples were caused by different genes; 144 couples were the one with hereditary deafness but the other one with the unknown cause; and 80 couples all had unknown cause. 67 of 278 deaf couples had normal hearing babies; 2 couples got the deaf offsprings and then 1 of them was confirmed to be compound *MYO7A* mutations by NGS. **Conclusion:** There is a high recurrence risk if a deaf-mute family. Genetic testing plays an important predicting role in genetic counseling for deaf-mute couples. **Key words:** Deafness; Genetic diseases; Genetic testing; Genes; Genetic counseling; Diagnosis.

**580F**

**Clinical and epidemiological description of congenital anomalies associated with visual and auditory deficit in Bogotá Colombia from 2001 to 2016.** *K. Sarmiento<sup>1</sup>, A. Ibáñez-Morantes<sup>2</sup>, F. Suárez-Obando<sup>2</sup>, J. Ángel<sup>2</sup>, P. Ayala-Ramírez<sup>2</sup>, N. Gelvez<sup>2</sup>, G. López<sup>2</sup>, J.C. Prieto<sup>2</sup>, C. Rodríguez<sup>2</sup>, M.L. Tamayo<sup>2</sup>, N. Tamayo<sup>2</sup>, I. Zarante<sup>2</sup>.* 1) Departamento ciencias fisiológicas, Facultad de Medicina. Pontificia Universidad Javeriana, Bogotá, Colombia; 2) Instituto de Genética Humana. Facultad de Medicina. Pontificia Universidad Javeriana, Bogotá, Colombia; 3) Secretaria de Salud Distrital. Bogotá, Colombia.

**Introduction:** Worldwide, it is estimated that 32.4 million people are blind and approximately 360 million suffer from hearing loss. The congenital anomalies that are associated with deafness and blindness affect globally the health of patients. In Colombia, the Institute of Human Genetics at the Pontificia Universidad Javeriana, with the support of the Colombian Administrative Department of Science, Technology and Innovation (Colciencias -contract 44842-656-2015 / 724-2015), develops the program ALVA (Comprehensive Care for Families with Orphan Diseases with Visual and Hearing Anomalies) that focuses on the study of these anomalies. **Objective:** To describe the epidemiology of congenital visual and hearing anomalies in the city of Bogotá between 2001 and 2016. **Methodology:** A retrospective analysis was carried out based on the ECLAMC design (Estudio Colaborativo Latinoamericano de Malformaciones Congénitas) of cases and controls (case-control ratio of 2: 1). The information was acquired from the Congenital Anomalies Surveillance and Monitoring Program of Bogotá. Newborns with auditory and/or visual abnormalities were selected and classified according to their clinical presentation in 6 groups: exclusively Audiological, exclusively visual, multiple birth defects (nonsyndromic), syndromic, teratogenic effect and mixed clinical presentation of audiological and visual compromise. **Results:** 2,541 newborns presented congenital visual and audiological anomalies detectable at birth, of which 52% were male. A prevalence rate was calculated according to each group: exclusively audiological 3.33/ 10,000; exclusively visual 0.06/10,000; multiple birth defects 3.73/ 10,000; syndromic 5.42/10,000; teratogenic 0.27/10,000 and mixed audiological and visual compromise 0.21/10,000. In comparison to the control group, significant differences were found associated with risk factors as a lower newborn's weight for all the groups of anomalies ( $p < 0,005$ ). The gestational age was significantly lower in the groups of audiological, multiple birth defects, syndromic and teratogenic ( $p < 0,005$ ). The maternal age was significantly higher in the mothers of the newborns with audiological, multiple birth defects and syndromic anomalies ( $p < 0,005$ ). **Conclusions:** Congenital auditory and visual abnormalities have a high prevalence and generate disability in Colombia. Better medical intervention in primary and tertiary prevention is required to reduce disability and improvement of rehabilitation.

**581T**

**Psychosocial impacts of Mendelian eye conditions: A systematic literature review.** C.S. DAmanda, L.A. Huryn, A.E. Turriff. National Institutes of Health/National Eye Institute, Bethesda, MD.

**Purpose:** To review systematically psychological and social impacts of living with a Mendelian eye condition on affected individuals and their family members. To improve understanding of the needs of these patients and their family members to improve clinical care and identify research gaps. **Methods:** A systematic review of material published through March 2018 was conducted using CINAHL, Embase, PsychInfo, PubMed, Scopus, and Web of Science to include peer-reviewed, original research reporting psychological and social impacts of Mendelian eye conditions on affected individuals and/or their family members. Two researchers screened studies for eligibility and recorded details of eligible studies in a data extraction table. Identified psychosocial impacts were iteratively coded using a thematic style analysis. **Results:** Of the 7120 studies identified in our search, 89 were eligible for inclusion. Retinitis Pigmentosa (n=26, 29%), Retinoblastoma (n=21, 24%), and Albinism (n=16, 18%) were the most frequent diagnoses evaluated. Most studies were quantitative (n=66, 74%) and had a cross-sectional design (n=78, 88%). While studies were conducted across 7 global geographic regions, the majority occurred in the European Union (n=33, 37%) and North America (n=21, 24%). Included studies were found to address impacts along 9 themes: mental health (n=44, 49%), relationships (n=37, 42%), quality of life (n=22, 25%), societal contributions (n=22, 25%), independence (n=16, 18%), coping (n=14, 16%), identity (n=14, 16%), stigma (n=14, 16%), and disclosure (n=7, 8%). There is evidence for higher rates of depression and anxiety, and lower quality of life across conditions and geographic regions. **Conclusions:** There is evidence suggesting Mendelian eye conditions negatively impact several domains of life, for both affected individuals and their family members. Future research should continue to explore understudied conditions and employ more rigorous study design. This research knowledge may be incorporated into intervention studies aimed at improving well-being in this population, patient management, clinical trials, and development of patient-centered outcomes.

**Are we ready for rapid genomic testing in acute paediatric care?**

**Attitudes of Australian health professionals.** Z. Stark<sup>1,2,3</sup>, A. Nisselle<sup>1,2,3</sup>, B. McClaren<sup>1,2,3</sup>, F. Lynch<sup>1,2,3</sup>, S. Best<sup>4</sup>, J.C. Long<sup>4</sup>, M. Martyn<sup>2,5</sup>, C. Patel<sup>6</sup>, L.J. Schlapbach<sup>7,8,9,10</sup>, C. Barnett<sup>11</sup>, C. Theda<sup>2,3,12</sup>, J. Pinner<sup>13</sup>, M.E. Dinger<sup>14,15,16</sup>, S. Lunke<sup>2,3</sup>, C.L. Gaff<sup>2,5,17</sup>. 1) Australian Genomics Health Alliance, Melbourne, VIC, Australia; 2) University of Melbourne, Melbourne, Australia; 3) Murdoch Children's Research Institute, Melbourne, Australia; 4) Australian Institute of Health Innovation, Macquarie University, Sydney, Australia; 5) Melbourne Genomics Health Alliance, Melbourne, Australia; 6) Genetic Health Queensland, Royal Brisbane and Women's Hospital, Brisbane, Australia; 7) Paediatric Critical Care Research Group, Mater Research Institute, The University of Queensland, Brisbane, Australia; 8) Paediatric Intensive Care Unit, Lady Client Children's Hospital, Brisbane, Australia; 9) Faculty of Medicine, The University of Queensland, Brisbane, Australia; 10) Department of Paediatrics, Bern University Hospital, Inselspital, University of Bern, Bern, Switzerland; 11) Paediatric and Reproductive Genetics Unit, Women and Children's Hospital, Adelaide, Australia; 12) Neonatal Services, Royal Women's Hospital, Melbourne, Australia; 13) Sydney Children's Hospital, Sydney, Australia; 14) Graven Institute of Medical Research, Sydney, Australia; 15) Genome.One, Sydney, Australia; 16) St. Vincent's Clinical School, University of New South Wales, Sydney, Australia; 17) Walter and Eliza Hall Institute, Melbourne, Australia.

**Aim** To investigate the attitudes of healthcare professionals towards the application of genomic testing in neonatal and paediatric intensive care units (NICU/PICU). **Methods** Before initiating a multi-centre implementation study of rapid genomic testing, we surveyed 289 participating intensive care physicians and genetics professionals, including clinical geneticists, genetic counsellors, and laboratory genomic scientists about perceived usefulness of results, preferences for service delivery models, and implementation readiness. We examined the confidence of intensivists with microarray and genomic testing, and conducted semi-structured interviews. **Results** The overall response rate was 58%, 46% for intensivists (79/170) and 76% (90/119) for genetics professionals. Intensivists reported moderate confidence with using microarray tests and lower confidence with genomic tests. The majority of intensivists (76%), clinical geneticists (87%) and genetic counsellors (81%) favoured a clinical genetics-led service delivery model of genomic testing in the NICU/PICU. Perceived utility of genomic results was lower in the intensivist group compared to the genetics professionals group (20% v 50%, p<0.001). While support for implementation was high, the main concerns expressed by genetics professionals related to implementation climate and organizational readiness. **Conclusion** Successful large-scale implementation of genomic testing in NICU/PICU will require the development of interdisciplinary service delivery models that support adoption of genomics by the intensive care workforce while ensuring safety, sustainability and efficiency.

**583T**

**Evaluation of the clinical utility of proactive genetic screening for medically actionable conditions.** *J. Oldziej, P. Aghajanian, Y. Niu, C. Neckelmann, H. Gao, S. Strom.* Fulgent Genetics, Temple City, CA.

With the introduction of the Precision Medicine Initiative in 2015, preventive medicine is becoming more commonplace within today's healthcare system. Consumers have an increased awareness of the importance of personalized health management and are taking a more proactive approach in their own individual disease prevention, diagnosis, and treatment plans, specifically within the field of Consumer Genomics. Fulgent Genetics' ACMG Secondary Findings Next Generation Sequencing (NGS) panel analyzes 59 genes outlined by the American College of Medical Genetics ("ACMG SF v2.0"). This physician-ordered test is designed to provide anyone the ability to test for genetic predispositions for common health concerns, including cancer- and cardiac-related issues. A total of 849 self-referred patients completed Fulgent's ACMG Secondary Findings NGS panel testing over the course of 5 months' time (November 2017-May 2018). Only findings determined to be clinically significant and actionable by the laboratory's clinical team were reported. Neither "Variants of Unknown Significance" nor single heterozygous variants in the recessive genes were reported. Of the total patients tested, 31 individuals (or 3.65%) had a clinically significant finding. The total number of patients with a cancer related finding was 11 (or 1.30%) and the total number of patients with a cardiac related finding was 20 (or 2.35%). There were no individuals identified as carrying any non-cancer or non-cardiac related finding within these 59 genes. No individuals tested were found to carry more than 1 variant. This study supports and justifies the utilization of population-wide genetic screening of these well-studied 59 genes. The Consumer Genomics, proactive approach to medicine will empower individuals in the prevention of their predisposition to develop certain common genetic diseases and will ultimately save healthcare time and money, as well as improve and elongate lives. We believe laboratories carry the responsibility of ensuring clear communication of the capabilities and limitations of this type of testing, as well as the meaning of results both positive and negative.

**Harmonizing outcomes for genomic medicine: Comparison of eMERGE outcomes to ClinGen outcome/intervention pairs.** *M.S. Williams<sup>1</sup>, W.K. Chung<sup>2</sup>, A. Fedotov<sup>3</sup>, K. Kiryluk<sup>4</sup>, C. Weng<sup>5</sup>, J.J. Connolly<sup>6</sup>, M. Harr<sup>7</sup>, H. Hakonarson<sup>8,9</sup>, K.A. Leppig<sup>8</sup>, E.B. Larson<sup>8</sup>, G.P. Jarvik<sup>10</sup>, D.L. Veenstra<sup>11</sup>, C. Hoell<sup>12</sup>, M.E. Smith<sup>12</sup>, I.A. Holm<sup>13</sup>, J.F. Peterson<sup>14</sup>, J.L. Williams<sup>1</sup>.* 1) Genomic Medicine Institute, Geisinger, Danville, PA; 2) Columbia University, Departments of Pediatrics and Medicine, New York, NY, USA; 3) Irving Institute for Clinical and Translational Research, Columbia University, New York, NY; 4) Department of Medicine, Division of Nephrology, Columbia University, New York, NY; 5) Department of Biomedical Informatics, Columbia University, New York, NY; 6) Children's Hospital of Philadelphia, Philadelphia, PA; 7) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 8) Genetic Services, Kaiser Permanente of Washington, Seattle, WA USA; 9) Kaiser Permanente Washington Health Research Institute, Seattle, WA, USA; 10) University of Washington, Departments of Medicine (Medical Genetics) and Genome Sciences, Seattle, WA, USA; 11) University of Washington, Department Pharmacy, Seattle, WA,; 12) Northwestern University, Center for Genetic Medicine, Chicago IL USA; 13) Division of Genetics and Genomics, Boston Children's Hospital, and Department of Pediatrics, Harvard Medical School, Boston MA USA; 14) Vanderbilt University Nashville TN USA.

**Introduction:** As genomic medicine moves from research to the clinic, evidence of the impact of genomic medicine interventions on health outcomes is needed. Standardized outcome measures to evaluate the impact of interventions targeted to specific genetic conditions are lacking. **Methods:** The electronic Medical Records and Genomics (eMERGE) Outcomes working group (OWG) developed measures to collect information on outcomes following the return of genomic results to participants for several genetic disorders. These outcomes were compared to outcome intervention pairs for the same genetic disorders developed independently by the Clinical Genome Resource's (ClinGen) Actionability working group (AWG). **Results:** A total of 12 disorders were scored. Three disorders were included in eMERGE, but were not scored by ClinGen, as they didn't fit the AWG criteria. In general, there was concordance between the defined outcomes of the two groups. The ClinGen outcomes tended to be higher level and the AWG scored outcomes represented a subset of outcomes referenced in the accompanying AWG evidence review. eMERGE OWG outcomes were more detailed and discrete, facilitating collection of relevant information from electronic health records. Five gene-disorder pairs had equivalent definitions between the OWG and AWG facilitating comparison of outcomes. Only two of the outcome intervention pairs scored by AWG were not present in the eMERGE outcomes. Both represented health outcomes rather than process or intermediate outcomes. eMERGE did not include many health outcomes due to the short follow-up time for participants. The remaining four had differences in the gene-disorder pair definitions that impacted the comparison. The eMERGE OWG grouped disorders into broader categories compared to the AWG. This illustrates the tension between pragmatic decisions to reduce the burden to collect outcomes of interest, at the expense of capturing outcomes that are specific to individual disorders lumped within these overarching categories. **Conclusion:** This project demonstrates that common outcomes for genomic medicine interventions can be identified. Some key differences in the definition of the disorders could inform approaches to collect relevant outcomes. Further work is needed to standardize outcomes across genomic medicine implementation projects and make these publicly available to enhance dissemination and assist in evaluating the impact of precision public health.

**The life of a “poor metabolizer” — through the eyes of medical genetics summaries.** *L.C. Dean, A.J. Malheiro, B.L. Kattman.* Medical Genetics and Human Variation, National Center for Biotechnology Information, Bethesda, MD.

An individual who is a poor metabolizer does not have adequate enzyme capacity to metabolize drug(s). Potential consequences include potentially severe adverse effects or toxicity (for active metabolites that are inactivated by the enzyme) or decreased or absent therapeutic effects (for pro-drugs that are pharmacologically activated by the enzyme). The enzyme CYP2D6 contributes to the metabolism of over a quarter of drugs prescribed in the USA today, including antidepressants, antiseizure drugs, antiarrhythmics, and more. Individuals who are carriers of two non-functional *CYP2D6* alleles have little or no enzyme activity and are defined as “CYP2D6 poor metabolizers”. Up to 10% of the US population fall in this category. NIH’s Medical Genetics Summaries (MGS, [www.ncbi.nlm.nih.gov/books/NBK61999](http://www.ncbi.nlm.nih.gov/books/NBK61999)) provides practical information about genetic testing to guide drug therapy including translating alleles into functional consequence and describing therapeutic recommendations based on genotype — so that therapy can be optimized for each individual. Developed as one of NCBI’s precision medicine resources, each MGS article focuses on one drug, and the gene(s) that influences the drug metabolism and response. MGS (1) synthesizes pharmacogenomic information from authoritative sources, such as FDA, and practice guidelines from medical and professional societies; (2) describes how to interpret alleles to help clinicians understand a lab report; (3) links to the relevant orderable genetic tests at NIH’s Genetic Testing Registry (GTR), and (4) presents dosing recommendations based on genotype from authoritative sources. The majority of individuals who are CYP2D6 poor metabolizers are unaware until they are prescribed a drug that requires this metabolic pathway. Some drugs may be metabolized by an alternative pathway in which case this phenotype may have little or no consequence. However, for a growing number of drugs, CYP2D6 poor metabolizers will respond differently than a normal metabolizer. For example, they may get little or no pain relief from codeine or tramadol, have an increased risk of relapse of breast cancer if taking tamoxifen; and be more likely to experience side effects if taking a tricyclic antidepressant. This presentation will demonstrate how to use MGS in clinic to help ensure that appropriate genetic testing is considered and lab reports are interpreted correctly to optimize initial dosing and therapeutic management for each individual based on genotype.

**586F**

**Clinical application of targeted whole exome sequencing (WES) at the Geneva University Hospital: An update.** *E.B Hammar<sup>1</sup>, S. Fokstuen<sup>1</sup>, M. Guipponi<sup>1,2</sup>, E. Ranza<sup>1</sup>, A. Paoloni-Giacobino<sup>1</sup>, K. Varvagiannis<sup>1</sup>, L. D’Amato-Sizonenko<sup>1</sup>, P. Makrythanasis<sup>2,4</sup>, L. Quteineh<sup>1</sup>, M.T. Carminho Amaro<sup>1</sup>, M. Lidgren<sup>1</sup>, F. Sloan-Béna<sup>1</sup>, S. Gimelli<sup>1</sup>, F.A. Santoni<sup>1,2</sup>, S. Laurent<sup>1</sup>, C. Gehrig<sup>1</sup>, A. Vannier<sup>1</sup>, T. Nospikel<sup>1</sup>, J.-L. Blouin<sup>1</sup>, M. Abramowicz<sup>1,2</sup>, S.E. Antonarakis<sup>2,3</sup>.* 1) Service of Genetic Medicine, University Hospitals of Geneva, Switzerland; 2) Department of Genetics and Development, University Medical Center (CMU), Geneva, Switzerland; 3) iGE3 Institute of Genetics and Genomics of Geneva, Geneva, Switzerland; 4) Biomedical Research Foundation of the Academy of Athens, Athens, Greece.

In 2012, we introduced in Geneva whole exome sequencing (WES) followed by targeted bioinformatics analysis of individual in silico gene panels for the diagnosis of Mendelian disorders and we have created a multidisciplinary working group, the Genome Clinic Task Force which meets once a week. During these meetings, clinical cases and molecular results are presented, the class of variant pathogenicity is debated and the final laboratory reports are critically discussed. Financial access to the analyses and ethical issues such as informed consent, disclosure of incidental findings and/or of VUS are also addressed. In Switzerland, reimbursement of diagnostic NGS tests is integrated in the public health insurance since January 2015, and our NGS approach was accredited by the governmental Swiss Accreditation Service (SAS) in early 2018. A cornucopia of diseases have been analyzed to date, including developmental delay, epilepsies, cardiac and renal diseases, sensory disabilities, and various genetic syndromes. To date, a total of 765 cases (235 with developmental delay (DD) and 530 with various other mendelian diseases (VDM)) have been analyzed. We found pathogenic variants (class 4 or 5) in 29% of patients with DD and in 32% with VDM; the average detection rate of (likely) causative variants was 31%. The decision to report VUS was made on an individual case basis. We regularly update our panels and invite colleagues from other specialties to discuss the results of their patients at our Genome Task Force. Our main aims are to 1) further develop the Task Force into an open access Genome board for the various medical specialties interested in genomics 2) implement reimbursement also for trio analysis especially for DD cases 3) introduce whole genome sequencing for specific cases 4) participate in a national platform for annotating local variants, in order to boost the development of personalized health care in Switzerland. .

**A novel web-based application for searching pharmacogenetic information for migalastat amenability in Fabry disease.** X. Wu<sup>1</sup>, J. Masanoff<sup>1</sup>, M. Mustafa<sup>1</sup>, M. Lyles<sup>1</sup>, V. Kessler<sup>1</sup>, B. Stockham<sup>2</sup>, B. Zipkin<sup>3</sup>. 1) Amicus Therapeutics, Inc., Cranbury, NJ; 2) Amicus Therapeutics UK Ltd, Buckinghamshire, UK; 3) Pharma Forward LLC, Madison, WI.

Fabry disease is a rare, X-linked disorder of  $\alpha$ -galactosidase A ( $\alpha$ -Gal A) deficiency caused by mutations in the gene encoding  $\alpha$ -Gal A (*GLA*). Migalastat, an oral pharmacological chaperone, was designed to treat Fabry disease by binding to and stabilizing specific mutant forms of  $\alpha$ -Gal A, the genotypes of which are referred to as *amenable* mutations. The amenability status of >1000 Fabry disease-associated *GLA* mutations has been determined using prespecified qualification rules and results from a good laboratory practice-validated in vitro assay. Given the large number of *GLA* mutations, it is challenging to verify that a mutation is amenable using conventional product labelling or other print materials. We developed a dynamic, web-based search tool ([galafoldamenabilitytable.com](http://galafoldamenabilitytable.com)) in collaboration with regulatory agencies to help healthcare professionals quickly and accurately determine the amenability of a specific mutation. The country/region-specific website (initially available in Canada, the European Union [EU], Japan, and South Korea) uses a mutation database that contains the amenable/nonamenable mutations approved in that country/region. The application classifies a queried mutation based on whether the search term matches an amenable mutation in the database ("amenable"), matches a nonamenable mutation in the database ("nonamenable"), does not match any mutation in the database ("not tested"), or does not conform to standard genetic mutation nomenclature ("not recognized"). A mutation confirmed as "not tested" may be submitted for amenability testing and the result added to the database. The easy-to-use interface is compatible with all web browsers and devices and displays in 27 languages. Between June 2016 and March 2018, the EU database was visited 4973 times by users from 28 countries, who submitted 6583 mutation searches. [Galafoldamenabilitytable.com](http://Galafoldamenabilitytable.com) is the first website hosting comprehensive pharmacogenetic information for a precision medicine and could serve as a product-labeling model for other precision medicines involving diverse genetic backgrounds.

**Growing the genetic counselor workforce: A successful local effort.**

C.A. Campbell<sup>1,2</sup>, T.K. Grider<sup>3</sup>, S. Feely<sup>2</sup>, K. Shipley<sup>4</sup>, K. Schaa<sup>5</sup>, J. Robillard<sup>6</sup>, S. Singh<sup>7</sup>. 1) Iowa Institute of Human Genetics, University of Iowa, Iowa City, IA; 2) University of Iowa, Department of Internal Medicine, Iowa City, IA; 3) University of Iowa, Department of Neurology, Iowa City, IA; 4) University of Iowa, Holden Comprehensive Cancer Center, Iowa City, IA; 5) University of Iowa, Department of Obstetrics and Gynecology, Iowa City, IA; 6) University of Iowa Carver College of Medicine, Iowa City, IA; 7) University of Iowa Hospitals and Clinics, Iowa City, IA.

Many healthcare systems are trying to grow the genetic counseling workforce to meet the needs of their patients as genetic counselors are integral to the implementation and delivery of precision medicine. An increasing number of genetic counselors also work in industry, laboratories, and insurance companies. Genetic counselors specializing in a growing number of specialties such as internal medicine, nephrology, neurology, psychiatry and cancer can assist in the implementation of genomic medicine into routine clinical care by educating non-genetics providers and patients about genomics and genomic testing. As the roles of genetic counselors continue to diversify, it can be challenging to recruit and retain these healthcare professionals. Like many hospitals in the nation, the University of Iowa Hospitals and Clinics (UIHC) had a shortage of genetic counselors which impacted the ability to care for patients as well as the ability to recruit physicians. Over the last four years, we have worked to improve the environment for genetic counselors through a series of initiatives. Our hypothesis was that implementation of education programs to attract local students to the profession combined with an improved work environment for genetic counselors, would result in growth of the local genetic counselor workforce. A summer undergraduate internship program has seen 600% growth in applicants over the past five years, and two of the past interns have been hired by the University of Iowa Hospitals and Clinics demonstrating the success of this long-term recruitment and education initiative. Commitment to pursue and successfully obtain state licensure of genetic counselors was of critical importance to grow and maintain the genetic counselor workforce. These and other education, infrastructure, and workplace satisfaction initiatives have resulted in the successful recruitment of fourteen genetic counselors in the last three years, over tripling the total number of genetic counselors at the hospital. Over two-thirds of these counselors have been hired in specialties such as cancer, cardiology, nephrology, neurology, pediatric neurology, and women's health. In summary, through a series of institutional led initiatives and creating a supportive culture, UIHC has been able to grow the genetic counselor workforce in a time of high demand. We believe the growth of this workforce will improve patient access to precision medicine thereby improving quality of care for Iowans.

**Evaluation of perceptions and attitudes of medical school undergraduate students towards medical genetics at El Bosque University in Colombia.** R. García-Robles, A.L. Montealegre Páez, G. Díaz Muñoz, S. Perdomo Velásquez. Instituto de Investigación en Nutrición, Genética y Metabolismo, Facultad de Medicina. Universidad El Bosque (Bogotá, Colombia).

**Background:** The increasing knowledge and great advances in medical genetics have encountered some needs and difficulties in terms of perception and attitudes of health professionals. The common perception is that this field involves exclusively some diseases or just research, and therefore it underestimates the importance of genetics in clinical practice. **Methods:** A virtual survey with 13 questions was applied to medical students attending 3<sup>rd</sup>-year (end of the basic cycle) and 6<sup>th</sup>-year (at the end of the clinical cycle) of medical training. Questions and response options were provided with Likert-type measurement scale (totally agree to totally disagree), and questions with a binomial answer option (YES / NO). **Results:** A total of 190 students were invited to participate, 118 accepted the invitation to respond the survey but only 112 (83 female and 29 male students) accepted to participate. 64.4% and 52.3% of 3<sup>rd</sup> and 6<sup>th</sup>-year students, respectively. 83 (74.1%) were female and 29 (25.9%) male students. The majority of answers show that students recognize the importance of genetics in medicine, but face some difficulties to acquire this knowledge. Students recognize the necessity of more accessible sources of genetic information with clear and simple terminology. **Discussion:** Our results are concordant with similar studies recognizing the relevance but also the need for more education in medical genetics. These aspects are of increasing importance due to the current developments in genomics and translational medicine.

**590F**

**Participants as partners in research: Communicating a timeline to research participants for results with a “fuzzy ending”.** N.S.Y. Liang<sup>1</sup>, E. Lau<sup>1</sup>, B.C. Lenahan<sup>2</sup>, I. Jordan<sup>2</sup>, K. Ohs<sup>2</sup>, J.M. Friedman<sup>1</sup>, P.H. Birch<sup>1</sup>. 1) University of British Columbia, Vancouver, Canada; 2) Parent Partner, Vancouver, Canada.

**Background** The IMAGINE project uses whole genome sequencing and metabolomics to identify genetic causes of atypical cerebral palsy in affected children. Preliminary results take 6 months, during which time there is little contact with participating families. During this period, parents speak of powerlessness, anxiety, disengagement from the research, and concern that they may have been forgotten: *“There’s nothing like the black hole of healthcare-waiting we spend our life in.”* **Aim** Our goal was to provide family-friendly, automated, informative study updates that continue to engage parents in the research. We also introduced the concept of a “fuzzy ending” to reflect the lack of a firm diagnostic endpoint due to on-going analyses and increasing scientific knowledge over time. **Method** At families’ suggestions, we co-developed an online timeline to visualize progress through the study. When a sample moves from one stage to the next, e.g., from “DNA extraction”, to “sequencing begins,” families receive an email link to an updated timeline, with optional pop-up text explanations. Parents’ evaluated the timeline via a brief survey. **Results** Feedback has been favourable: *“It’s like an order tracking bar on FedEx”* and *“keeping everyone on both sides informed feels more like active participation.”* The timeline reminds parents to notify researchers if their child’s health changes, which may help researchers to further define the child’s phenotype. Many parents wish to receive preliminary results, as indicated by the timeline: *“We want to be treated as adults - with the option of knowing everything the researchers know.”* The timeline also conveys that some families receive a definitive genetic diagnosis through our study, whereas for others, the result is inconclusive or negative. With guidance from parents, we have chosen to use the term “fuzzy ending” to convey this uncertainty and to indicate the possibility of ongoing genomic re-analysis. Rather than creating anxiety, our data suggest that some parents see the “fuzzy ending” as positive, offering hope that medical advances may provide more answers in the future. Anecdotally, the visual timeline appears to be helpful for non-English speakers, who make up 30% of our cohort, prompting us to implement and test other language versions. **Conclusion** In this pilot study, the visual timeline appears to engage parents as partners in the research by addressing their desire for ongoing involvement.

**Evaluating reach of genetic services to medically underserved populations.** *M. Lyon, D. Maiese, A. Keehn.* NCC, ACMG, Bethesda, MD.

**Purpose** In June 2017, the Health Resources Services Administration (HRSA) created the seven Regional Genetics Networks (RGNs), the National Genetics Education and Family Support Center (Family Center), and the National Coordinating Center for the Regional Genetics Networks (NCC) to improve access to quality genetic services for medically underserved populations. To understand the impact of this work, HRSA created five performance measures that examine the use of RGN educational materials, RGNs assistance in connecting patients with genetics services, and the use of telehealth modalities to provide genetic services. **Methods** Through an iterative process begun in August 2017, the RGNs, NCC, and HRSA crafted the five performance measures in Table 1.

<b>Performance Measure</b>	<b>Example Indicators Collected</b> <i>(Zip code/medically underserved collected for every measure)</i>
Number of providers, individuals, families that received education/training or resources developed by the RGNs	Resource analytics
Number of patients for whom the RGN program facilitated connections to a geneticist	RGN specified variable (race/ethnicity, public/private insurance)
Number of providers trained in an RGN supported event that focuses on telehealth modalities for genetics	Provider Specialty
Number of RGN sites that use telehealth modalities	Provider Specialty Modality: Teleconsultation or Telegenetics
Number of patients for whom telehealth modalities for genetics were used.	Insurance coverage RGN specified variable (race/ethnicity, public/private insurance)

**Results** Beginning in June 2018, the RGNs submitted data for each of the five performance measures. The results of the data presented will demonstrate how: 1) how many individuals, families, and providers were served by educational materials developed by the RGNs; 2) demonstrate how RGN activities (such as a toll-free phone line) can assist in connecting medically underserved patients with genetics providers; and 3) reveal how the use of telehealth modalities can increase access to genetic services for patients. This project is supported by the Health Resources and Services Administration (HRSA) of the U.S. Department of Health and Human Services (HHS) under Cooperative Agreement #UH9MC30770-02 from 6/2017-5/2020 for \$800,000 per award year. This information or content and conclusions are those of the author and should not be construed as the official position or policy of, nor should any endorsements be inferred by HRSA, HHS or the U.S. Government.

**592F**

**Genome Odyssey: Theatre as an effective way to teach population genetics concepts to children.** *A. Malaspina,* *Genome Odyssey Consortium.* University of Lausanne, Lausanne, Switzerland.

Over the course of about eight months a team of roughly 30 professionals in the arts and science worked together to create a theatre play intended for children. The starting point of the play was a scientific publication about the peopling of Australia and the intention was to communicate some scientific results to children as young as 8 years old. The play covered population genetic concepts, was meant to raise awareness about Aboriginal Australians while also conveying the fact that science is fun and is meant for all. We surveyed about 350 children before and after the play asking them the same questions to assess how much they learned from it. We present the results in this talk and show that we were able to convey scientific concepts effectively and to have an impact on implicit gender-science stereotypes.

**593T**

**Long-term impact of presymptomatic genetic testing for HD: Family narratives.** *J.M. Bollinger<sup>1</sup>, K.M. Stuttgen<sup>1,2</sup>, A. McCague<sup>1,2</sup>, R.L. Dvoskin<sup>1</sup>, B. Shpritz<sup>3</sup>, J. Brandt<sup>3,4</sup>, D.J.H. Mathews<sup>1</sup>.* 1) Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD; 2) Institute of Genetic Medicine, Johns Hopkins University, Baltimore, MD; 3) Department of Psychiatry and Behavioral Science, Johns Hopkins University, Baltimore, MD; 4) Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD.

In 1983, Huntington's disease (HD) became the first genetic disease mapped using DNA markers. From 1986-1998, the Johns Hopkins University Huntington's Disease Center offered presymptomatic genetic testing for HD in the context of a research study. Now, almost 30-years later, ongoing relationships with this original cohort have afforded us the unique opportunity to examine the long-term consequences of presymptomatic testing for HD. Prior studies on presymptomatic genetic testing have focused on the impact of testing on at-risk individuals over years, not decades, with little to no attention on the effect on family members. As the use of genomic sequencing in research and clinical care expands, more individuals are learning about genetic risks for conditions pre-symptomatically, in some cases incidentally, and with direct implications for their family members. Thus, it is imperative that we understand the implications of presymptomatic testing, for not only at-risk individuals, but also their families. We interviewed 40 at-risk probands who enrolled in the presymptomatic HD testing program at Hopkins between 1986 and 1998. Sixteen tested with expanded repeats for HD, 20 tested normal, and 4 declined testing. Interviewees were asked about their reasons for testing and the impact of receiving results (or not) on family relationships. 32/38 interviewees cited both personal and family reasons for testing (2 affected probands were unable to answer the question). The most often cited family reasons were reproductive decision-making (17), learning information for the sake of children/family (15), financial planning (14), decisions about relationships (7) and jobs (6), and planning long-term care (3). Personal reasons focused on easing anxiety and a need to know. Probands reported both positive and negative effects on their families of testing and/or learning their status. Positive effects included becoming closer to their family (5) and better understanding of family members (4). Negative effects included resenting family members' choices to be tested or not (7), feelings of survivor's guilt (5), and drifting away from family (4). Our data demonstrate the degree to which at-risk individuals focused on the impact of this testing not for themselves, but for their families. These data highlight a need to improve and develop new guidance for how we talk to and about family members in the context of genetic testing and research.

**594F**

**The burden of biased variant datasets: Examining enrollment and candidate genes for non-European rare disease probands in the Duke Task Force for Neonatal Genomics.** *E.F. Bullis<sup>1</sup>, E.M. Ghanaim<sup>1</sup>, A. Sadeghpour<sup>2</sup>, E.E. Davis<sup>2</sup>, S.H. Katsanis<sup>1</sup>.* 1) Duke University, Durham, CA; 2) Center for Human Disease Modeling, Duke University Medical Center, Durham, NC, USA.

Disproportionate representation of racial and ethnic diversity in variant databases has clinical and social implications for individuals of non-European descent. This has prompted researchers to promote diversity among participants in genomic studies, and to improve engagement with economically disadvantaged communities. We examined how race, ethnicity and socioeconomic status (SES) influenced a trio-based whole exome sequencing (WES) research study of families with probands who present with unexplained medical conditions. Following bioinformatic filtering for rare variants, the research team reported anecdotally that analysis for some families of under-represented ancestries required more resources due to an increased number of candidate variants. To probe this, we collected data from the Duke Task Force for Neonatal Genomics, a project that intersects WES data with *in vivo* models to elucidate the genetic basis for phenotypes. We compared self-reported race/ethnicity to the number of candidate genes derived from the WES data for each proband. We then layered the data with median household income to gauge any additional correlation and compared these factors to families who declined participation. Among the 101 probands (73 White; 20 non-White; 8 mixed), non-White and mixed probands ( $\bar{x}=14.15$ ; range=41) had an average of 6.1 more candidate genes ( $p=0.00035$ ) than white probands ( $\bar{x}=8.05$ ; range=31). Probands that self-identified as Latino were analyzed separately and then in combination with their reported race. Probands identifying as White and Latino ( $n=7$ ) were found on average to have 5 more candidate genes than White non-Latinos ( $n=61$ ) ( $p=0.012$ ). By comparing the 211 enrolled families to the 239 families that declined, we found that families who declined participation had \$8,222 lower median household income ( $p=0.015$ ). In addition, families with a higher number of candidate genes had lower median household incomes. Although the resources needed to analyze candidate genes for causality can range dramatically, more candidates broadly translate into a higher burden on the laboratory. Our analysis reinforces the perception that race, ethnicity, and SES are interconnected and can contribute to both the enrollment of families into genomic studies and the increased effort to analyze sequencing data. Future community endeavors will be necessary to alleviate such barriers for equitable access to actionable clinical results from genome sequencing.

**Gene editing: Emerging law and policy perspectives in Europe.** A.C. de Paor. School of Law and Government, Dublin City University, Glasnevin, Dublin 9.

Scientific and technological innovation is becoming more refined, resulting in an increase in the availability and use of genetic testing, and other cutting edge genetic technologies, including gene editing. CRISPR/Cas 9, a gene-editing technology at the cutting edge of science and medicine, is gaining attention worldwide and may ultimately be used to eradicate serious disease. Recent developments in the area of gene editing signal significant advances and growing application of this new technology in the future. Although offering substantial opportunities for understanding health and medicine, the emergence of gene-editing highlights a minefield of ethical, legal and practical challenges in both clinical and commercial contexts, and in society in general. In addition to the safety concerns arising with these genetic techniques and the unknown medical implications of gene editing for future generations, there are many ethical and legal questions arising. One concern centres on the potential trend towards facilitating the selection of embryos based upon genetic desirability and human enhancement. Disability perspectives are particularly relevant in this area. Advances in the field of genetics provide a new lens to view, identify and now eradicate disability. With developing gene-editing technologies there is a concern that the technology will be used to screen out disability, difference and diversity in society. This provokes a range of human rights concerns for persons with (current and future) disabilities, and those genetically predisposed to disability, including discrimination and stigmatisation. Without caution and appropriate regulatory controls, such developments may operate to devalue the lives of persons with disabilities, and may lead to the widespread view that persons with disabilities are inferior, which may result in discrimination and other mistreatment. In consideration of the connection between genetics and disability, this paper will highlight the key ethical, legal and policy concerns raised as gene editing advances and the consequences for disability rights, the right to non-discrimination, and respect for diversity and difference. The research looks particularly at the United Nations Convention on the Rights of Persons with Disabilities and how it may be used to guide best practice and policy in this area in Europe.

**The duty to recontact in genomics: Is the law out of touch?** B. Knoppers, A.M. Thorogood, S. Beland, M.H. Zawati. McGill University, Montreal, Quebec, Canada.

The evolving clinical implications of genomic data results present opportunities for invention and intervention, and raise ethical and legal questions, particularly with regards to the duty of physicians to provide medical follow-up. We compare case law and professional guidelines determining the content of the duty of care in the genetics context, as well as the contours of a physician's general ethical and legal duties to follow-up in different countries (Canada, U.S., UK, France, Australia, ...), highlighting differences and similarities between jurisdictions. Additionally, we review relevant literature and policy recommendations emanating from various organizations (American College of Medical Genetics, European Society of Human Genetics, ...). We find unsurprisingly, that there is currently no general legal duty for physicians to recontact patients in light of new clinical information. There may be specific situations however, where a legal duty to recontact arises. A comprehensive personalized medicine ecosystem is emerging aiming to improve the quality, availability, and currency of genomic data. This ecosystem will involve modification and expansion of the organizations and health professionals involved in health care delivery (to include for example genetics laboratories and databases), as well as automated genomic communication and interpretation tools, all of which make up an interpretive supply chain. Preemptive genomic sequencing, long term patient genomic data storage for reuse, in combination with Big Data collection and analysis, are creating new possibilities for continuous update. We anticipate that the dual evolution of the genomic knowledge base and individual patient data sets needed to capture the benefits of genomics will substantially expand the legal duty to follow-up. Moreover, the locus of this legal responsibility may also be shifting across a broader range of individuals in the interpretive supply chain (primary care physicians, genetics healthcare professionals, genetics laboratories, database managers, patients, ...). Evolving data management practices and recontact may also have implications regarding patients' privacy and right not to know, which we consider in our analysis.

**597T**

**Preferences and incidence of secondary findings in a cohort of adult patients undergoing exome sequencing.** S. Shickh<sup>1,2,11</sup>, K. Zakoor<sup>1</sup>, M. Gutierrez Salazar<sup>1,2</sup>, J. Gu<sup>1</sup>, N. Watkins<sup>1,3</sup>, M. Care<sup>3,4</sup>, S. Horsburgh<sup>4</sup>, O. Morar<sup>4</sup>, J. Murphy<sup>3,4</sup>, M. Szybowska<sup>4</sup>, DL. Nevay<sup>4</sup>, M. Aronson<sup>3,5</sup>, S. Panchal<sup>3,6</sup>, J. Stavropoulos<sup>7</sup>, C. Marshall<sup>1</sup>, N. Abdul<sup>1</sup>, S. Armel<sup>6</sup>, S. Khalouei<sup>1</sup>, R. Godoy<sup>6</sup>, K. Semotiuk<sup>1</sup>, C. Elser<sup>8</sup>, Y. Bombard<sup>2,11</sup>, C. Mighton<sup>1,2,11</sup>, D. Chitayat<sup>1</sup>, R. Kim<sup>1,4,7,8,9</sup>, J. So<sup>4,9</sup>, H. Faghfoury<sup>4,9</sup>, J. Silver<sup>4,9</sup>, C. Morel<sup>4,9</sup>, J. Lerner-Ellis<sup>1,10</sup>. 1) Pathology and Laboratory Medicine, Mount Sinai Hospital, Sinai Health System, Toronto, ON; 2) Genomics and Health Policy Research, Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, ON; 3) Department of Molecular Genetics, University of Toronto, Toronto, ON; 4) Fred A. Litwin Family Centre in Genetic Medicine, Toronto General Hospital and Mount Sinai Hospital, Toronto, Canada; 5) Familial Gastrointestinal Cancer Registry, Mount Sinai Hospital, Sinai Health System, Toronto, ON; 6) Marvella Koffler Breast Centre, Mount Sinai Hospital, Sinai Health System, Toronto, ON; 7) Hospital for Sick Children, Toronto, ON; 8) Princess Margaret Cancer Center, Toronto, ON; 9) Department of Medicine, University of Toronto, Toronto, Canada; 10) Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON; 11) Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON.

**Background and Purpose** Exome sequencing (ES) is increasingly utilized in practice, given its ability to improve diagnostic yield, inform surveillance and provide treatment options at a cost comparable to standard genetic tests. However, ES presents challenges for patients and clinicians, including generating secondary findings (SF). The American College of Medical Genetics and Genomics (ACMG) recommends that at minimum, patients undergoing ES be offered the option to receive results for 59 medically actionable genes, which ACMG defined as genes associated with highly penetrant disorders with available medical intervention. Despite the recommendations, there continues to be variation in the return of SF across laboratories and clinics which may reflect provider and patient preferences. Studies evaluating patient preferences have generally found that participants are interested in receiving results beyond those that are medically actionable. We sought to survey adult patients undergoing ES and their relatives to evaluate preferences for receiving SF and the frequency of SF. **Methods** We surveyed 40 adults patients suspected to have genetic disorders, but had previous uninformative results and were undergoing ES as part of a study at Mount Sinai Hospital in Toronto, Ontario and 31 of their relatives via questionnaire. The questionnaire asked participants about their level of interest in receiving SF for diseases with varying penetrance levels and types of genetic variants/conditions. Patients' exome data was also analyzed to evaluate the frequency of medically actionable results (ACMG 59 genes plus actionability list developed by the Clinical Genome Resource) and carrier results. **Results** Overall, probands and relatives were interested in receiving SF, with a high level of interest for diseases with higher penetrance (63/71) and later onset diseases with available treatments (70/71). Most participants were also interested in receiving carrier results (66/71) and variants of uncertain significance (64/71). Relatives tended to have a higher preference for receiving SF than probands. The prevalence of medically actionable variants and carrier results identified in this cohort will be reported on as well. As ES becomes increasingly utilized in clinical practice, understanding patient preferences and the frequency of different types of SF is critical as they can help to inform resource needs and guidelines on the return of SF.

**Genetic risk: Whether, when, and how to tell adolescents.** K.M. Stutgen<sup>1,2</sup>, A. McCague<sup>1,2</sup>, J.M. Bollinger<sup>1</sup>, R.L. Dvoskin<sup>1</sup>, B. Shpritz<sup>2</sup>, J. Brandt<sup>3,4</sup>, D.J.H. Mathews<sup>1</sup>. 1) Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD; 2) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 3) Department of Psychiatry and Behavioral Science, Johns Hopkins University School of Medicine, Baltimore, MD; 4) Department of Neurology, Johns Hopkins University School of Medicine, Baltimore, MD.

Genetic test results are often relevant not only to the person tested, but also to her/his children. Questions of whether, when, and how to disclose genetic test results to children can be difficult for parents to navigate. A better understanding of how parents and children feel about genetic risk/status, how it is communicated, and how it influences well-being and family relationships is vital in order for genetic counselors and other health care professionals to provide the best guidance possible. In-depth semi-structured interviews were conducted with at-risk parent/child pairs from two populations: families at risk for HD and families with hereditary cancers. Children in this study were ages 15-17. Parents and children were interviewed separately and were asked about topics that included: the genetic information that was communicated, outcome of the communication, factors that led to positive and negative experiences, and advice for other parents and children. In-depth semi-structured interviews were also conducted with genetic counselors (GCs) who had prior experience communicating with children about genetic risk information at the request of parents, or advising parents on how to do so. To date, interviews have been conducted with 17 parent-child pairs affected by/at-risk for hereditary cancer, 12 parent-child pairs affected by/at-risk for HD, and 19 GCs. Results suggest that while parents feel hesitant to burden children with information and/or children will not be able to handle it, children believe they are able to sense that something is wrong in the family and wish parents would be more forthcoming and offer more information. Both existing data and our data suggest that parents should start communicating with children at a young age, but conversations should occur gradually over time and should involve age-appropriate language. Additionally, our data suggest that parents should take time to process his/her genetic test results and/or diagnoses before communicating with their child to avoid becoming overly emotional when talking with children. Finally, both parents and genetic counselors expressed a need for more resources for parents and providers on how to communicate with children about genetic risk information as well as child-specific resources on various genetic conditions. We hope these data will help assist both parents and health professionals when faced with needing to communicate this information to children.

**The factors related with attitudes toward informed assent for genomic research.** Z. Yamagata<sup>1</sup>, K. Muto<sup>2</sup>. 1) University of Yamanashi, Yamanashi, Japan; 2) The University of Tokyo, Tokyo, Japan.

**Introduction:** The purpose of this study is to determine the factors related with attitudes of the general Japanese public toward genetic research on children and informed based on nationwide surveys conducted 2016. **Methods:** 2,000 people (age = 20–69) from the general Japanese population, were selected using a stratified two-phase sampling method. In a mail survey administered in 2016, the participants were surveyed regarding the following topics: (1) their attitudes toward genetic testing; (2) their perspective regarding informed assent; (3) their level of scientific literacy regarding genomics; and (4) their demographic information and socioeconomic status. **Results:** The response rate was 50.8% in 2016. Conducting genetic testing on children for disease susceptibilities was favored by 57.2% of participants. Regarding obtaining blood donations from children, 55.2% approved, 11.3% disapproved, and 34.8% were undecided. A higher proportion of participants with high genomic literacy levels approved of obtaining blood donations from children. The multiple logistic analysis odds ratio regarding genomic literacy was 1.40 (95% confidence interval = 1.08–1.52). Regarding whether seeking consent from children is appropriate, 52.0% of people answered that seeking consent from a child is acceptable if the child understands the details of the research. These responses were associated with participants with high genomic literacy. **Conclusions:** The results of this study suggest that people's genomic literacy is related to people's perspective on genomic research on children.

**A new model for genomics support of military healthcare providers:**

**Early findings from the MilSeq project.** M.D. Maxwell<sup>1,2,3</sup>, C.L. Blout<sup>1,2</sup>, K.D. Christensen<sup>1,2</sup>, C.L. Gardner<sup>3</sup>, J.B. Krier<sup>1,2</sup>, M. De Castro<sup>4</sup>, R.C. Green<sup>1,2,5,6</sup> for the *MilSeq Project*. 1) Brigham and Women's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) 59th Medical Wing, Joint Base San Antonio - Lackland Air Force Base, San Antonio, TX; 4) Air Force Medical Genetics Center and Molecular Diagnostic Laboratory, Keesler Air Force Base, Biloxi, MS; 5) Partners Personalized Medicine, Boston, MA; 6) The Broad Institute of MIT and Harvard, Cambridge, MA.

**Introduction:** As technological advancement, cost reduction and accessibility of genomic sequencing (GS) usher in an era of precision medicine, the demand for expert clinical interpretation exceeds the supply of trained genetic professionals. This shortage is intensified in the Military Health System (MHS), which employs 6 active-duty and 2 civilian geneticists, as well as a handful of genetic counselors (GCs) to provide services for over 1,300,000 service members. The MilSeq Project is a pilot study of GS in ostensibly healthy Airmen designed to explore the benefits and risks of GS implementation into the MHS. To address the professional shortage, we pilot a scalable model in which military healthcare providers (MHCPs) manage GS results with support from GCs and geneticists. **Methods:** MHCPs are briefly oriented, supervised and evaluated in their provision of genetic services by a Genome Resource Center (GRC) that can be locally or remotely staffed by GCs and geneticists. MHCPs are required to attend a 3-hour, GC-instructed training prior to disclosing results to Airmen. A GC is embedded in clinic for in-person consult and ongoing support, and MHCPs have access to a 24-hour virtual GRC. MHCP disclosures are audio recorded, transcribed and reviewed by the GRC for accuracy and appropriateness. Identified opportunities to improve MHCP practice are organized into 4 categories: (1) Knowledge limitation; (2) "Minor" adjustments for errors posing minimal risk to optimal care; (3) "Moderate" adjustments for errors posing some degree of suboptimal care; and (4) "Critical" adjustments for errors endangering patient safety. Feedback is provided to MHCPs after transcript review. **Results:** Of 7 transcripts reviewed to date, no critical errors have been identified. At least 1 opportunity for improvement has been identified in each of the other 3 categories. Qualitative review revealed emerging themes that would benefit from further education, including contextualizing within the pedigree, cascade testing and relative risk counseling. We will have 75 evaluated transcripts by the end of this phase of the MilSeq Project and additional data will be included in this presentation. **Conclusion:** In order for genomic services to be scalable in both the MHS and civilian healthcare, new service delivery models are needed. Here we present our experience with a model that provides for pre-disclosure training, real-time point-of-care consultation and post-disclosure evaluation and feedback.

**601T**

**A literacy-focused “modified” genetic counseling approach for the return of exome sequencing results to underserved and ancestrally diverse patients.** L.M. Amendola<sup>1</sup>, M. Gilmore<sup>2</sup>, K.P. Anderson<sup>3</sup>, B. Biesecker<sup>4</sup>, C. Guerra<sup>5</sup>, T.L. Kauffman<sup>6</sup>, R. Lee<sup>7</sup>, L. Riddle<sup>8</sup>, A.F. Rope<sup>8</sup>, B. Wilfond<sup>8</sup>, K.A.B. Goddard<sup>8</sup>, G. Joseph<sup>8</sup>. 1) Division of Medical Genetics, University of Washington, Seattle WA 98195, USA; 2) Center for Health Research, Kaiser Permanente Northwest, Portland OR 97227, USA; 3) Denver Health Ambulatory Care Services, Denver Health, Denver CO 80204, USA; 4) Research Triangle Institute, International, Washington DC 20005, USA; 5) University of California, San Francisco Department of Anthropology, History & Social Medicine, & Helen Diller Family Comprehensive Cancer Center, San Francisco CA 94143, USA; 6) University of California, San Francisco Cancer Genetics and Prevention Program, San Francisco CA 94143, USA; 7) Department of Genetics, Kaiser Permanente Northwest, Portland OR 97227, USA; 8) Department of Pediatrics and Seattle Children’s Research Institute, University of Washington, Seattle, WA, USA.

**Background:** Early research efforts on the application of exome sequencing in clinical practice have inadequately addressed diverse or underserved populations. Research conducted with genetics patients who have limited English proficiency and/or health literacy suggests a mismatch between the information provided by genetic counselors (GCs) and information desired and meaningful to patients. As part of the Clinical Sequencing Evidence-Generating Research (CSER) consortium, the Cancer Health Risk Assessment Reaching Many (CHARM) study will enroll participants with a focus on traditionally underserved populations including individuals with socioeconomic and racial/ethnic diversity as well as individuals with low health literacy. We will evaluate the disclosure of exome sequencing results via traditional genetic counseling or a literacy-focused “modified” genetic counseling approach in the context of hereditary cancer genetic testing. **Methods:** A work group within the CHARM study was convened to define the two results disclosure approaches. Here we describe the essential elements of each and implementation plans.

**Results:** Traditional genetic counseling (usual care) will include genetics terminology, scientific language and discussion of genetic concepts, such as inheritance patterns and disease penetrance. Modified counseling will adapt to the literacy level of the individual and will employ evidence-based communication techniques for individuals of lower health literacy, such as the use of plain language and teach back, and a more directive approach. In both arms, we will prioritize conveying essential information and address participant specific psychosocial concerns and questions. GCs conducting modified counseling will be trained via didactic lectures and role play. To ensure fidelity to the intervention, recordings of results disclosure conversations will be assessed to identify variation and protocol adherence. GCs providing traditional counseling will remain naïve to the modified model throughout the study. **Discussion:** We hypothesize that the modified approach will be non-inferior to traditional genetic counseling and may be more effective in terms of satisfaction with counseling, participant engagement, perception of communication, family communication, and understanding of and adherence to recommended care. The trial results will inform effective methods for results disclosure for exome sequencing across diverse healthcare settings and populations.

**602F**

**Communicating uncertainties in genomics: Results of a narrative literature review.** B.B. Biesecker<sup>1</sup>, H. Peay<sup>2</sup>, R. Paquin<sup>2</sup>, B. Boyea<sup>2</sup>, A. Wheeler<sup>2</sup>, M.A. Lewis<sup>2</sup>. 1) Research Triangle Institute, International, Washington DC, United States; 2) Research Triangle Institute, International Research Triangle Park, NC, United States.

Given the frequency of unknown variants returned after genome sequencing, there is critical need for evidence to inform best practices in communicating uncertainties. A narrative literature review on communicating clinical uncertainty identified 149 abstracts that met inclusion criteria from a search of PubMed, Web of Science, PsycINFO, and Communication Source databases. Twenty-nine abstracts described studies in genomics, 33 in cancer, 23 in other specialties and 53 in illness risk generally. Lacking best practices in genomics, existing evidence was synthesized for use in guiding communication of uncertainty practices and to inform study design in genomics. Evidence endorses: A) Use of positive framing when engaging patients in discussions of uncertainty. Examples include conveying a commitment to care for the patient, partnering and providing reassurance s/he is not alone. B) Prior to testing, helping patients anticipate the potential for uncertain findings. After testing, providing clear communication about what is known and unknown, and avoiding use of vague descriptors. C) Providing reassurance to patients that information is not being withheld. D) Communicating provider-patient shared ownership of uncertainty. E) Encouraging and providing opportunities for patients to ask questions. F) Communicating with credible authorities to facilitate effective management of uncertainty using reappraisal and reframing. Existing evidence informs several hypotheses: A) How uncertainty is communicated will affect not only understanding and risk perceptions but also how patients manage the threat of uncertainty over time. B) Many factors, including personality traits and situational factors, will play a role. C) Maintaining hope in an uncertain situation will promote effective coping and adaptation. D) For many individuals, managing information is a means of coping with illness-related uncertainty. For those who maintain perceptions of uncertainty to preserve hope, they avoid follow up care and seeking information as learning details may threaten their hope. Those who perceive uncertainty as a danger work to reduce it by seeking information and follow up care. Implications: This literature review and data synthesis provide guidance in communicating uncertainties in genomics, while simultaneously suggesting hypotheses to be tested to generate evidence to inform best practices.

**An iterative process to develop a statewide network of genetic counselors in Connecticut.** K. Sanghavi<sup>1</sup>, M. Gyure<sup>2</sup>, J. Brown<sup>2</sup>, K. Adams<sup>1</sup>. 1) The Jackson Laboratory for Genomic Medicine, Farmington, CT; 2) Institute for Systems Genomics and Dept. of Allied Health Sciences, University of Connecticut, Storrs, CT.

**Introduction:** The purpose of development of a Connecticut (CT) statewide network of genetic counselors (GCs) through an iterative process is to enhance the genetic counseling workforce in CT and identify areas in which the biomedical research community and GCs can be supported to address real or perceived gaps in representation of genetic counselors in state efforts such as Bioscience initiatives, as well as educational, research and networking opportunities. **Approaches:** An IRB-approved survey was administered digitally to the GCs providing genetic counseling services in CT to understand the landscape of genetic counseling services including the need of a statewide network of GCs in CT recognizing that CT provides licensure to GCs. Follow-up discussions with select respondents were scheduled to better understand the needs and inform the development of a statewide network of GCs in CT similar to other states such as FL, GA, PA, TX, and VA. Various stakeholders including the leadership of existing statewide associations such as Pennsylvania Association of Genetic Counselors were engaged in this iterative process. **Findings:** 34/36 (94%) respondents were interested in a statewide network of GCs in CT. Topic areas for consideration in the context of the content for statewide GC efforts included: Professional issues, CT Bioscience & GCs, educational and leadership needs, clinical/research rotation opportunities for students, innovative service delivery models, state genetics/genomics plan, and reimbursement for GCs. One respondent reported, "*Credentialing and billing have been an ongoing issue, even after obtaining licensure. I would appreciate peer input or a subcommittee in the statewide organization to address practice issues such as this.*" Initial follow-up discussions revealed an overall need to advocate the inclusion of GCs in statewide initiatives and the expansion of the number of GCs in CT. Next steps include interdisciplinary focus group discussions with different stakeholders including other state GC networks. **Conclusion:** The process of establishing a network with statewide partners and stakeholders provides an example of professional development opportunities for GCs to foster the sharing and dissemination of best practices within the biomedical and GC communities.

**604F**

**Genetic counseling services in Washington state: A capacity assessment.** N. Shridhar. Screening and Genetics Unit, Washington State Department of Health, Kent, WA.

In October 2017, the Journal of Genetic Counseling (JGC) published a paper (Hoskovec et al.) suggesting optimal genetic counselor (GC) levels to provide adequate access for genetic services in the United States. The paper posited two sets of GC to general population ratios (1:75,000 & 1:100,000), as satisfying the demand for GC's nationwide, and creating an equilibrium between demand and supply. At the Washington State Department of Health (DOH), the Screening and Genetics Unit (SGU) was already engaged in a patient access study evaluating wait times for access to genetic services. This study, a follow-up to a 2013 study, aimed to better understand the impact of the Affordable Care Act (ACA) implementation and Medicaid expansion on our state's capacity for genetic services. We did this by comparing patient wait times before and after the implementation of the two events we hypothesized would increase the need for genetic services statewide. Based on the JGC publication, we augmented our study to assess WA State capacity for genetic services as a function of both wait times (patient access to genetic services) and GC supply (number of GCs in WA providing direct patient care). To conduct this follow-up study in August 2017, the SGU contacted the same nine WA Regional Genetic Clinics across the state that were contacted in October 2013 for the first study. For both studies, patient access was measured using appointment wait times, in specific, the 'Third Next Available Appointment' methodology to accurately reflect the true patient load of each facility. To estimate WA GC capacity, we obtained the list of GC's currently licensed to provide services in our state, and determined if they were providing direct patient care. When we modeled the GC ratio for Washington State (per the JGC paper) to better understand our demand and supply scenario, we found that that we had a direct patient care GC to general population ratio that was in between the two scenarios (1:75000 & 1:100,000) posited by the paper for adequate supply of GC. And yet, we found that patient wait times for appointments to genetic services in Washington State have doubled between 2013 and 2017, with an average wait time of over 2 months. In this presentation, we will provide data that suggests that the JGC paper's low end estimate of 1:100,000 is too low a supply model to fit the current demand for GC in WA.

**605T****Return of data on genetic and lifestyle risks to participants of Estonian**

**Genome Center.** N. Tonisson<sup>1,2</sup>, M. Palover<sup>1,3</sup>, L. Leitsalu<sup>1</sup>, K. Krebs<sup>1,3</sup>, K. Läll<sup>1,5</sup>, M. Kals<sup>1,5</sup>, T. Nikopensius<sup>1</sup>, A. Reigo<sup>1</sup>, H. Alavere<sup>1</sup>, K. Fischer<sup>1,5</sup>, L. Azin Milani<sup>1,6</sup>, R. Mägi<sup>1</sup>, S. Reisberg<sup>1</sup>, A. Allik<sup>1</sup>, B. Kolk<sup>1</sup>, K. Metsalu<sup>1</sup>, M. Puusepp<sup>1</sup>, K. Mikkel<sup>1</sup>, M.L. Tammesoo<sup>1</sup>, E. Pintsaar<sup>1</sup>, T. Temberg<sup>1</sup>, T. Esko<sup>1,4</sup>, A. Metspalu<sup>1,3</sup>.

1) Estonian Genome Center / Institute of Genomics, University of Tartu, Tartu, Estonia; 2) Dept. of Clinical Genetics, United Laboratories, Tartu University Hospital, Tartu, Estonia; 3) Dept. of Biotechnology, Institute of Molecular and Cell Biology, University of Tartu, Tartu, Estonia; 4) Broad Institute of Harvard and MIT, Cambridge, MA, USA; 5) Institute of Mathematics and Statistics, University of Tartu, Tartu, Estonia; 6) Department of Medical Sciences, Molecular Medicine, University of Uppsala, Sweden; 7) Institute of Computer Science, University of Tartu, Tartu, Estonia.

**Introduction:** Estonian Genome Center / Institute of Genomics, University of Tartu, Estonia (EGCUT) holds genotype and health data of more than 52,000 individuals and is currently undergoing a large nationwide recruitment. From the end of 2017, EGCUT participants can come to counselling sessions on individual genetic risk predictions. Our standard reports include data on common diseases, high and moderate monogenic risk factors, carrier status, and pharmacogenetics. **Methods:** To date, nearly 5,000 biobank participants have been either whole genome or whole exome sequenced; 47,000 biobank participants have been genotyped with Illumina Global Screening Array. The reporting system includes a digital semi-automated report assembly system and participant portal for signing an informed consent for return of results and updating information. This portal is also used for setting the counselling appointment. The genetic risk assessments on common disorders are based on polygenic risk scores. Actionable genetic variants reported are selected, according to ACMG guidelines. Participants' immediate - and long-term feedback is continuously surveyed. **Results:** by May 2018, 914 participants have expressed interest through logging in to patient portal and 578 have attended genetic counselling sessions. **Conclusion:** The EGCUT initiative of return of results to population biobank participants provides insight on how healthy population responds to personalised genetic risk information. The long-term aim of the project is to promote introduction of personalised and translational genomics medicine in Estonia.

**606F****Understanding Fabry disease symptoms and impact on daily lives: A**

**qualitative study.** A. Hamed<sup>1</sup>, N. Greene<sup>1</sup>, C. Gwaltney<sup>2</sup>. 1) Sanofi Genzyme, Cambridge, MA United States; 2) Gwaltney Consulting, Westerly, RI, United States.

**Background:** Fabry disease (FD) is a multisystemic, X-linked, genetic lysosomal storage disorder resulting in accumulation of globotriaosylceramide and other  $\alpha$ -GalA substrates leading to irreversible tissue damage and impaired function of multiple organs. Clinical manifestations of FD are heterogeneous and may vary by age of onset, rate of progression, and severity. **Objectives:** The objective of this qualitative study is to gain an in-depth understanding of the most salient symptoms experienced by the FD patients and the impact on their daily lives. **Methods:** One-on-one concept elicitation interviews (CEI) were conducted with adult FD patients. Patients were recruited from US clinical sites and interviewed either in person or via telephone. A semi-structured CEI guide was used to obtain information on patient experiences of FD-related symptoms and impacts and to identify the language patients used to express the concepts associated with their condition. Interviews were transcribed and coded in order to identify themes in the data. The significance of FD-related symptom and impact was assessed by the frequency of patients' mention of each FD-specific concept. **Results:** A total of 37 FD patients were interviewed at six clinical site locations. Interviewed patients ranged in age from 23 to 74 years with a median age of 45.7 years. Twenty-two (60%) were women, 25 (68%) were married, and 32 (87%) were White. For concept saturation, 37 transcripts were categorized chronologically into 4 sub-groups. Complete concepts saturation of salient symptoms and impacts was achieved by the completion of the third group of interviews. Neuropathic symptoms, temperature intolerance, tiredness/fatigue, hearing/vision impairment, and gastrointestinal symptoms were most frequently mentioned by patients. The symptoms most-frequently reported spontaneously were tiredness, fatigue, and burning pain (each reported spontaneously by over 35% of the patients) and followed by heat intolerance and lack of sweating (each reported spontaneously by 32% of the patients). Work/school limitations, exercise limitations, social activity limitations, depression/memory problems, worry, fear, and difficulty with household responsibilities, were the most frequently reported daily impacts due to FD. **Conclusions:** FD patients reported a variety of symptoms and impairments impacting their daily lives. Reducing these symptoms is an important goal of FD treatment. (This work was funded by Sanofi Genzyme).

**607T****Using real-world pharmacogenomics knowledge resources to guide clinical decision-making.** *R. Hart<sup>1,2</sup>, G. Jarvik<sup>1</sup>, L. Garrison, Jr.<sup>3</sup>, B. Devine<sup>2,3</sup>.*

1) Division of Medical Genetics, University of Washington, Seattle, WA; 2) Institute for Public Health Genetics, University of Washington, Seattle, WA; 3) The Comparative Health Outcomes, Policy, and Economics Institute, School of Pharmacy, University of Washington, Seattle, WA.

Pharmacogenomic (PGx) testing can help to optimize drug therapy selection. Despite the availability of FDA Guidance and select expert-developed guidelines, however, clinical utility evidence gaps limit the uptake of PGx testing in clinical settings. Commercial PGx knowledge resource solutions may increase adoption. We investigated real-world data from a commercial PGx knowledge resource by characterizing the Clinical Pharmacogenomics Implementation Consortium (CPIC) level of evidence and sought to identify predictive factors for the clinical actionability made at the time of result interpretation. For 99,727 patients who underwent PGx testing, 90% of patients were tested for six or fewer drugs; 41% were male. Predictors that were statistically significant differed across the four clinical subgroups that were evaluated (pain, cardiology, psychiatry, gastroenterology). Twenty-eight of the 33 PGx gene-drug pairs, characterized by CPIC level of evidence lower than B, resulted in a warning or critical actionability recommendation (versus informational recommendation). This indicates a possible change in drug selection, and highlights a discrepancy in level of evidence determinations between public and commercial knowledge resources. To our knowledge, this is the largest retrospective study conducted to date on patients undergoing PGx testing in a broad set of clinical settings. Our findings provide a robust characterization of real-world PGx testing utilization data and demonstrate evidence of clinical actionability from a commercial PGx knowledge resource. Healthcare systems may wish to consider commercial knowledge resources to spur appropriate PGx test adoption. These solutions can adapt quicker than can centralized authoritative resources to synthesize clinical actionability data and inform time-sensitive clinical guidance. They often can be customized to the population of each Learning Health System, rather than rely on publicly available, standardized sets of PGx knowledge resources.

**608F****Pharmacy-supported return of pharmacogenomic test results: Preliminary data.** *E.T. Matey, J. Giri, J. Wright, J. Anderson, L. Oyen, W.T. Nicholson.* Mayo Clinic, ROCHESTER, MN.

Background: Mayo Clinic is conducting pre-emptive pharmacogenomic (PGx) testing for 10,000 biobank participants as part of a research study. Test results for 13 genes are in the process of being returned to the electronic health record (EHR). Pharmacy leadership advocated for pharmacist involvement in providing an eConsult (electronic review of PGx results for each patient's current medications with reference to drug-gene interactions). Primary care providers (PCPs) may need guidance to manage current medications based on drug-gene interactions. Hence, this eConsult process was established to support and encourage adoption by PCPs who did not order this test. Additionally, clinical decision support alerts are available to providers regarding major drug-gene interactions for future prescriptions. Methods: In addition to the PGx test results for the 13 genes, a supplemental report for over 300 medications based on PGx results was added to each patient's EHR. These medications were categorized as semi-urgent and clinically actionable. Semi-urgent: Potential medications to cause serious harm based on PGx results. Expected time for completion of a semi-urgent eConsult is 48 hours from time of assignment. Clinically actionable: Potential medications to cause an adverse drug reaction or have reduced efficacy. Expected time for completion of a clinically actionable eConsult is 5 business days from time of assignment. A pharmacist eConsult was provided only when patients had current medications that were identified as either semi-urgent or clinically actionable. Results: To date, 1519 PGx results have been returned to the EHR. Out of these, 426 patients had an eConsult completed. One percent (5/426) of these eConsults were semi-urgent and 99% (421/426) were clinically actionable. The average time per eConsult was 22 minutes. The eConsult time ranged from 4 to 75 minutes. Seven pharmacists consisting of PGx and medication therapy management pharmacists were involved in the completion of 426 eConsults. A total of 9114 minutes (152 hours) of pharmacist time was spent over a 3 month period (February through May). Future Direction: Evaluate pharmacists' time involved in the completion of the eConsults to assist pharmacy leadership with future resource allocation for Mayo Enterprise PGx implementation. Assess future adoption of PGx by clinicians and pharmacists across Mayo Enterprise and provide necessary tools such as education to support successful implementation.

**609T**

**Knowledge and attitudes on pharmacogenetics among pediatricians in America and Japan.** *S. Rahawi<sup>1,2</sup>, H. Naik<sup>1</sup>, K. Blake<sup>3</sup>, A. Owusu-Obeng<sup>4</sup>, R.M. Wasserman<sup>2</sup>, Y. Seki<sup>1,2</sup>, V.L. Funanage<sup>3</sup>, K. Oishi<sup>1</sup>, S.A. Scott<sup>1,2</sup>.* 1) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 2) Sema4, a Mount Sinai venture, Stamford, CT; 3) Nemours Children's Health System, Wilmington, DE, Jacksonville and Orlando, FL; 4) The Charles Bronfman Institute for Personalized Medicine, Icahn School of Medicine at Mount Sinai; and Pharmacy Department, The Mount Sinai Hospital, New York, NY.

Accumulating evidence supporting the clinical validity and/or utility of pharmacogenetic testing has prompted recent genotype-directed clinical practice recommendations for selected gene/drug pairs. However, common barriers to implementing pharmacogenetics into clinical practice include inconsistent evidence, inadequate reimbursement, and a lack of provider education. Previous studies have identified a general lack of professional knowledge on pharmacogenetics; however, this has not been tested among pediatricians. Importantly, ~17% of U.S. emergency department visits are due to pediatric adverse drug reactions, underscoring the potential utility of clinical pharmacogenetic testing for children. Consequently, we conducted an anonymous online survey to assess pediatrician knowledge of pharmacogenetics, preferences on educational tool design, and compared the responses of American (n=210) and Japanese (n=72) pediatricians. Over 50% of respondents had >10 years of experience and were based in teaching hospitals, and over 75% had prior undergraduate or graduate education in genetics. However, less than 10% felt they were 'very' or 'extremely' familiar with pharmacogenetics. This was further demonstrated by their lack of knowledge on codeine pharmacogenetics, as only 15% of providers correctly identified *CYP2D6* ultrarapid metabolizers as having an increased risk for respiratory depression and death following use of codeine. Moreover, the vast majority of respondents (93%) were previously unaware of the Clinical Pharmacogenetics Implementation Consortium (CPIC). Despite being unfamiliar with pharmacogenetics, over 75% of respondents indicated that clinical pharmacogenetics will be valuable and that pediatricians should be capable of applying this type of testing to their practice. In addition, respondents indicated their preference for educational tools, which included CME/CE courses, and seminars on interpretation and therapeutic recommendations. Interestingly, despite differences in federal medication regulatory agencies, results were similar across American and Japanese respondents. Although these results indicate that knowledge of pharmacogenetics among pediatricians is generally low, their interest in pharmacogenetic testing and related education is very high, which will likely facilitate future clinical implementation.

**Building quality assurance measures into an effective evidence based precision medicine program.** *A. Schultz, J. Baye, N. Petry, R. Wilke, J. Reiner, A. Aifaoui.* Sanford Imagenetics, Sioux Falls, SD.

April Schultz, Pharm D; Jordan Baye Pharm D, MA, BCPS; Natasha Petry Pharm D, BCACP; Russ Wilke MD PhD FACP; Jennifer Reiner PhD; Aissa Aifaoui Pharm D Genomic medicine, including pharmacogenomics, has become one of the most innovative mechanisms utilized by healthcare professionals to provide optimal clinical care for their patients. However, successful execution of a precision medicine program requires a multidisciplinary approach to ensure continuity of care from the bench to the bedside. Sanford Health's pharmacogenomics program, Imagenetics, has created a team inclusive of medical doctors, molecular laboratory directors, laboratory compliance specialists, and pharmacists to evaluate and validate laboratory and pharmacogenomics data prior to clinical utilization. Herein, we describe a model for quality assurance in the practice of precision medicine. This strategy involves monitoring of observed allele frequencies with expected frequencies published in public databases, validation of conversions between genotype/diplotype and metabolizer status, and review of the corresponding drug dosing guidelines. Inclusion of these validated data in the patient's medical record permits programmed decision support within the electronic medical record (EMR), ensuring valid clinical recommendations throughout the patient's lifetime.

**611T**

**Pharmacogenetic testing in primary care practice: How to speed up the transfer of knowledge?** K. Tremblay<sup>1</sup>, M.E. Blackburn<sup>2</sup>, C. Dubois-Bouchard<sup>2</sup>, M.P. Frigon<sup>1</sup>, S. Tardif<sup>1</sup>. 1) Université de Montréal / ECOGENE-21, Chicoutimi, Canada; 2) ECOBES Recherche et Transfert / Cégep de Jonquière, Canada.

**Introduction:** Some pharmacogenetic tests (PGt) are recommended by health authorities when prescribing drugs that can cause adverse events or be ineffective according to specific gene variants. However, medical professionals such as primary care physicians or pharmacists do not currently apply PGt testing, even if the possible advantages, such as improved therapeutic dosage and response, are generally well-recognized. **Objectives:** In this original research, objectives are 1) to understand how medical professionals and patients stand with regard to PGt and their potential application in clinical practice and 2) to make recommendations to improve the transfer of knowledge of PGt in clinical practice. **Methods:** We have conducted six focus groups in the Saguenay–Lac-Saint-Jean region (Quebec, Canada): two groups composed of general practitioners (GPs) (n=25), two groups composed of pharmacists (n=11) and two groups composed of patients (n=30). Part of the interview was based on real-life situations with examples of commonly prescribed drugs. In addition, we had asked all participants about their knowledge and perception of genetics in medical practice and what the roles of different professionals in regards to PGt could be. **Results:** The data highlighted a willingness in regard to PGt application in all interviewed groups. Questioned about their needs to make possible the implementation of PGt in their practice, GPs and pharmacists suggested to provide training, to develop software to link all patient's information, to present more evidence on the clinical utility and to clarify laws about confidentiality to avoid genetic discrimination by insurance companies. In addition, GPs and pharmacists have expressed the limitation of implementation of PGt in the healthcare system mainly because of a lack of information about the accessibility of these tests, the delay of obtaining results, cost-benefits studies and ethical considerations. The patients were generally in agreement with the PGt and trusted the medical professionals. **Conclusion:** We have been able to highlight a set of recommendations that could better help apply PGt knowledge in clinical practice. .

**612F**

**Pharmacist process for providing personalized eConsults to support large scale pre-emptive pharmacogenomic (PGx) testing.** J. Wright, E. Matey, J. Giri, J. Anderson, L. Oyen, N. Nicholas, H. Marker. Mayo Clinic, Rochester, MN.

**Background:** Pre-emptive pharmacogenomic (PGx) testing was performed on 10,000 Mayo Clinic Biobank participants. PGx results are in the process of being returned to patients' electronic health record. To support Primary Care Providers (PCPs) in adopting PGx results, pharmacists across the Mayo Clinic Enterprise were engaged to complete eConsults (electronic review of PGx results for each patient's current medications with reference to drug-gene interactions) for patients with drug-gene interactions. **Methods:** A train-the-trainer workflow model was designed to engage pharmacists across the institution whose daily workflow may not include performing eConsults. For this, PGx pharmacists were engaged whose role includes, but is not limited to, providing PGx guidance through eConsults and face-to-face consultation. This facilitated identification and resolve of issues that arose with the processes. Once the workflow was established, a team of "early adopter" pharmacists were trained. This group included Medication Therapy Management (MTM) pharmacists who had expressed interest in PGx and had experience in the eConsult process. MTM pharmacists' role consists of providing eConsults and face-to-face consultations. The "early adopters" collaborated with the PGx pharmacists to identify potential issues and further refine the workflow. The rollout will continue with the PGx pharmacists and 'early adopter' pharmacists training other MTM pharmacists. These aforementioned categories of pharmacists will then become trainers for the supervisors of inpatient and outpatient pharmacists across the institution. Supervisors will assign eConsults to their staff pharmacists and serve as a resource for PGx process questions. PGx, 'early adopter', and MTM pharmacists will continue to serve as trainers and a resource for PGx clinical questions to all pharmacists across the institution. A step-by-step guide was developed for pharmacists to standardize eConsults. The completed eConsults were electronically sent to the patient's respective PCP. **Future direction:** This train-the-trainer educational model will support adoption, dissemination, and utilization of PGx in clinical practice. Pharmacists across Mayo Clinic will be equipped to serve as a resource for PGx-related questions in partnership with other members of the care team to individualize patient care.

**613T**

**Disclosure of reclassified VUS results of deceased patients to family members: Current practices.** *S. Lascrain<sup>1</sup>, D. Thull<sup>2</sup>, A. Durst<sup>1</sup>, T. Bear<sup>1</sup>, PL. Ma<sup>2</sup>.* 1) School of Public Health, University of Pittsburgh Pittsburgh, PA; 2) Magee Womens Hospital of UPMC Pittsburgh, PA.

**Purpose:** A variant of uncertain significance result (VUS) is not uncommon in genetic testing. There is currently little regulation or guidance regarding the responsibility of genetics professionals when a VUS is reclassified after a patient has passed away. This study was designed to explore current practices and obtain opinions of genetics professionals on the disclosure of reclassified VUS results of a deceased patient to their relatives. **Methods:** A 35-question web-based survey was distributed to the >3,000 members of the National Society of Genetic Counselors on the listserv. **Results:** A total of 154 individuals completed the survey, 94% of respondents were genetic counselors and 45% reported between one and five years of clinical practice. Forty-five respondents (24%) reported receiving reclassified VUS results in deceased patients. Respondents were more likely to always attempt disclosure of variants reclassified as pathogenic (83%) vs. benign (73%). Most respondents reported not being aware of state or local policies on the disclosure of a deceased patient's reclassified VUS results. Approximately half of the respondents were not sure if an institutional policy existed. Respondents rated the impact of the results on family members and a duty to warn as extremely important factors in considering disclosure to relatives. Most respondents favored a legal mechanism to allow disclosure to relatives. A minority of respondents felt a consent obtained from the decedent prior to their death should be legally (10%) or ethically (27%) required for the updated results to be disclosed to relatives. **Conclusions:** Guidance on the disclosure of reclassified VUS results for a deceased patient is not readily available, though respondents who have experienced this situation commonly reported attempting disclosure in clinical practice. Additional research regarding the role for policy change or development is needed.

**614F**

**A strategic approach to institutional genomics excellence: The Center for Pediatric Genomics.** *J.M. Furgason, H. Aungst, A.M. Rupert, P. Dexheimer, N. Felicelli, J. Chen, J. Hendershot, S. Huitger, C. Van Horn, P.T Komarovalu, J.T. Whaley, J.B. Harley, L.J. Muglia, P.S. White.* Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

The Center for Pediatric Genomics (CpG) is a facilitation-based effort within Cincinnati Children's Hospital Medical Center (CCHMC) to create a vibrant and cohesive culture around precision genomic medicine. The Center utilizes a novel combination of grassroots efforts and more traditional mechanisms to engage clinicians, researchers, and the local community by recognizing, connecting, and educating stakeholders across institutional, social, and educational boundaries. The relatively wide disparity in genomics knowledge among populations of clinicians, researchers, and patients means that finding common areas to interact with these groups can be difficult. CpG's approach examines sources of uncertainty around genomics and tailors individualized programs that generate confidence, competency, and proficiency. This approach focuses on three main pillars: constituent-centric literacy programs, collaborative genomic science, and a comprehensive precision genomics data strategy. Academic research hospital settings require literacy programs to engage a diverse group of caregivers, clinician scientists, and both basic and translational genomics researchers, each of which has varied historical exposure to genomics. CpG uses a unique engagement strategy that relies on stakeholders to inform an educational curriculum that focuses on topics such as genomic technology, testing indications, report interpretation, and clinically relevant knowledge gaps. In 2017, CpG established the Midwest's largest annual symposium for genomic medicine (Precision Genomics Midwest). For patients and the local community, CpG seeks to be a resource that makes precision medicine research transparent and accessible, revealing the power their participation has to shape and improve healthcare. For academic excellence, CpG has invested nearly \$5M to fund 48 peer-reviewed pilot projects that has incentivised over 400 CCHMC investigators to form teams of clinicians and genomic researchers to take on challenges in translational genomics. CpG also supports essential infrastructure for precision medicine, maintaining a "precision genomics ecosystem" for the storage, analysis and sharing of genomics data that is linked to over 1 million pediatric patient records and 800,000 biosamples across 120 projects. It is supported by a bioinformatics team that engages investigators across the institution to guide development of resources that satisfy the needs of both technical and non-technical users alike.

**615T**

**Test2Learn: Leveraging personal genomic testing to advance primary care genomics education.** *M. Massart<sup>1</sup>, P. Empey<sup>2</sup>.* 1) Family Medicine, University of Pittsburgh, Pittsburgh, PA; 2) School of Pharmacy, University of Pittsburgh, Pittsburgh, PA.

Precision medicine, is rapidly transforming healthcare but has outpaced medical education. Many barriers to the integration of genomics into primary care have been outlined with large emphasis on knowledge deficiency (3, 4). Practitioners have limited exposure to genetics testing, and there has been slow integration of genomics education into medical school, residency programs and continuing medical education curricula (1, 2, 5-16). We have tested the effectiveness of a participatory model (Test2Learn) as a highly effective method of providing essential genomic competencies for primary care practitioners. Specifically, we have created an innovative and broadly scalable online genomics education program designed to achieve the competencies outlined by the Genetics-Genomics Competency Center (G2C2) for physicians and the American Academy of Family Practice recommended competencies in Medical Genetics. The Test2Learn program is a participatory genomic testing (PGT) model previously developed at the University of Pittsburgh School of Pharmacy (17). This platform uses 23andMe kits for optional PGT and includes (A) ethics content; (B) asynchronous video content as an out of the classroom genetics review, (C) new in-person flipped-classroom lectures; and (D) new exercises leveraging the learners' experience with PGT and available genetic data. Since primary care providers practice a broad scope of medicine including prenatal genetics (carrier status), wellness, genetic cancer risk assessment, and pharmacogenomics, we have demonstrated that the Test2Learn education model can be extended to enhance the learning for Family Medicine residents by including these content areas. We present the Test2Learn educational platform as a method to provide precision medicine education to primary care providers as well as the results assessing its effectiveness in engaging learners, improving genomics knowledge, and the skills to integrate precision medicine into patient care. 1. **Increased comprehension of a consent chatbot for research exome sequencing via rapid iteration.** *T.J. Schmidlen<sup>1</sup>, M. Snir<sup>2</sup>, G. Snir<sup>2</sup>, E. Simmons<sup>2</sup>, H.L. Kirchner<sup>1</sup>, D.H. Ledbetter<sup>1</sup>, A.C. Sturm<sup>1</sup>.* 1) Geisinger, Danville, PA; 2) Clear Genetics, Inc. San Francisco, CA.

Chatbots are computer programs that conduct conversations with humans. Geisinger's MyCode<sup>®</sup> Community Health Initiative partnered with Clear Genetics, Inc. to develop a consent chatbot for a large research biobank returning clinically actionable exome sequencing results. The MyCode<sup>®</sup> consent chatbot walks patients through components of the consent allowing them to opt to receive more or less detail on key topics (goals, benefits, risks, etc.). The platform uses conditional expressions, natural language processing, machine learning, and search indexing to reply to user questions. A link to the chatbot can be sent via MyGeisinger patient electronic health record (EHR) portal, via text message, or by email. It runs on any web browser and works on smartphones, tablets and computers. The chatbot is designed to record the decision (consent, considering, decline) in the patient's EHR. Comprehension of key concepts conveyed by the chatbot was collected via a 14-item multiple choice quiz. A link to the chatbot and comprehension quiz were posted to Amazon's Mechanical Turk with parameters restricting participant demographics to mirror age, income and education level of Geisinger patients. After one round of testing with 101 users (Group A), results were reviewed and the chatbot was updated to address questions with average correct scores of  $\leq 75\%$ . A second group of 102 users (Group B) tested the updated chatbot and comprehension results were compared to Group A. Total average comprehension score for all 14 items was high (80% Group A, 85% Group B). Group A scored  $< 75\%$  correct on 6 questions on the type and timing of results returned, purpose of the chatbot, and access to health records. A summary recap was added at the end of the chatbot to address these topics. Group B reviewed the chatbot with the summary recap and per-question average scores improved to  $> 75\%$  for all but one question. Updating the chatbot to include a summary recap resulted in significantly improved comprehension ( $p=0.003$ ) of key elements of the MyCode<sup>®</sup> consent. The MyCode<sup>®</sup> consent chatbot presents an engaging, effective alternative to deliver content that can be challenging for patients to comprehend in traditional paper or in-person consent interactions. The quantitative nature of the chatbot platform allows for rapid learning and successful iteration to improve comprehension. Further patient engagement through focus groups, online surveys, and remote, unmoderated user testing is underway.

**Ethical review processes for bioinformatics research using human genome data: Analysis of specific requirements in the changing environment of personal data protection regulations.** *M. Kokado, H. Okui, K. Kato.* Graduate School of Medicine, Osaka University, Suita, Osaka, Japan.

With dramatic advances in genomic research technology, especially the development of global database frameworks and information communication technology (ICT), the bioinformatics or statistical genomics research are making rapid progress. With respect to data sharing ELSI, concerns about privacy and security are emphasized and various devices are under consideration (e.g. S. Wang et al, 2017). In Japan, it is stipulated that the human genome research will be conducted in accordance with human genome research guidelines which have been established by the government. What the guidelines consider is the human genome research that starts with the collection of samples such as tissue or blood. However, there are increasing number of research projects using human genome data that are stored in the genomic databases such as National Bioscience Database Center (NBDC). At Osaka University, among the approved projects by the University ethics review committee for human genome research, 11 ongoing protocols are of such type and 6 of them have been approved in 2017. It is an urgent matter to clarify elements necessary for IRB review of such research and to establish a better research ethics review process. At the same time, regulations for personal data protection have been revised in many parts of the world including EU and Japan. The Japanese legislation, the APPI (Act on the Protection of Personal Information), has been revised and came into force in May 2017. In this paper, we will describe the current discussion about ethical considerations in human genomic data sharing and ethics review requirements for the human genome informatics research. We have reviewed procedures of various ethics review committees in Japan by consulting some human genome informatics researchers and IRB staffs. We have found that the increase in the bioinformatics research or statistical genomics research has been giving difficulties for ethics review committee members, because the changing regulations for personal data protection are very specialized. We have also found that there is a need in the committee to establish a standardized procedure for reviewing these bioinformatics projects.

**618F**

**Frequency, characteristics, and impact of discordant lab to clinician genetic test result interpretation in a single pediatric medical center.** *C. Berrios<sup>1,5</sup>, C. Saunders<sup>1,2,5</sup>, J. Thiffault<sup>1,2,5</sup>, L. Willig<sup>1,3,5</sup>, E. Farrow<sup>1,4,5</sup>.* 1) Center for Pediatric Genomic Medicine, Children's Mercy, Kansas City, MO; 2) Department of Pathology and Laboratory Medicine, Children's Mercy, Kansas City, MO; 3) Department of Nephrology, Children's Mercy, Kansas City, MO; 4) Department of Pediatrics, Children's Mercy, Kansas City, MO; 5) School of Medicine, University of Missouri Kansas City, Kansas City, MO.

Interpretation of genetic variation remains a significant challenge to the field of clinical genetics. Efforts have been made to standardize lab interpretations, but ultimately clinicians returning results have the final responsibility for interpretation of genetic test results. A first step in learning how to best leverage both lab and clinician knowledge to improve variant interpretation and clinical care is determining the scope and factors behind discordant interpretations between labs and clinicians. This study seeks to determine the frequency, directionality, test characteristics, and clinical impact of discordant lab to clinician genetic test result interpretations in a single pediatric medical center. From the institutional molecular genetics lab database all sequencing tests ordered between April 2016 and March 2017 were pulled. Separate lists were compiled for those ordered by a medical geneticist and by other specialties. Each list was randomized and tests were sequentially pulled from the randomized list for chart review. Data collected included provider specialty, lab and clinician classification of each reported variant and overall result interpretation, and medical decisions based on the result. Those with zero variants reported or no documentation found of clinician interpretation were removed. To date, 52 tests ordered by non-genetic specialists have been reviewed, 7 were removed for zero variants and 8 for lack of documentation. Of the 37 remaining for analysis, a non-diagnostic or indeterminate lab result was interpreted by the clinician as diagnostic in 3 cases and a diagnostic lab result was interpreted by the clinician as non-diagnostic in 2 cases, for a total of 13.5% discordance in overall result interpretation. Discordant interpretation occurred in 15.4% of send out and 12.5% of internal tests reviewed, and in 14.2% of panels and 9.1% of exomes. Each affected clinical care; impacting treatment recommendations (2), screening tests (1), and recurrence risks (5). The data suggests that discordance between lab and clinician genetic test result interpretation is not uncommon, but larger studies from varied institutions are needed to better understand the frequency and impact. Studies on the reasons for discordance will allow the development of strategies to leverage each group's knowledge to improve interpretation, ensure appropriate medical care, and avoid patient confusion.

**619T**

**Assessing the genetic literacy of the general population: A literature review.** *N. Akiyama<sup>1</sup>, M. Nishigaki<sup>2</sup>.* 1) Center for Medical Genetics, Chiba Children's Hospital, Chiba, Japan; 2) Human Health Sciences, Graduate School of Medicine, Kyoto University, Kyoto, Japan.

[Background] Owing to the recent developments in genome analysis technology, genetic testing has become broadly available. Understanding its meanings and related ethical issues would enable the general population to make informed decisions, after obtaining sufficient information. However, the minimum genetic/genomic literacy level that is required in the general population has not been defined clearly. [Aim of the study] We aimed to conceptualize contents of genetic literacy (genetic/genomic literacy) and their evaluation methods in the general population. [Method] We gathered and examined reports that measured the genetic/genomic literacy of general citizens, high school students, and university students over the past 20 years; the literature search was carried out using the following four databases: PubMed, Web of science, Scopus, and ICHUSI (Japanese database for medical literatures). The abstracts of the paper, obtained as a result of the search, were screened and thoroughly reviewed. [Result] We obtained 36 articles that served our purpose. These were largely grouped into those targeting the general population and those targeting the high-risk group of individuals with specific diseases. Genetic/genomic literacy was defined as the ability to perform the following tasks and measured: (1) understand genetic terms/phenomena, (2) use genetic knowledge, and (3) recognize genetics as a familiar event. [Discussion] Genetic/genomic literacy should enable the general population to: (1) understand the terms and phenomena related to heredity and genetic testing, (2) think about the expected results of the test, and (3) explore and discuss related ethical, legal and social issues. Initiatives to improve genetic/genomic literacy should focus on not only increasing genetic knowledge, but also providing opportunities to understand how new technologies can affect our lives actually.

**Are we understanding each other? Early lessons from recruiting non-English speaking families for a study investigating the utility of WES in underserved populations.** *B. Anguiano, S. Ackerman, J. Harris-Wai, H. Hoban, B. Lianoglou, M. Norstad, S. Outram, N. Rangwala, S. Rego, N. Sahin-Hodoglugil, B. Koenig.* UCSF, San Francisco, CA.

The Clinical Sequencing Evidence-Generating Research network is a national NIH-funded consortium that investigates the utility of genomic sequencing in diverse patient populations. The project encompasses six clinical sites, including the University of California, San Francisco, whose Program in Prenatal and Pediatric Genomic Sequencing (P3EGS) studies the clinical and personal utility of whole exome sequencing for children and pregnant women with suspected genetic conditions. Many prospective participants are monolingual Spanish speakers and the majority of clinical and research staff are not fluent in Spanish, necessitating a reliance on in-person or phone-based medical interpreters. The cultural and linguistic differences that characterize these encounters present unique challenges to recruitment in clinical settings. We elucidate the challenges encountered by the P3EGS in recruiting monolingual Spanish-speakers and outline initial strategies used to improve communication. Challenges include interpreters' lack of knowledge of genetic terminology, additional time required for an interpreted conversation with families, and increased likelihood of misapprehension when discussing complex topics such as insurance coverage, results interpretation, uncertainty, secondary findings, data sharing, and genetic discrimination. Strategies used to help overcome these barriers include a) a bilingual member of the team working directly with patients and families to assess the clarity and cultural appropriateness of professional interpretation and translated study materials, and b) observations of bilingual study enrollment sessions to assess the impact of professional medical interpretation on families' understandings of the research project and decisions about whether to participate. Insights gained were used to develop and refine English and Spanish-language study brochures tailored to prenatal and pediatric clinical settings, including reducing technical jargon and translating specific words to be comprehensible to a wide range of Spanish-speaking families. Preliminary findings suggest that more formal stakeholder engagement efforts with monolingual Spanish-speakers could be of benefit to the study. Further research is also needed to assess the experiences of non-English speaking participants to ensure they receive comprehensible information for complex clinical tests such as genomic sequencing.

**621T**

**High throughput counseling: A model for genetic testing results disclosure and patient management.** A. Arjunan, R. Ben-Shachar, J. Kostialik, G. Lazzarin, K. Johansen Taber. Counsyl, South San Francisco, CA.

**Objective:** As the availability, uptake, and complexity of genetic testing expands in the general obstetrics setting, primary care providers increasingly must offer genetic services. Non-invasive prenatal screening (NIPS) and expanded carrier screening (ECS) have dramatically widened the scope of information available to patients and providers alike, underscoring the importance of timely results delivery. We describe an automated system that utilizes online education and tele-genetic counseling to aid women's health professionals in effectively delivering genetic testing results. **Methods:** Providers were notified upon availability of patient results. For ECS results indicating a high reproductive risk, patients received an automated email directing them to schedule a consultation with a laboratory-based genetic counselor. Screen-positive NIPS results were delivered to the ordering provider, who could request that a laboratory-based genetic counselor contact the patient. All other results could be viewed directly by the patient in an online portal and were accompanied by written and video resources. Regardless of result type, patients had the option to speak to a genetic counselor, either on-demand or by scheduling an appointment. **Results:** Through December 2017, 278,318 ECS results and 67,122 NIPS results were issued via the system. Of this cohort, 41,050 (15%) ECS patients and 4,673 (7%) NIPS patients elected genetic counseling, resulting in a total of 47,793 consultations. Interestingly, many of the genetic consultations (50% for ECS and 95% for NIPS) were requested by patients who received negative results. Regardless of result type, patients frequently utilized on-demand services (32% of ECS consultations and 70% of NIPS consultations). Median consultation duration was ten minutes and nine minutes for ECS and NIPS results, respectively. The mean patient satisfaction rating for consultations was 4.9/5.0. **Conclusion:** The automated system provides large-scale prenatal genetic testing results delivery, education, and counseling consistent with clinical guidelines. These services are imperative to quality clinical care as genetic testing uptake grows among the general obstetric population.

**Precision medicine & genomic education for clinicians: Effectiveness of a novel online CME program.** E. Edelman<sup>1</sup>, P. Tanner<sup>1</sup>, L. Nicholson<sup>2</sup>, S. McConnell<sup>3</sup>, T. Ingram<sup>1</sup>, L. Steinmark<sup>1</sup>, K. Johansen Taber<sup>4</sup>, K. Reed<sup>1</sup>. 1) Genomic Education, The Jackson Laboratory, Bar Harbor, ME & Farmington, CT; 2) Scripps Translational Science Institute, La Jolla, CA; 3) American Medical Association, Chicago, IL; 4) Counsyl.

**INTRODUCTION** A number of challenges limit the integration of genomic technologies into patient care, one of which is the gap in genetics knowledge and skills among healthcare providers (HCPs). Indeed, HCPs have called for education to help navigate genomic testing decisions. While some education resources are available covering various genomic topics, evidence of the effectiveness or quality of such programs is limited. **OBJECTIVE** This study describes the development and evaluation of a novel genomics CME program. **METHODS** The Jackson Laboratory, American Medical Association, and Scripps Translational Science Institute developed "Precision Medicine for Your Practice," a 12-module, interactive online program that aims to help HCPs appropriately incorporate emerging genomic tests into patient care. The program framework was designed using adult education best practices such as patient-centered cases, skill-based practice, self-directed learning, expert feedback, and scaffolded instruction. Content was developed with input from target audience members and genetic experts. Modules were developed and disseminated on a biannual basis starting in 2016. The first five modules address: expanded carrier screening (M1), prenatal cell-free DNA (cfDNA) screening (M2), exploring somatic cancer panel testing (M3), interpreting somatic cancer panel results (M4), and genomic testing for the healthy patient (M5). M6-12 are in development and address diagnostic exome testing, pharmacogenomics, cardiogenomics, and neurogenomics. **RESULTS** As of 3/2018, 689 users enrolled in at least one module. M1 had 194 users, M2 142, M3 288, M4 160, and M5 136. 37% of users were physicians, 11% masters- and 7% bachelors-level nurses, 6% physician assistants, 6% genetic counselors, and 5% scientists. Among users who completed CME evaluations (32%), the average rating for the program was 4.5/5. After taking the program, 94% believed they were able to identify appropriate candidates for tests and interpret results for patient management. **CONCLUSION** Our approach to developing Precision Medicine for Your Practice was effective in helping HCPs of diverse backgrounds build skills around genomic testing. This program supports HCPs using genomic testing to identify preventative measures and treatments for appropriate patients, which can lead to improved patient outcomes. These findings can be used to further disseminate existing modules and also serve as a needs assessment for future education efforts.

**How is meiosis taught in high school? A critical gap for students.** *D.L. Newman<sup>1</sup>, G.E.C. Dy<sup>1,2</sup>, L.K. Wright<sup>1</sup>*. 1) School of Life Sciences, Rochester Institute of Technology, Rochester, NY; 2) Department of Biology, Washington University, Seattle, WA.

Understanding meiosis is essential for students, researchers, and practitioners in the field of genetics. While instruction on meiosis often begins in the middle school years, many students continue to struggle with these concepts throughout their undergraduate training. The DNA triangle framework (Wright et al, 2018), which links the chromosomal, molecular, and informational levels of DNA, can be used to conceptualize three important facets of meiosis: ploidy, homology, and homologous pairing. Previous work demonstrated that experts (university faculty) are able to appropriately integrate the molecular and informational levels of DNA to explain homology, integrate the chromosomal and informational levels to explain ploidy, and integrate the chromosomal and molecular levels to explain homologous pairing. Undergraduates, however, struggle to integrate multiple levels of DNA knowledge, especially at the molecular level. To better understand why this gap in molecular knowledge is so widespread, we interviewed 14 high school Biology teachers (experience ranging from 2 to 26 years) about their own mental models and their approaches to teaching meiosis. Perhaps not surprisingly, teachers held many of the same misconceptions documented in undergraduate biology majors. Analyzing the interview data through the lens of the DNA triangle, we found that the majority of teachers (11 of 14) did not incorporate *any* molecular-level knowledge into their own explanations of meiosis, and *none* emphasized DNA structure during meiosis instruction. Homology, for example, was explained at the chromosomal (same size and shape) and informational (same genes) levels, but not the molecular level (nearly the same sequence of DNA nucleotides). Analysis of 20 lesson plans about meiosis yielded similar results: instruction focused on the chromosomal and/or informational levels but *never* on the molecular level. During interviews, several teachers explicitly acknowledged the separation between instruction about DNA (i.e. structure and complementary base-pairing) from lessons on meiosis. While this work suggests a critical gap in the high school biology curriculum, it also highlights an opportunity to offer new professional development opportunities for high school teachers and curriculum developers. These results also partially explain why many undergraduate biology students have difficulty thinking about complex processes like meiosis at the molecular level.

**A teaching vignette: Our experience incorporating personalized pharmacogenetic testing into the PharmD curriculum.** *S.S. Oh<sup>1</sup>, R. Ta<sup>2</sup>, J. Sims<sup>2</sup>, J. Tinajero<sup>2</sup>, A. Liu<sup>2</sup>, T. Desai<sup>3</sup>, B.J. Guglielmo<sup>2</sup>, S. Guo<sup>3</sup>, A.H.B. Wu<sup>4</sup>, E.G. Burchard<sup>1,3</sup>*. 1) Medicine, UC San Francisco, San Francisco, CA; 2) School of Pharmacy, UC San Francisco, San Francisco, CA; 3) Bioengineering and Therapeutic Sciences, UC San Francisco, San Francisco, CA; 4) Laboratory Medicine, UC San Francisco, San Francisco, CA.

The popularity of direct-to-consumer genetic testing products and efforts to incorporate precision medicine in clinical practice place additional educational demands on providers. The utility of genomic data and their use in daily clinical practice depend on providers' knowledge and ability to interpret the data. However, the low prevalence of pharmacogenomics-related education in professional school curricula may hinder the acceptance of precision medicine in clinical practice. We therefore began to enhance pharmacogenetic (PGx) education by making it more personal. All first-year pharmacy students at the University of California, San Francisco are required to take Biopharmaceutical Sciences (BPS) 115 ("Genetics and Pharmacogenetics"). We piloted personalized PGx testing in 2013, when 22 BPS 115 students volunteered to be genotyped for pharmacogenomic variants in *CYP2C19*, a gene critical for drug metabolism. Course instructors devoted a "Reveal Day" lecture to review volunteers' allele distributions and the clinical implications of *CYP2C19* variants on drug metabolism. A qualitative evaluation of this pilot showed that students unanimously valued personalized PGx testing and enthusiastically encouraged its use as teaching material in future courses. We have since incorporated personalized PGx testing into BPS 115, and students' voluntary and anonymous participation in genotyping has increased. In 2017, we used 23andMe kits after receiving a grant to fund enough kits for the entire first-year class. Students are instructed on how to abstract their raw genetic data to interrogate PGx-related genes. The genome-wide SNP data allow us to test substantially more PGx genes and examine the influence of genetic ancestry on PGx. A major Reveal Day component now includes student-led activities such as role-playing patient/pharmacist and pharmacist/provider relationships using PGx test results. The role-plays have evolved in complexity and allow students to incorporate skills they are learning concurrently (e.g., motivational interviewing and navigating the subtleties of inter-professional relationships). We have shown that incorporating personalized PGx testing into the first-year PharmD curriculum leads to significant increases in knowledge (+1.0 Likert points) and more favorable attitudes (+0.3 Likert points) toward PGx and precision medicine. Our experience supports the use of personalized PGx testing as a teaching tool.

**Review of the current status of clinical practice guidelines in Japan for returning individual research results on genetic diseases.** *Y. Aizawa, F. Nagami.* Tohoku Medical Megabank Organization, Tohoku University, Japan.

We explored clinical practice guidelines for genetic diseases in Japan and studied the genomic information selection criteria for the return of individual research results. In 2013, the American College of Medical Genetics and Genomics (ACMG) had proposed a list of specific genes underlying medically actionable diseases for sequencing in clinical settings as secondary findings; the list has since been updated. Since the list was tailored for the United States, it needs to be carefully examined for applicability in other countries. In case researchers wish to return the genomic results to participants, it would be necessary to choose returnable genomic information in the research project. In Japan, we are on the path to develop a practical guideline regarding return of genomic results in research settings. Toward that, we compared the description of genetic diseases in Japanese clinical practice guidelines with that in the 59-gene list proposed by ACMG. We categorized the 59 genes into 32 diseases, and searched for published guidelines on the web to examine the description regarding each genetic disease, including clinical characteristics, diagnosis/genetic testing, and management. We could find at least one guideline for all diseases. These guidelines were developed during 2010 to 2018. Guidelines regarding half of the diseases provided comprehensive description, but that for few others mentioned only the clinical characteristics. Approximately 90 % of the diseases had at least one guideline mentioned about genetic testing; 80 % of the diseases had at least one guideline mentioned about genetic counseling. Approximately half of the diseases had at least one guideline mentioned regarding relatives at risk or pre-symptomatic individuals. There was a variety of descriptions about diseases, since their prevalence varied greatly. Taken together, our findings suggested that it is important to gather updated information regarding each genetic disease, in addition to understanding the basic information from clinical practice guidelines. Therefore, we propose the need to consider genomic information selection criteria with respect to the health system of each country, and recommend additional discussion regarding the return of genomic research results for developing a practical guideline in Japan.

**626F**

**Direct-to-consumer genetic testing for factor V Leiden and prothrombin 20210G>A: the consumer experience.** *S.L. Elson<sup>1</sup>, N.A. Furlotte<sup>1</sup>, B.S. Hromatka<sup>1</sup>, C.H. Wilson<sup>1</sup>, J.L. Mountain<sup>1</sup>, H.M. Rowbotham<sup>1</sup>, E.A. Varga<sup>2</sup>, U. Francke<sup>1,3</sup>.* 1) 23andMe, Inc., CA; 2) Nationwide Children's Hospital, Columbus, Ohio, USA; 3) Stanford University Department of Genetics, Stanford, California, USA.

**Background:** Variants in clotting factor genes are responsible for inherited predisposition to venous thromboembolism (VTE), a condition characterized by formation of blood clots in veins. The two most common genetic risk factors for VTE are factor V Leiden in the *F5* gene, and prothrombin 20210G>A in the *F2* gene. There is limited consensus about which individuals should be tested for these two variants to inform treatment and prevention decisions. Given a gap between clinical guidelines for testing and consumer and public health organizations' interest in greater awareness of the condition, we examined the impact of direct-to-consumer (DTC) testing for VTE risk. **Methods:** 2114 customers (1136 mutation-positive cases and 978 mutation-negative controls) of the personal genetics company 23andMe, Inc., who had received results online for *F5* and *F2* variants prior to November 2013 and had consented to participate in research, participated in a survey-based study to assess sharing of test results with health care providers and family members, lifestyle changes based on testing, and emotional responses to testing. **Results:** Most participants (approximately 90% of cases and 99% of controls) had not previously had testing for *F5* or *F2* variants. Cases were more likely than controls to have a personal history of VTE, and most demonstrated understanding, based on their 23andMe results, that they were at higher than average risk for developing a VTE. More cases than controls reported (1) sharing their results with family and health care providers (35% versus 5%), (2) receiving lifestyle recommendations (31% versus 14%), and (3) making behavioral changes (*e.g.*, taking steps to lose weight [25% versus 10%]; exercising more [30% versus 12%]) after receiving results. Both cases and controls were satisfied knowing their genetic probability for VTE (81% and 67%), and nearly all participants said they would choose to learn their genetic risk for VTE if given the option again. **Conclusion:** Individuals who received positive results for *F5* or *F2* variants were satisfied with having this knowledge and report sharing results with others and making positive behavioral and lifestyle changes.

**Engaging diverse communities with facilitated deliberation: Stakeholder perspectives from the Alabama Genomic Health Initiative.** *S.J. Knight<sup>1</sup>, G.S. Barsh<sup>2</sup>, K.M. Bowling<sup>2</sup>, A. Cannon<sup>1</sup>, J.J. Cimino<sup>1</sup>, G.M. Cooper<sup>2</sup>, W.A. Curry<sup>1</sup>, K. East<sup>2</sup>, J. Edberg<sup>1</sup>, M. Fouad<sup>1</sup>, A.C. Hurst<sup>1</sup>, M. Might<sup>1</sup>, T. May<sup>2</sup>, I.P. Moss<sup>1</sup>, M. Nakano<sup>1</sup>, J.H. Schach<sup>1</sup>, B.M. Shaw<sup>1</sup>, S.O. Sodeke<sup>3</sup>, S. Hardy<sup>1</sup>, E. Miskell<sup>1</sup>, J.L. Richards<sup>1</sup>, B.R. Korff.* 1) University of Alabama at Birmingham, Birmingham, AL; 2) HudsonAlpha Institute for Biotechnology, Huntsville, AL; 3) Tuskegee University, Tuskegee, AL.

The Alabama Genomic Health Initiative (AGHI) is a population-based program designed to return results of medically-actionable genomic variants to 10,000 adult volunteers residing in all 67 counties of the state. Engaging urban and rural Alabama residents in genomic research has required a multi-level strategy to understand perspectives from community members, community and state leaders, clinicians, and healthcare system executives and managers. We are employing a novel approach, facilitated deliberative process meetings, to understand the wide range of expectations, needs, and priorities of stakeholders from Alabama communities. We have convened two meetings to date, one in northern and the other in central Alabama. Stakeholders attended along with AGHI researchers. The facilitated deliberative process included education and opportunities to ask questions of AGHI scientists and clinicians. We invited participants to offer recommendations for AGHI action on two topics: 1) Challenges of recruitment of underrepresented populations in biomedical research and 2) Value of return of genome sequencing results. Participants voted to establish the priority of action items. A total of 67 stakeholders and researchers attended the two 2.5 hour meetings. There was greater representation of whites (69%) at the northern location and African Americans (83%) at the central site. Despite initial concern about trust and privacy, the discussions indicated a strong interest in AGHI and receiving results from genome sequencing. Suggestions to expand enrollment in rural regions included offering "pop-up" clinics in remote areas, partnering with local businesses and schools, and using existing community health models and resources for outreach. Both groups indicated that waiting to receive results might be a time of anticipation and anxiety for participants. Stakeholder priorities were rapid return of results, expectations about timelines, support during the waiting period, and attention to literacy in informational materials. One group emphasized the importance of ensuring that participants understand the implications of negative results and both groups stressed sensitivity to participant needs and the setting when providing information. Facilitated deliberative process provides a way to understand perspectives on genomic research held by diverse communities. These meetings have informed AGHI recruitment and return of results, and ultimately, will inform dissemination of findings.

**ELSI research on the use of electronic methods for participant engagement in medical research: Analysis from the perspective of ethical principles.** *A. Kogetsu, K. Kato.* Department of Biomedical Ethics and Public Policy, Graduate School of Medicine, Osaka University, Suita, Japan.

**[Background]** Recently, with the increase in the amount of data and the development and dissemination of ICT, electronic methods utilizing online systems are expected to be used for medical research. Electronic methods can be used for processes especially of the participant engagement in medical research. In addition, new projects which depend on electronic methods such as medical research using wearable devices or medical big data that accumulate in the medical facilities are also under development. However, it is not clear what kind of problems could arise when electronic methods are implemented for medical research. **[Objective]** To identify the benefits and problems associated with electronic methods for participant engagement in medical research and to examine its theoretical background. **[Method]** We divided participant engagement into four steps (i.e. recruitment, informed consent, provision of samples and data, and return of research results) and identified following points based on the eight principles of ethical clinical research<sup>1)</sup>: 1) what kind of ELSI would be solved (i.e. benefit brought by electronic methods) and 2) what are the ELSI to be addressed when electronic methods are implemented? **[Result]** Electronic methods can be useful for solving following ELSI: temporal and spatial constraints of research participation, return of research results to participants, informed consent on secondary usage of data, guarantee of the right for participants to refuse to participate or to withdraw their consent, and establishing collaborative partnership. However, the major points of ELSI that should be addressed when using electronic methods are: 1) digital divide for those unfamiliar with ICT and bias associated with it, which are revealed by the principles of social value and fair participant selection, 2) privacy protection and transparency of data which are based on the principle of respect for participants, and 3) confirmation of understanding of participants and appropriate presentation of information which are associated with the principle of informed consent. **[Discussion]** Although electronic methods can give effective means to exiting ELSI in the current medical research, it will generate other ELSI. Addressing such issues appropriately will lead to better medical research. **[References]** [1] Emanuel, E. J., Wendler, D., & Grady, C. (2008). An ethical framework for biomedical research. The Oxford textbook of clinical research ethics, 123-135.

**629T**

**TAG: A rapid assessment tool of genetic literacy.** *H. Milo Rasouly, N. Cuneo, J.J. Thompson, M. Marasa, J. Wynn, M. Verbitsky, G. Hripacsak, C. Weng, P. Appelbaum, W.K. Chung, S.R. Bakken, A.G. Gharavi.* Columbia University, New York, NY.

**BACKGROUND:** As genetic testing is being offered more frequently, general public awareness of genetics' concepts is desirable. Knowledge of an individual's baseline genetic literacy (GL) may facilitate the informed consent and the return of results process by tailoring sessions to each individual's understanding and expectations. Currently, there are no rapid, self-administered, validated tests to assess GL. **METHODS:** As part of the eMERGE consortium (Electronic MEDical Records and GENomics), we recruited a diverse cohort of 1132 individuals for genetic testing for a targeted panel of 68 medically actionable genes. The informed consent process was administered by a team of trained clinical research coordinators, and all participants were asked to answer a 56-item questionnaire, including questions about education, health literacy, numeracy and the Terms Associated with Genetics test (TAG), a new GL test developed for this study. TAG is a term-recognition quiz informed by the METER (Medical Term Recognition Test) health literacy format, which includes genetic-specific words and pseudo-words, and can be completed in under two minutes. Its content validity was established through expert review. **RESULTS:** 69% of the participants completed the questionnaire. TAG construct validity was supported by the known groups differences (education, health literacy and self-reported genetic knowledge), and concurrent measures techniques (four genetic knowledge questions). TAG identified 262 (34%) individuals as having low GL. Independent of education level, health literacy, and numeracy, low GL was significantly associated with lower satisfaction from the informed consent process ( $p < 0.005$ ), unrealistic expectations about genetic testing ( $p < 0.005$ ), and limited understanding of the legal protections against genetic discrimination ( $p < 10^{-6}$ ). Ten common genetic terms that providers may use in interactions with patients, including *actionability*, *pathogenicity* and *penetrance*, were not recognized as real words by the majority of the participants. **CONCLUSION:** The TAG test provides a simple method to identify individuals with low GL. We showed that low GL compromises the informed consent process and is associated with unrealistic expectations about genetic testing and lack of awareness of the limitations of legal protections. With the benefit of being a rapid and self-administered evaluation, it can inform future studies of GL and implementation of genetic testing in the clinic.

**Ancestry isn't the past, it's the future: Human genetics research and race.** *V. Moreno.* Anthropology, San Francisco State University, San Francisco, CA.

This pilot study seeks to understand why scientists continue to use race as a proxy in their scientific research, and to explore the other forms and techniques geneticists use to study or classify race. Interviews were conducted with ten geneticists from the University of California, San Francisco to solicit their views on the scientific validity of race, the ethical implications of classifying race, and the emerging significance of ancestry in genetic science. As these interviews revealed, the requirements to receive funding from federal institutions influence scientists' use of racial classifications. To ensure diversity and follow OMB Directive 15, many scientists report their findings using the racial classifications described in the directive. However, a majority of the participants opt for using "ethnicity" or "populations" as a term for the genetic groups they study in their published research in order to present their findings in a more socially conscience approach. Options for geographic origin of ancestors along with selected race and ethnicity are included in the self-identification process of research participants, since scientists wish to utilize this information subsequently in their scientific research. Grouping large populations according to similar genetic ancestry is performed using the technique of Ancestry Informative Markers (AIMs), a more accurate form of categorization and replacement of referring to racial categories. Thus, AIMs and the transition to increasingly descriptive self-identification reporting demonstrates a progressive approach to studying race; though, socioeconomic, cultural, and environmental factors should receive more attention for their effects on health in human genetics research.

**Survey on the perception of germline genome editing among the general public in Japan.** *K. Muto<sup>1,2</sup>, A. Ngai<sup>1</sup>, M. Uchiyama<sup>2</sup>.* 1) The Institute of Medical Science, The University of Tokyo, Tokyo, Japan; 2) Graduate School of Frontier Sciences, The University of Tokyo, Chiba, Japan.

Genome editing of human embryos could become a fundamental treatment approach for genetic diseases; however, technical and ethical issues need to be resolved before its application in clinical settings. Presently, the Japanese government has issued a statement prohibiting human germline editing and emphasizing the need for discussions that include a wide range of perspectives. However, we need to consider how to involve the general public in discussions. Therefore, we conducted online surveys independently in 2017 (N=10,881) and 2018 (N=10,739) in Japan who indicated that their disease conditions are related to their genetic makeup, and clarified their attitude toward this technology. The results clearly indicated that the Japanese people generally accepted the use of genome editing for disease-related genes, and this trend was higher in 2018. However, many were concerned about the risks. In addition, many Japanese people did not understand the technology well. To improve awareness and understanding about genome editing, it is important that scientists and science communicators create opportunities for the public to participate in relevant discussions without harming vulnerable participants. It is also important to continuously track changes in the acceptance of genome editing by the public.

**632F**

**Return of genomic results in the research context – review of the global situation.** *F. Nagami, Y. Aizawa.* Tohoku Medical Megabank Organization, Tohoku University, Sendai, Miyagi, Japan.

In the past decade, the appearance of next-generation sequencing (NGS) has drastically reduced the time and cost of sequencing individual genomes. Many cohort or biobank studies perform genomic analyses, including whole-genome and exome sequencing, using NGS, and millions of personal genomes have been read. During the same period, the commercial 'direct-to-consumer' services that provide genomic data have flourished. Thus, receiving genomic results has become a normal occurrence for the public. However, for research projects, the return of genomic results has remained difficult and infrequent and the global situation remain uncharacterized. Here, we performed a review on the return of genomic results obtained from research projects and found such returns to still be rare. We systematically reviewed literature from two years (2016-2017) obtained from the public databases, among around extracted 500 articles on return of genomic results, we found that only 27 articles mentioned actual returning in the research context. Of these 27 articles, 22 projects aim or plan to return genomic results to the participants. Those articles were not confined to specific countries, but were distributed across United States, Britain, Canada, Sweden, Estonia, Singapore, Germany, Australia, Switzerland, and Japan. These projects belonged to various categories, such as basic research using biobank samples, research aimed to increase the clinical usage of genomic information, return of secondary findings from the research with cancer patients, etc. Some projects published the gene list of return, and many projects referred to the list issued by American College of Medical Genetics and Genomics (ACMG) in 2013, the only list published by the public organization. The ACMG list was designed for clinical purpose but it still seems to be useful for research projects. In conclusion, the number of research projects that sequence personal genomes is increasing; however, our review reveals that a very limited number of projects are willing to return genomic results to participants. The literature survey indicates that the process for returning genomic results from each research project is burdensome. However, public awareness regarding the use of genome information is growing. Thus, the return of genomic results is gaining significance. The early attempts by the projects reviewed here to return genomic results will provide insights into the logistics and management of return of genomic data.

**633T****Airmen's attitudes toward genomic sequencing in the US Air Force:**

**Results from the MilSeq Project.** *D.K. Petersen<sup>1</sup>, S. Pereira<sup>1</sup>, J.O. Robinson<sup>1</sup>, R.L. Hsu<sup>1</sup>, M. Majumder<sup>1</sup>, E. Parasidis<sup>2</sup>, M. Mehlman<sup>3</sup>, K. Christensen<sup>4</sup>, M.D. Maxwell<sup>4</sup>, C. Blout<sup>4</sup>, M. Lebo<sup>5</sup>, R. Brenner<sup>6</sup>, C. Gardner<sup>7</sup>, M. De Castro<sup>8</sup>, R.C. Green<sup>8</sup>, A.L. McGuire<sup>8</sup>.* 1) Baylor College of Medicine, Houston, TX; 2) Ohio State University, Columbus, OH; 3) Case Western Reserve University School of Law, Cleveland, OH; 4) Brigham and Women's Hospital, Boston, MA; 5) Partner's Personalized Medicine, Cambridge, MA; 6) AFMS Personalized Medicine, Falls Church, VA; 7) Joint Base San Antonio - Lackland AFB, JBSA-Lackland AFB, TX; 8) Keesler AFB, Keesler Air Force Base, MN.

Genomic sequencing (GS) in active-duty military healthcare settings comes with a unique set of considerations. GS has the potential to return information that may impact a service member's perceived mission-readiness, duty assignments, and career. Although scholars have commented on this issue, little is known about the perspectives of those serving in the military. The MilSeq Project is a pilot study investigating the use of GS in the clinical care of apparently healthy, active-duty Airmen (n=75) in the United States Air Force (USAF). Participants completed a baseline survey prior to enrolling in the sequencing study. Here we describe Airmen's baseline attitudes towards the use of GS in the USAF, including perspectives on hypothetical testing for non-disease traits. The majority of participants reported that they trusted the Air Force with their genetic information (79%) and expected that GS would not influence their career (89%). However, participants were largely neutral or negative toward hypothetical scenarios in which the USAF would require all Airmen to undergo GS (55%, 24%, respectively), as well as using genetic information to make decisions about deployment (60%, 34%) or duty assignments (66%, 29%). Most participants were supportive of hypothetical testing for traits that could affect duty performance. These included tolerance for sleep deprivation (76%), extreme environments (71%), and starvation (57%); personal traits such as injury recovery (81%), intelligence (76%), and impulsivity (58%); and mental health risks such as anxiety (73%), PTSD (68%) and substance abuse (66%). As technologies and our ability to understand complex traits improve, our results suggest that military members would generally be receptive to learning genetic information that could inform their risk for developing conditions that may affect their duty-related performance. Moreover, Airmen showed favorable attitudes about the use of GS in a US military setting when not used for deployment or assignment decisions. We discuss the implications of Airmen's perspectives on the breadth of uses of GS, as well as their views on when and how its information should be applied in the Air Force setting.

**634F****The EXCEED study: Practical issues in design and conduct of a recall-by-genotype resource.**

*N.F. Reeve<sup>1</sup>, C. John<sup>1</sup>, R. Hsu<sup>1</sup>, R.C. Free<sup>2</sup>, E.J. Hollox<sup>3</sup>, D.J. Shepherd<sup>1</sup>, L.V. Wain<sup>1</sup>, S.E. Wallace<sup>1</sup>, M.D. Tobin<sup>1</sup>.* 1) Health Sciences, University of Leicester, Leicester, Leicestershire, United Kingdom; 2) NIHR Leicester Biomedical Research Centre – Respiratory, Glenfield Hospital, Groby Road, Leicester, LE3 9QP, United Kingdom; 3) Department of Genetics and Genome Biology, University of Leicester, Leicester, United Kingdom.

Resources like UK Biobank provide exciting opportunities for large-scale genetics and genomics, but the translation of findings to the clinic is challenging. Recall-by-genotype studies have a high potential to contribute to such translation, facilitating a deeper understanding of genetic variants that have been identified in genome-wide association studies (GWAS) as being related to complex traits and diseases. This approach involves bringing back participants based on their genotype(s) for detailed assessments chosen on the basis of the known or suspected mechanism of the relevant gene. Such studies can be observational in design or interventional, for example to evaluate the response or safety profile of a treatment conditional on genotype. Recall-by-genotype studies are expected to be highly valuable for medicines development and targeting of therapeutics in a precision medicine approach, but also raise questions as to how best to manage the recall process while respecting participant wishes. A strongly related issue is that of disclosing potentially sensitive results to participants. We have established the Extended Cohort for E-health, Environment, and DNA (EXCEED) including the capability to recall participants by phenotype or genotype. EXCEED has a comprehensive participant consent form, with 12 questions covering topics such as access to medical records, recall- by-phenotype and -genotype, and receiving genetic results. So far, 9,600 participants aged 40 to 69 years have been recruited to EXCEED, primarily from primary care services in Leicestershire, UK. All participants provide baseline lifestyle data, a saliva sample for DNA extraction, and consent to link to their primary healthcare record, and to recall-by-phenotype and -genotype. Some studies incorporating genetic analyses (such as Genomics England) actively seek clinically actionable variants. Most cohort studies do not but researchers accessing the resource may in the future through their investigations. In anticipation of this potential, at the time of consent, we asked whether participants would wish to be notified about clinically actionable variants; 99.5% of participants stated that they would wish to be informed in this situation. Understanding the reasons for participants' preferences, how these may change over time and how these can best be supported by future policies and procedures will be of key importance for longitudinal cohort studies.

**635T**

**Privacy attitudes and information sensitivity perceptions are associated with health services utilization.** C.K. Rubanovich<sup>1</sup>, C. Cheung<sup>2</sup>, C. Schaire<sup>3</sup>, C.S. Bloss<sup>3,4</sup>. 1) San Diego State University/University of California San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; 2) The Qualcomm Institute, California Institute for Telecommunications and Information Technology, University of California San Diego, La Jolla, CA; 3) Department of Psychiatry, School of Medicine, University of California San Diego, La Jolla, CA; 4) Department of Family Medicine and Public Health, School of Medicine, University of California San Diego, La Jolla, CA.

**Introduction:** The current "big data" era is one in which voluminous and granular personal data are collected on individuals and then stored. Given that the current era is also one in which concerns about privacy are growing, this study sought to identify which types of personal data are considered sensitive and whether perceived sensitivities are associated with health services utilization. **Methods:** Participants ( $n = 102$ ) completed surveys including measures of sensitivity of personal information, privacy concern, and health services utilization as part of a larger study focused on privacy attitudes in relation to emerging health technologies. In terms of sensitivity of personal information, twelve types of personal data were rated on a scale of 1 to 10, from not at all to very sensitive. Health services utilization was measured using the Health Care Utilization scale from the Stanford Patient Education Research Center, which included the number of physician visits in the last six months. Descriptive analysis compared non-utilizers (0 physician visits) to utilizers (1 or more physician visits), and linear regression models sought to test the association between health services utilization and sensitivity ratings with age as a co-variate. **Results:** Overall, the most sensitive information types were: 1) bank account information ( $M = 9.63$ ,  $SD = 1.36$ ), 2) electronic health records ( $M = 8.29$ ,  $SD = 2.37$ ), and 3) genetic test results ( $M = 8.18$ ,  $SD = 2.62$ ). Compared to non-utilizers, health services utilizers rated ten out of the twelve types of personal data as more sensitive. Controlling for age, health services utilization significantly predicted sensitivity ratings of medication ( $p = .008$ ), state of health at present ( $p = .009$ ), fitness at present ( $p = .046$ ), medical history ( $p = .027$ ), addictions ( $p = .049$ ), and electronic health records ( $p = .027$ ). **Conclusions:** Prior health services utilization was significantly associated with perceived sensitivity of personal data for data types that are health-related in nature. These findings may help guide the design of systems that elicit patient preferences in sharing health data, for instance, systems that seek to leverage large patient electronic health record databases for research. More broadly, these findings can inform our understanding of individual differences in privacy attitudes and perceptions of personal data.

**636F**

**Attitudes towards genetic testing among participants in the Jackson and Framingham Heart Studies.** K.W. Saylor<sup>1</sup>, L. Ekunwe<sup>2</sup>, D. Antoine-Lavigne<sup>2</sup>, D.E. Sellers<sup>3</sup>, S. McGraw<sup>4</sup>, D. Levy<sup>5,6</sup>, G.L. Splansky<sup>6</sup>, S. Joffe<sup>7</sup>. 1) Department of Public Policy, University of North Carolina, Chapel Hill, NC; 2) The Jackson Heart Study, Jackson, MS; 3) College of Human Ecology, Cornell University, New York, NY; 4) The Hastings Center, Garrison, NY; 5) Framingham Heart Study, Framingham, NY; 6) Population Sciences Branch, National Heart, Lung and Blood Institute of the National Institutes of Health, Bethesda, MD; 7) Department of Medical Ethics and Health Policy, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.

**PURPOSE:** To identify research participant characteristics associated with positive and negative attitudes towards genetic testing. Findings can inform participant engagement and education. **METHODS:** Secondary analysis of survey data from participants in genetic testing components of the Jackson Heart Study (JHS,  $n=960$ , mean age=63, 66% female, 100% African American), Framingham Heart Study (FHS,  $n=955$ , mean age=58, 55.2% female, 99% white), and FHS-Omni Cohort ( $n=160$ , mean age=64, 62% female, 88% African American/11% mixed race). Three endpoints (a 3-item ordinal attitude scale, and positive and negative word scores based on a checklist of attitude descriptors) were dichotomized as close to the 25<sup>th</sup> percentile as the data allowed. Final logistic regression models include participant characteristics common to models with the lowest Akaike and Bayesian information criteria. **RESULTS:** Survey response rates were 67-73% across cohorts. Most participants had positive attitudes towards genetic testing (median score 4.3-5/5). Participants endorsed a median of 2 positive words and 0-1 negative words. "Hopeful" and "optimistic" were endorsed by 45-70% of participants, "enthusiastic", "excited", "mixed feelings", "concerned" and "cautious" by 25-55%, "confused", "indifferent" and "worried" by 6-16%, and "pessimistic" and "horrified" by 1-5%. Characteristics associated with favorable attitudes included: greater genetics knowledge and subjective numeracy (JHS); greater experience with genetic testing, subjective numeracy, and religious attendance (FHS); and not being employed (FHS-Omni) (see Table).

	JHS OR [95% CI]	p-value	FHS OR [95% CI]	p-value	FHS-Omni OR [95% CI]	p-value
<b><u>More negative attitude about testing</u></b>						
Experience with genetic testing			0.45 [0.23-0.90]	-0.023		
Genetics knowledge	0.87 [0.80-0.96]	-0.004				
<b><u>Endorse more positive words</u></b>						
Genetics knowledge	1.29 [1.16-1.43]	(<0.001)				
Subjective numeracy	1.28 [1.13-1.45]	(<0.001)	1.17 [1.04-1.31]	-0.008		
Not employed					2.15 [1.04-4.74]	-0.04
<b><u>Endorse more negative words</u></b>						
Subjective numeracy	0.88 [0.80-0.98]	-0.017				
Religious attendance			1.20 [1.04-1.38]	-0.012		

**CONCLUSION:** Attitudes towards genetic testing were generally positive among participants in two major cardiovascular cohort studies. Greater numeracy, and experience with and knowledge of genetics were associated with more positive attitudes. These findings can help researchers moderate excessive enthusiasm or skepticism about genetic testing.

**637T**

**Ethnic identity and intentions to learn results in an exome sequencing study.** E. Turbitt<sup>1,2</sup>, M.C. Roberts<sup>3</sup>, B.M. Hollister<sup>1</sup>, K.L. Lewis<sup>4</sup>, L.G. Biesecker<sup>1</sup>, W.M.P. Klein<sup>1,3</sup>. 1) Social and Behavioral Research Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA; 2) Bioethics Core, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA; 3) Behavioral Research Program, National Cancer Institute, National Institutes of Health, Bethesda, MD, USA; 4) Medical Genomics and Metabolic Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA.

**Background.** Ethnic identity is part of one's social identity, derived from both knowledge about membership of one's ethnic group, and the value and emotional significance related to that membership. Endorsement of strong ethnic identity has been associated with better health outcomes. With evidence of racial disparities in genetic testing and research, there is a critical need to better understand the experiences of participants in studies involving genome sequencing among racially diverse cohorts. Considering its association with various health related factors, studying ethnic identity in the context of genome sequencing studies may add to our understanding of these disparities. We examined the potential association of ethnic identity with beliefs about and intentions to learn results of genome sequencing. **Methods.** A longitudinal cohort was recruited to implement genome sequencing among healthy participants who self-identify as African, African-American, or Afro-Caribbean, aged 45-65 years old ( $n=408$ ). Before receiving sequencing results, participants completed a survey assessing a range of social and behavioral constructs related to health, genome sequencing and ethnic identity. Bivariate and moderation analyses were performed. **Results.** Stronger ethnic identity was positively correlated with anticipated value of sequencing results ( $r = 0.14$ ,  $p < 0.01$ ) and benefits from sequencing study participation ( $r = 0.15$ ,  $p < 0.01$ ), but negatively correlated with expectations for harms from sequencing study participation ( $r = -0.12$ ,  $p < 0.05$ ). For participants with stronger ethnic identity, there was a positive association of perceived value of results with intentions to receive results ( $b = 0.56$ , 95% CI: 0.24, 0.89,  $p < 0.001$ ); whereas for those with weaker ethnic identity, there was no such association ( $b = -0.093$ , 95% CI: -0.36, 0.17,  $p = 0.50$ ). **Discussion.** Individuals with stronger ethnic identity may attend more to the value of sequencing results when deliberating whether to receive results. The findings of our study highlight that investigators recruiting participants from diverse backgrounds should consider the influence of ethnic identity on participants' beliefs about sequencing participation and their intentions to receive genome sequencing results. In addition, understanding the variation in ethnic identity and its influence on genome sequencing perceptions and intentions can inform development of culturally-sensitive protocols for research and clinical applications.

**Repurposing of whole-exome sequencing data for personalized medicine.** M. van der Lee<sup>1</sup>, W.G. Allard<sup>2</sup>, A.H.B. Bollen<sup>3</sup>, G.W.E. Santen<sup>3</sup>, C.A.L. Ruivenkamp<sup>3</sup>, F. Baas<sup>3</sup>, M. Kriek<sup>3</sup>, H.J. Guchelaar<sup>1</sup>, S.Y. Anvar<sup>1,2</sup>, J.J. Swen<sup>1</sup>. 1) Department of Clinical Pharmacy and Toxicology, Leiden University Medical Center, Leiden, Netherlands; 2) Department of Clinical Genetics, Leiden University Medical Center, Leiden, Netherlands; 3) Department of Human Genetics, Leiden University Medical Center, Leiden, Netherlands.

**Background** Whole exome sequencing (WES) is currently used on a wide scale within academic patient care. The resulting genetic data includes complementary information on pharmacogenetic (PGx) variants that could be used to optimize drug treatment where applicable. It allows personalized medicine rather than the established 'one size fits all' approach to prescribing drugs. Two consortia, the Dutch Pharmacogenetics Working Group (DPWG) and the Clinical Pharmacogenetics Implementation Consortium (CPIC), together provide therapeutic recommendations for more than 50 gene-drug pairs for patients with a known genotype. We set out to develop a new strategy to implement PGx screening into the routine genetic workflow and to combine this data with medication records and the DPWG guidelines. **Methods** From the DPWG guidelines, 45 actionable variants in 13 key pharmacogenes were selected for retrieval from WES data in a cohort of 500 child-parent trios. A trio based analysis was done to resolve phasing and identify *de novo* variants. Translation of variant-to-haplotype and haplotype to drug-metabolizer phenotype was done according to the DPWG guidelines. Medication records of included patients were matched to the drug-metabolizer-phenotypes based on specific codes for each pharmaceutical compound (ATC codes). **Results** 89% of the subjects carried at least one actionable variant, the majority carried at least 2 actionable variants (58.6%). Five variants were located in intronic or promoter regions which lacked coverage in WES data, leading to an inability to genotype HLA-A and HLA-B, and in many cases UGT1A1 and CYP2C19\*17. We had access to medication records for 351 (23.4%) subjects, of whom 4.8% were exposed to a gene-drug interaction requiring a drug change or dose adjustment, of which the majority were with analgesics (76.5%). **Conclusion** This study shows the feasibility of repurposing WES data for PGx purposes. It identifies actionable PGx variants in almost 90% of the study cohort. Due to the limitations of WES data, variant coverage in intronic regions and the detection of Copy Number Variants, these numbers are an underestimation of the true number of actionable variants. The next step will be the implementation of this method as a routine pre-emptive approach into the genetic diagnostic setting, which will aid the use of PGx based prescribing in clinical practice.

**An innovative software to scale genetic counseling needs in a time of increasing demand.** G. Snir<sup>1</sup>, L. Diskin<sup>2</sup>, N. Shrier-Shafir<sup>3</sup>, Y. Segal<sup>2</sup>, B. Chen M.<sup>3</sup>, M. Mizrahi<sup>2</sup>, S. Alboim<sup>2</sup>, S. Katz<sup>2</sup>, D. Cohen<sup>2</sup>, A. Golan<sup>2</sup>, M. Berger<sup>2</sup>, A. Beit-Or<sup>2</sup>, V. Nadler<sup>2</sup>, T. Wolf<sup>2</sup>, V. Katalan<sup>2</sup>, N. Ash<sup>2</sup>, Y. Wolf<sup>2</sup>, M. Snir<sup>1</sup>, H. Baris-Feldman<sup>3</sup>, M. Shohat<sup>1,2,4</sup>. 1) ClearGenetics, San Anselmo, CA; 2) Maccabi Health Services, Tel Aviv, Israel; 3) Meuhedet HMO, Tel Aviv, Israel; 4) Sackler School of Medicine, Tel Aviv University, Israel.

Increased prenatal testing options combined with limited genetic counseling personnel and short OB visits, present a challenge in delivering genetic counseling. We have introduced an innovative software to improve identification of high risk pregnancies and expedite access to genetic counseling in two HMOs in Israel. The software automatically collects from EMRs the results of nuchal translucency, biochemical screening markers and ultrasound findings, and generates a detailed, personalized report at 17 weeks. The patient and treating OB receive the report that graphically visualizes: A. The fetus's individual risk for Down syndrome, other chromosomal anomalies and other non-chromosomal genetic diseases B. The impact of normal result in amniocentesis (with CMA) or NIPT, or other options on each risk C. The medical recommendation for genetic counseling, amniocentesis, and other tests D. Administrative information regarding cost and coverage. In the initial launch, the software thresholds were set at a low stringency to allow the maximal freedom for referral to genetic counseling. The thresholds were then adjusted by a group of geneticists who reached a consensus on each of the rules in the software algorithm. All cases were manually reviewed for the first 6 months (15,932 cases), to ensure the quality of the generated recommendations. A high agreement was observed between the genetic counseling team and software's recommendations. Since May 2017, the software analyzed 36,180 pregnancies. Ultrasound finding was found in 12.7% of the pregnancies and medical recommendations for amniocentesis was given to 6.9% of the women. Before implementation, about 28% of pregnancies were referred to genetic counseling, either for a medical reason or patient request. The other 72% weren't regularly informed about their risk or prenatal testing options. Three months following software implementation, the referral rate stabilized at 8%. All other 92% of women received the personal software report to discuss with their OB. We present a unique software that performs universal screening for genetic counseling for all pregnancies, using triage criteria defined by medical geneticists, genetic counselors and OBs. The personal report that patients receive, properly informs of the risk and provides a simple tool to understand the value of the available prenatal testing options. This process expedites genetic counseling in high risk pregnancies while ensuring high quality of care to all.

**640F**

**A smartphone app to facilitate family communication of genetic results.** C.J Jujjavarapu, L.A Amendola, M.H.P Horike-Pyne, S.D Mooney, G.P.J Jarvik. University of Washington, Seattle, WA., USA.

The convergence of cost-efficient, reliable genomic technology and increasing information about the impact of genomic variation on health presents an opportunity to advance genomic medicine. However, a key challenge is the barriers to sharing of genetic results with family members. Medical results from genetic tests are unique in healthcare because the results of one individual might be important to the healthcare of relatives. Despite this importance, numerous studies have documented lack of family communication about genetic risk. Controlled trials of genetic counseling-based interventions have shown improved satisfaction but not higher rates of result communication with family members. This supports the need for fresh approaches. We built ShareDNA, a free smart phone app, to lower the barrier to familial test result sharing by allowing those with genetic test results to easily share that result with anyone contactable by text or email. Increased sharing of family test results can improve both cost effectiveness and health outcomes. The ShareDNA app allows either a clinical lab or the user to upload test results, which the user can then share with anyone in their contact list or whose contact information they enter. The app was built using Xcode and will soon be available on the Apple App Store. The app provides an introduction on how to use this service, requires users to create a username and password and upload their genetic test results. The app also helps users select which contact(s) they would like to send their information to and then generate a pre-written message to send to them with the results. Links to relevant websites and a directory of genetics providers are included. Usability testing sessions have been performed to better understand how potential users experience and perceive ShareDNA. The app was well-received with minor wording and functionality modifications suggestions. Knowing the genetic results of family members is important for optimal care. For example, biologic relatives of a patient with a positive cancer genetic result can be tested for the family-specific pathogenic variant for ~ 1/10<sup>th</sup> the cost of a multi-gene panel test. Knowledge of a familial variant enables preventative and early detection strategies and is cost-effective (PMID:25940718). Implementing novel strategies to support increased familial sharing of results, such as the ShareDNA app, are essential to capitalize on the full potential of genomic medicine.

**The role of emerging disease-modifying therapies in reproductive decision-making for cystic fibrosis and Duchenne muscular dystrophy carrier couples.** A.F. McCague<sup>1,2</sup>, K.M. Stuttgen<sup>1,2</sup>, J.M. Bollinger<sup>1</sup>, R.L. Dvoskin<sup>1</sup>, D.J.H. Mathews<sup>1</sup>. 1) Berman Institute of Bioethics, Johns Hopkins University, Baltimore, MD; 2) Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD.

Increasingly, people are making reproductive decisions with genetic test results in hand. As disease-modifying therapies emerge for serious genetic disease, it is important to understand how people are evaluating and using their genetic test results, in order to assist the medical genetics community in designing screening and counseling protocols. For example, there are now FDA-approved small molecule therapies for cystic fibrosis (CF) that have the potential to dramatically improve patient outcomes. New therapies are also becoming available for Duchenne muscular dystrophy (DMD). This study sought to evaluate the impact of disease-modifying therapies on reproductive decision-making for CF and DMD carrier couples. We conducted semi-structured interviews with 19 DMD mutation carriers and 10 CF mutation carriers whose partners are also carriers, including couples with and without affected children. Interview questions addressed the following domains: familiarity with the disease prior to testing; how genetic test results were communicated in the family; reproductive decision-making; if and how disease modifying therapies affected that decision-making; and views regarding preconception genetic testing. Among CF carriers, there was an even split between those who said that disease-modifying therapies had no effect on their reproductive decision-making, those who indicated that a therapy would change their reproductive planning only if it represented a cure, and those who said that they would be more willing to risk having an affected child due to the existence of therapies. For the majority of DMD carriers, the therapies either had no effect or would change their reproductive decisions only if they represented a cure. A minority responded that given the existence of an approved therapy, they would be more willing to risk having an affected child. Two minority themes present in the DMD—but not the CF—group were caveats about the cost and availability of therapies, as well as a willingness to risk having a carrier daughter, given available therapies. Others in both disease groups said they probably would have made the same decision, but the existence of therapeutic intervention may have lessened their anxiety surrounding the decision. These views were affected by numerous factors, including whether the couple had affected children and the severity of their child's disease, their personal experience with and knowledge of the therapies, and personal religious views.

**Development of patient "profiles" to tailor counseling for incidental genome sequencing results.** L. Carlsson<sup>1</sup>, C. Mighton<sup>1,2</sup>, M. Clausen<sup>2</sup>, S. Shickh<sup>1,2</sup>, S. Casalino<sup>2</sup>, T.H.M. Kim<sup>3</sup>, L. McCuaig<sup>1,2</sup>, E. Joshi<sup>1,2</sup>, N. Baxter<sup>1,2</sup>, A. Scheer<sup>1,2</sup>, C. Elser<sup>4</sup>, A. Eisen<sup>7</sup>, M. Evans<sup>1,2</sup>, R.H. Kim<sup>6,8,9</sup>, S. Panchal<sup>6</sup>, T. Graham<sup>7</sup>, M. Aronson<sup>1,8</sup>, C. Piccinin<sup>9</sup>, L. Winter-Paquette<sup>1,8</sup>, K. Semotiuk<sup>1,9</sup>, J. Lerner-Ellis<sup>1,8</sup>, J.C. Carroll<sup>1,8</sup>, J. Hamilton<sup>5</sup>, E. Glogowski<sup>1</sup>, K. Schrader<sup>4</sup>, K. Offit<sup>5</sup>, M. Robson<sup>5</sup>, K. Thorpe<sup>1</sup>, A. Laupacis<sup>1,2</sup>, Y. Bombard<sup>1,2</sup>. 1) University of Toronto, Toronto, ON; 2) St. Michael's Hospital, Toronto, ON; 3) GeneDX, Gaithersburg, MD; 4) BC Cancer Agency, Vancouver, BC; 5) Memorial Sloan Kettering Cancer Center, New York, NY; 6) University Health Network, Toronto, ON; 7) Sunnybrook Health Sciences Centre, Toronto, ON; 8) Mount Sinai Hospital, Sinai Health System, Toronto, ON; 9) The Hospital for Sick Children, Toronto, ON.

**Background:** Despite guidelines recommending return of medically actionable incidental results (IR), research indicates patients are interested in learning results beyond these. Providers should engage patients in shared decision-making prior to genome sequencing (GS), but this can be extremely time consuming given the myriad of IR and variation in preferences. There is a need to streamline pre-test counseling for IR. We identified patient profiles based on shared characteristics of patients' decision-making processes for learning IR. **Methods:** We conducted semi-structured interviews with participants as a qualitative component of a randomized trial of a decision aid (the Genomics ADVISER) for selecting IR. Participants had a personal or family history of cancer, received uninformative genetic test results, making GS potentially useful. Interviews explored factors participants considered when deliberating over learning IR. Interviews were transcribed and analysed with thematic analysis. Transcripts were coded, and themes identified using constant comparison. **Results:** Participants (n=31) were mostly female (28/31) and about half over 50 years old (16/31). We identified key characteristics that informed preferences for IR: contextual factors, disposition, attitudes toward IR, concerns about IR, and perceived utility of IR. Based on how these characteristics were shared by groups of participants, we identified five patient profiles. *Information Enthusiasts* self-identified as "planners" and valued learning most/all IR to enable planning and disease prevention because "knowledge is power". *Concerned* individuals defined themselves as "anxious," were reluctant to learn IR, anticipating negative psychological impacts from IR. Individuals of *Advanced Life Stage* primarily considered implications of IR for younger family members. *Reassurance Seekers* were reassured from previous negative genetic test results, which shaped their expectations for receiving no IR: "hopefully [GS will] be negative, too. And then I can rest easy". *Contemplators* were discerning about the value and limitations of IR, heavily weighing the health benefits with the impacts of not being able to "un-know" information. **Conclusions:** These profiles are a starting point towards tailoring shared decision making for IR to address the variation in patients' preferences. These profiles could guide clinicians' counseling by providing a framework to address common values, concerns and misconceptions about IR.

**Primary care providers' perspectives on the use of genome sequencing in research among healthy children.** *E. Joshi<sup>1</sup>, C. Mighton<sup>1,2</sup>, M. Clausen<sup>1</sup>, S. Casalino<sup>1</sup>, T.H.M. Kim<sup>1,3</sup>, C. Kowal<sup>3</sup>, C. Birken<sup>3</sup>, J.H. Maguire<sup>1,4,5</sup>, Y. Bombard<sup>1,2</sup>.*

1) Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada; 2) Institute of Health Policy, Management and Evaluation, University of Toronto, Toronto, ON; 3) The Hospital for Sick Children, Toronto, ON; 4) Department of Pediatrics, University of Toronto, Toronto, ON; 5) Department of Nutritional Sciences, University of Toronto, Toronto, ON.

**Background:** There is growing interest in using genome sequencing (GS) for healthy children in research studies to improve scientific knowledge of genetic variation and better characterize the relationship between genetics, environment and disease. Very little research has explored primary health-care providers' views on using GS in this context. This study aimed to explore physicians' perspectives on the use of GS in healthy children and overall perspectives towards the use of this technology in their care for patients.

**Methods:** We conducted in depth, semi-structured interviews with physicians who care for children in a longitudinal cohort study called TARGet Kids!. No GS was offered as part of this study. Interviews were audio-recorded, transcribed verbatim and analyzed by thematic analysis. Transcripts were coded for themes using constant comparison. **Results:** Participants were predominantly family physicians (10/16) and had practiced for over 10 years (11/16). Participants' perspectives on GS for healthy children diverged into two groups: (1) those who valued using results from GS in practice, and (2) those who were concerned about the current lack of evidence to support clinical use of GS. Those who focused on the value described a multitude of ways that they could use GS results to inform their patients' care through monitoring and preventive actions. They also expressed a desire to offer all GS results to parents, as they presumed parents would see value in the information. Participants who expressed concern about the current lack of evidence on the utility of GS questioned the clinical validity and utility of results, and challenged the appropriateness of using research data in their patients' care. They also favoured returning only medically actionable results to parents. Providers in both groups acknowledged that offering GS to healthy children conflicts with established screening principles. In addition, both groups shared concerns about the analytic validity and interpretation of GS results, the need for additional resources, potential for increased health system costs and inequities, and the possibility for genetic discrimination if results from GS research were to be adopted into clinical practice. **Conclusions:** Primary healthcare providers recognize that they will inevitably play a role in the use of GS towards precision medicine, but differ in their perceptions of the appropriateness and utility of GS in the care for healthy pediatric patients.

## 644F

**Quality of life is a major driver of patients' preferences for incidental genome sequencing results.** *C. Mighton<sup>1</sup>, L. Carlsson<sup>1,6</sup>, M. Clausen<sup>2</sup>, S. Shickh<sup>1,2</sup>, S. Casalino<sup>2</sup>, T.H.M. Kim<sup>3</sup>, L. McCuaig<sup>1,2</sup>, E. Joshi<sup>1,2</sup>, N. Baxter<sup>1,2</sup>, A. Scheer<sup>1,2</sup>, C. Elser<sup>3</sup>, A. Eisen<sup>4</sup>, M. Evans<sup>1,2</sup>, R.H. Kim<sup>5,8,9</sup>, S. Panchal<sup>5</sup>, T. Graham<sup>7</sup>, M. Aronson<sup>1,8</sup>, C. Piccinin<sup>9</sup>, L. Winter-Paquette<sup>1,8</sup>, K. Semotiuk<sup>1,9</sup>, J. Lerner-Ellis<sup>1,8</sup>, J.C. Carroll<sup>1,8</sup>, J. Hamilton<sup>5</sup>, E. Glogowski<sup>5</sup>, K. Schrader<sup>4</sup>, K. Offit<sup>5</sup>, M. Robson<sup>5</sup>, K. Thorpe<sup>1</sup>, A. Laupacis<sup>1,2</sup>, Y. Bombard<sup>1,2</sup>.* 1) University of Toronto, Toronto, ON; 2) St. Michael's Hospital, Toronto, ON; 3) GeneDx, Gaithersburg, MD; 4) BC Cancer Agency, Vancouver, BC; 5) Memorial Sloan Kettering Cancer Center, New York, NY; 6) University Health Network, Toronto, ON; 7) Sunnybrook Health Sciences Centre, Toronto, ON; 8) Mount Sinai Hospital, Sinai Health System, Toronto, ON; 9) The Hospital for Sick Children, Toronto, ON.

**Background:** Secondary or incidental results (IR) from genome sequencing (GS) are typically categorized based on their medical actionability (MA). However, patients are interested in learning results beyond those that are MA, as these findings can have personal utility. It has been suggested that personal utility should be considered in the evaluation of genetic tests, but it is a challenging concept to measure. We explored how patients making hypothetical decisions about learning IR perceive actionability and how actionability shapes preferences for IR, with the goal of capturing both personal and clinical utilities of learning IR. **Methods:** We conducted a qualitative study within an RCT of a decision aid (DA) for the selection of IR from GS (The Genomics ADvISER). Participants were adult cancer patients who had previously received an uninformative result from genetic testing related to their cancer. Participants used the DA or spoke with a genetic counselor to choose between five categories of IR: 1) Medically actionable, 2) common disease SNPs, 3) rare genetic disorders, 4) early-age brain diseases and 5) carrier status. Interviews were audio-recorded and transcribed verbatim. Transcripts were analyzed using thematic analysis; data was labelled with thematic and descriptive codes using constant comparison. **Results:** We interviewed 31 participants, who were predominately female (28/31) and about half were over 50 years old (16/31). Participants perceived actionability in all types of IR, not only those considered MA. Participants expressed that learning IR could allow them to take actions to control disease outcome, or to take control over aspects of their personal life in preparation for possible illness. An overarching motivator for both wishing to learn and not wishing to learn IR was preserving quality of life. For some participants, learning about any type of IR was perceived as a way to maintain their quality of life through taking actions such as disease prevention or preparation. For others, choosing not to learn particular categories of IR was seen as a way to preserve quality of life by avoiding potential negative psychological impacts of learning IR. **Conclusions:** Preserving quality of life was a strong motivator in patients' preferences for and against learning IR. Quality of life measures that incorporate the value of information and non-health outcomes would provide a more comprehensive evaluation of genetic tests and the impacts of IR from GS.

**645T**

**Whole genome sequencing: Parent-reported outcome measures.** *J. Nelson, M. Brown, L. Villarroel, D. Salyakina, J. McCafferty, P. Jayakar, K. Schain, B. Totapally, M. Diaz-Barbosa, J. Tsasaki, A. Quittner.* Research Institute, Nicklaus Children's Research Institute, Miami, FL.

**Objectives:** The use of genomic sequencing has the potential to significantly alter clinical practice, patient care, and health outcomes. Although the application of these techniques is moving forward rapidly, little is known about the psychosocial, behavioral or ethical effects of this technology, particularly in pediatrics. The aims of this study are to develop the first parent-reported outcome measures for families participating in whole genome sequencing (WGS). **Methods:** Open-ended, qualitative interviews were conducted with 11 parents whose children were undergoing WGS; about half were infants who underwent rapid WGS (rWGS) and half were children in our Odyssey genetics program. Parents were interviewed at time of enrollment and then at return of results. Two brief screening measures of depression (PHQ-9) and anxiety (GAD-7). Interviews were audio-recorded and transcribed for coding using NVivo. **Results:** To date, 15 families have been enrolled (rWGS = 6; Odyssey = 9); complete data were available on 11 families. The sample was racially and ethnically diverse; half identified as Hispanic. Mean age of children rWGS = 9.0 months; Odyssey = 7.4 years. Psychological screening at time of enrollment for those undergoing rWGS indicated that 50% to 67% of parents reported elevated depression and 67-100% reported elevated anxiety. For those in the Odyssey program at time of enrollment 33% of parents were elevated in both depression and anxiety. To date, the majority of infants undergoing rWGS have had a pathological variant identified (e.g., BRAT1, MAGEL2), whereas only 1 child in the Odyssey program has been identified with a new genetic variant. Themes emerging from the qualitative data for the rWGS group suggest that: 1) parents had limited understanding of information provided in the consent; 2) parents had very high expectations that the genetic diagnosis would lead to a significant change in management; 3) parents wanted better communication with their providers. Families in the Odyssey program had lower expectations for a new genetic diagnosis and reported less psychological distress. **Conclusions & Future Directions:** These preliminary results illustrate the importance of developing outcome measures that reflect the parents' experience with these new genetic testing technologies. Several implementation challenges were identified in launching this new personalized medicine program from both a family and provider perspective.

Green<sup>14,15,16</sup>, the PeopleSeq Consortium.* 1) Division of Genetics, Department of Medicine, Brigham and Women's Hospital, Boston, MA; 2) Section of Preventive Medicine and Epidemiology, Department of Medicine, Boston University School of Medicine, Boston, MA; 3) Department of Computer Science, Middlebury College, Middlebury, VT; 4) Department of Genetics and Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 5) School of Human Nutrition, McGill University, Montreal, Quebec, Canada; 6) Illumina Inc., San Diego, CA; 7) Geisinger, Danville, PA; 8) Harvard Personal Genome Project, Harvard Medical School, Boston, MA; 9) Open Humans Foundation, Boston, MA; 10) Department of Pathology and Laboratory Medicine, Robert Larner, M.D. College of Medicine of the University of Vermont, Burlington, VT; 11) Center for Medical Ethics and Health Policy, Baylor College of Medicine, Houston, TX; 12) Department of Behavioural Science and Health, University College London, London, UK; 13) SoundRocket, Ann Arbor, MI; 14) Harvard Medical School, Boston, MA; 15) The Broad Institute of MIT and Harvard, Cambridge, MA; 16) Partners Healthcare Personalized Medicine, Boston, MA.

**Purpose:** To compare differences over time in participants' concerns, motivations, and attitudes following genome sequencing in the PeopleSeq Consortium, a collaboration of academic and commercial predispositional sequencing projects in healthy adults. **Methods:** Web-based surveys were administered to healthy adults who obtained sequencing at four programs. Participants were categorized as early (2014-2015) or recent (2016-2017) respondents based on the year of survey completion. Chi-square tests were used to compare outcomes between early (n=292) and recent (n=244) respondents. Statistical significance was set at p=0.01 given the large number of analyses. **Results:** Study surveys were completed a median of 8 months after disclosure of genomic results. Age, race, education, marital status, health status, and prior genetic testing did not significantly differ between early and recent respondents. A slightly higher percentage of early respondents were male (66% vs 56%; p=0.02). When deciding to pursue sequencing, being very concerned about receiving unwanted information was significantly higher among early respondents (14% vs 4%; p<0.001). The following were less likely to be very important motivators for pursuing sequencing for early compared to recent respondents: "Interest in finding out what I can do to improve my health" (38% vs 51%; p=0.002) and "There is a medical condition in my family which may be genetic" (20% vs 30%; p=0.009). There was no significant difference between the groups on a composite measure of perceived utility of results. However, a higher percentage of early respondents strongly agreed that they learned something to improve their health that they did not know before (21% vs 13%; p=0.02) and were very satisfied with their decision to obtain sequencing (73% vs 60%; p=0.001). Early and recent respondents did not differ on their attitudes on access to sequencing without a medical professional or inclusion of results in medical care. **Conclusion:** Among early adopters of predispositional genome sequencing in the PeopleSeq Consortium, attitudes on access to sequencing and use in medical care did not differ between more recent and earlier respondents. Concerns and motivations did differ between the two groups, and may reflect a decrease in fear surrounding personal genomic information and an increase in anticipated health benefits. However, growing expectations of personal sequencing results may exceed current available evidence of clinical utility.

**647T**

**Clinician and parent perceptions of genomic sequencing in the Neonatal and Pediatric Intensive Care Units: A blinded randomized clinical trial at Rady Children's Hospital.** J. Cakic<sup>1,2,3</sup>, M. Gaughran<sup>1</sup>, C. Clarke<sup>1</sup>, M. Clark<sup>1</sup>, C. Bloss<sup>2</sup>, D. Dimmock<sup>1</sup>, S. Kingsmore<sup>1</sup>. 1) Rady Children's Institute for Genomic Medicine, San Diego, CA; 2) University of California- San Diego, San Diego, CA; 3) San Diego State University, San Diego, CA.

**Introduction:** Congenital anomalies are a leading cause of admission to a Neonatal Intensive Care Unit (NICU) or a Pediatric Intensive Care Unit (PICU). Studies have shown that genomic testing in newborns has resulted in a diagnostic yield between 20-58%, leading many researchers and clinicians to believe that early diagnoses may have clinical utility. However, there is no universally accepted definition of clinical utility. **Methods:** Clinicians and parents of newborns enrolled in a randomized controlled trial of rapid whole exome sequencing versus rapid whole genome sequencing of infants in the NICU and PICU completed baseline and follow-up surveys. To date, 154 newborns less than four months of age have been enrolled at Rady Children's Hospital in San Diego. Analysis and reporting are limited to symptom-driven pathogenic or likely pathogenic variants. Parents are also enrolled to allow each arm to reflex from a singleton to trio analysis to determine the need for trio genomic sequencing. Enrolled parents are asked to provide optional feedback at the time of enrollment, following results, and at one year post-enrollment. **Results:** Of the 154 patients tested, 34 (22%) have received a diagnosis, but clinician feedback from 145 clinician surveys shows 77% of clinicians who responded (141) found genomic testing to be Useful (48 of 141; 34%) or Very Useful (60 of 141; 43%). Clinicians also provide standardized information regarding what, if any, changes were made to clinical care. Parental perceptions of utility, harm, benefit, and understanding are also being explored. Unlike other studies of parental perceptions, only 14% (31 of 220) have post-graduate education, whereas 45.5% (100 of 220) do not have education beyond high school and 40.5% (89 of 220) report having some undergraduate college education making this cohort more representative of NICU and PICU demographics. Of the 220 surveys received, three parents reported of harm to the parent (3 of 220 parents; 1%) and two reported of harm to the child (2 of 100 probands; 2%). Alternatively, 74% (77 of 104) indicated that the results were useful. **Conclusion:** This study provides insights into both clinician and parental perceptions of genomic testing in newborns that can be used to create rigorous definitions of clinical changes in management and provide a deeper understanding of parental perceptions in order to shape best practices and adoption of genomic testing in the intensive care setting.

**Pragmatism in pharmacogenetics trials: A PRECIS-2 perspective on the Integrating Pharmacogenetics in Clinical Care (I-PICC) Study.** C.A. Brunette<sup>1</sup>, S.J. Miller<sup>1</sup>, N. Majahalmeh<sup>1</sup>, C. Hau<sup>1</sup>, L. MacMullen<sup>1</sup>, S. Advani<sup>1</sup>, A.J. Zimolzak<sup>1,2</sup>, J.L. Vassy<sup>1,3,4</sup>. 1) VA Boston Healthcare System, Boston, MA; 2) Boston University School of Medicine, Boston, MA; 3) Harvard Medical School, Boston, MA; 4) Division of General Internal Medicine and Primary Care, Brigham and Women's Hospital, Boston, MA.

**Background** Conducted in real-world clinical settings, pragmatic trials yield generalizable scientific evidence about novel healthcare innovations. Pharmacogenetic (PGx) testing in patient care is an emerging medical innovation in need of outcomes assessment. The I-PICC Study is an ongoing randomized trial collecting patient outcomes after *SLCO1B1* PGx testing for simvastatin myopathy risk. Examining the pragmatism of the I-PICC Study can help determine the generalizability of its eventual results. **Methods** We mapped the I-PICC Study design using the PRagmatic Explanatory Continuum Indicator Summary 2 (PRECIS-2) tool, which scores 9 clinical trial domains on a 5-point Likert continuum from explanatory to pragmatic. **Results** The I-PICC Study design is highly pragmatic in all PRECIS-2 domains (scores 3-5). 1) **Eligibility** criteria for providers and patients are inclusive and align with intended intervention recipients. 67% of available primary care providers (PCPs) were enrolled between July 31, 2016 and April 18, 2018. Of 6,142 eligible patients encountered, 81% were exposed to the intervention via an enrolled PCP. 2) Informatics methods are leveraged to automate PCP and patient **recruitment**. Patient contact is limited to a study letter and telephone consent. 3) The **setting**, 8 primary care clinics across the VA Boston Healthcare System (VABHS), matches where PGx testing might be applied in clinical medicine. 4) The study fits within the VABHS **organization** and requires no specialized training or resources beyond the *SLCO1B1* test, which is sent to a reference lab through usual send-out processes. 5) PCPs have **flexibility** in how they **deliver** PGx results to patients. 6) Patients have **flexibility** in how they **adhere** to any recommendations from the PGx results. 7) All **follow-up** occurs observationally through usual care, except a brief 12-month phone survey. 8) The **primary outcome**, LDL cholesterol, is a routine, clinically relevant biomarker but is a proxy for cardiovascular risk. 9) **Primary analysis** will include data from all enrollees as randomized. **Discussion** The I-PICC Study was designed to minimize interruption of clinical workflow as it enrolls and tracks patients in a trial of PGx testing in primary care. Its high level of pragmatism should enhance the generalizability of its findings to other healthcare systems interested in the potential impact of PGx testing on patient outcomes. The PRECIS-2 tool may be useful for the design of future trials of precision medicine.

**649T**

**Projected prevalence of actionable pharmacogenetic variants and associated drug use in the VHA patient population: Impact and implications of adopting clinical pharmacogenetics implementation consortium (CPIC) guidelines for treatment of veterans.** C. Chanfreau<sup>1</sup>, J.A. Lynch<sup>1,2</sup>, S.L. DuVall<sup>1</sup>, L.E. Hull<sup>1</sup>, S.M. Damrauer<sup>3</sup>, M.S. Icardi<sup>4</sup>, S. Tuteja<sup>3</sup>. 1) VA Salt Lake City Healthcare System, Salt Lake City, UT; 2) VA Bedford Healthcare System, Bedford, MA; 3) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 4) VA Iowa City Healthcare System, Pathology and Laboratory Medicine Services, Iowa City, IA.

**Background** Pharmacogenetic (PGx) tests identify genetic variations associated with drug metabolism, and have the potential to increase treatment efficacy and reduce the risk of adverse event. The evaluation and use of PGx within the Department of Veterans Affairs (VA) is an important topic due to high prevalence of Veterans with several chronic conditions and on multiple medications. We developed a model to estimate the impact and implications of adopting Clinical Pharmacogenetics Implementation Consortium (CPIC) guidelines in the treatment of the VA population, taking in account the genetic make-up of the population and the prevalence of drug use. **Objective** To estimate the prevalence of actionable gene variants with CPIC level A evidence (strong to moderate) and use of associated drugs among VA enrollees. **Material and Methods** We used variant frequencies from the NIH 1000 Genomes project and demographics of the VA population (20% African/80% Caucasian) to estimate the prevalence of CPIC level A variants among 8.9 million Veterans. We examined the use of associated drugs using VA pharmacy data (2012-2017). **Results** Most VA enrollees (98%) would carry at least one actionable variant. Drugs associated with those variants represent 7% of VA drug orders (n=110 millions). Over the past five years 4.1 million VA pharmacy users received at least one CPIC level A drug, with 27% receiving two drugs, 14% receiving three drugs, and 11% receiving 4 or more. Drug-gene interactions with potentially greater impact included *CYP2C9\*2/Warfarin* (20% predicted carriers among VA enrollees and 8% of VA pharmacy users, respectively), *CYP2C19\*17/Citalopram* (5% homozygous carriers; 9% users), *CYP2D6\*4/Tramadol* (3% homozygous carriers; 16% users), and *SLCO1B1\*5/Simvastatin* (26% carriers; 32% users). **Conclusions** Our findings illustrate the potential clinical impact of PGx testing to inform clinical care in a large integrated healthcare system. As PGx testing becomes more prevalent it has the power to transform the prescription practices for many common drugs. Combining VA comprehensive electronic health records data with genetic information ordered in practice, or collected from studies (e.g., the Million Veteran Program), will be instrumental in evaluating real life outcomes associated with PGx testing in a diverse population.

**Utilization of drugs with FDA and CPIC guidelines and pharmacogenetic testing in pediatric clinical settings.** D. Salyakina, I. Sotto, S. Roy, W. Wang, J. Gruber, S. Bahrami, R. Alkhouri, N. Mulas. Research Institute, Nicklaus Children's Hospital, Miami, FL.

Use of pharmacogenetic testing (PGx) in clinical settings is costly and still limited. As medical practice moves towards integrating PGx into pediatric clinic, it is important to assess the efficacy and utility associated with implementation. At the same time, it is not clear to which extent genetic testing is utilized in pediatric clinical settings. The primary goal of this study was to evaluate which medications labeled by the FDA as "Actionable PGx", "Testing required" or "Testing recommended" are utilized at the Nicklaus Children's Hospital and if all patients receiving these medications underwent genetic testing prior to treatment. In order to address this goal, we have retrospectively reviewed medical records for all patients that have received medications with PGx recommendations in 2013-2017. Out of 352 gene drug pairs documented by CPIC, 129 met inclusion criteria. Out of these, 39 pairs had clear CPIC guidelines. Further, 18 drugs from this list were utilized at Nicklaus Children's Hospital. The average number of patients receiving one of these drugs per year has ranged between 22 and 15,033. Thiopurines had clear guidelines and had PGx testing available for *TPMT* gene in the medical health records. *TPMT* gene testing utilization was retrospectively reviewed in 176 patients who received thiopurines as part of their clinical care. Only 36% of these patients had received PGx test prior to medication and 11 patients had a phenotype of "Intermediate Metabolizer" and needed additional monitoring. Our analysis has revealed that different service lines utilize inconsistent workflows. For instance, 75% of patients who received thiopurines in the gastroenterology (GI) service line did not have genetic test done. At the same time, other service lines predominantly tested *TPMT* enzyme activity levels in lieu of a genetic test. There is urgent need to standardize the application of PGx monitoring strategies in clinical practice for medications that pose increased risk of toxicity. In order to evaluate the importance of PGx in pediatric clinical settings, we still need to better understand the rate of toxicities associated with these medications, and the overall cost associated with the toxicities compared to the PGx testing recommended by FDA and CPIC.

**651T**

**Development and validation of the multi-dimensional index of clinical utility: A novel measure to assess value and aid decision-making in genomic medicine.** R.Z. Hayeems, S. Luca, A. Bhatt, E. Pullenayegum, M.S. Meyn, W.J. Ungar. 1) The Hospital for Sick Children, Toronto, Ontario, Canada; 2) UW Center for Human Genomics and Precision Medicine, University of Wisconsin, Madison, WI.

**Purpose:** Clinical utility is a term used to describe the value of genetic tests, but lacks a specific definition and measurement strategy. While the laboratory performance of genetic testing is improving significantly, policymakers require evidence of clinical value to inform decision-making. This study aims to develop and validate a novel measure of clinical utility for the field of genomic medicine. **Methods:** A literature-derived index of items reflecting on the concept of clinical utility was generated. Semi-structured interviews were conducted with clinicians to refine the concept and provide feedback on the structure, understandability, and importance of each item. Items were revised and grouped into 3 core domains. Clinicians then participated in an online Delphi survey and expert panel to rank item importance, rate clinical sensibility, and establish a scoring algorithm. **Results:** The literature review identified 26 plausible items for the index. Interviews were conducted with 35 clinicians from 9 specialty areas. Providers defined clinical utility as a multi-dimensional concept related to diagnostic thinking, patient management, family-centred care, and system efficiency. With the exception of oncology, there was general agreement across speciality groups on the importance of each item. Less important or redundant items were removed and ambiguously worded items were revised. A total of 113 clinicians completed a Delphi survey, rating the importance and sensibility of a reduced set of 20 index items. Of these clinicians, 45 (39.8%) were genetics professionals (MD or genetic counsellor) and 68 (60.2%) were specialists (e.g., pediatrician, neurologist). The majority agreed that the index items accurately reflected the concept of clinical utility (81.4%) and were clear and easy to understand (75.2%). Item mean rankings and qualitative feedback were synthesized to create a 17-item index with 4 domains, for which a scoring algorithm was established by 10 experts. Reliability and validity testing of the final index is underway. **Conclusion:** The development of a clinician reported outcome measure to capture the concept of clinical utility in genomics is an essential prerequisite for assessing the value of rapidly evolving genetic testing technologies on the cusp of clinical translation. Evidence of this sort will inform reimbursement and implementation decisions related to this complex technology.

**652F**

**Assessment of physician recommendations of warfarin genotype testing in a virtual clinic.** B.M. Hollister, K.E. Abdallah, W.D. Kistler, S. Persky, V.L. Bonham. Social and Behavioral Research Branch National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Advances in pharmacogenomic research have led to a better understanding of genetic variants that influence an individual's drug response. Currently, there is limited adoption of pharmacogenomic testing in clinical settings; however, warfarin response genotype testing has been under consideration for clinical use since 2007. Due to warfarin's narrow therapeutic range, identifying the optimal therapeutic dose for patients can be challenging and requires extensive monitoring of the patient. Variants in *CYP2C9* and *VKORC1* can be useful in predicting the best starting dose for patients. However, the trials evaluating the implementation of genotype-guided warfarin dosing have yielded mixed results, resulting in limited uptake of genotype testing. Despite investigations exploring the effectiveness of genotype-guided dosing, little is known about the willingness to integrate this testing by physicians. To address this, we used a virtual clinical interaction, which enables the exploration of this inquiry in a controlled setting, to investigate the use of warfarin genotype testing by physicians and their views on this test. We recruited internal and family medicine residents (N=153) from 7 residency programs in the United States. Residents were asked to interact with a virtual patient who was diagnosed with a deep vein thrombosis and expressed interest in genetic testing after receiving a recommendation for warfarin therapy. Following the virtual interaction, we asked the residents about their familiarity with pharmacogenomic testing and, specifically, warfarin genotype testing. Of the 153 residents who participated, none recommended warfarin genotype testing during the interaction with the virtual patient. 38% indicated that they were familiar with warfarin genotype testing after the virtual interaction; however, only one resident had ordered the test previously. 13% indicated that they felt warfarin genotype testing is useful. This lack of familiarity is unlikely due to limited knowledge of basic genetics, as most participants scored at least 70% on the Genetic Variation Knowledge Assessment Index. The absence of recommendation for warfarin genotype testing by residents in our sample suggests that the adoption of testing may be impacted by knowledge of the availability of genotype testing and its perceived utility in clinical practice. These results highlight a need for education and research regarding the implementation of pharmacogenomic testing.

**653T****Assessment of the human bioresource in K-NIH for precision medicine.**

*J.W. Kim, E.J. Kim, J.H. Park, H.H. Kim, J.Y. Jung, J.H. Kim.* Korea Institute of S&T Evaluation and Planning, Seoul, South Korea.

Cohort-based and epidemiological information, genomic information, and human-derived resources are essential elements for the development of precision medicine and clinical applications. In Korea, efforts are being made to build a national research resource infrastructure, but the issue of openness and usability of research resources continues to arise, necessitating the reorganization of research resource and the associated management system. This study evaluates the status of the major human resources currently held by the K-NIH and the usefulness of the research in precision medical research. The goal of this research is to identify and analyze the status of the collection, management, and utilization of research resources such as cohort and human resources that have been established by the National Institute for Health Research and to evaluate the utilization value as a precision medical research resource. As a result of the evaluation, it is difficult to use the cohort research resources possessed by National Institutes of Health Genome Center directly in the precision medical researches, considering the purpose of collection, the number of research subjects, and the nature of collected information and data. There is currently a lack of connections with external clinical information such as medical records and health checkup data, therefore the maturation of all necessary conditions needs to be set and met. Although the Ministry of Health's genome resources are produced in a significant amount based on the SNP chip information, it is limited to the use of precision medical care in consideration of the cohort management status, genetic information, and differences in the level of information linked to each platform. Overall, the research resources collected to so far are long-term follow-up cohorts and while the value of epidemiological information is recognized, there are limitations on the types of research resource data provided and lack of linkage with clinical information. For the purposes of precision medical research, a new cohort can be established by including the existing cohort at the National Institute of Health Genome Center. A much higher level is required in terms of the quantity and quality of collected data and human resources than in the past. For precision medical research, the full-scale medical cohort study, linkage with electronic medical record (EHR) should be established.

**654F****Attitudes of health professionals about the Cree encephalitis and Cree leukoencephalopathy education and carrier screening program, a population-based carrier screening program in a Canadian first nation.**

*J. Le Clerc-Blain<sup>1</sup>, V. Gosselin<sup>2</sup>, A. Bearskin<sup>3</sup>, J.E. Torrie<sup>4</sup>, G.A. Mitchell<sup>1,5,6</sup>, B.J. Wilson<sup>7</sup>, A. Richter<sup>1,5,6</sup>, AM. Laberge<sup>1,5,6</sup>.* 1) CHU Sainte-Justine Research Center, Montreal, QC, Canada; 2) Formerly Cree Board of Health and Social Services of James Bay, Chisasibi, QC, Canada; 3) Eeyou Awaash Foundation, Chisasibi, QC, Canada; 4) Cree Board of Health and Social Services of James Bay, Mistissini, QC, Canada; 5) Medical Genetics Division, CHU Sainte-Justine, Montreal, QC, Canada; 6) Department of Pediatrics, University of Montreal, Montreal, QC, Canada; 7) Division of Community Health and Humanities, Memorial University of Newfoundland, St. John's, NL, Canada.

**Background:** A population-based carrier screening program (CSP) was started in 2006 for Cree Encephalitis (CE) and Cree Leukoencephalopathy (CLE), two neurodegenerative autosomal recessive conditions with high carrier rates in Cree communities around eastern James Bay (JB) (Canada). Developed by local health authorities in collaboration with the Eeyou Awaash Foundation (a community family support group), the CE-CLE CSP informs the population about CE-CLE, carrier screening, and reproductive options for at-risk couples. **Objective:** Describe the attitudes of local health professionals (HPs) about the CE-CLE CSP. **Methodology:** HPs working in Cree communities around JB were asked to complete a survey on their knowledge of CE-CLE and attitudes about CE-CLE CSP. Hypothesis-driven statistical analysis was performed to test for associations between HPs' attitudes and their characteristics. **Results:** Response rate was 59.4% (164/276). Participants included nurses (102), general practitioners (19), community health representatives (28) and others (12). HPs' comfort level with providing information about the CSP was associated with their knowledge level ( $p < 0.001$ ), program awareness ( $p = 0.018$ ), and having cared for a family with an affected child ( $p < 0.001$ ), but not with number of years working in JB, job type, family history, or spoken languages. HPs who felt they did their job when someone chose screening and HPs who worried that a couple didn't understand what it's like to have an affected baby when they choose to keep an affected pregnancy were both more likely to perceive a higher pressure to screen ( $p = 0.037$  and  $p = 0.011$ , respectively). Importance given to informed consent for screening was associated with knowledge level ( $p = 0.023$ ), but not with perceived pressure to screen, level of concern about perceived potential screening impacts, or program awareness. Perception of program goals was associated with job type ( $p = 0.001$ ), but not with level of knowledge, having cared for a family with an affected child, program awareness, number of years working in JB, or level of concern about perceived potential screening impacts. **Conclusion:** Our findings suggest that training of HPs who are meant to discuss carrier screening with their patients should focus not only on increasing their knowledge and awareness of the program, but also provide opportunities to meet with families who were affected with the targeted diseases and address perceptions of pressure to screen and program goals.

**3063W****CD163: A possible novel candidate gene for Moyamoya disease.** L.

*Pisani<sup>1</sup>, K. Kolla<sup>2</sup>, R. Arora<sup>3</sup>, A. Blevins<sup>4</sup>, K. Monaghan<sup>1</sup>, J. Juusola<sup>4</sup>.* 1) Dept. of Pediatrics, Division of Clinical Genetics, Northwell Health, NY; 2) Comprehensive cancer center, Medstar Georgetown Hospital, D.C; 3) Dept. of Neurology, Northwell Health, NY; 4) GeneDx, MD.

Moyamoya disease (MMD) is a progressive disorder characterized by the stenosis or occlusion of the internal carotid artery bifurcation, resulting in the development of an abnormal collateral vasculature at the base of the brain. Cerebral hemorrhage and strokes are the main clinical features, as well as chronic migraines, visual disturbances, developmental delay and seizures. Its etiology is still largely unknown, though the p.R4859K polymorphism in *RNF213* has been recently identified via GWAS as important risk for MMD in the East Asian population. We report a 25 year-old woman of Brazilian descent with stenosis of the right middle cerebral artery and history of right centrum semiovale ischemia at age 17, followed by development of chronic migraines. She was 29 weeks pregnant with her first child. Family history was remarkable for MMD in a maternal uncle and his 10 year-old daughter, as well a severe stroke and aneurysm in the patient's mother at age 43, and fatal strokes in the 40s-50s in multiple maternal relatives, over three generations. Given the clinical presentation and finding compatible with MMD, the extensive family history, and the urgent need of an action plan for her delivery, Whole Exome Sequencing (WES) was elected. WES revealed a heterozygous p.Q676X variant in *CD163*, maternally inherited. This variant is predicted to cause loss of normal protein function through protein truncation or nonsense-mediated mRNA decay; it has not been observed in large population cohorts, nor has been reported as pathogenic or benign. CD163 is a scavenger receptor expressed on the surface of most monocytes and tissue macrophages and, in its soluble form, in the serum. Amongst its functions, it has been demonstrated that CD163 is involved in the adhesion of monocytes to the endothelial cells, and C163+ macrophages have been demonstrated in tissues actively regenerating after an ischemic injury. CD163 has also proven to be a mediator of the late down regulation of both acute and chronic inflammation. While not all the functions nor ligands of CD163 have been completely defined, evidence suggests that this protein plays a role in the pathogenesis of MMD, as in a recent study elevated levels of soluble CD163 have been reported in affected individuals, significantly higher than those of controls, irrespective of the patients *RNF213* genotype. Further testing of family members and research is necessary to better clarify the role of *CD163* in the pathogenesis of MMD.

**3064T****Novel risk genes and mechanisms implicated by exome sequencing of**

**2756 individuals with pulmonary arterial hypertension.** N. Zhu<sup>1,2</sup>, M. Paucilo<sup>3,4</sup>, K. Lutz<sup>3,4</sup>, C.L. Welch<sup>1</sup>, J. Wang<sup>1,2</sup>, C. Gonzaga-Jauregui<sup>5</sup>, J.G. Reid<sup>6</sup>, J.D. Overton<sup>3</sup>, A. Baras<sup>7</sup>, A. Walsworth<sup>3,4</sup>, Y. Shen<sup>2,6</sup>, W.K. Chung<sup>1,7,8</sup>, W.C. Nichols<sup>3,4</sup>.

1) Department of Pediatrics, Columbia University Medical Center, New York, NY; 2) Department of System Biology, Columbia University, New York, NY; 3) Division of human genetics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 4) Department of Pediatrics, University of Cincinnati, College of Medicine, Cincinnati, OH; 5) Regeneron Genetics Center, Regeneron Pharmaceuticals, Tarrytown, NY; 6) Department of Biomedical Informatics, Columbia University, New York, NY; 7) Herbert Irving Comprehensive Cancer Center, Columbia University Medical center, New York, NY; 8) Department of Medicine, Columbia University Medical Center, New York, NY.

Pulmonary arterial hypertension (PAH) is a rare disease characterized by remodeling of pulmonary arterioles leading to increased arterial pressure and resistance, right ventricular hypertrophy and heart failure. Despite clinical advances, the long-term prognosis remains poor for many PAH patients. Genetics play an important role in the pathogenesis of PAH, and there are eleven known risk genes underlying ~70% of familial cases (FPAH) and ~10% of sporadic idiopathic cases (IPAH). However, the majority of idiopathic cases, as well as PAH associated with other diseases (APAH) remain genetically undefined. To identify new variants in known risk genes, we performed targeted and exome sequencing in 2756 PAH cases from the US PH Biobank. The cohort included 1124 IPAH, 1225 APAH (58.9% connective tissue disorders, 21.8% congenital heart disease and 19.3% other), and 97 FPAH cases. Most of the patients were adults (mean age of onset = 38.6 years) and, as expected for this disease, the female: male ratio was 4:1. We observed that 278 cases (10% overall: 12.7% IPAH, 5% APAH, 76.3% FPAH) carried rare predicted pathogenic variants in at least one of the 11 known risk genes (*ACVRL1*, *BMPR1A*, *BMPR1B*, *BMPR2*, *CAV1*, *EIF2AK4*, *ENG*, *KNCK3*, *SMAD4*, *SMAD9*, *TBX4*). Eight patients carried rare deleterious variants in two risk genes. Of note, 114/235 (48.5%) of the variants in known risk genes are novel. To identify new risk genes, we performed gene-based rare variant association tests using 1832 unrelated European cases and 12,927 European controls (7509 gnomAD, 5418 Columbia controls). The frequency of rare synonymous variants was identical in cases and controls, supporting negligible batch effects. Using a variable threshold of predicted deleteriousness for missense variant inclusion, we identified *KLK1* (kallikrein-1,  $p=1.30E-07$ ) as a new candidate risk gene. For IPAH (813 cases), *KLK1* ( $p=2.00E-08$ , 10 carriers) and *GGCX* ( $p=9.02E-07$ , 12 carriers) reached genome-wide significance. *KLK1* is expressed in pulmonary arterial cells and has an established role in vascular remodeling and has not previously been associated with PAH. Other top-ranked associations included an enrichment in SMAD3 transcription targets (*RCVRN*, *MYO5B*, *NOTCH4*, *FLNA*, *PAX6*, *NR3C1*, *SMAD5*;  $p=0.0009$ ) and calcium ion binding regulation (*PNLIPRP1*, *SPARC*, *NOTCH4*, *MAN1B1*;  $p=0.009$ ). These data increase the number of known risk genes and suggest new mechanisms for IPAH that could provide targets for therapy.

## 3065F

**A new form of inherited cardiomyopathy leads to changes in heterochromatin structure in man and mice.** *N. Abdelfatah<sup>1</sup>, R. Chen<sup>2</sup>, D. Belke<sup>1</sup>, C. Fielding<sup>3</sup>, K. Ito<sup>3</sup>, J. Gross<sup>2</sup>, H. Duff<sup>1</sup>, B. Gerull<sup>1,2</sup>.* 1) Department of Cardiac Sciences and Libin Cardiovascular Institute, University of Calgary; 2) Comprehensive Heart Failure Center and Department of Medicine I, University Hospital Würzburg, Würzburg, Germany; 3) Transgenic Services, Centre for Genome Engineering, Cumming School of Medicine, University of Calgary.

**Introduction:** Nuclear envelope proteins have been shown to play an important role in the pathogenesis of inherited dilated cardiomyopathy (DCM). We recently discovered a novel homozygous mutation in the LEM domain of the inner nuclear membrane (INM) protein LEMD2 causing juvenile onset of arrhythmic cardiomyopathy and bilateral cataract in the Hutterite population. Previous studies on patient fibroblasts suggested that the mutation may cause a proliferation defect and cell senescence. In addition, myocyte disarray and extensive interstitial fibrosis along with extensive changes of myocyte nuclei were observed in cardiac tissue of a deceased patient. **Purpose:** To understand the role of LEMD2 in the heart using an in vivo knock-out (KO) and knock-in (KI) mouse model. **Methods and Result:** In vivo homozygous KO, as well as KI mouse models, were created using CRISPR-Cas9 system. Survival studies were accomplished for both lines at different embryonic stages. KO mice died between embryonic day 10.5 and 11.0 and were smaller in size. Histology showed ventricular wall thinning and abnormalities of the outflow tract development. On the other hand, most homozygous KI mice survived until 3 weeks of age before they died due to severe heart failure. Histology already at E13.5 and P21 demonstrated ventricular wall thinning and dilatation of the right and left ventricle with extensive cardiac remodeling and fibrosis. Furthermore, TEM of hearts from both lines revealed remarkable changes of myocyte nuclei similar seen in cardiac tissue from patients. Next, echocardiography was used to determine cardiac function at 3 weeks old KI mice. Homozygous KI mice showed significantly decreased fractional shortening and ejection fraction compared to wildtype littermates ( $9.39 \pm 5.6$  vs.  $23.427 \pm 2.2$ ,  $p < 0.0001$  for FS (%);  $20.322 \pm 11.4$  vs  $47.345 \pm 3.7$ ,  $p < 0.0001$  for EF). Homozygous hearts also showed dilatation and wall thinning indicated by decreased value of LVIdD ( $p < 0.01$ ) and IVSd ( $p < 0.01$ ), respectively. The phenotype represents the human homolog of dilated cardiomyopathy in mice. **Conclusion** Knock-out of LEMD2, as well as a mutated LEM domain in mice, lead to remarkable changes in nuclei with abnormal heterochromatin formation as seen in humans. Homozygous mice of both models show structural and functional abnormalities during cardiac development suggesting the involvement of LEMD2 in this process. Future work will determine the underlying mechanisms causing cardiomyopathy in mice and man.

## 3066W

**Characterization of Egyptian genetic variation in relation to cardiovascular phenotype.** *Y. Aguib<sup>1,2</sup>, M. Allouba<sup>1,2</sup>, R. Walsh<sup>2</sup>, M. Elkhateb<sup>1</sup>, N. Shehata<sup>1,2</sup>, A. Afify<sup>1</sup>, S. Halawa<sup>1,3</sup>, R. Govind<sup>2</sup>, N. Whiffin<sup>2</sup>, B. Sami<sup>1</sup>, D. Yehia<sup>1</sup>, S. ElShorbagy<sup>1</sup>, E. Abdel Rahman<sup>1</sup>, W. ElMozy<sup>1</sup>, A. Essam<sup>1</sup>, M. Maghawry<sup>1</sup>, S. Lee<sup>2</sup>, S. Cook<sup>2,4</sup>, P. Barton<sup>2</sup>, J. Ware<sup>2</sup>, H. Aguib<sup>1,2</sup>, A. ElGuindy<sup>1,2</sup>, M. Yacoub<sup>1,2</sup>.* 1) Aswan Heart Centre, Magdi Yacoub Foundation, Aswan, Egypt; 2) Imperial College London, UK; 3) American University in Cairo, Egypt; 4) National Heart Centre Singapore, Duke-National University of Singapore, Singapore.

**Background & Objectives:** Genetic and phenotypic databases for variant interpretation are key for the development of precision medicine, taking ethnicity into consideration. The Egyptian and North African population is not represented in the Exome and Genome Aggregation Consortia (ExAC and gnomAD), which are the most comprehensive population data sets, posing a major challenge in data interpretation. To address this, a study of 1000 Egyptian healthy volunteers (E-HVols) was initiated. **Methods:** Recruited E-HVols undergo cardiovascular phenotyping (CMR, ECG and ECHO). Genetic make-up is studied using a panel of 174 genes implicated in Inherited Cardiac Conditions (ICC). Variant calling is performed using a custom designed bioinformatics pipeline based on the Genome Analysis ToolKit and variants are annotated using CardioClassifier. Results are compared to existing reference datasets. CMR studies are conducted to investigate geometry, dynamism and function in the different heart chambers, aorta and pulmonary. Computerised algorithms were developed for detailed morphology analysis of healthy aortic and ventricular structure. Feature Tracking for LV motion analysis and computational modelling were used to capture and quantify dynamic changes of both shape and flow and to identify disease-based variations in patients. Also, circulating protein biomarkers (serum/plasma) are assessed. **Results:** A database comprising clinical data, genetic variation in ICC genes and imaging data derived morphological parameters was established. 2% among self-declared E-HVols were diabetic (excluded), 22.3% had a BMI >30. NGS Data (408/650) obtained provide an ethnically-matched control data set and are utilized for better interpretation of variants in our clinical setting. In core HCM/DCM genes, for instance, novel rare variants were identified in E-HVols, including a truncating variant in *TTN* and in 9 Individuals homozygosity was identified (28 core HCM/DCM analysed). Long-term clinical follow-up will reveal the impact of identified variants and can impact their classification. For 200 E-HVols demographic and anthropometric data, advanced imaging combined with 3D modelling and novel computerized analysis were analysed and used as a powerful tool to define geometry and function of the aortic root and aorta. **Conclusions:** Expanding the number of this initial sample will enhance the clinical utility of our data and their integration in precision medicine approaches.

**Defining the genetic architecture of hypertrophic cardiomyopathy in the Egyptian population.** *M. Allouba*<sup>1,2</sup>, *Y. Aguib*<sup>1,2</sup>, *R. Walsh*<sup>2</sup>, *R. Govind*<sup>2</sup>, *N. Whiffin*<sup>2</sup>, *S. Halawa*<sup>1,3</sup>, *A. Maher*<sup>1</sup>, *A. Afify*<sup>1</sup>, *A. Galal*<sup>1</sup>, *R. Buchan*<sup>2</sup>, *H. Kassem*<sup>1,4</sup>, *B. Samy*<sup>1</sup>, *R. Azer*<sup>1</sup>, *M. Elkhateb*<sup>1</sup>, *F. Mohamed*<sup>1</sup>, *A. Elguindy*<sup>1,2</sup>, *S. Cook*<sup>1,5</sup>, *P. Barton*<sup>2</sup>, *J. Ware*<sup>2</sup>, *M. Yacoub*<sup>1,2</sup>. 1) Aswan Heart Centre-Magdi Yacoub Foundation, Aswan, Egypt; 2) Imperial College London, UK; 3) The American University in Cairo, Egypt; 4) Faculty of Medicine Alexandria University, Egypt; 5) National Heart Centre Research Institute Singapore, Duke-National University of Singapore.

**Introduction:** Hypertrophic cardiomyopathy (HCM) is a heterogeneous disease with regards to phenotype, genotype and mode of inheritance. It affects 1:500 individuals in the general population and appears to be influenced by ethnicity. In Egypt, HCM constitutes a substantial burden of disease, yet, its genetic determinants have not been adequately studied. **Aim:** To analyse the genetic architecture of HCM in the Egyptian population in comparison to a Caucasian HCM cohort as well as to global and ethnically-matched healthy controls. **Methods:** In this work, genetic data from 500 HCM patients and 408 Egyptian healthy Volunteers (EHVOLs) are studied using the Illumina Trusight Cardio Sequencing Kit comprising 174 genes with reported roles in Inherited Cardiac Conditions (ICC). **Results:** Currently, 1098 Egyptian patients, with a mean age of 34.9±18, have been recruited to the National HCM Program at our hospital. 285 patients have underwent myectomy with a 3-year survival rate of 98.9%. Analyzed data reveal unique features of the Egyptian HCM cohort. A novel truncating variant in *MYH7* was identified among 8 Egyptian patients. This significantly enriched ( $p < 0.0005$ ) variant in the clinical cohort over local controls as well as its absence in ExAC suggests that it could be reclassified from a “variant of uncertain significance” to likely “pathogenic” as per the guidelines by the American College of Medical Genetics and Genomics (ACMG). Induced pluripotent stem cell (iPSC)-derived cardiomyocytes are being generated to investigate the level of expression of the truncated variant relative to the wild type allele. Its functional role remains to be studied. In addition, a set of 16 core HCM genes was selected for the analysis of the frequency of homozygous variants among Egyptian patients. 6 and 9 patients harbored rare and common homozygous variants in the selected genes, respectively. This reflects the high rate of intermarriages in this population. **Conclusions:** The genetic architecture of HCM in the Egyptian population shows several unique features with regards to the novel truncating variant in *MYH7* and homozygosity in core HCM genes. This findings could provide new mechanistic insights into the pathogenesis of HCM and improve the efficacy of current treatment strategies.

**Identification of genetic defects in phenotypically defined subtypes of patients with Ebstein anomaly.** *R. Cabrera*<sup>1</sup>, *M.C. Miranda-Fernández*<sup>1</sup>, *C.J. Hernández-Toro*<sup>1</sup>, *V.M. Huertas-Quiñones*<sup>1,2,3</sup>, *P. Laissue*<sup>3</sup>, *S. Ramírez-Oyaga*<sup>1</sup>, *M. Carreño*<sup>1</sup>, *I. Pineda*<sup>1</sup>, *C.M. Restrepo*<sup>3</sup>, *C.T. Silva*<sup>3</sup>, *A. García*<sup>1,3,4,6</sup>, *N. Sandoval*<sup>1,3</sup>, *M. Barrera-Castañeda*<sup>1</sup>, *K.J. Moreno Medina*<sup>1</sup>, *R.J. Dennis Verano*<sup>1,5</sup>. 1) Fundación Cardioinfantil - Instituto de Cardiología, Bogotá, DC, Colombia; 2) Universidad Nacional de Colombia, Bogotá, Colombia; 3) Universidad del Rosario, Bogotá, Colombia; 4) Universidad El Bosque, Bogotá, Colombia; 5) Pontificia Universidad Javeriana, Bogotá, Colombia; 6) Universidad Militar Nueva Granada, Bogotá, Colombia.

Objectives Ebstein Anomaly (EA) is a rare congenital heart defect (CHD) with a poorly characterized genetic etiology and heterogeneous clinical presentation. As a reference institution for complex CHD, we have assembled one of the largest single center cohorts of patients with EA. We hypothesize that phenotypic diversity in Ebstein Anomaly patients reflects an underlying heterogeneity in genetic causes, and that major genetic causes can be found in at least some patient subgroups. **Methods** A comprehensive cross-sectional phenotypic characterization of 147 EA patients from one of the main referral institutions for CHD in Colombia was carried out. The most prevalent comorbidities and distinct subgroups within the patient cohort were identified through multivariate cluster analysis. Patients from the most homogeneous phenotypically-defined subtypes were submitted to genome-wide molecular analyses (Whole Exome Sequencing and/or cytogenetic microarray analysis). Relevant variants were identified by gene function filtering and population probability analysis. **Results** The data show that EA is a heterogeneous disease, frequently associated with cardiovascular and noncardiovascular comorbidities. Patients with WPW and SVT represent a homogeneous subgroup that presents with a less severe spectrum of disease and better survival when adequately managed. Similarly, patients with a syndromic presentation also represent a distinct subgroup. Whole exome sequencing can identify variants in known and novel EA-associated genes that are highly likely to be causative in a significant number of familial and isolated cases of the WPW/SVT subtype of EA patients. Some of these genes have been implicated in the transcriptional regulation of the Endothelial-Mesenchymal Transition underlying Tricuspid valve delamination. Furthermore, syndromic patients are likely to show chromosomal abnormalities, and two novel chromosomal regions deleted in syndromic patients with EA were identified. Genetic causes in non-WPW/SVT/nonsyndromic EA cases remain to be identified. **Conclusions** Multivariate analysis can reveal clinically relevant patterns in comorbidity datasets of phenotypically heterogeneous disease cohorts. This analysis can identify relevant subtypes of EA patients and empowers the identification of genetic variants. This approach can be used in the identification of novel causal genes in CHD and other rare diseases.

**The phenotype of a CRISPR mouse model of a human gap junction C2 (connexin 47) mutant causing lymphedema.** *R.P. Erickson<sup>1</sup>, R. Kyjat<sup>1</sup>, D.J. Mustacich<sup>1</sup>, M. Bernas<sup>2</sup>, M. Witte<sup>1</sup>.* 1) University of Arizona, Tucson, AZ; 2) TCU and UNTHSC School of Medicine, Ft. Worth, Texas.

Ferrell, et al (doi 10.1016/j.ajhg.2010.04.010) reported 2 mutations of *GJC2* (*CX47*) in 2 families of dominantly inherited lymphedema with variable penetrance and expressivity while Ostergaard, et al (doi 10.1036/jmg.2010.085563) soon added 2 more lymphedema-causing mutations in *CX47* families with full penetrance and great variation in expressivity. We sought to make a mouse model of lymphedema caused by *Cx47* mutations using the CRISPR approach to create mice carrying one of these mutations, the R260C mutation. Due to differences in sequence, the human R260 is at position R257 in mice, and, due to codon usage differences, the mutation requires a 2 bp change in mice. Three guides were selected and produced by PCR using as a template an Addgene pX330 plasmid carrying the scaffold portion of the guide. SgRNAs (single guide RNAs) were designed to target R257 flanking sequences in the *Cx47* gene. Microinjection was performed by continuous flow injection of the Cas9/gRNA/ssODN mixture into the pronucleus of 1-cell C57BL/6J (BL6) zygotes. In addition to studying heterozygotes and homozygotes on the BL6 background, an F<sub>1</sub> was made between male BL6 carriers of the mutation and females of the 129/J and A/J strains. Heterozygous offspring were backcrossed to their mothers to create an N<sub>1</sub> generation with 75% of the new genetic background. Evans blue dye (EBD) (~50ul of 5 g/dl), was injected intradermally into all four paws, ears and snout serially to sequentially highlight the regional lymphatic systems and the central collection system which were examined by sequential dissection of the peritoneal cavity (iliac and cysterna chyli), thoracic cavity (thoracic duct), axillary, jugular, popliteal and sacral regions. Alterations in the lymphatic system were only found (and confirmed by blinded observation) in homozygous mutant mice on the BL6 background, consisting of an increase in the number of lymph nodes in the jugular region, as well as an increase in the number and/or size of lymph nodes in the iliac region. We detected no phenotypic alterations in heterozygotes on the other 2 (75%) backgrounds and no lymphedema was identified in any of the mice. Thus, the phenotype was not obviously lymphedema-causing but altered the lymphatic architecture by creating extra lymph node niches. These results confirm a role for Connexin 47 in lymphatic development but also indicate differing phenotypic consequences between man and mouse. .

**SMAD4 rare variants in individuals and families with thoracic aortic aneurysms and dissection.** *D. Guo<sup>1</sup>, X. Duan<sup>1</sup>, E. Regalado<sup>1</sup>, J. Cosell<sup>2,3</sup>, A. Estrera<sup>4</sup>, H. Safi<sup>5</sup>, M. Bamshad<sup>5,6</sup>, D. Nickerson<sup>5</sup>, S. LeMaire<sup>2,3</sup>, J. Backer<sup>7</sup>, D. Milewicz<sup>7</sup>, Montalcino Aortic Consortium; University of Washington Center for Mendelian Genomics, Seattle, USA. 1) Department of Internal Medicine, The University of Texas Health Science Center at Houston McGovern Medical School, Houston, TX. 1) Department of Internal Medicine, The University of Texas Health Science Center at Houston McGovern Medical School, Houston, USA; 2) Michael E. DeBakey Department of Surgery, Baylor College of Medicine, Houston, USA; 3) Department of Cardiovascular Surgery, Texas Heart Institute, Houston, USA; 4) Cardiothoracic Vascular Surgery, The University of Texas Health Science Center at Houston McGovern Medical School, Houston, USA; 5) Department of Genome Sciences, University of Washington, Seattle, USA; 6) Department of Pediatrics University of Washington, Seattle, USA; 7) Center for Medical Genetics, Department of Cardiology, Ghent University Hospital, Ghent, Belgium.*

Pathogenic variants in a number of genes lead to heritable thoracic aortic disease (HTAD) have been identified and the majority of these genes encode proteins involved in smooth muscle cell contraction and adhesion to the extracellular matrix or the transforming growth factor beta signaling pathway. In particular, *SMAD4* pathogenic variants cause juvenile polyposis (JPS) and hereditary hemorrhagic telangiectasia (HHT), and 40% of these cases also have thoracic aortic disease. *SMAD4* variants have not been reported in thoracic aortic disease families without JPS-HHT and thus far the variants reported are loss of function or missense variants located in the MH2 domain of the protein. Analysis of exome sequencing data from 223 unsolved families with HTAD identified a rare variant in *SMAD4*, c.290G>T (p.Arg97Leu), that segregated with aortic disease in family TAA281. In this family, the proband and her brother had ascending aortic dissections at the age of 24 and 41 years, respectively, and their father had an ascending aortic aneurysm repair at age 75; none of them had JPS-HHT. This *SMAD4* variant, located in the MH1 domain, is absent in population databases, predicted to be damaging, and has a CADD score of 33. Cellular studies using the HEK293T and an immortalized smooth muscle cells (SMC) lines revealed that the *SMAD4* p.Arg97Leu alteration increased *SMAD4* ubiquitination and 26S proteasome-mediated protein degradation. SMCs infected with lentivirus expressing the *SMAD4* p.Arg97Leu variant demonstrated reduced expression of SMC contractile proteins when compared to SMCs infected with wildtype *SMAD4*. In addition, exome sequencing data of 355 individuals with dissections under the age of 56 years and no family history or syndromic features identified two other rare nonsynonymous *SMAD4* variants: p.Met24Val identified in a 37 year old patient with type A aortic dissection and p.Pro246Thr in a 54 year old patient with type A aortic dissection, and no features of JPS-HHT. These variants have very low minor allele frequencies in the gnomAD database and CADD scores of >15. These findings support the conclusion that *SMAD4* rare missense variants disrupting *SMAD4* cellular function can lead to thoracic aortic disease in individuals who do not have JPS or HHT. .

**Genetic variants in familial abdominal aortic aneurysms.** A. Ijpm<sup>1</sup>, D. Heijtsman<sup>2</sup>, H.T. Bruggenwirth<sup>2</sup>, D. Majoer-Krakauer<sup>2</sup>. 1) Erasmus Medical Center, Clinical Bioinformatics Unit, Department of Pathology, Rotterdam, Netherlands; 2) Erasmus Medical Center, Department of Clinical Genetics, Rotterdam, Netherlands.

**Introduction:** Abdominal Aortic Aneurysm (AAA) has a prevalence of 5% in the elderly population. An AAA occurs when the aorta below the renal arteries expands to a diameter of 3cm or more. In the Netherlands, each year approximately 5000 AAA patients are hospitalized and around 750 people die due to AAA rupture. **Hypothesis:** Approximately 20% of AAA patients are familial and our hypothesis is that genetic predisposition is a significant cause for abdominal aneurysm pathology. Our goal is to identify the genes that play a role in the formation of AAA. **Methods:** Our study population consists of approximately 1250 AAA patients. So far we sequenced 548 of these AAA patients. Complete Genomics whole genome sequencing (WGS) was performed in 3 families (15 individuals) and whole exome sequencing (WES) on the illumina platform using Agilent Haloplex and CRE sureselect exome capturing technology was performed in 71 families (175 individuals) and 358 single familial AAA patients. Burden analysis was used to identify genes enriched in our AAA population. **Results:** We present the detailed workflow of the analysis of the genomics data. We will discuss several candidate genes identified such as the enrichment for variants we identified in the COL4A2 gene. **Conclusions:** In 118 out of 512 families a variant in a diagnostic AAA gene was found. Analysis of all genes in the exome dataset led to the identification of several candidate genes that show variants in more than one AAA family and that have not been linked to AAA before.

**3072W**

**Investigation of the molecular basis of systemic to pulmonary arteriovenous malformations.** R.P. Martin<sup>1</sup>, D. Valle<sup>1</sup>, H. Dietz<sup>1</sup>, N. Sobreira<sup>1</sup>, S.E. Mitchell<sup>1</sup>. 1) McKusick-Nathans Institute of Genetic Medicine, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Radiology, Johns Hopkins University School of Medicine, Baltimore, MD.

Arteriovenous malformations of the pulmonary vascular (PAVM) bed are anomalies characterized by vascular shunts in normally ventilated lung tissue. PAVM with a systemic source is a rare condition and considered to be a specific entity (SPAVM). Dyspnea and the classical triad of cyanosis, clubbing of the digits and polycythemia, as a result of undersaturation in conventional PAVM, are not present in SPAVM systemic because it is a left-to-right shunt. Because of lack of symptoms, the discovery of these malformations is often an accidental finding. Most patients are young asymptomatic adults, predominantly male. SPAVMs are subject to systemic pressure, and so may lead to pulmonary hypertension or may grow and rupture. The molecular basis of SPAVM remains unknown. As part of the Baylor-Hopkins Center for Mendelian Genomics project, we performed whole exome sequencing on 6 unrelated probands with SPAVM. One proband was part of a multiplex family with 9 affected individuals from 3 generations presenting with SPAVM and/or aortic root aneurysm in early age. Using PhenoDB analysis tool, we selected the heterozygous and homozygous, rare (MAF<1%) and functional variants in each proband. These genes and variants were evaluated for their ClinVar, HGMD, OMIM, GWAS, mouse model phenotypes and other annotations to identify the best candidate variants in each proband. Genes that were mutated in 3 or more probands were also selected. None of the probands had pathogenic variants in *ENG*, *ACVRL1*, *SMAD4*, *GDF2*, or *RASA1*. One proband had a rare, heterozygous variant in exon 8 of *EPHB4* (c.G1448A:p.R483Q). Amyere et al. (2017) described loss of function variants as the cause of multifocal capillary malformations (CM) associated with arteriovenous malformations (AVM), a phenotype that mimics *RASA1*-related CM-AVM1 and also hereditary hemorrhagic telangiectasia. Vivanti et al. (2018) described loss of function variants in *EPHB4* as responsible for vein of Galen aneurysmal malformation. The *EPHB4*-R483Q variant identified in one of our probands was reported in only 16 of 224462 alleles in gnomAD and is likely the cause of the SPAVM phenotype in this proband expanding the phenotype associated with pathogenic variants in this gene. Furthermore, we are also analyzing the genes mutated in at least 3 unrelated probands to possibly identify a novel candidate gene responsible for SPAVM. We suggest that SPAVM is a rare distinct phenotype with a still unknown molecular basis.

**3073T**

**The novel RNF213 variant observed in patient with moyamoya and systemic artery stenosis diseases.** O. Migita<sup>1,2</sup>, M. Mizuno<sup>1</sup>, M. Ozawa<sup>1</sup>, K. Aso<sup>1</sup>, H. Yamamoto<sup>1</sup>, K. Hata<sup>2</sup>. 1) St. Marianna University School of Medicine, Kawasaki-shi, Miyamae-ku, Kanagawa, Japan; 2) National Research Institute for Child Health and Development, Tokyo, Japan.

The *ring finger protein 213 (RNF213)* gene was reported as a susceptible gene for moyamoya disease and intracranial major artery stenosis. According to ClinVar, which is curated database of published variants, 35 registered variants had been observed as risk, pathogenic variants or variants of uncertain significance. But the role of RNF213 in moyamoya diseases is still unclear. A three year old boy presented with progressive mitral valve regurgitation. He was born to unconsanguineous parents. When he was first year old, he was referred to St. Marianna University Hospital by patient local physician because of his heart murmur which was found in his health check-up. He was received reconstructive surgery of mitral valve, because the regurgitation had been worsen. But four day after the operation, he had seizure and cerebral infarction. He had extensive cerebral infarction in the MCA, ACA area, and narrowing the basilar arteries. The possibility of moyamoya Disease and hereditary vascular diseases was suggested. To address to hereditary vascular disease, whole exam sequencing was employed to search for pathogenic mutations, and revealed that he had *RNF213* novel mutation. Subsequently, systemic MRI imaging showed that his artery disease were not showed only intracranial artery, but also renal artery, iliac artery and other systemic arteries. Further research should be needed to reveal the role of the *RNF213* variants in pathogenic machinery of moyamoya disease. This result of the present case may provide new insight for association between *RNF213* gene mutation and moyamoya disease.

**3074F**

**Preliminary variant classification results from the Dilated Cardiomyopathy (DCM) Precision Medicine Study.** A. Morales<sup>1</sup>, D.D. Kinnamon<sup>1</sup>, E. Jordan<sup>1</sup>, J. Platt<sup>3</sup>, M. Vatta<sup>4,5</sup>, M. Dorschner<sup>6</sup>, R.E. Hershberger<sup>1,2</sup>. 1) Division of Human Genetics, Department of Internal Medicine, The Ohio State University, Columbus, OH; 2) Division of Cardiovascular Medicine, Department of Internal Medicine, The Ohio State University, Columbus, OH; 3) Stanford Center for Inherited Cardiovascular Disease, Stanford University, Palo Alto, CA; 4) Department of Medical and Molecular Genetics, Indiana University, Indianapolis, IN; 5) Invitae, San Francisco, CA; 6) Department of Pathology, University of Washington, Seattle, WA.

The DCM Precision Medicine Study, funded to recruit 1300 families of European and African Ancestry (EA and AA), as well as of Hispanic ethnicity (HE), aims to define the genetic basis of DCM. For the study, which involves returning results after analysis of 37 DCM genes, variant classification rules were developed based on the published *MYH7* ClinGen Cardiomyopathy Expert Panel (*MYH7* EP) approach. Modifications were made to 9/33 (27%) criteria evaluated by the *MYH7* EP, including use of hotspot data for *RBM20*, consideration of recessive DCM, and the development of evidence levels for variants encoding a premature stop of translation. Other modifications leveraged our DNA analysis pipeline, including automated confidence interval calculations for minor allele frequencies <0.05% (applied to all target genes), computational data predictions using REVEL scores, and a stand-alone benign classification for *TTN* missense variants. Having medical records to validate study participant phenotypes, *de novo* criteria required demonstrating parental absence of a phenotype. Similarly, the criterion for benign impact regarding concern for an alternate molecular basis for disease was deemed not applicable due to probands' phenotypes expected to be within the spectrum of the study genes. Variants that were of low-quality, synonymous, or outside canonical splice sites were not analyzed. Curation proceeded for 79 variants based on 27 criteria in 98 clinically confirmed probands (59 non-HE EA; 34 non-HE AA; 5 HE EA), revealing 45% with variants of uncertain significance (VUSs) and 11% with likely pathogenic (LP) variants, the latter found mostly (n=9) in non-HE EA. Multiple variants were identified in 19%. Variants reached LP classifications based on case and segregation data, rarity in reference populations, predicted loss of function, other known pathogenic missense change affecting the same codon, and hotspot location. While 9 of our 27 criteria (33%) depend on case or family data, none of the variants met *de novo* and strong segregation criteria. In conclusion, using a new variant classification approach tailored for DCM, approximately half of the probands had VUSs identified, most with LP variants are EA, and 19% have multiple variants. Our results not only highlight the value of multiple family units but also illustrate the challenges in variant interpretation for genetically heterogeneous conditions, warranting more research to move ahead with VUS resolution for DCM.

**3075W**

**Autosomal recessive cutis laxa syndrome with cardiovascular involvement.** *H. Morisaki<sup>1,2</sup>, M. Horiuchi<sup>3</sup>, M. Hibino<sup>4</sup>, Y. Sakaï<sup>5</sup>, R. Seki<sup>6</sup>, K. Kosaki<sup>7</sup>, T. Morisaki<sup>2,8</sup>.* 1) Dept Medical Genetics, Sakakibara Heart Institute, Fuchu, Tokyo, Japan; 2) Dept Bioscience and Genetics, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan; 3) Div Perinatology and Gynecology, National Cerebral and Cardiovascular Center, Suita, Osaka, Japan; 4) Dept Cardiac Surgery, Nagoya University Graduate School of Medicine, Showa, Nagoya, Japan; 5) Dept Cardiovascular Surgery, Nagoya Daini Red Cross Hospital, Showa, Nagoya, Japan; 6) Dept Cardiovascular Internal Medicine, Sakakibara Heart Institute, Fuchu, Tokyo, Japan; 7) Ctr for Medical Genetics, Keio University School of Medicine, Shinjuku, Tokyo, Japan; 8) Div Molecular Pathology, Inst of Medical Science, The University of Tokyo, Minato, Tokyo, Japan.

Autosomal recessive cutis laxa syndrome type 1 (ARCL1) is a rare connective tissue disorder, characterized by generalized cutis laxa with pulmonary emphysema and/or vascular complications. ARCL1 is classified into three types (ARCL1A, ARCL1B and ARCL1C) according to responsible genes, fibulin-5 (*FBLN5*), fibulin-4 (*FBLN4/EFEMP2*) and *LTBP4*, respectively. The clinical severity of ARCL1 is highly variable, ranging from perinatal lethality to limited cardiovascular / respiratory involvement. Here, we report three ARCL1 cases with distinctive clinical features. The first case was a female fetus with *FBLN4* biallelic mutations presenting hydrops fetalis at 31<sup>w</sup> weeks gestation. Fetal echocardiography at 32wk revealed severe TR, MR, PR, with a highly tortuous, elongated and narrowed descending aorta. Autopsy revealed severe tortuosity of total aorta with thickened wall and narrow lumen, along with kinky aneurysm in subclavian and iliac arteries. The second case was a 4-month-old boy with compound heterozygous *FBLN4* mutations. Echocardiography revealed severe aortic regurgitation, dilatation of ascending aorta with isthmal narrowing and poststenotic dilatation. Brain MRI showed sporadic small infarction in addition to severe tortuosity in vertebral-basilar arteries. He presented general joint hypermobility and mild cutis laxa, though he didn't show any other characteristic skeletal features. Dilatation of ascending aorta was progressive and reached 44mm at 2y8m, followed by a successful surgical repair at 2y9m. The third case was a 26-year-old male with *LTBP4* mutations. He suffered asthma from early infancy and bone fractures in an elbow and fingers in his childhood. He felt shortness of breath at age 24 and visited our hospital. He presented marfanoid features with arachnodactyly, joint hypermobility, a characteristic face with retrognathia, bifid uvula and downslanting eyes, and redundant skin with sagging cheeks. Echocardiography revealed severe MR due to prominent MV prolapse with degenerative valves. Thoracic-abdominal-pelvic CT revealed severe emphysema and multiple bladder diverticula. He was successfully treated by mitral valve reconstruction and tricuspid valve annuloplasty to reduce MR/TR. Cutis laxa syndromes are highly heterogeneous with respect to organ involvement and severity. Since ARCL1 often accompanies cardiovascular complications, genetic study will help earlier diagnosis for presymptomatic cases to prevent further cardiovascular events.

**3076T**

**Congenital mydriasis in the multisystemic smooth muscle dysfunction syndrome: A harbinger of progressive vasculopathy, expanding the phenotype of the ACTA2 R179C mutation.** *J.N. Peeden<sup>1,2</sup>, R. Booher<sup>1</sup>.* 1) Medicine, East Tennessee Children's Hospital, Knoxville, TN., USA; 2) University of Tennessee Department of Medicine.

We report a patient who has the Multisystemic Smooth Muscle Dysfunction Syndrome (MSSMD), in order to draw attention to the progressive vasculopathy associated with this disorder and to expand the phenotype of the ACTA2 R179C mutation. The cardinal findings of which are present at birth. Born at term, He had hydronephrosis upon prenatal ultrasonography. He was noted to have a massively enlarged bladder and severe right hydronephrosis. He had no reflux. He would not void spontaneously. Upon cystoscopy, a rudimentary urethral valve was resected. He required intermittent catheterization to achieve bladder emptying. A small patent ductus arteriosus was confirmed on echocardiography. Ophthalmology consultation confirmed congenital mydriasis. Pupils were 7 to 7 ½ mm and non reactive. At six months, subclinical hypoxia was noted. Chest x-ray showed findings consistent with bronchopulmonary dysplasia. At cardiac catheterization systemic pulmonary artery pressure was found. There was a large PDA without evidence of coarctation. During surgery to repair the PDA, tissue was so friable and would not hold suture or bovine patch. Prolonged cross clamping of the aorta was required to achieve hemostasis, thereafter the patient developed spastic paraplegia. Other than paraplegia, the patient was normal neurologically. At age 5 he has an episode of left arm shaking that could not be stopped with pressure. EEG was normal. At age 8 he developed altered mental status. Multifocal strokes were present upon MRI, along with grossly abnormal neurovasculature. Multiple acute cortical infarctions due to hypoperfusion/infarction were found. MRA revealed a moyamoya pattern with fusiform aneurysmal dilation of bilateral petrous internal carotid arteries. He underwent bilateral encephalo-duro-arterio-myo-synangiosis successfully. He was found to have a de novo ACTA2 c. 535C>T in exon 6, leading to p.R179C amino acid substitution. Although the repair of PDA in children with ACTA2 mutations and the MSSMD syndrome have been successful, fatalities have occurred during surgery. Our patient survived, with significant neurological injury. Vascular friability, is we believe more likely with the R179C mutation. The knowledge then of the precise mutation (R179C) would identify a child at risk for surgical complications and progressive neurovascular disease; moreover a longitudinal review of our patient's clinical course expands the phenotype of this disorder.

## 3077F

**Further defining the extent of pleiotropy for genes with *de novo* pathogenic variants predisposing to Moyamoya disease, intellectual disability, and congenital heart disease.** A. Pinard<sup>1</sup>, S. Guey<sup>2</sup>, D. Guo<sup>3</sup>, S. Wallace<sup>4</sup>, N. Kharas<sup>5</sup>, E.S. Regalado<sup>1</sup>, E.M. Hostetler<sup>1</sup>, A.Z. Sharrief<sup>6</sup>, M.J. Bamshad<sup>5</sup>, D.A. Nickerson<sup>5</sup>, E. Tournier-Lasserre<sup>2,6</sup>, D.M Milewicz<sup>1</sup>, University of Washington Center for Mendelian Genomics. 1) Department of Internal Medicine, The University of Texas Health Science Center at Houston, Houston, TX 77030, USA; 2) Inserm UMR-S1161, Génétique et physiopathologie des maladies cérébro-vasculaires, Université Paris Diderot, Sorbonne Paris Cité, Paris, France; 3) Department of Neurobiology and Anatomy, The University of Texas Health Science Center at Houston McGovern Medical School, TX 77030, USA; 4) Department of Neurology, The University of Texas Health Science Center at Houston McGovern Medical School, TX 77030, USA; 5) Department of Genome Sciences, University of Washington, Seattle, WA 98195, USA; 6) AP-HP, Service de génétique moléculaire neurovasculaire, Centre de Référence des Maladies Vasculaires Rares du Cerveau et de l'œil, Groupe Hospitalier Saint-Louis Lariboisière, Paris, France.

Moyamoya disease (MMD) is a genetically heterogeneous occlusive cerebrovascular disease, often with pediatric onset, characterized by bilateral occlusion of the distal internal carotid artery, leading to compensatory collateral vessel formation at the base of the brain. Several genes have been identified increasing the risk for Moyamoya angiopathy but the majority of cases do not have an identified genetic trigger. Therefore, to identify novel genes for MMD, we performed whole exome sequencing in 41 trios and concentrated on *de novo* variants. Interestingly, we discovered 4 *de novo* rare pathogenic variants in three genes, *CHD4* (p.Arg1127Gln), *CNOT3* (p.Gln215\* and p.Leu522Ile) and *SETD5* (p.Glu642Asnfs\*15). *CHD4* *de novo* pathogenic variants are enriched in cases with congenital heart disease, intellectual disability, and distinctive dysmorphisms and including a case with MMD. *CNOT3* *de novo* pathogenic variants were reported in developmental disorder patients, and *SETD5* haploinsufficiency is established to predispose to global developmental delay with variable dysmorphic features. The phenotypes of our 4 *de novo* patients are overlapping with previously published phenotypes with 3/4 presenting with developmental delay, 2/4 intellectual disability, 2/4 facial abnormality, 1/4 bicuspid aortic valve, and 1/4 genitourinary defect. We then mined exome data from 158 additional probands with MMD, isolated or with affected family members, filtered for variants predicted to disrupt the protein sequence, and kept variants with a CADD score greater than 20. These three genes are invariant in the general population for both missense and loss of function (LoF) variants. Nevertheless, we found 9 additional rare pathogenic variants, including 5 missense and 1 splice donor site LoF variant in *CHD4*, 1 missense in two unrelated MMD probands in *CNOT3*, and 2 missenses in *SETD5*. *CHD4*, *CNOT3* and *SETD5* encode proteins involved in chromatin remodeling (component of NuRD, CCR4-NOT, and NCoR complex, respectively) and, together with a previously reported gene for MMD-like cerebrovascular disease, *YY1AP1* encoding a component of the INO80 chromatin remodeling complex, suggest altered chromatin remodeling as an underlying cause of MMD. Furthermore, this data support the hypothesis that MMD results from defective differentiation of smooth muscle cells in the cerebral arteries and expands our understanding of the phenotypic pleiotropy associated with genetic disruption of chromatin remodeling.

Pulmonary arterial hypertension (PAH) and pulmonary veno-occlusive disease (PVOD) are closely related forms of pulmonary hypertension but in contrast to hereditary PVOD for which a single gene has been identified and whose mutations provoke a recessively transmitted disease with high penetrance, several genes have been implicated in PAH since the discovery of *BMPR2* mutations in 2000. Here, we sought to determine the genetic architecture of PH according to gene mutations found in a cohort of French patients. Methods: Genetic analysis was prospectively performed on 268 PAH and PVOD patients (adult and pediatric cases). We developed a targeted capture strategy using SeqCap EZ choice library (Roche Nimblegen) coupled with multiplexing and high-throughput sequencing using the Miseq system (Illumina). We designed a gene panel including 9 genes analyzed for molecular diagnosis of PH (*BMPR2*, *TBX4*, *EIF2AK4*, *CAV1*, *KCNK3*, *SMAD9*, *ACVRL1*, *ENG*, *BMP9*). The *BMP10* gene, a *BMP9* paralog, was also included in the capture design. Standard bioinformatics pipelines were used for sequence analyses. Identified variants were classified according to ACMG. Following pedigree analysis and clinical examination, 181 patients were classified as sporadic idiopathic PAH (iPAH), 11 as familial PAH (fPAH), 13 as drug or toxin induced PAH and 63 as PVOD. A pathogenic mutation was identified in 49 of the 268 analyzed patients. Identification of bi-allelic *EIF2AK4* mutations in one initially suspected PAH case led us to reclassify this patient as PVOD. Thus 35 mutations were identified in iPAH patients (19.4% of iPAH), 6 in fPAH patients (54.5% of fPAH) and 8 in PVOD patients (12.5% of PVOD). 31 *BMPR2* mutations (25 iPAH, 6 fPAH), 5 *TBX4* mutations (5 iPAH), 2 *ACVRL1* (2 iPAH) 2 *BMP9* (2 iPAH), 1 *SMAD9* (1iPAH) and 8 biallelic *EIF2AK4* mutations (8 PVOD) were found. A truncating mutation (C.370C>T, p.Arg124\*) was found in the *BMP10* gene in a young female patient who was diagnosed with PAH at 11 yrs with severe evolution. No pathogenic mutation was identified in *KCNK3* and *CAV1* but 2 variants of unknown significance were identified in these genes. Conclusions: Gene panel sequencing is an efficient tool to improve the knowledge of PH genetic architecture. Our results confirm the involvement of genes previously described in hPAH, even rarely involved, reveal the emerging role of *TBX4* in adult PAH while this gene was initially described as a major gene in pediatric PAH and suggest *BMP10* as a new candidate.

**3079T**

**High clinical impact *KCNQ1* mutation present in 1/40 Amish: Culturally-appropriate return of results from population whole exome sequencing (WES).** E.A. Streeten<sup>1</sup>, V. See<sup>1</sup>, L.J. Jeng<sup>1</sup>, K. Maloney<sup>1</sup>, T.I. Pollin<sup>1</sup>, M. Daue<sup>1</sup>, B. Mitchell<sup>1</sup>, A.R. Shuldiner<sup>2,3</sup>. 1) Endocrinology, University of Maryland School of Medicine, Baltimore, MD; 2) Regeneron Pharmaceuticals; 3) Cardiology, University of Maryland School of Medicine.

**Background:** Mutations in *KCNQ1* cause Long QT Syndrome, Type 1 (LQTS1), with an estimated frequency of 1/2000. From research WES of 4950 Old Order Amish, we identified an exonic missense variant in *KCNQ1* (c.671C>T, p.T224M), which we classified as likely pathogenic per ACMG/AMP guidelines. One in 40 Amish carry this variant, with carriers demonstrating longer EKG-derived QTc intervals compared to non-carriers (b=20 msec; p=10<sup>-23</sup>). Since beta blocker (BB) therapy reduces the risk of syncope and sudden cardiac death (SCD) in LQTS1 by 70-90%, we performed follow up clinical phenotyping of the variant to inform treatment recommendations and enable genetic counseling. **Methods:** Following IRB approval, 124 Amish were notified that they carry a genetic change that put them at risk for heart problems. To date, 87 individuals have accepted an invitation to enroll in a study that would clarify their risk. At a first home visit, we obtained a comprehensive medical history including personal history of syncope, 3-generation family history (FH), repeat EKG, and blood for CLIA confirmation. After variant confirmation, we returned for a second home visit to provide treatment recommendations (Heart Rhythm Society guidelines) and genetic counseling. Twenty-six non-variant carrier Amish individuals were enrolled as controls. **Results:** All p.T224M variants were CLIA-confirmed. Mean QTc was 480±29 ms in cases, 423±20 ms in controls, p=0.000011 (normal ranges: M<450 ms, F<460 ms). Syncope was noted in 28 (33%) cases vs 4 (17%) controls (p=0.17), with non-vasovagal syncope in 7 (17%) cases vs zero controls (p=0.039). A FH of SCD in 1<sup>st</sup> or 2<sup>nd</sup> degree relatives was noted in 34 (40%) cases vs zero controls (p = 0.00006). A FH of SCD < 30 yo was noted in 9 (10%) cases, including two crib deaths, a 6 yo walking and a 12 yo swimming, vs zero controls (p=0.008). Of 36 visit #2 completed, 33 (94%) cases met guidelines for BB therapy. Of these, 19 (58%) agreed to start BB, which was coordinated with local primary care providers. Cascade testing was recommended for all 1<sup>st</sup> degree relatives. **Conclusions:** A *KCNQ1* likely pathogenic variant was present in 1/40 Amish and associated with a high risk of syncope and FH of early sudden death. Increased awareness, cascade and population screening, and treatment of affected individuals will likely prevent significant arrhythmogenic morbidity and mortality.

**Targeting ER stress for collagen IV disorders reveals tissue specific outcomes and reduces intracerebral haemorrhaging.** T. Van Agtmael<sup>1</sup>, F. Jones<sup>1</sup>, L. Murray<sup>1</sup>, S. McNeilly<sup>1</sup>, A. Dean<sup>1</sup>, A. Aman<sup>1</sup>, K. Kadler<sup>2</sup>. 1) Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, G12 8QQ United Kingdom; 2) Wellcome Centre for Cell-Matrix Research, University of Manchester, Manchester, M13 9PT, UK.

Mutations in the collagen genes *COL4A1* and *COL4A2* cause Mendelian eye, kidney and cerebrovascular disease including intracerebral haemorrhage (ICH), and common collagen IV variants are a risk factor for sporadic ICH. Development of novel treatment for these diseases is urgently needed and requires understanding of pathomolecular disease mechanisms. While mutations cause endoplasmic reticulum (ER) stress and basement membrane (BM) defects, their relative contribution to disease and the potential of ER-stress as a therapeutic target remains unclear. To address this mice were treated with the chemical chaperones, PBA and TUDCA, as a preventative therapy from conception for 5 months or as a 1 month treatment from 4 months of age, when the disease is developed. This revealed that preventative oral treatment of *Col4a1* mutant mice with PBA and TUDCA reduced sporadic adult ICH and tubular kidney defects. In contrast, glomerular kidney disease and eye disease remained. Interestingly, ICH was also reduced following treatment of adult mice with established disease. PBA acted by reducing ER-stress which was accompanied by increased collagen IV incorporation into basement membranes (BM). However, chemical chaperone treatment did not improve BM structure with a reduced ability of basement membrane to withstand mechanical stress. Comparative analysis between ER stress, matrix defects and pathology suggested that Mendelian collagen disorders have tissue specific disease mechanisms. These data provide mechanistic insight into *COL4A1* disease, and identify that alleviating ER-stress is a valid therapeutic target for treating sporadic ICH which may be feasible using FDA-approved compounds. Future treatments for collagen IV patients will require stratification based on the clinical presentation in patients and mechanism of mutations.

**A *PLN* nonsense variant causes dilated cardiomyopathy with heart failure in a novel autosomal recessive inheritance mode.** *D.W. Wang<sup>1</sup>, Z. Li<sup>2</sup>, P. Chen<sup>2</sup>, J. Xu<sup>2</sup>, H. Wang<sup>2</sup>, D-W. Wang<sup>2</sup>.* 1) State Key Laboratory of Reproductive Medicine and The Center for Clinical Reproductive Medicine, Jiangsu Province Hospital, Nanjing, Jiangsu Province, China; 2) Division of Cardiology, Departments of Internal Medicine and Genetic Diagnosis Center, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.

**Background**—Pathogenic variants in human phospholamban coding gene (*PLN*) are responsible for autosomal dominant hereditary dilated cardiomyopathy (DCM) with heart failure. **Methods and Results**—We performed high-depth targeted next-generation sequencing using a cardiomyopathy-panel containing 80 disease-related genes in 650 patients with cardiomyopathy to identify potential pathogenic *PLN* variants. A novel homozygous nonsense variant (p.Glu2Ter, c.4G>T) in *PLN* gene was identified in a 36-year-old male suffered from DCM with heart failure out of 650 unrelated cardiomyopathy patients. Whole-exome sequencing and Sanger sequencing were used to comprehensively evaluate the genetic cause of the proband and his pedigree. No more DCM-causing variant or likely pathogenic copy number variation was identified. The *PLN*-p.Glu2Ter variant is in an evolutionary highly conservative area across multiple species (phyloP score=2.7). The *PLN*-p.Glu2Ter variant was not detected in 800 unrelated healthy controls. Western blots showed that the variant significantly reduced the phospholamban expression. In pedigree analysis, we found that all heterozygous *PLN*-p.Glu2Ter carriers had normal heart size and cardiac function, which revealed an autosomal recessive inheritance mode. **Conclusions**—Our study identifies a novel pathogenic variant of *PLN*, and enriches a novel pathogenic inheritance mode of *PLN* causing DCM and heart failure.

**A new catecholaminergic polymorphic ventricular tachycardia mechanism associated with numerous sudden deaths.** *M. Blancard<sup>1</sup>, Z. Touat-Hamici<sup>1</sup>, L. Yin<sup>2</sup>, G. Vaksman<sup>3</sup>, N. Roux-Buisson<sup>4</sup>, V. Fressart<sup>5</sup>, D. Klug<sup>6</sup>, N. Neyroud<sup>7</sup>, I. Denjoy<sup>8</sup>, J. Ramos-Franco<sup>8</sup>, A.M. Gomez<sup>2</sup>, P. Guicheney<sup>1</sup>.* 1) INSERM UMRS1166, Sorbonne University, Paris, France; 2) INSERM UMRS1180, Paris-Sud University, Châtenay-Malabry, France; 3) Hôpital Privé de la Louvière, Lille, France; 4) Université Joseph Fourier, Grenoble, France; 5) Unité de Cardiogénétique et Myogénétique, AP-HP, Groupe Pitié-Salpêtrière, Paris, France; 6) CHRU Lille - Hôpital Cardiologique, Lille Cedex, France; 7) AP-HP, Hôpital Bichat, Département de Cardiologie, Paris, France; 8) Rush University Medical Center, Chicago, IL 60612, USA.

**Background:** Catecholaminergic polymorphic ventricular tachycardia (CPVT) is a rare genetic arrhythmia triggered by exercise or acute emotion in patients with normal resting electrocardiogram. The major disease-causing gene for the dominant form, *RYR2*, encodes the cardiac ryanodine receptor (RyR2), while rare variants in RyR2-associated proteins (calsequestrin 2, triadin), encoded by *CASQ2* and *TRDN*, are identified in recessive forms of CPVT. We reported two French families with numerous sudden deaths and a novel *RYR2* variant. **Methods:** Family members were evaluated by exercise stress test, and CPVT genes were sequenced. Spontaneous Ca<sup>2+</sup> release was evaluated by fluorescent microscopy in HEK293 cells expressing RyR2 wild type or the novel variant with Fura-2 AM as loading dye. Cells were challenged with either 8-Bromo-cAMP or forskolin to mimic adrenergic stress. **Results:** In a four-generation family, eight sudden cardiac deaths occurred before the age of 30 years. The proband had a first syncope at the age of 10, then experienced an aborted sudden cardiac death at the age of 14 in a context of emotion and moderate hypokalemia. The grand-parents were consanguineous. We identified a novel *RYR2* missense variant inducing the loss of a negative charge located out of the four classical domains where CPVT mutations are commonly found. This well conserved residue is located in a RyR2 domain of unknown function. Genotyping clearly showed that the affected subjects were all carriers of at least one copy of the *RYR2* variant. Three sisters were homozygous while eleven other patients were heterozygous carriers. We also identified the same variant at the heterozygous state in another family where two sudden deaths occurred. The analysis of spontaneous calcium release in presence of various calcium concentrations revealed no difference between the WT and the mutant RyR2 at basal conditions which excluded the most classical mechanism of a leaky mutant channel. WT-RyR2 transfected cells pretreated with stable c-AMP or forskolin showed the expected increase in SOICR activity while mutant cells did not present any enhanced activity. **Conclusions:** We identified a novel loss-of-function RyR2 variant, unresponsive to adrenergic stimulation, responsible for the high number of sudden deaths occurring in two families.

**3083F**

**Six arterial tortuosity case with novel and known homozygous and compound heterozygote missense variations in the SLC2A10 gene: Genotype/phenotype correlations.** A. Kablan<sup>1</sup>, E. Mihci<sup>2</sup>, A. Kocabas<sup>3</sup>, B. Nur<sup>2</sup>, F. Kardelen<sup>3</sup>, M. Cousin<sup>4,5</sup>, F. Uysal<sup>6</sup>, O. Bostan<sup>6</sup>, E. Cil<sup>6</sup>, E. Klee<sup>4,5</sup>, S.G. Temel<sup>1</sup>. 1) Uludag University, Faculty of Medicine, Department of Medical Genetics, Bursa, Turkey; 2) Akdeniz University School Of Medicine Department of Pediatrics Division of Pediatric Genetics Antalya, Turkey; 3) Health Science University, Antalya Training and Research Hospital, Department of Pediatric Cardiology, Turkey; 4) Center for Individualized Medicine, Mayo Clinic, Rochester, MN, USA; 5) Department of Clinical Genomics, Mayo Clinic, Rochester, MN, USA; 6) Uludag University, Faculty of Medicine, Department of Pediatric Cardiology, Bursa, Turkey.

Arterial tortuosity syndrome (ATS) is a rare autosomal recessive connective tissue disorder, mainly characterized by tortuosity and elongation of the large and medium-sized arteries with predisposition to stenosis and aneurysm. ATS is caused by mutations in the *SLC2A10* gene, encoding for the facilitative glucose transporter 10 (GLUT10) and is described typically in pediatric patients. We report 3 unrelated boy, 2 unrelated men and one girl with ATS. The main clinical findings of all our cases included elongated face, saggy cheeks, micrognathia, malar hypoplasia, joint hypermobility and hyperextensible skin. Sequencing of the *SLC2A10* gene in the probands revealed the presence of two novel pathogenic homozygous missense variants (c.727C>A/c.395C>A), one compound heterozygote missense variants (c.314G>A, c.727C>A) and one known homozygous missense variant (c.1465G>C) (2 case from sama family, one unrelated case). Heterozygous *SLC2A10* mutations were confirmed in both mothers and fathers. The missense variants lead to a p.Gln243Lys, p.Arg132Gln and p.Gly489Arg change in the seventh transmembrane domain, endofacial loop and in the twelfth transmembrane domain of GLUT10, respectively. Genotype/phenotype correlations with detailed clinical, radiological data and genetic findings of our cases will be discussed. Because ATS resembles some Connective Tissue Disorders (CTDs) like Loey-Dietz and Marfan syndrome, timely differential diagnosis is extremely important for early diagnosis, management of the disease and for intervention of aneurysms to prevent serious vascular complications. Molecular diagnosis is mandatory to distinguish ATS from other CTDs with strictly overlapping clinical signs and with a high rate of more severe cardiovascular events and to define targeted clinical follow-up and timely cardiovascular surgery when needed. .

**3084W**

**A novel de novo heterozygous variant in ACTC1 in a patient with a Noonan syndrome phenotype.** V.E.H. Kim<sup>1</sup>, M. Buscarilli<sup>1</sup>, G.L. Yamamoto<sup>1,2</sup>, R.S. Honjo<sup>1</sup>, J.R.M. Ceroni<sup>1</sup>, A.C. Malaquias<sup>2</sup>, C.A. Kim<sup>1</sup>, A.A.L. Jorge<sup>3</sup>, D.R. Bertola<sup>1,2</sup>. 1) Departamento de Genética, Instituto da Criança dos Hospital das Clínicas da FMUSP, São Paulo, SP, Brazil; 2) Centro de Pesquisas sobre o Genoma Humano e Células Tronco – Instituto de Biociências – USP; 3) Unidade de Endocrinologia Genética LIM/25 - Disciplina de Endocrinologia do Hospital das Clínica das FMUSP – HC – FMUSP.

The alpha-cardiac actin gene (*ACTC1*) has an essential role on the interaction domain with myosin heavy chain, mediating the heart function. *ACTC1* disturbance is a known cause of cardiomyopathy and arrhythmia, as well as structural cardiac defects, such as septal defects and valvar anomalies, including Ebstein anomaly. Furthermore, in a large Lebanese Maronite family, besides the cardiac anomaly, some of the affected individuals harboring a variant in *ACTC1* presented midline defects, suggesting a role not only in heart embryology. Noonan syndrome is a genetic heterogenous RASopathy with more than ten genes responsible for this disorder, characterized mainly by short stature, facial dysmorphisms, including hypertelorism, sternal deformity, cardiac defect and cryptorchidism. The diagnostic yield of the molecular analysis achieves approximately 80%. We report on an isolated case, a 13 year-old male patient presenting typical features of Noonan syndrome, with Ebstein anomaly, atrial septal defects and Wolf-Parkinson-White syndrome. Whole-exome sequencing of the patient and his parents was performed and a novel, de novo heterozygous missense mutation in *ACTC1* was identified. No pathogenic variants either in known genes associated with a RASopathy or in other genes associated with a monogenic disorder have been found. Since the employment of next-generation sequencing as a tool for the discovery of new genes responsible for monogenic disorders, six novel genes have been associated with Noonan syndrome in a small percentage of the cases. Still, the whole spectrum of molecular basis of this disorder is not completely known. We could not rule out for certainty that the *ACTC1* variant in the present patient is responsible only for the cardiac anomaly, but this is the second reported case harboring *ACTC1* variant and showing other signs besides heart defect. In the patients previously reported, although the authors did not consider the diagnosis of Noonan syndrome, several of them presented ocular hypertelorism and pectus deformity, cardinal features of Noonan syndrome. It is possible to speculate that this specific actin could play a role in a more widespread embryonal development leading to clinical features within a Noonan syndrome phenotype. FAPESP 2013/08028-1; CNPq 304130/2016-8.

**Whole exome sequencing identifies a novel candidate gene in an Ashkenazi Jewish family with Tetralogy of Fallot.** J. Liu, A. Sara, J.Y. Liu, P. Gupta, J. Fan, J. Wang. Medicine - Cardiology, University of California, Los Angeles, Los Angeles, CA.

Tetralogy of Fallot (ToF) is a congenital cardiac malformation consisting of four separate defects of the heart. Up to a quarter of ToF patients consist of individuals with chromosomal anomalies, such as trisomy 21 (Down Syndrome) or chromosome 22q11.2 deletion syndrome (DiGeorge Syndrome). However, due to intricate inheritance patterns and suspected multifactorial disease causation, around 70% of ToF cases are idiopathic. Yet, with a familial recurrence rate of 3%, an underlying genetic cause is strongly suspected. Here, we evaluate the genetic origin of ToF in a family of two affected sisters with unaffected parents. Using whole exome sequencing (WES) and computational analysis, we uncovered compound heterozygous variants in our affected patients within the DSPP gene. DSPP, or dentin sialophosphoprotein, is mainly established to serve a vital role in odontogenesis. While previous western blotting and RT-PCR analysis in mice demonstrate absence of DSPP in non-mineralized cardiac tissue, the gene's possible role in cardiogenesis has yet to be substantially characterized. Continued progress of this project aims to address the genetic contribution of DSPP as a developmental factor for ToF, which would facilitate the creation of targeted treatments in the future. Furthermore, the project contributes to the advancement of therapies that take individual variability in genes into account, and thus contributes data to a growing field of precision medicine.

**3086F**

**Whole exome sequencing improves diagnostic precision in individuals affected with thoracic aortic aneurysm and dissection.** B. Wolford<sup>1</sup>, W. Hornsby<sup>2</sup>, D. Guo<sup>3</sup>, W. Zhou<sup>1</sup>, M. Lin<sup>2</sup>, L. Farhat<sup>4</sup>, J. McNamara<sup>2</sup>, A. Driscoll<sup>5</sup>, X. Wu<sup>6</sup>, E. Schmidt<sup>1</sup>, C. Brummett<sup>6</sup>, H. Patel<sup>6</sup>, K. Eagle<sup>2</sup>, D. Milewicz<sup>2</sup>, J. Kitzman<sup>1,6</sup>, C. Willer<sup>1,2,6</sup>, B. Yang<sup>6</sup>. 1) Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, Michigan; 2) Department of Internal Medicine, University of Michigan, Ann Arbor, Michigan; 3) Department of Internal Medicine, University of Texas Health Science Center at Houston (UTHealth), Houston, Texas; 4) Department of Cardiac Surgery, University of Michigan, Ann Arbor, Michigan; 5) Department of Anesthesiology, University of Michigan, Ann Arbor, Michigan; 6) Department of Human Genetics, University of Michigan, Ann Arbor, Michigan.

Thoracic aortic aneurysm and dissection (TAAD) is a genetically heterogeneous and highly heritable disease involving dilation of the aorta (aneurysm) and possible tearing of aortic wall (dissection) or rupture. A genetic diagnosis is critical for precise clinical care since familial or syndromic TAAD is an indication for earlier surgical intervention due to increased risk of dissection or rupture of an aneurysm. This study demonstrates the use of research-level whole exome sequencing (WES) in the diagnosis and management of TAAD. WES was performed in 265 thoracic aortic dissection (Stanford type A and B) or rupture cases from the University of Michigan Cardiovascular Health Improvement Project (CHIP) Biorepository, and 265 age-, sex-, and ancestry-matched unaffected controls from the Michigan Genomics Initiative (MGI) biobank. After quality control, 249 non-trauma dissection cases and 258 controls were retained. Annotation of variants in 11 TAAD genes, identified *a priori*, was performed blinded to a sample's case or control status. Rare variants were annotated as pathogenic based on ACMG guidelines and established criteria for specific aortopathy genes or as variants of unknown significance (VUS) if lacking proof of pathogenicity. We replicated the WES-pathogenic variants using Molecular Inversion Probe Sequencing (MIPS). We identified 24 pathogenic variants across 6 genes (*COL3A1*, *FBN1*, *LOX*, *PRKG1*, *SMAD3*, *TGFBR2*) in 26 individuals representing 10.4% of cases and 0% of controls. For 17 individuals these results align with previous clinical diagnoses. However, for 9 individuals, research-level WES and annotation of pathogenic variants adds diagnostic precision by providing a diagnosis (n=8) or correcting a diagnosis (n=1). We also identified 4 individuals with diagnoses based on previous CLIA genetic testing which need revision after research-level WES and annotation as VUS. Although previous work demonstrates an increased burden of VUS in dissection cases < 56 years of age, VUS burden in aortopathy genes was not increased in our cohort ( $\chi^2 = 2.94$ , p-value=0.086). This demonstrates the need for greater understanding and careful interpretation of VUS in clinical practice. This work suggests that research-level WES increases diagnostic precision and can be used to support clinical decision making for TAAD patients and cascade screening of family members. We plan to return these results to patients in collaboration with aortic surgeons and genetic counselors.

Chauvin-Robinet<sup>1,2</sup>, L. Faivre<sup>1,2</sup>. 1) Reference Center for Developmental Anomalies, Department of Medical Genetics, Dijon University Hospital, Dijon, France; 2) INSERM U1231, LNC UMR1231 GAD, Burgundy University, Dijon, France; 3) Pediatrics Department of Cardiology, Dijon University Hospital, Dijon, France; 4) Gynecology and Obstetrics Department, Dijon University Hospital, Dijon, France; 5) Department of Cardiology, Dijon University Hospital, Dijon, France; 6) Pathology Department, Dijon University Hospital, Dijon, France.

PRDM16 (positive regulatory domain 16, NM\_022114.3, 1p36.32, #605557) located in the critical region for cardiomyopathy defined by Gajecka et al. (2010) encodes a zinc finger transcription factor involved in leukemogenesis, palatogenesis, neurogenesis, and brown adipose tissue differentiation. In 2013, Arndt et al resequenced PRDM16 in 75 non syndromic individuals with left ventricular noncompaction (LVNC, #615373) and in a series of 131 cardiac biopsies from individuals with dilated cardiomyopathy (CMD, #615373). Eight of these samples were found to carry putatively deleterious sequence changes in PRDM16. We present the first case of PRDM16 mutation in a fetus of a 37-year-old female, gravida 1, para 0. The third trimester obstetric ultrasound revealed a hydropic fetus with hydramnios and expanded hypocinetic heart. Familial history was negative. Exome sequencing identified a de novo c.1057C>T (p.Gln353\*) heterozygous variant in PRDM16 never reported in gnomAD. The CADD and GERP scores were respectively 38 and 4.56. In ExAC, the gene appears to be intolerant to the loss of function (pLI=1). It also identified three variants of unknown significance (VOUS), according to the ACMG (American College of Medical Genetics and Genomics) guidelines, in genes described in association with cardiomyopathy; two in the titin gene (TTN, NM\_001256850.1): a de novo missense variant c.44319A>C (p.Lys14773Asn) and a splice variant c.33043+5A>G inherited from the mother; one in the Lim Domain-Binding 3 gene (LDB3, NM\_001080116.1), c.349G>A (p.Asp117Asn) inherited from the mother. The familial segregation tests of all the variants were verified by Sanger sequencing. The parents elected to terminate the pregnancy at 31 weeks of gestation and 3 days, and a 2610g, 48cm, eutrophic fetus was delivered with facial dysmorphism due to hydrops. The phenotype showed a isolated cardiomegaly with a fibroelastotic thickening of the endocardium of the ventricles predominant on the left and a thickened fibrotic interventricular septum. Noted that echocardiographies of the parents were both normal. Besides to the PRDM16 de novo probably pathogenic variant, the TTN and LDB3 VOUS could possibly contribute to the severity of the cardiac phenotype of the fetus. Because of the genetic heterogeneity of cardiomyopathies, large panels or even WES should be considered as the main approaches for the molecular diagnosis in particular in fetal presentations, where multiple hits seem to be common.

**Genome-editing patient-specific induced pluripotent stem cells to investigate the functional role of RARG gene in doxorubicin-induced cardiotoxicity.** H. Huang<sup>1</sup>, E. Christidi<sup>1</sup>, L. Brunham<sup>1,2,3</sup>. 1) Centre for Heart Lung Innovation, Department of Medicine, University of British Columbia, Vancouver, BC, Canada; 2) Translational Laboratory in Genetic Medicine, Agency for Science, Technology and Research, Singapore; 3) Department of Medicine, National University of Singapore, Singapore.

**Background:** Doxorubicin is a commonly used chemotherapy drug that used to treat many adult and childhood cancers, but its clinical usefulness is limited by doxorubicin-induced cardiotoxicity (DIC). The risk of DIC increases sharply at doses above 550 mg/m<sup>2</sup>. However, some patients suffer from DIC even at low doses, suggesting the presence of genetic susceptibility to this adverse drug reaction. **Approach:** The molecular mechanisms of DIC are still not fully understood. A genetic variant (rs2229774, p. Ser427Leu) located in Retinoic Acid Receptor Gamma (*RARG*) gene was identified by a genome-wide association study (GWAS) to be associated with DIC. The functional role of genetic variation in *RARG* on DIC is currently unknown. The goal of this study was to investigate the role of *RARG* in DIC. To do so, we performed genome editing in patient-specific induced pluripotent stem cells (iPSCs) to introduce the rs2229774 variant or inactivate the *RARG* gene, and characterized the cellular phenotypes of isogenic pairs of iPSC-derived cardiomyocytes (CMs). **Results:** Using CRISPR/Cas9 techniques, we successfully inactivated the *RARG* gene in iPSCs, which was confirmed by qPCR gene expression assay, and introduced the rs2229774 variant in both the heterozygous and homozygous state. With cell viability assays, we show that whereas presence of rs2229774 does not alter the response to doxorubicin, inactivation of *RARG* renders the cardiomyocytes less susceptibility to DIC. **Conclusion:** Our results provide evidence for a functional role of *RARG* in DIC, while at the same time suggesting that this effect may not be mediated by rs2229774. More broadly, our results demonstrate the utility of genome-editing in iPSCs to investigate the functional significance of GWAS variants and genes associated with drug response.

**3089F****Genotype-phenotype: Phenotype differences when studying individual mutations in the cysteines of cbEGF-like domains in fibrillin-1 gene**

**(FBN1).** J.A. Aragon-Martin, Y.B.A. Wan, M. Garcia, A.H. Child. Genetics Department, Molecular and Clinical Sciences Research Institute, London, United Kingdom.

**Background:** Marfan syndrome (MFS) is a monogenic autosomal dominant connective tissue disorder that is phenotypically heterogeneous [cardiovascular (Thoracic Aortic Aneurysm – TAA), ocular (Ectopia Lentis – EL), skeletal (Scoliosis)] and reported to be due to mutations in *FBN1*. There are 43 cbEGF-like domains that contain 6 highly conserved cysteine residues that form disulphide bonds between themselves: C<sup>1</sup>-C<sup>2</sup>, C<sup>2</sup>-C<sup>4</sup> and C<sup>4</sup>-C<sup>6</sup>. Previous studies *in vitro* (proteolysis of recombinant fibrillin-1 fragments) showed that individual mutations in cbEGF domains can affect these domains differently and may suggest an explanation for some genotype-phenotype relationship in MFS. **Methods:** Patients (n=75 – 33M:42F) with mutations in one of the 6 cysteine residues in any of the 43 cbEGF-like domains were entered in the study. Clinical data was obtained from the Marfan clinic at St George's Hospital and the genotypes from the *FBN1* mutation-screening database in the Sonalee Laboratory. A genotype-phenotype database was created with this data. A new column was added to record the name of the substituted amino acid. The results from the phenotypes thoracic aortic dissection and thoracic aortic aneurysm were combined and named TAAD since both of them can lead to death. Only TAAD and EL were studied since skeletal and other features can be seen in the general population. **Results:** When looking at cysteine residues in C<sup>1</sup>, C<sup>2</sup>, C<sup>3</sup>, C<sup>4</sup>, C<sup>5</sup> or C<sup>6</sup> individually: females were less likely to have TAAD phenotype but more likely to have EL phenotype when the amino acid substituted in C<sup>1</sup> was tyrosine (Y – p=0.0476) or in C<sup>3</sup> was arginine (R – p=0.0286). When looking at all cysteine residues together: females were less likely than men to express TAAD phenotype (p=0.0145); females were less likely to have TAAD phenotype when the amino acid substituted was either Y (p=0.0052) or R (p=0.0112); both sexes were more protected from EL phenotype but had a high incidence of TAAD when the amino acid substituted was tryptophan (W – p=0.0476). **Conclusions:** Predisposition to TAAD or EL phenotype is partially determined by the amino acid replacing cysteine. It is imperative to look at a larger cohort (UMD) to clarify further these findings. Sex difference may be due to hormonal influence or protective gene on the X chromosome. We suggest looking at copy number variations and methylation to better understand variability in this cohort and also in family members with the same mutation.

**3090W****Heterozygote Familial Hypercholesterolemia (HeFH) genotype-phenotype correlations among two AstraZeneca sponsored studies.**

K. Carss<sup>1</sup>, J. Hostyk<sup>2</sup>, S. Petrovski<sup>1</sup>, R. March<sup>1</sup>, D.B. Goldstein<sup>2</sup>, C. Haefliger<sup>1</sup>. 1) AstraZeneca Centre for Genomics Research, Precision Medicine and Genomics, IMED Biotech Unit, AstraZeneca, Cambridge, UK; 2) Institute for Genomic Medicine, Columbia University Medical Center, New York, USA.

Heterozygote familial hypercholesterolemia (HeFH) is a disease of lipid metabolism that affects ~1/500 individuals and leads to early coronary heart disease. Here, we present whole-exome sequencing (WES) results from HeFH patients from two AstraZeneca clinical trials designed to assess the efficacy of rosuvastatin on this population (n=369 unrelated cases). The aims of this study were threefold. First, to identify pathogenic variants in known genes, second to identify putative novel candidate HeFH genes using a collapsing analysis approach, and third to leverage the rich phenotypic data available to identify genotype-phenotype correlations. Overall, pathogenic variants were identified in known HeFH-associated genes in 263 (71.3%) cases: 251 (68%) in *LDLR*, 10 (2.7%) in *APOB*, and 2 (0.5%) in *PCSK9*. We applied rare-variant gene-based collapsing analysis comparing 106 (28.7%) unsolved cases to a collection of ancestry-matched 5,930 sequenced population controls. While no novel gene achieved genome-wide significance ( $p < 2.7 \times 10^{-6}$ ), this analysis has provided a list of candidate genes. We also identified several interesting genotype-phenotype correlations. Although the age of diagnosis is unknown, we found that patients with a pathogenic protein-truncating *LDLR* variant were recruited into the studies at a younger age than patients with a pathogenic missense *LDLR* variant (24.5 years vs 43 years median;  $p = 0.032$ ). After correction for clinical covariates, patients with a *APOB* molecular diagnosis also have higher baseline high-density lipoprotein cholesterol (HDL-C) levels than patients without ( $p = 5.2 \times 10^{-3}$ ). Specific recurring *LDLR* variants were found to affect baseline low-density lipoprotein cholesterol (LDL-C) levels, including ENSP00000454071.1:p.Pro309LysfsTer59 ( $p = 1.7 \times 10^{-7}$ ). In conclusion, exome sequencing followed by a diagnostic variant screen, collapsing analysis, and genotype-phenotype correlation analysis yields deeper insight into the genetic architecture and clinical characteristics of the HeFH patient population.

**3091T**

**Electronic health record phenotypes of patients with rare loss-of-function variants within genes associated with heart disease.** C. Haggerty, L. Jing, D. Hartzel, D. Carey, B. Formwalt on behalf of the DiscovEHR collaboration. Geisinger, Danville, PA.

The prevalence of rare, putative loss of function (LOF) variants in the human genome is much higher than expected. Thus, while specific variants are rare, their collective effect on patient health may be significant. This study tested this hypothesis for genes associated with heart disease using whole exomes from the DiscovEHR cohort of 92,445. We reviewed general cardiomyopathy and arrhythmia gene panels from 4 commercial labs and computed their union and intersection (i.e., genes appearing on all cardiomyopathy or all arrhythmia panels). We identified rare (MAF<0.001) putative LOF (frameshift, splice site, stop gain) and other protein altering variants (missense, stop loss), and cross-referenced with ClinVar. We selected: 1) cases: having a LOF or “two-star” (and above) pathogenic/likely pathogenic missense variant in any gene on the panel intersection list; and 2) controls: lacking any LOF or nonsynonymous variant (not annotated as benign/likely benign) on the panel union list. We performed genome-wide association (PheWAS), compared echocardiographic and electrocardiographic data linearly adjusted for age and sex, and modeled Cox proportional hazards for all-cause mortality adjusted for sex, body mass index and diabetes. 16,917 individuals (18.3%) carried none of over 40,000 variants in 110 genes associated with cardiomyopathy or arrhythmia (controls). 3,979 individuals (4.3%) carried at least one rare variant in the 52 consensus genes (cases). By age and sex-adjusted PheWAS, the cases had significantly increased odds for numerous cardiac diagnoses, including conduction disorders, cardiomyopathies, and heart failure (Table). Cases also had slightly lower left ventricular ejection fraction (1.1% absolute,  $p=1 \times 10^{-9}$ ), and longer PR (3.6ms,  $p=1 \times 10^{-8}$ ) and QTc (4.0ms,  $p=4 \times 10^{-9}$ ) intervals. Finally, cases had 15% higher mortality risk ( $p=0.02$ ). In conclusion, regardless of specific gene-disease associations, the presence of a rare LOF or known pathogenic missense variant in cardiomyopathy or arrhythmia genes is associated with increased risk for heart disease and early mortality, in contrast to previous data using such genome-first approaches. Future studies will incorporate such high level genomic data into polygenic risk models to potentially improve outcome predictions.

PheWAS findings		
	Odds Ratio	p
Other cardiac conduction disorders	8.4	6.00E-06
Other hypertrophic cardiomyopathy	3.7	1.00E-06
Primary/intrinsic cardiomyopathies	2.7	3.00E-26
Systolic heart failure	1.7	3.00E-10

**Characterization of the genetic architecture and identification of novel genes and variants in an infantile cardiomyopathy cohort.** C. Gonzaga-Jauregui<sup>1</sup>, T. Lee<sup>2</sup>, J. Staples<sup>1</sup>, Y. Shen<sup>3,4</sup>, J. Wang<sup>3,4</sup>, F. Dewey<sup>1</sup>, J.G. Reid<sup>1</sup>, J.D. Overton<sup>1</sup>, W.K. Chung<sup>2,5</sup>. 1) 777 Old Saw Mill River Road, Tarrytown, NY, 10591 USA; 2) Department of Pediatrics, Columbia University Medical Center, New York, New York, USA; 3) Department of Systems Biology, Columbia University Medical Center, New York, New York, USA; 4) Department of Biomedical Informatics, Columbia University Medical Center, New York, New York, USA; 5) Department of Medicine, Columbia University Medical Center, New York, New York, USA.

Cardiomyopathies are a genetically and clinically heterogeneous group of disorders that affect the cardiac muscle. These disorders can cause the heart to become enlarged, increase its thickness, or reduce its contractility leading to reduced heart function and heart failure. Cardiomyopathies can be broadly divided into hypertrophic, dilated, restrictive, arrhythmogenic right ventricular, left ventricular noncompaction, and mixed. To date, several genes have been identified as contributing to different types of cardiomyopathy. Mutations in some cardiomyopathy associated genes can confer a spectrum of heart disease from hypertrophic to dilated cardiomyopathy, while others are associated with syndromic presentations in which cardiomyopathy is one component. We performed whole-exome sequencing in a cohort of 50 probands with cardiomyopathy of infantile onset, their parents, and other family members when available. We performed rare variant family based analyses, either under a trio-based approach if parents were unaffected or pedigree-guided in cases positive for a family history of cardiomyopathy. We identified known and novel rare variants in known cardiomyopathy associated genes in 17 probands, including variants in myosin and myosin binding structural proteins like *MYBPC3* and *MYH7*, and additional cardiomyopathy genes like *TTN*, *TNNI3*, *TNNC1*, *DES*, and *BAG3*. Additionally, we identified probands with variants in *PTPN11* and *RAF1*, both associated with Noonan syndrome that can include hypertrophic cardiomyopathy as a feature. We identified either *de novo* or compound heterozygous inherited variants in novel cardiomyopathy genes. These novel genes can be functionally classified as affecting cardiomyocyte structure or involved in signal transduction or energy homeostasis of the cardiac muscle. For example, we identified a *de novo* missense mutation in *MRAS*, a member of the RAS oncogene family expressed in the heart, in a child with prenatal hypertrophic cardiomyopathy. In another proband with a diagnosis of dilated cardiomyopathy, we identified compound heterozygous frameshift and missense variants in the myosin light chain kinase 3 gene, *MYLK3*, which has specific and high expression in cardiomyocytes and promotes sarcomere formation. These findings expand our understanding of the genetic architecture of genetic cardiomyopathies, the mechanisms involved in their pathogenesis, and potentially identify novel therapeutic targets.

## 3093W

**Familial autonomic ganglionopathy and neurogenic orthostatic hypotension associated with rare *CHRNA3* variants.** J.A. Phillips<sup>1</sup>, C.A. Shihao<sup>2</sup>, F. Vetrini<sup>3</sup>, P. Ward<sup>4</sup>, J.H. Sheehan<sup>5</sup>, J. Meiler<sup>6</sup>, J.A. Capra<sup>5</sup>, L. Fairbrother<sup>7</sup>, M.E. Koziura<sup>1</sup>, J.D. Cogan<sup>1</sup>, J.H. Newman<sup>2</sup>, Y. Yang<sup>6,7</sup>, R. Hamid<sup>1</sup>. 1) Pediatrics, Vanderbilt University Medical Center, Nashville, TN; 2) Medicine, Vanderbilt University Medical Center, Nashville, TN; 3) Biochemistry, Vanderbilt University School of Medicine, Nashville, TN; 4) Chemistry, Vanderbilt University School of Medicine, Nashville, TN; 5) Biological Sciences, Vanderbilt University School of Medicine, Nashville, TN; 6) Baylor Genetics, Houston, TX; 7) Baylor College of Medicine, Houston, TX.

**Aims:** To determine the molecular basis of a new Mendelian cause of autonomic failure. **Methods:** The proband developed orthostatic hypotension (OH) and dizziness on standing at 39 yrs of age. At 40 yrs of age he was noted to have miotic pupils, and hyperpigmentation of his back at the Vanderbilt Autonomic Dysfunction Center. Plasma catecholamines were low and remained so on standing but dopamine levels were wnl. He was diagnosed with neurogenic OH due to severe autonomic failure (AF) and miosis of unknown etiology, and telangiectasia macularis eruptive perstans. His sister developed AF and miosis in her late teens. Their parents, brother and the proband's 3 children had no autonomic problems. At 64 yrs of age the proband was consented (IRB protocol NHGRI 15-HG0130) and enrolled by the Vanderbilt Undiagnosed Diseases Network (UDN) clinical site. **Results:** UDN WES results showed that the affected sibs are compound heterozygotes for c.907\_908delCT (p.L303Dfs\*115)/c.688G>A (p.D230N) variants in the acetylcholine receptor, neuronal nicotinic, alpha 3 subunit (*CHRNA3*) gene inherited from their mother and father, respectively, and their non-affected brother had a nI/p.D230N genotype. *CHRNA3* is a subunit of nicotinic acetylcholine receptors (nAChRs) that regulate blood pressure (BP) by release of catestatin, an inhibitor of catecholamine secretion and modulation of synaptic transmission in peripheral autonomic ganglia. The p.D230N variant was predicted to be damaging/probably damaging (SIFT/PolyPhen2) and by our structural modeling lies on the interface between *CHRNA3* and other nAChR subunits, and would destabilize the nAChR pentameric complex. Common variants (CV) in *CHRNA3* associate with inter-individual variations in autonomic function including BP, catestatin and epinephrine levels (PMID10318955). Knock-out (KO) mice without detectable *Chrna3* have severe AF and widely dilated pupils (PMID 10318955). Patients with AChR autoantibodies against the alpha 3 subunit develop severe AF secondary to autonomic ganglionopathy (PMID10995864). **Conclusions:** 1) Our sibs with severe AF and miosis are compound heterozygotes for *CHRNA3* rare variants (RV) that co segregate with their phenotype and have predicted effects on nAChR structure, and 2) since it has been shown that *CHRNA3* CV associate with variations in autonomic function and a murine *Chrna3* KO model has AF, we hypothesize that our affected sibs may have a new Mendelian AF disorder caused by their *CHRNA3* RV.

## 3094T

**Rare variants in *CAPN2* underlie isolated hypoplastic left heart syndrome.** J.J. White<sup>1</sup>, E.I.T. Helle<sup>2</sup>, M.M. Jenkins<sup>3</sup>, K.L. McBride<sup>4</sup>, S. Mital<sup>5</sup>, D.A. Nickerson<sup>6</sup>, J.X. Chong<sup>7</sup>, E. Blue<sup>7</sup>, M.J. Bamshad<sup>1,6</sup>, National Birth Defects Prevention Study, University of Washington Center for Mendelian Genomics. 1) Pediatrics, University of Washington, Seattle, WA; 2) Children's Hospital, University of Helsinki, Finland; 3) National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA; 4) Center for Cardiovascular Research, Nationwide Children's Hospital, Department of Pediatrics, Ohio State University, Columbus OH; 5) Department of Pediatrics, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada; 6) Department of Genome Sciences, University of Washington, Seattle, WA; 7) Division of Medical Genetics Department of Medicine, University of Washington Seattle WA.

Hypoplastic left heart syndrome (HLHS) is a severe congenital heart defect (CHD) characterized by hypoplasia of the left ventricle and aorta, stenosis or atresia of the aortic and mitral valves and an intact ventricular septum. HLHS represents ~4-8% of all CHD but accounts for 25% of deaths due to CHD. Seventy percent of HLHS cases are isolated (i.e., non-syndromic) but despite intense investigation, the genetic basis of HLHS remains largely unknown. We performed exome sequencing on ~330 probands with isolated HLHS (iHLHS) born to unaffected parents aggregated from four independent cohorts. Under *de novo*, recessive, and dominant models, only twelve probands (3.6%) had a rare, predicted pathogenic variant (five of which were *de novo*) in a gene previously known to underlie either iHLHS (*MYH6*, *NOTCH1*) or syndromic HLHS (*KDM6A*, *KMT2D*), and one proband had a known pathogenic variant per ClinVar in a gene (*ACTC1*) underlying other CHDs. No additional compelling candidate genes were identified under any Mendelian model. These results led us to hypothesize that iHLHS in this cohort was not due to single, large effect alleles in known or novel genes in >95% of families. Gene-based association testing of rare variants using SKAT-O in 211 iHLHS cases for which ancestry-matched controls without CHD (N=1,067) were available identified a single gene, *CAPN2* (p=3.8e-6), that reached genome-wide significance (3,048 genes with >=10 alt alleles; Bonferroni p<1.6e-5). This signal was driven by 11 (5%) cases heterozygous for rare (MAF < 0.001), predicted deleterious (9 with CADD>=15) missense variants in *CAPN2*. Homozygous loss of *Capn2* in mice results in a thin ventricular wall and is embryonic lethal, suggesting it is a promising candidate gene for iHLHS. However, all of the *CAPN2* variants in full trios (n=3) were inherited from an unaffected parent, suggesting that in those families, a variant in *CAPN2* is necessary but not sufficient to cause iHLHS. Using the presence of a *CAPN2* variant as a covariate, a conditional analysis revealed suggestive associations with *PITX2* (p=2.9e-5) and *ARHGAP31* (p=4.54e-5). *PITX2* is a key regulator of heart morphogenesis, and *ARHGAP31* underlies Adams-Oliver syndrome, a rare cause of syndromic HLHS. Two probands were heterozygous for variants in two of these three genes. Collectively, these results provide support that iHLHS is a digenic/oligogenic trait and identifies a novel pathway involved in its pathogenesis.

**3095F**

**Aortic root dilation and mitral valve prolapse in a patient with Tatton-Brown-Rahman syndrome.** *H. Nguyen, AC. Tsai.* Section of Genetics, Children's Hospital of Colorado, Aurora, CO.

Tatton-Brown-Rahman syndrome (TBRS; MIM #615879) is a recently described genetic overgrowth disorder characterized by tall stature, distinctive facial features and intellectual disability. Germline variants in *DNMT3A* (2p23.3) are causative for TBRS, and to date, fewer than 30 patients with over 20 variants have been reported. We report a 25 y. o. male with an initial clinical impression of Lujan-Fryns syndrome (LFS) based on overlapping clinical features with TBRS. Upon genetic testing by an expanded trio NGS panel, the patient was found to carry the *DNMT3A* variant c.1685G>A p.C562Y. While the C562Y variant has not been previously reported, a different missense change at this residue (C562R) has been described as likely pathogenic for TBRS. The physical features of our patient include: tall thin stature, autistic characteristics / repetitive behaviors, prominent glabella, deep set eyes, frontal upsweep, thick eyebrows, prominent nose, high palate, pectus carinatum, slumped posture with kyphosis, bilateral pes planus, and bilateral hindfoot deformities. He has moderate to severe intellectual disability and anxiety, agitation, and sleep disturbances that are non-responsive to psychotropic medications. Surprisingly, EKG abnormalities were detected upon medication screening, and a subsequent cardiac echocardiogram showed aortic root dilation (mild to moderate; aortic root 4.16cm Z-score 3.99) along with mitral valve prolapse. It has been suggested that phenotypic similarities exist between LFS and Marfan syndrome. Since these cardiac findings are known to be associated with Marfan-like syndrome, but not TBRS, we suggest an overlap in otherwise unestablished formal diagnostic criteria for TBRS and LFS. Interestingly, the causative gene for LFS, *MED12* has not been reported in TBRS. *MED12* is a coactivator involved in the regulated transcription of nearly all RNA polymerase II-dependent genes, and recent data indicate that DNMT DNA methyltransferases regulate RNA transcription by controlled methylation of CpG islands at gene promoters. As such, we postulate not only a clinical link, but a potential cellular link between the two disease mechanisms. Furthermore, given the potential association with cardiac defects, we recommend a baseline screening echocardiogram for patients diagnosed with TBRS due to pathogenic variants of *DNMT3A*.

**3096W**

**Aortic dissection in a woman with a variant of uncertain significance in *TGFBR2* gene.** *D. Aguilar y Mendez<sup>1</sup>, G. Torre Amione<sup>2</sup>, F. Castilleja Leal<sup>3</sup>, A. Rojas Martinez<sup>4</sup>, J. Yañez Sanchez<sup>5</sup>, C. Britton Robles<sup>5</sup>.* 1) Centro de Cancer de Mama Tec Salud, Monterrey, Nuevo Leon, Mexico; 2) Instituto de Cardiología y Medicina Vascular, Tec Salud, Tecnológico de Monterrey, San Pedro Garza Garcia, Nuevo Leon, Mexico; 3) Internal Medicine Institute, Escuela Nacional de Medicina Tecnológico de Monterrey, San Pedro Garza Garcia, Nuevo Leon, Mexico; 4) Tecnológico de Monterrey, Escuela Nacional de Medicina, Monterrey, Nuevo Leon, Mexico; 5) Instituto de Cardiología y Medicina Vascular, Centro Medico Zambrano Hellion, San Pedro Garza Garcia, Nuevo Leon, Mexico.

Case report: A 30 y.o. female debuting with a thoracic aortic aneurysm (TAA) was assessed by suspicion of Marfan Syndrome. The patient has not family history of Marfan Syndrome and does not meet the revised Ghent criteria. A molecular panel for variants associated to TAA, including Marfan Syndrome, Loeys Dietz syndrome, vascular Ehlers Danlos, and familial TAA genes associated (*ACTA2*, *CBS*, *COL3A1*, *COL5A1*, *COL5A2*, *EFEMP2*, *FBN1*, *FBN2*, *FLNA*, *MAT2A*, *MED12*, *MYH11*, *MYLK*, *NOTCH1*, *PLOD1*, *PRKG1*, *SKI*, *SLC2A10*, *SMAD3*, *SMAD4*, *SMAD6*, *TGFB2*, *TGFB3*, *TGFBR1*, *TGFBR2*) was requested, since TAA has genetic etiology in about 5 percent of the cases. The sequence analysis demonstrated the presence of the germline variant of uncertain significance c.1493C>G (p.Pro498Arg) in *TGFBR2*. Variants in TGF-B receptor 2 (*TGFBR2*) are associated to the Loeys-Dietz syndrome (LDS), an autosomal dominant syndrome with widespread systemic involvement characterized by the triad of arterial tortuosity and aneurysms, hypertelorism, and bifid uvula or cleft palate. Mutations in the *TGFBR1* and *TGFBR2* genes are involved in LDS with frequencies of 20-25 and 55-60%, respectively. To assess the pathologic classification of the identified variant, first degree relatives of the proband (2 sibs and 2 children) were clinically examined and evaluated by echocardiography. Both children showed bifid uvula, umbilical hernia and subtle aortic anomalies by echocardiography; one of them had additionally joint hyperlaxity and food allergy, while the other had hypertelorism. Patient sisters showed myopia, food allergy and colitis. Her parents were not studied. Molecular studies also demonstrated the variant c.1493C>G (p.Pro498Arg) in *TGFBR* in both children, while the sisters were negative. We propose that variant c.1493C>G (p.Pro498Arg) in *TGFBR2* is pathologic. This case was solved by a close collaboration between cardiologists and geneticist. Multidisciplinary approach is essential to interpreting clinical relevance of monogenic diseases panel test results in order to provide an accurate, timely genetics diagnosis and ultimately improve the clinical care of patient and in risk relatives with cardiovascular diseases.

**3097T**

**A national registry of patients with inheritable connective tissue disorders to identify genetic modifiers of clinical severity through whole exome sequencing.** *J.F. Calderon<sup>1</sup>, Y. Jimenez<sup>1</sup>, L. Cruz-Fernandes<sup>1</sup>, G.M. Repetto<sup>1,2,3</sup>, G. Lay-Son<sup>1,2,3</sup>.* 1) Center for Genetics and Genomics - ICIM, Universidad del Desarrollo, Santiago, RM, Chile; 2) Clínica Alemana de Santiago, Santiago, Chile; 3) Hospital Padre Hurtado, Santiago, Chile.

Aneurysms occur when an artery wall weakens and blood flow comes in between the different layers of the vessel and generates a bulge that can dissect and rupture. Young and middle-aged patients that suffer from aneurysms are usually carriers of genetic variants that predispose for this condition. This group of diseases is called Inheritable Connective Tissue Disorders (ICTDs), and are defined as those caused by mutations in genes that encode for proteins of the Extracellular Matrix (ECM). ICTDs affect patients since birth and their symptoms are present in the musculoskeletal system, skin, eye and respiratory system. However, the most life-threatening feature of these diseases is the enlargement and rupture of big vessels, most prominently, the aorta. These diseases include Marfan Syndrome (MFS), Loeys-Dietz Syndrome (LDS), Ehlers-Danlos Syndrome type IV (vEDS) among others. They are also referred to as TGF $\beta$  vasculopathies because they are all caused by mutations in genes that code for different effectors or regulators of the Transforming Growth Factor beta (TGF $\beta$ ) signaling pathway, including ECM components that play active roles in the signaling activity of this pathway. We hypothesized that the wide range of phenotypic severity in patients with ICTDs is likely caused by unknown genetic variants in the genome that modify the ECM-TGF $\beta$  signaling equilibrium beyond the effect of the pathogenic mutation. We aimed to collect a significant number of Chilean patients with ICTDs (n=200) in a database that encompasses every relevant clinical aspect in order to identify these genetic modifiers of clinical severity. Results: We have created a Chilean Registry of ICTDs as a platform for understanding the effect of genetic modifiers in the clinical course of patients with ICTDs. This online database integrates clinical information from many specialists in a patient-centered structure that will also hold Whole Exome Sequencing (WES) data with sufficient complexity to enable us to generate relevant genotype-phenotype correlations for the diseases studied. We have now identified more than 10 families with more than two affected members, with contrasting clinical courses. WES for these subjects is undergoing. With this information, we will interrogate molecular mechanisms behind this variation through in vitro, genome-engineering techniques and translate these findings into improved treatment of Chilean patients. This project is funded by Fondecyt Initiation Grant N°11170353.

**3098F**

**Disruption of the gut barrier modulates lesion burden in mouse models of CCM.** *C. Gallione<sup>1</sup>, A. Peiper<sup>1</sup>, H. Pardo<sup>1</sup>, E. Griffin<sup>1</sup>, R. Lightle<sup>2</sup>, T. Moore<sup>2</sup>, R. Girard<sup>2</sup>, D. Dalldorf<sup>1</sup>, N. Hobson<sup>2</sup>, Y. Cao<sup>2</sup>, J. Koskimäki<sup>2</sup>, R. Shenkar<sup>2</sup>, I. Awad<sup>2</sup>, D. Marchuk<sup>1</sup>.* 1) Duke University Medical Center, Durham, NC; 2) University of Chicago, Chicago, IL.

Cerebral Cavernous Malformations (CCM, MIM 116860) are clusters of dilated capillaries with defective endothelial barrier function, leading to repetitive brain hemorrhage with serious neurologic sequelae. The lesions can occur sporadically or can be inherited as an autosomal dominant trait caused by loss-of-function mutations in one of three genes. Recent work using Cre-inducible deletion of *Ccm* genes in mice has shown that early postnatal lesion development is stimulated by LPS released from the gut microbiome, signaling through the TLR4 receptor, and activating downstream pathways driving lesion genesis. However, the inducible KO model of CCM does not faithfully recapitulate relevant features of the human disease, including later age-of-onset, anatomic lesion location, or chronic hemorrhage. Thus, the intriguing "gut microbiome-to-brain" link of CCM pathogenesis requires further study. We have generated a stochastic, chronic CCM mouse model where the lesions develop chronically over time in the setting of *Ccm* heterozygosity, recapitulating the human disease. We here use this chronic CCM model to test whether the integrity of the gut epithelial barrier plays a role in CCM lesion formation. We administered Dextran Sodium Sulfate (DSS) to adult mice and weanlings in our mouse model and investigated lesion burden and lesion phenotypes. Since DSS is a rather severe treatment (commonly used to create mouse models of ulcerative colitis), we also employed a less severe and more physiologically-relevant method to disrupt the gut barrier. Tween-80 is a common food additive used as a food emulsifier, but chronic administration to mice will disrupt the gut barrier. Mice were thus treated with Tween-80 at a concentration used in processed foods. We found that the mean lesion volumes were significantly greater in brains of mice treated with either DSS or emulsifier compared to placebos, including greater lesional bleeding. These combined data further strengthen the hypothesis that CCM lesion development and hemorrhage in the brain is modulated by the microbial composition of the gut. Furthermore, these data motivate future studies in human CCM cohorts that attempt to reduce lesion burden and pathogenesis in the human disease by modulating the gut microbiome.

**The molecular and physiological roles of ABCC6: More than meets the eyes.** O. Le Saux<sup>1</sup>, V. Pomozi<sup>1</sup>, C. Brampton<sup>1</sup>, J. Zoll<sup>1</sup>, B. Calio<sup>1</sup>, K. Pham<sup>1</sup>, G. Kauffenstein<sup>2,3</sup>, G. Leftheriotis<sup>4</sup>, L. Martin<sup>2,3</sup>. 1) Cell and Molecular Biology, University of Hawaii John A. Burns School of Medicine, Honolulu, HI; 2) PXE Health and Research Center, University Hospital of Angers, 49045 Angers, France; 3) UMR CNRS 6015-Inserm 1083, School of Medicine, Bretagne Loire University, Angers, France; 4) Faculty of Medicine, University of Nice-Sophia Antipolis, 06107 Nice, France.

Ectopic mineralization of soft tissues occurs in aging, diabetes, hypercholesterolemia, and renal failure as well as genetic disorders. Several mechanisms have evolved to prevent calcification, notably the *ABCC6* gene. *ABCC6* is primarily expressed in liver, kidneys and facilitates the cellular efflux of ATP, which is converted into pyrophosphate (PPi) and adenosine, both major inhibitors of calcification. *ABCC6* deficiencies underlie the disorders pseudoxanthoma elasticum (PXE), and some cases of Generalized Arterial Calcification of Infancy (GACI, also associated with *ENPP1* mutations). The explication of these conditions places *ABCC6* as an upstream modulator of the well-known *ENPP1*→*CD73* pathway generating PPi and adenosine. The clinical manifestations associated with this pathway are a spectrum of related calcification diseases, PXE, GACI, as well as ACDC (Arterial Calcification Due to CD73 deficiency). Studying the association of typical cardiovascular risk factors (hyperlipidemia, myocardial infarction) and *ABCC6* deficiency has revealed unrecognized facets of *ABCC6* functions probably related to its ability to modulate extracellular purines. Indeed, we found that *ABCC6* haploinsufficiency enhances dyslipidemia and atherosclerosis. Furthermore, we found that mice lacking *ABCC6* suffer less decrement in cardiac function after myocardial infarction than WT controls. Because *ABCC6* functions upstream of *ENPP1* and *CD73* enzymes that influence numerous physiological processes, we investigated the expression of genes implicated in nucleotide and phosphate metabolism in PXE patients and *Abcc6*<sup>-/-</sup> mice and we found many tissue-specific alterations. Our results demonstrate that *ABCC6*'s primary function, facilitating the cellular efflux of nucleotides (including ATP) influences multiple pathways, giving it a pluripotent physiological role affecting the regulation of calcification, atherosclerosis, and cardioprotection.

**Common variants in TGFβ/BMP9 pathway genes and disease severity phenotypes in hereditary hemorrhagic telangiectasia.** L. Pawlikowska<sup>1,2</sup>, J. Nelson<sup>1</sup>, D. Guo<sup>1</sup>, K. DeKay<sup>1</sup>, K. Yan<sup>1</sup>, C.E. McCulloch<sup>3</sup>, D.A. Marchuk<sup>4</sup>, M.T. Lawton<sup>5</sup>, H. Kim<sup>1,2,3</sup>, M.E. Faughnan<sup>6,7</sup>, *The Brain Vascular Malformation Consortium HHT Investigator Group*. 1) Center for Cerebrovascular Research, Dept of Anesthesia and Perioperative Care, University of California - San Francisco, San Francisco, CA; 2) Institute for Human Genetics, University of California San Francisco, San Francisco, CA; 3) Dept of Epidemiology and Biostatistics, University of California San Francisco, San Francisco, CA; 4) Dept of Molecular Genetics and Microbiology, Duke University Medical Center, Durham, NC; 5) Dept of Neurosurgery, Barrow Neurological Institute, Phoenix, AZ; 6) Division of Respiratory, Dept of Medicine and Li Ka Shing Knowledge Institute, St. Michael's Hospital, Toronto, Canada; 7) Division of Respiratory, Dept of Medicine, University of Toronto, Toronto, Canada.

Hereditary hemorrhagic telangiectasia (HHT) is an autosomal dominant disorder caused by mutations in TGFβ/BMP9 signaling pathway genes (most commonly in *ENG*, *ACVRL1*, *SMAD4*). HHT patients have skin and mucosal telangiectases that can cause chronic or severe bleeding, and brain, lung and liver vascular malformations (VM) and arteriovenous malformations (AVM) that can lead to ischemic stroke or intracerebral hemorrhage (ICH). The considerable clinical heterogeneity of HHT, even among family members with the same mutation, suggests a possible role for genetic modifier effects. Common variants in *ACVRL1*, *ENG*, *PTPN14* and *ADAM17* were previously reported to be associated with VM in HHT. We hypothesized that other common variants in TGFβ/BMP9 pathway genes modulate HHT disease severity phenotypes.

**Methods.** We genotyped 760 Caucasian HHT patients recruited by the Brain Vascular Malformation Consortium (BVMC) with the Affymetrix UK Biobank Axiom array. After QC (subject call rate ≥98%, variant call rate ≥99%, minor allele frequency ≥1%, HWE  $p \geq 0.0001$ ), we evaluated 463 variants in or within 5 kb of 23 TGFβ/BMP9 pathway genes for association with 3 HHT severity phenotypes: any organ VM (brain VM, liver VM and/or lung AVM), anemia from severe bleeding (epistaxis and/or gastrointestinal bleeding), and stroke (ischemic stroke from lung AVM and/or intracerebral hemorrhage from brain VM). We used additive models adjusted for age, sex and 20 principal components and evaluated statistical significance for each phenotype using false discovery rates (FDR). **Results.** Among 712 Caucasian subjects, 490 had at least one organ VM (71%), 345 (51%) had anemia and 48 (7%) reported stroke. At FDR  $q < 0.25$ , no variants were associated with any organ VM, 2 variants in *PTPN14* were associated with anemia and 4 variants (in *ADAM17*, *PTPN14* and 2 in *SMAD7*) were associated with stroke. The strongest finding was for stroke and intronic rs116026081 in *ADAM17* (OR=8.5,  $p=0.00002$ , FDR  $q=0.008$ ). **Conclusions.** Several common variants in the TGFβ/BMP9 signaling pathway were associated with anemia or stroke in HHT patients. We are replicating these associations in a second, independent cohort of 800 HHT patients. This work extends previously reported association of genetic variation in *ADAM17* and *PTPN14* with lung VM to different HHT severity phenotypes, suggesting that genetic modifiers in these loci may influence multiple aspects of HHT disease.

**Recombinant human ENPP1-Fc protein prevents neointima formation in generalized arterial calcification of infancy by generating AMP.** F. Rutsch<sup>1</sup>, Y. Yan<sup>2</sup>, I. Buers<sup>1</sup>, K. Kintzinger<sup>1</sup>, K. Askew<sup>2</sup>, Y. Nitschke<sup>1</sup>. 1) Muenster University Children's Hospital, Muenster, Germany; 2) Alexion Pharmaceuticals, 100 College St, New Haven, USA.

**Introduction:** Generalized arterial calcification of infancy (GACI) is associated with widespread arterial calcification and stenoses often leading to death in early life. Most frequently, the disease is caused by loss of function variants in *ENPP1*. Based on a literature review, arterial stenoses are present in at least 72.4% of GACI cases. *ENPP1* encodes for ectonucleotide pyrophosphatase/phosphodiesterase 1 (ENPP1), which cleaves ATP to generate inorganic pyrophosphate (PP<sub>i</sub>) and adenosine monophosphate (AMP) extracellularly. The disease phenotype is recapitulated in *ttw/ttw* mice carrying a spontaneous *Enpp1* nonsense variant and in *Enpp1* knockout mice, the latter of which are known to develop increased neointima formation compared to wild type mice when treated with carotid ligation. This study was designed to identify the mechanism by which ENPP1 deficiency causes neointima formation leading to arterial stenoses and to effectively prevent neointima formation in an animal model of GACI by systemic administration of recombinant human (rh)ENPP1-Fc protein. **Methods and Results:** We evaluated the effect of rhENPP1-Fc on *ENPP1* silenced human vascular smooth muscle cells (VSMC) and on *ttw/ttw* mice treated with carotid ligation. We first demonstrated that silencing *ENPP1* in VSMC results in up to tenfold increase in proliferation relative to that of cells transfected with negative control siRNA. Addition of either rhENPP1-Fc, adenosine monophosphate or adenosine restored silenced *ENPP1*-associated VSMC proliferation. In contrast, neither PP<sub>i</sub> nor etidronate, a current off-label treatment for GACI, had an effect on VSMC proliferation. *Ttw/ttw* mice treated with carotid ligation showed increased neointima formation compared to wild type animals reflecting intima proliferation. Subcutaneous administration of rhENPP1-Fc protein 1 mg/kg every other day reduced neointima formation induced by carotid ligation in the *ttw/ttw* mice to the same level as in wild type animals. **Conclusion:** We conclude that ENPP1 inhibits neointima formation by generating adenosine monophosphate. Subcutaneous administration of recombinant human ENPP1-Fc protein may serve as a therapeutic approach to effectively prevent neointima formation and arterial stenoses in GACI.

**Metabolomic signature of angiotensin-like protein 3 deficiency: Fasting and postprandial effects of loss-of-function genetic variants.** E. Tikkanen<sup>1</sup>, I. Minicocci<sup>2</sup>, J. Hällström<sup>1</sup>, S. Soidinsalo<sup>1</sup>, P. Würtz<sup>1</sup>, M. Jauhiainen<sup>3</sup>, V. Olkkonen<sup>3,4</sup>, M. Arca<sup>2</sup>. 1) Nightingale Health Ltd., Helsinki, Finland; 2) Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Italy; 3) Minerva Foundation Institute for Medical Research, Helsinki, Finland; 4) Department of Anatomy, Faculty of Medicine, University of Helsinki, Finland.

**Background** - Angiotensin-like 3 (ANGPTL3) is a promising therapeutic target for lowering atherogenic lipid levels and decreasing cardiovascular disease risk. **Aims** - We aimed to determine detailed metabolic effects of ANGPTL3 deficiency. **Methods** - The study population consisted of cases with familial combined hypolipidemia (FHBL2) caused by a loss-of-function mutation in ANGPTL3 gene (N=6 homozygous and N=32 heterozygous carriers) and their controls (N=38). We used nuclear magnetic resonance (NMR) profiling to quantify a wide range of metabolic measures, including lipid concentrations in lipoprotein subclasses, fatty acids, amino acids, and ketone bodies. We compared metabolic signatures of cases and controls in fasting state and after an energy-rich meal. In addition, we used genetic association data from up to 24,925 individuals to compare the metabolic signature of ANGPTL3 loss-of-function (LoF) mutation with an ANGPTL3 common variant (rs2131925) and a major triglyceride-rich lipoproteins-associated genetic variant (rs964184) in the APOC3-APOA5-APOA4-APOA1 gene cluster. **Results** - Individuals with ANGPTL3 deficiency (FHBL2) had markedly reduced levels of triglycerides, total cholesterol, free cholesterol and cholesterol esters in all major lipoproteins and their subclasses. They also showed reduced levels of most fatty acids, citrate and acetate, and elevated 3-beta-hydroxybutyrate, a surrogate biomarker of fatty acid beta-oxidation. Homozygous ANGPTL3 LoF variant carriers showed a significant postprandial reduction of cholesterol in large, medium and small VLDL particles as well as in circulating fatty acids, whereas the postprandial response in heterozygous carriers resembled that of controls. ANGPTL3 LoF, ANGPTL3 rs2131925\_G and rs964184\_C carriers displayed similar alterations in VLDL and LDL associated lipid parameters, but the common variant-associated HDL levels differed from those of ANGPTL3 LoF carriers. **Conclusions** - In addition to reductions in all major lipoprotein subclasses, ANGPTL3 deficiency results in elevated 3-beta-hydroxybutyrate suggesting enhanced fatty acid beta-oxidation as well as reduced circulating fatty acids putatively alleviating ectopic fat deposition.

**Novel ACTN2 mutations are associated with cardiomyopathy and hypertrophy in human cardiac tissue and iPSC-derived cardiomyocytes.** M.E. Lindholm<sup>1,2</sup>, H. Zhu<sup>1,2</sup>, Y. Huang<sup>1</sup>, E.A. Ashley<sup>1,2</sup>, M. Wheeler<sup>1,2</sup>. 1) School of Medicine, Stanford University, Palo Alto, CA; 2) Stanford Center for Inherited Cardiovascular Disease, Stanford Cardiovascular Institute, Stanford University, Palo Alto, CA.

**Introduction**In cardiac and skeletal muscle, alpha-actinins are critical cytoskeletal proteins that anchor actin filaments within the sarcomere. Mutations in ACTN2, the isoform present in cardiac and skeletal muscle, have been associated with cardiac abnormalities, including arrhythmias, hypertrophic and dilated cardiomyopathies. However, the mechanisms behind how ACTN2 mutations lead to cardiac dysfunction remain poorly understood. The aim of the present study was to investigate the effects of two novel ACTN2 mutations on cardiac and skeletal muscle phenotypes in human tissue and patient-specific iPSC-derived cardiomyocytes. **Methods and results**We identified patients in the Stanford Center for Inherited Cardiovascular Disease database with ACTN2 mutations. We identified patients with negative clinical panel sequencing, sequenced ACTN2 and found six families with rare or novel ACTN2 variants using a custom mutation pipeline optimized for rare variant discovery. We identified one patient homozygous for a stop-gain mutation (p.Q860X) in ACTN2 and a family with an exon 8-10 deletion. In heart transplant tissue of the homozygous stop-gain patient, we observed mild hypertrophy and interstitial fibrosis. There was no evidence of variation in ACTN2 protein expression, indicating absence of nonsense mediated decay. We used siRNA to knock down ACTN2 in neonatal rat ventricular cardiomyocytes and a human myoblast cell line and observed dramatic changes in cell size and morphology. Patient-derived iPSC-cardiomyocytes were hypertrophic and displayed sarcomeric structural disarray compared to control iPSC-cardiomyocytes. **Conclusions**The molecular effects of ACTN2 on a cellular level and how it causes cardiomyopathy have not been fully elucidated. Here, we provide evidence that two loss of function genetic variants in ACTN2 lead to cardiomyocyte hypertrophy and cardiac abnormalities.

**Patient-specific iPSC disease modeling reveals tissue-specific molecular mechanisms of LMNA-associated cardiac disease.** H.P. Widyastuti<sup>1,2,3</sup>, M. Mehrabi<sup>4</sup>, C.H.H. Nguyen<sup>2,3</sup>, L.A. McCarthy<sup>4</sup>, A. Grosberg<sup>4</sup>, M.V. Zaragoza<sup>1,2,3</sup>. 1) Department of Biological Chemistry, University of California, Irvine, Irvine, California, USA; 2) UCI Cardiogenomics Program, Department of Pediatrics, University of California, Irvine, Irvine, California, USA; 3) Sue and Bill Gross Stem Cell Research Center, University of California, Irvine, Irvine, California, USA; 4) Department of Biomedical Engineering and The Edwards Lifesciences Center for Advanced Cardiovascular Technology, University of California, Irvine, Irvine, California, USA.

Lamin A/C are intermediate filament proteins that construct the nuclear lamina of a cell encoded by the LMNA gene. Lamin A/C has been implicated in processes such as chromatin localization and cell differentiation. Consequently, mutations in LMNA gene have detrimental effect in cell functions which results in diseases collectively termed as laminopathies which include LMNA-related dilated cardiomyopathy. In a large affected family, we recently identified a heterozygous novel LMNA splice-site mutation (LMNA c.357-2A>G) predicted to result in exon skipping and premature truncation. Our group aims to elucidate the molecular mechanisms contributing to the pathology of LMNA-related cardiac disease by developing an in-vitro, patient-specific disease model. Dermal fibroblasts, obtained from affected and unaffected family members, were reprogrammed to induced pluripotent stem cells (iPSCs). One control and one patient-derived iPSCs were differentiated into cardiomyocytes (iPSC-CMs) for molecular and protein studies. Sanger sequencing of LMNA transcripts revealed evidence of the predicted exon skipping and frame shift exclusively in patient iPSC-CMs, indicating the expression of the mutant allele albeit at a low level compared to the normal allele. Western Blot studies showed that patient iPSC-CMs had a reduced level of Lamin A/C protein compared to control iPSC-CMs but no evidence of the mutant truncated protein. Interestingly, when the same studies were performed on patient and control fibroblast, mutant allele expression or reduction in Lamin A/C protein level was not observed. Taken together, our results provide insight to the molecular mechanism of LMNA-associated cardiomyopathy and reveal the tissue specificity of this mutation.

**3105W****Associations of inflammatory cytokines (IL-6 and IL-16) with coronary artery disease in Sudan.** *H.H. Musa<sup>1</sup>, M.M. Yahia<sup>1</sup>, I.H. Musa<sup>2</sup>, E.A. Elbahir<sup>3</sup>.*

1) Medical Microbiology, Faculty of Medical Laboratory Sciences, University of Khartoum, Khartoum, Sudan; 2) Sudan Medical Specialization Boards, Khartoum, Sudan; 3) Sudan Heart Center, Khartoum, Sudan.

**Background:** Cardiovascular disorders are the second most common causes of adult deaths in sub-Saharan Africa. Lifestyle and environmental factors play an important role in coronary artery disease (CAD) development, and family clustering suggests a genetic predisposition. IL-6 and IL-16 play important role in the processing of inflammatory disease such as coronary artery disease. IL-6 was associated with acute ischemic condition, while IL-16 is multifunctional cytokines that was initially recognized as chemo-attract factor. The aim of this study was to detect the association of IL-6 and IL-16 genes with CAD in Sudanese population. **Methods:** A case control study was conducted for coronary artery disease patients who attended the Sudan Heart Institute and healthy controls from January 2014 to April 2016. Demographic data and medical histories were collected using a structured questionnaire. Blood samples from each participant were collected to estimate lipids profiles and DNA extraction. Total cholesterol, triglyceride, low density lipoprotein and high density lipoprotein were measured using an enzymatic colorimetric method. Genomic DNA was isolated using the G-spin Kits (INTRON Biotechnology). Mutation in IL-6 and IL-16 genes was detected using PCR-RFLP.

**Results:** Among the patients 64% were males and 41% were at 51-61 years, 63% were from Northern Sudan, physical activity was common in 60% of the patients. The risk factors for coronary artery disease were hypertension 62%, angina 62%, smoking 38%, diabetes 33%, tobacco user 31%, alcohol 24% and stroke 2%. Most patients have family history of stroke 93%, hypertension 36%, diabetes 34%, angina 9%, and heart attack 4%. Total cholesterol and low density lipoprotein were significantly different ( $P > 0.05$ ) between cases and controls, and they were significantly associated with IL-16 genotype. While, IL-6 genotype has no significant effect on lipids markers. Multivariate logistic analysis indicated that all risk factors for coronary artery diseases were strongly associated with IL-6 genotype ( $P$  value  $< 0.05$ , OR  $> 1$ ). Whereas, IL-16 genotype was significantly associated with gender and physical activity. **Conclusion:** The study conclude that IL-6 and IL-16 genes can be use as a risk factor for coronary artery disease in Sudan.

**3106T****Atrial fibrillation genetic risk differentiates cardioembolic stroke from other stroke subtypes.** *C.D. Anderson<sup>1,9,10</sup>, S.L. Pulit<sup>1,2,3</sup>, L.C. Kistler Stroke Research Center, Massachusetts General Hospital, Boston, MA, USA; 11) Computational Genomics, Vertex Pharmaceuticals, Boston, MA, USA (current address); 12) Cardiology Preventive Medicine Sections, Evans Department of Medicine, Boston University School of Medicine, Boston, MA, USA; 13) Department of Epidemiology, Boston University School of Public Health, Boston, MA, USA; 14) Cardiac Arrhythmia Service, Massachusetts General Hospital, Boston, MA, USA; 15) Department of Neurology, University of Maryland School of Medicine, Baltimore, MD, USA; 16) Department of Neurology, Veterans Affairs Medical Center, Baltimore, MD, USA.

Atrial fibrillation (AF) affects ~34 million individuals worldwide and is associated with a five-fold increased risk of ischemic stroke. Strokes caused by AF are classified as cardioembolic, and secondary prevention of cardioembolic (CE) stroke focuses on identifying AF as a potential cause and preventatively treating with anticoagulants. However, presence of AF can remain occult even after extensive workup, and whether AF in the context of stroke carries the same stroke risk as pre-existing AF is unknown. We thus sought to understand whether AF genetic risk is an important and potentially useful determinant of CE stroke risk. We first assessed whether stroke patients with AF have a genetic predisposition to AF and then evaluated the extent to which genetic risk factors for AF capture the heritability of CE stroke. We performed a genome-wide association of AF and CE stroke in 13,390 ischemic stroke cases and 28,026 referents. Associated SNPs ( $p < 5 \times 10^{-8}$ ), in particular at the *PITX2* and *ZFHX3* loci, were consistent in effect across the two phenotypes, as expected. Using AF-associated SNPs ( $p < 4.4 \times 10^{-4}$ ) from an independent meta-analysis, we observed strong correlation between previously-reported AF genetic risk, AF in the presence of stroke, and CE stroke (Pearson's  $r = 0.77$  and  $0.76$ , respectively). Heritability estimates revealed AF and CE stroke to be similarly heritable (20.0% and 19.5%, respectively). We next derived an AF polygenic risk score (PRS) using 934 previously-implicated AF SNPs. The PRS, adjusted for clinical AF risk factors, was associated with CE stroke (odds ratio (OR) per standard deviation (SD) = 1.40,  $p = 1.45 \times 10^{-6}$ ) and explained ~20% of the heritable component of CE stroke risk. The AF PRS also associated with stroke of undetermined cause ( $p = 0.004$ ), but none of the other primary stroke subtypes (all  $p > 0.1$ ). Despite the fact that CE stroke often affects older adults with multiple clinical comorbidities, increasing AF risk due to non-genetic factors, our results suggest that CE stroke patients have enrichment for AF genetic risk. Future work in AF and CE stroke may reveal how PRSs based on AF-associated SNPs could be used either to predict individuals at highest risk of CE stroke to be more closely monitored, or help distinguish between clinical etiopathologic subtypes of stroke.

**3107F****An oligogenic model for congenital heart defects: whole-genome sequencing of congenitally corrected transposition of great arteries shows a mutation load effect at 228 loci involved in cardiac patterning.**

S. Benko<sup>1</sup>, F. Bajolle<sup>2</sup>, Y. Benadjaoud<sup>1</sup>, A. Desgrange<sup>3</sup>, F. Jabot-Hanin<sup>4</sup>, J-F. Delouze<sup>5</sup>, P. Nitschke<sup>4</sup>, S. Meilhac<sup>4</sup>, J. Amiel<sup>4</sup>, D. Bonnet<sup>4</sup>, S. Lyonnet<sup>4</sup>. 1) UMR-1163 INSERM, Institut Imagine and Université Paris Descartes, Paris, France; 2) Pediatric Cardiology, Hopital Necker - Enfants malades, Paris, France; 3) Imagine-Institut Pasteur group of Heart Morphogenesis; 4) BIP-D Plateforme de Bioinformatique Paris-Descartes, Institut Imagine, Paris, France; 5) Centre National de Génotypage, Paris, France.

Congenital heart disease (CHD) is a major public health issue. About 20% of CHD correspond to misconnections between cardiac segments. Aiming to understand the genetic mechanisms that controls the alignment of cardiac segments, we focused on the congenitally corrected transposition of the great arteries (CCTGA), a typical example of cardiac misalignment, expected to result from anomalies of cardiac tube looping and outflow tract (OFT) rotation. CCTGA is characterized by a left/right inversion of the ventricles and the transposition of the great arteries, corresponding thus to a double atrio-ventricular and ventriculo-arterial discordant connections. We established a cohort of 47 non-syndromic and mostly sporadic CCTGA patients. The DNAs of CCTGA trios (patient and both parents) and siblings were submitted to next generation sequencing. The first analyses of our dataset under the hypothesis of *de novo* genomic alterations, did not reveal shared major gene(s). The data were further analysed under the hypothesis of a complex model of inheritance with incomplete penetrance. Candidate causative variations were prioritized using four criteria: (1) low frequency in public databases (<1%), (2) prediction of a deleterious effect, (3) evolutionary conservation, and (4) location in a gene involved in heart tube morphogenesis, OFT development and/or left-right asymmetry patterning (1,465 genes). A total gene set of 228 genes matched each of these criteria, with a mean number of 6.5 deleterious variant per affected case. We hypothesized that the highly heterogeneous combinations of susceptibility rare variants, mostly inherited from the healthy mother and father respectively, functionally converge to give rise to the CCTGA phenotype. To prove that a given allele combination is associated with CCTGA, we also showed a highly significant enrichment of rare variant in cases vs. parents and controls, any given deleterious variant combination within the CCTGA gene set being specific to the affected individual. Taken together, 44/47 CCTGA cases could be explained by a complex oligogenic mutation load of segregated alleles at loci mostly involved in heart tube looping, OFT morphogenesis and establishment of left-right asymmetry. Finally, the set of 228 CCTGA loci, comprised several genes whose LOF mutations are known to result in syndromic CHD, suggesting the CCTGA alleles are hypomorphic, and that CCTGA is a laterality defect limited to a cardiac segment.

**3108W****Recurrent copy number variation in patients with thoracic aortic aneurysm affects dosage sensitive genes expressed in aorta.**

E. Brosens<sup>1</sup>, J.M.A. Verhagen<sup>1</sup>, H.T. Brüggewirth<sup>1</sup>, T.J. van Ham<sup>1</sup>, R.W.W. Brouwer<sup>2</sup>, H. Eussen<sup>1</sup>, R.M. van der Helm<sup>1</sup>, T. Hofstra<sup>1</sup>, J.A. Bekkers<sup>3</sup>, J.W. Roos-Hesselink<sup>4</sup>, M.W. Wessels<sup>1</sup>, I.M.B.H. van de Laar<sup>1</sup>.

1) Department of Clinical Genetics, Erasmus University Medical Center, Rotterdam, Zuid-Holland, Netherlands; 2) Center for Biomics, Erasmus University Medical Center, Rotterdam, Zuid-Holland, Netherlands; 3) Department of Cardiothoracic Surgery, Erasmus University Medical Center, Rotterdam, Zuid-Holland, Netherlands; 4) Department of Cardiology, Erasmus University Medical Center, Rotterdam, Zuid-Holland, Netherlands.

Thoracic aortic aneurysms (TAA) are life-threatening. As approximately 20% of patients have at least one affected first-degree family member, it often is considered an inherited disorder. Genes of the Transforming growth factor- $\beta$  signaling and vascular smooth muscle cell contractility pathway have emerged as key players in TAA pathogenesis. Environmental factors and genetic modifiers, including copy number variants (CNVs), are thought to explain the clinical variability. Genes with changes in expression in the aorta as a result of CNVs could contribute to TAA formation. Therefore, we determined the CNV profiles of 167 patients and prioritized CNVs based on gene content and population frequency. Next, we quantified gene expression in 5 control aortic biopsies, 1 patient with Turner syndrome and 15 patients without a genetic diagnosis. We could confirm the presence of previously described modifying CNV in our cohort: 3p11 loss (n=2), 16p13 gain (n=2) and 22q11 gain (n=3). Moreover, we identified 67 rare CNVs, 54 of which were non-recurrent. CNVs were enriched for genes involved in fibroblast growth factor signaling and extracellular matrix organization. Four genes affected by a recurrent loss (including *EPHA3*) and 15 genes by a recurrent gain (including *MYH11*) had expression in aorta. Of the genes affected by a CNV 5 (*NAT8L*, *SLC19A3*, *LNFG*, *FGF7* and *ABCC6*) were differentially expressed between patient and control cohorts. Screening of 121 TAA patient exomes for variation in genes affected by the identified CNV (n=289) resulted in the identification of 63 putative deleterious variants in 24 genes. We did not detect loss of function variants in dosage sensitive genes (n=31), nor were recessive variants unmasked by a CN loss: all variants (n=18) in genes intolerant to recessive variation (n=44) were heterozygous. The expression of 5 genes on chromosome X in the Turner patient was reduced compared to controls: *PLCXD1*, *BMX*, *PLP1*, *GPM6B* and *F8A1*. Interestingly, the main TAA candidate gene on chromosome X (*BGN*) was highly expressed, but within the control aorta expression range. The impact on vascular development of changes in expression of main candidate genes is currently evaluated using zebrafish genetic models. To conclude, we could confirm the presence of previously described modifier CNVs and found new rare recurrent CNVs. CNV could contribute to TAA formation substantially as many patients have a rare CNV involving a gene expressed in the aorta.

**3109T**

**A genome-wide polygenic risk score for low-density lipoprotein cholesterol is associated with coronary artery disease risk in >400,000 individuals in the UK biobank.** K. Chaudhary, G. Nadkarni, R. Do. The Charles Bronfman Institute for Personalized Medicine, Department of Genetics and Genomics, Icahn School of Medicine at Mount Sinai, New York, NY 10029, USA.

Plasma levels of low density lipoprotein cholesterol (LDL-C) is one of the strongest risk factors for coronary artery disease (CAD). Genome wide association (GWA) studies have identified associations between single nucleotide variants (SNVs) and LDL-C levels. Furthermore, polygenic risk scores (PRS) for LDL-C have been shown to be strongly associated with LDL-C and coronary artery disease (CAD) risk. In the present study, we evaluated the predictive power of PRS generated from different sets of SNVs ranging from LDL-C significant SNVs to the full set of SNVs genome-wide. We calculated PRSs using GWA summary statistics for LDL-C from the Global Lipids Genetics Consortium and tested for association with CAD risk in 21,000 cases and 387,961 controls of self-identified White British ancestry in the UK Biobank. We calculated PRS using three different sets of SNVs: (a) 138 loci significantly associated with LDL-C; (b) 46,766 SNVs using pruning thresholds of  $r^2 < 0.8$  and association  $P < 0.05$ ; and (c) the full set of 2,373,476 SNVs genome-wide with effect sizes adjusted for linkage disequilibrium (LD) using LDpred. We calculated the area under the receiver operating characteristic curve (AUROC), and performed logistic regression after adjusting for age, sex, four principal components and type of genotyping array. Across all three sets of PRS, we observed associations of the PRS generated from the 138 LDL-C loci with CAD risk when comparing the top 0.25 percentile of the PRS to the remaining 99.75 percentile (OR=1.4,  $P < 0.005$ ). Stronger associations were observed for both the PRS generated from pruning (OR=1.9,  $P < 1 \times 10^{-8}$ ) and LDpred (OR=1.5,  $P = 0.0006$ ). In general, we observed an increase in the magnitude of the association between PRS and CAD risk in the extremes of the PRS distribution. In conclusion, PRS for LDL-C is strongly associated with CAD risk in a large study sample of White British individuals. Further work is in progress in examining additional sets of LDL-C SNVs for the effect of PRS on CAD risk. **The role ROR-alpha target genes post-mortem advanced atherosclerotic plaques and patients with CAD.** N. Coban<sup>1</sup>, A.F. Erkan<sup>2</sup>, C. Gulec<sup>1</sup>, B. Ekici<sup>2</sup>, F. Guclu-Geyik<sup>3</sup>, M. Cavlak<sup>3</sup>, T. Erginel<sup>4</sup>, N. Erginel-Unaltuna<sup>1</sup>: 1) Department of Genetic, Aziz Sancar Institute for Experimental Medicine, Istanbul University, , Istanbul, Turkey; 2) Department of Cardiology, Medical Faculty, Ufuk University, Ankara, Turkey; 3) Hacettepe University Faculty of Medicine, Department of Forensic Medicine, Ankara; 4) General Surgery Department, Istanbul Training and Research Hospital, Istanbul.

**Aim:** ROR-alpha is a member of nuclear receptor family of transcription factors, and therefore has ligand-dependent activity. Melatonin and cholesterol are two known ligands of ROR-alpha both were shown to be important for atherosclerosis. Aim of the present study was determined the expression profiles of *ROR-alpha* and its target genes (*ABCA1*, *CYP19A1* and *MIF*) in post-mortem advanced atherosclerotic plaques. In addition, the polymorphisms of two target genes have been investigated and associated with coronary artery disease (CAD). **Methods:** The advanced atherosclerotic plaques (CHD-P) and without plaque (CHD-nonP) artery samples from post-mortem cases with coronary heart disease (CHD). The *ROR-alpha*, *ABCA1*, *CYP19A1* and *MIF* expression levels were analyzed using qRT-PCR technique. In addition, unselected 332 Turkish CAD (coronary lesion with 50-100% stenosis) and control (coronary lesion with <30% stenosis) were genotyped for *MIF* and *CYP19A1* polymorphism using hybridization probes in RealTime PCR LC480 device. Blood samples were drawn before coronary angiography. Gensini and SYNTAX scores and myocardial blush grade (MBG) were assessed. **Results:** Expression results showed two target genes (*ABCA1* and *MIF*) were up-regulated and a target gene (*CYP19A1*) were down-regulated (fold change >1.5) in advanced atherosclerotic plaques. The *ROR-alpha* was not expressed significantly lower in advanced atherosclerotic plaques (CHD-P) as compared to CHD-nonP (Fold change, 0.9). In addition, *CYP19A1* rs10046 C/T, not *MIF* gene -173 G/C, polymorphism was significantly associated with the angiographic severity in patients with CAD ( $p < 0.05$ ). **Conclusion:** It shows that reduced expression of *CYP19A1* may play an effective role in the development of atheroma. The expression levels of *ROR-alpha* some target genes were found to associations with advanced atherosclerosis in CHD cases causing sudden death.

**Gain of function variation in *SOS1* as a cause of dilated cardiomyopathy.**

J.R. Cowan, L. Salyer, D.D. Kinammon, A. Morales, E. Jordan, R.E. Hershberger. Division of Human Genetics, Department of Internal Medicine, The Ohio State University, Columbus, OH.

**Background and significance:** Dilated cardiomyopathy (DCM) is a genetically heterogeneous cardiac disease characterized by progressive ventricular enlargement and reduced systolic function. Genetic overlap is observed between DCM and hypertrophic cardiomyopathy (HCM), a primary cardiac manifestation in several distinct disorders arising from defective Ras signaling, including Noonan syndrome (NS). Here, we report genetic and functional analyses implicating the Ras signaling protein, *SOS1*, in the pathogenesis of DCM. **Methods and Results:** Exome sequencing identified an A-band Titin truncating variant [*TTN*tv; p.(Val30827Serfs\*22)] in a large, multiplex pedigree with aggressive, early-onset DCM. Reduced severity in individuals carrying only the *TTN*tv indicated that it was unlikely to be the sole genetic factor operating in this family. The presence of a rare *SOS1* variant [p.(Glu191Lys)] cosegregating alongside the *TTN*tv in the most severely affected family members suggested its potential involvement as an additional risk factor. Exome sequencing results from four other families identified five additional *SOS1* variants with potential disease involvement [p.(Ile607Thr), p.(Gly719Ala), p.(Arg744Gly), p.(Asp910His), p.(Arg1201Trp)]. Impacted amino acids occupied a number of functional domains relevant to *SOS1* activity, including the N-terminal histone fold, as well as the C-terminal catalytic unit. As several lines of evidence have implicated dysregulated Ras signaling in the pathogenesis of DCM, we assessed functional impact of each variant on activation of ERK and AKT. Relative expression levels were determined by western blot in HEK293T cells transfected with variant or wildtype human *SOS1* expression constructs. Increased pERK expression relative to wildtype levels was seen for all six *SOS1* variants, with fold differences for four reaching statistical significance (1.58 - 2.47; p-values 0.0002 - 0.0311). No significant differences in AKT signaling were observed for any variants. These signaling profiles parallel those observed in NS and support adding DCM to the clinical spectrum associated with gain of function variation in *SOS1*. **Conclusions:** Our analyses provide the first reported evidence for gain of function variation in *SOS1* as a cause of DCM.

**The effect of genetic determinants of arsenic metabolism efficiency on hypertension risk.**

D.A. Delgado<sup>1</sup>, L.S. Chen<sup>1</sup>, F. Jasmine<sup>1</sup>, M.G. Kibriya<sup>1</sup>, T. Islam<sup>2</sup>, A. Ahmed<sup>2</sup>, Y. Chen<sup>3</sup>, H. Ahsan<sup>1,4,5,6</sup>, B.L. Pierce<sup>1,4,5</sup>. 1) University of Chicago, Chicago, IL; 2) UChicago Research Bangladesh, Dhaka, Bangladesh; 3) Department of Environmental Medicine, New York University School of Medicine, New York, NY; 4) Department of Human Genetics, University of Chicago, Chicago, IL 60615; 5) Comprehensive Cancer Center, University of Chicago, Chicago, IL 60615; 6) Department of Medicine, University of Chicago, Chicago, IL 60615.

Epidemiologic studies report inconsistent associations between inorganic arsenic (iAs) exposure and hypertension (HTN) at high and low-to-moderate levels of exposure. One limitation of these prior studies is the lack of individual-level measurements of arsenic and arsenic metabolites in urine. In the current study, we leverage SNPs known to influence arsenic metabolism efficiency in a Mendelian randomization (MR) approach to understand the relationship between arsenic exposure and HTN risk. We used data on three genetic variants known to influence arsenic metabolism efficiency (*AS3MT* SNPs rs9527 and rs11191527; and *FTCD* SNP rs61735836) and HTN and blood pressure phenotypes on 4,886 Bangladeshi individuals with a wide range of exposure to arsenic through naturally-contaminated drinking water. Arsenic metabolism efficiency is represented by the percentage of arsenic in urine that is dimethylarsinic acid (DMA), the end metabolite in a series of reduction and methylation reactions that act as a detoxification mechanism. We used two MR methods to estimate the association between arsenic-related SNPs and HTN risk: 1) a two-stage sequential regression, which uses individual level data on a subset of 1,663 individuals with arsenic metabolite data to generate genetically-predicted values of DMA% and 2) the inverse-variance weighted (IVW) and simple median meta-analysis methods, which uses summary statistics on up to 4,886 individuals. The high efficiency alleles of rs9527, rs11191527, and rs61735836 were strongly associated with DMA% ( $\beta = 3.7$ ,  $P = 1 \times 10^{-11}$ ;  $\beta = 2.1$ ,  $P = 6 \times 10^{-8}$ ; and  $\beta = 5.4$ ,  $P < 2 \times 10^{-16}$ ; respectively) and associated with increased odds of HTN, though not significantly (OR = 1.15, OR = 1.07, and OR = 1.04, respectively). Both MR methods suggest increasing DMA% is associated with increased odds of HTN, though the effect is not significant with the two-stage sequential regression (OR = 1.016 (0.994, 1.038)) and IVW method (OR = 1.020 (0.997, 1.043)). Under the simple median MR method, the high efficiency alleles of the arsenic-related SNPs are significantly associated with increased odds of HTN (OR = 1.036 (1.001, 1.075)). Analyses using continuous measures of systolic and diastolic blood pressure showed consistent results. In summary, we leveraged individual genetic variation in arsenic methylation capacity to evaluate the effect of DMA% on HTN risk. Under MR assumptions, our findings suggest efficient metabolism of iAs increases the risk of HTN.

**Rare variants in previously identified linkage regions associated with carotid plaque in Dominican families.** *N. Dueker<sup>1</sup>, A. Beecham<sup>1</sup>, L. Wang<sup>1,2</sup>, S.H. Blanton<sup>1,2</sup>, C. Dong<sup>3</sup>, B. Doliner<sup>1</sup>, R.L. Sacco<sup>2,3</sup>, T. Rundek<sup>3</sup>.* 1) John P. Hussman Institute for Human Genomics, University of Miami, Miami, FL; 2) Dr. John T. Macdonald Department of Human Genetics, University of Miami, Miami, FL; 3) Departments of Neurology and Public Health Sciences, Miller School of Medicine, University of Miami, Miami, FL.

Carotid plaque is a subclinical marker of atherosclerosis and a well-established predictor of stroke and cardiovascular disease (CVD). We have previously shown measures of carotid plaque to be heritable in a sample of 100 Dominican families and found evidence for linkage and association of common variants (CVs) on 7q36, 11p15, 14q32 and 15q23 with plaque presence. Our current study aimed to further characterize these QTLs by identifying rare variants (RVs) (minor allele frequency < 5%) associated with plaque presence. To achieve this aim we sequenced the 1 LOD unit down region on 7q36, 11p15, 14q32 and 15q23 in twelve Dominican families with evidence for linkage to plaque presence. Using these data, we performed RV gene-based analyses on 454 genes within the four QTLs using the Sequence Association Test for familial data (F-SKAT). Gene-based analyses were performed under two filtering algorithms; exonic RVs and non-synonymous RVs. A Bonferroni correction was applied to correct for 908 tests ( $p < 5.5 \times 10^{-5}$ ). Within the twelve families, sequencing identified 11,769 RVs, of which, 623 were non-synonymous. In exonic RV analyses, three genes showed suggestive association with plaque presence and nominal evidence for replication in an additional sample of 22 Dominican families with Exome Array data; *PARVA* ( $p = 0.03$  in sequenced and replication families), *DPP6* ( $p = 0.006$  sequenced families;  $p = 0.03$  replication families) and *NOM1* ( $p = 0.02$  sequenced families;  $p = 0.03$  replication families). We previously reported CVs in *PARVA* and *DPP6* to be associated with plaque; therefore, the current study extends these findings to suggest that RVs within these genes may also play a role in carotid plaque pathogenesis. Variants in these genes have been associated with coronary artery disease (*PARVA* and *DPP6*), heart failure mortality (*PARVA*) and idiopathic ventricular fibrillation (*DPP6*), making them excellent candidate genes for carotid plaque. In non-synonymous RV analyses, *NRDE2* ( $p = 0.04$  in sequenced families;  $p = 0.002$  in replication families) and *ZNF143* ( $p = 0.002$  sequenced families;  $p = 0.04$  replication families) showed suggestive association in the sequenced families and nominal evidence for replication. Taken together, these results provide evidence for a role of RVs within our previously-identified linkage regions on 7q36, 11p15, 14q32 and 15q23 in carotid plaque presence.

**TRPV4 variants found to be suggestively associated with lung, renal and menstruation phenotypes in BioVU fail to replicate in UK Biobank and GERA cohorts.** *M.G. Ehm<sup>1</sup>, D.K. Ranatunga<sup>2</sup>, K.K. Thai<sup>2</sup>, M.N. Chiano<sup>1</sup>, O. Kirichek<sup>1</sup>, A. Lawton<sup>1</sup>, T.J. Hoffman<sup>3</sup>, D.J. Behm<sup>1</sup>, N. Risch<sup>3</sup>, A.S. Go<sup>3</sup>, C.A. Schaefer<sup>1</sup>, D.M. Waterworth<sup>1</sup>.* 1) GlaxoSmithKline, Research & Development, Collegeville, PA & Stevenage, UK; 2) Kaiser Permanente, Division of Research, 2000 Broadway, Oakland, CA 94612; 3) UCSF, 513 Parnassus Avenue, San Francisco CA 94117.

Transient receptor potential vanilloid-4 (*TRPV4*) encodes a Ca(2+)-permeable, nonselective cation channel thought to be involved in the regulation of systemic osmotic pressure, being investigated pre-clinically for various indications including brain, cardiovascular and joint diseases. A *TRPV4* blocker (GSK2798745) was in development for pulmonary edema associated with heart failure. Current mechanistic understanding derives mainly from preclinical data. A phenotype-wide association study (PheWAS) for variants (*TRPV4* V562I and E840K) was conducted using 29,000 participants typed using exome genotyping chip and evaluated for 1,502 phenotypes within BioVU, a hospital electronic health record (EHR) linked biobank. While none of the results were statistically significant after correction for multiple testing, associations were observed between p.E840K variant and pulmonary edema (odds ratio [OR] 1.97,  $p = 4 \times 10^{-4}$ ) as well as five lung infection phenotypes (OR range 1.7-3.1,  $p < 0.01$ ), renal failure and menstruation-related disorders ( $p < 0.05$ ). These results aligned well with preclinical data and with human *TRPV4* expression, which is highest in the kidney and bronchial epithelia. We conducted two studies to assess if these results replicated: the UK Biobank (UKB) and Kaiser RPGEH GERA cohort, a population-based health care system sample of 100,000 with linked genotypic and EHR data. Both studies evaluated associations of genotyped or well-imputed ( $R^2 > 0.80$ ) *TRPV4* variants p.V562I, p.E840K and a promoter variant (rs4766635) with MAFs of 0.012, 0.011 and 0.484, respectively with 21 phenotypes. No significant associations were observed between the *TRPV4* variants and phenotypes tested, either in GERA or UKB cohorts, nor the meta-analysis despite 80% power to detect genetic effects that overlap effect ranges identified at BioVU. The lack of replication could be due to the differing case settings across the cohorts, differing composition of cohorts with respect to selection of controls, differing uses of ICD codes to describe underlying clinical conditions or the initial association results were possibly false positives. Availability of multiple large, diverse, well-powered cohorts provide the opportunity to efficiently and quickly investigate genetic evidence for drug targets using real-world data which provides multiple insights into the epidemiology and biology of drug targets and associated conditions.

**Transcriptome signature of hypertension in African Americans: Findings from machine learning.** A. Gaye, S. Davis, G. Gibbons. National Institutes of Health, Bethesda, MD.

**Background** In multifactorial disease or related quantitative traits, the mechanism underlying the phenotype necessarily involves multiple determinants. Therefore, the full picture is more likely to emerge from investigations that integrate a range of interacting determinants. The aim of this work is to use a machine learning approach and leverage analysis of the transcriptome for the identification of functional/putative causal DNA variants that contribute to the pathobiological pathways that mediate a complex trait such as Hypertension. **Methods** The data consist of mRNA sequencing from whole-blood and genotype data (multi-ethnic array) from 178 participants of the Minority Health Genomics and Translational Research Bio-Repository Database (MH-GRID) study. A total of 16223 mRNAs (whole transcriptome) were used as predictors in a random forest classification analysis of Hypertension (HTN) to identify the set of mRNAs that predict HTN. Then the cis-variants that predict the expression of that set of mRNAs were identified. Finally, that group of cis-variants was linked back to the phenotype and cis-variants that predict Hypertension with high performance were identified. **Results** We identified 34 mRNAs that classify hypertensive vs. control with an area under the curve (AUC) = 0.93. Two of the mRNAs are encoded by genes that knock out animal models showed to be associated with vascular smooth muscle cell proliferation and abnormal development of intersegmental vessels. Three of the 92 cis-variants that, together, classify HTN with AUC=92 have been previously reported in GWAS of cardiovascular related phenotypes such as obesity, body mass index and heart rate. **Conclusion** Conventional statistical methods have provided extremely robust findings. However, due to various challenges many weaker but genuine signals are lost in the process whilst complex interactions are difficult to model. In this work, we used random forest classification to provide new insights and extend our knowledge. This unbiased approach revealed a set of mRNAs enriched for pathways that are plausible modulators of HTN by modulating vascular tone and/or vascular remodeling. The cis-variants that influence the expression of those mRNAs proved to be very good predictors of HTN.

Blood pressure (BP) homeostasis and kidney function are intimately linked, and chronic kidney disease (CKD) and hypertension (HT) often occur concurrently. However, whether high BP precedes CKD or gradually deteriorating kidney function is also a primary cause of HT is controversial, and can be confounded by subclinical disease in observational studies. We used genetic risk scores (GRS) for BP traits (systolic [SBP], diastolic [DBP] and pulse pressure [PP]) and kidney function (estimated glomerular filtration rate [eGFR]) to assess associations with clinically diagnosed phenotypes in a phenome-wide association study (PheWAS) in 188,008 European Americans from the Million Veteran Program (MVP). GRSs used European-derived effect estimates from the United Kingdom Biobank (UKB) study for BP-traits (N-SNPs = 545, N-Samples = 141k) and the CKDGen consortium for eGFR (N-SNPs = 128, N-Sample range = 239k-567k) for trait-increasing alleles from GWAS index single nucleotide polymorphisms (SNPs). We regressed 1,813 phenotypes onto each GRS using logistic regression adjusting for 10 principal components. SBP, BP and PP-weighted results were highly correlated. HT ( $P < 1 \times 10^{-305}$ ) and essential HT ( $P < 1 \times 10^{-305}$ ) were the strongest associations with SBP-weighted GRS followed by hypertensive heart and/or renal disease ( $P = 3 \times 10^{-173}$ ) and hypertensive CKD ( $P = 5 \times 10^{-141}$ ). In addition to disease groupings related to heart and vascular conditions, groupings related to the kidney including renal failure ( $P = 3 \times 10^{-36}$ ), gout ( $P = 2 \times 10^{-35}$ ), CKD ( $P = 1 \times 10^{-26}$ ), and acute renal failure ( $P = 1 \times 10^{-19}$ ) were among the top associations with BP-weighted GRSs. The eGFR-weighted GRS was inversely associated with kidney conditions including CKD ( $P = 2 \times 10^{-108}$ ), renal failure ( $P = 2 \times 10^{-84}$ ), CKD Stage III ( $P = 1 \times 10^{-54}$ ), gout ( $P = 3 \times 10^{-7}$ ), hypertensive CKD ( $P = 4 \times 10^{-28}$ ), and hypertensive heart and/or renal disease ( $P = 2 \times 10^{-19}$ ). The eGFR-weighted GRS was also positively associated with calculi formation including kidney calculus ( $P = 3 \times 10^{-16}$ ), urinary calculus ( $P = 4 \times 10^{-15}$ ) and ureter calculus ( $P = 1 \times 10^{-5}$ ). However, eGFR-weighted GRS was not associated with essential HT ( $P = 0.08$ ) or HT ( $P = 0.09$ ). Additional analyses, adjusting for observed BP, eGFR, adjustment for GRSs, as well as Mendelian Randomization studies are underway. In this large GRS PheWAS study, genetically predicted BP-traits are associated with CKD, but genetically predicted kidney function is not associated with primary HT.

**Rare variants in the 22q11.2 deletion region may contribute to the development of conotruncal heart defects in non-deleted patients.** D.A. Hammond<sup>1,2</sup>, D.M. Taylor<sup>1,2</sup>, B. Morrow<sup>3</sup>, W.K. Chung<sup>4</sup>, Y. Shen<sup>4</sup>, J.W. Newburger<sup>5</sup>, C.E. Seidman<sup>6</sup>, M. Brueckner<sup>6</sup>, G.A. Porter, Jr.<sup>7</sup>, R.W. Kim<sup>8</sup>, D. Srivastava<sup>9</sup>, M. Tristani-Firouzi<sup>10</sup>, B.D. Gelb<sup>11</sup>, A.J. Agopian<sup>12</sup>, L.E. Mitchell<sup>12</sup>, E. Goldmuntz<sup>1,2</sup>. 1) Children's Hospital of Philadelphia, Philadelphia, PA; 2) University of Pennsylvania, Philadelphia, PA; 3) Albert Einstein College of Medicine, Bronx, NY; 4) Columbia University, New York, NY; 5) Children's Hospital Boston, Boston MA; 6) Yale University School of Medicine, New Haven, CT; 7) University of Rochester Medical Center, Rochester, NY; 8) Children's Hospital Los Angeles, Los Angeles, CA; 9) Gladstone Institutes/UCSF, San Francisco, CA; 10) University of Utah School of Medicine, Salt Lake City, UT; 11) Icahn School of Medicine at Mount Sinai, New York, NY; 12) UTHealth School of Public Health, Houston, TX.

Conotruncal defects (CTDs) are an important subtype of congenital heart defects that are associated with high morbidity and early mortality. It is estimated that approximately 80% of individuals with 22q11.2 deletion syndrome have CTDs, suggesting that genes within the chromosome 22q11.2 region may be critical to the development of CTDs. We therefore hypothesized that variation in genes in the region contribute to risk of CTDs in non-deleted individuals. In this study, we assessed the association of rare variants in genes within the chromosome 22q11.2 deletion region in individuals with CTDs who do not have a 22q11.2 deletion. **Methods:** Whole exome sequence (WES) data from 472 parent-child trios from the Pediatric Cardiac Genomic Consortium (PCGC) with a clinical diagnosis of CTDs were tested for association of rare variants (minor allele frequency <0.05) in genes within the 22q11.2 region using the family-based association test (FBAT) to obtain variant level p-values. The variant level p-values were then used to assess gene-level associations and to conduct a competitive gene-set analysis (all genes in the 22q11.2 region) via the Multi-marker Analysis of GenoMic Annotation (MAGMA). **Results:** We found a statistically significant association between CTDs and the set of all genes in the 22q11.2 region (p-value =  $8.19 \times 10^{-3}$ ) and with two of the genes within the region: RAN-binding protein 1 (*RANBP1*, p = 0.03) and DiGeorge Syndrome Critical Region Gene 6 (*DGCR6*, p =  $3.8 \times 10^{-3}$ ). **Conclusions:** Our findings suggest that rare variants within genes located in the 22q11.2 region contribute to the development of CTDs.

## 3118T

**Spontaneous coronary artery dissection is infrequent in individuals with thoracic aortopathies despite shared genetic susceptibility.** H.L. Hill<sup>1,2</sup>, M. Ghannam<sup>1</sup>, M. Yang<sup>1,2</sup>, N.L. Pugh<sup>3</sup>, F.M. Asch<sup>4</sup>, W. Hornsby<sup>5</sup>, A. Driscoll<sup>6</sup>, J. McNamara<sup>7</sup>, C.J. Willer<sup>1,2</sup>, E.S. Regalado<sup>8</sup>, GenTAC Investigators<sup>1</sup>, MAC Investigators<sup>9</sup>, D.M. Milewicz<sup>6</sup>, K.A. Eagle<sup>1</sup>, S.K. Ganesh<sup>1,2</sup>. 1) Division of Cardiovascular Medicine, Department of Internal Medicine, University of Michigan, Ann Arbor, Michigan; 2) Department of Human Genetics, University of Michigan, Ann Arbor, Michigan; 3) Center for Clinical Research Network Coordination, Biostatistics and Epidemiology Division, RTI International, Research Triangle Park, NC; 4) MedStar Health Research Institute, Hyattsville, MD; 5) Cardiovascular Health Improvement Project (CHIP) biorepository; 6) Division of Medical Genetics, Department of Internal Medicine, McGovern Medical School, The University of Texas Health Science Center at Houston, Houston, Texas; 7) Genetically Triggered Thoracic Aortic Aneurysms and Cardiovascular Conditions (GenTAC) Consortium; 8) Montalcino Aortic Consortium (MAC).

Spontaneous coronary artery dissection (SCAD) is an underdiagnosed nonatherosclerotic precipitant of acute coronary syndrome. Genetic testing in case series has identified pathogenic mutations in genes underlying familial thoracic aortic aneurysm and dissection (TAAD) and related disorders. We hypothesized that individuals with TAAD are at elevated risk for SCAD and that phenotypic profiling of affected individuals can inform clinical risk stratification. Three clinical databases enrolling individuals with TAAD (n=6,838) were queried for a history of SCAD events. Retrograde aortic and iatrogenic dissections were excluded. Queried datasets included the (1) NIH-supported multicenter Genetically Triggered Thoracic Aortic Aneurysms and Cardiovascular Conditions (GenTAC) consortium national registry; (2) Montalcino Aortic Consortium (MAC) international registry; and (3) Cardiovascular Health Improvement Project (CHIP) biorepository at the University of Michigan Frankel Cardiovascular Center. Phenotypic profiles of individuals experiencing SCAD were compared against unaffected GenTAC controls using tests of independence. Querying 6,838 individuals with genetically-associated TAAD identified 11 cases of SCAD (0.2%). The GenTAC (n=3,542) and MAC (n=987) registries included 8 (0.2%) and 3 (0.3%) cases of SCAD, respectively. No SCAD events were identified in the CHIP biorepository (n=2,309). Genetic testing of aortopathy genes performed as part of routine clinical care confirmed pathogenic mutations in 7 (63.6%) SCAD subjects affecting the *COL3A1* (n=2), *TGFBR2* (n=2), *TGFBR1* (n=1), *FBN1* (n=1), and *PRKG1* (n=1) genes. Affected individuals were predominantly Caucasian (n=9, 81.8%) females (n=9, 81.8%) experiencing SCAD at an average age of  $35.6 \pm 11.0$  years. Dissections affected main or proximal coronary arteries in 5 cases (45.5%). Additional dissections of the internal carotid (n=2), iliac (n=2), vertebral (n=1), and subclavian (n=1) arteries were identified in SCAD cases. Prevalence of SCAD in the setting of heritable thoracic aortopathy is low, consistent with reports of low frequency of pathogenic findings in known arteriopathy genes among individuals primarily presenting with SCAD. While our phenotype analysis was limited by small case counts, the presence of aortic branch vessel dissections may suggest an increased risk for SCAD. Our findings implicate SCAD as part of a systemic vasculopathy and support evidence for genetic susceptibility.

**Genome-wide linkage and association studies of circulating apolipoproteins CIII and E levels in Amerindians.** W.-C. Hsueh, A. Nair, C. Koroglu, S. Kobes, W.C. Knowler, L.J. Baier, R.L. Hanson. NIDDK, Phoenix, AZ.

Apolipoprotein CIII (apoCIII) is an important component of major lipoproteins. We previously reported that an nsSNP (rs147210663, A43T) in *APOC3* has a large effect on lipid levels, particularly triglycerides ( $\beta \approx 1$  SD unit per copy of the T allele) in Amerindians. Thus, we conducted genome-wide searches for genetic variants affecting circulating apoCIII and apoE, which correlates strongly with apoCIII ( $r=0.64$ ). Both population-based linkage and association approaches were conducted in 1,910 nondiabetic Pima Indians. A custom SNP array (~0.5m SNPs) was designed for Pima Indians. Empirical estimates of IBD among all pairs of subjects for linkage analysis were obtained with Beagle. The genome-wide significance threshold for linkage is  $LOD=3.7$ , and for association is  $p < 1.2E-7$  after correction for multiple testing. After adjusting for effects of sex, age and genetic ancestry, we identified 1 region with strong evidence for linkage for apoCIII, covering the *APOC3* coding region (on chr11q,  $LOD=12.5$ ,  $p=1.4E-14$ , explaining 7.4% variance, or  $\sigma^2$ ). In GWAS, only 1 region on 11q with strong evidence for association was observed. The *APOC3* A43T SNP had the strongest association ( $MAF=2.4\%$ ,  $p=3.5E-23$ ,  $\beta=1.06 \pm 0.11$  SD unit,  $\% \sigma^2$  explained=5.6%). For apoE, while only 1 strong linkage signal was observed (in the *APOE* region on 19q,  $LOD=6.0$ ,  $p=7.7E-8$ , explaining 8.1%  $\sigma^2$ ), 3 regions with suggestive association were observed for apoE (top SNPs: on 11q, A43T in *APOC3*; on 15q, rs17746210 near *OCA2*; and on 19q, rs35136575 near *APOE*;  $p=3.0 - 7.7E-7$ ). Mediation analysis suggested that the effect of A43T SNP on apoE was entirely mediated through apoCIII (mediation=100%,  $p=2.5E-24$ ). In both coding regions, there appear to be more than 1 SNP contributing to association/linkage signals. After controlling for rs147210663, a SNP in *SIK3* (rs35190172) also showed significant association ( $p=1.0E-6$ ) with apoCIII. For apoE, rs71352239 and rs7259004 on 19q remained significantly associated with apoE ( $p=3.9E-7$ ) after controlling for SNPs with stronger associations. Our findings identify evidence for linkage and association for these 2 apolipoproteins in their coding regions, and suggest that multiple variants in the same genomic region may contribute to the genetic signals. Our findings also suggest that some genetic influences on apoE may be mediated via apoCIII. Fine-mapping studies based on sequencing data are ongoing with the aim at identifying functional variants that may explain these signals.

**Placental growth factor locus is associated with decreased risk of coronary artery disease and incident major adverse cardiac events.** P.

Huang<sup>1,2</sup>, Y. Han<sup>1,2</sup>, Q. Jia<sup>1,2</sup>, N.C. Woodward<sup>1,2</sup>, J. Gukasyan<sup>1,2</sup>, W.H.W. Tang<sup>3,4</sup>, S.L. Hazen<sup>3,4</sup>, H. Allayee<sup>1,2</sup>, J.A. Hartiala<sup>1,2</sup>. 1) Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA; 2) Department of Biochemistry & Molecular Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA; 3) Department of Cardiovascular Medicine, Cleveland Clinic, Cleveland, OH; 4) Department of Cellular & Molecular Medicine, Cleveland Clinic, Cleveland, OH.

Recent studies show that PIGF levels are elevated in coronary artery disease (CAD) patients and are associated with adverse cardiac events. Although placental growth factor (PIGF) is an important cytokine involved in angiogenesis, cardiac remodeling and inflammation, it is not known whether the association between PIGF levels and CAD outcomes is causal. To address this question, we carried out a 2-stage genome-wide association study (GWAS) to identify genetic determinants controlling PIGF levels and then evaluated association of the variants with CAD. In stage 1, we performed a GWAS with ~2.5 million single nucleotide polymorphisms (SNPs) in ~2000 subjects from the GeneBank cohort. Suggestive associations near *PGF* (rs11850328,  $p=1.2 \times 10^{-7}$ ) on chr14q24.3 and in intergenic region on chr2p16.1 (rs6545625,  $p=7.5 \times 10^{-7}$ ) from stage 1 were genotyped in an independent sample of ~2000 additional GeneBank subjects, of which only rs11850328 (G/A) showed consistent evidence for association in stage 2. A combined analysis with ~4000 subjects yielded a genome-wide significance signal with the *PGF* locus and serum PIGF levels ( $p=2.8 \times 10^{-6}$ ). Interestingly, the minor allele A was also associated with decreased risk of incident major cardiac events (MACE) in ~4,000 GeneBank subjects (HR= 0.87; 95% CI 0.76-0.99;  $p=0.04$ ). Since PIGF levels had also been previously associated with atherosclerotic plaque destabilization and cardiac repair, we tested whether history of myocardial infarction (HxMI) modified the association between the *PGF* variant and MACE. Notably, rs11850328 yielded a significant interaction with HxMI ( $p=0.009$ ), prompting us to perform a stratified analysis. The A allele did not influence risk of MACE among those with HxMI ( $p=0.70$ ) but decreased risk of future events 2-fold in subjects with no history of CAD/MI (HR 0.50, 95% CI 0.30-0.81,  $p=0.005$ ). Consistent with these observations, the A allele also significantly decreased risk of CAD (OR=0.98, 95% CI 0.97-0.99;  $p=2.9 \times 10^{-5}$ ) in an independent dataset of >500,000 Caucasian subjects. Our data indicate that genetic variants increasing PIGF levels show decreased risk of CAD, but these observations were somewhat unexpected since higher levels of PIGF are clinically associated with increased risk of CAD. Thus, additional studies will be needed to determine the biological mechanism for the opposite associations we observe between genetic determinants of serum PIGF and risk of CAD.

**A multiplex pedigree illustrates the challenges of applying a Mendelian monogenic paradigm to the interpretation of rare variants in familial dilated cardiomyopathy.** E. Jordan, A. Morales, D. Kinnamon, K. Zareba, J. Cowan, L. Salyer, S. Raman, R. Hershberger. The Ohio State University, Columbus, OH.

Familial dilated cardiomyopathy (DCM) has a genetic basis. Identifying genetic risk and detecting early clinical evidence of DCM in at-risk relatives holds promise to mitigate, and ultimately prevent, development of disease. We report a family in which a proband and 5 affected relatives harbor a rare *RBM20* variant in exon 9 encoding a premature stop of translation, NM\_001134363.1:c.2062C>T (p.Arg688X). *RBM20*, ribonucleic acid (RNA)-binding protein 20, has roles in RNA binding and regulation of mRNA splicing of key genes involved in cardiac development. To date, the only proven pathogenic *RBM20* variants are missense variants present in the exon 9 hotspot (encompassing amino acid positions 634, 636, 637, 638). After expanding the pedigree to include phenotype and genotype data from 15 individuals, two-point parametric linkage analysis performed under an autosomal dominant disease model provided moderate evidence that the *RBM20* variant segregates with affection with left ventricular enlargement, systolic dysfunction, or DCM (LOD = 1.69 at  $\theta = 0.001$ ). Moreover, cardiac magnetic resonance imaging (CMR) in 12 relatives (7 with and 5 without the *RBM20* variant) also showed greater left ventricular end diastolic dimensions ( $5.9 \pm 1.0$  vs.  $5.2 \pm 0.4$  cm) and volumes ( $121 \pm 45$  vs.  $87 \pm 9$  ml/m<sup>2</sup>), lower ejection fractions ( $47 \pm 14\%$  vs.  $58 \pm 4\%$ ), a larger extent of midwall fibrosis, and higher native T1 and T2 values in those with the variant. While these findings hint at biological relevance, this is a variant of uncertain significance (VUS) based on our variant classification standards adapted from the published *MYH7* ClinGen Cardiomyopathy Expert Panel approach. This classification is primarily due to the lack of evidence of loss of function as a pathogenic mechanism in *RBM20* and limited case data. In addition, CMR abnormalities suggesting early DCM were observed in 4 of 5 individuals without the *RBM20* variant, suggesting that additional unidentified genetic variation may contribute to DCM in this family. This observation is consistent with our preliminary data showing that 19% of DCM probands carry multiple variants, classified as VUS, likely pathogenic, or pathogenic, in established DCM genes. Our observations suggest that the genetic background of DCM may be more complex than previously appreciated. Further elucidation of the disease model will be necessary to enable the clinical application of genetic information in the prevention of this disease.

**The transcriptomic signature and regulatory landscape of iPSC-derived megakaryocytes and platelets.** K. Kammers<sup>1</sup>, M.A. Taub<sup>2</sup>, B. Rodriguez<sup>3</sup>, I. Ruczinski<sup>4</sup>, L.R. Yanek<sup>4</sup>, A.D. Johnson<sup>2</sup>, N. Faraday<sup>4</sup>, L.C. Becker<sup>4</sup>, R.A. Mathias<sup>4</sup>. 1) Division of Biostatistics and Bioinformatics, Department of Oncology, Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Johns Hopkins University School of Medicine, Baltimore, MD; 2) Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3) NHLBI Population Sciences Branch, The Framingham Heart Study, Framingham, MA; 4) The GeneSTAR Research Program, Johns Hopkins University School of Medicine, Baltimore, MD.

GWAS studies have identified platelet aggregation loci, but because these are largely intronic/intergenic, their mechanistic link to platelet function is unclear. To address these gaps, we performed expression-quantitative trait locus (eQTL) analyses of RNA sequencing data on platelets and iPSC-derived megakaryocytes (MKs), to define the transcriptome signature and its genetic regulatory landscape in both cell types in African American (AA) and European American (EA) subjects. Using 1,003,451 SNPs from the Illumina 1M GWAS array, analyses were performed stratified by ancestry and cell type, with a 1Mb window around each gene and adjusting for relevant covariates with MatrixEQTL. Significance was defined as a q-value < 0.05. Genes with median FPKM $\leq$ 1 were excluded, yielding ~10,000 genes in the MKs and ~3,000 in the platelets, 94% of which are also expressed in the MKs. In MKs (N=107 EA, N=87 AA), we found 8,629 and 1,280 eQTLs in the two groups, respectively. For platelets (N=185 EA, N=112 AA), we identified 23,355 eQTLs in EAs and 5,740 in AAs. We found high tissue specificity compared to 44 tissues in Genotype-Tissue Expression project (GTEx): 34% of MK and 55% of platelet eQTLs are not reported in GTEx. The identified eQTLs reveal significant enrichment ( $p < 10^{-100}$ ) in super-enhancers previously reported to be specific to MKs with similar patterns of enrichment for both sets of eQTLs, but stronger enrichment in platelets. In general across both cell types and for both ancestries, the highest enrichment was for promoter proximal H3K27ac and H3K4me3 bound promoter regions reported in MKs. Additionally, we found that the eQTLs that map to these known super enhancer regions are significantly enriched for several key pathways in platelet physiology: platelet degranulation, platelet activation/aggregation, and hemostasis. These results offer promising insights into the regulatory signature of platelets and MKs, with significant overlap in genes expressed, eQTLs detected, and enrichment within known super enhancers relevant to platelet biology, which in turn could shed light on these clinically and pharmacologically important tissues. We are currently extending these analyses to leverage whole genome sequence data generated through the NHLBI TOPMed Program to overcome limitations of poor coverage of the GWAS array in the AAs, and to better refine the regulatory signature without relying on the tagging approach of the GWAS.

**3123W****Associations of genetically-inferred ancestry with hypertension traits.**

Velez Edwards<sup>2,3,4,5</sup> on behalf of the Million Veteran Program. 1) Division of Epidemiology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA; 2) Vanderbilt Genetics Institute, Vanderbilt University, Nashville, TN, USA; 3) Institute for Medicine and Public Health, Vanderbilt University Medical Center, Nashville, TN, USA; 4) Biomedical Laboratory Research and Development, Tennessee Valley Healthcare System (626)/Vanderbilt University, Nashville, TN, USA; 5) Department of Obstetrics and Gynecology, Vanderbilt University Medical Center, Nashville, TN, USA; 6) Nephrology Section, Memphis VA Medical Center, Memphis TN, USA; 7) Department of Epidemiology, Emory University Rollins School of Public Health, Department of Biomedical Informatics, Emory University School of Medicine, Atlanta, GA, USA; 8) Atlanta VAMC and Emory Clinical Cardiovascular Research Institute, Atlanta, GA, USA; 9) VA Boston Healthcare, Section of Cardiology and Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; 10) Division of Nephrology and Hypertension, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA.

Hypertension is a risk factor for cardiovascular disease, has considerable impact on global healthcare, and underlying blood pressure (BP) traits are substantially heritable. Ethnic disparities in hypertension prevalence are well documented, though the influence of genetic factors is unclear. Our goal was to find associations of BP traits with genetic ancestry to determine whether ancestral geographic origin could explain racial disparities. We analyzed genetically inferred ancestry proportions from five 1000 Genomes reference populations [British in England and Scotland (GBR), Peruvians from Lima, Peru (PEL), Yoruba in Ibadan, Nigeria (YRI), Han Chinese in Beijing, China (CHB), and Luhya in Webuye, Kenya (LWK)] with four continuous BP traits (systolic BP [SBP], diastolic BP [DBP], pulse pressure [PP], and mean arterial pressure [MAP]), and the binary outcomes hypertension and drug-resistant hypertension in 59,927 black, 220,495 white, and 21,273 Hispanic individuals from the Million Veteran Program using electronic health records linked to genotypes. Continuous traits and binary outcomes were modeled using linear and logistic regression, respectively, for each ancestry proportion adjusted for age, age<sup>2</sup>, sex, and body mass index. Results were meta-analyzed to report effect estimates per 10% difference for a given inferred ancestry proportion in all samples. Percent GBR was negatively associated with BP ( $P=2.13 \times 10^{-19}$ ,  $7.92 \times 10^{-8}$ ,  $4.41 \times 10^{-11}$ , and  $3.57 \times 10^{-13}$  for SBP, DBP, PP, and MAP respectively; coefficient range -0.10 to -0.21), and was protective against hypertension ( $P=2.59 \times 10^{-5}$ , odds ratio [OR]=0.98) relative to other ancestries. YRI percentage was positively associated with BP ( $P=1.63 \times 10^{-23}$ ,  $1.94 \times 10^{-26}$ , 0.012, and  $3.26 \times 10^{-29}$  for SBP, DBP, PP, and MAP respectively; coefficient range 0.06–0.32 mm Hg) and was positively associated with hypertension risk ( $P=3.10 \times 10^{-11}$ , OR=1.04) and drug-resistant hypertension risk ( $P=1.86 \times 10^{-4}$ , OR=1.04) compared with other ancestries. Percent PEL was positively associated with SBP ( $P=6.68 \times 10^{-3}$ , beta=0.09 mm Hg) and PP ( $P=3.69 \times 10^{-15}$ , beta=0.21 mm Hg), but inversely associated with DBP ( $P=2.84 \times 10^{-5}$ , beta=-0.11 mm Hg). These results demonstrate that genetic ancestry is a significant risk factor for BP traits, provide insight into the geographic origin of genetic factors underlying hypertension risk, and establish that a portion of BP trait racial disparities are due to genetic differences between continental groups.

**3124T****Whole genome sequencing analysis of blood pressure phenotypes in the NHLBI Trans-Omics for Precision Medicine Program.**

T. Kelly<sup>1</sup>, X. Sun<sup>1</sup>, J. Brody<sup>2</sup>, TOPMed Blood Pressure Working Group. 1) Department of Epidemiology, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; 2) Cardiovascular Health Research Unit, University of Washington, Seattle, WA.

Although genome-wide association studies (GWAS) have made important strides in localizing genomic regions associated with blood pressure (BP) phenotypes, the causal mechanisms underlying the vast majority of identified signals remain unknown. Whole genome sequencing (WGS) provides an opportunity for not only novel genomic discoveries but also high resolution refinement of previously identified GWAS signals. We pooled high-depth WGS and phenotype data from 32,263 participants from 12 cohorts from phases 1 and 2 of the Trans-Omics for Precision Medicine (TOPMed) program. These data were used to conduct WGS association analyses of systolic BP (SBP) and diastolic BP (DBP). Genotype quality filtering included the removal of variants lying in low complexity regions, along with those with a minor allele count (MAC)<10, Hardy Weinberg p-values< $1 \times 10^{-9}$ , and missingness>5%. For participants using antihypertension medications, 10 mmHg and 5 mmHg were added to SBP and DBP, respectively. BP values were then regressed on important covariables including age, sex, body mass index (BMI), study, and the first 10 principal components within each ancestry group. The ancestry-specific, residualized BP values were inverse-normal transformed, rescaled by variance, and pooled for the analysis. These pooled residuals were used as outcomes in a linear mixed model with the same adjustments, but also including a variance component associated with the genetic relationship matrix plus separate residual variance components for each ancestry group. In an effort to minimize cost and computational time, the full mixed model was only used for variants with  $P < 1 \times 10^{-4}$  in an initial scan that used a linear model. All analyses were supported by the Analysis Commons. Among 44 novel loci achieving  $P < 1 \times 10^{-6}$ , two rare variants achieved genome-wide significance, including one at *EIF3LP1* for SBP (rs191347507; MAC=11;  $P=4.78 \times 10^{-9}$ ) and one at *RNGTT* for DBP (rs578046022; MAC=91;  $P=2.73 \times 10^{-9}$ ). Twenty previously reported loci also achieved  $P < 1 \times 10^{-6}$ , including three attaining genome-wide significance, *PRDM8/FGF5* for both SBP and DBP (rs16998073; MAC=15,888;  $P=7.22 \times 10^{-9}$  and  $1.80 \times 10^{-9}$ , respectively), *SOX6* for SBP (rs34610248; MAC=10,552;  $P=3.62 \times 10^{-9}$ ) and a novel variant at *MRPL4/ICAM1* for SBP (rs563785784; MAC=33;  $P=4.95 \times 10^{-9}$ ). These discovery analyses provide empirical evidence that WGS studies across diverse ancestry groups may yield new genomic signals for BP.

Venous thromboembolism (VTE) is a heritable, life-threatening condition with known genetic predictors. The most recent agnostic search for genetic association focused on common variation (PMID 25772935). Here we studied rare variation using whole-genome sequence (WGS). In TOPMed, we performed a pooled case-control analysis using data from 3 cohort studies (nested case-control) and 3 case-only collections. Case-control matching was performed within sex-ancestry-study groups, based on age at diagnosis for cases and age at last follow-up for controls. Excess controls from one of the cohort studies were matched with cases from the case-only collections. The matched sample set consisted of 8,911 participants with an average ratio of 1.9 controls per case (5,816 controls and 3,095 cases) with 88% European-American (EA), 10% African-American (AA) and 2% other ancestries. Mixed-model logistic regression was used for single-variant and aggregate tests. Covariates were sex, sample set, age, and  $\ln(\text{case/control ratio per matched set})$ . Single-variant tests (minor allele count filter > 5) identified 6 loci known to be associated with VTE (PMID 25772935, PMID 20212171) and one novel locus. Conditioning on the known associations did not identify any new associations in previously known loci and the new locus remained significant. Significant variant rs10963226 ( $p = 3e-8$ ) at the novel locus had a MAF of 0.0001 in EA and 0.04 in AA participants. The high quality variant rs10963226 lies in the first intron of one of the *SH3GL2* transcripts. Chromatin capture data indicates that the region overlapping rs10963226 interacts with the promoter of *SH3GL2* suggesting rs10963226 may have a regulatory role. Furthermore, *SH3GL2* has been reported to interact with coagulation factor XIII A subunit [PMID: 21900206]. These observations suggest that the rare variant association in the *SH3GL2* locus is biologically plausible. Burden and SKAT tests were performed using variants with MAF < 0.01, aggregating by sliding-window (50 kb and 5kb) and also by genes after applying various genome annotation filters. Only the analysis that aggregated loss of function and missense variants in each gene had a significant result (< Bonferroni  $p$ -value  $2e-6$ ). The unit identified in this analysis was the gene *PROC*, a locus well known to be associated with VTE based on family studies. In summary, the WGS data confirmed previously known loci containing common and rare variants and identified a new locus.

**The CTLA4 gene is associated with Kawasaki disease and coronary artery lesions: Case-control and family-based studies.** Y. Lee<sup>1,2,4,5</sup>, M. Chen<sup>1</sup>, N. Chiu<sup>1</sup>, H. Chi<sup>1</sup>, F. Huang<sup>1</sup>, K. Yang<sup>1</sup>, L. Chang<sup>1</sup>, H. Lee<sup>1</sup>, S. Lin<sup>1</sup>, W. Chen<sup>2</sup>, C. Lin<sup>2</sup>, H. Chan<sup>2</sup>, W. Lin<sup>2</sup>, S. Chnag<sup>2</sup>, T. Chnag<sup>2</sup>, H. Yang<sup>2</sup>, M. Lin<sup>2</sup>, L. Chang<sup>2</sup>. 1) MacKay Children's Hospital, Taipei, Taiwan; 2) MacKay Memorial Hospital, Taipei, Taiwan; 3) National Taiwan University Hospital, Taipei, Taiwan; 4) Macky Medical College, New Taipei, Taiwan; 5) Taipei Medical University, Taipei, Taiwan.

**Background:** Kawasaki disease (KD) is a febrile disease of children complicated with coronary artery lesions (CALs). The cytotoxic T-lymphocyte-associated protein 4 (CTLA4) increases during the acute stage of KD. **Methods:** 720 unrelated KD children and 1058 controls were genotyped for SNP rs5742909:C>T, rs231775:A>G, and rs3087243:G>A of the CTLA4 gene. Hardy-Weinberg equilibrium test, linkage disequilibrium, and haplotype frequency were assessed by Haploview 4.2. The genotype, allele, carrier, and haplotype distributions of patients and controls were compared using  $\chi^2$  test. Family-based data were analysed using Transmission-disequilibrium test. **Results:** Genotype rs3087243A/G was significantly less frequent in KD patients than in controls, OR (95%CI) = 0.76 (0.61-0.96),  $P_c = 0.046$ . So was haplotype CAG, OR = 0.17 (0.06-0.48),  $P_c = 0.0096$ . Allele rs231775A was significantly less frequent in patients with CALs than in those without CALs, OR = 0.72 (0.54-0.95),  $P_c = 0.04$  while allele rs231775G was significantly more frequent, OR = 1.39 (1.05-1.84),  $P_c = 0.04$ . Genotype rs3087243G/G was significantly more frequent in patients with CALs than in controls, OR = 1.55 (1.10-2.18),  $P_c = 0.021$ . Carrier A was significantly less frequent in patients with CALs than in controls, OR = 0.64 (0.46-0.91),  $P_c = 0.021$ . So was genotype A/G, OR = 0.64 (0.45-0.91),  $P_c = 0.026$ . Haplotype CGG was significantly more frequent in CAL patients than in controls, OR (95%CI) = 1.37 (1.07 - 1.76),  $P_c = 0.048$ . Haplotype CAG was not found in CAL patients, OR (95%CI) = 0.06 (0.00 - 0.94),  $P_c = 0.026$ . TDT confirmed the association. **Conclusions:** The CTLA4 gene is associated with KD and CALs.

**Genetic liability for clinical risk factors differentially associates with heart failure subtypes.** R.T. Levinson, E. Farber-Eger, B.D. Lowery, J.D. Mosley, Q.S. Wells. Vanderbilt University Medical Center, Nashville, TN.

**Background:** Heart failure (HF) is a heterogeneous syndrome associated with significant morbidity and mortality, and is commonly sub-grouped into HF with preserved ( $\geq 50\%$ ) and reduced ( $\leq 40\%$ ) ejection fraction (HFpEF and HFrEF). Genome-wide association studies (GWAS) of all-HF have identified few risk loci. No GWAS of HF subtypes have been reported and whether genetic risk for HF subtypes is shared is unknown. Patients with HFpEF and HFrEF have similar, yet distinct clinical profiles, and the relative contribution of established risk factors to HF subtypes is incompletely defined. We proposed to interrogate these relationships by assessing the association of HF subtypes with polygenic liability for clinical risk factors. **Methods:** HF subjects with genotyping data (Illumina MEGA Array) were identified from Vanderbilt University Medical Center's electronic health record (EHR) using a random forest classifier and assigned to a HF subtype by ejection fraction. HF cases with any EF  $\leq 40\%$  were considered HFrEF (1,383 cases), and those with no EF  $< 50\%$  were considered HFpEF (920 cases). Polygenic risk scores for coronary artery disease (CAD), body mass index (BMI), fasting insulin, high-density lipoprotein (HDL), low-density lipoprotein (LDL), and triglycerides were constructed using published GWAS and tested for association with HFpEF and HFrEF phenotypes. **Results:** Higher genetically predicted BMI was strongly associated with both HF subtypes, though the association was stronger with HFpEF ( $p=1.8e-05$  vs  $5.6e-04$ ). Genetic risk for CAD was strongly associated with HFrEF ( $p=6.8e-05$ ) but not with HFpEF ( $p=0.2$ ). There was a trend toward association between higher genetically predicted fasting insulin levels and HFpEF ( $p=0.07$ ), but there was no association with HFrEF ( $p=0.6$ ). Genetically predicted LDL and triglycerides were not associated with either HF subtype, while weak associations were seen between HDL and both HFpEF ( $p=0.09$ ) and HFrEF ( $p=0.1$ ). **Conclusions:** HF subtypes show different patterns of association with genetic risk for clinical risk factors. Genetic risk for CAD is strongly associated with HFrEF, while HFpEF is most strongly associated with obesity and metabolic dysregulation. These data suggest the genetic architectures of HF subtype risk are distinct.

**The roles of SMYD4 in epigenetic regulation of cardiac development in zebrafish.** D. Ma<sup>1,2</sup>, D.Y. Xiao<sup>1</sup>, H.Y. Wang<sup>2</sup>, L.L. Hao<sup>1</sup>, X. Guo<sup>2</sup>, X.J. Ma<sup>2</sup>, Y.Y. Qian<sup>2</sup>, J. Ma<sup>1,2</sup>, J. Zhang<sup>1</sup>, W. Sheng<sup>2</sup>, W.N. Shou<sup>3</sup>, G.Y. Huang<sup>2</sup>. 1) Fudan University, Shanghai, China; 2) Children's Hospital of Fudan University, Shanghai, China; 3) Indiana University School of Medicine, Indianapolis, IN, USA.

SMYD4 belongs to a family of lysine methyltransferases. We analyzed the role of *smyd4* in zebrafish development by generating a *smyd4* mutant zebrafish line (*smyd4*<sup>L544Efs<sup>+</sup></sup>) using the CRISPR/Cas9 technology. The maternal and zygotic *smyd4*<sup>L544Efs<sup>+</sup></sup> mutants demonstrated severe cardiac malformations, including defects in left-right patterning and looping and hypoplastic ventricles, suggesting that *smyd4* was critical for heart development. Importantly, we identified two rare SMYD4 genetic variants in a 208-patient cohort with congenital heart defects. Both biochemical and functional analyses indicated that SMYD4(G345D) was pathogenic. Our data suggested that *smyd4* functions as a histone methyltransferase and, by interacting with HDAC1, also serves as a potential modulator for histone acetylation. Transcriptome and bioinformatics analyses of *smyd4*<sup>L544Efs<sup>+</sup></sup> and wild-type developing hearts suggested that *smyd4* is a key epigenetic regulator involved in regulating endoplasmic reticulum-mediated protein processing and several important metabolic pathways in developing zebrafish hearts.

**Trans-ethnic meta-analysis of genome-wide association studies for coronary artery disease reveals genetic differences between Japanese and Europeans.** *H. Matsunaga<sup>1,2</sup>, K. Ito<sup>2</sup>, M. Akiyama<sup>3</sup>, S. Koyama<sup>2</sup>, Y. Onouchi<sup>2</sup>, K. Ozaki<sup>2</sup>, H. Morita<sup>1</sup>, M. Kubo<sup>3</sup>, H. Akazawa<sup>1</sup>, Y. Kamatani<sup>3</sup>, I. Komuro<sup>1</sup>.* 1) The University of Tokyo, Department of Cardiovascular Medicine, Tokyo; 2) RIKEN Center for Integrative Medical Sciences, Laboratory for Cardiovascular Diseases, Kanagawa; 3) RIKEN Center for Integrative Medical Sciences, Laboratory for Statistical Analysis, Kanagawa.

Coronary artery disease (CAD) is a leading cause of death worldwide. Although genome-wide association studies (GWAS) have revealed more than 150 loci associated with CAD and have gradually elucidated complex traits, the causal genes and pathways are not fully understood. In addition, it has been reported that the prevalence of CAD was lower in Japanese than in Europeans, but the reasons are unclear. To evaluate the contribution of genetic factors for CAD and understand the genetic differences between Japanese and Europeans, we carried out Japanese GWAS, followed by trans-ethnic meta-analysis for CAD. First, we conducted a meta-analysis of two GWAS that included 12,494 cases and 28,879 controls, and 2,808 cases and 7,261 controls, respectively, in the Japanese population. Next, to further identify related loci for CAD, we performed trans-ethnic meta-analysis using the result of UK Biobank and CARDIoGRAMplusC4D. To prioritize candidate causal genes at significant loci, we searched quantitative trait loci (QTL) through GTEx, BIOS and BioBank Japan clinical data. In the Japanese GWAS, we found 17 loci significantly associated with CAD. Of which just 1 was new. In the trans-ethnic meta-analysis, we discovered 76 CAD risk loci, of which 4 were novel. Since the new locus in the Japanese meta-GWAS and one of the new loci in the trans-ethnic meta-analysis were located within the same region, we finally identified 4 new loci: on 1q21, 6p21, 10q26, 11q22. We found that these new loci were related to immune system, diabetes mellitus and dyslipidemia by QTL analyses. Moreover, we compared effect sizes for CAD at the 76 loci, which exceeded the genome-wide significance threshold in the trans-ethnic meta-analysis, to assess the genetic differences between Japanese and Europeans. Among the 76 loci, 60 loci had a larger effect in the first Japanese GWAS than in the European GWAS (78.9%,  $P$  for sign test =  $3.85 \times 10^{-7}$ ). To verify this result, we also compared the second Japanese GWAS and the European GWAS. Of the 76 loci, 54 loci had a larger effect in Japanese than in Europeans (71.1%,  $P$  for sign test =  $3.13 \times 10^{-7}$ ). Then, the heritability explained by the 76 loci in the Japanese population was larger than that of the European population. Accordingly, we suggested that Japanese were genetically liable to CAD compared to Europeans. Our results showed that there were genetic differences between Japanese and Europeans, which provided new insights into the pathogenesis of CAD.

**A genetic predictor of thyroid stimulating hormone levels is inversely associated with atrial fibrillation risk.** *J.D. Mosley<sup>1,2</sup>, Q.S. Wells<sup>1</sup>, M.B. Shoemaker<sup>1</sup>, C.M. Shaffer<sup>1</sup>, P. Straub<sup>1</sup>, L. Bastarache<sup>2</sup>, G.P. Jarvik<sup>3</sup>, E.B. Larson<sup>3,4</sup>, D.R. Velez Edwards<sup>5</sup>, T.L. Edwards<sup>1</sup>, L.K. Davis<sup>1</sup>, M.G. Hayes<sup>6</sup>, P.T. Ellinor<sup>7</sup>, D.M. Roden<sup>1,2,8</sup>, J-E. Salem<sup>1,9</sup>.* 1) Vanderbilt University Medical Center, Nashville, TN; 2) Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN; 3) Departments of Medicine and Genome Sciences, University of Washington, Seattle, WA; 4) Kaiser Permanente Washington Health Research Institute, Seattle, WA; 5) Department of Obstetrics and Gynecology and Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN; 6) Department of Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL; 7) Cardiovascular Research Center, Massachusetts General Hospital, Charlestown, MA; 8) Department of Pharmacology, Vanderbilt University Medical Center, Nashville, TN; 9) Department of Pharmacology, Sorbonne Universite, Paris, France.

**Background:** Thyroid hormones (thyroxine [T4] and triiodothyronine [T3]) are released from the thyroid gland and regulate metabolic activity in multiple tissues. Thyroid hormone levels are regulated by a feedback mechanism governed by thyroid stimulating hormone (TSH), which is inversely associated with T4 levels, and is measured clinically to ascertain thyroid function. Excess thyroid hormone (thyrotoxicosis) is a well-recognized cause of the cardiac arrhythmia atrial fibrillation (AF). We hypothesized that we could identify diseases associated with thyroid hormone regulation by performing genome-wide scanning in an electronic health record data set using a genetic predictor of TSH levels. **Methods:** We used weightings for 24 SNPs associated with plasma TSH levels at genome-wide significance in a European ancestry (EA) cohort to compute genetically predicted TSH levels in an EHR cohort comprising 61,667 EA individuals with 1,216 measured clinical phenotypes with over 150 cases. The performance of the predictor was ascertained in 6,797 and 3,019 individuals with clinically measured TSH and free T4 (FT4) levels, respectively. Genome-wide association testing was used to identify clinical phenotypes associated with genetically predicted TSH levels. The observed association with AF described below was validated in an independent GWAS of 17,931 AF cases and 115,142 controls using an inverse variance weighted average method in conjunction with summary statistics data. **Results:** Genetically predicted TSH levels accounted for 5.8% and 0.5% of the measured phenotypic variance of TSH and FT4 levels, respectively. There were 17 phenotypes associated with predicted TSH levels at FDR  $q < 0.1$ . Fifteen of these were thyroid diseases and had directionally expected associations. For instance, higher predicted TSH was associated with hypothyroidism (OR = 1.18 [95% CI 1.15-1.21],  $p = 7.1 \times 10^{-38}$ ) per s.d. change in genetically predicted levels and lower TSH was associated with thyrotoxicosis (OR = 0.82 [0.77-0.86],  $p = 7.1 \times 10^{-12}$ ). Higher TSH was also associated with decreased AF risk (OR = 0.95 [0.93-0.98],  $p = 1.3 \times 10^{-3}$ ). This AF association persisted after excluding individuals with thyroid disease (OR = 0.92 [0.89-0.95],  $p = 3.4 \times 10^{-6}$ ). In the AF validation cohort, each s.d. increase in TSH levels was associated with a decreased risk of AF (OR = 0.86 [0.79-0.94],  $p = 0.001$ ). **Conclusions:** Genetically predicted TSH levels are inversely associated with atrial fibrillation risk.

**Genome-wide association study of carotid artery disease in the eMERGE**

**Network.** M.R. Palmer<sup>1</sup>, D.S. Kim<sup>2</sup>, D.R. Crosslin<sup>3</sup>, I.B. Stanaway<sup>2</sup>, E.A. Rosenthal<sup>1</sup>, D. Carrell<sup>4</sup>, I. Kullo<sup>5</sup>, M.S. Williams<sup>5</sup>, E. Larson<sup>4</sup>, G.P. Jarvik<sup>1</sup> on behalf of the eMERGE consortium. 1) Medical Genetics, University of Washington, Seattle, WA; 2) University of Michigan, Ann Arbor, MI; 3) Biomedical Informatics and Medical Education, University of Washington, Seattle, WA; 4) Kaiser Permanente Health Research Institute, Seattle, WA; 5) Mayo Clinic, Rochester, MN; 6) Genomic Medicine Institute, Geisinger Health System, Danville, PA.

**Introduction:** The prevalence of symptomatic carotid artery disease (CAAD) in the United States is estimated at 2-9%, with 5-9% prevalence in patients over 65 years old, and is a major risk factor for stroke. We aim to discover genetic variants associated with CAAD in the electronic Medical Records and Genomics (eMERGE) Network. **Methods:** We identified adult CAAD cases and controls from electronic health records at eight eMERGE sites using a phenotype algorithm, which included carotid stenosis measurements extracted from image reports, and ICD-9 and CPT codes. We used a novel approach to deploy a single natural language processing (NLP) algorithm across multiple eMERGE sites. Participants were genotyped on various platforms, and all imputed to the Haplotype Reference Consortium data. Logistic regression analyses were performed in PLINK 1.9. We performed pooled and stratified analyses by genetically determined race/ethnicity, and adjusted for age, sex, and ancestry principal components.

Basic demographics	Case 1,794	Control 17,959
Female	667 (37%)	10,391 (58%)
Male	1,126 (63%)	7,568 (42%)
Median Age (IQR)	73 (66 - 78)	64 (53 - 75)
African American	61 (3%)	4,056 (23%)
Caucasian	1,665 (93%)	12,214 (68%)
Unknown/Other	68 (4.2%)	1689 (9.5%)

**Results:** Our phenotype algorithm identified 1,794 CAAD cases and 17,959 controls (Table 1). In the pooled analysis, two loci reached genome-wide significance, at chr. 6 in *LPA* (rs10455872-G, OR(CI)=1.50 (1.30-1.73),  $p=2.1 \times 10^{-8}$ , MAF=0.053) and at an intergenic SNV on chr. 7 (rs6952610-T, OR(CI)=1.25 (1.16-1.36),  $p=4.3 \times 10^{-8}$ , MAF=0.43). The chr. 7 association remained significant in the presence of the *LPA* SNV as a covariate. The *LPA* SNV is also associated with coronary heart disease (CHD; 4,199 cases, 11,679 controls) in this study (OR(CI)=1.27(1.13-1.43),  $p=5 \times 10^{-8}$ ) but the chr7 SNV is not (OR(CI)=1.03(0.97-1.09),  $p=0.37$ ). *LPA* variants associated with elevated levels of its product, lipoprotein(a) (Lp(a)), have previously been associated with CAAD and CHD risk, including rs10455872. **Conclusions:** We replicated the known association of Lp(a) level associated *LPA* SNVs with CAAD and CHD. We identified a novel locus associated with CAAD on chromosome 7 at 7q11.22, which is robust to adjustment for the associated *LPA* variant and was not associated with CHD.

**Genetic sequencing and mass spectrometry biomarkers link diagnosis**

**and treatment precision for cardiovascular disease.** J.E. Posey<sup>1</sup>, E. Venner<sup>2</sup>, T. Jonsson<sup>3</sup>, S. Eisea<sup>1</sup>, D. Muzny<sup>2</sup>, R.A. Gibbs<sup>1,2</sup>, S. Scherer<sup>1,2</sup>, L. Guo<sup>3</sup>, C.T. Caskey<sup>1</sup>. 1) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX, USA; 3) Metabolon, Morrisville, North Carolina, USA.

Cardiovascular disease is the leading cause of death in the USA. We have used whole genome sequencing (WGS) and mass spectrometry analyte quantitation to improve diagnosis of disease risk and monitor therapy intervention. Our study serves as a model for additional precision medicine disease interventions. Plasma metabolite analysis allows a global assessment of cholesterol pathway function and therapeutic response. Consistent with the known mechanism of HMG CoA reductase inhibition, 21 individuals on statin therapy had a lower average cholesterol:3-hydroxy-3-methylglutarate (CHO:HMG) ratio (15.033) compared to 94 individuals not on statin therapy (26.479, two tailed  $t < 0.0001$ ). Analysis of WGS data did not reveal any variants predicted to impact protein structure or function. However, in analysis of variants predicted to affect transcription of cholesterol pathway genes, we identified 26 variants in this cohort, including 6 in cases being treated for HLD, and 8 in cases predicted to be at increased risk of HLD based on CHO:HMG ratio. No potential molecular etiology was identified in individuals predicted to be protected from HLD based on CHO:HMG ratio. Interpretation of non-coding variants in WGS data remains challenging; we propose that at present, metabolic biomarkers can provide a more accurate assessment of the cholesterol pathway, including *de novo* synthesis and statin response, in a given individual. These observations will need to be demonstrated in a larger cohort. We also analyzed plasma metabolite data for the presence of 19 commonly prescribed or over-the-counter drugs. We found 13 drugs present in 32 subjects and cross-referenced their corresponding genetic variants observed in genes having a PharmGKB "Strength of Evidence" level of 2B or higher for appropriate gene-drug pairs. While we observed preliminary clear examples where alternative SSRIs may be considered in the treatment of depression, data for genetic variants and statins were less clear and further analyses are ongoing. We demonstrate that WGS and metabolome analysis can be a precision medicine approach to diagnosis and treatment of cardiovascular disease. Interpretation of the clinical impact of non-coding variants remains challenging, and plasma mass spectrometry analysis supports a true interrogation of the cholesterol pathway and therapeutic response, and will support future efforts to resolve questions variant pathogenicity for genes within the cholesterol pathway.

**Investigating disease progression through single-cell transcriptional profiling of CD45+ immune cells at the atherosclerotic plaque.** A. Sartori<sup>1</sup>, K. Thanopoulou<sup>2</sup>, C. Borel<sup>1</sup>, E. Falconnet<sup>1</sup>, L. Romano<sup>1</sup>, C. Howald<sup>1</sup>, I. Galani<sup>2</sup>, E. Andreakos<sup>2</sup>, E. T. Dermizakis<sup>3,4</sup>. 1) University of Geneva, Geneva, Switzerland; 2) Laboratory of Immunobiology, Center for Clinical, Experimental Surgery and Translational Research, Biomedical Research Foundation of the Academy of Athens, Athens, Greece; 3) iGE3 Institute of Genetics and Genomics of Geneva, Switzerland; 4) SIB, Swiss Institute of Bioinformatics, Geneva, Switzerland.

Atherosclerosis is the main cause of cardiovascular diseases, which in turn are the leading cause of mortality worldwide. It is also a chronic and progressive vascular disease of large- and medium-sized arteries characterized by the deposition of fat molecules into their inner wall. This is mostly due to accumulation of low-density lipoproteins (LDL) in the arteria intima which are trapped and turned into oxidized lipoproteins, leading to an innate inflammatory response which results in the formation of an atherosclerotic plaque. In this study, we aim to define the «resident» cell immune diversity at the atherosclerotic plaques level using single cell transcriptomics. In addition, we are investigating transcriptional differences due to atherosclerotic plaque cell composition in symptomatic individuals (i.e. who had plaque fissuring) compared to asymptomatic individuals to better understand the atherosclerosis progression process. We generated single-cell RNA-seq data from CD45+ sorted cells from carotid tissue from 5 symptomatic and 5 asymptomatic patients using drop-seq technology. We have sequenced 16225 single-cells in total, detecting a median of 1152 genes in each cell. Preliminary cluster analysis identified a distinctive pattern of co-expression among genes able to differentiate cells from symptomatic and asymptomatic subjects, demonstrating the presence of a distinctive transcriptional signature in the disease progression. Further work is aiming to identify subpopulations of CD45+ cells present in both types of atherosclerotic plaques, comparison of their signals with circulating immune cells and their possible implication in the transition to a symptomatic, more severe, stage.

Damrauer<sup>11,15</sup>. 1) Yale University, New Haven, CT; 2) Center for Population Genomics, MAVERIC, VA Boston Healthcare, Boston, MA; 3) Massachusetts General Hospital, Boston, MA; 4) Unit of Genomic of Complex Diseases, IIB Sant Pau, Research Institute of Hospital Sant Pau, Barcelona, Spain; 5) Cardiovascular Medicine Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; 6) VINCI, VA Salt Lake City Healthcare System, Salt Lake City, UT; 7) Stanford University, Palo Alto, CA; 8) Emory University, Atlanta, GA; 9) Boston University, Boston, MA; 10) Vanderbilt University, Nashville, TN; 11) Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 12) Boston VA Healthcare System, Boston, MA; 13) University of Washington, Seattle, WA; 14) University of Texas Health Science Center, Houston, TX; 15) Corporal Michael Crescenz VA Medical Center, Philadelphia, PA.

Introduction: Peripheral artery disease (PAD) affects over 200 million individuals worldwide. A recent GWAS identified novel genetic evidence for association of a prothrombotic coagulation protein variant (the factor V Leiden mutation) with risk of prevalent PAD, indicating a possible role of coagulation and thrombosis in PAD. Objective: We assessed the causal role of plasma levels of factor VII (FVII), factor VIII (FVIII), and von Willebrand factor (VWF) in the development of PAD using a 2-sample Mendelian randomization (MR) approach. Methods: We performed 2-sample MR using the inverse variance weighted (IVW) approach to calculate the causal odds ratio for each hemostatic factor with PAD among individuals of European ancestry (EA). We combined variants having genome-wide significant associations with plasma levels of FVII (9 loci), FVIII (16 loci), and VWF (5 loci) from GWAS performed by the Cohorts for Heart and Aging Research in Genomic Epidemiology Consortium to construct a single genetic instrument for each hemostatic factor. We then tested the association of each of these three instruments with PAD using summary statistics from a VA Million Veteran Program PAD GWAS. We used Egger Regression and the weighted median approach as sensitivity analyses. A Bonferroni p-value cutoff was used to determine significance [ $p < 0.016$  based on the number of hemostatic factors tested ( $n=3$ )]. Results: There were 23,434, 32,610, and 46,354 EA participants for the CHARGE FVII, FVIII, and VWF GWAS meta-analyses respectively. Among 227,817 EA individuals in MVP, there were 24,009 individuals with prevalent PAD. MR analysis using the IVW approach demonstrated statistically significant associations with PAD for FVIII (OR = 1.31, CI 95% 1.13-1.51,  $p = 0.0003$ ) and vWF (OR = 1.24, CI 95% 1.07-1.43,  $p = 0.003$ ), but not for FVII (OR = 1.07, CI 95% 0.89-1.28,  $p = 0.45$ ). Egger regression and the weighted median approaches yielded similar effect estimates and confidence intervals. Conclusions: These data suggest a fundamental role of the component factors FVIII and/or VWF in the pathobiology of PAD and promote further study to characterize the role of thrombosis in this highly prevalent and morbid disease.

**The TAGA Study: A new family study for the genetic analysis of aortic abdominal aneurysm.** M. Vázquez-Santiago<sup>1</sup>, J.M. Romero<sup>1,2</sup>, J. Dilme<sup>1,2</sup>, J. Giner<sup>3</sup>, A. Martínez-Perez<sup>1</sup>, A. Buil<sup>4</sup>, O. Sibila<sup>3</sup>, V. Plaza<sup>3</sup>, M. Camacho<sup>1</sup>, J.M. Soria<sup>1</sup>, J.R. Escudero<sup>1,2</sup>, M. Sabater-Lleal<sup>1,3</sup>. 1) Unit of Genomics of Complex Diseases (IIB-Sant Pau), Barcelona, Spain; 2) Joint Services of Angiology, Vascular and Endovascular Surgery, University Hospital Sant Pau-Hospital Dos de Maig, Barcelona, Spain; 3) Department of Respiratory Medicine, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; 4) Institute of Biological Psychiatry, Sankt Hans Hospital, Roskilde, Denmark; 5) Department of Medicine, Karolinska Institutet, Stockholm, Sweden.

**Introduction:** Aneurysms are characterized by structural deterioration of the vascular wall leading to progressive dilatation and, potentially, rupture of the aorta. Abdominal aortic aneurysms (AAA) are responsible for approximately 11,000 deaths/year in the US, with no current effective medical therapies, highlighting the need to better understand factors influencing pathogenesis and disease progression, and its relation to its most important comorbidities. In this direction, we have designed and collected the TAGA Study (Triple-A Genetic Analysis), a family study collected through a *proband* with AAA. **Methods:** The TAGA Study comprises 405 individuals related in 12 large Spanish families. Cases were defined as those with dilation in abdominal aortic diameter (AAOD) higher than 30 mm in adults. We applied variance component methods to calculate heritabilities and phenotypic correlations (splitted into genetic and environmental correlations) between 60 quantitative traits and the AAOD, using R package *solaris* as interface for SOLAR-Eclipse software.

**Results:** Heritability of AAOD was 0.34 (CI=0.24-0.44). Among the main related arteries, the strongest genetic correlation was observed between AAOD and the diameter of left femoral artery ( $r^2=0.79$ ;  $p=3.9 \times 10^{-6}$ ). We also observed significant phenotypic correlations between AAOD and serum creatinine levels ( $r^2=0.35$ ;  $p=9.3 \times 10^{-13}$ ), and lung function tests, the strongest being with forced vital capacity observed (FVC) ( $r^2=0.38$ ;  $p=1.6 \times 10^{-12}$ ), forced expiratory volume in 1 second (FEV1) ( $r^2=0.37$ ;  $p=6.4 \times 10^{-13}$ ), and post dilator FVC ( $r^2=0.32$ ;  $p=8.0 \times 10^{-9}$ ). **Discussion:** Our results indicate that one third of the variability in AAOD is explained by genes, which suggests that well-design genetic studies may be a suitable tool to elucidate novel biological mechanisms underlying this phenotype. We also present phenotypic, genetic and environmental correlation results that indicate that common genetic factors regulate normal variation in the diameter of the main related arteries. While we found strong phenotypic correlations between markers of respiratory alterations and AAOD, these were mainly driven by non-genetic factors independent of smoking. In-depth study of novel intermediate phenotypes genetically correlated with AAOD can be a powerful tool to prioritize the main biological traits and mechanisms underlying AAA formation and development. **Grant:** Spanish Ministry of Health, ISCIII (Miguel Servet CP17/00142).

**Significant enrichment of damaging recessive genotypes in cilia genes is associated with laterality defects in a cohort of 2391 trios with congenital heart disease.** W.S. Watkins<sup>1</sup>, E.J. Hernandez<sup>1,2</sup>, B.W. Bisgrove<sup>3</sup>, B.L. Demerest<sup>4</sup>, B.D. Gelb<sup>4</sup>, D. Bernstein<sup>5</sup>, G. Porter<sup>6</sup>, J.W. Newburger<sup>7</sup>, C.E. Seidman<sup>8</sup>, W.K. Chung<sup>9</sup>, E. Goldmuntz<sup>10</sup>, L.B. Jorde<sup>1</sup>, H.J. Yost<sup>3</sup>, M. Yandell<sup>1,2</sup>, M. Tristani-Firouzi<sup>11</sup>, Pediatric Cardiac Genomics Consortium. 1) Department of Human Genetics, University of Utah, Salt Lake City, UT; 2) USTAR Center for Genetic Discovery, University of Utah, Salt Lake City, UT; 3) Department of Neurobiology & Anatomy, University of Utah, Salt Lake City, UT; 4) Mindich Child Health and Development Institute, Departments of Pediatrics and Genetics & Genomic Sciences, Icahn School of Medicine at Mount Sinai, New York, NY; 5) Department of Pediatrics, Stanford University School of Medicine, Palo Alto, CA; 6) Department of Pediatrics, University of Rochester Medical Center, Rochester, NY; 7) Department of Cardiology, Boston Children's Hospital, Boston, MA; 8) Departments of Genetics and Medicine, and HHMI; Harvard Medical School; 9) Departments of Pediatrics and Medicine, Columbia University, New York, NY; 10) Division of Cardiology, Department of Pediatrics, Children's Hospital of Philadelphia, PA; 11) Department of Pediatrics, University of Utah, Salt Lake City, Utah.

To investigate the genetic contribution of cilia genes to human congenital heart disease (CHD), we used a burden test approach to assess 2391 trios from the Pediatric Cardiac Genomics Consortium (PCGC) for damaging variation in 3 cilia gene lists: a "gold-standard" list of genes encoding ciliary components, SysCilia,  $n=302$ ; a broader list of cilia genes curated from model organisms,  $n=669$ ; and a list of *FOXJ1*-responsive genes derived from zebrafish,  $n=116$ . Proband and parent exomes were joint-genotyped with GATK/VQSR and all trio relationships were verified. Damaging recessive and compound heterozygous genotypes were identified using the Variant Annotation, Analysis & Search Tool (VAASST3). Genotypes were defined as damaging by a VAASST3 burden  $p$ -value of  $< 0.005$ , consistent with our previous study (PMID 28991257). These CHD probands are highly enriched for damaging compound heterozygous and recessive genotypes in SysCilia and cilia-related genes ( $p$ -value  $< 1e-5$ ). *FOXJ1*-responsive genes also show modest enrichment ( $p$ -value  $< 0.026$ ). In contrast, random genes containing a length-normalized equal number of rare variants (gnomAD,  $maf \leq 0.005$ ) and house-keeping gene lists of equal size show no significant enrichment ( $p$ -value  $> 0.2$ ). Cilia genes also demonstrate little enrichment for damaging *de novo* variants, in sharp contrast to chromatin-related genes ( $n=163$ ) which are known to be highly-enriched in damaging *de novo* variation but only moderately enriched in damaging recessive genotypes. We also find that laterality defects are significantly more common in probands with damaged cilia genes than other cardiac phenotypes, such as conotruncal or left ventricular outflow tract obstructive disorders ( $p$ -value  $\leq 0.015$ ). These results indicate that segregating, rare variation in cilia and cilia-related genes contributes to human CHD, particularly laterality defects.

**Background/aims:** Observational and animal-based studies suggest an aetiological role of glycine in coronary heart disease (CHD). Five genetic loci have been reported for glycine, including *CPS1*, which is more strongly associated in women and for which a sex-specific cardioprotective effect has been proposed. We aimed to (1) identify additional genetic loci for plasma glycine levels, (2) investigate the causal role of glycine on risk of CHD in men and women, and (3) characterise the biological pathways underlying the glycine-CHD association. **Methods:** We performed a meta-GWAS for glycine in up to 80,003 participants from 3 novel studies and 2 publicly available summary-level GWAS datasets. Sex-specific effect sizes were estimated in 30,226 men and 31,957 women. Using two-sample Mendelian randomization (MR), we assessed the genetic association of glycine with CHD risk, based on 88,800 sex-combined cases and 9,852 female and 21,994 male cases for sex-specific analyses. We tested the genetic association of glycine with CHD risk factors, including systolic (SBP) and diastolic blood pressure (DBP), blood lipids and 13 potentially relevant blood cell traits. The role of CHD risk factors as potential mediators of the glycine-CHD association was assessed using multivariable MR. **Results:** We identified 27 loci, of which 6 are in genes encoding enzymes of glycine metabolism and 22 have not previously been linked to glycine. Genetically predicted glycine was significantly associated with CHD in sex-combined analyses (OR [95% CI] per SD genetically higher glycine=0.95 [0.92,0.98]). Based on a subset of the CHD cases, there was no evidence that this association differed by sex (women: OR = 0.95 [0.91,1.00]; men: OR = 0.93 [0.84,1.02]; *p* for sex difference=0.60). After taking into account the sex-specific effect on glycine, the genetic glycine-CHD association based on *CPS1* only did not differ by sex. Glycine was genetically associated with SBP and DBP but not with other CHD risk factors. Adjusting for genetically predicted SBP and DBP attenuated the association of glycine with CHD. **Conclusion:** Using substantially enhanced genetic predictors for glycine, we demonstrated that glycine is genetically associated with lower CHD risk, which suggests a cardio-protective role of glycine. Despite previous suggestions, there was no evidence that the effect of glycine was sex-specific. We also found that the inverse relationship between glycine and CHD may be explained by blood pressure.

**The relationships between genotype and histopathological alterations in hypertrophic obstructive cardiomyopathy patients.** KL. Yin, Y. Ma, CS. Zhu, Y. Sun, WZ. Zhou, H. Yang, WK. Li, BM. Han, XW. Liu, HY. Wang, SY. Wang, Z. Zhou. State Key Laboratory of Cardiovascular Disease, Fuwai Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, People's Republic of China.

**Aims:** Genotype has been related to specific phenotype of hypertrophic cardiomyopathy (HCM) patients, but its relationship with histopathological alterations remains uncertain. The purpose of the study is to explore whether there are differences in the relationship between the genotype and histopathological alterations under different genetic backgrounds. **Methods:** A 93-cardiomyopathy-related-gene panel was used to screen 193 Chinese patients with hypertrophic obstructive cardiomyopathy (HOCM), and all rare variants were further verified by Sanger sequencing. The pathogenicity of all variants was classified into 5 categories according to American College of Medical Genetics and Genomics (ACMG). In addition to variants of unknown significance (VUS), an additional tier, VUS-LP was used to define those VUS that lacked one piece of supporting evidence for classification as LP. The effects of different numbers or pathogenicities of 8 major sarcomeric variants on histopathological alterations and phenotypes were evaluated in HOCM patients using clinical parameters or 177 septal tissue sections with Masson trichromatic staining, respectively. **Results:** The overall diagnosis rate was 45.1%. 7 splicing variants predicted with *in silico* tools were validated in cardiac tissues, and all but the novel canonical variant in *ACTN2* (c.1515+1G>T) were confirmed to cause aberrant splicing. Notably, the patients with VUS-LP variants shared similar clinical and histopathological characteristics to those with LP/P variants. The existence of any variant or LP/P variants, regardless of number, was related to an earlier diagnosis and LV dysfunction. Moreover, compared with the patients with VUS and no variants, those with LP/P and VUS-LP variants exhibited relatively severe phenotypes and significantly worse histopathological alterations including hypertrophy, disarray, interstitial and replacement fibrosis. **Conclusions:** For the first time, the characteristic effects of genotype, including the numbers and pathogenicities of variants, on the histopathological alterations and certain phenotypes were revealed through large-scale comprehensive examinations of tissue sections and panel screening. This approach not only filled in the gaps between genotype and histopathological alterations in HCM patients but also had the potential to contribute to the prediction of clinical outcomes. The additional tier of VUS-LP had significance for the future pathogenicity interpretations.

## 3139T

**A new African risk factor for ventricular arrhythmia.** P. Guicheney<sup>1</sup>, M. Blancard<sup>1</sup>, A. Debbiche<sup>1</sup>, K. Kato<sup>1</sup>, C. Cardin<sup>2</sup>, G. Guichard<sup>3</sup>, E. Gandjbakhch<sup>1,4</sup>, V. Probst<sup>5</sup>, M. Hocini<sup>6</sup>, F. Extramiana<sup>7</sup>, M. Haissaguerre<sup>6</sup>, O. Geoffroy<sup>6</sup>, A. Leenhardt<sup>7</sup>, J.S. Rougier<sup>8</sup>. 1) Inserm, Sorbonne University, UMRS1166, Paris, France; 2) University Hospital Rangueil, Toulouse, France; 3) University of Bern, Institute of Biochemistry and Molecular Medicine, Bern, Switzerland; 4) AP-HP, Hôpital Pitié-Salpêtrière, Département de Cardiologie, Paris, France; 5) CHU Nantes, L'institut du thorax, Service de Cardiologie, Nantes, France; 6) L'Institut de Rythmologie et Modélisation Cardiaque (LIRYC), Université de Bordeaux, Bordeaux, France; 7) AP-HP, Hôpital Bichat, Département de Cardiologie, Paris, France; 8) CHU Sud Réunion, La Réunion, France.

**Objectives:** Cardiac channelopathies are genetic disorders associated with an increased risk of ventricular arrhythmia and sudden death (SD) in young individuals with a structurally normal heart. An important aspect of such cardiac diseases is the precise calcium regulation. One of the most important effector is the voltage-gated calcium channel Ca<sub>v</sub>1.2. Several variants in Ca<sub>v</sub>1.2 have been implicated in various arrhythmic syndromes. We screened 19 patients with ventricular fibrillation in the absence of any cardiac structural abnormalities for variants in Cav1.2 subunit genes. All these patients presented short-coupled premature ventricular beats or torsade de pointes originating from Purkinje fibres. **Methods:** Ca<sub>v</sub>1.2 related genes, *CACNA1C*, *CACNB2* and *CACNA2D1*, were screened in probands by exome sequencing. Missense variants were introduced in Ca<sub>v</sub>1.2 alpha subunit plasmid by mutagenesis to assess their pathogenicity using patch clamp approaches. **Results:** The first symptoms occurred in the probands at a mean age of 32.9 ± 10.9 years, eight were male, and six had a family history of sudden death. Missense variants in *CACNA1C* encoding the Ca<sub>v</sub>1.2 alpha subunit were identified in four individuals. Two variants were found in an inhabitant of La Reunion Island found, Ca<sub>v</sub>1.2-T1787M and Ca<sub>v</sub>1.2-C1992F. Interestingly, we previously identified Ca<sub>v</sub>1.2-T1787M in another patient originating from Cameroon with syncope and early repolarisation pattern on ECG recording, in combination with the African pro-arrhythmic Na<sub>v</sub>1.5-S1103Y variant of the cardiac sodium channel. Although the mean allele frequency of Ca<sub>v</sub>1.2-T1787M was of superior to 1% (MAF=0.016) in the African population according to ExAC database, we performed patch-clamp analysis. It revealed that the C-terminal Ca<sub>v</sub>1.2-T1787M; 1) reduces the calcium and barium currents probably by increasing the C-terminal auto-inhibition mechanism and 2) increases the voltage-dependent inhibition. The other variants did not induce major changes of the channel function. **Conclusion:** We identified a new loss-of-function variant, Ca<sub>v</sub>1.2-T1787M, present in 0.8% of the African population, as a new potential risk factor for lethal-ventricular arrhythmia combined other risk factors.

## 3140F

**Genetic variants of electrical storm in post myocardial infarction patients.** A. Rangaraju<sup>1</sup>, S. Krishnan<sup>2</sup>, G. Aparna<sup>3</sup>, S. Shankaran<sup>3</sup>, A. Mannan<sup>3</sup>, H. Bhaganagar<sup>2,4</sup>. 1) Krishna Institute of Medical Sciences and Research centre, Telangana, India; 2) Division of Pacing & Electrophysiology, Krishna Institute of Medical Sciences, Minister Road, Secunderabad, Telangana, India; 3) STRAND Life Sciences, Bangalore, India; 4) Arrhythmia Research & Training Society (ARTS), Hyderabad, India.

Sudden Cardiac Death (SCD) in patients with remote myocardial infarction (MI) is due to the occurrence 'Ventricular Tachycardia' (VT). Few patients in this subset during their natural history develop Electrical storm (ES) which is defined as "Three or more distinct episodes of ventricular tachycardia (VT)/ventricular fibrillation (VF) within 24h, requiring the intervention of the defibrillator or ICD. Though a few clinical pointers exist, the occurrence of ES in a patient with remote myocardial infarction (MI) is generally unpredictable. It has a reported incidence of 10 -28% and an in-hospital mortality of 60 - 70%. Genetic markers for this entity have not been studied. Consecutive ten patients with Left ventricular dysfunction (LVEF< 35%), underlying remote myocardial infarction (>1 year), presented to our institute with ES and hemodynamically unstable monomorphic VT, were included in the study. To ensure homogeneity of the phenotype, we selected patients with a specific substrate presenting only with monomorphic unstable VT. After taking the informed consent, genetic analysis was performed in all patients by next generation sequencing (NGS) of SCD panel. 145 genes associated with arrhythmias and coronary artery disease were assessed which revealed 25 rare variants in 19 genes, predominantly in *RYR2*, *SCN5A*, *KCNJ11*, *KCNE1* and *KCNH2*, *CACNA1B*, *CACNA1C*, *CACNA1D* and desmosomal genes – *DSP* and *DSG2*. These are essentially cardiac ion channel genes and whose role is established in LQT and other arrhythmic disorders. Of the 25 rare variants, pVal125Leu of *SCN5A* was found to be pathogenic while p.Val30Met of *DSP* and p.Thr1107Met of *RYR2* revealed mixed interpretations of pathogenicity. We hypothesize that underlying pathophysiology of SCD due to ES of unstable VT may be similar to that of Ion channelopathies. Variations in genes coding for cardiac ion channels (*SCN5A*, *KCNE1*) that are currently being used to stratify arrhythmic risk in patients with inherited syndromes of SCD, may also be associated with occurrence of ES in patients with remote MI. The clinical relevance of this study is the possibility that identification of such genetic variants may better risk stratify high-risk MI subsets prone to electrical storm. However, studies on larger cohorts in various ethnic groups are required, as multiple genes among the panel seem to influence the function and a cumulative effect of various mutations play a role in the manifestation of the conditions.

**3141W****Mouse and human genomic studies identify modifiers of blood pressure and supravalvar aortic stenosis in elastin insufficiency and Williams Beuren syndrome.**

*B. Kozel\**, *P.C.R Parrish\**, *R.H. Knutsen<sup>1</sup>*, *A. Troia<sup>1</sup>*, *A. Wardlaw<sup>1</sup>*, *C.J. Billington<sup>1</sup>*, *D. Liu<sup>1</sup>*, *Y.P. Fu<sup>2</sup>*. 1) Laboratory of Vascular and Matrix Genetics, Translational Vascular Medicine Branch, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; 2) Office of Biostatistics Research, National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD.

In rare diseases of haploinsufficiency, phenotype severity typically varies among affected individuals. However, identification of genetic modifiers is challenging due to small sample size. Williams Beuren syndrome (WBS), a microdeletion disorder that causes a vascular disease notable for stenosis of the aorta (SVAS), occurs in approximately 1 in 10,000 births and shows significant phenotypic variation. To approach this power problem, we have used a two-pronged approach, combining modifier work in humans and in murine models to identify common genes and pathways that underlie the difference in vascular disease severity among individuals with elastin insufficiency. In our mouse studies, we used quantitative trait locus analysis in *Eln*<sup>-/-</sup> mice of different genetic backgrounds, followed by congenic line development to identify modifiers of blood pressure and aortic diameter. This work identified differences in renin-angiotensin signaling and reactive oxygen species generation as potential modifiers. Those findings were then confirmed in a cohort of human patients with the condition. In our primary human studies, we performed exome sequencing in 104 well-phenotyped WBS patients and used SKAT-O and gene set enrichment analysis to identify genes and pathways with increased variation in patients with no vs. severe aortic disease. We tested several mechanisms to improve power for our studies including extreme phenotype modeling and gene-set/pathway-based approaches. While not meeting stringent criteria for statistical significance, pathway testing revealed that patients with more severe disease had more variation in connective tissue and VEGF signaling pathways. In addition, discovery based gene set enrichment analysis suggested a role for inflammation in SVAS pathogenesis. These primary findings are being replicated in a larger (>400 subject) cohort and we have successfully targeted relevant inflammatory pathways in our mouse models, showing complimentary results. Taken together, our studies in humans and mice have allowed us to detect important genomic variations that contribute to disease severity among individuals with WBS with small sample numbers. The use of complimentary models allows for the results of lower powered studies to be directly tested by secondary methods to assure replicability and biological significance. \*PCR is the first author for this work and BAK is the senior author but will present in PCR's absence.

**3142T****Whole genome sequencing approach to identify genetic variation**

**influencing heart failure: A Singaporean perspective.** *C. Bellis<sup>1</sup>*, *N. Bertin<sup>2</sup>*, *CA. Lin<sup>1</sup>*, *TH. Koh<sup>1</sup>*, *C. Wang<sup>3</sup>*, *WW. Soon<sup>4</sup>*, *A. Wilm<sup>5</sup>*, *CC. Shih<sup>5</sup>*, *RS. Foo<sup>6,7</sup>*, *AM. Richards<sup>8</sup>*, *CS. Lam<sup>9,10</sup>*, *J. Liu<sup>1</sup>*, *SG10K consortium.* 1) Human Genetics 2, Genome Institute of Singapore, Agency for Science, Technology and Research of Singapore (A\*STAR), Singapore; 2) Centre for Big Data and Integrative Genomics (c-BIG), Genome Institute of Singapore, Agency for Science, Technology and Research; 3) Computational and Systems Biology, Genome Institute of Singapore, Agency for Science, Technology and Research of Singapore, Singapore; 4) Next Generation Sequencing Platform, Genome Institute of Singapore, Agency for Science, Technology and Research of Singapore, Singapore; 5) Scientific and Research Computing, Genome Institute of Singapore, Agency for Science, Technology and Research of Singapore, Singapore; 6) Cardiovascular Research Institute, National University Health System, Singapore; 7) Human Genetics 3, Genome Institute of Singapore, Agency for Science, Technology and Research of Singapore, Singapore; 8) Duke-National University of Singapore, Singapore; 9) National Heart Centre Singapore, Singapore; 10) Singapore Bioimaging Consortium, Agency for Science, Technology and Research of Singapore, Singapore.

Heart failure (HF) is the final common pathway of cardiovascular diseases (CVD) and leading cause of CVD hospitalizations in Singapore and worldwide with a mortality rate that rivals most cancers (>50% mortality in 5 years). Also similar to cancer, HF is a staged disease where early detection and treatment are vital for prevention of disease progression from Stage A (risk factors) to Stage B (subclinical structural heart disease) and Stage C (symptomatic HF). Cardiac imaging is critical for the detection of early subclinical disease. Currently, there is a gap in the understanding of the mechanisms underlying disease progression and effective therapies are limited, particularly for the proportion of the HF population with preserved ejection fraction (HFPEF or "diastolic HF") for which there is no effective therapy to date (in contrast to HF with reduced ejection fraction [HFREF] or "systolic HF"). The central aim of this project is to uncover disease predisposition by studying the full allelic spectrum of genetic determinants in carefully defined clinical cohorts (SHOP [The Singapore Heart Failure Outcomes and Phenotypes study] and ATTRaCT [The Asian neTwork for Translational Research and Cardiovascular Trials; <https://www.a-star.edu.sg/attract/About-Us/Overview>]) that have been recruited for this study. To achieve such an aim, a research strategy has been developed with the following approach; recent advancements in genomic technologies allow simultaneous performance of whole-genome sequencing (WGS) to uncover common genetic variants as well as rare (possible protein-coding) changes, extending us the opportunity to perform comprehensive genetic and genomic analyses. Genotypes will be systematically assessed for associations with either HF subtype. In our analyses, we will compare (a) HF vs non-HF controls; (b) HFREF vs HFPEF. Currently, we have sequenced approximately 1,500 participants across the SHOP and ATTRaCT heart failure cohort studies, which include controls and cases (~70% HFREF). Patients enrolled in the ATTRaCT cohort have been extensively/fine-grained phenotyped through detailed and careful imaging with cardiac magnetic resonance (CMR) and advanced molecular studies that we will integrate into our analysis for genotype association.

**3143F****Genetic risk scores for cardiometabolic traits in sub-Saharan Africans.**

*K. Ekoru, A.A. Adeyemo, G. Chen, A.P. Dourmatey, J. Zhou, A.R. Bentley, D. Shriner, C.N. Rotimi, the AADM study investigators.* Center for Research on Genomics and Global Health, National Human Genome Research Institute, Bethesda, MD.

**Background** Genetic risk scores (GRS) have been shown to be robustly associated with several traits and are increasingly being proposed for use in clinical prediction. However, their evidence base derives mostly from studies in populations of European and/or Asian ancestry. The utility of GRS in cardiometabolic trait risk prediction has not been assessed in sub-Saharan African populations. We evaluated GRS for a set of cardiometabolic traits incorporating genetic variants from published GWAS and assess their potential for risk prediction in a large genetic epidemiology study. **Methods** Participants were African men and women aged 18 years or older (N=5231, 63% women) enrolled from Ghana, Nigeria and Kenya in the AADM Study. GRS were constructed by summing the number of risk alleles (0, 1, 2) over unique SNPs reported in the NHGRI-EBI Catalog for each of twelve traits, including body mass index (BMI), waist circumference (WC), hip circumference (HC), waist-to-hip ratio (WHR), systolic blood pressure (SBP), diastolic blood pressure (DBP), fasting plasma glucose (FPG), triglycerides (TG), total cholesterol (TC), LDL-cholesterol (LDL), HDL-cholesterol (HDL) and type 2 diabetes (T2D). The predictive potential of the GRS for each trait was assessed using the additional phenotypic variance explained over that explained by age, sex, BMI (where appropriate) and principal components of ancestry. **Results** GRS for BMI, TG, TC, LDL, HDL and WHR were significantly associated with the respective traits. For every additional risk allele, BMI increased by 0.02 kg/m<sup>2</sup>, TG by 0.469 mg/dL, TC by 0.52 mg/dL, LDL by 0.557 mg/dL, HDL by 0.146 mg/dL and WHR by 0.0004. The additional variation explained by GRS for these traits ranged from 0.4% in WHR to 32.6% in HDL. GRS was significantly associated with T2D (OR=1.021, P<0.0001) and explained an additional 14.3% of variation in the probability of having T2D. GRS was not significantly associated with SBP, DBP, WC or HC. **Conclusion** The strength of association and predictive ability of GRS for cardiometabolic traits show marked variation in African ancestry populations, probably reflecting population differences in associated variants, LD and effect size, among others. More genome wide studies in African populations are likely to identify significant variants not currently included in our prediction models with the possibility of better optimization of GRS for clinical risk prediction of cardiometabolic traits in African ancestry populations.

**3144W****Genomics to medicine - P5 FinHealth Study.** *K. Kristiansson<sup>1</sup>, M. Kinnunen<sup>1</sup>, P. Wurtz<sup>2</sup>, M. Marttila<sup>1</sup>, A. Haukkala<sup>2</sup>, M. Brunfeldt<sup>1</sup>, H. Kääriäinen<sup>1</sup>, M. Perola<sup>1</sup>.*

1) National Institute for Health and Welfare, Helsinki, Finland; 2) Nightingale Health Ltd, Helsinki, Finland; 3) University of Helsinki, Helsinki, Finland.

**Introduction** Research on omics, including genomics and metabolomics, has identified thousands of genomic regions and several blood metabolites linked to common human diseases and features. This new knowledge combined with large amounts of samples collected to biobanks could provide new tools for predictive, preventive, personalized, and participatory (P4) health-care. **Methods** P5 study, P4 + Population health, studies the value of returning genetic and metabolomic risk information on coronary heart disease, type 2 diabetes and venous thromboembolism. We have invited 6.000 FinHealth 2017 study participants in our study. Prospective clinical significance of the risk scores will be based on analysis and follow-up of 30.000 Finnish individuals. **Results** So far, clinical utilization of omics is fairly diminutive and, above all, unvalidated. We will analyze the genetic and metabolomic profile of the P5 participants and develop and test a protocol for returning them health related risk information. The impact of our intervention will be studied by following up the participants by questionnaires and through national health registers for five years. **Conclusions** We hypothesize that 1) combining genetic and metabolomic risk with traditional risk factors adds value to the personal risk assessment of these diseases, 2) such risk information can be provided online, and 3) receiving genetic and metabolomic risk information will have an effect on the health of the study participants.

**3145T****Overview of the NHLBI Trans-Omics for Precision Medicine (TOPMed)****program: Whole-genome sequencing of >100,000 deeply phenotyped**

**individuals.** C. Laurie<sup>1</sup>, T. Blackwell<sup>2</sup>, G. Abecasis<sup>3</sup>, K. Rice<sup>4</sup>, J. Wilson<sup>5</sup>, D. Nickerson<sup>6</sup>, S. Gabriel<sup>7</sup>, R. Gibbs<sup>8</sup>, S. Dutcher<sup>9</sup>, S. Germer<sup>10</sup>, D. Arnett<sup>11</sup>, A. Ashley-Koch<sup>9</sup>, K. Barnes<sup>10</sup>, E. Boerwinkle<sup>11</sup>, S. Rich<sup>12</sup>, E. Silverman<sup>13</sup>, R. Beer<sup>14</sup>, J. Mikulla<sup>14</sup>, P. Srinivas<sup>14</sup>, W. Gan<sup>14</sup>, G. Papanicolaou<sup>14</sup>, C. Jaquish<sup>14</sup>, NHLBI Trans-Omics for Precision Medicine (TOPMed) Consortium. 1) University of Washington, Seattle, WA., USA; 2) University of Michigan, Ann Arbor, MI, USA; 3) University of Mississippi, Jackson, MS, USA; 4) The Broad Institute, Massachusetts Institute of Technology, Cambridge, MA, USA; 5) Baylor College of Medicine Human Genome Sequencing Center, Houston, TX, USA; 6) Washington University, St. Louis, MO, USA; 7) New York Genome Center, New York, NY, USA; 8) University of Kentucky, Lexington, KY, USA; 9) Duke University, Durham, NC, USA; 10) University of Colorado at Denver, Denver, CO, USA; 11) University of Texas Health Science Center at Houston, Houston, TX, USA; 12) University of Virginia, Charlottesville, VA, USA; 13) Brigham and Women's Hospital, Boston, MA, USA; 14) National Heart, Lung and Blood Institute, Bethesda, MD, USA.

A primary goal of the NHLBI TOPMed program is to improve scientific understanding of the fundamental biological processes that underlie heart, lung, blood, and sleep disorders. TOPMed is providing deep whole-genome sequencing (WGS) to pre-existing 'parent' studies having large samples of human subjects with deep phenotypic characterization (biochemical, physiological, clinical, behavioral, and anatomical measures) and environmental exposure data. WGS was performed to an average depth of >30x. A support vector machine quality filter was trained with known variants and Mendelian-inconsistent variants. The average pairwise non-reference genotype discordance rate among 69 pairs of duplicate samples was estimated at  $5 \times 10^{-5}$ . Currently, >100,000 samples have completed sequencing, with ~700 million variants discovered. Genotypes are being called jointly over all studies to facilitate cross-study analyses, including the use of common controls. TOPMed studies include prospective cohorts; cross-sectional case-control studies; family-based studies; and 'synthetic cohorts' consisting of cases from multiple sources with common controls from other sources. The prospective cohorts provide large numbers of disease risk factors, subclinical disease measures, and incident disease cases, while the case-control studies provide large numbers of prevalent disease cases. Extended family structures can provide improved power to detect rare variant effects. Well-represented diseases include asthma, COPD, atrial fibrillation, stroke and venous thromboembolism. Among currently sequenced individuals, the approximate ancestral/ethnic composition is 43% European-American, 31% African-American, 19% Hispanic/Latino, 5% Asian and 3% other groups. Discovery of genotype-phenotype associations frequently includes pooled analysis across ancestry groups and studies, using statistical models that account for population structure and relatedness. The resources of TOPMed are being made available to the scientific community as a series of 'data freezes': genotypes and phenotypes via dbGaP; read alignments via the SRA; and variants via the Bravo variant server and dbSNP. Genotypes for a set of 18.5k samples have been released on dbGaP, another freeze of 55k is being released in Q2 2018, and a freeze of >100k is planned for Q1 2019. Genotypic data are contained in study-specific accessions with names containing "NHLBI TOPMed", while most phenotypic data are in parent study accessions.

**3146F****Phenome wide scan of two LPA loss-of-function variants reveals insights**

**for drug development.** S.E. Ruotsalainen<sup>1</sup>, S. Surakka<sup>1,2</sup>, J. Koskela<sup>1</sup>, V. Salomaa<sup>3</sup>, A. Palotie<sup>1,4</sup>, M.J. Daly<sup>1,4,5</sup>, S. Ripatti<sup>1,4,5</sup>. 1) Institute for Molecular Medicine Finland, Helsinki, Finland; 2) Department of Internal Medicine, University of Michigan, Ann Arbor, MI, US; 3) National Institute for Health and Welfare, Helsinki, Finland; 4) Broad Institute of MIT and Harvard, Cambridge, Massachusetts, US; 5) Department of Public Health, University of Helsinki, Helsinki, Finland.

Lipoprotein(a), Lp(a), level is a highly heritable, independent causal risk factor for coronary heart disease. Genetic variation in and around *LPA* gene accounts for 75% of the heritability. Two known loss-of-function (LoF) variants in *LPA* that are enriched in the Finnish population (9.6 and 1.4-fold compared to Europeans) have previously been shown to have protective effect on cardiovascular diseases through decreased Lp(a) levels. Lp(a) levels have also been associated with risk of multiple diseases, including Type 2 diabetes (J Lipid Res. 2018 May;59(5):884-891) and vascular dementia (Jpn J Psychiatry Neurol. 1987 Dec;41(4):743-8.). We set to test the association between the *LPA* LoF variants and a wide range of quantitative biomarkers and disease endpoints through a phenome-wide association scan (PheWAS). We calculated *LPA* LoF dosage and tested its association with 620 disease endpoints derived from hospital discharge registry, prescription drug registry and causes of death registry with decades of follow-up and covering the whole nation and 108 biochemical and physiological quantitative measurements. We performed our study using data set of over 27,000 Finns from population-based FINRISK Study with genome-wide genotype data linked to nationwide health registries. We used logistic regression for endpoints, and linear regression for quantitative measurements to get the associations with *LPA* LoF dosage. In the PheWAS scan, the *LPA* LoF dosage is associated with lower risk for cardiovascular diseases, including vascular dementia (OR = 0.339,  $p = 0.0013$ ) and arrhythmias (OR = 0.80,  $p = 0.0028$ ). On the other hand, the *LPA* LoF dosage increases risk for multiple sun exposure related skin disorders, especially actinic keratosis (OR = 1.451,  $p = 0.00044$ ). In our PheWAS for quantitative traits, we see a strong lowering effect for Lp(a) level as expected ( $-0.63$  SD per LoF allele,  $p = 2.07e-84$ ), and also for multiple inflammatory markers including interleukins 4/6/12p70 and FGF ( $p$ -values < 0.007). In total, *LPA* LoF dosage was associated with 12 disease endpoints and 6 quantitative measures. Our results highlight the potential disease areas in addition to CHD where an intervention of lowering Lp(a) levels may provide protective effects, but also some of the potential side effects identified through elevated risk in our PheWAS scan. It also shows the power of rich electronic health record data in combination with enriched LoF variants in Finns.

**3147W**

**MyGeneRank: A mobile app for polygenic risk estimation.** *N.E. Wineinger, S. Liu, Y. Zhang, A. Torkamani.* Scripps Translational Science Institute, Scripps Research Institute, La Jolla, CA, USA.

Recent studies have demonstrated clinical and personal utility of genetic risk profiling for a subset of common adult-onset diseases in the form of polygenic risk (PR) scores. Coronary artery disease (CAD) has been a popular target of studies on PR as researchers have demonstrated preferential uptake and effectiveness of preventative actions and behaviors based on an individual's estimated PR. Despite general public interest, there exist many barriers which limit the adoption of PR utilization outside of the traditional scientific environment, including access, validity, and interpretability. In effort to study some of these factors, we developed a free, mobile app called MyGeneRank (MGR). MGR uses genetic data supplied by the user from direct-to-consumer genetic testing services (e.g., via access provided through 23andMe's API) and provides unbiased, ancestry-adjusted PR estimates of CAD to the user through the app. Within MGR, users electing to participate in the study are asked a short series of questionnaires assessing their health characteristics and behaviors related to CAD, and can access information aimed to guide the user in their understanding of their PR as well as determine how non-genetic, modifiable factors influence their overall risk. The iPhone version of the app was released in late 2017, and includes 540 unique study participants at the time of this writing with an Android version in internal testing. Nearly half of the study participants are over the age of 40, with one-third over 50. Approximately 75% of users have opted-in to allow us to access objective health metrics captured by Apple's HealthKit. Based upon genetically derived estimates, 75% of users are 90% or more European. But despite including individuals of non-European ancestry in our study, we have observed no evidence of bias in the PR estimation we provide to users ( $p=0.36$ ). This presentation will also detail the backend and user-facing architecture of MGR, our methods for eliminating bias due to population stratification, and how we are leveraging the smartphone to identify relationships with new forms of phenotypic data.

**Causal association between birth weight and adult diseases: Evidence from a Mendelian randomisation analysis.** *X. Zhou<sup>1</sup>, P. Zeng<sup>2</sup>.* 1) University of Michigan, Ann Arbor, MI; 2) Xuzhou Medical University, Xuzhou, Jiangsu 221004, China.

Birth weight is a widely used surrogate measurement of early life development, which has long been hypothesized to have a profound long-term impact on individual's predisposition to various diseases at adulthood — a hypothesis commonly referred to as the fetal origins of adult diseases. To investigate the fetal origins of adult diseases hypothesis and determine the extent to which birth weight causally affects various adult diseases, we performed a series of comprehensive Mendelian randomisation analyses to examine the causal effects of birth weight on 21 adult diseases and 38 other complex traits. Our study relies on summary statistics obtained from 37 genome-wide association studies with sample sizes ranging from 4,798 (for rheumatoid arthritis) to 339,224 (for body mass index), thus representing the largest and most comprehensive Mendelian randomisation analysis performed on birth weight to date. The large sample size used in our study allows us to fully establish an inverse causal relationship between birth weight and three adult diseases that include CAD, myocardial infarction (MI) and T2D. These inferred causal relationships are robust with respect to the selection of instrumental variables and to the choice of statistical methods, and are carefully validated in the present study through various sensitive analyses. In addition, our analysis also suggests that the lack of causality evidence between birth weight and the other diseases may be partly due to a lack of statistical power resulting from relatively small sample sizes for the remaining diseases. Finally, we investigate the possibility that any of the analyzed 38 complex traits may mediate the causal effects of birth weight on CAD, MI or T2D. Overall, our study provides important causality evidence supporting the fetal origins hypothesis for three adult diseases and suggests that increasing sample size is likely needed to reveal causal effects of birth weight for the other disorders.

**GWAS of resistant hypertension in over 70,000 participants from the Million Veteran Program identifies genes with altered expression in the adrenal gland.** J.N. Hellwege<sup>1,2</sup>, A. Giri<sup>2,3</sup>, E.S. Torstenson<sup>1,2</sup>, J.M. Luther<sup>4</sup>, J.M. Keaton<sup>1,2</sup>, O. Wilson<sup>2,5</sup>, C.P. Kovcsdy<sup>6</sup>, C. Robinson-Cohen<sup>6</sup>, C.P. Chung<sup>4,7</sup>, K.A. Birdwell<sup>8,9</sup>, Y.V. Sun<sup>9</sup>, P.W.F. Wilson<sup>10</sup>, P.S. Tsao<sup>11</sup>, C.J. O'Donnell<sup>12</sup>, D.R. Velez Edwards<sup>2,3</sup>, A.M. Hung<sup>2,5</sup>, T.L. Edwards<sup>1,2</sup> on behalf of the VA Million Veteran Program. 1) Division of Epidemiology, Department of Medicine, Institute for Medicine and Public Health, Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Tennessee Valley Healthcare System (626)/Vanderbilt University, Nashville, TN, USA; 2) Biomedical Laboratory Research and Development, Tennessee Valley Healthcare System (626)/Vanderbilt University, Nashville, TN, USA; 3) Department of Obstetrics & Gynecology, Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN, USA; 4) Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA; 5) Division of Nephrology and Hypertension, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA; 6) Nephrology Section, Memphis VA Medical Center, Memphis TN, USA; 7) Division of Rheumatology, Department of Medicine, Vanderbilt University Medical Center, Nashville, TN, USA; 8) Division of Nephrology, Department of Medicine, Nashville Veteran Affairs Hospital, Nashville, TN, USA; 9) Department of Epidemiology, Emory University Rollins School of Public Health, Department of Biomedical Informatics, Emory University School of Medicine, Atlanta, GA, USA; 10) Atlanta VAMC and Emory Clinical Cardiovascular Research Institute, Atlanta, GA, USA; 11) VA Palo Alto Health Care System; Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford, CA, USA; 12) VA Boston Healthcare, Section of Cardiology and Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA.

Resistant hypertension (rHTN) is the failure to achieve outpatient blood pressure (BP) control to <140/90 mmHg, despite use of three antihypertensive drugs including a thiazide diuretic or use of four or more drugs regardless of achieving control. rHTN is associated with worse health outcomes than controlled hypertension (cHTN) and is more common in African ancestry individuals. Previous GWAS of rHTN with a smaller sample did not identify significant associations. We performed a large GWAS of rHTN using electronic health records linked to genotypes in the VA Million Veteran Program across European American (EA, 78%) and African American (AA, 22%) individuals. All participants had eGFR  $\geq 60$  ml/min/1.73m<sup>2</sup>. rHTN vs. cHTN was regressed onto additively coded genotypes imputed to 1000 Genomes, adjusting for age, age<sup>2</sup>, sex, body mass index, and 10 principal components within ethnicity. Inverse-variance-weighted fixed-effects meta-analysis across ethnicities included a total of 16,830 cases of rHTN and 53,376 cases of cHTN as controls. Eleven SNPs were genome-wide significant in trans-ethnic meta-analysis in or nearby *CASZ1*, *WNT2B*, *KCNK3*, *FBN2*, *HOXA13-HOTTIP*, *BLK*, *LSP1*, and *RXFP2*, and 3 intergenic SNPs (rs9398815, rs35444, and rs74429862). Two additional SNPs were significant in AA only (5,071 rHTN) near *CACNA1D* and *GUSBP10-MIR3147*, with lead SNPs too rare in EA to confirm associations. All loci, with the exception of *GUSBP10-MIR3147*, have also been associated with BP, and *CACNA1D* is targeted by calcium channel blockers often used in African ancestry patients. We also applied genetically-predicted gene expression association analysis using S-PrediXcan and 44 tissue eQTL references from the GTEx Project. Increasing expression of *RXFP2* and *FBN2* in adrenal tissue was associated with increased risk of rHTN (p-values =  $9.48 \times 10^{-17}$  and  $1.89 \times 10^{-7}$ , respectively). *RXFP2* is a relaxin receptor, which causes vasodilation, increases cardiac output and renal perfusion, and has been investigated as a treatment for heart failure. *FBN2* encodes fibrillin 2, which is a component of connective tissue microfibrils, and shares functions with *FBN1*, the Marfan syndrome gene. Inclusion of expression data from RNA sequencing of tubules and glomeruli isolated from human kidneys with S-PrediXcan analysis is in preparation. This is the first study to identify significant loci influencing rHTN risk, as well as genes with expression changes contributing to the pathophysiology of rHTN.

## 3150W

**Common variants do not explain significant linkage peaks of carotid artery traits in exceptionally long-lived families.** A.L. Kuipers<sup>1</sup>, M.K. Wojczynski<sup>2</sup>, E.J.M. Barinas-Mitchell<sup>3</sup>, R.L. Minster<sup>3</sup>, L. Wang<sup>2</sup>, L. Christiansen<sup>4</sup>, A. Kulminski<sup>5</sup>, B. Thyagarajan<sup>6</sup>, M.A. Province<sup>2</sup>, A.B. Newman<sup>1</sup> On behalf of the Long Life Family Study. 1) Epidemiology, University of Pittsburgh, Pittsburgh, PA; 2) Genetics, Washington University of St. Louis, St. Louis, MO; 3) Human Genetics, University of Pittsburgh, Pittsburgh, PA; 4) Epidemiology, Biostatistics and Biodemography, Danish Aging Research Center, Odense C, Denmark; 5) Social Science Research Institute, Duke University, Durham, NC; 6) Laboratory Medicine and Pathology, University of Minnesota, Minneapolis, MN.

Dozens of common genetic variants with small effects on vascular disease have been identified. Yet, it is likely that rare private variants with large effects exist within families. In order to test this, we used data captured via B-mode ultrasonography of the carotid arteries in the Long Life Family Study (N=2020), a family-based study of exceptional longevity. We previously found strong evidence of genetic linkage to carotid artery interadventitial diameter and atherosclerotic plaque on chromosomes 3 and 17 (max LOD, peak cM[cM range]: 5.3,20[113–134] and 3.2,8[72–89]), respectively. Haplotypes generated from genotypes typed on the Human Omni Chip 2.5 v1 (Illumina, CA) were used as linkage markers, and multipoint identity-by-descent estimates were calculated by Loki. In the current study, we performed linkage analysis allowing for heterogeneity between families (HLOD) using SOLAR to refine the peaks. We also tested for genetic association between variants under the refined peaks with a minor allele frequency  $\geq 1\%$  and carotid artery traits using lmeKin in R. We then performed linkage analyses conditioned on any suggestive or significant variant under the peak to estimate the variant's effect on the linkage signal. All models were adjusted for age, age<sup>2</sup>, sex, and field center, and the association analyses were additionally adjusted for principal components of population substructure. By identifying the top 15% of families contributing to the linkage signals, we were able to narrow the peaks to <5 cM regions (chromosome, peak cM[cM range]: 3,120[119–123] and 17,82[80–83]). However, no common variants in these regions were significantly associated with the carotid artery trait of interest. One chromosome 3 SNP, rs13100154, was suggestive of an association with carotid artery interadventitial diameter (P= $4.2 \times 10^{-6}$ ). The magnitude of the linkage peak was only attenuated by ~5% after adjustment for this SNP, suggesting that neither it nor a variant in linkage disequilibrium with it was responsible for the significant linkage peak on chromosome 3. Therefore, common genetic variation does not explain the significant genetic linkage identified for carotid artery traits in these exceptionally long-lived families. We are currently sequencing these regions in families of interest in an attempt to identify rare variants with significant effects on carotid artery traits.

**Assessment of anthropometric and lifestyle risk factors for the prediction of cardiovascular diseases in three generations cohort among North Indian population.** *R. Kumar<sup>1,2</sup>, B. Doza<sup>2</sup>*. 1) Govt. Sen. Sec. School, Aliwal, Punjab, India; 2) Dept. of Human Genetics, G.N.D.U. Amritsar, Punjab, India.

The present study has attempted to evaluate comparative three anthropometric indicators (BMI, waist circumference and WHR) and five socio-economic lifestyle factors (food habits, physical activity, exercise, smoking and alcohol) to identify the most distinctive indicators for pre-hypertension and hypertension for a specific community in Punjab. No such study has been performed in this region based on sensitivity, specificity and likelihood ratio with three generations. Among male parental generation the waist circumference and WHR for pre-hypertension; WHR and exercise for hypertension and waist circumference and BMI for pre-hypertension and hypertension among female parental generation were better indicators to assess CVD risk factors. High sensitivity suggested that waist circumference and BMI performed well in female parental generations. The results of the analysis of present data suggested waist circumference for almost all the generations with average high sensitivity upto 97% and 99% for female parental generation in the prediction of pre-hypertension and hypertension. BMI and WHR may be considered with respect to sensitivity in the second level of best predictor for both pre-hypertension and hypertension. If we compare positive likelihood ratio of the three generations with respect to all the indicators then it was observed that LR+ value of BMI has been consistently higher among all the generations as compared to waist circumference and WHR. Therefore, it is suggested that combination of waist circumference and BMI would be the better predictors to assess CVD risk.

**Bilirubin and ischemic heart disease: A two-sample Mendelian randomization study.** *J. Lee, C. Jeon, S. Jee*. Yonsei university, Seoul, Korea, Republic of.

Bilirubin is an endogenous antioxidant which protects cells against oxidative stress. Increased plasma levels of bilirubin have been associated with reduced risk of ischemic heart disease (IHD) in previous studies. Nonetheless, whether the associations reflect a true protective effect of bilirubin on IHD, rather than confounding or reverse causation remains unknown. Therefore, we applied the two-sample Mendelian randomization to evaluate the causal association that bilirubin levels and IHD risk among Korean populations. A total of 5 genetic variants (rs10490012, rs12993249, rs2119503, rs4149014, and rs73233620) were selected as genetic instruments for serum bilirubin levels using a community-based cohort, the Korean Genome and Epidemiology Study (KoGES) comprising 33,598 subjects. Then we evaluated their impact on ischemic heart disease using the Korean Cancer Prevention Study-II (KCPS-II) cohort. We found no significant association between serum bilirubin levels and IHD. Sensitivity analyses demonstrated consistent association, suggesting robustness of our observation. Further studies to conform the observed interaction among other ethnicities are warranted.

**Cohort profile of the EPOZ study: 40 years of follow-up.** *N. Terzikhan, M.A. Ikram, H.H.H. Adams.* Erasmus medical centre, The Netherlands, Zuid Holland, Netherlands.

EPOZ (Epidemiologisch Preventief Onderzoek Zoetermeer, translated: Epidemiological Preventive Study Zoetermeer), is a population-based prospective cohort study in two districts of Zoetermeer, a suburban residential community that is near The Hague in the Netherlands. The study included 10,361 persons aged 5 to 91 years at the baseline year (1975) and was originally concerned with the prevalence of various chronic diseases. All participants were included between 1975 and 1978 (78% response). Currently, it has over 40 years of follow-up and includes focus cohorts with extensive repeated measurements of cardiovascular, neurological and bone health. For the first focus cohort, families with children between 5 to 19 years of age were invited to participate in a focus study on cardiovascular risk factors. In total, 4,649 (82% response) took part of this study. From this group a random sample of 596 children was selected for annual follow-up between 1975 and 1993. In 2002, additional measurements of cardiovascular risk factors were collected. The median number of visits was 15 (range 2 to 19). For the second focus cohort, 909 subjects aged between 60 and 90 years were randomly selected to assess eligibility for MRI brain scan. Of these 909 individuals, 819 subjects were eligible. Among the eligible participants, 514 (63%) agreed to have an MRI brain scan and each individual received up to three scans during 1995-2009. Recently, we performed genome-wide genotyping in the focus cohort and are in the process of acquiring additional omics data, including gene expression in multiple tissues and methylation, for both cohorts. While EPOZ has already been part of ongoing collaborative efforts, we are eager to promote this unique and rich dataset among the international community.

**Role of segregation in multiplex families for variant discovery in cardiac birth defects.** *L.J. Martin<sup>1</sup>, V. Pilipenko<sup>1</sup>, D.W. Benson<sup>2</sup>.* 1) Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; 2) Pediatrics, Medical College of Wisconsin, Milwaukee, WI.

**Introduction.** Cardiovascular malformations (CVM) are the most common birth defects with an incidence of 2 to 5 per 100 live births. Although CVM heritability provides strong evidence of a genetic basis, in most cases the cause remains unknown. Exome data for CVM case series has generated large numbers of potential variants but definitive evidence of causality has remained elusive except in a small percentage of cases. Given the strong heritability, we hypothesized that segregation of variants in a kindred will aid in novel gene discovery. **Methods.** Whole exome sequencing was performed on 52 individuals from 4 families ascertained by a proband with hypoplastic left heart syndrome (HLHS). Each family had at least 3 additional individuals with CVM. Analysis of exomes from probands, identified rare variants with informatics support (RVIS, minor allele frequency  $\leq 0.01$  and Combined Annotation Dependent Depletion score  $\geq 20$ ). Variants which did not meet these criteria were defined as non-RVIS. Family specific two point logarithm of the odds (LOD) scores were used to identify segregating with CVM using a dominant model and 80% penetrance. **Results.** A total of 702 RVIS variants in 668 genes were identified in the 4 probands. Additional analysis included RVIS sharing among probands and higher evidence of functionality, but no strong candidates were identified. However, when looking at linkage evidence in these families only 1 RVIS, rs200183228, a non-synonymous variant in *SORCS2* had a LOD score  $\geq 1$  (LOD = 1.3). On the other hand, there were 109 non-RVIS variants with LOD scores  $\geq 1.0$ , including 10 variants with LOD  $\geq 1.5$ , and one LOD  $> 2.0$  (rs34053053 in *CTTN*). Since 97% of segregating variants were common, these results suggest that although a single variant is unlikely to explain CVM multiple common segregating variants contribute to CVM in these families. **Conclusions.** These results suggest that for CVM, conventional identification of candidate variants using allele frequency and predicted informatic functionality may miss a large proportion of variants which segregate with CVM. For birth defects such as CVM which exhibit strong familial transmission, yet for which single variants are not sufficient, utilization of segregation could be a powerful tool to identify novel candidates missed by current strategies.

**3155F****Association between genetic variants of functional candidate genes and its interaction with smoking on the risk of coronary acute syndrome in an admixed population.**

L. Franco<sup>1</sup>, N. Gallego-Lopera<sup>1</sup>, C. Velarde<sup>1</sup>, C. Vergara<sup>2</sup>, D. Valencia<sup>1</sup>, K. Betancur<sup>3,4</sup>, J. García<sup>5</sup>, N. González<sup>2</sup>, H. Cuervo<sup>3,4</sup>, C. Saldarriaga<sup>3,4</sup>, C. Martínez<sup>4</sup>, K. Marisancen<sup>1</sup>, P. Parra<sup>1</sup>, S. Carvalho<sup>1</sup>, L. Parra<sup>1</sup>, E. Jiménez<sup>1</sup>, JP. Bedoya<sup>1</sup>, I. Ortiz<sup>1</sup>, G. Bedoya<sup>6</sup>, A. Valencia-Duarte<sup>1,2</sup>. 1) Universidad Pontificia Bolivariana, Medellín, Colombia; 2) Division of Infection Diseases, John Hopkins University, Baltimore, United States; 3) Facultad de Medicina, Universidad Pontificia Bolivariana, Medellín, Colombia; 4) Clínica CardioVID, Medellín, Colombia; 5) Facultad de Medicina, Universidad de Antioquia, Medellín, Colombia; 6) Grupo Genética Molecular, Universidad de Antioquia, Medellín, Colombia.

Cardiovascular diseases are the main cause of mortality in the world and the acute coronary syndrome (ACS) is the most important clinical manifestation. The development of ACS events is a consequence of the interaction between multiple genes and environmental factors. This study evaluated the association between genetic variants related to lipid metabolism, inflammation and platelet aggregation and its interaction with smoking on the risk to develop ACS in young adults from Antioquia (Colombia). The study included 332 patients with diagnosis of early ACS and 432 healthy subjects. Polymorphisms in the genes *PCSK9*(rs11206510), *SORT1* (rs646776, rs599839), *LPA*(rs3798220, rs10455872), *ABCB1*(rs1045642), *ZPR1-APOA5-A4-C3-A1*(rs964184), *LDLR*(rs6511720), *APOE*(rs429358, rs7412), *APOE-APOC1*(rs4420638), *IL10*(rs1800872, rs1800896), *TNF- $\alpha$* (rs1799964), *IFN- $\gamma$* (rs1861493), *ABO*(rs579459), *CXCL12*(rs501120, rs1746048), *PAI-1*(rs2227631) and *ITGB3*(rs5918) were genotyped using RTPCR. Association of each variant was evaluated using logistic regression models stratified by smoking, and adjusted by conventional risk factors and genetic ancestry. Rs10455872 in *LPA*(G allele, OR = 2.68; IC 95%=1.64–4.38) and rs599839 in *SORT1* (G allele, OR = 0.74; IC 95%=0.57–0.95) were associated with ACS independently of smoking status. Smoking significantly (interaction term p-value<0.05) modified the effect of the genetic variants *ZPR1-APOA5-A4-C3-A1*(rs964184), *LDLR*(rs6511720) and *PAI-1*(rs2227631) on ACS; so, allele G of rs964184 (OR= 1.90; CI 95% = 1.33-2.71), allele T of rs6511720 (OR = 0.41; CI 95% = 0.19-0.90) and allele A of rs2227631 (OR= 0.67; CI 95%=0.46 - 0.98) were associated with ACS only in non-smokers, although p-values of interaction were not significant and this was not due to a lower power in the group of smokers. In conclusion, we found evidence that smoking status modifies the risk of SNPs in candidate genes for ACS, highlighting the importance of evaluating the role of environmental factors in genetic associations. .

**Variants affecting menopausal timing associate with CVD, stroke and blood pressure in >26,000 Finns.** A. Joensuu, H. Mattsson, V. Salomaa, M. Perola, K. Auro. Department of Public Health Solutions, National Institute for Health and Welfare, Helsinki, Finland.

**Background & Aims:** Age at natural menopause (ANM) associates with the prevalence of several diseases, including cardiovascular diseases (CVD) and breast cancer. Whether this is due to common genetic background or to the effects of menopause itself remains unclear. Our aim was to study the combined effect of genomic variants affecting the timing of menopause by creating a polygenic risk score (PRS) and studying its association with disease endpoints in both females and males. **Materials & Methods:** Our study sample consists of 26,832 subjects aged 25-74 at baseline (14,039 females and 12,793 males) from five independent population-based Finnish FINRISK studies (baseline years 1992, 1997, 2002, 2007 and 2012) with follow-up of disease endpoints from national registers up to the year 2015. A meta-analysis by Day et al (Nat Genet. 2015) detected 54 variants associated with ANM - our study was able to use 50 of these (of which 6 genotyped and 44 imputed with a mean information quality score of 0.98) to form the PRS. The PRS was calculated by multiplying the amount of effective alleles per variant with the effect size reported in Day et al. and summing the effects of all variants together. We studied the association of the PRS with CVD endpoints, diabetes and breast cancer with logistic regression and with CVD risk factors with linear regression. We corrected the analyses for baseline study year, study area, ever smoking, socioeconomic status, as well as baseline age in risk factor analysis and age at end of follow-up in endpoint analysis. We restricted the logistic analysis to individuals with follow up to at least 40 years of age (mean follow-up end age 65.2 years). **Results:** The PRS (range -12.6 - -6.2) was validated by confirming its correlation with age at last period in postmenopausal women ( $p=1.8 \times 10^{-7}$ ,  $N=2170$ ). In men, the PRS did not associate with any disease endpoint, whereas in women the PRS associated ( $p<0.05$ ) with CVD and stroke, with a lower menopausal age genetic score increasing the risk of these diseases. Breast cancer was not associated ( $p=0.21$ ) with the PRS. Of CVD risk factors, the PRS associated only with systolic blood pressure in men ( $\beta=0.43$ ,  $p=0.028$ ). **Conclusions:** Our results suggest that menopausal timing and CVD risk may have a common genetic background, which is seen also in males through elevated blood pressure. Interestingly, no association was seen with breast cancer and the menopausal age PRS.

## 3157T

**Characterizing proof-of-concept genes for familial hypercholesterolemia *in vivo* using zebrafish model systems.** B.V.V. Manoj Kumar<sup>1,2</sup>, A. Emma-nouillidou<sup>1,2</sup>, P. Ranefall<sup>3</sup>, B. von der Heyde<sup>1,2</sup>, T. Kingstrom<sup>1,2,4</sup>, J. Ledin<sup>2,4</sup>, A. Larsson<sup>5</sup>, H. Brooke<sup>6</sup>, C. Wahlby<sup>2,3</sup>, E. Ingelsson<sup>5,7</sup>, M. den Hoed<sup>1,2</sup>. 1) Department of Immunology, Genetics and Pathology, Uppsala University, Sweden; 2) Science for Life Laboratory, Uppsala University, Sweden; 3) Department of Information Technology, Uppsala University, Sweden; 4) Department of Organismal Biology, Uppsala University, Sweden; 5) Department of Medical Sciences, Uppsala University, Sweden; 6) Department of Public Health and Caring Sciences, Uppsala University, Sweden; 7) Department of Medicine, Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford.

Small-scale studies suggest that zebrafish larvae represent a promising model system for genetic screens in dyslipidemia and early-stage atherosclerosis, the main mechanisms underlying coronary artery disease (CAD). We expanded the phenotypic pipeline, increased the throughput, and validated the model system using a large screen for familial hypercholesterolemia proof-of-concept genes. We used a multiplexed CRISPR-Cas9 approach to target zebrafish orthologues of *APOE*, *APOB* and *LDLR*. Offspring (n=384) of founder mutants were overfed on a cholesterol supplemented diet from 5 to 9 days post fertilization (dpf). At 10 dpf, vascular atherogenic traits and body size were visualized using an automated positioning system and fluorescence microscope, and quantified using custom-written scripts. After imaging, whole-body lipid fractions and glucose levels were assessed using enzymatic assays and normalized for protein content. CRISPR-Cas9-induced mutations were identified using paired-end sequencing (2x250 bp) and annotated using Ensembl's VEP. Association analyses were performed using hierarchical linear models or zero-inflated negative binomial regression, adjusting for body size, time of day and batch. A risk score comprising the number of mutated alleles across the four zebrafish orthologues of *APOE*, *APOB* and *LDLR* for which we observed sufficient genetic variation was associated with 0.094±0.035 SD higher LDLc levels and 0.138±0.070 SD more vascular lipid deposition. At the level of individual genes, each additional mutated allele in *apoea* was associated with higher whole-body LDLc levels and with more vascular co-localization of lipids and neutrophils; each additional mutated allele in *apobb.1* resulted in more vascular co-localization of lipids and neutrophils; and each additional mutated allele in *ldlra* resulted in more vascular infiltration by lipids, and in less vascular co-localization of macrophages and neutrophils. Our results suggest that systematically characterizing candidate genes across robustly associated loci identified in large-scale genetic association studies in humans using zebrafish model systems will likely help increase our understanding of disease etiology and may help identify novel targets that can be translated into efficient medication for prevention and treatment.

Atrial fibrillation (AF) is the most common arrhythmia affecting over 33 million individuals worldwide. Although AF is typically considered a primary electrical disorder, the mechanisms underlying AF remain incompletely understood. The National Heart Lung and Blood Institute's Trans-Omics for Precision Medicine (TOPMed) Program includes longitudinal and cohort studies in which high depth, whole genome sequencing was performed in over 18,000 individuals between 2014 and 2017. In this case-control study, we included 2,781 early onset AF cases from 9 studies and identified 4,959 controls of genetically determined European ancestry from the remaining TOPMed participants. Early onset AF was defined as AF onset <66 years of age. Rare loss of function variants in genes at AF loci and common genetic variation across the whole genome were tested for association with early onset AF. Replication of common and rare variant associations were conducted with 346,546 unrelated UK Biobank participants of European ancestry and 42,783 participants in the MyCode study, respectively. Among early-onset AF cases, 72.1% were male; the mean age of AF onset was 48.7±10.2 years. Samples were sequenced at a mean depth of 37.8 fold and mean genome coverage of 99.1%. In an analysis of common variants, we observed an association with 5 known loci and 1 recently identified locus (*NAV2*). This *NAV2* locus was replicated in the UK Biobank (OR, 1.11; 95% CI, 1.07-1.15;  $P=9.70 \times 10^{-10}$ ). In an analysis of rare variants, we found at least one loss-of-function variant in *TTN*, the gene encoding the sarcomeric protein titin, in 2.1% of cases and in 1.1% in controls. The proportion of individuals with early-onset AF who carried a loss-of-function variant in *TTN* was higher in those with an earlier age of AF onset ( $P$  value for trend  $4.92 \times 10^{-4}$ ); 6.5% of individuals with AF onset before age 30 carried a *TTN* loss-of-function variant (OR, 5.94; 95% CI, 2.64-13.35;  $P=1.65 \times 10^{-5}$ ). The association between *TTN* loss of function variants and early onset AF was replicated in MyCode, comprised of 1,582 early-onset AF cases and 41,200 controls (OR, 2.16; 95% CI, 1.19-3.92;  $P=0.01$ ). In sum, we discovered that *TTN* is a disease susceptibility gene for early onset AF. Our findings expand the role for *TTN* in cardiovascular disease.

**3159W****Gene-based genome-wide association analysis implicates novel genes involved in venous thromboembolism in African, Asian, and European populations.** *W. Hernandez<sup>1</sup>, M. Pividori<sup>2</sup>, A. Barbeira<sup>2</sup>, R. Bonazzola<sup>2</sup>, J. Liao<sup>3</sup>, H. Im<sup>2</sup>.*

1) Section of Cardiology, Section of Genetic Medicine, University of Chicago, Chicago, IL; 2) Section of Genetic Medicine, University of Chicago, Chicago, IL; 3) Section of Cardiology, University of Chicago, Chicago, IL.

Venous thromboembolism (VTE) is a chronic multifactorial disease encompassing deep vein thrombosis (DVT) and pulmonary embolism (PE) and the third most common life-threatening cardiovascular condition world-wide. Epidemiological studies have shown that the prevalence of VTE varies significantly across ethnic/racial groups, yet the genetic basis for these differences remains largely undefined. Our aim was to integrate genomic and transcriptomic data to elucidate molecular mechanisms and examine the genetic heterogeneity underlying VTE risk among different ethnic populations. We applied a novel gene-based statistical method, MULTIXcan, to VTE cases and controls of African (cases=141; controls=6,450), Asian (cases=127; controls=8,356), and European (cases=8,053; controls=318,007) ancestry populations from the UK Biobank to identify genes associated with VTE risk (Bonferroni correction was  $2.9 \times 10^{-6}$ ). Among our European cohort – in addition to the well-established associations *F5*, *F11*, *SLC19A2* ( $p \leq 5.00E-32$ ), we found *EDEM2* and *PROCR* to be associated with VTE risk ( $p \leq 5.57E-17$ ). Loci within or near this region have been previously associated with circulating Protein C concentration, one of the most important endogenous anticoagulants. We also found *EXOSC4*, part of the exosome complex, to be associated with VTE risk in African and European populations ( $p=2.58E-07$  and  $p=2.57E-09$ , respectively). The exosome complex recently has emerged as an important mediator in vascular remodeling and consequently vascular diseases. The most significant finding among our Asian cohort was *ELMO1* ( $p=7.56E-12$ ), although a novel finding in humans, *ELMO1* deficient mice have been shown to have enhanced thrombus formation. By harnessing the large scale data from the UK Biobank and the latest advances in bioinformatics and genomics our study provides new molecular insight into the underlying mechanism that may regulate VTE susceptibility in diverse populations and highlights the importance of conducting ethnic-specific research.

Stroke is a leading cause of mortality and morbidity worldwide. Stroke subtypes have different risk factors and clinical presentations, with ischemic stroke (IS) accounting for 85% of all events. Several large studies have been undertaken to identify genetic predictors of IS, but the identified loci do not explain a large proportion of the genetic risk. Additionally, most have been undertaken only in Europeans (EUR) or have not reported ancestry-stratified results for non-EUR samples. We aimed to discover novel genetic loci for IS, within and across ancestral groups, in the Million Veteran Program (MVP) cohort. Prevalent IS was ascertained within MVP using both the Tirschwell algorithm and more sensitive algorithm developed within MVP. Preliminary analyses focused on EUR and African American (AFR) veterans with 20,686 Tirschwell cases [5,038 AFR; 15,648 EUR] & 6,993 algorithm cases [1,784 AFR; 5,209 EUR] identified in the initial ~350,000 individuals genotyped. GWAS was performed using 1000G imputed dosages, within each sex and ancestry stratum, adjusting for age and first 10 ancestry-specific PCs, then combined in an inverse-weighted meta-analysis. No loci reached genome-wide significance ( $p < 5E-08$ ) in initial MVP analyses, regardless of phenotype algorithm or ancestry stratum. Of the 18 SNPs reported by the recent MEGASTROKE trans-ethnic meta-analysis for cases (N=60,341) of any ischemic stroke (AIS), *PITX2*, *FOXF2*, *CDK6*, *MMP12*, and *ZCCHC14* replicated in MVP using the Tirschwell criteria, and *MMP12* and *ZCCHC14* using the MVP algorithm (Bonferroni threshold for 20 loci =  $p < 0.0025$ ). Of the 8 AIS loci from the MEGASTROKE EUR-only analysis (N=34,217 cases), *FOXF2* and *HDAC9-TWIST1* replicated in MVP (EUR-only). Most loci that did not replicate did achieve a  $p$ -value  $< 0.05$  and had MVP odds ratios in the expected directions (with overlapping 95% CI). Failure to replicate may be due to the smaller number of IS cases within MVP and the differential population make-up of the respective trans-ethnic analyses, as 29% of MEGASTROKE AIS cases are East Asian. Further analyses are underway using an additional 110K samples from MVP and including Hispanic and Asian American individuals. As well, full summary results from the MEGASTROKE analyses have been obtained to complete the largest IS GWAS to date, a mega-analysis of MVP + MEGASTROKE, in time for presentation at this meeting.

**Abstract** We previously carried out a large-scale genetic analysis of the choline-derived metabolite betaine, whose levels are associated with development of coronary artery disease (CAD). These efforts identified a variant of *CPS1* (carbamoyl-phosphate synthase 1), the rate limiting enzyme in the urea cycle, as being strongly associated with decreased levels of betaine, increased glycine levels, and decreased risk of CAD in women but not men. Based on these data, we sought to determine whether plasma glycine levels represent a novel causal biomarker for risk of CAD using a genetics approach. We first carried out a meta-analysis of GWAS summary level data for plasma glycine levels in up to 30,118 European ancestry subjects and identified five previously known (*CPS1*, *ALDH1L1-SLC41A3*, *PPP1R3B-LOC157273*, *GLDC*, *GCSH-PKD1L2*) and seven novel (*ACADM*, *PHGDH*, *COX18-ADAMTS3*, *PSPH*, *TRIB1*, *PTPRD*, *ABO*) genome-wide significant ( $p < 5 \times 10^{-8}$ ) loci. Although stratified meta-analyses for glycine levels in men ( $n \sim 19,000$ ) and women ( $n \sim 11,000$ ) separately did not reveal any additional loci beyond those in the combined analysis, the significance level at the *PHGDH* and *PTPRD* loci was one order of magnitude stronger in females despite a smaller sample size ( $p < 10^{-6}$  in females;  $p < 10^{-5}$  in males, respectively). Of the seven novel loci, glycine-raising variants at the *PSPH*, *TRIB1* and *ABO* loci were also significantly (Bonferroni-adjusted  $p < 7.1 \times 10^{-3}$ ) associated with decreased risk of CAD based on GWAS summary level data in a dataset of >500,000 cases and controls from UK Biobank and the CARDIoGRAM+C4D Consortium. A combined analysis further demonstrated that the joint effects of the seven glycine-raising alleles were modestly but significantly associated with decreased risk of CAD (OR=0.98, 95% CI 0.98-0.99,  $p = 2.1 \times 10^{-12}$ ). In summary, our analysis identified seven novel loci for plasma glycine levels, but it was not possible to determine whether the association of some of these loci with CAD is causally mediated through glycine since several of these loci have previously been associated with other known CAD risk factors, such as plasma LDL and total cholesterol levels. Thus, additional studies will be required to determine if there is a causal link between glycine and risk of CAD, and whether any of the novel loci exhibit sex-specific associations with CAD outcomes.

## 3162W

**Genetic determinants of plasma bioactive lipids, potential novel biomarkers of cardiovascular disease.**

K. McGurk<sup>1</sup>, A. Nicolaou<sup>2</sup>, B. Keavney<sup>1</sup>. 1) Division of Cardiovascular Sciences, University of Manchester, Manchester, United Kingdom; 2) Division of Pharmacy & Optometry, University of Manchester, Manchester, United Kingdom.

Bioactive lipids have key roles in cardiovascular disease (CVD). Although some lipid classes have been associated with CVD, genetics studies to date have focused on few of the many species now measurable. Signalling lipids of the eicosanoid, endocannabinoid and ceramide classes have potent roles in inflammation, vasodilation and cell death. Heritability and family-based GWAS analyses may identify particularly heritable lipid biomarkers for prioritisation in large scale Mendelian randomisation studies to determine causal relationships. We analysed 175 eicosanoid, endocannabinoid and sphingolipid species in 204 plasma samples from 31 British Caucasian families, using liquid chromatography coupled to tandem mass spectrometry. Baseline heritability estimates (QTDT and GCTA) were determined and GWAS (FaST-LMM and GCTA) was performed. Certain species were found significantly heritable, particularly from the endocannabinoid and ceramide classes (20%-70%; corrected  $p < 0.05$ ). DHET species, formed in a pathway involving CYP450 enzymes, were the most heritable eicosanoid species measured (47% - 58%, corrected  $p = < 0.05$ ). Baseline GWAS analyses identified suggestive associations between lipid concentrations and SNPs in genes known to be involved in the metabolism of these lipids (e.g. CYP450 enzymes). A top associated SNP with an endocannabinoid congener was also identified in previously published GWAS for coronary artery disease, indicating a novel causal role for these bioactive lipids. Many ceramide species correlated with cardiovascular phenotypes (e.g. hypertension) previously measured in the cohort. Although a small number of eicosanoids were also found to be significantly heritable, the baseline associations at GWAS were not as promising as those for endocannabinoids and ceramides. GWAS analyses of a further 800 samples, from 170 families, will be presented at the meeting. We demonstrate for the first time estimates of heritability and GWAS analyses for this array of bioactive lipids. Although found at pg/ml concentrations much lower than cholesterol, many of the heritability estimates are similar to plasma genetic biomarkers of CVD (e.g. cholesterol  $h^2$  30%-50%). The results from the extended cohort will be used to identify causal metabolic pathways, novel diagnostics and drug targets for CVD intervention.

## 3163T

Stefansson<sup>1,2</sup>. 1) deCode genetics/Amgen Inc., Reykjavik, Iceland; 2) Faculty of Medicine, University of Iceland, Reykjavik, Iceland; 3) Department of Medi-cine, Landspítali National University Hospital of Iceland, Reykjavik, Iceland; 4) Department of Pediatric Cardiology, Skane University Hospital, Lund, Sweden; 5) Department of Clinical Sciences Lund, Clinical Physiology, Lund University, Lund, Sweden; 6) Childrens Hospital, Landspítali National University Hospital of Iceland, Reykjavik, Iceland; 7) Department of Internal Medicine, Akureyri Hospital, Akureyri, Iceland; 8) Department of Family Medicine, University of Iceland, Reykjavik, Iceland; 9) Department of Development, Primary Health Care of the Capital Area, Reykjavik, Iceland; 10) School of Engineering and Natural Sciences, University of Iceland, Reykjavik, Iceland.

Features of the electrocardiogram's QRS complex, reflecting ventricular de-polarization, associate with adverse outcomes. Previous genome-wide asso-ciation studies have tested four QRS measures and found variants at 58 loci, mostly common. We tested 32.5 million variants for association with ten QRS measures in 12 ECG leads, using 434,000 electrocardiograms from 81,303 Icelanders. We found 190 associations at 130 loci, 123 at 86 new QRS loci, of which 19 are associations with rare or low-frequency coding variants with large effects. Assessment of genes highly expressed in heart identified additional 13 rare coding variants at 10 QRS loci, four of which are new loci. We tested the QRS variants for association with other cardiovascular phenotypes and found 23 new disease associations. We demonstrate the substantial advantage of analysing individual components of the QRS complex in conjunction with other cardiovascular phenotype information to further the understanding of the genetic basis of cardiac conduction and disease.

## 3164F

**Genomic loci associated with lipid traits in Latinos.** I. Kullo<sup>1</sup>, G. Schaib<sup>2</sup>, K. Ding<sup>1</sup>, E. DeFilippis<sup>1</sup>, M. de Andrade<sup>1</sup>, L. Mandarino<sup>1</sup>, S. Thibodeau<sup>1</sup>. 1) Mayo Clinic Minnesota, Rochester, MN; 2) Mayo Clinic Arizona, Scottsdale, AZ.

**Background.** To identify novel genetic loci and replicate previously identified loci influencing inter-individual variation in lipid traits in Latinos, we conducted a genome-wide association study (GWAS) in individuals participating in the Sangre Por Salud biobank. **Methods.** Participants (n=999, age 38.9 ± 12.3 yrs, 72% female) underwent genotyping of ~1.2 million SNPs on the Illumina Infinium Multiethnic array. Total and HDL cholesterol and triglycerides were measured using standard methods and LDL cholesterol was estimated by the Friedewald formula. Association analyses were performed adjusting for age, sex, BMI, and three principal components. **Results.** Mean levels of total, HDL and LDL cholesterol were: 182.2 ± 36.0, 50.2 ± 14.1, and 105.3 ± 29.2 (mg/dL). Mean triglycerides levels were 138.1 ± 110.0 (mg/dL). Several loci were associated with lipid traits at a genome-wide significant level (Table). Three novel loci, including intergenic variants near *PCDH7* (p=2.5E-07) and *ZFAT* (p=5.6E-08), were associated with log-transformed triglycerides. *PCDH7* has been previously reported to modify the effect of waist-to-hip ratio on total cholesterol (Surakka et al., 2015, *PLoS Genetics*), and *ZFAT* was associat-ed with hip circumference adjusted for BMI (Shungin et al. 2015, *Nature*). Among 95 loci identified previously as being associated with lipid traits in a large meta-analysis (n=~100,000), ~80% were replicated at a FDR < 0.05. **Conclusion.** We identified three novel loci associated with triglyceride levels in a Latino cohort. The majority of loci previously associated with lipid traits in European ancestry individuals were replicated at FDR < 0.05.

**A comprehensive evaluation of the genetic architecture of sudden cardiac arrest.** *R.N. Mitchell<sup>1</sup>, F.N. Ashar<sup>1</sup>, D.E. Arking<sup>1</sup>, N. Sotoodehnia<sup>2</sup>, SCD working group of the CHARGE Consortium.* 1) Institute of Genetic Medicine, Johns Hopkins, Baltimore, MD; 2) Cardiovascular Health Research Unit, Division of Cardiology, Departments of Medicine and Epidemiology, University of Washington, Seattle, WA.

**Background.** Sudden cardiac arrest (SCA) accounts for 10% of adult mortality in Western populations. While several risk factors are observationally associated with SCA, the genetic architecture of SCA in the general population remains unknown. Furthermore, understanding which risk factors are causal may help target prevention strategies. **Methods.** We carried out a large genome-wide association study (GWAS) for SCA ( $n=3,939$  cases, 25,989 non-cases) to examine common variation genome-wide and in candidate arrhythmia genes. We also exploited Mendelian randomization methods using cross-trait multi-variant genetic risk score associations (GRSA) to assess causal relationships of 18 risk factors with SCA. **Results.** No variants were associated with SCA at genome-wide significance, nor were common variants in candidate arrhythmia genes associated with SCA at nominal significance. Using cross-trait GRSA, we established genetic correlation between SCA and (1) coronary artery disease (CAD) and traditional CAD risk factors (blood pressure, lipids, and diabetes), (2) height and BMI, and (3) electrical instability traits (QT and atrial fibrillation), suggesting etiologic roles for these traits in SCA risk. **Conclusions.** Our findings show that a comprehensive approach to the genetic architecture of SCA can shed light on the determinants of a complex life-threatening condition with multiple influencing factors in the general population. The results of this genetic analysis, both positive and negative findings, have implications for evaluating the genetic architecture of patients with a family history of SCA, and for efforts to prevent SCA in high-risk populations and the general community.

**3166T**

**Metabolomic consequences of PCSK9 inhibition compared with statin therapy.** *P. Würtz.* Nightingale Health Ltd, Helsinki, Finland.

**Abstract—**Both statins and PCSK9 inhibitors lower blood low-density lipoprotein cholesterol (LDL-C) levels to reduce risk of cardiovascular events. We performed detailed metabolic profiling of a large randomized statin trial, and compared the results with the effects of genetic inhibition of PCSK9, acting as a naturally occurring trial. Altogether 228 circulating metabolic measures were quantified by nuclear magnetic resonance spectroscopy, including lipoprotein subclass concentrations and their lipid composition, fatty acids, and amino acids, for 5,359 individuals in the PROSPER trial. The corresponding metabolic measures were analyzed in eight cohorts ( $N=72,185$ ) using *PCSK9* rs11591147 to mimic the therapeutic effects of PCSK9 inhibitors. Scaled to an equivalent lowering of LDL-C, the effects of genetic inhibition of PCSK9 on 228 metabolic markers were generally consistent with those of statin therapy ( $R^2=0.88$ ). However, discrepancies were observed for very-low-density lipoprotein (VLDL) lipid measures. For instance, genetic inhibition of PCSK9 had weaker effects on lowering of VLDL-cholesterol compared with statin therapy (54% vs. 77% reduction, relative to the lowering effect on LDL-C). Genetic inhibition of PCSK9 showed no significant effects on amino acids, ketones, or a marker of inflammation, whereas statin treatment weakly lowered GlycA levels. Genetic inhibition of PCSK9 had similar metabolic effects as statin therapy on detailed lipid and metabolite profiles. However, PCSK9 inhibitors are predicted to have weaker effects on VLDL lipids compared with statins for an equivalent lowering of LDL-C, which potentially translate into smaller reductions in cardiovascular disease risk. **Keywords-** metabolic profiling, cholesterol lowering, Mendelian randomization, lipoproteins, drug development.

**Towards a multi-modal health assessment: Gaining insights into cardio-metabolic conditions.** I. Shomorony<sup>1</sup>, E. Cirulli<sup>1</sup>, L. Huang<sup>1</sup>, W. Li<sup>1</sup>, C. Swisher<sup>1</sup>, N. Schenker-Ahmed<sup>1</sup>, M. Hicks<sup>1</sup>, L. Napier<sup>1</sup>, C. Hou<sup>1</sup>, J. Yu<sup>1</sup>, R. Heister<sup>1</sup>, T. Caskey<sup>1</sup>, D. Karow<sup>1</sup>, J.C. Venter<sup>2</sup>, E. Kirkness<sup>1</sup>, N. Shah<sup>1</sup>. 1) Human Longevity, Inc, San Diego, CA; 2) J. Craig Venter Institute, San Diego, CA.

Despite the enormous U.S. healthcare spending of \$3.3 trillion in 2016, one in three individuals aged 50-75 die prematurely from major age-related chronic diseases. While cardio-metabolic factors remain one of the major risk contributors, the molecular underpinning of their effects is not yet fully understood. We introduce a unique platform of deep quantitative multimodal phenotyping that seeks to provide a comprehensive, predictive, preventative, and personalized assessment of an individual's health status. The offered multimodal assays include whole genome sequencing, advanced imaging, metagenomic sequencing, metabolome, electrocardiogram, and clinical labs. This platform provides critical data not only to identify previously undiagnosed disease states but also to identify early disease biomarkers. We present an analysis of the multimodal datasets that were collected for 1,253 seemingly healthy adults (median age 53; 63% male). To the best of our knowledge, this is the largest cohort with such a wide range of data modalities analyzed to date. To study disease risk and patterns of comorbidity in this high-dimensional dataset, we took an "unsupervised" approach and analyzed the cross-modality association network. More precisely, we identified pairs of variables across the different data modalities with statistically significant associations and used these pairs to construct an association network. The analysis of the cluster structure in this network reveals signatures and biomarkers for specific traits and conditions. In particular, the set of markers making up the "cardio-metabolic" cluster allowed us to identify individuals sharing similar molecular signatures and determine risk groups within the cardiac- and metabolic- disease conditions. This shows how the underlying structures in the association network can be used to define a clinically relevant health profile, thus providing a comprehensive view into an individual's health status.

**Untargeted metabolomics analysis identifies and replicates serum metabolites associated with kidney function among Bogalusa Heart Study and Multi-Ethnic Study of Atherosclerosis participants.** J.L. Nierenberg<sup>1</sup>, J. He<sup>1</sup>, C. Li<sup>2</sup>, X. Gu<sup>1,3</sup>, X. Mi<sup>1</sup>, S. Li<sup>1</sup>, L.A. Bazzano<sup>1</sup>, W. Chen<sup>1</sup>, J. Kinchen<sup>4</sup>, C.M. Rebholz<sup>5,6</sup>, J. Coresh<sup>5,6</sup>, A.S. Levey<sup>7</sup>, L.A. Inker<sup>8</sup>, M.G. Shlipak<sup>8</sup>, T.N. Kelly<sup>1</sup>. 1) Department of Epidemiology, Tulane University, New Orleans, LA, USA; 2) Department of Epidemiology & Biostatistics, College of Public Health, University of Georgia, Athens, GA, USA; 3) Department of Epidemiology, Fwui Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China; 4) Metabolon, Inc., Durham, NC, USA; 5) Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA; 6) Welch Center for Prevention, Epidemiology, and Clinical Research, Johns Hopkins University, Baltimore, MD, USA; 7) Division of Nephrology, Tufts Medical Center, Boston, MA, USA; 8) Department of General Internal Medicine, University of California San Francisco, San Francisco, CA, USA.

**Background:** Biological pathways related to reduced kidney function remain largely unknown. **Methods:** Untargeted ultrahigh performance liquid chromatography-tandem mass spectroscopy was utilized to detect and quantify serum metabolites. We used multivariate adjusted linear regression to examine associations between single metabolites and estimated glomerular filtration rate (eGFR, calculated with the creatinine based CKD-EPI equation) among 1,243 Bogalusa Heart Study participants (median eGFR: 94.4, 5<sup>th</sup>-95<sup>th</sup> percentile: 66.0-119.6 mL/min/1.73 m<sup>2</sup>). Replication (determined by statistical significance and consistent effect direction) was tested using gold standard measured glomerular filtration rate (mGFR) among 260 Multi-Ethnic Study of Atherosclerosis participants (median mGFR: 72.0, 5<sup>th</sup>-95<sup>th</sup> percentile: 43.5-105.0 mL/min/1.73 m<sup>2</sup>). All analyses used Bonferroni-corrected alpha-thresholds. **Results:** Twelve associated novel metabolites were comprised of carbohydrate (advanced glycation end-product), cofactor and vitamin (ascorbate & aldarate, nicotinate & nicotinamide, tocopherol & vitamin A), lipid (mevalonate and fatty acid & BCAA), nucleotide (pyrimidine metabolism, thymine containing), and xenobiotic (drug and bacterial/fungal) sub-pathways, along with two without fully characterized pathways (**Table**). **Discussion:** This analysis identified novel metabolites associated with kidney function, providing insight into pathway alterations in this complex phenotype.

**The Hutchinson-Gilford progeria syndrome mutation, *LMNA* c.1824C>T, is present as a somatic mutation in chronic kidney disease.** *H. T. Helgadottir<sup>1</sup>, N. Viceconte<sup>1</sup>, A. Witasz<sup>2</sup>, E. Wallén Arzt<sup>1</sup>, A. Sola Carvajal<sup>1</sup>, G. Revéchon<sup>1</sup>, A. Thorell<sup>3</sup>, D. McGuinness<sup>4</sup>, P.G. Shields<sup>1</sup>, A. Wernerson<sup>2</sup>, P. Stenvinke<sup>3</sup>, M. Eriksson<sup>1</sup>.* 1) Karolinska Institutet, Department of Biosciences and Nutrition, Center for Innovative Medicine, Huddinge, Sweden; 2) Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Division of Renal Medicine, Stockholm, Sweden; 3) Karolinska Institutet, Department of Clinical Sciences, Danderyds Hospital, Department of Surgery, Ersta Hospital, Stockholm, Sweden; 4) University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom.

Premature vascular aging is a hallmark of chronic kidney disease (CKD). The uremic phenotype include arteriosclerosis, loss of vascular smooth muscle cells, calcification and increased arterial stiffness. A similar vascular phenotype is also observed in children with the very rare premature aging disease Hutchinson-Gilford progeria syndrome (HGPS). While the risk factors for vascular disease in CKD include hypertension, dyslipidemia, hyperphosphatemia and diabetes, HGPS is almost exclusively caused by a single-nucleotide mutation in the *LMNA* gene, c.1824C>T. The mutation leads to increased production of a truncated lamin A protein (named progerin), resulting in dysregulation of cell functions. Progerin has also been found at low levels in fibroblasts, skin and arteries from non-progeroid individuals, but its underlying mechanism is unknown. Here we analyzed the presence of progerin expression in epigastric arteries obtained from CKD stage 5 patients (GFR <15 ml/min) and healthy controls, and its contribution to premature vascular aging. Immunofluorescence of uremic epigastric arteries showed progerin positive cells in 70% of the arteries (46±2 yrs, n=40). Progerin positive cells were almost exclusively detected in the tunica media, up to 7.4% of cells. The number of progerin positive cells correlated with number of years with the disease ( $P=0.03$ ,  $r = 0.34$ ). The arteries with higher frequency of progerin positive cells had an increased activation of DNA repair ( $P=0.005$ ,  $r = 0.63$ ) and increased senescence that correlated with increased vascular calcification. Somatic mutation analysis of DNA extracted from progerin stained sections from CKD arteries (n=27), using digital droplet PCR, identified the *LMNA* c.1824C>T mutation in 55% of the sections. The same somatic mutation was also detected as a rare event in DNA from blood of all CKD patients tested (n=26), and was more common than in the healthy controls ( $P=0.04$ ). Our results suggest that rare somatic mutations may become a risk when increased tissue regeneration is induced, and provide novel mechanistic insight to the underlying phenotype of premature vascular aging.

**Background:** Angiotensin-converting enzyme inhibitor (ACEi) and angiotensin receptor blocker (ARB) treatment is commonly used in hypertension, diabetic nephropathy and heart failure. A rare but potentially severe adverse reaction is angioedema, which is a swelling in the skin or mucosa. When located in the head and neck region it can be life-threatening due to asphyxiation. The objective of this genome-wide association study (GWAS) was to test whether any common genetic variant predisposes to angioedema induced by an ACEi or ARB. **Method:** 173 cases recruited in Sweden were genotyped on Illumina HumanOmni2.5 arrays, and compared with 4890 population controls genotyped on Illumina HumanOmniExpress 700K arrays. The merged genotyped dataset was imputed up to 7.6 million SNPs, and corrected for principal components 1-4. The genome-wide significance p-value threshold was set to  $p < 5 \times 10^{-8}$ . For the replication, 156 new cases and 58 treated controls from Sweden and Denmark were genotyped using TaqMan SNP genotyping assays, and  $p < 0.05$  was considered statistically significant. A meta-analysis was performed using the present GWAS, the Swedish/Danish replication cohort, plus 175 cases of ACEi-induced angioedema and 489 ACEi-treated controls from a previous GWAS in USA.<sup>1</sup> Functional annotations were obtained by testing top hits for linkage disequilibrium (LD) with variants in transcription factor binding sites and chromatin state models.<sup>2,3</sup> **Results:** SNPs in intron 1 of the *Calcium-activated potassium channel subunit alpha-1 (KCNMA1)* gene on chromosome 10 were significantly associated with angioedema (OR=2.47, 95% CI=1.79-3.42,  $p=4.31 \times 10^{-6}$ ). The subsequent replication and meta-analysis showed a tendency in the same direction (OR=1.51, 95% CI=0.56-4.09,  $p=0.42$ , and OR=1.89, CI=1.47-2.44,  $p=7.57 \times 10^{-7}$ , respectively). The associated *KCNMA1* SNPs lacked evidence of functional activity, but were in LD with variants located in transcription factor binding sites in relevant tissues. **Conclusion:** Our data suggest that common intronic variants of the *KCNMA1* gene may be associated with risk of angioedema induced by ACEi or ARB treatment. Future studies based on whole exome sequencing will show whether rare coding variants in *KCNMA1* or other genes contribute to angioedema risk. **References:** 1. Paré G, et al. **Independent effects of lifestyle and genetic factors on risk for coronary artery disease in a large and deeply-phenotyped cohort.** A. T. Magis<sup>1</sup>, X. Xu<sup>1</sup>, O. Manor<sup>1</sup>, M.P. Conomos<sup>1</sup>, J.E. Rohwer<sup>1</sup>, E. Sheng<sup>1</sup>, S.M. Speck<sup>2</sup>, G.S. Omenn<sup>3,4</sup>, N.D. Price<sup>1,3</sup>, J.C. Lovejoy<sup>1,3</sup>, L. Hood<sup>1,3,5</sup>. 1) Arivale, Inc, Seattle, WA; 2) Internal Medicine, University of Washington Medical Center, Seattle, WA; 3) Institute for Systems Biology, Seattle, WA; 4) Departments of Computational Medicine and Bioinformatics, Internal Medicine, Human Genetics, and School of Public Health, University of Michigan, Ann Arbor, MI; 5) Providence St. Joseph Health, Seattle, WA.

Genetic factors as well as unhealthy behaviors such as poor diet, lack of physical activity, and smoking are well-understood as risk factors for coronary artery disease (CAD), the leading cause of death worldwide. A recent seminal study showed that lifestyle and genetic risk factors are independently associated with long-term CAD outcomes but did not investigate their impacts on intermediate phenotypes. The goal of the current study was to characterize the independent impacts of genetic risk as well as lifestyle factors on risk for CAD using a large cohort of deeply-phenotyped individuals. Our study included 2,735 individuals participating in a commercial lifestyle coaching program (Arivale). Data collected included whole genome sequencing, 70 clinical tests, 273 plasma proteins, 961 metabolites, and 16S rRNA sequencing of the gut microbiome. Genetic risk for CAD was estimated using a validated polygenic risk score. Lifestyle risk factors examined were weekly physical activity, dietary pattern, and smoking status. Statistical associations between genetic risk, lifestyle risk factors, and phenotypes were identified using generalized estimating equations (GEE) adjusted for confounders including age, sex, race, observation month, BMI, and medication use. Our results show that, controlling for lifestyle, genetic risk for CAD is most significantly (FDR<0.05) associated with higher LDL cholesterol and LDL-P, lower absolute monocytes count, and higher levels of the protein granulin and the metabolite campesterol. In contrast, controlling for genetics and the other lifestyle risk factors, unhealthy diet is most significantly associated with higher insulin, hs-CRP, and triglycerides, lower omega-3 fatty acids, higher levels of the metabolites carotene diol and beta-cryptoxanthin, and several microbiome changes. Lack of physical activity is most significantly associated with lower HDL cholesterol and HDL-P, higher levels of the proteins leptin and fatty acid binding protein 4, lower levels of the metabolite phenyllactate, and decreased gut microbiome diversity. Smoking is most significantly associated with increased white cell count and increased levels of the metabolites cotinine and o-cresol sulfate, as well as decreased abundance of many microbiome taxa. Interestingly, relatively few phenotypes are associated with multiple risk factors. Our study improves the systemic understanding of CAD risk factors and provides a basis for personalized strategic interventions.

**A phenome-wide association study of genes involved in genetic syndrome reveals pleiotropic effects of common and rare alleles.** C. Tcheandjieu<sup>1,2,3</sup>, P. Saha<sup>1,2,3</sup>, P. Potiny<sup>1,2,3</sup>, S. Gustafsson<sup>1,3</sup>, E. Inglesson<sup>1,3</sup>, J. Priest<sup>1,2,3</sup>. 1) Stanford Cardiovascular Medicine, Stanford, CA; 2) Department of pediatric Cardiology; 3) Stanford school of Medicine.

Genetic syndromes (GS) are characterized by a defined set of symptoms or phenotypes which may be linked to one or more distinct loci. The clinical evaluation of a genetic syndrome relies upon recognition of a characteristic pattern of signs or symptoms to guide targeted genetic testing for confirmation of the diagnosis. However, individuals displaying component phenotypes of a complex syndrome may not meet criteria for clinical diagnosis or genetic testing. Here, we present a phenome-wide association study approach exploring pleiotropy of common and rare alleles in genes involved in GS. Using the UK Biobank, a large prospective cohort study of ~500,000 individuals with genotyping and health-related information, we systematically identified 60 phenotypes related to Alagille, Marfan, Usher, and Noonan syndromes by mapping human phenotype ontology (HPO) terms of each syndrome to ICD10 code diseases reported in the hospital admission record of each participant. We performed, in individuals from European ancestry, a logistic regression adjusted on age, sex, and the first 5 genetic principal components for each phenotype and each SNP in the target genes (*JAG1*, *FBN1*, *PTPN11*, *NOTCH2*, and *MAP2K1*). SKAT-o test was performed at the gene and FDR was used for multiple testing corrections. Several SNPs in *JAG1* (for Alagille syndrome) and *PTPN11* (for Noonan syndrome) were associated with diastolic BP, systolic BP, and urine microalbumin level ( $p < 10^{-6}$ ). In addition, SNPs in *PTPN11* were associated with mitral regurgitation ( $p < 10^{-9}$ ) hypothyroidism ( $p < 10^{-6}$ ) and body mass index ( $p < 10^{-6}$ ). Consistent with this, at a gene level, *JAG1* was associated with systolic BP ( $p = 3 \times 10^{-25}$ ), diastolic BP ( $p = 1 \times 10^{-27}$ ), chronic bronchitis ( $p = 1 \times 10^{-24}$ ) and, cataract ( $p = 5 \times 10^{-24}$ ); while *PTPN11* was associated with hypothyroidism ( $p = 8.8 \times 10^{-25}$ ), diastolic BP ( $p = 9.4 \times 10^{-25}$ ), urine micro albumin level ( $p = 6 \times 10^{-23}$ ) and umbilical hernia ( $p = 6 \times 10^{-23}$ ). Our preliminary observations clearly relate polymorphisms in *JAG1* and *PTPN11* in the general population with phenotypes observed in Alagille and Noonan syndromes. Increased urine microalbumin is likely a secondary phenotype related to kidney injury from elevated blood pressure. Our results suggest that SNPs in syndromic genes are causative of individual component phenotypes present in a general population. Further research is needed to characterize the pleiotropic effect of alleles in genes in persons without the corresponding genetic syndrome.

**3173F****Replication of a single nucleotide polymorphism variant in *CETP* gene associated with HDL level with tiled regression in the *ClinSeq*® Study.**

H. Sung<sup>1</sup>, J.A. Sabourin<sup>1</sup>, K. Lewis<sup>2</sup>, J.C. Mullikin<sup>3,4</sup>, L.G. Biesecker<sup>2</sup>, A.F. Wilson<sup>1</sup>, NISC Comparative Sequencing Program. 1) Genometrics section, Computational and Statistical Genomics Branch, NHGRI, NIH, Baltimore, MD, USA; 2) Medical Genomics and Metabolic Genetics Branch, NHGRI, NIH, Bethesda, MD, USA; 3) Comparative Genomics Analysis Unit, Cancer Genetics and Comparative Genomics Branch, NHGRI, NIH, Bethesda, MD, USA; 4) National Institutes of Health Intramural Sequencing Center (NISC), NHGRI, NIH, Bethesda, MD, USA.

*ClinSeq*® is a large-scale medical sequencing study designed to investigate associations of sequence variants with traits related to Coronary Artery Disease (CAD). The study currently includes more than 1000 non-smoking participants between the ages of 45 to 65 with normal to severe coronary artery calcification scores. About 200 CAD-related traits were measured at the NIH Clinical Research Center in Bethesda, MD. Exome sequencing was performed with four distinct capture kits at the NIH Intramural Sequencing Center (NISC): Agilent SureSelect with 38 Mb and 50 Mb (Index and ICGC) capture kits for 396 and 320 individuals, respectively, TruSeq (V1 and V2) for 285 individuals, and SeqCap EX Exom+UTR for 18 individuals respectively. Data cleaning was performed within each capture kit data set and then across data sets after merging within-cleaned capture kits. Only single nucleotide variants (SNVs) common to all capture kits were merged yielding 590,441 SNVs in 886 unrelated European Americans (EAs) for further analysis. Tests of association of each SNV with High Density Lipoprotein (HDL) level was performed on untransformed, log-transformed and rank-inverse transformed HDL adjusting for age, sex, BMI, and the usage of cholesterol lowering medication with simple linear regression and tiled regression. Using simple linear regression, rs1532625 in the intron of *CETP* gene was found to have the most significant association for untransformed and transformed HDL after Bonferroni correction, replicating the study by Reilly et al. [2013]. For untransformed and transformed HDL, one additional SNV, rs7205804 was found to be significant in the intron of the *CETP* at a significance level of 1e-06. Using tiled regression to identify variants that jointly and independently predict HDL over all variants tested, rs1532625, the most significant SNV found with simple linear regression, was selected in the final multiple-regression model. However, rs7205804, the second most significant variant in the simple linear regression analysis was not included in the final tiled regression model because of its high correlation with rs1532625. Rather than test variants individually, which can lead to increased type I error because of unrecognized correlation, testing variants in a multiple regression context reduces type I error and helps in prioritizing variants for additional follow-up.

Vandenberg<sup>1</sup>, R. Duggirala<sup>1</sup>, D.C. Glahn<sup>4,5</sup>, P.J. Meikle<sup>2</sup>, J. Blangero<sup>1</sup>, J.E. Curran<sup>1</sup>. 1) STDO and Department of Human Genetics, School of Medicine, University of Texas Rio Grande Valley, Brownsville, TX, USA; 2) Eli Lilly and Company, Indianapolis, IN, USA; 3) Menzies Institute for Medical Research, University of Tasmania, Hobart, TAS, Australia; 4) Olin Neuropsychiatric Research Center, Institute of Living, Hartford Hospital, Hartford, CT, USA; 5) Department of Psychiatry, Yale University School of Medicine, New Haven, CT, USA; 6) Baker Heart and Diabetes Institute, Melbourne, VIC, Australia.

Cardiovascular disease (CVD) is complex group of disorders that together are the leading cause of death worldwide. Identification of drug targets for preventative treatment is of significant clinical interest. Angiopoietin-like 3 (ANGPTL3) is one such CVD target, with clinical trials of inhibition of this protein currently underway. ANGPTL3 is a liver protein that has roles in lipid metabolism through the inhibition of lipoprotein lipase and endothelial lipase. Studies of ANGPTL3 in humans have focused on the classical clinical lipid parameters (HDL, LDL, TG, cholesterol). Given the potential for ANGPTL3 as a CVD drug target, deeper examination of clinically relevant phenotypes and disease outcomes is warranted. ANGPTL3 levels were measured in 1048 individuals from the San Antonio Family Heart Study. Using variance component modelling in SOLAR we found ANGPTL3 levels to be significantly heritable, ( $h^2=0.33$ ;  $P=1.19 \times 10^{-16}$ ). Given the recognized importance of ANGPTL3 levels in CVD we assessed the CVD relationship with protein levels in this cohort. We found that CVD was significantly associated with ANGPTL3 levels, with higher levels of ANGPTL3 associated with CVD, suggesting that lower ANGPTL3 levels are cardioprotective, ( $\beta=-0.89$  SDU,  $P=0.001$ ). Coding variants in *ANGPTL3* were tested for association with protein levels, identifying an unequivocal association of decreased ANGPTL3 levels ( $\beta=-1.66$  SDU,  $P=9.25 \times 10^{-13}$ ) with a 5 bp loss-of-function deletion, rs569107562. Previously identified by others as causing familial hypolipidemia in homozygous carriers, we identified 22 heterozygotes with this variant in a single Mexican American family. With lipidome profiling of 319 lipid species available in our cohort, we determined that rs569107562 carriers had significant reductions in levels of several phosphatidylinositol (PI) species including PI(36:2) ( $\beta=-1.38$  SDU,  $P=1.57 \times 10^{-7}$ ). ANGPTL3 levels overall also showed a strong positive association with PI levels (PI(36:2),  $\beta=0.77$  SDU,  $P=1.40 \times 10^{-5}$ ). The relationship between individual lipids and the therapeutic potential of reducing ANGPTL3 levels warrants further exploration in light of current research that suggests that statin based therapies work through PI reduction. This pedigree based study has used lipidome profiles and CVD outcomes to identify deeper phenotypic associations with ANGPTL3 levels than previously explored. Together this highlights the importance of decreasing ANGPTL3 levels for cardioprotection.

**Next-generation sequencing aligned to high-resolution nuclear magnetic resonance (NMR) measurements reveal role of rare variation in circulating metabolic biomarkers.** F. Riveros Mckay Aguilera<sup>1</sup>, C. Oliver Williams<sup>2,4</sup>, S. Karthikeyan<sup>2</sup>, K. Walter<sup>1</sup>, K. Kundu<sup>1,3</sup>, J. Danesh<sup>1,2,3</sup>, E. Wheeler<sup>1</sup>, E. Zeggini<sup>1</sup>, A. Butterworth<sup>2,3</sup>, I. Barroso<sup>1,6</sup>. 1) Wellcome Sanger Institute, Cambridge, United Kingdom; 2) MRC/BHF Cardiovascular Epidemiology Unit, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK; 3) The National Institute for Health Research Blood and Transplant Unit (NIHR BTRU) in Donor Health and Genomics, University of Cambridge, Cambridge, UK; 4) Homerton College, Hills Road, Cambridge, CB2 8PH, UK; 5) Department of Haematology, University of Cambridge, Cambridge Biomedical Campus, Long Road, Cambridge CB2 0PT, UK; 6) University of Cambridge Metabolic Research Laboratories and NIHR Cambridge Biomedical Research Centre, Wellcome Trust-MRC Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge, UK.

Circulating metabolite levels can be used as biomarkers, or risk factors, for cardiovascular disease (CVD). To establish the role of rare coding variation in circulating metabolic biomarker levels, we measured 226 serum lipoproteins, lipids and other amino acids and proteins in INTERVAL participants by NMR. Gene-based association analyses included whole-exome sequence (WES) data from 3,741 participants (discovery), and 3,401 whole-genome sequences (WGS) from independent participants (validation). To increase power at the validation stage, we used correlated NMR traits as covariates in the analysis. Compared to unadjusted tests, this approach increased power in known gene-trait associations (e.g. 11 additional gene-trait associations for *PCSK9*), and identified *ACSL1*, *MYCN*, *FBXO36* and *B4GALNT3* as novel gene-trait associations ( $P < 2.5 \times 10^{-6}$ ). Gene-set analyses identified novel association of loss-of-function (LoF) variants in the regulation of the pyruvate dehydrogenase (PDH) complex pathway, with lipoproteins in three broad categories intermediate density lipoproteins (IDL), low density lipoproteins (LDL) and circulating cholesterol ( $P_{\text{META-SKAT}} < 2.41 \times 10^{-9}$ ). This pathway is crucial for metabolic flexibility. In addition, genes near established HDL-associated loci were enriched for likely deleterious missense and LoF variants ( $P_{\text{Bonferroni}} < 0.005$ ) in 18 HDL related traits, suggesting this gene set is enriched for effector transcripts. Exploring phenotypic tails of 49 lipoprotein and lipid measurements, we found enrichment ( $P_{\text{permutation}} < 0.00037$ ) of likely deleterious rare variation in lipoprotein disorder and metabolism gene sets (e.g. hyperlipidaemia and HDL remodelling) in the lower tails of four measurements which are CVD risk factors (e.g. cholesterol in small VLDL and concentration of small HDL particles), demonstrating that rare "protective" variation is prevalent in the phenotypic tails of a healthy population. These findings provide novel biological insights into lipoprotein and lipid metabolism through rare variant analyses.

**Influence of a coronary-artery-disease-associated genetic variant on *FURIN* expression and effect of furin on macrophage behavior.** S. Ye<sup>1,2</sup>, G. Zhao<sup>2</sup>, W. Yang<sup>2</sup>, J. Wu<sup>2</sup>, B. Chen<sup>2</sup>, X. Yang<sup>2</sup>, J. Chen<sup>3</sup>, D.G. McVey<sup>1</sup>, C. Andreadi<sup>1</sup>, P. Gong<sup>1</sup>, T.R. Webb<sup>1</sup>, N.J. Samani<sup>1</sup>. 1) University of Leicester, Leicester, United Kingdom; 2) Shantou University Medical College, Shantou, China; 3) Beijing University Shenzhen Hospital, Shenzhen, China.

**Objective**— Genome-wide association studies have revealed a robust association between genetic variation on chromosome 15q26.1 and coronary artery disease (CAD) susceptibility; however, the underlying biological mechanism is still unknown. The lead CAD-associated genetic variant (rs17514846) at this locus resides in the *FURIN* gene. In advanced atherosclerotic plaques, furin is expressed primarily in macrophages. We investigated whether this CAD-associated variant alters *FURIN* expression and whether furin affects monocyte/macrophage behavior. **Approach and Results**— A quantitative RT-PCR analysis showed that leukocytes from individuals carrying the CAD risk allele of rs17514846 had increased *FURIN* expression. A chromatin immunoprecipitation assay revealed higher RNA polymerase II occupancy in the *FURIN* gene in mononuclear cells of individuals carrying this allele. A reporter gene assay in transiently transfected monocytes/macrophages indicated that the CAD risk allele had higher transcriptional activity than the non-risk allele. An analysis of isogenic monocyte cell lines created by CRISPR-mediated genome editing showed that isogenic cells homozygous for the risk allele had higher *FURIN* expression levels than isogenic cells homozygous for the non-risk allele. An electrophoretic mobility shift assay exhibited preferential binding of a nuclear protein to the risk allele. Studies of monocytes/macrophages with lentivirus-mediated furin overexpression or shRNA-induced furin knockdown showed that furin overexpression promoted monocyte/macrophage migration, increased proliferation and reduced apoptosis, whereas furin knockdown had the opposite effect. **Conclusion**— Our study shows that the CAD-associated genetic variant increases *FURIN* expression and that furin promotes monocyte/macrophage migration and proliferation while inhibiting apoptosis, providing a mechanistic explanation for the association between variation at the chromosome 15q26.1 locus and CAD risk.

**Modifiable risk factors and heart failure: A Mendelian randomization study.** S. Grover<sup>1</sup>, S. Rapp<sup>2</sup>, P.S. Wild<sup>2</sup>, I.R. Koenig<sup>1</sup>. 1) Institut für Medizinische Biometrie und Statistik, Universität zu Lübeck, Universitätsklinikum Schleswig-Holstein, Campus Lübeck, Lübeck, Germany; 2) Präventive Kardiologie und Medizinische Prävention, Zentrum für Kardiologie, Universitätsmedizin der Johannes-Gutenberg-Universität Mainz, Mainz, Germany.

Heart failure (HF) is a highly heterogeneous syndrome, and its diagnosis and treatment continues to pose serious challenges. Availability of improved imaging techniques has further lead to revised diagnostic groups with systolic (HF with reduced ejection fraction, HFREF) and diastolic HF (HF with preserved ejection fraction, HFPEF) contributing equally to increased morbidity and mortality rates. These subtypes of HF are assumed to be heterogeneous with regard to genetic aetiology and risk factors. Observational studies have reported obesity (OBS), hypertension (HTN) and diabetes (DBS) as likely risk factors associated with cardiovascular diseases (CVD). We perform a two sample Mendelian randomization (MR) study evaluating the causal effect of OBS, HTN and DBS on HF, HFREF and HFPEF in a European population of 3000 HF cases. To identify candidate instrument variables (IV) for judging the effect of risk factors on HF risk, we use glycated hemoglobin (HbA1c) and diagnosis of diabetes as the measures of diabetes, BMI and WHR for obesity, SBP and DBP for hypertension. We prioritize genetic loci that had reached genome-wide significant associations ( $P < 5 \times 10^{-8}$ ) in the largest available GWAS studies in European populations to date for all the risk factors. Inverse variance weighted (IVW) method, MR Egger and Weighted Median method are used to judge the causal effect. In addition to detection of pleiotropic variants through the heterogeneity Q test and the I<sup>2</sup> index, MR Egger method and funnel shaped distribution of individual SNP level causal effect estimates are also used. Furthermore, sensitivity analyses are conducted on the basis of instruments comprising a subgroup of SNPs with known biological function in predisposition to risk factors. In the absence of potential pleiotropic variants, MR approach overcomes the issues of confounding and reverse causality inherent in observational studies with an increased power in the presence of multiple SNPs. This approach may help us to identify causal markers for specific HF subtypes for potential intervention and to define underlying biological pathways.

**Utilizing admixture mapping to identify genomic regions associated with coronary artery calcification in African Americans.** Z. Liu<sup>1</sup>, N.F. Hansen<sup>1</sup>, J.C. Mullikin<sup>1,2</sup>. 1) Comparative Genomics and Cancer Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; 2) NIH Intramural Sequencing Center, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD.

Admixture mapping is a powerful technique to identify genetic loci for heritable traits. We set out to map loci for coronary artery calcification (CAC), which occurs in higher rates in European Americans than African Americans. African Americans have varying proportions of African ancestry, due to the admixture of European and African ancestral populations. Proceeding on the assumption that causal variants are more frequently found on DNA segments that were inherited from the ancestral population with the higher disease risk, we employed admixture mapping to identify genetic loci with excess local European ancestry in African Americans displaying our phenotype, and thereafter targeted these loci to map disease genes. The ClinSeq@A2 cohort includes 502 participants of self-reported African descent, aged 45-65 at enrollment, each of whom was exome sequenced and measured for CAC-related phenotypes. After QC, 475 individuals were retained. To infer local ancestry, we performed SEQMIX analyses using European and African datasets from the 1000 Genomes Project as references. We then averaged the inferred local ancestry across the entire genome for all individuals, and results showed that our study participants had an average of 23% European and 77% African ancestry. For global ancestry, we used LASER to calculate principal components (PCs), which explained variations among individual genotypes. The PC estimation of global ancestry showed high correlation with genome-wide averaged local ancestry ( $r < -0.97$ ). Based on the Agatston CAC scoring, we divided our samples into cases (CAC score  $> 0$ ; N = 135) vs. controls (CAC score = 0; N = 340), and performed admixture mapping between local European ancestry and CAC, adjusting for global European ancestry, age, sex, BMI and lipid statin. Results showed that chromosomal region 9p13 had the top association signal between local European ancestry and the presence of CAC (min  $P = 1.39E-03$ ,  $\beta = 1.58$ ), however, our results did not reach a genome-wide significant threshold of  $7.48E-04$  after multiple-testing correction. These results suggested that this region may harbor CAC related genes that lead to prevalence differences in racial-ethnic groups. We will perform a gene-based test within this region to further identify genes and verify them in an independent dataset. Admixture mapping is complementary to genetic association studies in admixed populations when the trait has prevalence deviations in racial-ethnic groups.

**3179F**

**Investigating pleiotropic architecture of 92 plasma proteins related to cardiovascular disease.** *L. Repetto<sup>1</sup>, Z. Ning<sup>2</sup>, A. Bretherick<sup>3</sup>, J.F. Wilson<sup>1,3</sup>, X. Shen<sup>1,2</sup>.* 1) Centre for Global Health Research, Usher Institute of Population Health Sciences and Informatics, University of Edinburgh, Teviot Place, Edinburgh, United Kingdom; 2) Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden; 3) MRC Human Genetics Unit, Institute of Genetics and Molecular Medicine, University of Edinburgh, Western General Hospital, Crewe Road, Edinburgh, United Kingdom.

**Motivation:** Multivariate genome-wide association analyses have been proven to provide higher power than standard univariate analyses in terms of discovering novel pleiotropic loci for a range of complex traits, e.g. omics phenotypes. This provides an opportunity to further understand the genotype-phenotype map between the genome and complex disease through omics measurements. **Results:** We measured a panel of 92 cardiovascular disease (CVD) -related plasma proteins in an isolated Scottish population (ORCADES) and conducted a 92-trait combined multivariate genome scan, using summary association statistics from 92 single-trait scans. We discovered 27 pleiotropic pQTL, and we replicate 17 multi-protein associations and examine the pleiotropic genetic effects using an independent cohort from Croatia (VIS). The replicated loci include the well-known ABO locus for blood types, whose association with CVD has been reported but not fully understood. Here, we provide a new multi-protein insight into the ABO-CVD connection. **Conclusion:** Our study provides new insights into shared genetic architecture across a set of human plasma proteins, as mediators of CVD. The analysis pipeline emphasizes the importance of secondary multivariate analysis of summary association statistics, as one can gain substantial statistical power and genetic interpretation that are difficult to achieve using conventional analyses.

**3180W**

**Toward precision medicine: LpPLA2 activity and a LpPLA2 GRS show an effect on cardiovascular outcomes stratified by glycaemic control.** *M.K. Siddiqui<sup>1</sup>, G.S. Smith<sup>1</sup>, C. Gao<sup>2</sup>, L. Wallentin<sup>3</sup>, H. White<sup>4</sup>, D. Waterworth<sup>5</sup>, C.N.A. Palmer<sup>1</sup>.* 1) University of Dundee, Dundee, United Kingdom; 2) Parexel International, Durham, NC, USA; 3) Department of Medical Sciences and Uppsala Clinical Research Center, Uppsala University, Uppsala, Sweden; 4) Green Lane Cardiovascular Service, Auckland City Hospital, and Auckland University, Auckland New Zealand; 5) GlaxoSmithKline, King of Prussia, PA, USA.

Lipoprotein-associated phospholipase A2 (LpPLA2) activity has a well-established biological and statistical association with major adverse cardiovascular events (MACE), independent of other risk factors. However, clinical trials for an LpPLA2 inhibitor darapladib has failed to show a significant reduction in MACE. Recently, it has been demonstrated that there is increased expression of LpPLA2 coding *PLA2G7* gene in adipose tissues of individuals with type 2 diabetes (T2D). We examined the impact of glycaemic control (GC) on the association between LpPLA2 and MACE and demonstrate consistent results in the STABILITY trial of darapladib. Further, we developed a genetic risk score (GRS) for this biomarker and performed a Mendelian randomization (MR) experiment to confirm our findings. Discovery analyses were performed in the GoDARTS cohort of T2D (n=7420). Subjects were classified as having good (HbA1c<48 mmol/mol, n=1979) or poor (HbA1c≥48 mmol/mol, n=5441) GC. The association was analysed using survival analyses with 10 years of follow-up from the time of LpPLA2 measurement. In the STABILITY trial, we would expect that darapladib would confer a protective effect against major coronary events (MCE) for diabetics (n=15,828). Therefore, participants were stratified by T2D status. 33.6 % of those on darapladib and 34% on placebo had type 2 diabetes. MR was conducted in the GoDARTS cohort by selecting SNPs from previous GWAS studies of LpPLA2 activity. In the GoDARTS study, amongst individuals with good GC, the highest quartile of LpPLA2 (Q4) had 1.2 times the hazards of MACE compared to the lowest quartile (Q1) (*Pvalue*=0.04), whereas for individuals with poor GC the hazards were 1.4 (*Pvalue*<1×10<sup>-3</sup>), an increase of 20%. In STABILITY, amongst participants with T2D, those randomized to receive darapladib were significantly protected against having a MCE, HR 0.72 (*Pvalue*=4 ×10<sup>-3</sup>) compared to placebo. MR analysis showed that the GRS was associated with MACE, the highest quartile showed hazards of 1.26 (*Pvalue*=9×10<sup>-3</sup>) compared to the lowest. However, when stratified, the effect was only evident in the sub-group with poor GC. These results suggest that high LpPLA2 activity might be especially important in patients with poorly controlled T2D. Therefore further investigation of the effects of darapladib in relation to T2D seems warranted. Further, the preliminary GRS suggests that personalised risk could be predicted without the need to directly measure enzyme levels.

**3181T**

**Investigation of the role of Growth Differentiation Factor 15 (GDF15) in human metabolic syndrome through population genetics.** *E.M. Wigmore<sup>1</sup>, S.M. Lemmela<sup>2</sup>, J. Merino<sup>3</sup>, A. Platt<sup>1</sup>, R. March<sup>1</sup>, A. Palotie<sup>2,3</sup>, M.J. Daly<sup>2,3</sup>, M. Kinnunen<sup>2</sup>, A. Matakidou<sup>1</sup>. 1) Centre for Genomics Research, Precision Medicine and Genomics, IMED Biotech Unit, AstraZeneca, Cambridge, UK; 2) Institute of Molecular Medicine Finland (FIMM), University of Helsinki, Helsinki, Finland; 3) Broad Institute of MIT and Harvard, Cambridge, USA.*

GDF15 is a stress responsive cytokine known to be upregulated in type 2 diabetes and cardiovascular disease. Recent data from animal models have reported that knock-out of *GDF15* results in increased body weight, whereas overexpression leads to reductions in body weight and fat mass and improved metabolic parameters. These studies have identified GDF15 as a potential target for the treatment of obesity and related diseases (Xiong et al., 2017). However, data supporting its causal role in human disease are currently lacking. Here, we utilise a well characterised, Finnish, population-based cohort with baseline serum protein levels (n= 5,817) to examine GDF15 phenotypic and genetic associations. Associations of serum GDF15 levels with clinical phenotypes have to-date been analysed for 166 clinical endpoints and 18 quantitative traits (n=184, multiplicity adjusted significance  $p < 2.7 \times 10^{-4}$ ). The most significant associations observed were with key components of metabolic syndrome: type 2 diabetes (OR= 1.5,  $P = 7.0 \times 10^{-12}$ ), serum insulin (beta= 0.02,  $P = 8.4 \times 10^{-12}$ ), serum triglycerides (beta= 0.14,  $P = 5.8 \times 10^{-23}$ ) and waist-to-hip ratio (beta= 0.066,  $P = 3.8 \times 10^{-10}$ ). Associations remained significant after correction for type 2 diabetes and body mass index (BMI). Consistent with previous reports we also observed associations with major cardiovascular events (OR=1.2,  $P = 1.1 \times 10^{-6}$ ), hypertension (OR=1.2,  $P = 1.1 \times 10^{-6}$ ), heart failure (OR=1.4,  $P = 5.4 \times 10^{-6}$ ), chronic kidney disease (OR=2.3,  $P = 8.5 \times 10^{-7}$ ) and cancer (OR=1.2,  $P = 4.8 \times 10^{-5}$ ) but not with diseases of the respiratory, neurological or gastrointestinal systems. These data support the previously reported role of GDF15 secretion as an adaptive response specific to cardiometabolic disease. To identify genetic drivers of serum GDF15, a genome-wide association analysis (GWAS) was performed. We identified a 100kb locus around the *GDF15* gene that strongly associated with protein levels ( $P = 4.6 \times 10^{-83}$ ) and fine mapping analysis identified four putative causal variants (rs16982345, rs1054221, rs3787023, rs189593084). These data provide the genetic instruments for Mendelian Randomisation methodologies that allow assessment of causality between GDF15 and body mass index and adiposity and clarification of its likely clinical utility as a human therapeutic target.

**Mutation spectrum in a large cohort of hypertrophic cardiomyopathy patients in Korea.** *D. Yang<sup>1</sup>, MW. Seong<sup>1,2</sup>, SC. Lee<sup>3</sup>, CS. Ki<sup>4</sup>, SH. Seo<sup>5</sup>, M. Kim<sup>6</sup>, SI. Cho<sup>7</sup>, DY. Kang<sup>6</sup>, SP. Lee<sup>7</sup>, HK. Kim<sup>7</sup>, DW. Sohn<sup>7</sup>, S. Park<sup>7</sup>.* 1) Seoul National UnivDepartment of Laboratory Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea; 2) Biomedical Research Institute, Seoul National University Hospital, Seoul, Korea; 3) Department of Internal Medicine, Samsung Medical Center, Sungkunkwan University College of Medicine, Seoul, Korea; 4) Department of Laboratory Medicine, Samsung Medical Center, Sungkunkwan University College of Medicine, Seoul, Korea; 5) Department of Laboratory Medicine, Seoul National University Bundand Hospital, Seoul National University College of Medicine, Seoul, Korea; 6) Department of Internal Medicine, Asan Medical Center, Seoul, Korea; 7) Department of Internal Medicine, Seoul National University Hospital, Seoul National University College of Medicine, Seoul, Korea.

**Purpose:** Hypertrophic cardiomyopathy (HCM) is characterized by left ventricular hypertrophy, particularly involving the interventricular septum, increased risk of sudden cardiac death, atrial fibrillation, and heart failure. Although progression in field of molecular genetics afford us insights into complex mechanism of the HCM, still identifying de novo and inherited variant is important. Here, we aimed to determine the mutational spectrum of the 36 HCM-related genes in a large cohort comprising 381 HCM patients referred to our laboratory. **Methods:** 36 hypertrophic cardiomyopathy-related genes were analyzed among 381 patients referred to our laboratory for genetic testing from 16 different hospitals throughout the country during 2013-2016. **Results:** Among 381 patients, 164 (43.0%) had single or multiple likely pathogenic (LP)/pathogenic (P) variants. Of 164 patients harboring one or more LP/P variants, 14 (8.5%) had multiple heterozygous LP/P variants, and 10 (6.1%) had genetic abnormalities in genes associated with systemic diseases accompanying HCM. **Conclusions:** To our knowledge, this is the largest nationwide study to reveal the mutational spectrum in Korean HCM patients using a comprehensive gene panel. Our results indicate that a comprehensive gene panel including non-sarcomere as well as sarcomere genes might be useful to diagnose HCM genetically.

**3183W**

**Sodium, potassium and cardiovascular disease in the UK Biobank: Observational analyses, GWAS and Mendelian randomization.** *D. Zanetti<sup>1,2</sup>, H. Bergman<sup>3</sup>, T.L. Assimes<sup>2</sup>, E. Ingelsson<sup>1,2</sup>*. 1) Stanford Cardiovascular Institute, Stanford University, Stanford, CA; 2) Department of Medicine, Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford, CA; 3) Department of Medical Epidemiology and Biostatistics, Karolinska Institute, Sweden.

**Background** Urinary sodium and potassium have been suggested to be associated with cardiovascular diseases (CVD) and type 2 diabetes mellitus (T2D), but it is unknown whether these associations are causal. Mendelian randomization (MR) is a new method to address this important question. **Methods** We performed multivariable regression models and multivariable-adjusted Cox proportional hazards models to assess associations of urinary sodium and potassium with several cardiovascular risk factors and outcomes in 483,063 participants of the UK Biobank. Further, we performed genome-wide association studies (GWAS) of sodium and potassium and we assessed the causal relationship of the above associations using the two-sample MR approach combining analyses in UK Biobank with publicly available data from GWAS. **Results** In our observational analyses, urinary sodium and potassium showed significant positive associations with body fat percentage, body mass index (BMI), and waist-to-hip ratio (WHR) ( $\beta$ , 0.05-0.17; per SD change in exposure and outcome) after Bonferroni correction ( $P \leq 2.1 \times 10^{-3}$ ). High sodium was associated with increased systolic blood pressure (SBP) ( $\beta$ , 0.02; per SD change in exposure and outcome); whereas high potassium was associated with lower SBP and diastolic blood pressure (DBP) ( $\beta$ , -0.11 and -0.08; per SD change in exposure and outcome, respectively). Urinary sodium showed significant inverse associations with atrial fibrillation (hazard ratio; 0.88), lipid-lowering medication and T2D (odds ratio [OR]; 0.96 and 0.97; respectively), whereas potassium showed significant positive association with lipid-lowering medication (OR; 1.03). We identified 38 genome-wide significant independent loci associated with sodium, and 12 for potassium. The MR analyses showed no evidence of causal associations of urinary sodium and potassium with SBP and DBP, BMI and WHR, or lipid levels (high and low-density lipoprotein cholesterol and triglycerides). The statistical power of our MR analyses to detect a causal effect of 0.15 SD change in outcome per 1-SD change in exposure was  $\geq 80\%$ . Sensitivity analyses provided consistent results and indicated no significant directional horizontal pleiotropy. **Conclusion** Our study indicates that although urinary sodium and potassium, used as a proxy for sodium and potassium intake, are associated with several cardiometabolic outcomes in observational analyses; the associations with blood pressure, obesity and lipid levels are unlikely to be causal.

**3184T**

**Genome-wide analysis of ex vivo coagulation biomarkers provides new insights into the genetic risk for venous thromboembolism.** *J.D. Backman<sup>1</sup>, S.E. McCarthy<sup>1</sup>, C. O'Dushlaine<sup>1</sup>, A. Marcketta<sup>1</sup>, A.H. Li<sup>1</sup>, J.H. Chung<sup>1</sup>, D.J. Carey<sup>2</sup>, D.H. Ledbetter<sup>2</sup>, O. Gottesman<sup>1</sup>, J.D. Overton<sup>1</sup>, J.G. Reid<sup>1</sup>, A. Baras<sup>1</sup>, F.E. Dewey<sup>1</sup>, T.M. Teslovich<sup>1</sup>*. 1) Regeneron Genetics Center, Tarrytown, NY; 2) Geisinger Health System, Danville, PA.

Venous thromboembolism (VTE) is a chronic, debilitating, and potentially life-threatening disease in which blood clots form abnormally and disrupt blood flow in the deep veins (Deep Vein Thrombosis), oftentimes embolizing and becoming lodged in the lungs (Pulmonary Embolism). The etiology of VTE involves a complex interplay of environmental risk factors and genetic predisposition, with hypercoagulability, inflammation, and reduced blood flow believed to be the triad of conditions that ultimately culminate in a thrombotic event. However, despite a strong genetic role and the apparent involvement of multiple tissues and biological pathways, insights from genetic studies of VTE have been limited, pointing primarily to variation in coagulation-related genes as the most prominent drivers of genetic risk. We hypothesized that the genetic analysis of coagulation-relevant phenotypes such as activated partial thromboplastin time (aPTT) and international normalized ratio of prothrombin time (INR), which measure the intrinsic and extrinsic coagulation pathways, respectively, can provide new insights into the etiology of VTE. We conducted the largest genome-wide analysis (GWAS) of aPTT and INR reported to date, identifying 5 novel association signals for aPTT and 11 novel association signals for INR in the DiscovEHR cohort (aPTT N=23,325; INR N=32,301). To evaluate clinical implications, we tested each variant for association with VTE risk in a total of 18,502 cases and 470,396 controls from the DiscovEHR and UK Biobank cohorts. We observed significant associations with VTE risk for 8 of the 23 independent variants we analyzed, including 3 variants in *F5* that associate with VTE independently of *F5* Leiden. As a complementary approach to our discovery analyses, we also queried the GWAS catalog for variants with links to 17 different hemostatic traits and performed follow-up analyses to determine whether these markers are associated with VTE risk. Of the 274 independent signals we mined from published studies, 72 variants were significantly associated with VTE risk after multiple-testing correction ( $P \leq 1.8E-4$ ). Several of these signals map to genes with minimal prior evidence for association with VTE, including *SCARA5*, *TC2N*, and *CLEC4M*. While further vetting and functional follow-up is required, these findings offer up potential new therapeutic targets for VTE treatment and provide novel insight into the genetic variation that predisposes to thrombotic event risk.

## 3185F

**Heritability of atrial fibrillation across a spectrum of clinical risk factors.**

L. Weng<sup>1,2</sup>, S. Choi<sup>2</sup>, A. Hall<sup>1,2</sup>, C. Roselli<sup>2</sup>, M. Chaffin<sup>2</sup>, P. Ellinor<sup>1,2</sup>, S. Lubitz<sup>1,2</sup>.

1) Massachusetts General Hospital, Boston, MA; 2) The Broad Institute of Harvard and MIT, Cambridge, MA.

**Background:** Atrial fibrillation (AF) is a common and morbid arrhythmia. Although AF is heritable (SNP-heritability [ $h^2_g$ ] 22%), the lifetime risk of AF is also influenced by clinical risk factors. The contributions of genetic predisposition to AF heritability across the spectrum of clinical risk factor burden has not been assessed. **Methods:** Our study included 345,373 unrelated individuals of European ancestry (AF-free at baseline) from the UK Biobank. We defined clinical risk factors for AF including obesity, smoking status, type 2 diabetes, hypertension, and coronary artery disease based on baseline interviews and medical data. Incident AF was ascertained through medical data or death records during follow-up. We assessed  $h^2_g$  of AF using a variance components method (BOLT-REML) on ~650K genotyped common/low-frequency variants (minor allele frequencies  $\geq 0.5\%$ ) across a spectrum of clinical risk factor burden (0, 1, and  $\geq 2$  clinical risk factors). All analyses were adjusted for baseline age, sex, array, and AF-related principal components of ancestry. **Results:** A total 9,337 individuals developed AF during follow-up. The baseline age was higher among those who developed incident AF than in those who did not (mean 62.7 vs. 57.1 years), and more were male (65% vs 46%). The overall  $h^2_g$  for incident AF was 17.4% (95%CI 15.2%-19.7%), and 15.5% (9.7%-21.4%) in individuals without any clinical risk factors. Similarly, the  $h^2_g$  for individuals with 1 or  $\geq 2$  clinical risks factors was 14.5% (8.6%-20.4%) and 17.2% (9.33%-25.0%), respectively. **Conclusion:** The additive genetic heritability of incident AF is about 17% and does not vary substantially by clinical risk factor burden. Thus, genetic variation is a significant contributor to AF susceptibility regardless of an individual's clinical risk factor profile.

## 3186W

**Identification of novel structural variations affecting common and complex disease risks with >16,000 whole genome sequences from ARIC and HCHS/SOL.**

G. Jun<sup>1</sup>, F.J. Sedlazeck<sup>2</sup>, H. Chen<sup>1</sup>, B. Yu<sup>1</sup>, Q. Qi<sup>3</sup>, O. Krashenina<sup>2</sup>, A. Carroll<sup>4</sup>, X. Liu<sup>1</sup>, A. Mansfield<sup>2</sup>, S. Zarate<sup>4</sup>, G. Metcalfe<sup>2</sup>, D. Muzny<sup>2</sup>, S. Lindstrom<sup>5,6</sup>, E. Selvin<sup>7</sup>, R. Kaplan<sup>3</sup>, W.J. Salerno<sup>2</sup>, R. Gibbs<sup>2</sup>, E. Boerwinkle<sup>1,2</sup>.

1) Human Genetics Center, School of Public Health, University of Texas Health Science Center at Houston, Houston, TX; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 3) Department of Epidemiology & Population Health, Albert Einstein College of Medicine, Bronx, NY; 4) DNAnexus, Mountain View, CA; 5) Fred Hutchinson Cancer Research Center, Seattle, WA; 6) Department of Epidemiology, School of Public Health, University of Washington, Seattle, WA; 7) Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University Baltimore, MD.

Despite their clear impact on Mendelian diseases, the contribution of structural variation (SV) to common complex phenotypes has been relatively understudied. A key missing opportunity has been the lack of available high-quality SV data in large deeply-phenotyped cohorts. We analyzed whole genome sequencing (WGS) data from 16,424 individuals: 6,369 European Americans (EAs) and 2,282 African Americans (AAs) from the Atherosclerosis Risk in Communities (ARIC) study and 7,772 individuals from Hispanic Community Health Study/Study of Latinos (HCHS/SOL) sequenced by NHGRI Centers for Common Disease Genomics (CCDG) and NHLBI Trans-Omics for Precision Medicine (TOPMed) projects. We developed a massively parallel SV discovery and genotyping pipeline, Parliament2, that integrates discovery from multiple methods across a large number of samples to maximize discovery sensitivity. We ran the Parliament SV discovery pipeline followed by muCNV multi-sample genotyper to obtain 163,292 deletions and 71,815 duplications. Most of SVs were rare with median MAF of 0.06%. We observed relatively more common SVs in AAs (median MAF 0.13%) than in EAs (0.05%) and in Hispanic/Latinos (0.03%). We assessed the contribution of individual SVs to multiple cardiometabolic, hematology and liver function quantitative traits (e.g. glucose, HbA1c, red blood cell indices, blood pressure, cholesterol, AST, ALT, and GGT). We identified a 2400-bp deletion overlapping *HBA2* in human alpha globin cluster to be significantly associated with lower hemoglobin ( $p=6.85 \times 10^{-21}$ ), hematocrit ( $p=6.38 \times 10^{-9}$ ), and higher HbA1c ( $p=1.74 \times 10^{-12}$ ) levels. MAF was 18% in AAs, 0.5% in EAs, and 5.0% in Hispanic/Latinos. We also discovered an 800-bp deletion in *BCRP3* at 22q11.23 that was significantly associated with higher gamma-glutamyltransferase (GGT) levels ( $p=5.7 \times 10^{-13}$ ), a clinical marker of liver and cardiometabolic diseases, located at approximately 9 kilobase downstream of *GGT1* that encodes type I GGT enzyme. This deletion was common (MAF 49%) in AAs, rare in EAs (MAF 0.26%), and intermediate (MAF 11%) in Hispanic/Latinos. In AAs, this variant explained 1.4% of variability of GGT levels. Our results suggest that structural variations may partially explain racial differences in the distributions of several biomarkers. These results establish a precedent for analysis of SV data for comprehensive assessment of the genetic architecture of common complex phenotypes.

Carr<sup>1</sup>, M. White<sup>1</sup>, A.J. Cassidy<sup>1</sup>, E.V. Baranova<sup>2</sup>, P. Hallberg<sup>3</sup>, E.R. Rasmussen<sup>5</sup>, N. Eriksson<sup>6</sup>, K. Bloch<sup>7</sup>, A. Alfrevic<sup>8</sup>, A.H. Maitland-van der Zee<sup>3,8</sup>, M. Wadelius<sup>4</sup>, C.N.A. Palmer<sup>1</sup> on behalf of PREDICTION-ADR. 1) Division of Molecular and Clinical Medicine, University of Dundee, Ninewells Hospital and Medical School, Dundee, Angus, United Kingdom; 2) Tayside Centre for genomic Analysis, School of Medicine, University of Dundee, Dundee, U.K.; 3) Division of Pharmacoepidemiology and Clinical Pharmacology, Utrecht University, Utrecht, The Netherlands; 4) Department of Medical Sciences, clinical Pharmacology and Science for Life Laboratory, Uppsala University, Uppsala, Sweden; 5) Department of Otorhinolaryngology, Head & Neck Surgery and Audiology, Rigshospitalet, University of Copenhagen, Denmark; 6) Uppsala Clinical Research Centre, Uppsala, Sweden; 7) Department of Molecular and Clinical Pharmacology, university of Liverpool, Liverpool, U.K.; 8) Department of Respiratory Medicine, Academic Medical Centre, University of Amsterdam, The Netherlands.

**Aims:** Angioedema occurring in the head and neck region is a rare extreme life-threatening reaction to angiotensin converting enzyme inhibitors (ACEI) and angiotensin receptor blockers (ARB). The European consortium PREDICTION-ADR was launched in 2013 to investigate the genetic variation responsible for extreme adverse drug reactions (ADRs) induced by ACEI or ARB and statins, using ascertained cases. **Methods and results:** Adjudicated cases of extreme ACEI or ARB-induced angioedema (ACEI-AE, ARB-AE) and controls had been recruited in 4 different centres: Uppsala (Sweden), Dundee (Scotland), Utrecht (The Netherlands), Liverpool (England). Sequencing of 1066 samples (408 ACEI and ARB cases, 658 controls) was performed using exome-enriched sequence data (SureSelect QXT, XT and XT2 reagents, Agilent Technologies, Wokingham, UK). After QC control, 1033 individuals (387 cases, 646 controls) with 128,157 SNPs (MAF<1%) and 50,838 SNPs (MAF>1%) were analysed. Common and rare *F5* variants seemed to be associated with ACEI-AE and ARB-AE phenotype. Common variant rs6025 (MAF=0.05) was found significantly associated with both ACEI and ARB angioedema [OR: 2.85, 95% confidence interval (CI): 1.89-4.25] where those homozygous for Arg534 had increased odds of developing ACEI-AE or ARB-AE. A group of 5 rare variants (MAF=5x10<sup>-4</sup>) in the *F5* gene (rs140530655, CHR1:169529903, rs200157005, rs149389480, rs143509841), was found to trend toward significance, p-value=2.09x10<sup>-3</sup> (corrected threshold for SKAT-0 analysis : 10<sup>-4</sup>). A combined genetic risk score (GRS) of these variants and rs6020 showed individuals carrying at least one of these variants had 2.21 (95% CI: 1.49-3.27) times the odds of having ACEI-AE or ARB-AE. **Conclusion:** This study suggests a role of the anticoagulation system in angioedema. Carrying an alternative variant of *F5* (rs6025, rs6020, rs200157005, rs149389480, rs143509841, CHR1:169529903 and CHR1:169529903) increases the odds of developing angioedema when treated with ACEI or ARB.

**Natural genetic variation of the human atrial transcriptome, proteome and metabolome.** I. Assum<sup>1,2</sup>, J. Krause<sup>3,4</sup>, M. Scheinhardt<sup>4</sup>, T. Zeller<sup>3,4</sup>, R. Schnabel<sup>3,4</sup>, M. Heinig<sup>1,2</sup>. 1) Institute of Computational Biology, Helmholtz Center Munich, Neuherberg, Germany; 2) Department of Informatics, Technical University of Munich, Garching, Germany; 3) University Heart Center Hamburg, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; 4) DZHK (German Center for Cardiovascular Research), partner site Hamburg/Kiel/Lübeck, Hamburg, Germany; 5) Institute of Medical Biometry and Statistics, University of Lübeck, University Hospital of Schleswig-Holstein, Campus Lübeck, Lübeck, Germany.

Genome-wide Association Studies (GWAS) have uncovered thousands of disease associated genetic loci. A common approach to identify underlying causal variants and genes is to consider tissue specific, cis-acting expression quantitative trait loci (cis eQTL). However, little is known about the downstream consequences on protein and metabolite levels. Here, we present a comprehensive systems genetics approach in human heart atrial appendage tissue samples from patients undergoing bypass surgery (N=75). This is the first survey that combines proteomics in disease relevant tissue with transcriptomics and metabolomics measurements. This unique data set allowed for the identification of widespread effects of genetic variants on cis regulatory elements for transcript (eQTL), protein (pQTL) and metabolite (mQTL) levels, as well as for an integrated analysis across molecular levels. We focused on a subclass of pQTLs, where the genetic variation in protein concentrations cannot be explained by the regulation of their corresponding mRNA and is most likely the result of posttranscriptional regulation or missense mutations. Our findings represent a powerful resource to follow up and understand genetic regulatory mechanisms, particularly for protein and metabolite variations related to cardiovascular disease. As an example we identified highly significant eQTL as well as pQTL for *MYOZ1* - a GWAS hit for atrial fibrillation, a disease directly related to atrial tissue.

**Linkage evidence and TOPMed whole genome sequencing identify multiple genes on chromosome 1 with rare variants associated with blood pressure.** K.Y. He<sup>1</sup>, H. Wang<sup>2</sup>, K. Schwander<sup>3</sup>, J.A. Smith<sup>4</sup>, T.N. Kelly<sup>5</sup>, X. Zhu<sup>1</sup>, D.K. Arnett<sup>6</sup>, TOPMed Blood Pressure Working Group. 1) Case Western Reserve University, Cleveland, OH; 2) Brigham and Women's Hospital, Boston, MA; 3) Washington University in St. Louis, St. Louis, MO; 4) University of Michigan School of Public Health, Ann Arbor, MI; 5) Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; 6) University of Kentucky College of Public Health, Lexington, KY.

Elevated blood pressure or hypertension is a major risk factor for coronary heart disease and cerebrovascular disease. The prevalence of hypertension in African Americans is among the highest in the world. We followed up a 33 Mb region with a linkage peak on 1q31 associated with pulse pressure (MLOD = 3.8) that was previously identified with 4,394 African American subjects (1,802 families) in the Family Blood Pressure Program, consisting of HyperGEN, GENOA, and GenNet. Here, we analyzed 2,806 African-American subjects in HyperGEN and GENOA that were whole-genome sequenced by TOPMed as a discovery cohort by conducting gene-based and single SNP association analysis in the linkage region for 3 blood pressure (BP) traits: SBP, DBP, and PP. We hypothesized that the linkage peak could be partially explained by low frequency and rare variants that are segregating in the families contributing to the linkage peak. Our analysis was restricted to variants that segregate at least twice within families that passed a variable threshold for family-specific LOD scores. We used functional annotation to focus on 174 protein-coding genes and analyzed functional coding variants and non-coding variants (MAF < 1%; CADD > 10) separately. Our analysis of selected functional coding and non-coding variants resulted in 46 unique genes with either burden or SKAT  $p < 0.05$  for at least 1 BP trait in the discovery cohort. These 46 genes were carried forward for verification analysis in 9 independent TOPMed studies consisting of 27,214 individuals of African, European, and Asian descent. In the multi-ancestry meta-analysis of functional coding variants, we observed 2 genes significantly associated with SBP and passed Bonferroni correction for multiple testing (*NAV1*,  $p = 0.0016$  for SKAT; *PTPN7*,  $p = 0.0012$  for burden test). For non-coding variants, there was 1 gene significantly associated with PP and passed the multiple testing threshold (*MR1*,  $p = 1.37 \times 10^{-6}$  for burden test). *MR1* is especially noteworthy because we identified 5 non-coding rare variants significantly associated with PP in the meta-analysis of African Americans ( $p = 0.0087$  for burden test) and passed the Bonferroni correction in the meta-analysis of European Americans ( $p = 1.7 \times 10^{-4}$  for burden test). Additional tissue-specific functional annotation analysis and gene expression association analysis are currently underway.

**Gender and age possibly affect the moderation of BDNF Val66Met genotype on psychosocial stress-related cardiovascular disease risk factors in a large harmonized sample?** R. Jiang<sup>1</sup>, M.A. Babyak<sup>1</sup>, A. Singh<sup>1</sup>, B.H. Brummett<sup>1</sup>, E.R. Hauser<sup>2,3</sup>, I.C. Siegler<sup>1</sup>, W.E. Kraus<sup>2</sup>, K.M. Huffman<sup>2</sup>, R.B. Williams<sup>1</sup>. 1) Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC; 2) Duke Molecular Physiology Institute, Duke University Medical Center, Durham, NC.

Our previous studies have shown that the *BDNF* Val66Met genotype moderates the association between psychosocial stress and risk factors of cardiovascular disease (CVD), namely a significant gene×stress interaction effect on the outcomes. However, the effect is inconsistent in the literature, perhaps due in part to small sample sizes with non-standardized measurements in individual studies, as well as failure to account for possible age and gender effect. This study examines whether the three-way interaction, age×gene×stress or gender×gene×stress, is associated with depressive symptoms and metabolic traits using a large harmonized dataset (N=33030) from 10 studies consisting of Duke in-house and dbGap public access datasets. Stress was scored using a validated algorithm based on specific stress components in each study. Depressive symptoms were assessed by available Center for Epidemiological Studies Depression Scale (CES-D) or proxy depression measures. Stress and depression measures were standardized within each study by transforming to z-scores. The three-way interaction was tested in a random intercepts model adjustment for age/gender. All analyses were stratified by race. Study source was specified as a random effect. No significant gender×gene×stress interaction was observed for any phenotype, but a marginally significant effect of age×gene×stress was observed on total cholesterol levels ( $P = 0.089$ ) and LDL ( $P = 0.044$ ) in whites. At older ages, the Val/Val carriers had higher total cholesterol (TCHOL) and LDL with increased stress levels compared with Met carriers, while at younger ages, the Val/Val carriers had lower TCHOL and LDL with increased stress levels compared with Met carriers. The further two-way interaction of gene×stress was not significant when stratified by race or gender. The association between stress and phenotypes was strong and consistent. Overall there were no significant three-way or two-way interactions after multiple testing correction, and no age or gender or genotype effect was associated stress-related risk factors in this large harmonized sample. The results of this study suggest that in a large individual participant data meta-analysis, previously observed relationships of the *BDNF* Val66Met were not replicated.

**Mega-analysis of the *EBF1* GxE association: Evaluation of differences in gene-by-stress interaction across race, sex, and age in harmonized datasets of over 27,000 individuals.** A. Singh<sup>1,2,3</sup>, M.A. Babyak<sup>1,2</sup>, B.H. Brummett<sup>1,2</sup>, W.E. Kraus<sup>3,4</sup>, I.C. Siegler<sup>1,2</sup>, E.R. Hauser<sup>3,5</sup>, R.B. Williams<sup>1,2</sup>. 1) Behavioral Medicine Research Center, Duke University School of Medicine, Durham, NC, USA; 2) Department of Psychiatry and Behavioral Sciences, Duke University School of Medicine, Durham, NC, USA; 3) Duke Molecular Physiology Institute, Duke University School of Medicine, Durham, NC, USA; 4) Department of Medicine, Duke University School of Medicine, Durham, NC, USA; 5) Department of Biostatistics and Bioinformatics, Duke University School of Medicine, Durham, NC, USA.

Developing robust estimates of the interactions among individual's genetic makeup and complex physiological aspects of race, sex, and age is critical in a precision medicine framework. In our prior work (Singh et al., *EJHG*, 2015) we identified a novel CVD-risk gene *EBF1* in the Multi-Ethnic Study of Atherosclerosis (MESA) White samples, where a common variant (rs4704963) contributed to inter-individual differences in central obesity (i.e., hip circumference, HIPCM) in the presence of chronic psychosocial stress. We replicated this association in multiple studies using synthetic stress measure derived by our algorithm based on proxy indicators of stress (Singh et al., *Gen. Epi*, 2015). Further, we observed this association only in female and predominantly in older White samples, suggesting race, sex, and age related differences. We now extend this prior work by testing for the *EBF1* SNPxSTRESS interaction with respect to HIPCM in a mega-analysis (i.e., joint analysis of the pooled samples), using harmonized data from 27,249 participants derived from nine studies, with a focus on formal testing of differences across race, sex, and age. We tested the 4-ways interaction term including SNP, stress, sex and race, which was not statistically significant at  $p < 0.05$ . We next fit the 3-ways interactions SNPxSTRESSxSEX, SNPxSTRESSxRACE, and SNPxSTRESSxAGE in regression models. Out of all these 3-ways interactions, only SNPxSTRESSxSEX resulted in a statistically significant association with HIPCM ( $p = 9.48E-04$ ). In order to better describe the differences among race, sex, and age with respect to the *EBF1* GxE association, we stratified the analysis by race, sex, and age (using bins age  $\leq 44$  and age  $> 44$ , based on the change in distribution of HIPCM over age). The SNPxSTRESS term  $p$ -values for all Whites (2.47E-07) and all Blacks (0.01), White Females (1.33E-07), Black Females (0.036), White Females of age  $> 44$  (1.26E-07), and Black Females of age  $> 44$  (0.046) were statistically significant. The  $p$ -values of the same interaction term for White Males (0.21), Black Males (0.20), White Females of age  $\leq 44$  (0.28), and Black Females of age  $\leq 44$  (0.96) were not statistically significant. We also observed the sex difference in stress main effect. Our work provides additional confirmation that common variation in *EBF1* contributes to inter-individual differences in human obesity in the presence of stress, and that the SNPxSTRESS interaction differs depending on the sex of participants.

**Multi-ancestry genome-wide meta-analysis incorporating gene-sleep duration interactions in 62,970 individuals identified potential novel loci for blood pressure.** H. Wang<sup>1,2</sup>, J. Lee<sup>1,2</sup>, R. Noordam<sup>3</sup>, D. Mook-Kanamori<sup>4,5</sup>, S. Redline<sup>1,2</sup>, CHARGE Gene-Lifestyle Interactions working group. 1) Division of Sleep and Circadian Disorders, Brigham and Women's Hospital, Boston, Massachusetts, USA; 2) Division of Sleep Medicine, Harvard Medical School, Boston, Massachusetts, USA; 3) Department of Internal Medicine, Section Gerontology and Geriatrics, Leiden University Medical Center, Leiden, the Netherlands; 4) Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, the Netherlands; 5) Department of Public Health and Primary Care, Leiden University Medical Center, Leiden, the Netherlands.

Long and short sleep duration are associated with elevated blood pressure (BP), possibly through effects on molecular pathways that influence neuro-endocrine and vascular systems. We hypothesized that differences in sleep duration may modify the effect of genetic factors on BP. Therefore, to gain new insights into the genetic basis of sleep-related BP variation, we conducted multi-ancestry genome-wide gene by sleep duration interaction analyses on four BP traits (systolic BP, diastolic BP, mean arterial pressure, and pulse pressure). Short and long sleepers were defined as cohort-specific 20% and 80% quantiles of age- and sex- adjusted sleep duration residuals. Analyses were performed with and without adjustment for BMI to investigate biological pathways independent of obesity. The primary analysis included 62,970 individuals, of which 40,385 were of European and 15,021 were of African ancestry, from 28 cohort studies. In multi-ancestry analysis, we identified 15 known and 20 potentially novel loci for BP ( $p < 5 \times 10^{-8}$ ), of which 3 loci displayed significant interactions with long sleep duration (*PODXL*, *C20orf96*, *CYYR1*;  $p < 5 \times 10^{-8}$ ). Secondary ancestry-specific analyses identified 9 known and 59 potentially novel loci in individuals of African ancestry and 4 known and 7 potentially novel loci in those of European ancestry. Novel loci overlapped genes enriched for expression in the hypothalamus, including several genes previously associated with cognitive and psychological traits (*CNTN5*, *PTPRN2*, *ASTN2*, *ROBO1*, etc.). These data suggest that long sleep duration, as a direct exposure or marker of other disorders, may modify genetic susceptibility to hypertension. Replication analyses using independent samples are ongoing.

## 3193T

**Genetic association studies of small vessel ischemic stroke stratified by APOE  $\epsilon$ 2/3/4 genotype.** J. Chung<sup>1,2</sup>, T. Jaworek<sup>3</sup>, S. Marini<sup>1,2</sup>, B.D. Mitchell<sup>3,4</sup>, J. Rosand<sup>1,2</sup>, C.D. Anderson<sup>1,2</sup>, International Stroke Genetics Consortium. 1) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA, USA; 2) Program in Medical and Population Genetics, Broad Institute, Boston, MA, USA; 3) Department of Medicine, Program for Personalized and Genomic Medicine, University of Maryland School of Medicine, Baltimore, MD, USA; 4) Geriatrics Research and Education Clinical Center, Baltimore Veterans Administration Medical Center, Baltimore, MD, USA.

**Background** Alzheimer's disease (AD) and cerebral small vessel disease (CSVD) share multiple clinical risk factors and pathological features. Apolipoprotein E (APOE)  $\epsilon$ 4 genotype is a well-known genetic risk factor for AD as well as for CSVD. A recent genome-wide association study (GWAS) in AD identified distinct genetic associations after stratification by APOE genotypes. We performed a similar GWAS for small vessel stroke (SVS), an acute manifestation of CSVD, stratified by APOE genotypes under the hypothesis that a similar novel result could be expected. **Methods** We analyzed samples from 7 genotyping platforms in the NINDS Stroke Genetics Network (NINDS-SiGN) of 2,436 subjects (145 cases; 2,291 controls) with APOE genotypes  $\epsilon$ 22 or  $\epsilon$ 23 ( $\epsilon$ 2+), 15,819 subjects (1,350 cases; 14,469 controls) with  $\epsilon$ 33, and 5,317 subjects (396 cases; 4,921 controls) with  $\epsilon$ 34 or  $\epsilon$ 44 ( $\epsilon$ 4+). After imputation to the Haplotype Reference Consortium, variants were tested for association in logistic regression against SVS status, adjusting for age, sex, and population structure. GWAS of SVS risk within APOE genotypes  $\epsilon$ 2/3/4 were conducted in each platform, with results combined by meta-analysis. **Results** We observed genome-wide significant associations at four novel loci including *ISL1* (rs115984524, minor allele frequency [MAF]=2.7%,  $P=1.3 \times 10^{-8}$ , heterogeneity  $I^2=75.7$ ) and *UNC13C* (rs79250948, MAF=1.4%,  $P=3.1 \times 10^{-8}$ ,  $I^2=83.4$ ) in the APOE  $\epsilon$ 2+ subgroup, *VN1R95P* (rs402464, MAF=1.6%,  $P=1.0 \times 10^{-8}$ ,  $I^2=80.6$ ) in the  $\epsilon$ 3, *KCNA4* (rs72883710, MAF=7.2%,  $P=1.2 \times 10^{-8}$ ,  $I^2=23.6$ ) in the  $\epsilon$ 4+. Cross-referencing these associations in GTEx, rs115984524, rs79250948 and rs72883710 are significant cis-eQTL for *ISL1* ( $P=0.02$  in pituitary), *UNC13C* ( $P=0.02$  in artery aorta) and *KCNA4* ( $P=0.007$  in adipose subcutaneous), respectively. **Conclusion** Our GWAS of SVS stratified by APOE  $\epsilon$ 2/3/4 alleles reveals several novel loci, as was the case for analogous analyses in AD. Among those, *ISL1*, related to insulin gene regulation and mature-onset diabetes, seems particularly promising given the emerging importance of glucose dysregulation in SVD pathogenesis. High heterogeneity was observed among some findings but may be due to small sample size. We have begun to replicate these associations in independent datasets across SVD traits in the International Stroke Genetics Consortium.

## 3194F

**Hyperuricemia is an early onset metabolic disorder causally associated with cardiovascular disease event in Han Chinese.** K.M. Chiang<sup>1</sup>, Y.C. Tsay<sup>2</sup>, D.C. Wu<sup>2</sup>, H.C. Yang<sup>2</sup>, Y.T. Huang<sup>2</sup>, C.H. Chen<sup>2</sup>, W.H. Pan<sup>1</sup>. 1) Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan; 2) Institute of Statistical Science, Academia Sinica, Taipei, Taiwan.

**Background:** Serum uric acid (SUA) has been gradually recognized as a potential risk factor for cardiovascular disease (CVD) in recent decades. However, whether the relationship is causal remains a topic of controversy. **Methods:** In this study, we employed two methods to show the importance of SUA in the pathogenesis of CVD development. Firstly, we performed an onset sequence study to examine the onset sequence of hyperuricemia in relation to five cardiometabolic diseases. Secondly, we carried out a Mendelian-randomization (MR) study, a nature's randomized trial, to make causal inference for the SUA-CVD relationship based on the weighted genetic risk score (wGRS) constructed from the SUA-associated single nucleotide polymorphisms (SNPs). The information and SNPs collected from the Cardiovascular Disease Risk Factors Two-Township Study (N=4,330) and Taiwan Biobank (n=10,000) was used, respectively. **Results:** The results of onset sequence study show that both of susceptible males and females tended to have onsets of hyperuricemia, hypo- $\alpha$ -lipoproteinemia in young adulthood, followed by other cardiometabolic diseases. For the MR analysis, the high SUA-wGRS group had a significantly elevated cumulative lifetime risk of CVD, compared to the low group (High vs. Low: odds ratio, OR=1.62, CI: 1.17-2.23,  $p=0.003$ ) with the adjustment for sex (Male vs. Female: OR=2.85, CI: 1.99-4.07,  $p<0.001$ ). Similar results were obtained using wGRS derived from other population's SUA influential SNPs. **Conclusions:** In this study, we showed that hyperuricemia is an earlier onset metabolic disorder compared to hypertension, hypertriglyceridemia and diabetes, indicating high SUA may play an upstream role in the cardiometabolic disease development. Our results from MR study, support a causal role of hyperuricemia on the CVD development.

**Genetic association of arterial stiffness index with incident coronary artery disease and congestive heart failure.** S.M. Zekava<sup>1,2,3,4,5</sup>, M. Haas<sup>2</sup>, K. Aragam<sup>2,4,5</sup>, C. Emdin<sup>2,6</sup>, A.V. Khera<sup>2,4,5,7</sup>, D. Klarin<sup>2,4,5</sup>, H. Zhao<sup>3,8</sup>, P. Natarajan<sup>2,4,5,7</sup>. 1) Yale School of Medicine, New Haven, CT; 2) Program in Medical and Population Genetics, Broad Institute of MIT and Harvard, Cambridge, MA; 3) Computational Biology & Bioinformatics Program, Yale University, New Haven, CT; 4) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA; 5) Cardiovascular Research Center, Massachusetts General Hospital, Boston, MA; 6) Harvard Medical School, Boston, MA; 7) Department of Medicine, Harvard Medical School, Boston, MA; 8) Department of Biostatistics, Yale School of Public Health, New Haven, CT.

Arterial stiffness index (ASI) is a noninvasive, rapid measurement extracted from finger infrared analysis. ASI has been independently associated with cardiovascular disease risk in multiple epidemiological studies; however, it is unknown whether these associations represent causal relationships. Here, we used Mendelian randomization to determine whether a genetic predisposition to increased arterial stiffness is associated with increased risk for incident CHF and CAD. We first performed a genome-wide association analysis of arterial stiffness index in 131,686 participants from the UK Biobank. Using these results, we developed a 744-variant polygenic risk score that robustly associated with ASI ( $P < 1 \times 10^{-300}$ , F-statistic=10,020), and tested its association with incident CHF and CAD through Mendelian randomization. Across nearly 400K participants of the UK Biobank and 200K participants of the CARDIOGRAM-plusC4D consortium, we do not find evidence supporting a causal association with incident CAD ( $P > 0.05$ ). However, we do observe evidence supporting a causal association of ASI with incident CHF (HR=1.23 per SD increase in genetically-mediated ASI,  $P = 5.7 \times 10^{-3}$ ), independent of other cardiometabolic risk factors. Furthermore, we find that the association with incident CHF is present only among individuals without hypertension (HR=1.52 per SD increase in genetically-mediated ASI,  $P = 1.3 \times 10^{-4}$ ) and not among those with hypertension ( $P > 0.05$ ) ( $P_{\text{interaction}} = 9.6 \times 10^{-3}$ ). These results are consistent with a causal association between ASI and CHF but not between ASI and CAD, and support ASI as an orthogonal clinical tool particularly for individuals without hypertension. Furthermore, these data suggest that reducing ASI, particularly among those without hypertension, may reduce risk for CHF.

**Genome-wide Mendelian randomization under pervasive pleiotropy.**

Q. Zhao<sup>1</sup>, J. Wang<sup>1</sup>, J. Bowden<sup>2</sup>, G. Heman<sup>2</sup>, Y. Chen<sup>3</sup>, G. Davey Smith<sup>2</sup>, N. Zhang<sup>1</sup>, D.S. Small<sup>1</sup>. 1) University of Pennsylvania, Philadelphia, PA; 2) University of Bristol, Bristol, UK; 3) University of Michigan, Ann Arbor, MI.

Mendelian randomization (MR) uses genetic variants as instrumental variables (IV) to estimate the causal effect of biomarkers on complex traits. The recent "omnigenic" model suggests that, for most complex traits, there are extremely large numbers of weak genetic signals spread across the genome. This poses two major challenges to MR: most genetic instruments for the target biomarker are expected to be weak, and it is highly likely that they influence the trait via other causal pathways (aka horizontal pleiotropy) and thus violate a core IV assumption—exclusion restriction. We propose a principled statistical method, MR-RAPS (Robust Adjusted Profile Score), that allows the utilization of all instruments across the genome, both weak and strong in magnitude. MR-RAPS requires GWAS summary data and consistently estimates the causal effects under pervasive but balanced pleiotropy. It is also robust to invalid IVs with large direct effects on the outcome as long as they are sparse. Through extensive validation studies, we find MR-RAPS to be much more powerful and robust than existing MR methods, especially in scenarios with many weak genetic IVs. We further propose a comprehensive framework, GRAPPLE (Genome-wide mR Analysis under Pervasive Pleiotropy), for causal discoveries using MR-RAPS. Through an integrated workflow, GRAPPLE allows the identification and adjustment of multiple unbalanced pleiotropy pathways. Through mode analysis of the RAPS likelihood, GRAPPLE also identifies the causal direction. Finally, GRAPPLE allows for sample overlap in the GWAS cohorts. We apply GRAPPLE to public GWAS summary data to screen for causal relationships between blood lipids, BMI, CRP (C-reactive protein), and a panel of disease outcomes. In real data scenarios where the causal relationships are known, GRAPPLE reaffirms the relationships and substantially improves the statistical power and diagnostics. Our new findings include: 1. There are multiple pleiotropic pathways between CRP and CAD (coronary artery disease); 2. HDL cholesterol has a statistically significant protective effect on type 2 diabetes and CAD; The last finding of HDL and CAD is consistent with the inverse association long witnessed in observational epidemiology, but contrasts sharply with the null findings in most existing MR studies of HDL. This suggests that the recent controversy of the HDL hypothesis may be due to insufficient statistical power when only strong SNPs are used in MR analyses.

**3197F**

**NOTCH3 p.R544C mutation is a common and significant risk factor for ischemic stroke in Taiwanese population.** Y.C. Liao<sup>1,2</sup>, C.P. Chung<sup>1,2</sup>, M.H. Chang<sup>2</sup>, Y.C. Lee<sup>1,2</sup>. 1) Taipei Veterans General Hospital, Taipei, Taiwan; 2) Department of Neurology, National Yang-Ming University School of Medicine, Taipei, Taiwan; 3) Department of Neurology, Taichung Veterans General Hospital, Taipei, Taiwan.

**Objective** Mutations in *NOTCH3* gene cause cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL), which was previously considered a rare familial disease with the prevalence of 2-5 cases per 100,000. A recent study showed that the frequency of cysteine-altering *NOTCH3* mutations in public exomic database is 100-fold higher than that expected. We previously found 70.5% of the CADASIL pedigrees in Taiwan was attributed to the *NOTCH3* p.R544C mutation and approximately 3% of the CADASIL patients carried a homozygous p.R544C mutation, suggesting that this mutation may be prevalent in Taiwanese population. The present study aims at determining the frequency of *NOTCH3* p.R544C mutation in Taiwanese general population and investigating its influence on ischemic stroke. **Methods** The study participants included 6647 anonymous healthy subjects from Taiwan Biobank, 490 stroke-free individuals enrolled from Taipei Veterans General Hospital, and 815 ischemic stroke patients recruited from two medical centers in Taiwan. Genotyping of *NOTCH3* p.R544C mutation was performed using Applied Biosystems TaqMan technology. The genetic effect of *NOTCH3* p.R544C mutation was evaluated by multivariate regression model with adjustment of traditional vascular risk factors. The Trial of Org 10172 in Acute Stroke Treatment (TOAST) classification was used to define stroke subtypes. **Results** Sixty-one of the 6647 community controls was found to carry the *NOTCH3* p.R544C heterozygous mutation, suggesting 0.9% of Taiwanese general populations harboring this genetic risk factor. From the 490 stroke-free, cognitive-intact individuals recruited from hospital, four were found to carry the p.R544C mutation and all of them had diffuse leukoencephalopathy on magnetic resonance images of brain. The *NOTCH3* p.R544C mutation was detected in 16 of the 815 (1.96%) ischemic stroke patients, including one with cardioembolic stroke and 15 with small vessel occlusion. *NOTCH3* p.R544C mutation conferred a 6.89-fold risk for lacunar infarct and a 2.18-fold risk for overall stroke. **Conclusions** *NOTCH3* p.R544C mutation is a common and significant risk factor for ischemic stroke in Taiwanese population. This genetic risk factor is not only detected in familial stroke patients, but also present in one percent of Taiwanese population. Screening the *NOTCH3* p.R544C mutation in asymptomatic persons may help primary stroke prevention via blood pressure control and smoking cessation.

**An extreme phenotype approach identifies novel genes associated with carotid plaque in a multi-ethnic cohort.** B. Doliner<sup>1</sup>, N. Dueker<sup>2</sup>, S.H. Blanton<sup>2</sup>, L. Wang<sup>2</sup>, C. Dong<sup>2</sup>, H. Gardner<sup>2</sup>, R. Sacco<sup>1,2</sup>, T. Rundek<sup>1,2</sup>. 1) Department of Neurology, University of Miami, Miami, FL; 2) Department of Human Genetics, University of Miami, Miami, FL.

Identifying subclinical cardiovascular disease confers a benefit to patients in the absence of traditional risk factors. Carotid plaque is an accepted marker of subclinical atherosclerosis and predictor of cardiovascular events. Specific genetic variants contributing to plaque have not been well established. We previously identified linkage and association of common variants (CVs) on four chromosomal regions with total carotid plaque area (TCPA). However, identified variants account for only a portion of the total heritability. We aimed to identify additional CVs contributing to TCPA using an extreme phenotype approach in a multi-ethnic cohort. To identify TCPA extremes, the residual TCPA for each participant was determined by regressing TCPA on significant known risk factors. Individuals in the upper and lower 10% (Hispanics; n=180) or 20% (non-Hispanic blacks, n=94 and whites, n=60) threshold of the residual distributions were included in this study. Participants were genotyped using the Affymetrix 6.0 SNP array and these data were imputed to the 1000 Genomes phase 1, version 3 reference panel. Using logistic regression, adjusting for principal components of ancestry, a genome-wide association study was performed separately in each of the three race/ethnic groups and results were meta-analyzed using METAL. Genome-wide gene-based analyses were performed using VEGAS2 and overrepresentation enrichment pathway analysis was implemented in WebGestalt 2.0. Among SNP based meta-analyses, nine SNPs were suggestively associated with extreme TCPA ( $p < 0.0001$ ). The top SNP, rs10779703, was an intronic variant in *RERE* ( $p = 2.0 \times 10^{-6}$ ). In gene-based meta-analyses, 19 genes were suggestively associated with extreme TCPA ( $p < 0.001$ ) and pathway analyses revealed an enrichment for the bitter taste receptors (TAS2Rs) among these genes. This pathway consisted of two G-protein coupled receptors, *TAS2R50* ( $p = 4.9 \times 10^{-4}$ ) and *TAS2R20* ( $p = 6.9 \times 10^{-4}$ ), as well as a downstream component of the signaling cascade, *ITPR3* ( $p = 7.9 \times 10^{-4}$ ), known to modulate intracellular calcium release. TAS2R agonists induce vasodilation in vascular smooth muscle (VSM) and have anti-mitogenic properties in airway smooth muscle by downregulating growth factors and promoting apoptosis in Bnip-3 linked pathway. VSM proliferation is a core component of atherogenesis and, as such, variation in bitter taste receptors may influence atherosclerosis, making taste receptor genes promising candidates for carotid plaque.

To date, majority of participants included in genome wide association studies (GWAS) are of European descent (EUD). American Indian (AI) populations remain underrepresented in GWAS, including lipid levels, inflammatory markers, and subclinical cardiovascular disease (CVD). The Tsimané are a Bolivian AI population of forager-horticulturalists living a traditional lifestyle similar to that experienced throughout human pre-history. This population exhibits low-density lipoprotein cholesterol (LDL) level similar to the target levels of current statin and add-on pharmacological interventions, such as PCSK9 inhibitors. Given their genetic architecture and unique CVD risk profile, this population provides a unique opportunity to study the genetic underpinnings of CVD health. Admixture estimates are 97% Native American, <1% African, and 3% European ancestry on average. All samples were genotyped on the Illumina MEGA array and imputed to 1000 genomes phase 3. We performed GWAS association analysis for serum lipid values (LDL, high-density lipoprotein cholesterol [HDL], triglyceride [TG] and total cholesterol [TC], n=829) and presence of atherosclerotic plaques (carotid or femoral artery, n=303) in 1,214 individuals representing 180 families with 8,602 relative pair types with genotype and imputed data (Illumina MEGA array imputed to both the TOPMed and 1000 Genomes AMR reference panel). We performed linear mixed models, assumed an additive genetic model, adjusted for sex, age, body mass index and ancestry principal components, and accounted for family structure through kinship coefficients. In this subset of data, we identified a novel variant (rs7770909) associated with the presence of plaques in the right carotid artery ( $p = 1.7823 \times 10^{-8}$ ). Further, we replicated many previously identified lipids loci, and have several suggestive associations pending replication. The identification of potential novel CVD-risk loci in the Tsimané underscores the importance of examining diverse populations. We hope these findings, like past investigations in population isolates, will lead to identification of CVD-associated variants that offer protection against CVD.

**3200F****Whole genome sequencing identifies multiple rare variants in GT-Pase-activating protein (DLC1) associated with sleep disordered breathing. J. Liang<sup>1</sup>, K. He<sup>1</sup>, J. Lee<sup>2</sup>, B. Cade<sup>2</sup>, H. Wang<sup>2</sup>, X. Guo<sup>3</sup>, D. Gottlieb<sup>2</sup>, S. Gharib<sup>4</sup>, J. Rotter<sup>5</sup>, X. Lin<sup>6</sup>, S. Redline<sup>2</sup>, X. Zhu<sup>1</sup> On Behalf of the TOPMed Sleep Working Group.**

H. Chan School of Public Health, Boston, Massachusetts.

Average nocturnal oxygen saturation (SaO<sub>2</sub>) is a clinically relevant measure of physiological stress associated with sleep disordered breathing that predicts cardiovascular disease and mortality. We report genetic associations of average SaO<sub>2</sub> measured during sleep using the high depth whole genome sequencing data from the NHLBI TOPMed project. To improve power, we focused our analyses on a 21 Mb linkage region identified in European Americans from the Cleveland Family Study (CFS). We prioritized the low frequency and rare variants that contributed to the observed linkage evidence. Non-coding variants were filtered using CADD scores >10, reflecting in silico pathogenicity. We identified 12 candidate genes ( $P < 0.05$ ) associated with average nocturnal SaO<sub>2</sub> in this region. Follow-up analysis of these variants in the 12 candidate genes in 5 independent samples enrolled in the TOPMed project identified 6 coding and 51 noncoding variants in GTPase-activating protein (DLC1) significantly associated with average nocturnal SaO<sub>2</sub> after Bonferroni correction in gene based tests ( $P = 0.021$  for coding and  $P = 2.11 \times 10^{-6}$  for noncoding variants). The noncoding variants were significantly enriched in regulatory features in the Human Lung Fibroblast cell line ( $P = 0.003$ ) and significantly contribute to the DLC1 expression level in human skin cells-transformed fibroblasts ( $P = 2.6 \times 10^{-4}$ ). The polygenic score built on the effect sizes estimated from the independent samples explained 0.97% of the variation in SaO<sub>2</sub> levels and a significant portion of the observed linkage evidence in CFS ( $P < 0.001$ ). Although DLC1 has been reported to be associated with lung function, our analysis demonstrated that the low and rare variant association of DLC1 with average nocturnal SaO<sub>2</sub> persisted after adjusting for spirometric measures of lung function, suggesting pleiotropic effects. This analysis highlights that although individual effect sizes of rare and low-frequency variant are often small, when aggregated, they may account for substantial variation of polygenic human phenotypes such as SaO<sub>2</sub>, and these variants can be uncovered by family cohorts with moderate sample size.

## 3201W

**Investigation of novel variations of *ORAI1* gene and their association with Kawasaki disease.** K. Thiha<sup>1</sup>, Y. Mashimo<sup>1</sup>, H. Suzuki<sup>2</sup>, H. Hamada<sup>3</sup>, A. Hata<sup>4</sup>, T. Hara<sup>4</sup>, T. Tanaka<sup>5</sup>, K. Ito<sup>6</sup>, Y. Onouchi<sup>1,6</sup>. 1) Department of Public Health, Chiba University Graduate School of Medicine, Chiba, Japan; 2) Department of Pediatrics, Wakayama Medical University, Wakayama, Japan; 3) Department of Pediatrics, Tokyo Women's Medical University, Yachiyo Medical Center, Yachiyo, Chiba, Japan; 4) Fukuoka Children's Hospital and Medical Center for Infectious Diseases, Fukuoka, Japan; 5) Department of Human Genetics and Disease Diversity, Tokyo Medical and Dental University (TMDU), Tokyo, Japan; 6) Laboratory for Cardiovascular Disease, RIKEN Center for Integrative Medical Sciences, Yokohama, Japan.

Kawasaki disease (KD; MIM#611775) is an acute systemic vasculitis syndrome which predominantly affects children younger than 5 years and is the leading cause of acquired heart disease of childhood in developed countries. Genome-wide studies have identified several common susceptibility variants for KD but the involvement of rare variants in KD pathogenesis is largely un-investigated. In this study we conducted a large scale association study for rare variants of *ORAI1* gene in which one common and one rare variants have been reported to confer KD. The study included 3,900 KD and 2,645 controls to determine *ORAI1* protein coding region using direct sequencing. The scoring for deleteriousness of the single variants as well as insertion/deletion variants were predicted by Combined Annotation Dependent Depletion (CADD). The Collapse method was applied for variants with low allele frequencies for which  $\geq 0.75$  of statistic power to detect association with  $P < 0.05$  under assumption of odds ratio of 3.0 was not expected. Association of the individual as well as collapsed multiple rare variants with KD were assessed by Fisher's exact test. Thirty-four variants (5 common ones with minor allele frequencies (MAF)  $\geq 0.05$  and 29 rare ones with MAF  $< 0.01$ ) were identified within 903 bases of *ORAI1* coding region. The 27 rare variants were previously not examined and had no association with KD either as a single variant or as a single collapsed one. Interestingly, six rare deleterious missense variants (MAF  $< 0.001$ , C-score  $\geq 20$ ) including p.Gly98Asp which has been proved to lead constitutive  $Ca^{2+}$  entry to the cell were exclusively seen in KD patients (OR =  $\infty$ ,  $p = 0.046$ ). Conversely, frameshift variants ( $n = 5$ ), identified near the N-terminus and assumed to disrupt *ORAI1* function, showed the opposite trend of association (OR = 0.35,  $p = 0.24$ ). These findings suggest involvement of rare variants of *ORAI1* into KD pathogenesis and further support our hypothesis that upregulation of  $Ca^{2+}$ /NFAT pathway underlies KD inflammation. Precise information about the functional significance (i.e. neutral, disruptive or gain-of-function) might be helpful in assessing association in the gene-based collapsing method.

Population isolates, such as Finland, show an enrichment of loss-of-function (LoF) variants with potential impact on phenotypes and disease risk. We tested if some of the LoF variants were associated with blood lipids in Finns. Our study consisted of 2,017 autosomal LoF variants with MAF between 1.0e-03 and 0.1 in 1,781 genes. We tested their association with LDL-C, HDL-C, TC and triglycerides in the population-based FINRISK cohort (N=25,414) with genome-wide genotyping and imputation using a Finnish imputation reference panel. We found high-effect lipid-modulating LoF variants in four genes without previously reported studies of human knockouts. Protein-disrupting variants in *ANGPTL4* (rs746226153, MAF=4.8e-03, effect=-0.30 mmol/L,  $P = 7.9e-10$ ) and *ANGPTL8* (rs760351239, MAF=1.9e-03, effect=-0.48 mmol/L,  $P = 4.2e-08$ ) were associated with lower triglyceride levels. Angptl4 and Angptl8 are LPL-inhibiting proteins, with an essential role in triglyceride trafficking during fasting and feeding respectively. The triglyceride-lowering effect of the *ANGPTL4* and *ANGPTL8* LoF mutations was stronger in individuals with longer and shorter fasting times respectively, which is in line with murine models. We also observed LoF variants with substantial HDL-increasing effect in *LIPG* (rs200435657, MAF=1.7e-03, effect=0.10 mmol/L,  $P = 2.7e-13$ ) and *CETP* (rs751916721, MAF=1.5e-03, effect=0.19 mmol/L,  $P = 9.0e-34$ ). Pooling individuals from five Finnish population-based cohorts (N=38,618) we observe a protection against coronary artery disease by the *ANGPTL4* (OR=0.57,  $P = 8.2e-03$ ) and *ANGPTL8* (OR=0.24,  $P = 6.1e-03$ ) LoF alleles. The *ANGPTL8* truncating variant was also associated with lower risk of diabetes (OR=0.47,  $P = 0.042$ ). In a phenome-wide scan across EHR data, the *ANGPTL4* LoF allele associated with an increased risk of lymphatic disorders: Non-Hodgkin lymphoma (OR=3.04,  $P = 0.018$ ) and lymphoma (OR=2.77,  $P = 0.028$ ). The therapeutic safety of *ANGPTL4* inhibition has been questioned due to lymphatic lipid accumulation in animals. A phenome-wide screen of the *ANGPTL8* LoF mutation showed increased risk of multiple metabolic and psychiatric endpoints, including thyroid gland disorders (OR=3.60,  $P = 1.9e-04$ ), inflammatory liver disease (OR=8.40,  $P = 0.0119$ ) and depression (OR=2.20,  $P = 0.018$ ). Our study shows the potential in combining genome data with rich nationwide health registry data in an isolated population such as Finland to learn about potential drug targets and their possible safety.

**3203F****Bayesian whole genome association analysis of gene-age interactions.**

*M. Kerin*<sup>1,2</sup>, *K. Sharp*<sup>1</sup>, *J. Marchini*<sup>1,2</sup>. 1) University of Oxford, Oxford, Oxfordshire, United Kingdom; 2) Wellcome Trust Center for Human Genetics, University of Oxford.

Age is often included in genetic association studies as an important explanatory factor, but few studies have investigated interactions between age and genetic variants, and whether this can explain a fraction of the heritability in a given trait. We have developed a Bayesian whole genome regression approach that jointly models the main effects of each SNP as well as multiplicative SNP-age interaction effects. Our model has separate sparse spike and slab priors on the effect sizes of main effects and interaction effects. We use Variational Bayes to fit the model and use a mixture of exact and gradient-based updates to optimize over the hyper-parameters. This avoids having to search over a grid of hyper-parameter values. The method estimates the proportion of variance explained (PVE) by main effects and by SNP-age interactions, as well as identifying loci with non-zero main and interaction effects. The method is implemented in C++ using multi-threading to increase computational efficiency. The computational complexity of the method is linear in sample size and number of SNPs. On the simulated data with 10,000 individuals at 100,000 SNP loci the method takes 30 minutes to run to convergence using 5 cores. When data is simulated PVE by main effects and by SNP-age interactions of 0.4 and 0.1, our method produces estimates of 0.398 (se 0.003) and 0.099 (se 0.001) respectively. We applied the method to a genetic association study of Pulse Pressure in 342,673 participants at 721,836 genotyped SNPs from the UK Biobank study. Running on a single core, our analysis takes a median of 83 hours and uses 240GB of RAM. The method estimates that ~1% of SNPs have a non-zero main effect and that the PVE by main effects is 11.69%. For SNP-age interactions our method infers a PVE of only 0.12%. However, our method infers 8 loci with a posterior probability of inclusion (PIP) above 0.9. Using a simpler GWAS approach that analyzes each SNP independently, we find that all of these 8 SNPs show genome-wide significant main effects, but 3 of the 8 SNPs (rs4717862, rs4908857 and rs35688424) do not show significant SNP-Age interaction effects. We have observed that two of these SNPs (rs4717862 and rs35688424) are near genes (*ELN* and *MRC2*) that play a role in extracellular matrix remodelling.

**3204W****A statistical method for testing pleiotropy using GWAS summary statistics.** *X. Li, X. Zhu.* Department of Population and Quantitative Health Sciences, School of Medicine, Case Western Reserve University, Cleveland, OH.

Genome-wide association studies (GWASs) have identified many genetic loci which appear to harbor variants that are associated with multiple traits, which terms a cross-phenotype (CP) association. CP association can be caused by biological, mediated or spurious pleiotropy. In this study we propose a two stage method using summary statistics from GWAS to differentiate biological, mediated and spurious pleiotropy. At stage 1 we separate spurious pleiotropy from the others. At stage 2 we further separate mediated from biological pleiotropy. Our simulations suggest that the proposed method can differentiate different pleiotropies. We applied our method to the summary statistics of height and BMI from GIANT consortium (Yengo et al. 2018 bioRxiv). Among the reported 3,290 and 716 independent common variants for height and BMI, respectively, 302 variants demonstrate either biological pleiotropy or colocalization effects after adjusting for multiple tests ( $P < 1.52E-5$ ), suggesting shared genetic pathways. We also applied the method to the 901 reported systolic, diastolic and pulse blood pressure loci (Evangelou et al. 2017 bioRxiv) using the summary statistics from the International Consortium of Blood Pressure. We observed eight loci with biological pleiotropy/colocalization evidence, including *PKHD1*, *VMP1*, *ULK4*, *HSD52-MIR4711*, *CDKN2B*, *FAM208B*, *CCDC30/CLDN19* and *PDE3A/CACNA1C* ( $P < 5.55E-5$ ). Our study demonstrates that summary statistics from GWAS can further help to understand the inter-phenotype relationship contributed by genetic factors.

**3205T**

**Joint modeling of rare inherited and *de novo* variants identifies congenital heart disease risk genes.** M. Li<sup>1</sup>, L. Jin<sup>2</sup>, Q. Lu<sup>3</sup>, S. Jin<sup>4</sup>, X. Zeng<sup>4</sup>, W. Dong<sup>4</sup>, M. Brueckner<sup>4</sup>, R. Lifton<sup>4,5</sup>, H. Zhao<sup>1,6</sup>. 1) Department of Biostatistics, Yale School of Public Health; 2) Department of Molecular, Cellular and Developmental Biology, Yale University; 3) Department of Biostatistics and Medical Informatics, University of Wisconsin-Madison; 4) Department of Genetics, Yale University; 5) Laboratory of Human Genetics and Genomics, Rockefeller University; 6) Program of Computational Biology and Bioinformatics, Yale University.

Recent studies have demonstrated the important role of *de novo* mutations (DNMs) in the etiology of early-onset diseases. The study of DNMs in congenital heart disease (CHD) parent-offspring trios has led to the identification of multiple disease genes. However, gene identification based on DNMs remains challenging due to low mutation rate. With few recurrence of DNMs in the same gene, such studies may be underpowered. In this project, we describe a hierarchical Bayesian framework for gene-level association test which jointly analyzes *de novo* and rare inherited variants. By explicitly modeling the joint probability of multiple types of variants in trios, our method has higher statistical power than analyses based on DNMs only. We incorporated gene-level annotations (e.g. gene length and sequence context) and data from a reference panel (e.g. gnomAD) to accurately characterize the expected frequencies of both *de novo* and transmitted rare variants, which further improved the statistical power of our method. We applied our model to whole-exome sequencing data from 2,645 CHD parent-offspring trios (Jin et al. 2017), and confirmed a number of previous findings. We replicated multiple known CHD genes that were previously identified using DNM enrichment analysis (e.g. *PTPN11*, *KMT2D*, and *CHD7*), as well as a few risk genes that were enriched for rare, transmitted damaging variants (e.g. *GDF1* and *MYH6*). More importantly, our model implicated novel risk genes for CHD. One example is *SULF1*, a gene that is intolerant to loss-of-function variants ( $pLI=0.88$ ), specifically abundant in mouse developing heart, and known to associate with mesomelia-synostosis syndrome. These results suggest that, through joint modeling of rare inherited and *de novo* variants, our method can effectively improve disease gene discovery. Our analysis also identified novel risk genes and provided new insight into the genetic basis of CHD. Our method may benefit future sequencing-based studies in disease trios and accelerate findings of risk genes.

**3206F**

**Multi-phenotype genome-wide association study of protein levels in individuals with pulmonary arterial hypertension.** E. Pileckyte<sup>1</sup>, M. Kaakinen<sup>1,2</sup>, C.J. Rhodes<sup>2</sup>, M. Wilkins<sup>2</sup>, I. Prokopenko<sup>2</sup>, NIH Bioresource for Rare Diseases. 1) Section of Genomics of Common Disease, Department of Medicine, Imperial College London, London, United Kingdom; 2) The Centre for Pharmacology and Therapeutics, Department of Medicine, Imperial College London, London, United Kingdom.

Genome-wide association studies (GWAS) have identified numerous genetic risk factors associated with complex human traits and diseases but large proportion of heritability remains unexplained. To increase the locus discovery power, intermediate phenotypes, e.g. protein levels, and multi-phenotype analyses can be used. We aimed to identify genetic risk variants underlying susceptibility to pulmonary arterial hypertension (PAH), a rare but severe complex disease. We performed standard GWAS and multi-phenotype (MP) GWAS of SOMAscan platform 1,124 blood plasma protein levels in 128 European idiopathic, heritable, or drug-/toxin-induced PAH patients to identify one-variant-one-phenotype and one-variant-multiple-phenotypes associations, respectively. We defined proteins related to cardiovascular, metabolic, inflammatory, pulmonary, immune processes, and stress response, based on SOMAscan protein platform classification. Prior to analysis, each protein level was natural logarithm transformed and adjusted for age, sex, and four principal components to control for population stratification. The resulting residuals were further inverse-normal transformed to assure normality. In standard GWAS, we discovered 27 protein quantitative loci (pQTLs) with genome-wide significance corrected for multiple testing ( $P\text{-value}<4.45\times 10^{-11}$ ), among which four were novel *trans*-pQTLs: at *ELK2AP* for DR3, near *TMEM215* for Properdin, near *MIR4435-1* for C1r, and near *RETNLB* for HGFA. We then performed MP-GWAS using SCOPA software that implements "reverse regression" approach. We analysed a cluster of 26 proteins with pulmonary, stress response, and immune functions, and identified one pQTL at *PDGFRB* with genome-wide significance ( $P\text{-value}<5\times 10^{-6}$ ). The association is driven by proteins Calcineurin alpha isozyme, Cathepsin H, epidermal growth factor receptor (ERBB1), Nectin-like protein 2, and platelet-derived growth factor receptor beta polypeptide (PDGF Rb). The pQTL is novel for the first four proteins and is in *trans*. Calcineurin alpha isozyme, Cathepsin H, and ERBB1 are involved in blood vessel and lung development, and Calcineurin alpha isozyme mutations are associated with cardiac hypertrophy, an abnormal heart muscle enlargement, that can be caused by hypertension. Nectin-like protein 2 and ERBB1 mutations are involved in lung cancer. These large-scale proteomics GWAS in PAH patients identified potentially PAH-specific pQTLs not reported previously in studies of healthy individuals.

**A multi-phenotype analysis of coagulation factor plasma levels identifies genetic variants influencing levels of fibrinogen and Factor XIII.** M. Lerro<sup>1</sup>, P. Wells<sup>2</sup>, P. Morange<sup>3</sup>, D. Tregouet<sup>4,5</sup>, F. Gagnon<sup>1</sup>. 1) University of Toronto, Toronto, Ontario, Canada; 2) University of Ottawa, Ottawa, Canada; 3) INSERM, Marseille, France; 4) Sorbonne Universites, Paris, France; 5) ICAN, Paris, France.

Plasma levels of coagulation-related proteins affect risk of venous thromboembolism (VTE). Genetic variants that explain their levels have been identified in analyses using a univariate outcome. We assessed association of genome-wide SNPs with plasma levels of 13 coagulation-related proteins using groups of variables as multivariate outcomes in a sample (n=255) of five French-Canadian pedigrees ascertained on VTE. Testing of associations with multiple outcomes can be more powerful when using correlated traits and it allows fewer statistical tests. Proteins were clustered into correlated groups based on plasma levels and association analyses were performed for each group. Four clusters were identified using a PCA-based approach: 1. vWF and FVIII; 2. FIX, FX, and prothrombin; 3. plasminogen activator inhibitor, FXI, FXI, and tissue factor pathway inhibitor; 4. fibrinogen and FXIII. 489,241 SNPs were tested for association while controlling for age, sex, and family structure. The cluster of FVIII and vWF showed a significant association on chromosome nine at the ABO locus (p = 5E-8), a known predictor, and a suggestive association on chromosome 15 in SRP14-AS1 (p = 6E-7). SRP14-AS1 relates to the exportation of proteins from cells. Fibrinogen and FXIII showed an association on chromosome 6 at BTBD9 (p = 9E-8) and on chromosome 20 within MACROD2 (p=5E-9). The SNP identified in BTBD9 has been previously associated with ischemic stroke. MACROD2 is associated with the presence of anti-phospholipid antibodies. Antiphospholipid syndrome is a condition associated with VTE, and was an exclusion criterion of the FVL study. Additionally, MACROD2 variants have been seen to be associated with plasma levels of MMP7, a protein that is elevated in patients following a VTE event. The genetic associations showed strong signals in single-outcome analyses, but were not genome-wide significant, demonstrating improvements made by this approach. We are currently replicating in a second French sample. We also tested for differential expression of the genes MACROD2 and BTBD9 in blood of a separate VTE case-control study to understand potential mechanisms. BTBD9 was more highly expressed in cases than controls after adjustment for blood cell type proportions (p = 3E-3), and MACROD2 showed under-expression in cases, but this was not significant (p = 9E-2). We plan to further examine the effects of the identified variants by testing their association with nearby DNA methylation.

**Investigating the role of  $\beta 4GALT-1$  and  $\beta 4GALT-1 N352S$  in lipid metabolism and atherosclerosis.** G. Della Gatta<sup>1</sup>, C. Van Hout<sup>1</sup>, M. Montasser<sup>2</sup>, B. Shen<sup>3</sup>, N. Li<sup>3</sup>, L. Miloscio<sup>1</sup>, G. Tzoneva<sup>1</sup>, S. Taylor<sup>2</sup>, E. Streeter<sup>2</sup>, G. Gong<sup>2</sup>, S. Hartford<sup>3</sup>, D. White<sup>3</sup>, E. Pefanis<sup>3</sup>, T. Persaud<sup>1</sup>, V. Gusarova<sup>3</sup>, J. Haller<sup>3</sup>, C. Schoenherr<sup>1,3</sup>, B. Zambrowicz<sup>3</sup>, A. Economides<sup>1,3</sup>, A.R. Shuldiner<sup>1,2</sup>. 1) Regeneron Genetics Center, Regeneron Pharmaceuticals, Tarrytown, NY 10591, USA; 2) School of Medicine, Division of Endocrinology, Diabetes and Nutrition, and Program for Personalized and Genomic Medicine University of Maryland, Baltimore, MD, 21201, USA; 3) Regeneron Pharmaceuticals, Tarrytown, NY 10591, USA.

The distinctive genomic architecture of founder populations, such as the Old Order Amish (OOA) of Lancaster PA, provides unique opportunities to discover novel genotype-phenotype associations relevant to human health and disease. Exome sequencing (n=5,297) in the OOA identified a variant, c.1055A>G in the  $\beta 4$ -galactosyltransferase-I gene corresponding to an asparagine to serine substitution at position 352 of  $\beta 4GALT-1$  protein (N352S). While very rare in the general population, the N352S variant drifted to a frequency of 6% in the Amish.  $\beta 4GALT-1$  N352S carriers showed: (1) lower LDL-cholesterol (17.3 and 31.2 mg/dL LDL in heterozygotes and homozygotes, respectively (p=1.3x10<sup>-9</sup>); (2) lower fibrinogen (p=3.2x10<sup>-6</sup>); (3) and decreased coronary artery calcification (p=0.04).  $\beta 4GALT-1$  belongs to the beta-1,4-galactosyltransferase family of type II membrane-bound glycoproteins that mostly reside in the trans-Golgi apparatus.  $\beta 4GALT-1$  contributes to the synthesis of N-linked glycan chains, transferring galactose from UDP-galactose to N-acetylglucosamine (GlcNAc). The N352S variant resides very close to the active site of the enzyme. To understand the mechanisms underlying the cardioprotective effects of N352S on serum lipids and fibrinogen, we measured by LC-MS N-linked glycan profiles in serum of N352N and N352S homozygotes (n=12 each). Compared to N352N homozygotes, N352S homozygotes had significantly decreased galactosylation of total serum glycoproteins (6.7%), fibrinogen (15.1%) and IgG (25.7%, p<0.0001 for all). Moreover, ELISA assays on the same samples, showed significant decreases of LDL-c, APOB and PCSK9 protein levels (32%, p= 0.0003; 32%, p=0.001; 14%, p=0.07, respectively) as well as an increase of APOA1 levels (26%, p= 0.002) in N352S homozygotes compared to the N352N homozygotes. Finally, preliminary *in vivo* analyses of  $\beta 4galt-1$  gene-specific liver KO using Cas9 ready mice and gRNA delivery by AAV8, showed that liver-specific  $\beta 4galt-1$  KO leads to lower serum LDL-c (55%, p<0.0001, at 8 weeks from AAV8 injection) compared to Cas9 ready liver knock out control mice. Overall, our data suggest a previously uncharacterized role of  $\beta 4GALT-1$  in cholesterol metabolism. Further studies of  $\beta 4GALT-1$  could lead to the discovery of new molecular pathways and therapeutic targets for lipid disorders and cardiovascular disease.

**Inter-species differences in response to hypoxia and oxidative stress in iPSC-derived cardiomyocytes from humans and chimpanzees.** *M.C. Ward<sup>1</sup>, Y. Gilad<sup>1,2</sup>*. 1) Department of Medicine, University of Chicago, IL; 2) Department of Human Genetics, University of Chicago, IL.

The basis for complex polygenic diseases such as cardiovascular disease is unclear; however despite anatomical similarities, there appear to be differences in susceptibility between primates. For example, humans are prone to ischaemia-induced myocardial infarction unlike chimpanzees, which tend to suffer from fibrotic disease. At a molecular level, it has been suggested that differences in oxidative stress contribute to inter-species susceptibility to disease. However, it has been difficult to test whether these are true intrinsic inter-species differences due to uncontrolled effects of environmental factors and small sample sizes. The ability to differentiate cardiomyocytes from induced pluripotent stem cells (iPSCs), in both species, now allows for direct inter-species comparisons. In order to understand human-specific regulatory adaptations in the heart, and to gain insight into the evolution of disease susceptibility and resistance, we developed a model of hypoxia and oxidative stress in human and chimpanzee cardiomyocytes. We differentiated eight human and seven chimpanzee iPSC lines, together with six technical replicates, into cardiac troponin-positive iPSC-derived cardiomyocytes under normoxic conditions. We subjected these cells to 6 hours of hypoxia, followed by 6 or 24 hours of re-oxygenation, and collected genome-wide gene expression data, as well as measurements of cellular stress at each time-point. The overall cellular and transcriptional response to hypoxic stress is highly correlated across species with 1,920 genes responding similarly between humans and chimpanzees. 636 genes show a species-specific trajectory during the course of the experiment, while 147 genes show a species-specific response only in the hypoxic state. For example, *RASD1* is up-regulated specifically in human following hypoxia, and is a coronary artery disease GWAS hit of unknown function. Our results provide the first direct molecular measurements following cellular stress in human and chimpanzee cardiomyocytes, and suggest a degree of species-specificity in the transcriptional response in these two closely related species.

**Integrative Bayesian analysis of high-throughput functionalization assays identifies variants controlling the expression of CD36 and other platelet genes.** *A. Ghazi<sup>1</sup>, N. Madan<sup>2</sup>, L. Edelstein<sup>2</sup>, E. Chen<sup>3</sup>, C. Shaw<sup>2</sup>*. 1) Quantitative and Computational Biosciences, Baylor College of Medicine, Houston, TX; 2) Cardeza Foundation for Hematologic Research, Thomas Jefferson University, Philadelphia, PA; 3) Molecular and Human Genetics, Baylor College of Medicine, Houston, TX.

Most human DNA is non-coding, and recent studies have shown the importance of non-coding variation for gene regulation in both pathological and physiological functions. There is a considerable level of gene expression and phenotypic variation in human platelets that associates with non-coding genetic variants. However, inspecting the function and transcriptional impact of individual variants on regulatory activity with traditional assays is time-consuming and costly. The Massively Parallel Reporter Assay (MPRA) addresses this problem by examining the transcriptional activity of thousands of variants in parallel using next-generation sequencing (NGS). We have used MPRA to study the impact of non-coding regulatory variation present in human megakaryocytes, which give rise to human platelets. The use of MPRA study permits for the first time the examination of platelet eQTLs for functional analysis. However this assay in turn poses large statistical problems: a heavy multiple testing burden, high levels of noise, and experimental data structure that defies the assumptions underlying traditional statistical methods. In order to gain the statistical efficiency needed to address these problems, this project introduces a fully Bayesian negative binomial model of MPRA data that allows for the integration of diverse prior information. We've applied this model to existing MPRA datasets, showing that the new method identifies large numbers of putatively functional variants and provides clear inference on model parameters. We also investigate the ability of a diverse set of external genomic annotations to provide prior information depending on MPRA assay cell types and conditions. Finally, we also show that this variety of Bayesian negative binomial models are readily extensible to other high-throughput NGS-based assays such as CRISPR screens. To pilot our approach, we performed our own MPRA experiment on eighty-one variants in CD36, an important platelet lipoprotein receptor. Using our statistical method, the MPRA results and additional validation experiments lead us to identify a single SNP, rs2366739, that causes a large negative reduction in CD36 expression. An ongoing platelet-focused, large scale MPRA is testing the impact of thousands of variants on many platelet-related genes.

**DIVaH: A variant calling algorithm to identify CRISPR/Cas9 induced mutations in zebrafish.** E. Mazzaferro<sup>1,2</sup>, D. Manyara Wairimu<sup>1,2</sup>, C. Song<sup>1,2</sup>, M. den Hoed<sup>1,2</sup>. 1) Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; 2) Science for Life Laboratory, Uppsala University, Uppsala, Sweden.

The rapid development and progress of genome editing and sequencing techniques facilitates modeling of diseases and studying of gene function *in vivo*. However, while being an essential step to identify causal genes, haplotype-specific calling of CRISPR/Cas9-induced mutations remains challenging. We developed an algorithm to accomplish this in a computationally efficient manner. The variant calling algorithm DIVaH (Danio rerio Identification of Variant by Haplotype) can identify CRISPR/Cas9-induced mutations from paired-end sequencing of 150 to 400 bp amplicons across multiple targeted sites in a large number of samples haplotype specifically. The algorithm extracts sequencing reads from each BAM file, identifies unique strings, excludes reads that occur fewer than five times or that do not match the reference sequence, and identifies the two most observed sequences at each targeted site. The two strings are then aligned against the reference sequence to identify the mutations present in each of them. i.e. insertions, deletions, or mismatches of one or more nucleotides. Fish are considered homozygous for mutations on the most observed allele if the condition is TRUE, and to be (compound) heterozygous for mutations on the two most prominent alleles otherwise. To test the algorithm, it was applied alongside two validated variant calling algorithms, i.e. VarScan and Freebayes, to paired-end sequencing results from 384 zebrafish larvae with 0 to 2 mutated alleles in 0 to 7 CRISPR/Cas9-targeted proof-of-concept genes for familial hypercholesterolemia (i.e. 6513 BAM files). The script could process each BAM file in an average of 5 secs, and the results show that DIVaH identified 2x more indels than VarScan and Freebayes, with a length of up to 170 bp. The subsequent association analysis showed a significant association of LDL cholesterol levels with the number of mutated alleles in *apoEa*, and of vascular lipid deposition with the number of mutated alleles in *Idlra*, amongst others. Our results show that DIVaH reliably and efficiently calls CRISPR-Cas9-induced mutations and haplotypes in large numbers of BAM files in batch. This facilitates the translation of results from genetic association studies in humans using high-throughput zebrafish model systems.

**Novel molecular signatures for heart failure: A comprehensive study of mRNA, lncRNA, and miRNA expression.** Y. Wang<sup>1</sup>, X. Hua<sup>2</sup>, Q. Xiong<sup>1</sup>, P. Jia<sup>1</sup>, Z. Zhao<sup>1</sup>, J. Song<sup>2</sup>. 1) Center of Precision Health, School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX; 2) Department of Cardiac Surgery, State Key Laboratory of Cardiovascular Disease Fuwai Hospital, National Center for Cardiovascular Diseases, Chinese Academy of Medical Sciences and Peking Union Medical College, China.

Heart failure (HF), characterized by structural and functional impairment of the heart, has been a major cause of hospitalization, morbidity and mortality. Although numerous advances have been made in understanding its disease etiology and molecular mechanisms, a systematic investigation of the genetic changes at the transcriptional level has not been much done yet. Such a study may help us find molecular markers or features underlying the cellular condition during heart failure, and hopefully, discovering the biomarkers for the development of therapeutic strategy for HF. In addition to protein-coding genes, recent studies have revealed non-coding RNAs, such as microRNAs (miRNAs) and long noncoding RNAs (lncRNAs), may play important regulatory roles in the pathogenesis of HF. So far, the specific noncoding RNAs and their roles in HF still remain as preliminary, but promising. In this study, we generated whole transcriptome data from both mRNA and small RNA of 21 HF samples and 9 matched control samples using Illumina HiSeq 2500 platform. Using our in-house transcriptomic data analysis pipeline, we identified 126 protein-coding genes, 42 miRNAs, and 16 lncRNAs that are differentially expressed in the HF samples versus the controls. Our further analysis of these differentially expressed mRNAs, miRNAs and lncRNAs indicated that they were related to the HF-associated pathways and biological processes, such as regulation of Insulin-like Growth Factor (IGF) transport and regulation of blood pressure. These results supported these gene signatures to be involved in the HF pathogenesis. We further investigated their co-regulation by developing miRNA-mRNA and lncRNA-mRNA regulatory network approaches. Several differentially expressed miRNAs (e.g., *miR-190-5p*, *miR-129-5p* and *mir-1-3p*), lncRNAs (e.g., *LOC101926975*, *PDZRN3-AS1* and *BANCR*) and genes (e.g., *JAK2*, *PROS1* and *BDNF*) were found to be critical in the co-regulatory network, indicating their potential co-functional roles in HF condition. Finally, some of the results were validated by an independent transcriptional dataset (7 HF and 6 matched control samples) by using the same approach (RNA-seq and small RNA-seq) and a proteomic dataset (4 matched HF and one mixed controls of 5 matched samples) based on TMT quantitation. In summary, we identified a number of novel, differentially expressed mRNAs, miRNAs and lncRNAs, and their co-regulation results provided insights into the molecular mechanisms of HF.

**Pre-annotation of genomic variants related to cardiovascular phenotypes for clinical reporting with the Neptune Pipeline.** *E. Venner, Y. Jiang, D. Murdoch, S.E. Kalla, M. Murugan, T.J. Wu, C. Kovar, K. Walker, J. Hu, T. Chiang, W. Salerno, G. Metcalf, D. Muzney, R. Gibbs.* Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX.

Pairing electronic medical records (EMR) with genomic data will drive precision medicine, but clinical reporting of genomic data is a costly and manual process. As a pilot project that enables precision medicine in an active clinical setting, we are validating a new clinical assay of 158 genes known to be associated with cardiovascular phenotypes, including coronary artery disease, arrhythmia, cardiomyopathy and aortic aneurysm. We will be launching this test with our clinical partners in the third quarter of 2018. To address this challenge, we have developed Neptune, an analytical platform to sign-out and deliver clinical reports. Following DNA sequencing and processing with the Human Genome Sequencing Center's Mercury Pipeline (PMID: 24475911), clinical DNA samples are analyzed via Neptune's custom annotation software that identifies a small subset of variants for manual review and addition to a "VIP" database of clinically-relevant variation. When all variants that require review in a sample have been curated, clinical reports are automatically generated, integrating SNVs, Indels, CNVs and CPIC level A pharmacogenomic variants. A structured version of the report is available in xml and json formats, with an HL7-FHIR standards compliant version in development. To facilitate clinical reporting for this new project, we have begun to augment our existing VIP database with annotations of variants and key publications specific to these cardiovascular genes. We have begun identifying publications with functional and case/control data that are relevant to this project. These publications are being pre-assessed in order to speed up reporting during the project. In addition, we are curating over 8,000 variants, identified in the ARIC cohort [PMID: 2646917] that lack strong ClinVar curations but which are likely to show up in our cohorts. By managing variant classifications and interpretations in a VIP database, we decouple variant curation from reporting, which in turn simplifies the logistics of the variant interpretation process and facilitates variant classification by external partners.

**Validation of CNV detection in targeted panels and results from reanalysis of a historical cohort of cardiac patients.** *S.P. Sadedin<sup>1</sup>, C. Ieng<sup>2</sup>, A. Oshtack<sup>1</sup>.* 1) Murdoch Childrens Research Institute, Parkville, Victoria, Australia; 2) Victorian Clinical Genetics Services, Parkville, Victoria, Australia.

Copy number variants (CNVs) are a well known cause of rare genetic disease, and are routinely screened for in clinical laboratories. Historically, this has been performed either by microarray (to detect larger imbalances), or single-gene methods when a candidate gene can be identified. However, sensitive detection of intragenic and whole gene deletions and duplications across a wide set of genes, has remained challenging. Targeted sequencing gene panels used for detection of SNVs and indels can also detect CNVs. However the data generated is subject to distortions and biases that make this application significantly more challenging than detection of SNVs and indels. These challenges are compounded by a paucity of positive controls and reference samples for use in validation. Here we present our experience from validating CNV detection for clinical use in a targeted gene panel of 130 genes related to cardiac disease. Our method includes use of Ximmer, a freely available CNV simulation and analysis framework that supports rapid evaluation and tuning of CNV detection performance. Using Ximmer, we perform a comprehensive comparison of methods for CNV calling and identify factors affecting sensitivity and precision. By combining Ximmer results with sequencing of a set of positive controls, we are able to confidently predict performance over each exon. Using the accredited analysis pipeline, we re-analysed samples from a historical cohort of 545 patients, informing on the increase in diagnostic yield from application of CNV calling in cardiac testing.

**3215F**

**A comprehensive and accurate knowledgebase system for variant clinical interpretation using ACMG-AMP standard guideline in inherited cardiac diseases and hereditary cancers.** C. Chen, Q. Song, F. Xu, P. Yu, G. Hu. Admera Health LLC, South Plainfield, NJ.

With the rapid development and adoption of next-generation sequencing (NGS) technologies, the complexity of variant interpretation has increased significantly and new challenges have emerged in the clinical interpretation of Mendelian and complex diseases. While the American College of Medical Genetics and Genomics (ACMG) and the Association for Molecular Pathology (AMP) recommended standards and guidelines for the interpretation of sequence variations in 2015, it did not offer specific approaches or algorithms for implementing these guidelines in detail, making discrepancies of variant interpretation widely exist between intra- and inter-laboratory settings. Here we present a crowdsourced knowledgebase system to provide accurate clinical interpretation of variants related to a number of human inherited diseases, including inherited cardiac diseases and hereditary cancers. Strictly following the 28 criteria provided by ACMG-AMP standards and guidelines, we have built a knowledgebase which curated comprehensive information from Human Gene Mutation Database (HGMD), ClinVar, 1000 Genome Project, dbSNP, and other population, disease-specific, and sequence related databases, combined with a number of *in silico* predictive algorithms (such as SIFT and PolyPhen-2). The comprehensive knowledgebase is able to provide reliable and consistent genetic variant interpretation with the five-tier classification system (Pathogenic/Likely pathogenic/Benign/Likely Benign/Uncertain significance) and help human interpreters understand the clinical significance of genetic variants intuitively. Our implementation allows any potential new variants to be included and provides the most updated information to the scientific community. The knowledgebase can be easily used by researchers and clinicians, and will significantly enhance our understanding of the functional consequences of genetic variants in human diseases.

**3216W**

**How well can we classify coronary artery disease using all genetic data and choosing the best classification algorithm.** D. Gola<sup>1,2</sup>, T. Andlauer<sup>3</sup>, N. Mirza-Schreiber<sup>3</sup>, L. Zeng<sup>4</sup>, G. Delgado<sup>5</sup>, M. Kleber<sup>6</sup>, I. Gerge<sup>6</sup>, W. März<sup>5</sup>, S. Kanoni<sup>6</sup>, P. Deloukas<sup>6,7,8</sup>, H. Schunkert<sup>9,12</sup>, N. Samani<sup>6</sup>, J. Erdmann<sup>2,10,11</sup>, B. Müller-Myhsok<sup>3</sup>, I.R. König<sup>1,2,13</sup>. 1) Institut für Medizinische Biometrie und Statistik, Universität zu Lübeck, Lübeck, Schleswig-Holstein, Germany; 2) German Centre for Cardiovascular Research (DZHK), partner site Hamburg/Kiel/Lübeck, Lübeck, Germany; 3) Department of Translational Research in Psychiatry, Max Planck Institute of Psychiatry, Munich, Germany; 4) Deutsches Herzzentrum München, Technische Universität München, München, Germany; 5) Medical Clinic V, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; 6) Department of Human Genetics, Wellcome Trust Sanger Institute, Hinxton, United Kingdom; 7) William Harvey Research Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, London, United Kingdom; 8) Princess Al-Jawhara Al-Brahim Centre of Excellence in Research of Hereditary Disorders (PACER-HD), King Abdulaziz University, Jeddah, Saudi Arabia; 9) Department of Cardiovascular Sciences University of Leicester and NIHR Leicester Cardiovascular Biomedical Research Unit, Glenfield Hospital, Leicester, United Kingdom; 10) Institute for Cardiogenetics, Universität zu Lübeck, Lübeck, Germany; 11) University Heart Center Lübeck, Lübeck, Germany; 12) DZHK, partner site Munich Heart Alliance, Munich, Germany; 13) Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL).

Coronary artery disease (CAD) is the leading global cause of mortality and has substantial heritability with a polygenic architecture. Recent approaches of risk prediction were restricted in that they did not utilize the complete genetic information available, but rather focused on genetic loci found to be associated to CAD. Also, they were based on simple genomic risk scores (RS) not taking possible interdependencies between variants into account. We therefore benchmarked RS, logistic (penalized) regression, naïve Bayes (NB), random forests (RF), support vector machines (SVM) and gradient boosting (GB) on a dataset of 7736 CAD cases and 6774 controls from Germany to identify the algorithms for most accurate classification of CAD patients. After training, the final models were validated on an independent dataset of 527 CAD cases and 473 controls out of the same population and two further independent datasets from UK (1874 CAD cases, 1874 controls) and Germany, France and UK (365 CAD cases, 401 controls). We found RS using 50 633 genetic markers to be the most suitable algorithm for CAD classification, yielding an area under the receiver operating curve (AUC) of 0.92 (95% CI [0.90, 0.95]) in the validation data from the same population. NB and SVM performed better than RF and GB, with AUC of about 0.81 and 0.75, respectively. Applied to datasets from slightly different populations, however, all classification models had markedly reduced AUC of 0.5 – 0.6. We conclude that using all available genetic information can boost classification performance, although intensive validation of prediction models is crucial to assess their usability in populations different from those used to build the models.

**Mosaic mutations contribute to congenital heart disease.** A. Hsieh<sup>1</sup>, S. Morton<sup>2</sup>, H. Qi<sup>3</sup>, K.B. Manheimer<sup>4</sup>, D. Bernstein<sup>5</sup>, R.W. Kim<sup>6</sup>, J.W. Newburger<sup>7</sup>, G.A. Porter Jr.<sup>7</sup>, D. Srivastava<sup>8</sup>, M. Tristani-Firouzi<sup>9</sup>, M. Brueckner<sup>10</sup>, R.P. Lifton<sup>10</sup>, C.E. Seidman<sup>2</sup>, E. Goldmuntz<sup>12</sup>, B.D. Gelb<sup>4</sup>, J.G. Seidman<sup>2,11</sup>, W.K. Chung<sup>1</sup>, Y. Shen<sup>1,13</sup>. 1) Columbia University Medical Center, New York, NY; 2) Boston Children's Hospital, Boston, MA; 3) Columbia University, New York, NY; 4) Icahn School of Medicine at Mount Sinai, New York, NY; 5) Stanford University School of Medicine, Palo Alto, CA; 6) Children's Hospital Los Angeles, Los Angeles, CA; 7) University of Rochester Medical Center, Rochester, NY; 8) University of California San Francisco, San Francisco, CA; 9) University of Utah School of Medicine, Salt Lake City, UT; 10) Yale University School of Medicine, New Haven, CT; 11) Harvard Medical School, Boston, MA; 12) Children's Hospital of Philadelphia, Philadelphia, PA; 13) JP Sulzberger Genome Center, New York, NY.

Mosaicism is due to post-zygotic *de novo* mutation, resulting in two or more cell populations with distinct genotypes in a single individual. These post-zygotic events have been implicated in developmental disorders such as structural brain malformations, epilepsy, and autism, but their role in congenital heart disease (CHD) and other congenital anomalies is still unclear. Additionally, current estimates of the fraction of *de novo* events occurring post-zygotically and the mosaic mutation rate per individual are unstable due to differences in sequencing depth or variant calling methods. To systematically estimate the contribution of mosaicism to CHD, we developed a new computational method to characterize mosaic single nucleotide variants from exome sequencing data. We use an expectation-maximization algorithm to jointly estimate the fraction of mosaics among apparent *de novo* mutations and the false discovery rate of candidate mosaics. We applied our method to data from 2645 CHD proband-parents trios from the Pediatric Cardiac Genomics Consortium and Pediatric Heart Network programs. We detected a total of 288 high-confidence protein-coding mosaic mutations from these blood samples, an average of 0.11 per individual. Independent sequencing confirmed 90% of selected candidates. Among the mosaics in genes highly expressed in developing heart, the variants predicted to be damaging tended to have a higher variant allele fraction than likely-benign variants ( $P=0.016$ ), suggesting that damaging mosaics contribute to CHD and that their contribution is positively correlated with the percentage of cells carrying the mutations. In particular, we observed deleterious mosaics in genes involved in known biological processes relevant to CHD or developmental disorders, such as *ISL1*, *SETD2*, *NOVA2*, *SMAD9*, *LZTR1*, and *FZD5*. However, comparing the proportions of damaging and non-damaging mosaic and germline *de novo* variants in high heart expression genes, we find that mosaic variants detected in blood as a class are less likely to be pathogenic than germline variants ( $P=0.005$ ), probably due to having a smaller chance of being present in the heart during development. Finally, we calibrated detection power given sequencing depth and estimated that the true frequency of coding mosaics with level of mosaicism greater than 20% in the blood is 0.17 per patient, representing an understudied but substantial fraction of the genetic risk to congenital anomalies and other diseases.

**3218F**

**An artificial intelligence-based next-generation integrated genetic-epigenetic prediction of 5-year risk for symptomatic coronary heart disease.** M.V. Dogan<sup>1,2</sup>, R.L. Simons<sup>3</sup>, S.R.H. Beach<sup>4</sup>, A. Lendasse<sup>5</sup>, R.A. Philibert<sup>1,2,6,7</sup>. 1) Biomedical Engineering, University of Iowa, Iowa City, IA; 2) Cardio Diagnostics LLC, Coralville, IA; 3) Sociology, University of Georgia, Athens, GA; 4) Psychology, University of Georgia, Athens, GA; 5) Mechanical and Industrial Engineering, University of Iowa, Iowa City, IA; 6) Psychiatry, University of Iowa, Iowa City, IA; 7) Behavioral Diagnostics, Coralville, IA.

Coronary heart disease (CHD) is responsible for >300,000 deaths annually. CHD associated morbidity and mortality can be reduced if those at risk can be identified well in advance, to put in place prevention interventions prior to the occurrence of an acute coronary event. Currently, there are several approaches used to infer risk for CHD. However, their limitations call for additional efforts to more sensitively predict risk for developing symptomatic CHD. To that end, we recently developed a Precision Medicine tool that in addition to predicting 5-year risk, can also be used to guide personalized prevention interventions and monitor changes in risk over time. It was developed using an application of artificial intelligence, machine learning, in the Framingham Heart Study to mine integrated genetic-epigenetic biosignatures that capture the complex interplay between our genome and the environment in conferring risk for CHD. The training and test sets consisted of 1180 (19/695 females and 23/485 males developed symptomatic CHD within 5-years) and 524 (8/293 females and 12/231 males developed symptomatic CHD within 5-years) individuals, respectively, of Northern European ancestry. Non-linear data mining and modeling techniques were employed on the training set to identify prediction signatures from genome-wide SNP and DNA methylation (DNAm) data. As a result, 14 DNAm and 10 SNPs were identified and trained on the training set (training bootstrap average sensitivity and specificity of 0.61 and 0.71, respectively), which then, predicted the 5-year risk in the test set with a sensitivity and specificity of 0.60 and 0.69, respectively. Performance was compared to that of the Framingham Risk Score (FRS) and the ASCVD Risk Estimator. The sensitivity and specificity in the test set were 0.05 and 0.99, respectively, for FRS, and 0.38 and 0.85, respectively, for ASCVD. Even with a small number of incident cases, our tool performed with superior sensitivity, which is vital because, while a false positive would result in additional testing, a false negative can be detrimental. Unlike genetics, because DNAm is dynamic, it can be mapped to actionable risk factors to inform personalized interventions. Post-interventions, changes in DNAm can be used to re-assess changes in risk and hence, continuously monitor heart health. Additional efforts are ongoing to optimize, validate and extend our tool to further improve performance in larger, more ethnically diverse cohorts.

**PseudoNet: reconstructing pseudo-time in single-cell RNA-seq data using neural networks.** J. Lakkis<sup>1</sup>, G. Hu<sup>1,4</sup>, C. Xue<sup>2</sup>, H. Pan<sup>2</sup>, S.B. Trignano<sup>2</sup>, H. Zhang<sup>2</sup>, M.P. Reilly<sup>2</sup>, N.R. Zhang<sup>3</sup>, M. Li<sup>1</sup>. 1) Department of Biostatistics Epidemiology, and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 2) Division of Cardiology, Department of Medicine, Columbia University Medical Center, New York, NY; 3) Department of Statistics, University of Pennsylvania Wharton School of Business, Philadelphia, PA; 4) School of Mathematical Sciences and LPMC, Nankai University, Tianjin, PR China.

Single-cell gene expression profiling can be used to quantify transcriptional dynamics in temporal processes, such as cell differentiation, using computational methods to label each cell with a "pseudo-time." Pseudo-time analysis models the gradual transition of a cell rather than assigning it to a discrete cluster. Popular pseudotime reconstruction methods such as Monocle2 do not scale well as the number of cells increases. As a result, these methods cannot jointly analyze data across multiple subjects when each subject has a few thousand single cells. As single-cell RNA-seq becomes widely used in biomedical research, many research groups are now sequencing a large number of cells across many subjects. It is important to identify genes whose expression changes over pseudo-time across subjects in different disease conditions. However, when analyzing data individually, it becomes challenging to compare gene expression across subjects as the estimated pseudotimes are not on the same scale. To overcome these limitations, we present PseudoNet, a new, supervised machine learning approach for pseudotime reconstruction to model a non-branching temporal cell process. A feedforward neural network is trained to predict the probability that a cell is near a pre-specified end of the temporal process based on its gene expression, and the predicted probability is used as a proxy for pseudo-time. Training is performed on cells that are known or are certain to be near either end of the temporal process. PseudoNet efficiently borrows information across subjects and returns a pseudotime standardized to the [0, 1] scale, which allows the identification of genes that are differentially expressed over pseudo-time across subjects in different conditions. To evaluate the performance of PseudoNet, we analyze benchmark datasets for cell cycle and cell differentiation, where true cell states are known. We show that our method requires less computation time and classifies cells with greater accuracy and higher resolution than other popular pseudo-time reconstruction methods. We also apply this method to a single-cell RNA-seq dataset consisting of monocyte gene expression data for 15 patients, totaling ~60,000 single cells. We show that PseudoNet identifies genes differentially expressed between healthy people and those with cardiometabolic disease risk factors (e.g., smoking, diabetes, high blood lipids). An R package of PseudoNet is made available.

**Biomarker predictors of acute ischemic stroke: Results of metabolome in ischemic stroke study (MISS).** C. Bejar<sup>1</sup>, B. Apple<sup>1</sup>, L. Reddivari<sup>2</sup>, E. Sidorov<sup>1</sup>, J.K.P. Vanamala<sup>2</sup>, D.K. Sanghera<sup>1</sup>. 1) University of Oklahoma Health Science Center, Oklahoma City, OK; 2) Penn State University, University Park, PA, USA.

Acute ischemic stroke (AIS) is the fourth leading cause of death in the United States. Despite advances in research, early detection and treatment strategies still suffer from significant limitations. There has been an increased interest to identify novel biomarkers, which may correlate with disease etiologies using advanced metabolite profiling. However, most such studies have been performed in animals; very few studies have examined AIS in humans. This investigation is part of our ongoing Metabolome in Ischemic Stroke Study (MISS) in which we have performed a global metabolome profiling using serum samples of 119 subjects. These include 44 MISS patients admitted at the OU Medical Center's emergency and were diagnosed with the AIS; on these blood and urine samples available at both acute- (within 72 hours of AIS) and chronic phase (2-3 month follow-up); 31 chronic patients who had stroke in the past, and their specimens were collected only at the chronic phase. We also investigated 44 age- and gender- matched healthy controls for comparison. The global metabolomic profiles were generated using AB Sciex TripleTOF 5600 for untargeted analysis and Thermo Scientific Q Exactive Plus for targeted analysis. We identified and prioritize top 1,919 metabolites that correlated with AIS in serum. Putative identities were assigned to ~70 metabolites, and both known and novel metabolites were confirmed using appropriate standards. Several metabolites exhibited significantly altered patterns between patients and controls in serum and urine. Myo-inositol, 2,3 Hydroxybenzoic Acid, Pyridoxic Acid, Allantoin, Hydroxyphenyllactate, Ketoisovalerate, and few essential amino acids were significantly perturbed ( $p < 0.0001$ ) among the AIS patients at both acute and chronic phase, while the magnitude of variation was significantly pronounced at the acute phase (which ranged from 20% to 50%) compared with the chronic phase. However, the other essential amino acids including BCAAs, Histidine, Methionine, Proline, and Serine were only reduced during the acute phase. Our results suggest that the dysregulation of specific metabolic pathways may have long-term or irreversible effects after the cerebral ischemic episode. These findings once replicated in the expanded MISS cohort would provide novel insights on underlying molecular pathways altered in AIS and may facilitate the development of diagnostic and therapeutic approaches for early detection and prevention. .

**Metabolic profiling and sequencing at biobank scale for prioritizing drug targets.** S. Ruosaari. Nightingale Health, Helsinki, Finland.

Advances in metabolomics now allow comprehensive biomarker profiling of entire biobanks and clinical trials. This provides a plethora of scientific opportunities such as discovery of novel biomarkers for onset of cardiovascular diseases and tracking their progression, as well as etiological insights into established cardiometabolic risk factors. Here we showcase scientific applications in combining metabolomic data with large-scale genomics and electronic health care records in entire biobank cohorts. Nightingale Health Ltd has developed a metabolomics platform for large-scale 'omics and screening projects. Previous studies show that the platform significantly improves risk stratification in primary and secondary CVD prevention (Circulation 2015;131:774). Also, it has been used to examine metabolomic consequences of PCSK9 inhibition in ~72,000 individuals from European cohort studies using a loss-of-function variant in PCSK9 R46L to mimic the therapeutic effects of PCSK9 inhibitors (unpublished data). To clarify the clinical utility of the findings, the metabolomics platform is currently being applied to profile close to 1,000,000 biobanked blood samples from diverse ethnicities with extensive electronic health care records, and the resulting biomarker data will be made available for the medical research community. Simultaneously, the metabolomic profiling is for the first time being piloted in healthcare settings for guiding clinical decision making for individual patient, exemplifying how metabolomic profiling of large biobank studies pave way for precision medicine approaches with strong evidence base. The benefits of metabolomic profiling in a precision medicine setting are clear. They help improve risk stratification and provide more clear clinical interpretation of the biomarker results. We also illustrate the benefits of tracking the metabolomic effects in response to various lifestyle and pharmacological interventions. These results demonstrate the translational utility of NMR metabolomics studies in large biobanks providing enhanced cardiovascular risk prediction and novel means to track effectiveness of interventions.

**Genetic background drives molecular variability in a large-scale collection of iPSC-derived cardiomyocytes.** M.K.R. Donovan<sup>1,2</sup>, A. D'Antonio-Chronowska<sup>3</sup>, P. Benaglio<sup>3</sup>, E.N. Smith<sup>3</sup>, M. D'Antonio<sup>4</sup>, K.A. Frazer<sup>3,4</sup>.

1) Bioinformatics and Systems Biology Graduate Program, University of California, San Diego, La Jolla, CA 92093, USA; 2) Department of Biomedical Informatics, University of California, San Diego, La Jolla, CA 92093, USA; 3) Department of Pediatrics, University of California, San Diego, La Jolla, CA 92093, USA; 4) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA 92093, USA.

Induced pluripotent stem cell (iPSC)-derived cardiomyocytes (iPSC-CMs) have emerged as a promising model system to identify and characterize regulatory variation underlying cardiac traits and disease. Using 144 iPSCs from whole-genome sequenced individuals, we have derived the largest collection of iPSC-CMs to date. We characterized heterogeneity, including: 1) varying differentiation efficiencies of iPSCs, and 2) iPSC-CM cellular compositions, to examine its impact on using large collections of iPSC-CMs for studying regulatory variation. We investigated if iPSC molecular and regulatory characteristics were predictive of differentiation outcome. Sex was significantly associated ( $p = 0.0025$  Fisher's exact test), with female iPSCs differentiating successfully more often than male iPSCs. Analyzing RNA-seq for all 144 iPSC lines, we also observed increased erosion of the inactive X chromosome in successfully differentiated female iPSCs. Gene expression (bulk RNA-seq) analysis in iPSCs revealed that *TLE3*, a master regulator of the Wnt-signaling pathway, was under-expressed in successfully differentiated iPSCs, consistent with proper Wnt signaling being critical to the success of iPSC-CM differentiation. We performed single cell RNA-seq on 8 iPSC-CMs (33,914 cells) with a range of differentiation efficiencies (%cTnT), and observed that two distinct cell populations were present. The majority of cells belonged to population 1, which was strongly enriched for cardiac development-associated genes including *TNNT2* (cTnT), *NKX2-5*, and *MYL7* (MLC2a), while population 2 was enriched for functions associated with the extracellular matrix. The percentage of population 1 cells in each iPSC-CM sample was directly reflective of its differentiation efficiency. To investigate the extent to which cellular heterogeneity impacts the association between genetic variation and molecular phenotypes in iPSC-CMs, we analyzed RNA-seq, ATAC-seq, and ChIP-seq for H3K27ac from 24 iPSC-CMs derived from 5 MZ twin pairs. We estimated the relative distributions of the two cellular populations in all 24 iPSC-CM lines with CiberSort, and showed that while in the unadjusted samples genetic background accounted for most molecular variability, using cell population as a covariate resulted in an even higher association. Overall, our study shows that molecular phenotypes in iPSC-CMs are largely associated with genetic background, which supports the use of large collections of iPSC-CMs for genetic studies.

**Disease Navigator: Utilizing model organisms for functionalizing human genome variation.** *M. Tomczuk<sup>1</sup>, J. De Pons<sup>2</sup>, C. Smith<sup>1</sup>, J. Richardson<sup>1</sup>, J. Blake<sup>1</sup>, C. Bult<sup>1</sup>, M. Shimoyama<sup>2</sup>.* 1) Mouse Genome Informatics, The Jackson Laboratory, Bar Harbor, ME; 2) Rat Genome Database, Medical College of Wisconsin, Milwaukee, WI.

Integration of and accessibility to multiple datasets can accelerate new discoveries and can aid in understanding human health, and in disease prevention, diagnosis and generation of therapies. The Disease Navigator, a project that is part of the NIH Data Commons pilot initiative, is a new portal that links human genomic, expression and phenotypic disease data with relevant model organism information from the Alliance of Genome Resources to help elucidate the mechanisms of human disease. The Alliance of Genome Resources ([www.alliance.org](http://www.alliance.org)) is a consortium of six model organism databases (Mouse Genome Database—MGD, Rat Genome Database—RGD, Saccharomyces Genome Database, WormBase, FlyBase, and Zebrafish Information Network), and the Gene Ontology Consortium – all working together to standardize and incorporate data from human and these organisms into a single integrated resource. Disease Navigator currently focuses on cardiovascular disease, particularly cardiomyopathy, and incorporates human data from the Genotype-Tissue Expression (GTEx) project and Trans-Omics for Precision Medicine (TOPMed), and animal model data from MGD and RGD. Disease terms are sourced from ontologies/vocabularies (Disease Ontology, Mammalian Phenotype Ontology, Human Phenotype Ontology, Vertebrate Trait Ontology, CheBI and Uberon). The portal is gene-centric and contains disease-associated genes from human, mouse, and rat. Additional material includes quantitative phenotype data, rat and mouse strains and models, genomic data and eQTL from TopMed, human gene expression data from GTEx, and human gene variation data from ClinVAR. We will show how the Disease Navigator integrates datasets and can be used to take advantage of model organism data to understand the functional significance of human genome variation. A search by a human gene returns links to gene reports for the human and mouse and rat orthologs, eQTL data, expression data, and associated disease models. A search by disease term such as cardiomyopathy, returns genes, variants, genotypes, QTLs, heritable phenotypes, strains, disease models and expression data. Lists of genes associated to a disease term can be further analyzed for functional commonalities or identify overlap with other genes. Future efforts will add more diseases, genomic and phenotypic data from other model organisms and multiple human projects, as well as tools to aid in analysis of the myriad of available data. Supported by NIH grant U41 HG001315-24S1.

**Comprehensive analysis of chromatin organization delineates regulatory programs of human cardiomyocyte differentiation.** *Y. Zhang<sup>1</sup>, S. Preiss<sup>1,2</sup>, T. Li<sup>3</sup>, H. Yang<sup>3</sup>, J. Grinstein<sup>3</sup>, E. Destici<sup>3</sup>, A. Lee<sup>1</sup>, S. Chee<sup>1</sup>, Z. Ye<sup>1</sup>, K. Ma<sup>1</sup>, N. Tedesch<sup>3</sup>, S. Kuan<sup>1</sup>, J. Vevers<sup>1</sup>, S. Evans<sup>4,5</sup>, N. Chi<sup>3</sup>, B. Ren<sup>1,2,6</sup>.* 1) Ludwig Institute for Cancer Research, San Diego, CA; 2) Department of Cellular and Molecular Medicine, UCSD; 3) Department of Medicine, Division of Cardiology, UCSD; 4) Department of Medicine, UCSD; 5) Department of Pharmacology and Skaggs School of Pharmacy and Pharmaceutical Sciences, UCSD; 6) Institute of Genomic Medicine, and Moores Cancer Center, UCSD.

Chromosome conformation capture technologies have revealed important impacts of chromatin folding on gene regulation. However, little is known about how the 3D chromatin structure is established and reorganized during human cardiomyocyte development and dysregulated in heart diseases. Here, we performed high-resolution in-situ Hi-C, histone ChIP-seq and ATAC-seq to interrogate the chromatin architecture during six key developmental stages of human cardiomyocyte differentiation. We find substantial dynamic organization of the chromatin structure at all scales including compartments, topologically associated domains (TADs) and chromatin loops. Interestingly, chromatin loop interactions correlate with stage-specific gene expression program and form interaction hubs on the promoters of cardiac transcription factors. Integration of chromatin loops with noncoding variants identified in genome-wide association studies (GWAS) predicts multiple candidate genes for heart diseases, including several ion channel genes involved in cardiac conduction and genes involved in early cardiac differentiation. Our work provides a rich resource not only for understanding the chromatin structure changes during cardiac development, but also resolving the impact of non-coding variants in heart diseases.

**Mapping of HiChIP chromatin looping QTLs in human coronary artery smooth muscle cells and their relationship to other regulatory and disease variation.** *M. Pjanic*<sup>1,2</sup>, *M. Dacre*<sup>3</sup>, *Q. Zhao*<sup>1,2</sup>, *T. Nguyen*<sup>1,2</sup>, *B. Liu*<sup>4</sup>, *R. Wirka*<sup>1,2</sup>, *T. Wang*<sup>5</sup>, *C.L. Miller*<sup>5</sup>, *H. Fraser*<sup>5</sup>, *T. Quertermous*<sup>1,2</sup>. 1) Department of Medicine, Division of Cardiovascular Medicine, School of Medicine, Stanford, CA; 2) Cardiovascular Institute, Stanford University, Stanford, CA; 3) Department of Biology, Stanford, CA; 4) Department of Genetics, Stanford, CA; 5) Department of Public Health Sciences, School of Medicine, University of Virginia, Charlottesville, VA.

Coronary artery disease (CAD) has become a major chronic condition in modern human societies and is the global leading cause of death in both men and women. Given that approximately half of the risk for CAD is genetic in nature, in this work we aimed to annotate the human genome by mapping regulatory variation to identify disease mechanisms. Toward that end, we have conducted the first large-scale pooling approach for HiChIP to map chromatin looping QTLs (cQTLs) in disease-related human coronary artery smooth muscle cells (HCASMC). We pooled chromatin extracts from 71 individuals and performed the HiChIP protocol with H3K27ac immunoprecipitation. We processed data as described by the Fraser Lab to identify statistically significant SNPs with different pre- vs. post-frequency as related to chromosomal looping. From a total number of 3,636,814 analyzed SNPs, we obtained 24,260 high confidence cQTLs with  $p < 0.001$ . By applying binomial statistics to test the significance of overlaps between GWAS Catalog variants and cQTL variants in a window of 100 bp, we report that HCASMC cQTLs are enriched in disease-associated SNPs from CARDIoGRAMplusC4D Consortium GWAS studies that comprise a collection of risk SNPs for CAD and myocardial infarction ( $p < 1e-4$ ). In addition, when broader regions of 1 kb surrounding cQTLs were tested, a significant GWAS term was "coronary artery calcification", a risk factor for adverse outcomes in patients with CAD. When transcription factor (TF) position weight matrix (PWM) enrichment was examined in the narrow region of +/-25 bp surrounding the cQTLs, we report enrichment for PWMs for smooth muscle related TFs SRF and TEAD1, as well as CAD associated TFs TCF21 and SMAD3. Our results indicate that by applying the pooled approach and characterizing cQTL variants, we can obtain novel information regarding the regulation of gene transcription, and identify chromatin looping as a genetic mechanism that may be regulated by allelic variation to modulate the risk of CAD.

**A promoter interaction map for cardiovascular disease genetics.** *L.E. Montefiori*<sup>1</sup>, *D.R. Sobreira*<sup>1</sup>, *N.J. Sakabe*<sup>1</sup>, *I. Aneas*<sup>1</sup>, *A.C. Joslin*<sup>1</sup>, *G.T. Hansen*<sup>1</sup>, *G. Bozek*<sup>1</sup>, *I.P. Moskowitz*<sup>2</sup>, *E.M. McNally*<sup>3</sup>, *M.A. Nobrega*<sup>1</sup>. 1) Human Genetics, University of Chicago, Chicago, IL; 2) Department of Pediatrics and Pathology, The University of Chicago, Chicago IL; 3) Center for Genetic Medicine, Northwestern University Feinberg School of Medicine, Chicago IL.

Over 500 genetic loci have been associated with risk of cardiovascular diseases (CVDs), however most loci are located in gene-distal non-coding regions and their target genes are not known. We generated high-resolution promoter capture Hi-C (PCHI-C) maps in human induced pluripotent stem cells (iPSCs) and iPSC-derived cardiomyocytes (CMs) to provide a resource for identifying and prioritizing the functional targets of CVD associations. We validated these maps by demonstrating that promoters preferentially contact distal sequences enriched for tissue-specific transcription factor motifs and are enriched for chromatin marks that correlate with dynamic changes in gene expression. Furthermore, the majority (80%) of PCHI-C interactions occurred within topologically associating domains (TADs), indicating that this approach recapitulates known features of genome organization. Using the CM PCHI-C map, we linked 1,999 CVD-associated SNPs to 347 target genes; importantly, these genes were enriched for causing cardiovascular phenotypes when deleted in the mouse. Remarkably, more than 90% of SNP-target gene interactions did not involve the nearest gene, while 40% of SNPs interacted with at least two genes. Furthermore, CVD-associated SNPs that corresponded to expression quantitative trait loci (eQTLs) identified in left ventricle tissue were significantly more likely to loop to their associated gene than expected by chance. Our findings suggest that PCHI-C provides an important layer of information to help resolve the functional targets of cardiovascular disease risk loci.

**Methylation at nucleotide C62 in spliceosomal RNA U6 alters mRNA splicing which is important for embryonic development.** A. Ogren<sup>1</sup>, N. Kibiryeve<sup>2</sup>, J. Marshall<sup>2</sup>, J. O'Brien Jr.<sup>2</sup>, D.C. Bittel<sup>1,2</sup>. 1) Kansas City University of Medicine and Bioscience, Kansas City, MO 64106; 2) Children's Mercy Hospital, Kansas City, MO 64108.

Understanding the regulation of development can help elucidate the pathogenesis behind many developmental defects found in humans and other vertebrates. Evidence has shown that alternative splicing of mRNA plays a role in developmental regulation, but we know little about the underlying mechanisms. Notably, a subset of small noncoding RNAs known as scaRNAs (small cajal body associated RNAs) contribute to spliceosome maturation and function through covalently modifying spliceosomal RNAs by either methylating or pseudouridylating specific nucleotides, but the developmental significance of these modifications are not well understood. Our focus is on one such scaRNA, known as snord94 or U94, that methylates one specific cytosine (C62) on spliceosomal RNA U6, thus potentially altering spliceosome function during embryogenesis. We previously showed that mRNA splicing is significantly different in myocardium from infants with congenital heart defects (CHD) compared to controls. Furthermore, we showed that modifying expression of scaRNAs changes splicing in human cells, and zebrafish and quail cells and embryos. Here we present evidence that methylation at C62 in U6 is associated with altered splicing and CHD. The potential importance of scaRNAs as a developmentally important regulatory mechanism controlling alternative splicing of mRNA is unappreciated and needs more research.

**Enhancer-associated long non-coding RNA regulates CTGF locus in calcific aortic valve stenosis.** A. Chignon, M. Rosa, M.C. Boulanger, G. Mkannez, D. Argaud, R. Devillers, S. Thériault, Y. Bossé, P. Mathieu. Institut universitaire de cardiologie et de pneumologie de Québec, Université Laval, Quebec City, QC, G1V 4G5, Canada.

**Introduction:** Calcific aortic valve stenosis (CAVS) is a chronic and prevalent heart valve disorder characterized by ectopic mineralization and a fibrogenic response. Growing evidence suggests that long non-coding RNAs (lncRNAs) are transcribed at regulatory loci such as enhancers. In topologically associated domains (TAD), lncRNA may be located in hub enhancers that orchestrate the transcription process. Whether an enhancer-associated lncRNA participates to CAVS and controls gene expression of dysregulated loci is presently unknown. **Methods:** The expression of lncRNAs was determined by RNA sequencing in 19 calcific aortic valves vs 8 normal valves, and dysregulated noncoding transcripts were prioritized by functional annotation of epigenetic marks. Functional characterization was carried out by chromatin immunoprecipitation (ChIP) and gene expression analyses. **Results:** Transcriptomic analysis by RNA sequencing combined with the analysis of H3K27ac epigenetic mark identified that one lncRNA located in an enhancer is dysregulated in CAVS. The overexpressed lncRNA is localized in a TAD comprising the *CTGF* locus, a gene involved in the control of fibrosis. Annotation of the locus in aorta indicates the presence of a cluster of enhancer with CTCF binding sites suggesting the presence of a hub enhancer. ChIP data indicate that H3K27ac at the lncRNA locus is increased by several-fold in the presence of CAVS. The lncRNA is localized in both the nucleus and the cytosol. Whole-genome chromatin conformation capture (Hi-C) data analysis indicates that the lncRNA locus interacts with *CTGF*, a pro-fibrotic gene that shares the same TAD. Treatment of human valve interstitial cells (VICs) with TGF- $\beta$ , a factor known to up-regulate CTGF, increased the expression of the lncRNA by 2.95 fold. An oligonucleotide antisense-mediated knockdown of the lncRNA lowered its expression and largely abrogated TGF- $\beta$ -mediated expression of CTGF. In addition, antisense-mediated knockdown of the lncRNA reduced the expression of COL1A1 and the secretion of pro-collagen-1 $\alpha$ . **Conclusion:** An epigenetically activated enhancer-associated lncRNA in CAVS controls the *CTGF* locus and promotes fibrogenesis.

**Gene expression profiling of coronary vasculopathy and rejection episodes after cardiac transplantation.** O. McDaniel, M. Garrett, L. McDaniel, C. Moore. Univ Mississippi Med Ctr, Jackson, MS.

Identification of biological markers in the context of coronary vasculopathy (CV) and or allograft rejection episode (RE) after cardiac transplantation is useful for early detection of the development of CV and/or RE. Rejection after cardiac transplantation is a complex immunologic response involving multiple signaling processes, associated with inflammatory pathways. The expression of the innate and adaptive immunity signaling proteins such as cytokines and Toll-like receptors are increased in peripheral blood mononuclear cells (PBMCs) and cardiac tissues during cardiac dysfunction. The goal was to screen by microarray analysis cluster of genes associated with these events and further verify association levels with CV and RE. CDNA microarray was developed from PBMCs of patients with RE and or CV using a combined Human 19K and 8K gene probes. The resulting database was normalized and underwent an unsupervised cluster analysis comparing samples associated with RE/CV vs. no rejection, no CV. Gene ontology-response to stimuli demonstrated in the following distribution: H19K- Grade 0 vs. grade 3 Rejection Gene Ontology Regulation of immune response (IR) 26.58% Innate immune response 26.58% Positive regulation of IR 21.5% Adaptive IR 10.36% Humoral IR 7.59% Therefore, extracting only the gene subset of interest we studied expression levels of innate immune response and cytokine genes in association with RE and CV in a new group of patients who undergone cardiac transplantation. The TLR2, and TLR4 which are expressed in cardiac myocytes were elevated in PBMCs, plasma and biopsy specimen in response to rejection and CV. The mean  $\pm$ SEM level of TLR2 mRNA was increased only 1.8-fold in PBMCs ( $p < 0.05$ ) but 4.5-fold in biopsy samples from patients with grade 3A rejection or grade III CV vs. grade 1A/null. Protein concentration of IL-18 and Interferon-gamma (IFN- $\gamma$ ) were in direct correlation with RE and CV. Nonetheless, in the presence of increased concentration of IL-10 and decreased IFN- $\gamma$  in spite of increased IL-18, the grafts were rejection free. In conclusion, peripheral concentration of cytokines correlate with the local production seen in biopsy specimens. Thus, expression profiles of the innate immune signaling pathway may detect signals to predict early rejection episodes.

**Using endothelial cell molecular QTLs to dissect coronary artery disease risk.** L.K. Stolze<sup>1</sup>, M.B. Whalen<sup>1</sup>, N.K. Hadeli<sup>1</sup>, A. Eshghi<sup>1</sup>, A. Conklin<sup>1</sup>, R. Victor<sup>2</sup>, C.E. Romanoski<sup>1</sup>. 1) Department of Cellular and Molecular Medicine, University of Arizona, Tucson, AZ; 2) Department of Molecular and Cellular Biology, University of Arizona, Tucson, AZ.

The leading cause of mortality worldwide is Coronary Artery Disease (CAD), which is caused by genetic and environmental risk factors. Estimates show CAD to be approximately 50% heritable, and accordingly, Genome-Wide Association Studies in over hundreds of thousands of individuals have revealed more than 160 risk haplotypes enriched in CAD patients versus controls. Still, the majority of associated loci reside outside the coding genome, suggesting regulatory function by way of unidentified mechanisms. Further, given the specificity of gene regulation, non-coding variants that perturb target gene expression likely function in specific cell types and disease-promoting activation states. The overarching goal of this project is to overcome challenges in identifying functional non-coding genetic variants linked to CAD risk by exploiting knowledge of regulatory networks in vascular endothelial cells that play a critical role in the onset of CAD pathogenesis. Our strategy is to build and analyze a comprehensive dataset detailing epigenetic molecular traits genome-wide in a population of over 50 primary arterial endothelial cell cultures isolated from aortic explants of individuals from both sexes and three major ancestral populations. This unique dataset includes genotypes, chromatin accessibility, histone modification, transcription factor binding, and transcriptomics genome-wide to identify regulatory elements whose functions are impaired by non-coding genetic variation. We collected molecular phenotypes from endothelial cells with and without exposure to the pro-inflammatory cytokine interleukin 1 beta. This design enables our discovery of genetically-driven individual responsiveness to heightened systemic inflammation that is a risk factor for CAD. Associations detected in these studies will provide important insights into common genetic variants that perturb endothelial-specific gene expression profiles in quiescent and pro-inflammatory states. Non-coding genetic variants that associate with epigenetic phenotypes provide evidence of the mechanisms by which CAD associated loci effect disease risk. Further, associations specific to the inflammatory setting demonstrate gene-by-environment interactions whereby risk alleles only drive risk in this disease-promoting environment. Taken together, our findings have implications not only for the functional genetics of CAD, but also inform studies of cell type-specific gene expression in endothelial cells.

**3231W**

**Rejuvenation of senescent endothelial progenitor cells by extracellular vesicles derived from mesenchymal stromal cells.** L. Wang<sup>1,2</sup>, J.Q. Wei<sup>3,4</sup>, J.M. Hare<sup>3,4</sup>, C. Dong<sup>3,4</sup>. 1) John P. Hussman Institute for Human Genomics; 2) Dr. John T. Macdonald Foundation Department of Human Genetics; 3) Interdisciplinary Stem Cell Institute; 4) Department of Medicine, University of Miami Miller School of Medicine, Miami, FL 33136.

Endothelial progenitor cells (EPCs) play a crucial role in vascular repair and angiogenesis. EPC senescence resulting from aging or exposure to other cardiovascular (CV) risk factors not only augments atherosclerosis, the underlying cause of ischemic CV diseases, but also diminishes angiogenesis following ischemic events. Thus, rejuvenating endogenous senescent EPCs in individuals at risk for CV diseases is of substantial clinical importance. Clinical trials on mesenchymal stromal cell (MSC) transplantation showed that young allogeneic MSCs but not aged autologous MSCs improved circulating EPC functionality in patients with dilated cardiomyopathy (DCM)—a disease characterized with microvascular lesions. We hypothesize that MSCs secrete bioactive factors to regulate EPC functions. To test this hypothesis, we used a transwell system to co-culture MSCs and EPCs without direct cell-cell contact. We found that young but not aged MSCs rejuvenated aged EPCs, as evidenced by decreased expression of cellular senescence markers (senescence-associated  $\beta$ -galactosidase, p16<sup>INK4A</sup> and p19<sup>ARF</sup>), and increased proliferation and differentiation capacity. Extracellular vesicles (EVs) are secreted by most types of cells and contain bioactive molecules to mediate intercellular communication. To further test if rejuvenation of EPCs by MSCs is mediated by EVs, we treated senescent EPCs with EVs purified from culture media of MSCs and demonstrated that EVs derived from young but not aged MSCs were capable of rejuvenating aged EPCs. Once EVs are taken up by the recipient cells either by receptor-mediated endocytosis or fusion of membranes, cargos packaged inside EVs, such as miRNA, are released to regulate gene expression in the recipient cells. We and others have shown that miR-126 is essential to maintain endothelial cell functionality and angiogenesis. The expression of miR-126 decreases during aging in both EPCs and MSCs. In an attempt to generate competent EVs for EPC rejuvenation, we overexpressed miR-126 in old MSCs to make them secrete “tailored” EVs (TEVs) loaded with miR-126. These TEVs from aged MSCs effectively rejuvenated aged EPCs *in vitro* and promoted angiogenesis *in vivo* in a mouse hind limb ischemia model (n=3, P<0.05). Our data support that EVs mediate the effects of MSCs on EPCs. In addition, our study suggests that EVs is a promising platform for developing an acellular therapeutic approach to rejuvenate senescent EPCs to treat ischemic CV disease.

**Coronary artery disease genes SMAD3 and TCF21 promote opposing interactive genetic programs that regulate smooth muscle cell differentiation and disease risk.** Q. Zhao<sup>1</sup>, D. Iyer<sup>1</sup>, R. Wirka<sup>1</sup>, A. Naravane<sup>1</sup>, T. Nguyen<sup>1</sup>, B. Liu<sup>2</sup>, M. Nagao<sup>1</sup>, P. Cheng<sup>1</sup>, C.L. Miller<sup>3</sup>, J.B. Kim<sup>1</sup>, M. Pjanic<sup>1</sup>, T. Quertermous<sup>1</sup>. 1) Division of Cardiovascular Medicine, Stanford University School of Medicine, Stanford, CA; 2) Department of Genetics, Stanford University School of Medicine, Stanford, CA; 3) Center for Public Health Genomics, Department of Public Health Sciences, Biochemistry and Genetics, and Biomedical Engineering, University of Virginia, Charlottesville, VA.

Although numerous genetic loci have been associated with coronary artery disease (CAD) with genome wide association studies, efforts are needed to identify the causal genes in these loci and link them into fundamental signaling pathways. Recent studies have investigated the disease mechanism of CAD associated gene *SMAD3*, a central transcription factor (TF) in the TGF $\beta$  pathway, investigating its role in smooth muscle biology. *In vitro* studies in human coronary artery smooth muscle cells (HCASMC) revealed that *SMAD3* modulates cellular phenotype, promoting expression of differentiation marker genes while inhibiting proliferation. RNA sequencing and chromatin immunoprecipitation sequencing studies in HCASMC identified downstream genes that reside in pathways which mediate vascular development and atherosclerosis processes in this cell type. HCASMC phenotype, and gene expression patterns promoted by *SMAD3* were noted to have opposing direction of effect compared to another CAD associated TF, *TCF21*. At sites of *SMAD3* and *TCF21* colocalization on DNA, *SMAD3* binding was inversely correlated with *TCF21* binding, due in part to *TCF21* locally blocking chromatin accessibility at the *SMAD3* binding site. Further, *TCF21* was able to directly inhibit *SMAD3* activation of gene expression in transfection reporter gene studies. In contrast to *TCF21* which is protective toward CAD, *SMAD3* expression in HCASMC was shown to be directly correlated with disease risk. We propose that *SMAD3* inhibits dedifferentiation that is required for HCASMC to expand and stabilize disease plaque, counteracting the protective dedifferentiating activity of *TCF21* and promoting disease risk.

Olthoff<sup>3</sup>, A. Shaked<sup>4</sup>, D.J. Rader<sup>1,5</sup>, B.E. Engelhardt<sup>6</sup>, S.F.A. Grant<sup>2,7</sup>, C.D. Brown<sup>1</sup>.* 1) University of Pennsylvania, Philadelphia, PA; 2) Division of Human Genetics, The Children's Hospital of Philadelphia, Philadelphia, PA; 3) Department of Medicine, Columbia University, New York, NY; 4) Division of Transplant Surgery, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 5) Department of Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; 6) Department of Computer Science, Princeton University, Princeton, NJ; 7) Department of Pediatrics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA.

We performed ChIP-Seq experiments for H3K4me3 and H3K27ac histone modifications, annotated putative noncoding functional regions, and identified 972 such regions with genotype-associated activity in the human liver (i.e., hQTL-Peaks). We integrated these findings with genome-wide gene expression data collected in human liver tissue and high-resolution promoter-focused Capture-C data obtained from the human liver-derived HepG2 cell line. We found 2,625 genes with genotype-associated expression levels (i.e., eQTL-Genes) and identified 29,328 significant promoter-H3K4me3 peak and 40,839 promoter-H3K27ac peak interactions. We showed that genes interacting with hQTL-Peaks are significantly more likely to have eQTLs relative to the genes that do not interact with hQTL-Peaks. 116 Gene-Peak pairs in the human liver showed evidence of shared genetic causality. Interestingly, such hQTL-Peaks were often not assigned to their nearest gene; in 71% of the co-regulated gene-peak pairs, there was at least one other gene that is closer to the hQTL-Peak than the eQTL-Gene that it was assigned to. Next, we integrated our findings with GWAS summary statistics for nine phenotypes, including coronary artery disease, blood lipid traits, and blood pressure traits. We found a total of 83 GWAS-Gene and 22 GWAS-Peak pairs with evidence of shared genetic causality. In 44% of the GWAS loci, our findings supported the previously reported gene as the likely causal gene. In 23% of the loci, our findings helped refine the causal gene among several that were suggested to be causal in the literature, and in the remaining loci (33%), our findings pinpointed to novel putatively causal genes in GWAS loci. In loci where we identified putatively causal regulatory region in the absence of a candidate causal gene, we took advantage of our chromatin conformation capture interaction data and identified gene promoters that make contact with the candidate regulatory regions at GWAS loci. Overall, our findings highlight the benefits of integrating multiple cellular traits for the identification and characterization of disease-causing genes and regulatory regions and contribute to basic understanding of genetic and epigenetic regulation of gene expression in the human liver tissue.

**Epigenome-wide methylation survival analyses identify seven loci associated with time to recurrent stroke and composite vascular endpoints in participants from the Vitamin Intervention for Stroke Prevention (VISP) clinical trial.**

*N.M. Davis Armstrong<sup>1</sup>, W.M. Chen<sup>2,3</sup>, F.C. Hsu<sup>4</sup>, M.S. Brewer<sup>1</sup>, S.R. Williams<sup>5</sup>, M.M. Sale<sup>2,3</sup>, B.B. Worrall<sup>2,5</sup>, K.L. Keene<sup>1,6</sup>.* 1) Department of Biology, East Carolina University, Greenville, NC; 2) Center for Public Health Genomics, University of Virginia, Charlottesville, VA; 3) Department of Public Health Sciences, University of Virginia, Charlottesville, VA; 4) Department of Biostatistical Sciences, Division of Public Health, Wake Forest School of Medicine, Winston-Salem, NC; 5) Department of Neurology, University of Virginia, Charlottesville, VA; 6) Center for Health Disparities, East Carolina University, Greenville, NC.

Aberrent DNA methylation has been implicated in both cardiovascular disease and stroke. To test for associations of DNA methylation and time to recurrent stroke and composite vascular endpoints, we performed epigenome-wide survival analyses using Cox proportional hazards regression models. Methylation  $\beta$ -values were generated from DNA extracted via whole blood of 180 participants from the Vitamin Intervention for Stroke Prevention (VISP) clinical trial, using Illumina HumanMethylation450K arrays. VISP was a multi-center, double-blind, randomized, controlled trial designed to determine whether daily supplementation of B vitamins (folic acid, B6, and B12) reduced recurrent stroke, myocardial infarction (MI), or death. After filtering,  $\beta$ -values for 473,864 autosomal CpG loci were analyzed, adjusted for covariates, and stratified by race: 76 African Americans (AA) and 104 European Americans (EA). The outcomes of interest included (1) VISP recurrent stroke, defined as a stroke during a two-year follow-up and (2) composite vascular endpoint, described as a coronary artery bypass graft, MI, angioplasty, cardiac collapse resuscitation, fatal coronary endpoint, or VISP recurrent stroke. In total, seven loci reached or exceeded genome-wide significance ( $p \leq 1.05 \times 10^{-7}$ ): four loci for AA recurrent stroke, two for AA composite endpoint, and one for EA composite endpoint. The most significant association was observed in the AA recurrent stroke analysis for methylation locus cg04059318, located in exon 1 of the *KLLN* gene and upstream of *PTEN* ( $p = 4.52 \times 10^{-8}$ ). Studies have suggested that neuronal *PTEN* loss results in neuroprotection against ischemia acutely, but contributes to vascular cognitive impairment long-term. cg00076998, located upstream of *PIK3CB* was the most significant locus associated with the AA composite endpoint ( $p = 7.87 \times 10^{-8}$ ). *PIK3CB* has been described to mediate pulmonary vascular smooth muscle proliferation, as well as being a key regulator in Akt cellular signaling. cg02365967, located in exon 35 of *HERC2*, was the only CpG locus reaching genome-wide significance in the EA analyses (composite endpoint,  $p = 8.01 \times 10^{-8}$ ). *HERC2* is involved in the regulation and prevention of adverse arterial remodeling. In conclusion, our survival analyses identified seven statistically significant loci associated with time to VISP recurrent stroke or composite vascular endpoint, several of which were located in gene regions with plausible stroke and cardiovascular implications.

**3235T****Determining the genetic basis of anthracycline-cardiotoxicity by transcriptomic response QTL mapping in a panel of induced cardiomyocytes.**

*D.A. Knowles<sup>1,2</sup>, C.K. Burrows<sup>3</sup>, J.D. Blischak<sup>3</sup>, K.M. Patterson<sup>3</sup>, D.J. Serie<sup>4</sup>, N. Norton<sup>5</sup>, C. Ober<sup>6</sup>, J.K. Pritchard<sup>1,6,7</sup>, Y. Gilad<sup>8,9</sup>.* 1) Department of Genetics, Stanford University, Stanford, CA; 2) Department of Radiology, Stanford University, Stanford, CA; 3) Department of Human Genetics, University of Chicago, Chicago, IL; 4) Department of Health Sciences Research, Mayo Clinic, Jacksonville, USA; 5) Department of Cancer Biology, Mayo Clinic, Jacksonville, USA; 6) Department of Biology, Stanford University, Stanford, CA; 7) Howard Hughes Medical Institute, Stanford University, CA; 8) Department of Medicine, University of Chicago, Chicago, IL.

Anthracycline-induced cardiotoxicity (ACT) is a key limiting factor in setting optimal chemotherapy regimes, with almost half of patients expected to develop congestive heart failure given high doses. However, the genetic basis of sensitivity to anthracyclines remains unclear. We created a panel of iP-SC-derived cardiomyocytes from 45 individuals and performed RNA-seq after 24h exposure to varying doxorubicin dosages. The transcriptomic response is substantial: the majority of genes are differentially expressed and over 6000 genes show evidence of differential splicing, the later driven by reduced splicing fidelity in the presence of doxorubicin. We show that inter-individual variation in transcriptional response is predictive of in vitro cell damage, which in turn is associated with in vivo ACT risk. We developed an efficient linear mixed model, *suez*, which detects 447 response-expression quantitative trait loci (QTLs). Combining *suez* with our RNA splicing quantification algorithm LeafCutter we find 42 response-splicing QTLs. These molecular response QTLs are enriched for lower p-values in ACT genome-wide association and enable prediction of cellular damage, supporting the in vivo relevance of our map of genetic regulation of cellular response to anthracyclines. .

**3236F****Enhancer-mediated enrichment of interacting JMJD3-DDX21 to ENPP2 locus prevents R-loop formation and promotes transcription elongation.**

*D. Argaud, M.C. Boulanger, G. Mkannez, P. Mathieu.* Quebec Heart and Lung Institute, Université Laval, Quebec, Quebec, Canada.

**Introduction:** *ENPP2*, which encodes for the enzyme autotaxin (ATX), plays an important role in cancer and in chronic inflammatory disorders such as fibrosis, arthritis, and cardiovascular diseases. Growing evidence suggests that epigenetic processes control inflammation. To this effect, JMJD3, a H3K27me3 demethylase, participates to the regulation of several inflammatory genes. However, the molecular interplay between JMJD3 and other H3K27me3 demethylase such as UTX in regulating inflammation is still largely unknown. In this work, we investigated the role of H3K27me3 demethylase and its interactome on the regulation of the *ENPP2* locus. **Methods:** HEK293T cells were treated with LPS and functional characterization of gene expression was carried out. Chromatin immunoprecipitation coupled with qPCR (ChIP-q-PCR) was used to evaluate the recruitment of JMJD3 and its interactome to the *ENPP2* locus. CRISPR-Cas9 was used to evaluate the functional role of a distant-acting enhancer. **Results:** In reporter assay, LPS increased the activity of promoter region of *ENPP2*. LPS also promoted the expression of *ENPP2*, through a NF- $\kappa$ B pathway, involving the recruitment of p65 on two  $\kappa$ B consensus sequences located in the promoter. Simultaneously, the level of H3K27me3, a histone repressive mark, was removed by UTX. Knockdown of JMJD3 with small interfering RNA (siRNA) prevented LPS-mediated expression of *ENPP2*. JMJD3 controlled the expression of *ENPP2* in a nonenzymatic manner and was recruited to the transcription start site (TSS) and within the gene body. Mass spectrometry analysis revealed a novel interaction for JMJD3 with DDX21, a RNA helicase that unwinds R-loops created by hybridization between nascent RNA transcript and DNA template. ChIP re-ChIP experiments confirmed the co-recruitment of JMJD3-DDX21 as a protein complex at TSS. Upon LPS treatment, JMJD3 is necessary for DDX21 recruitment to TSS and within the gene body, allowing the resolution of aberrant R-loops. CRISPR-Cas9-mediated deletion of a distant-acting enhancer, located at 82kb from *ENPP2*, decreased the expression of *ENPP2* and lowered the recruitment of JMJD3-DDX21 complex at TSS and the progression of this complex through the gene body. **Conclusions:** UTX is necessary for the removal of H3K27me3, whereas enhancer-mediated enrichment of novel JMJD3-DDX21 interaction at *ENPP2* locus is necessary for transcription elongation via the suppression of aberrant R loops formation in response to inflammatory stimulus. .

**Genetic and environmental effects on vascular endothelium gene regulation and cardiovascular traits.** A.S. Findley<sup>1</sup>, A.L. Richards<sup>1</sup>, C. Petrin<sup>1</sup>, A.S. Shanku<sup>1</sup>, A. Alazizi<sup>1</sup>, E. Doman<sup>1</sup>, O. Davis<sup>1</sup>, N. Hauff<sup>2</sup>, Y. Sorokin<sup>2</sup>, X. Wen<sup>3</sup>, R. Pique-Regi<sup>1,2</sup>, F. Luca<sup>1,2</sup>. 1) Center for Molecular Medicine and Genetics, Wayne State University, Detroit, MI; 2) Department of Obstetrics and Gynecology, Wayne State University, Detroit, MI; 3) Department of Biostatistics, University of Michigan, Ann Arbor, MI.

GWAS and large-scale eQTL studies, such as GTEx, have identified thousands of genetic variants associated with complex traits and gene expression. However, only a limited number of environmental factors are measured in these studies, potentially confounding genetic effect sizes when the underlying environment is heterogeneous. Measuring molecular phenotypes (gene expression, chromatin accessibility) in tightly controlled cellular environments provides a more tractable setting in which to study gene-environment interactions in the absence of other confounding variables. Here we have exposed human umbilical vein endothelial cells (HUVECs) from 17 healthy donors to 4 treatments (retinoic acid, dexamethasone, caffeine, and selenium) and appropriate vehicle-controls for 6 hours. We genotyped and performed RNA-seq and ATAC-seq to model genetic and environmental effects on gene regulation and chromatin accessibility in the vascular endothelium, a common site of pathology in cardiovascular disease. All four treatments induced significant alterations in the transcriptional and chromatin landscapes. We found that genes near regions of differentially accessible chromatin were more likely to be differentially expressed (OR = [3.41, 6.52],  $p < 10^{-6}$ ). Additionally, we have identified transcription factor footprints in each condition and developed predictions for the effect of regulatory variants on transcription factor binding. Combining our treatment-specific predictions with GTEx eQTLs from the aorta, coronary, and tibial arteries, we identified 7,788 eGenes and observed an enrichment in eQTLs for variants predicted to disrupt transcription factor binding during treatment with dexamethasone, caffeine, and retinoic acid, indicating that these environmental conditions are latently present in GTEx samples. Indeed 71 genes have response eQTLs (reQTLs) (FDR = 10%). Using conditional allele-specific expression we validated 50% ( $p=10^{-8}$  compared to chance) of the reQTLs that we were able to test. We observed a 3.35-fold enrichment for genes associated with complex traits in GWAS for our reQTL genes compared to genes without a reQTL ( $p = 2.32 \times 10^{-9}$ ). Our approach leverages molecular phenotyping data in response to tightly controlled treatments to characterize the complex interplay between genes and environment and their role in complex traits, highlighting the importance of latent environmental exposures in large-scale datasets.

## 3238T

**Trans-eQTL and GWAS associations at ZNF800 missense variant rs62621812 suggest an extensive regulatory role in adipose tissue.** A.K. Iyengar<sup>1</sup>, J.P. Davis<sup>1</sup>, C.K. Raulerson<sup>1</sup>, S.M. Brotman<sup>1</sup>, A. Ko<sup>2</sup>, P. Pajukanta<sup>2,3</sup>, M. Laakso<sup>4</sup>, K.L. Mohlke<sup>1</sup>. 1) Department of Genetics, University of North Carolina, Chapel Hill, NC; 2) Department of Human Genetics, David Geffen School of Medicine at UCLA, Los Angeles, CA; 3) Molecular Biology Institute at UCLA, Los Angeles, CA; 4) University of Eastern Finland, School of Medicine, Kuopio, Finland.

Subcutaneous adipose *trans*-eQTL studies have identified variants associated with expression level of multiple distant genes (>5 Mb away), suggesting that they serve as master regulators of adipose gene expression. We examined trait associations and molecular and biological mechanisms of an adipose *trans*-eQTL signal represented by zinc finger protein ZNF800 variant rs62621812, encoding Pro103Ser, previously shown to be associated ( $P \leq 5 \times 10^{-8}$ ) with expression level of nine distant genes in a microarray analysis of the Metabolic Syndrome in Men (METSIM) study ( $n=770$ ). To assess the potential contribution of this signal to adipose-related traits, we explored GWAS results in the UK Biobank ( $n>478,000$ ). rs62621812 was associated ( $P \leq 5 \times 10^{-8}$ ) with 19 obesity-related traits including whole body impedance ( $P=2 \times 10^{-30}$ ). To identify additional target genes, we analyzed METSIM adipose RNA-seq-based expression levels ( $n=434$ ). rs62621812 was associated ( $P \leq 5 \times 10^{-8}$ ) with five additional distant genes, and six of the total 14 target genes are known transcriptional regulators, which may expand the network of genes regulated by this signal. The Pro103Ser substitution was also associated with increased expression of ZNF800 in *cis* ( $P \leq 3 \times 10^{-16}$ ). To detect possible molecular mechanisms for the *cis* association, we functionally annotated the variants in linkage disequilibrium ( $r^2 > 0.6$ , GoT2D EUR) with rs62621812 as well as the strongest GWAS variants ( $P \leq 5 \times 10^{-8}$ ) for whole body impedance. The lead Pro103Ser substitution variant was predicted by Polyphen and SIFT to be benign. Of 30 other variants, two are located in regulatory elements as predicted by adjacent H3K27ac and H3K4me1 marks, interaction with the ZNF800 promoter in adipocyte Capture Hi-C data, and/or cross-species sequence conservation, suggesting that these variants may instead or also regulate expression of ZNF800. To further investigate the role of ZNF800 in adipose-specific gene regulation, we are using a CRISPR-Cas9 approach to knock out ZNF800 function in SGBS and SW872 preadipocytes. We have produced two independent clones that exhibit 50-60% decreased ZNF800 expression, and experiments are underway to further alter ZNF800 function and assess effects on target gene expression and adipocyte function. Determining the effects of this putative master regulator in adipose tissue could provide greater insight into the molecular mechanisms of *trans*-eQTLs and the biological mechanisms underlying obesity.

**Large chromosome 4q25 intergenic deletion disrupts chromatin structure and leads to familial sinus node dysfunction.** *H. Murata*<sup>1,2</sup>, *P. Lindenbaum*<sup>1</sup>, *S. Le Scouarnec*<sup>1</sup>, *E. Baron*<sup>1</sup>, *A. Rajalu*<sup>3</sup>, *F. Kyndt*<sup>3</sup>, *JF. Deleuze*<sup>4</sup>, *H. Le Marec*<sup>3</sup>, *V. Probst*<sup>1,3</sup>, *R. Redon*<sup>1,3</sup>, *JJ. Schott*<sup>1,3</sup>. 1) l'institut du thorax, INSERM, CNRS, UNIV Nantes, Nantes, France; 2) Department of Cardiovascular Medicine, Nippon Medical School, Tokyo, Japan; 3) l'institut du thorax, CHU Nantes, Nantes, France; 4) Centre National de Recherche en Génomique Humaine, CEA, Evry, France.

Sinus node dysfunction (SND) refers to several conditions causing physiologically inappropriate atrial rates. Genetics of human SND remains poorly understood with few genes identified (*HCN4*, *SCN5A*, *GJA5*, *KCNQ1*, *MYH6* and *ANK2*) and further genetic heterogeneity. Here we report two families with SND segregating with an intergenic deletion associated with long-range *cis*-regulatory elements (CREs) of *PITX2*. We first applied exome sequencing to a 4-generation family presenting 16 patients with SND, atrial fibrillation and/or repolarization abnormalities that did not allow to identify the disease-causing gene within a 16.5-cM linkage interval ( $Z_{max}=5.9$ ,  $\theta=0$ ) on chr.4q25 although immunoblot of a muscle biopsy revealed a striking decrease in ANK-B expression. We then applied 30x whole genome sequencing (WGS) in 2 patients and identified 72 rare (<0.1%) SNVs and a 15-Kb deletion using LUMPY in the candidate interval. This intergenic deletion, which was located between *PITX2* and *ANK2* and contained a CTCF motif, was segregating in all patients and was not found in 855 French control genomes. We also applied WGS on a second family presenting 5 patients with SND and negative for all SND genes and identified a 91-Kb deletion overlapping the initial deletion. CTCF functions as a genome organizer mediating genomic interactions between genes and CREs. To clarify a possible regulatory function of the 1.5-Mb intergenic region containing the deletion, we interrogated 3 epigenetic databases. High-throughput chromosome conformation capture (Hi-C) data (1) revealed that this intergenic region was placed in a topologically associating domain (TAD) containing *PITX2*. Chromatin interaction analysis by paired-end tag (ChIA-PET) data of CTCF in MCF-7 (2) suggested several possible functional chromatin loops in the TAD. Of them, a CTCF-mediated chromatin loop corresponding to a 300-Kb genomic region was clarified as a possible CRE using histone modification data from Roadmap. The region ranging between the intra-deletion CTCF motif and another distal motif was repressed in H3K27me3 profiles of fetal heart and H1 ESC-derived mesenchymal stem cells, while the region was activated in H3K27ac profiles of H1 ESC-derived mesendoderm cells. Thus, this CRE may regulate expression of *PITX2* and/or *ANK2* in pacemaker cell differentiation. Ongoing experiments on patient's iPSC-derived cardiomyocytes will further characterize the disease mechanism. (1) Leung *et al.* Nature, 2015 (2) Li *et al.* Cell, 2011.

**Dynamic effects of genetic variation on gene expression during cardiomyocyte differentiation.** *K. Rhodes*<sup>1</sup>, *R. Elorbany*<sup>2</sup>, *B. Strober*<sup>3</sup>, *N. Krishnan*<sup>4</sup>, *A. Battle*<sup>3,4</sup>, *Y. Gilad*<sup>1,2</sup>. 1) Human Genetics, University of Chicago, Chicago, IL; 2) Genetic Medicine, University of Chicago, Chicago, IL; 3) Biomedical Engineering, Johns Hopkins University, Baltimore, MD; 4) Computer Science, Johns Hopkins University, Baltimore, MD.

Gene regulatory changes during developmental processes contribute to complex traits and diseases in humans. In order to fully understand the mechanisms through which regulatory variants generate phenotypic effects during development, it is necessary to study their effect *through time* as cells differentiate from a pluripotent state to a mature one. Such research has previously been challenging in humans due to ethical and practical limitations regarding the use of human fetal tissues. To address these challenges, we leveraged the ability to differentiate induced pluripotent stem cells (iPSCs) to cardiomyocytes *in vitro*. We differentiated 19 Yoruba iPSC lines to cardiomyocytes and collected RNA-sequencing data every 24 hours for 16 days. We combined this high-resolution time course dataset and existing genotype information to understand temporal patterns of gene regulation. First, we identified *cis*-eQTLs in each time step independently; we found ~100 genome-wide significant eGenes (eFDR = .05) per time step. We determined that eQTL summary statistics from proximal time points are more strongly correlated than distal time points, confirming that time is a primary factor in explaining gene regulatory changes in our data. We next developed a statistical model to identify *cis*-eQTLs whose effects change as a function of time throughout cardiomyocyte differentiation, or "dynamic eQTLs". Using this approach, we found 556 significant dynamic eGenes (eFDR = .01). We characterized the genomic and epigenomic contexts of dynamic eQTLs. We found that early-acting dynamic QTLs are enriched for iPSC enhancer and promoter marks while late-acting dynamic QTLs are enriched for enhancer and promoter marks from primary heart tissue. Lastly, we explored the potential role of these dynamic QTLs in the context of cardiovascular disease. The dynamic QTLs we identified reveal another level of genetically encoded regulation spanning developmental time and could impact cardiac traits and cardiovascular disease.

**Dissecting NF- $\kappa$ B function using multi-species, multi-tissue epigenomic comparisons.** M.D. Wilson<sup>1,2</sup>, A. Alizada<sup>1,2</sup>, N. Khyzha<sup>3,4</sup>, L. Wang<sup>1,2</sup>, L. Antounians<sup>1,2</sup>, A. Medina-Rivera<sup>1,5</sup>, M. Liang<sup>1,2</sup>, M. Khor<sup>1,2,4</sup>, J.E. Fish<sup>3,4</sup>. 1) Genetics and Genome Biology, SickKids Research Institute, Toronto, Ontario, Canada; 2) University of Toronto, Department of Molecular Genetics, Toronto, Canada; 3) University of Toronto, Department of Laboratory Medicine and Pathobiology, Toronto, Canada; 4) University Health Network, Toronto General Hospital Research Institute, Toronto, Canada; 5) Universidad Nacional Autónoma de México, International Laboratory for Research in Human Genomics, Juriquilla, Mexico.

The nuclear factor kappa-light-chain-enhancer of activated B cells (NF- $\kappa$ B) transcription factor plays an ancient and prominent role in orchestrating inflammation and innate immunity. Genome-wide DNA binding assays of the human NF- $\kappa$ B subunit RELA (p65) has revealed tens of thousands of NF- $\kappa$ B binding sites and hundreds of target genes. However, the function of individual RELA binding sites and the extent to which NF- $\kappa$ B occupancy has evolved within mammals are not well understood. Here we characterized the genome-wide binding of RELA in primary vascular endothelial cells (ECs) isolated from the aortas of human, mouse and cow. ECs were stimulated acutely with the pro-inflammatory cytokine tumor necrosis factor alpha (TNFA). We profiled RELA and JUN occupancy, open chromatin, select histone modifications, and RNA expression revealing distinct modes of RELA binding. We found ~5000 RELA sites conserved in all three species, ~2000 of which were also bound in multiple human cell types. This conserved core of NF- $\kappa$ B binding sites were enriched for genes controlling and pro-inflammatory responses, human disease mutations, and were also prominent components of ~40 inflammation induced super-enhancers (SEs) common to several tissues. To gain insight into the function of individual conserved NF- $\kappa$ B binding sites we focused on the inflammation-induced SE proximal to the monocyte recruiting chemokine *CCL2*, which we detected as a SE in all three species and across multiple cell types. We tested the functional significance of six conserved RELA binding sites comprising this SE using CRISPR/Cas9 genome editing. We found that only the most proximal upstream RELA binding site could abolish the induction of *CCL2* upon TNFA treatment. This site also contains a disease-associated variant that can modulate *CCL2* induction. Overall, our cross-species and cross-tissues analyses give new insights into NF- $\kappa$ B biology, its pathogenesis, and function in inflammation-induced SEs in mammals.

Long-range chromosomal interactions bring distal regulatory elements and promoters together to regulate gene expression in biological processes. By performing promoter capture Hi-C (PCHi-C) on human embryonic stem cell-derived cardiomyocytes (hESC-CMs), we show that such promoter interactions are a key mechanism by which enhancers contact their target genes after hESC-CM differentiation from hESCs. We also show that the promoter interactome of hESC-CMs is associated with expression quantitative trait loci (eQTLs) in cardiac left ventricular tissue; captures the dynamic process of genome reorganisation after hESC-CM differentiation; overlaps genome-wide association study (GWAS) regions associated with heart rate; and identifies new candidate genes in such regions. These findings indicate that regulatory elements in hESC-CMs identified by our approach control gene expression involved in ventricular conduction and rhythm of the heart. The study of promoter interactions in other hESC-derived cell types may be of utility in functional investigation of GWAS-associated regions.

**Circulating miR-92a could be a possible biomarker of change in blood pressure: A four-year follow-up study.** R. Fujii<sup>1</sup>, H. Yamada<sup>2</sup>, E. Munetsuna<sup>3</sup>, M. Yamazaki<sup>4</sup>, K. Ohashi<sup>4</sup>, H. Ishikawa<sup>4</sup>, K. Maeda<sup>4</sup>, C. Hagiwara<sup>4</sup>, Y. Ando<sup>4</sup>, S. Hashimoto<sup>2</sup>, N. Hamajima<sup>5</sup>, K. Suzuki<sup>1</sup>. 1) Department of Preventive Medical Sciences, Fujita Health University School of Health Sciences, Toyoake, Aichi, Japan; 2) Department of Hygiene, Fujita Health University School of Medicine, Toyoake, Aichi, Japan; 3) Department of Biochemistry, Fujita Health University School of Medicine, Toyoake, Aichi, Japan; 4) Department of Clinical Biochemistry, Fujita Health University School of Health Sciences, Toyoake, Aichi, Japan; 5) Department of Healthcare Administration, Nagoya University Graduate School of Medicine, Nagoya, Aichi, Japan.

MicroRNAs (miRNAs) are small non-coding RNAs of ~25 nucleotides in length that play a crucial role in several pathophysiological conditions and diseases. Recent experimental studies have revealed that miRNAs are key regulators in developing hypertension via endothelial dysfunction. The association of miRNAs and hypertension in human has been investigated in cross-sectional studies, with few studies in longitudinal analysis. The aim of our study was to examine the relationship between the expression levels of circulating miRNAs and change in blood pressure (BP). A total of 229 residents who participated in the health-check up in both 2012 and 2016, in Hokkaido, Japan were finally analyzed. The study protocol and procedure was approved by the Ethics Review Committee of Fujita Health University. Written informed consent was obtained from all participants. The quantitative real-time polymerase chain reaction was used to determine the expression levels of nine circulating miRNAs that previously reported in cross-sectional studies. Log-transformed values of each miRNA were used in our statistical analysis. Mean blood pressure (MBP) was calculated using systolic blood pressure (SBP) and diastolic blood pressure (DBP). The % change in BP from 2012 to 2016 was calculated according to the following formula: % change of BP =  $(BP_{2016} - BP_{2012}) / BP_{2012} \times 100$ . Hypertension was defined as SBP  $\geq$  130 and/or DBP  $\geq$  85 and taking antihypertensive agents. The mean age (SD) of this population at the baseline survey in 2012 was 63.7 (8.5), and the proportion of male was 45.9%. In a cross-sectional analysis using the baseline data, miR-92a was nominally correlated with MBP after the Bonferroni correction ( $P = 0.06$ ), and then selected for further analyses. The expression level of miR-92a was significantly associated with % change in MBP after adjusting for potential confounders with the standardized  $\beta$  of 0.180,  $P = 0.04$ ), but was not an independent risk factor for incidence of hypertension ( $P = 0.30$ ). We found that the circulating miR-92a level was associated with a significant change in MBP in a population-based study. The results suggested that the circulating level of miR-92a could be a biomarker of change in BP. Further experimental studies are needed to elucidate biological mechanisms underlying this relationship.

**Identification and annotation of cardiac relevant long noncoding RNAs in iPSC-derived cardiomyocytes.** M. D'Antonio<sup>1</sup>, P. Benaglio<sup>2</sup>, W.W. Greenwald<sup>3</sup>, A. D'Antonio-Chronowska<sup>1</sup>, H. Matsui<sup>1</sup>, E.N. Smith<sup>1</sup>, K.A. Frazer<sup>1,2</sup>. 1) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA; 2) Department of Pediatrics and Rady Children's Hospital, University of California San Diego, La Jolla, CA; 3) Bioinformatics and Systems Biology, University of California San Diego, La Jolla, CA.

Over 97% of the human genome is estimated to be non-coding; yet a large portion of these non-coding regions are still actively transcribed. Tens of thousands of these transcripts are long non-coding RNAs (lncRNAs), and while most have unknown function, some have been found to affect central processes in cardiac biology including metabolism, hypertrophy, conduction, differentiation, and proliferation. Un-annotated lncRNAs could therefore play important roles in human cardiac traits, disease, or development. To facilitate genome-wide identification and annotation of cardiac relevant lncRNAs, we have generated data from iPSC-derived cardiomyocytes (iPSC-CMs) from iPSCORE including: RNA-seq from 144 lines; NKX2-5 ChIP-Seq, H3K27ac ChIP-Seq, and GroSeq from 7 lines; and Hi-C from 13 lines. We initially examined whether patterns of lncRNA regulation were similar to those of protein coding genes, and observed that, as with protein coding genes, high NKX2-5 binding was correlated with high histone acetylation and transcription of lncRNAs in iPSC-CMs. We therefore designed a "cardiac functional prediction score" based on rank of the strength of nearby NKX2-5 peaks, H3K27ac peaks, and GRO-seq transcripts at the TSS ( $\pm$  2kb) of each lncRNA genome-wide. This score both recovered known cardiac relevant lncRNAs, including *MALAT1* and *CDKN2B-AS1 (ANRIL)*, and highlighted novel cardiac relevant lncRNAs, including a lowly expressed Gencode lncRNA (*RP11-57G10.8*) with unknown function located 34 kb upstream of *SIRT1*, and an unnamed lncRNA located in *MYLK3*. To identify potential targets of putative novel cardiac relevant lncRNAs, we integrated high-depth iPSC-CM HiC maps with gene expression data from the 144 iPSC-CM lines. We calculated the correlations between the colocalized lncRNA and protein-coding genes and found 22 loops with expression correlations significantly different from zero ( $FDR < 0.05$ ), of which 18 were positively correlated and four were negatively correlated. Interestingly, the most significant association was between the 3' end of *PRDM16*, a transcription factor involved in dilated cardiomyopathy, and *LINC00982*, a lncRNA associated with cell proliferation and cell cycle progression. These analyses highlight similarities between the regulation of protein coding and lncRNA genes and provide a method for identifying and annotating tissue relevant lncRNAs.

**External chromatin accessibility quantitative trait loci (caQTLs) are enriched for association with human GWAS data independently of internal caQTLs.** *W.W. Greenwald<sup>1</sup>, A. D'Antonio-Chronowska<sup>2</sup>, H. Matsui<sup>2</sup>, E.N. Smith<sup>3</sup>, K.A. Frazer<sup>2,3</sup>.* 1) Bioinformatics and Systems Biology Graduate Program, University of California, San Diego, La Jolla, CA; 2) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA; 3) Department of Pediatrics and Rady Children's Hospital, University of California, San Diego, La Jolla, CA.

Epigenetic information has successfully been leveraged to identify causal variants and genes underlying human diseases. In particular, accessible chromatin has been shown to be highly enriched for trait- and disease-associated genetic variation in relevant cell types. Genetic variants that modify accessible chromatin (i.e. chromatin accessibility quantitative trait loci, caQTLs) are therefore promising candidate causal variants. These variants can be located within accessible chromatin peaks (internal caQTLs) or outside peaks (external caQTLs), but as the few caQTL studies performed to date have been biased toward internal caQTL discovery, the functional impact and disease-relevance of external caQTLs is largely unknown. To study this question, we have undertaken the largest caQTL study to date in 152 induced pluripotent stem cells (iPSCs) and their derived cardiomyocytes (iPSC-CMs). These cell lines come from 134 individuals in iPSCORE for which we have deep whole genome sequencing, gene expression data, and HiC reference maps. We identified ~900k and ~1m ATAC-peaks in iPSCs and iPSC-CMs, respectively – one of the largest sets of ATAC peaks to date. Using matrixQTL, we identified 4,297 ATAC peaks associated with genetic variation (caPeaks; FDR<0.05) in iPSC, and 4,018 in iPSC-CM. Although the majority of caPeaks were cell type specific, 835 of the caPeaks overlapped between the two cell types (OR=43.01,  $p<10^{-320}$ ). Notably, we found 94% of lead caQTLs to be external caQTLs. To understand the disease relevance of caPeaks and caQTLs, we examined GWAS enrichment in iPSC-CM features using FGWAS on UK BioBank data for pulse rate. We observed 2.7 fold enrichment within caPeaks above all ATAC peaks (20 fold above background), and a 7.2 fold enrichment for caQTLs fold above background, even when jointly modeled with the ATAC peaks. As the majority of caQTLs were external, these variants are therefore a highly promising novel annotation that could improve prioritization of causal variants. Ongoing analyses include characterization of how cell-type, chromatin state, and 3D architecture modify how caQTLs and caPeaks are enriched for disease and trait genetic signals across a range of heart relevant GWAS studies. Overall, this study is the first to identify caQTLs in multiple cell types using samples with the same genetic backgrounds, and to show that caQTLs which are external to accessible chromatin regions are highly enriched for association with human GWAS data.

**3246W**

**Susceptibility enhancers for coronary artery disease: From association to mechanism.** *M.U. Kaikkonen<sup>1</sup>, I. Selvarajan<sup>1</sup>, A. Ravindran<sup>1</sup>, P. Polonen<sup>2</sup>, A. Toropainen<sup>1</sup>, M. Heinaniemi<sup>2</sup>, M. Laakso<sup>3</sup>, C. Romanoski<sup>4</sup>, M. Civelek<sup>5</sup>.* 1) A.I. Virtanen Institute, University of Eastern Finland, Kuopio, Kuopio, Finland; 2) School of Medicine, University of Eastern Finland, Kuopio, Finland; 3) Institute of Clinical Medicine, Internal Medicine, University of Eastern Finland, Finland; 4) Department of Cellular and Molecular Medicine, University of Arizona, Tucson, USA; 5) Center for Public Health Genomics, Department of Biomedical Engineering, University of Virginia, Charlottesville, VA, USA.

Over 98% of SNPs associated with coronary artery disease are located in the noncoding sequences with yet undefined function. We and others have previously shown that a large fraction of associations affect gene regulation by perturbing enhancers, which are regulatory elements responsible for cell type-specific expression. Importantly, a significant number of susceptibility regions fall within enhancer elements specific to disease-relevant cell type and activation state. Still, a major challenge for understanding the biological function of susceptibility enhancers is the precise identification of their target genes. Here, we studied cell and stimulus-specific enhancers in all of the major cell types present in the atherosclerotic vascular wall; namely, endothelial cells, smooth muscle cells and macrophages. From these data, we discovered thousands of enhancers that overlap with coronary artery disease risk variants. Next, we sought to determine the enhancer target genes by 1) identifying the coding genes in physical contact with the susceptibility enhancers based on chromatin interaction data, 2) performing eQTL analysis in aorta and in the individual cell types, and 3) establishing enhancer-promoter links from correlation in enhancer and gene activity patterns across GRO-seq datasets. Altogether, hundreds of target genes were identified using the three methods, many exhibiting high cell-type specificity. The data collected will be used to identify networks of genes involved in disease pathogenesis and to select genes for functional studies. Altogether, we present here a comprehensive effort to identify and characterize the role of enhancer variants across disease relevant cell types to provide a mechanistic interpretation of the genetic basis of coronary artery disease.

**Aberrant mechanosensing triggers acute aortic dissections in a mouse model with a low penetrant risk allele in *Myh11*<sup>R247C</sup>.** S. Wang, C. Kwartler, T. Zhang, A. Peters, D. Milewicz. University of Texas Health Science Center at Houston.

The major risk factors for acute aortic dissections are hypertension (HTN) and pathogenic variants in heritable thoracic aortic disease (HTAD) genes. We have determined that individuals with early onset aortic dissections without a family history or syndromic features have an increased burden of rare genetic variants of unknown significance (VUSs) in HTAD genes. Furthermore, a subset of the VUSs identified in these cases are confirmed to disrupt protein function but to a lesser extent and termed these "risk variants". We assessed the role of one of these risk variants by engineering a mouse model with a homozygous *Myh11* missense variant (*Myh11*<sup>R247C</sup>) in the motor head of the smooth muscle myosin heavy chain. The mutated alteration decreases aortic contractility but does not cause aortic disease in mice. When hypertension is induced by feeding the mice L-NAME and high salt diet, blood pressures were both significantly increased within 2 weeks in wildtype (WT) and mutant mice. With induction of HTN, about 20% of mutant mice (4/22) die within 2 weeks but none of the WT mice (0/20) ( $p < 0.05$ ). Necropsy identified pericardial tamponade due to a retrograde dissection in the aortic root as the cause of death in the mutant mice. Electron microscopy analyses found abnormal formation of focal adhesions (FAs) in the mutant mice compared with WT, leading to greater distortion of FAs in the mutant mice when HTN was induced. RNA sequencing and pathway analysis of the *Myh11*<sup>R247C</sup> aortas identified the FA signaling as the major pathway altered in the mutant mouse with HTN. Phosphorylated FAK was increased in *Myh11*<sup>R247C</sup> aortas at baseline compared with WT, and increased further in *Myh11*<sup>R247C</sup> aortas with HTN induction. When smooth muscle cells (SMCs) were seeded on fibronectin-coated plates to engage FAs, levels of phosphorylated regulatory light chain were dramatically increased in *Myh11*<sup>R247C</sup> SMCs compared with WT, presumably to compensate for the defective myosin motor. Apoptosis markers, Bid and Bax, were also increased. To determine if FAK signaling and elevated apoptosis were involved in aortic dissection in the mutant mice, either a FAK inhibitor or p53 inhibitor were administered 7 days before and during HTN induction. Both treatments completely prevent dissection deaths ( $p < 0.05$  for both treatments). These data indicated aberrant mechanosensing through focal adhesions leading to increased apoptosis trigger aortic dissections in the *Myh11*<sup>R247C</sup> mouse model.

**3249W****Single cell profiling of cardiovascular development under hyperglycemic conditions reveals mechanistic links to congenital heart disease.** *J.E.*

*Gorzynski<sup>1,2</sup>, S.C. Juneja<sup>2</sup>, M.E. Slocumb<sup>3</sup>, S.L. Paige<sup>3</sup>, J.R. Priest<sup>1</sup>.* 1) Genetics, Stanford University, Stanford, CA; 2) Comparative Medicine, Stanford University, Stanford, CA; 3) Pediatric Cardiology, Stanford University, Stanford, CA.

**Background:** Maternal diabetes of any etiology (type 1, type 2, gestational) is known to increase the risk of congenital heart disease in offspring, an effect linked to elevated glucose levels in multiple clinical observations. However, the mechanism by which a hyperglycemic fetal environment resulting from increased maternal blood glucose alters cardiac development is unknown.

**Methods:** We performed single cell transcriptomics of explanted cardiac tissue from embryonic day 12.5 murine hearts. The hearts were exposed to physiologic conditions (normal glucose & insulin) or diabetic conditions (elevated glucose & insulin). Cell types were identified and segregated using previously validated transcriptional markers. Within each cell type cluster, control and experimental groups were compared to identify cell-type specific transcriptome changes in response to diabetic conditions. **Results:** We identified four cardiac specific cell types: cardiomyocytes, epicardial cells, endothelial cells and mesenchymal cells. In all cell types we observed an anabolic response to hyperglycemia (increased transcription of ribosomal and decreased transcription of mitochondrial genes). The diabetic group of cardiomyocytes and mesenchymal cells showed decreased expression of *ACTA2* (pval=6.56e-33, 2.25e-17 respectively). Additionally, endothelial cells in the diabetic group showed a decrease in *PFN1* (pval 7.33 e-23), a gene which codes for an actin binding protein. **Discussion:** Our novel data highlight the utility of single-cell transcriptome analysis in identifying cell-type specific responses to disease conditions. Genes involved in protein synthesis and cellular respiration were perturbed in all cell types, while changes in expression to genes responsible for cellular structure and contraction were unique to cardiomyocytes, mesenchymal cells and endothelial cells. This suggests a combinatorial effect of multiple cell types in mediating the emergence of congenital heart disease in the setting of maternal diabetes, representing multiple potential therapeutic targets for disease prevention.

**655T****Juvenile hyaline fibromatosis is an autosomal recessive genetic disease.**

**Four cases report.** J. Aparicio<sup>1</sup>, M.L. Hurtado Hernandez<sup>2</sup>, M. Barrientos Perez<sup>3</sup>, S. Chatelain Mercado<sup>4</sup>. 1) Genetics; 2) Cytogenetics; 3) Endocrinology, Hospital Para El Niño Poblano, San Andrés Cholula Puebla, Mexico; 4) Biotechnology, Metropolitan University of Mexico City.

*Juvenile hyaline fibromatosis (JHF) is considered a non frequent genetic, autosomal recessive; characterized by connective tissue disorder characterized by multiple subcutaneous nodules, gingival hypertrophy, osteolytic lesions, and joint deformities (contractures). As one of the main clinical symptoms, are multiple subcutaneous nodules, articular contractures, and gingival hypertrophy after 6 months of life. After one year old the subcutaneous nodules appears more frequently among teenagers a great variety of deformations are observed with movement limitations. 70 cases with JHC approximately are reported in the literature.* The hyaline fibromatosis juvenile (FHJ) is a rare genetic disease of connective tissue. It is characterized by multiple cutaneous nodules, hypertrophy, gingival, joint contractures and osteolytic injury FHJ is associated to genes that encodes the protein-2 morphogenesis (CMG2 or ANTXR2) located on the long arm of chromosome 4 (4q21.21). FHJ has an autosomal recessive Mendelian Inheritance pattern. The official name of this gene is "anthrax toxin receptor 2." Mutations in the ANTXR2 gene (also known as the CMG2 gene) cause FHJ. The ANTXR2 gene is therefore uncharged of producing a specific protein which is associated with the formation of small blood vessels (capillaries) A It is believed that this particular ANTXR2 protein keeps the normal structure of basement membranes, which are tiny structures that separate and support cells in a great variety of tissues. The main clinical features of the disease are caused by the accumulation of a clear (hyaline) substance in different parts of the body. The nature of this substance is not clear, but its chemical composition is made up of a protein and sugar molecules. It is believed that mutations in the ANTXR2 gene disrupt the formation of basement membranes, was the hyaline substance leaks through and alters various structure tissues body.

**656F****Whole exome sequencing to identify candidate genes associated with hereditary predisposition to UM.**

M.H. Abdel-Rahman<sup>1,2,3</sup>, K.M Sample<sup>1</sup>, B. Kelly<sup>4</sup>, D. Gordon<sup>4</sup>, P. Johansson<sup>5</sup>, R. Pilarski<sup>2,3</sup>, G. Boru<sup>1</sup>, T. Grosse<sup>1</sup>, J.B. Massengill<sup>1</sup>, D.D. Kinnamon<sup>2</sup>, F.H. Davidoff<sup>1</sup>, N. Hayward<sup>2</sup>, P. White<sup>4,6</sup>, C.M. Ce-bulla<sup>1,3</sup>. 1) Ophthalmology Department, The Ohio State University, Columbus, Ohio; 2) Division of Human Genetics, The Ohio State University, Columbus, Ohio; 3) The Ohio State University Comprehensive Cancer Center, Columbus, Ohio; 4) The Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, Ohio; 5) QIMR Berghofer Medical Research Institute, Brisbane, Australia; 6) Department of Pediatrics, The Ohio State University, Columbus, Ohio.

Objective: About 12% of uveal melanoma (UM) patients have features suggestive of hereditary cancer predisposition. Germline mutation in *BAP1* explains only 3-4% of these patients, suggesting the existence of other candidate genes. The goal of this study was to identify novel genes associated with hereditary predisposition to UM. Methods: Exome sequencing was carried out for 29 unrelated high-risk UM patients with no detectable mutations or deletions in *BAP1* and 10 of their relatives. The probands included 25 with familial UM, one with bilateral UM, one with congenital UM and 2 patients with strong family history of cancers observed in the BAP1-Tumor Predisposition. The relatives included 7 with UM, one with ovarian cancer and the unaffected parents of the congenital UM case. UM relatives were first degree in two instances and third degree in four. Results: We focused our initial analysis on genes with established association with hereditary predisposition to cancer, which are routinely tested in diagnostic laboratories. We identified coding pathogenic or potentially pathogenic variants in 5 cancer predisposition genes (*CHEK2*, *MLH1*, *PALB2*, *SMARCE1*, and *RET*) in 5 patients. In addition, 18 missense variants of uncertain significance (based on ACMG criteria) were identified in 11 patients. Biallelic inactivation of *PALB2* (somatic frameshift mutation and low RNA expression) and *MLH1* (loss of heterozygosity and loss of protein expression) were observed in the tumors from the respective patients. No evidence of biallelic inactivation of *CHEK2* or *SMARCE1* was observed in the tumors. Given the rarity of UM, we next assessed unreported or rare (MAF<0.0001) variants in potential cancer associated genes. Variants in cancer associated genes, mostly missense variants of uncertain significance, were identified in 24/29 patients. In 17 of those, more than one gene was impacted. Several of these variants were in genes in the DNA damage repair pathway. In one family, we confirmed functional alterations in three potential candidate tumor suppressor genes. Conclusions: The study provides limited/moderate evidence of gene/disease association of germline mutation in *PALB2* and *MLH1* with hereditary predisposition to UM. It also identifies several other potential candidate genes. The results suggest locus heterogeneity in predisposition to UM and potential multi-genic etiology in a subset of patients. Validation in a larger UM cohort is warranted.

**Clinical relevance of screening tools for detection of cancer predisposition syndromes in an Asian cohort of childhood tumors.** S. Chan<sup>1</sup>, W. Chew<sup>1</sup>, N.D. Ishak<sup>1</sup>, W. Lim<sup>2</sup>, S. Li<sup>1</sup>, S. Tan<sup>3</sup>, J. Teo<sup>2</sup>, T. Shaw<sup>1</sup>, K. Chang<sup>3</sup>, Y. Chen<sup>3</sup>, P. Iyer<sup>3</sup>, E. Tan<sup>3</sup>, M. Seng<sup>3</sup>, M. Chan<sup>3</sup>, A. Tan<sup>3</sup>, S. Low<sup>4</sup>, S. Soh<sup>3</sup>, A. Loh<sup>3</sup>, J. Ngeow<sup>1</sup>. 1) National Cancer Centre Singapore, Singapore; 2) SingHealth Duke-NUS Institute of Precision Medicine (PRISM), Singapore; 3) KK Women's and Children's Hospital, Singapore; 4) National Neuroscience Institute, Singapore.

**PURPOSE** Detection of cancer predisposition syndromes (CPS) is a challenge for pediatric oncologists, especially in cohorts with unknown prevalence of germline mutations. We assessed the utility of two clinical screening checklists for CPS validated by genomic sequencing and concurrently profiled the prevalence and spectrum of germline mutations in our Asian cohort of pediatric solid tumors. **PATIENTS AND METHODS** We evaluated 102 patients under age 19 years recruited at our tertiary medical center over a period of 31 months. Patient records were reviewed against two published checklists and germline mutations in 100 cancer-associated genes were profiled through a combination of whole-exome sequencing and multiplex ligation-dependent probe amplification on blood-derived genomic DNA. **RESULTS** Fifty-four patients met clinical criteria for CPS on both checklists, of which 10 (18.5%) harbored germline mutations in associated genes identified by sequencing. Specificity of screening was markedly improved by combining criteria of both checklists without effect on sensitivity. The 10 children (9.8%) had pathogenic germline mutations in six known cancer predisposition genes: *TP53*, *DICER1*, *NF1*, *FH*, *SDHD* and *VHL*. *TP53* was most frequently mutated, affecting five children with adrenocortical carcinoma, sarcomas and diffuse astrocytoma. Multiple pathogenic germline mutations were found in two patients. Disparity in prevalence of germline mutations across tumor types suggested variable genetic susceptibility and implied potential contribution of novel susceptibility genes. A family history of cancer was observed in only 50% of children with pathogenic germline mutations. **CONCLUSION** Currently available CPS screening checklists are adequately sensitive to detect at-risk children and are relevant for clinical application. Our study showed that 9.8% of Asian pediatric solid tumors have a heritable component, consistent with cohorts from other populations.

**658T**

**Novel *PTEN* gene variant associated with growing teratoma syndrome.** S.L. Cole<sup>1</sup>, B.P. Tullius<sup>1,2</sup>, S. Aradya<sup>3</sup>, V. Triano<sup>1</sup>, E.C. Huang<sup>4</sup>, T. Sanchez<sup>5</sup>, A. Pawar<sup>6</sup>, S.P. Shankar<sup>1</sup>. 1) Division Genomic Medicine, Department of Pediatric, UC Davis Health, Sacramento, CA; 2) Division of Hematology/Oncology/BMT, Nationwide Children's Hospital, Columbus, OH; 3) Invitae, San Francisco, CA; 4) Department of Pathology and Laboratory Medicine, University of California, Davis Medical Center, Sacramento, CA; 5) Department of Radiology, University of California, Davis Medical Center, Sacramento, CA; 6) Department of Pediatrics, University of California, Davis Medical Center, Sacramento, CA.

Pathogenic variants in *PTEN* have been reported to cause autosomal dominant cancer predisposition syndromes including Bannayan-Riley-Ruvalcaba syndrome, Cowden syndrome 1, Lhermitte-Duclos syndrome and Macrocephaly/autism syndrome. We report the **first** association of a novel heterozygous pathogenic variant c.685\_686dupTC (p.Gly230Glnfs\*27) in *PTEN* in a 2 year 4 month old female, presenting with ovarian germ cell tumor (OGCT) complicated by growing teratoma syndrome (GTS). Our patient, the youngest reported thus far, presented with urinary urgency and abdominal pain for the preceding 5 months, that acutely worsened on the day of presentation. An abdominal CT scan revealed a soft tissue mass occupying the pelvis. AFP was elevated to 3057.1 ng/mL and beta-HCG was 2554 mIU/mL. She underwent gross total resection of the left adnexal mass accompanied by a left salpingo-oophorectomy. Histologically, the tumor consisted predominantly of malignant teratoma - adenocarcinoma from the mature teratoma admixed and choriocarcinoma consistent with a malignant OGCT staged as FIGO Ib. After surgery, the patient received 3 cycles of adjuvant chemotherapy consisting of cisplatin, etoposide, and bleomycin. During her treatment, her serum HCG became undetectable 1.5 months after resection, and AFP dropped to normal levels at 4 months after resection. Seven months after completion of her chemotherapy, a surveillance CT scan identified a new mass at the original site. Tumor markers AFP, beta-HCG, as well as CA125 were not elevated. The patient underwent surgical resection. Pathology showed a mature teratoma with predominantly intestinal/mucinous differentiation. Retinoblastoma 1 (pRB) protein immunostaining was negative. The second tumor gave rise to concern for GTS. She was referred to genetics where growth parameters were noted at > 2 standard deviations above the mean and scattered nevi, and a hypopigmented macule were identified. Overgrowth syndrome was suspected, and genetic testing was obtained. An overgrowth panel revealed, a novel heterozygous pathogenic variant c.685\_686dupTC (p.Gly230Glnfs\*27) in *PTEN*. Parental testing is pending. Immature germ cell tumors are rare in the pediatric population and the emergence of GTS an even more rare complication following the treatment of this type of malignancy. The *PTEN* finding changes her management and we recommended screening for *PTEN* associated tumors per NCCN Clinical Practice Guidelines in Oncology.

**659F**

**Assessing the prevalence and clinical implications of secondary findings for hereditary cancer predisposition among patients with chronic kidney disease.** *E. Groopman<sup>1</sup>, M. Marasa<sup>1</sup>, S. Sanna-Cherchi<sup>1</sup>, K. Kiryluk<sup>1</sup>, D. Goldstein<sup>2,3</sup>, A. Gharavi<sup>2</sup>.* 1) Department of Medicine, Division of Nephrology, Columbia University, New York, NY, USA; 2) Institute for Genomic Medicine, Columbia University, Hammer Health Sciences, 1408, 701 West 168th Street, New York, NY, USA; 3) Department of Genetics & Development, Columbia University, Hammer Health Sciences, 1702, 701, West 168th Street, New York, NY, USA.

The broadening use of whole-exome sequencing (WES) necessitates assessment of not only diagnostic yield but also the rate of secondary findings across clinical indications. The latter include hereditary cancers, whose detection among patients referred for non-cancer indications can prompt further testing and shape care. WES is increasingly applied for patients with chronic kidney disease (CKD), for whom secondary findings for hereditary cancer have high clinical relevance, given that immunosuppression is a first-line therapy for many CKD subtypes and in renal transplantation. Yet, the prevalence of pathogenic variants in germline cancer predisposition genes among CKD patients has not been assessed. We assessed the frequency of secondary findings for hereditary cancers among 2,521 patients exome sequenced for all-cause CKD at Columbia University Medical Center. We analyzed WES data for pathogenic variants in a set of 148 known germline cancer predisposition genes, including all the ACMG 59 cancer predisposition genes and those deemed medically actionable germline cancer genes by ClinGen. We examined yield and implications for clinical care. The cohort had median age 46y; 43.5% were female and 48.2% self-identified as non-white Europeans. Overall 4.4% of cases had pathogenic variants, spanning 46 of the 148 hereditary cancer genes tested. Yield did not differ significantly between pediatric and adult (age > 21y) cases (OR=1.28 [0.67, 2.67], P=0.55) or Europeans and non-White Europeans (OR=0.96 [0.64, 1.42], P=0.85). 31 (1.2%) individuals had a pathogenic variant in an ACMG 59 cancer gene: findings in *BRCA1/2* (N=14) and *PMS2* (N=4) were most frequent. A further 0.7% had pathogenic variants in other highly actionable cancer genes, including *ATM* (0.36%), *CHEK2* (0.12%), and *PALB2* (0.04%). In addition, 1.9% had lower penetrance cancer risk alleles, including *APC* p.11307K (1.2%), *HOXB13* p.G84E (0.2%), and *MITF* p.G312K (0.2%). Beyond indicating subspecialty referral, the genetic diagnosis would directly inform nephrologic care, including immediately shaping therapy for the 95 cases receiving immunosuppression (for their primary nephropathy or renal transplant). Our results reveal a novel utility of genomic sequencing to yield findings which while not explicative for the primary test indication, nonetheless inform its management, encouraging expanded use of WES in CKD and supporting similar studies in other disease cohorts.

**660W**

**Exome sequencing in high breast and ovarian cancer incidence families which lack detectable mutations in established cancer susceptibility genes.** *P.A. Kenny, M.A. Girtman, J.A. Deviley, D.R. Meier, C.R. Vos, C.S. Richmond, K.A. Lofgren.* Kabara Cancer Research Institute, Gunderson Medical Foundation, La Crosse, WI.

At our center, a standard 25 gene panel has proved useful for the identification of pathogenic germline mutations in many families with a high penetrance of breast and ovarian cancer, yet there remain several families with very high cancer incidence but from whom these assays have not identified pathogenic alleles. To attempt to define the genetic mechanism of susceptibility in such cases, we are conducting germline whole exome sequencing in affected individuals. Here we describe the identification of strong candidate susceptibility variants in two such families. Both variants cause loss-of-function of DNA repair genes not previously implicated in breast cancer, but which share properties with genes with known roles in maintenance of genome integrity. In one individual, with a personal history of ovarian cancer and two independent breast tumors, we identified a novel point mutation in *POLD2* which introduces a mutation at a residue which is biochemically conserved in all animal species thus far sequenced. In the second individual, a frameshift mutation was detected in *ERCC4*. In both cases, the variants found have not been observed in large exome datasets (e.g. ExAC) or reported in ClinVar. Our study highlights the potential utility of whole exome sequencing as a discovery tool in those families with high cancer incidence yet which lack mutations in known hereditary cancer predisposition genes.

## 661T

**APC testing in pediatric patients.** S.C. Knapke, L. Susswein, E. Webb, K.J. Postula, Y. Wang, R.T. Klein, K.S. Hruska. GeneDx, Gaithersburg, MD.

**Background:** Familial Adenomatous Polyposis (FAP) is a genetic syndrome characterized by extensive colorectal polyposis and high risk for colorectal cancer due to pathogenic variants in *APC*. Additional cancers, benign tumors and clinical features are also part of the phenotype for individuals with FAP. In many cases, FAP presents in childhood or adolescence. Data are currently lacking, however, with regards to the utility of *APC* gene testing in pediatric patients with personal histories suggestive of FAP. **Purpose:** This descriptive analysis aims to identify common indications for *APC* gene testing and calculate the overall and indication-specific yields in pediatric patients with FAP-related features. **Methods:** Test results and clinical history were reviewed for pediatric patients undergoing hereditary cancer testing that included *APC*. Individuals were included if they were <18yrs at testing and reported a personal history of FAP-related features. Individuals who had targeted variant testing were excluded. Descriptive statistics were employed. **Results:** Among 186 pediatric patients with a personal history of FAP-related features, 12 (6.5%) were found to have a pathogenic or likely pathogenic variant (PV) in *APC*. The most common indications for testing included colorectal adenomatous polyps/polyposis (30), CHRPE (17), medulloblastoma (16), desmoid (15), pilomatixoma (11), colorectal cancer (9) and hepatoblastoma (8). Yield of testing was highest in individuals with colorectal adenomatous polyps/polyposis (7/30, 23.3%), fibroma/fibromatosis (2/12, 16.7%) and medulloblastoma (2/16, 12.5%). No *APC* PVs were identified in individuals with CHRPE, pilomatixoma, colorectal cancer, desmoid or hepatoblastoma. The *APC* yield was highest for individuals whose testing included *APC* only (7/51, 13.7%), followed by a large multigene colorectal cancer panel (6/56, 10.7%). **Conclusions:** The approach to, indications for, and yield of *APC* gene testing in pediatric patients is highly variable. These results support the pursuit of genetic counseling and consideration of *APC* testing for pediatric patients with diagnoses including adenomatous polyps/polyposis, medulloblastoma and fibromas. Although no PVs were identified in individuals with CHRPE or hepatoblastoma, *APC* testing should still be considered for these indications based on previously published data. These results also suggest that testing for *APC* only or a multigene colorectal panel can be considered with comparable yield.

Zangen<sup>2,8</sup>. 1) Shaare Zedek Medical Center, Jerusalem, Israel; 2) Faculty of Medicine, The Hebrew University of Jerusalem, Hadassah Medical School, Jerusalem, Israel; 3) Pediatric Endocrinology Clinic, Assaf Harofeh Medical Center, Zerifin, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 4) Division of Medical Genetics, Department of Medicine, University of Washington, Seattle, WA; 5) Department of Genome Sciences, University of Washington, Seattle, WA; 6) Department of Developmental Biology and Cancer Research, IMRIC, Faculty of Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel; 7) Department of Genetics, Alexander Silberman Institute of Life Sciences, The Hebrew University of Jerusalem, Israel; 8) Division of Pediatric Endocrinology, Hadassah Hebrew University Medical Center, Jerusalem, Israel.

Genetic characterization of ovarian dysgenesis patients has revealed critical pathways in ovarian development, but the process remains incompletely understood. In two sisters of non-consanguineous Ethiopian origin with XX-ovarian dysgenesis, whole exome sequencing revealed compound heterozygosity for nonsense truncating *BRCA2* mutations. Compound heterozygotes had reduced *BRCA2* mRNA (3.5-fold, p=2.29e-06) and reduced *BRCA2* protein (7-fold, p=6.7e-12). DNA damage response was impaired, with pronounced chromosomal breakage and failure of RAD51 recruitment to DNA damage sites. The *BRCA2* nonsense mutations are modeled in *Drosophila* by knockout of the *BRCA2* ortholog. *Dmbrca2* null flies (*Dmbrca2<sup>ΔKO</sup>*) were sterile, with gonadal dysgenesis in both sexes. Ovarioles in female *Dmbrca2<sup>ΔKO</sup>* had extensive disintegration of their egg chambers before developing to stage 10, with cell envelope destruction, DNA condensation, and extensive apoptosis. Testes from *Dmbrca2<sup>ΔKO</sup>* males were smaller and underdeveloped, with aberrant DNA location, lack of actin structures and abnormal expression of cleaved caspase-3. The patients' phenotype was significantly milder than the Fanconi anemia D1 syndrome previously described with biallelic *BRCA2* mutations. Beyond the major presentation of ovarian dysgenesis, the sisters (ages 15y and 20y) had microcephaly with normal intelligence; one sister had survived leukemia at age 5y following standard therapy. Originally there was no family history of breast or ovarian cancer. When the mother was identified as a *BRCA2* carrier, surveillance ultrasound revealed stage III ovarian cancer. These results reveal a novel role for *BRCA2* in ovarian development. Homologous recombination, in which *BRCA2* plays a critical role, is important for both DNA damage repair and for normal meiosis. Several recently identified genetic bases of ovarian dysgenesis are genes encoding proteins involved in meiotic processes such as homologous recombination and chromosome segregation (e.g. *HFM1*, *MCM8*, *MCM9*, *SYCE1*, *STAG3*, *SPIDR*). Our findings thus indicate an emerging concept of ovarian dysgenesis as a consequence of defects in meiotic processes, many of which are also important for DNA repair. This suggests that chromosomal breakage assays may be a useful screening tool in ovarian dysgenesis. Increased chromosomal breakage could suggest a DNA repair defect as the underlying genetic basis, as well as indicate possible cancer predisposition requiring surveillance.

Cerchietti<sup>1</sup>. 1) Weill Cornell Medicine, New York City, NY; 2) Memorial Sloan-Kettering Cancer Center, New York, New York; 3) Creighton University, Omaha, Nebraska; 4) Mayo Clinic, Rochester, Minnesota; 5) Cancer Research Center of Lyon, Lyon, France; 6) University of Utah, Salt Lake City UT; 7) Analytic and Translational Genetics Unit, Massachusetts General Hospital, Boston, Massachusetts; 8) University of Chicago, Chicago, Illinois; 9) Dana-Farber Cancer Institute, Boston, Massachusetts; 10) Icahn School of Medicine, New York, New York.

We identified familial and early-onset multiple myeloma kindreds with truncating mutations in lysine-specific demethylase 1 (LSD1/KDM1A), an epigenetic transcriptional repressor that primarily demethylates histone H3 on lysine 4 and regulates hematopoietic stem cell self-renewal. In addition, we found higher rates of germline truncating and predicted deleterious missense KDM1A mutations in patients with multiple myeloma unselected for family history compared with controls. Both monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma cells have significantly lower KDM1A transcript levels compared with normal PCs. Transcriptome analysis of multiple myeloma cells from KDM1A mutation carriers shows enrichment of pathways and MYC target genes previously associated with myeloma pathogenesis. In mice, antigen challenge followed by pharmacologic inhibition of KDM1A promoted PC expansion, enhanced secondary immune response, elicited appearance of serum paraprotein, and mediated upregulation of MYC transcriptional targets. These changes are consistent with the development of MGUS. Collectively, our findings show that KDM1A is the first autosomal dominant multiple myeloma germline predisposition gene providing new insights into its mechanistic roles as a tumor suppressor during post-germinal center B-cell differentiation. We will provide updated data on mouse models of Kdm1A mutation as well.

**Introduction:** Ataxia telangiectasia (AT) is a rare autosomal-recessive disorder caused by variants in the AT-mutated (*ATM*) gene. It is generally characterized by childhood-onset cerebellar ataxia, telangiectasia, oculomotor apraxia, cancer predisposition, particularly lymphoid tumors, immunodeficiency, and hyper-radiosensitivity. The phenotypic studies show a continuous spectrum from severe classical childhood-onset AT to a mild adult-onset disorder, depending on the residual kinase activity. Germline *ATM* heterozygosity is estimated to 0.5%-1% of the general population, and provides a 2 to 4 fold increase in breast cancers risk. **Materials and Methods:** We present the atypical case of a 69-year-old man with breast cancer diagnosed at 65 years. Diagnostic gene panel test in DNA extracted from blood detected a c.7271T>G missense *ATM* variant with an allelic frequency of 90%, confirmed by Sanger sequencing.

**Results:** Reverse phenotyping showed an attenuated AT phenotype, as previously reported with this variant, including essential tremor since childhood, signs of cerebellar and proprioceptive ataxia, absence of telangiectasia and oculomotor apraxia. Additional tests revealed an inversion of the chromosome 7 in 4 out of 50 metaphases, compatible with a late-onset AT, minor elevation of immunoglobulins, and normal rate of alpha foeto-protein. Tumor sequencing revealed an allelic frequency for the variant at 85%, and at 69% in the peritumoral tissue (allelic frequency in DNA extracted from fibroblasts and saliva in progress). Of note, the proband's daughter is non-carrier of the variant, confirming the existence of wild type allele in some germinal cells. After excluding other causes of mosaicism (sample contamination, recent transfusion, leukemia, bone marrow transplant), SNP-array was performed and evidenced an isodisomy of the whole 11q chromosome. These molecular results permitted to adapt the therapy of the patient, because of an indication of radiotherapy for bone metastasis. Functional studies of the patient's cells showed a strong spontaneous genomic instability with partial and delayed activation of the *ATM* protein, in favor of a moderate radiosensitivity as compared in homozygous *ATM* carriers, with a high risk of radiation-induced complications, leading to a fractionated and spread radiotherapy. **Conclusion:** The diagnosis work-up of a sporadic male breast cancer have led to the identification of a late onset AT supported by a mosaic uniparental isodisomy.

**665F**

**A mouse model to study tissue-specific response to Brca1 loss.** *J.O Olayiwola, S.G Rao, J.G Jackson.* Department of Biochemistry and Molecular Biology, Tulane University School of Medicine, New Orleans, LA.

Female *BRCA1* mutation carriers have an 85-90% lifetime risk of developing breast cancer by age 70. Although all cells in the body of a carrier are heterozygous for *BRCA1*, tumors overwhelmingly develop in the breast. Presently, there is no satisfying mechanistic explanation for this tissue specificity. To address this, we created a mouse model of tet-inducible Cre recombinase and combined with a tdTomato fluorescent protein reporter allele. Using adult mice with all the required alleles, and control mice lacking one or two alleles, we administered water or doxycycline ad libitum and then tested for Cre expression and tdTomato expression following recombination. In mice with all required alleles given doxycycline, fluorescence microscopy showed virtually all cells underwent recombination. Very low levels of leakiness as shown by infrequent tdTomato expression was present in tissues of mice administered water. Thus, we show a system of temporally controlled Cre induction in all tissues of adult mice. To investigate and compare responses of different tissues to loss of *Brca1*, we bred our doxycycline inducible Cre mice to *Brca1*<sup>F22-24F22-24</sup> p53<sup>-/-</sup> male mice to generate inducible Cre, *Brca1*<sup>F22-24F22-24</sup> p53<sup>-/-</sup> mice. Doxycycline administration to these mice led to *Brca1* recombination in all tissues examined as evidenced by excision of exons 22 through 24; which holds the second BRCT domain. Preliminary studies in a small cohort have shown that mice can survive up to 3 months post *Brca1* recombination, the recombination is depicted in mammary, intestine, liver and tail DNA of this mice. Currently, we are examining acute cellular responses and the p53 pathway response in tissues, as well as mouse survival in response to *Brca1* deletion.

**Evidence of reduced penetrance in BRCA2 truncating variant c.658\_659del (p.Val220Ilefs\*4).** *N. Singh, E. Mundt, B. Roa, S. Manley, K. Bowles.* Myriad Genetic Laboratories, Inc., Salt Lake City, UT.

**Background:** The cancer risks associated with pathogenic variants in *BRCA2* have been well studied. Although these cancer risks are known to vary, it can be difficult to assess variant specific penetrance estimates. Here we present evidence of lower cancer risks associated with truncating variant c.658\_659del (p.Val220Ilefs\*4) based on a laboratory specific classification tool, Pheno analysis, with support from published literature. Pheno analysis is a computerized statistical tool used to provide evidence for variant classification. **Methods:** All evidence of pathogenicity for the variant was evaluated both at the time of initial classification and over time as new data became available. Pheno calculates a variant specific score based on the personal and family cancer histories of each proband with the variant and compares those scores to matched controls. Pheno has been thoroughly validated and tested showing PPVs and NPVS of >99.5%. **Results:** *BRCA2* c.658\_659del (p.Val220Ilefs\*4) creates a frameshift inserting four novel amino acids and predicts premature protein truncation leading to an initial classification of a pathogenic variant (PV). Although a truncating variant in the middle of the gene is expected to confer loss of function and typical *BRCA2* cancer risks, the Pheno analysis shows that the cancer histories for multiple unrelated probands with this specific variant are less severe than the matched controls with other *BRCA2* PVs. In addition, this variant has been observed in trans with other *BRCA2* PVs in many individuals with Fanconi anemia. The collective evidence support this variant having reduced penetrance, as it does not appear to be associated with embryonic lethality as expected with some highly penetrant *BRCA2* PVs. **Conclusions:** New evidence for the *BRCA2* c.658\_659del (p.Val220Ilefs\*4) variant indicates the cancer risks associated with this variant are lower than expected for a pathogenic *BRCA2* variant. Given this updated information, our laboratory has revised the classification of this variant to "special interpretation" to alert providers of the reduced penetrance associated with this variant so they can make patient specific decisions regarding screening and management. This example of a reduced penetrance truncating variant highlights the importance of both developing tools capable of showing penetrance differences as well as regularly reviewing variant classifications and their underlying evidence.

## 667T

**A *RAD51C* mutation causing HBOC is expanded in the Newfoundland population likely due to a founder effect.** S. Werdyani<sup>1</sup>, L. Dawson<sup>1,2</sup>, K. Smith<sup>1</sup>, S. Hansford<sup>1,2</sup>, R. Ndikumana<sup>3</sup>, T. Young<sup>1</sup>, D. O'Rielly<sup>1</sup>. 1) Discipline of Genetics, Faculty of Medicine, Memorial University, St. John's, NL, Canada; 2) Department of Gynecology and Obstetrics, Eastern Health, St. John's, NL, Canada; 3) Department of Pathology, Eastern Health, St. John's, NL, Canada.

**Background:** Extended families from the founder population of Newfoundland (NL) provide an excellent source for genomic investigation. The main objective of this study was to identify deleterious genetic variation(s) that lead to hereditary breast and ovarian cancer (HBOC) in *BRCA1/2*-negative cases from NL. **Methods:** Five women from 4 extended NL families were diagnosed with HBOC and enrolled in the study. Genomic DNA was extracted from whole blood and sequenced by an Illumina® NGS multigene panel covering HBOC susceptibility genes. Haplotype analysis was performed using 7 microsatellite markers flanking the *RAD51C* variant on chromosome 17q22. TaqMan genotyping was performed on 907 controls and 62 unrelated ovarian cancer cases from the NL population. RNA was extracted from peripheral blood of the proband and her unaffected mother, then it was reverse transcribed into cDNA and sequenced. Sanger sequencing of tumor tissue was also performed.

**Results:** Five women from 4 extended NL families that were *BRCA1/2*-negative carried the *RAD51C* c.571+4A>G mutation (rs587780257). This mutation was detected in 9 additional individuals including 2 women with HBOC, 1 with pancreatic cancer, 4 unaffected (one of whom had her ovaries removed at age 37); and 2 unaffected males. In contrast, the variant was absent in 15 unaffected family members. Haplotype analysis identified ~4 Mbp region that encompasses the c.571+4A>G mutation, and we find that this disease-associated haplotype is shared across all 4 families, suggesting a shared common ancestor. Of the 907 ethnically-matched controls, 3 were heterozygous for the mutation, estimating a MAF of 0.002 in NL, which is 100X higher compared to dbSNP (0.00002). Furthermore, the mutation was not detected in 62 unrelated ovarian cancer cases from this population. RT-PCR in blood revealed that c.571+4A>G causes aberrant splicing (skipping of exon 3, or exons 3 and 4) resulting in a truncated Rad51C protein in carriers. Sequencing of tumor tissue (from 2 female mutation carriers from 2 separate families) revealed loss of heterozygosity. **Conclusion:** Our study suggests that *RAD51C* c. 571+4A>G variant is likely pathogenic and associated with breast, ovarian, and possibly pancreatic cancer. This mutation is also amplified in the NL population, probably due to a founder effect. Further investigations including gene and protein expression profiling are ongoing.

## 668F

**Multilocus inherited neoplasia alleles syndrome (MINAS): New cases of double heterozygosity for pathogenic cancer predisposition gene variants revealed by whole genome sequencing.** J. Whitworth<sup>1</sup>, P. Smith<sup>1</sup>, J.E. Martin<sup>1</sup>, R. Casey<sup>1</sup>, K. Carss<sup>2,3</sup>, J. Stephens<sup>2,3</sup>, K. Stirrups<sup>2,3</sup>, C. Penkett<sup>2,3</sup>, R. Mapeta<sup>2</sup>, S. Ashford<sup>2,3</sup>, K. Megy<sup>2,3</sup>, R. Armstrong<sup>1,2,4</sup>, J. Barwell<sup>5</sup>, J. Cook<sup>6</sup>, A.B. Skytte<sup>7</sup>, M. Tischkowitz<sup>1,2</sup>, E. Maher<sup>1,2</sup>, NIHR-BioResource Rare Diseases Consortium. 1) Department of Medical Genetics, University of Cambridge and NIHR Cambridge Biomedical Research Centre and Cancer Research UK Cambridge Centre, Cambridge Biomedical Campus, Cambridge, CB2 0QQ, United Kingdom; 2) NIHR BioResource, Cambridge University Hospitals, Cambridge Biomedical Campus, Cambridge, CB2 0QQ, United Kingdom; 3) Department of Haematology, University of Cambridge, NHS Blood and Transplant Centre, Cambridge Biomedical Campus, Cambridge, CB2 0PT; 4) East Anglian Medical Genetics Service, Cambridge Biomedical Campus, Cambridge, CB2 0QQ, United Kingdom; 5) Department of Clinical Genetics, University Hospitals of Leicester, Leicester Royal Infirmary, Leicester, LE1 5VWW, United Kingdom; 6) Department of Clinical Genetics, Sheffield Children's NHS Foundation Trust, Sheffield, S5 7AU, United Kingdom; 7) Department of Clinical Genetics, Aarhus University Hospital, Aarhus, DK-8200, Denmark.

Pathogenic variants in cancer predisposition genes (CPGs) such as *BRCA1*, *BRCA2*, *MSH2*, *MLH1*, *VHL*, *RET* etc. are characteristically associated with specific tumor phenotypes and germline genetic testing has previously focused on small groups of genes associated with those phenotypes. However, diagnostic investigation using large CPG panel assays and genome wide sequencing approaches such as WES and WGS is becoming increasingly prevalent. Consequences of this shift include the detection of pathogenic variants in individuals with an atypical tumor phenotype as well as identification of cases who harbor variants in two or more CPGs that would individually be considered to confer sufficient risk to prompt genetic counselling. This phenomenon of MINAS (Multiple Inherited Neoplasia Allele Syndrome; see Whitworth et al JAMA Oncology, 2016) can pose a number of clinical and diagnostic challenges (e.g. whether combinations of CPG variants will act synergistically and increased penetrance and/or atypical phenotypes). We have investigated the frequency of MINAS in a variety of patient cohorts. Among 440 individuals with multiple primary tumours without a genetic diagnosis, whole genome sequencing and variant assessment (based on ACMG guidelines) of 83 CPGs identified 3 patients with MINAS including combinations of variants affecting *FH1MAX*, *FLCN/CHEK2* and *PMS2/BMP1A*. In addition, a parent child dyad with wild type gastrointestinal stromal tumor both harbored pathogenic variants in *SDHA* and *PALB2*. We have compiled details of 122 cases of MINAS in the published literature and will present an assessment of its consequences for clinical management of the proband and their family. The phenotypic effects of particular aberrant gene combinations are more predictable if information regarding other occurrences of it are available. We have therefore established a database for sharing MINAS cases within the Leiden Open Variant Database environment (<https://databases.lovd.nl/shared/diseases/04296>).

**669W**

**Exploring the range of renal lesions in DICER1 syndrome.** *M. Apellaniz-Ruiz<sup>1,2</sup>, G.M. Vujanic<sup>3</sup>, P.S. Thorne<sup>4,5</sup>, J.R. Priest<sup>6</sup>, W.D. Foulkes<sup>1,2,7,8</sup>.* 1) Department of Human Genetics, McGill University, Montréal, QC, Canada; 2) Lady Davis Institute, Segal Cancer Centre, Jewish General Hospital, Montréal, QC, Canada; 3) Department of Pathology, Sidra Medicine, Doha, Qatar; 4) Department of Pediatric Laboratory Medicine, The Hospital for Sick Children, Toronto, ON, Canada; 5) Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada; 6) Minneapolis, Minnesota, USA; 7) Department of Medical Genetics, Research Institute of the McGill University Health Centre, Montreal, Quebec, Canada; 8) Program in Cancer Genetics, Departments of Oncology, McGill University, Montreal, Quebec, Canada.

**Introduction:** DICER1 syndrome is a rare pediatric tumor predisposition syndrome caused by germline (typically truncating) mutations in *DICER1* and characterized by an array of benign and malignant conditions including pediatric cystic nephroma (pCN), anaplastic sarcoma of the kidney (ASK) and Wilms tumor. pCN is a benign multicystic tumor lacking blastemal and solid elements, differentiating it from cystic partially differentiated nephroblastoma (CPDN) and cystic Wilms tumor (cWT). Malignant progression of pCN to ASK has rarely been reported and is supported by the presence of *DICER1* mutations in both lesions. The involvement of *DICER1* mutations in cystic renal lesions other than CN is unclear. Thus, we studied the pathologic features and *DICER1* mutation status in a series of uncommon pediatric renal lesions. **Methods:** A series of 14 FFPE kidney tumor samples including CN (n=2), CPDN (n=6), cWT (n=2) and other lesions (n=4) was collected. Tumor and normal DNA was screened for *DICER1* variants using a Fluidigm array covering exons and exon–intron boundaries. Sanger sequencing was used to validate the variants. Immunohistochemical staining for WT1 was performed. **Results:** We identified 4 samples with *DICER1* mutations fitting the classic two-hit model: germline truncating and somatic hotspot RNase IIIb mutations. Two were pCN, as expected. The third case was a 5-year old male with a multicystic renal lesion. It was piecemeal biopsied, and despite the numerous cysts, the presence of solid areas composed of undifferentiated stroma lacking blastema ruled out pCN and CPDN, and favoured a stromal WT. The fourth case was a 9-month old female with a multiloculated cystic lesion. Several foci of small primitive cells with WT1 nuclear expression were present in the septa and were interpreted as blastema. Based on this, the lesion was categorized as CPDN. In both these latter cases, the first “hit” was in the germline. **Conclusions:** The diagnosis of a cystic kidney tumor should prompt consideration of testing for DICER1 syndrome, even if the lesions do not fit the classical description of DICER1-associated lesions. Both molecular genetics and specialist pathology review are essential to refine the diagnosis and to offer appropriate management to patients with uncommon lesions, and their relatives.

**670T**

**Leukemia in a patient with 15q overgrowth syndrome.** *E.E. Bode<sup>1</sup>, R. Gupta<sup>3</sup>, A.M. Cherry<sup>2</sup>, L. Muffly<sup>2</sup>, M. Manning<sup>1,2</sup>.* 1) Department of Pathology, Stanford University, Stanford, CA; 2) Division of Medical Genetics, Stanford University, Stanford, CA; 3) Division of Blood and Marrow Transplant, Stanford University, Stanford, CA.

Overgrowth syndromes are rare genetic conditions which present as global or segmental hyperplasia and are often associated with increased risk of malignancy. Trisomy of the terminal portion of 15q which includes the IGF1R gene, produces a rare overgrowth phenotype that has been termed 15q overgrowth syndrome (15q OGS). Upregulation of IGF1R has long been implicated in oncogenesis of multiple cancer types, including acute leukemias, and has been shown to render cells more susceptible to other transforming events. To date, too few cases of 15q OGS syndrome have been reported to identify any cancer predisposition. We present a case of a 34 year-old female with intellectual disability, macrocephaly, and subtle dysmorphic features who was diagnosed with mixed phenotype acute leukemia (lymphoid and myeloid). Prior to initiation of therapy she was referred to medical genetics for further evaluation and was identified as having a chromosomal translocation resulting in a partial trisomy of chromosome 15q, consistent with 15q OGS. A review of the literature for cases of malignancy in individuals with increased copy number of 15q revealed only one other reported patient. Given the small number of reported cases, we cannot rule out an increased risk of cancer associated with this chromosomal overgrowth syndrome. Although concerns have been raised regarding treatment feasibility in the setting of chromosomal disorders, the reported patient underwent successful treatment by hematopoietic stem-cell transplant.

**671F**

**Assessing the modifying capacity of *CD36* in Lynch syndrome compared to that observed in familial adenomatous polyposis.** *T. Connor*<sup>1,2,5</sup>, *C. Oldmeadow*<sup>4</sup>, *B. Talseth-Palmer*<sup>4</sup>, *P. Pockney*<sup>4,5,6</sup>, *R. Thom*<sup>4</sup>, *R. Scott*<sup>2,3</sup>. 1) Junior Medical Officer Unit HNELHD, John Hunter Hospital, Newcastle, Australia; 2) Hunter Area Pathology Services, Lookout Road, New Lambton 2305; 3) Medical Genetics School or Biomedical Sciences and Pharmacy Newcastle; 4) Hunter Medical Research Institute Lookout Road, New Lambton; 5) University of Newcastle Newcastle; 6) Division of Surgery, John Hunter Hospital, Newcastle.

Genetic variants associated with Familial Adenomatous Polyposis (FAP) and Lynch Syndrome (LS) have long been studied to determine their role in the pathogenesis of these two diseases. From studies of FAP it became quickly recognised that a genotype phenotype correlation existed. For LS a more complex association has emerged that appears to be specific to which of four genes is implicated in the disease. Notwithstanding there appears in LS evidence that disease expression may be modified by either genetic and or environmental factors. The genotype/phenotype correlations observed in FAP are approximations and are not highly correlated. For example, the mutational hotspot at codon 1309 in *APC*s frequently reported as being associated with an extremely severe phenotype yet not all individuals who harbour the codon 1309 variant present with severe disease. For LS no genotype/phenotype correlations have been described, probably as a result of DNA mismatch repair being necessary for the maintenance of genomic stability. Nevertheless, patients who carry the same mutation in one of the four MMR repair genes can have vastly different ages of disease onset. An explanation for such variation in phenotype in both FAP and LS is the presence of modifier genes that can influence the age of disease diagnosis and the presenting phenotype. A number of modifier genes has been reported for LS but little has been forthcoming for FAP. Recently, we have shown that *CD36* has been implicated, in mouse models of FAP, to be a modifier of disease, as judged by an increase in tumor multiplicity in this mouse model. This association has recently been shown to influence the degree of symptomatic polyposis in a large cohort of FAP patients but did not address the association with colorectal cancer. In the current study we have examined the role of a number of single nucleotide polymorphisms (SNPs) in *CD36* in LS to determine whether the modifying effect of variants in this gene are directly associated with colorectal cancer development in a population of patients known to be at high risk of this disease. The identification of modifiers of disease risk in FAP and LS will have implications for surveillance and prophylactic measures that need to be taken to reduce the risk of these patients presenting with advanced disease.

**672W**

**Synonymous but not silent: A synonymous *VHL* mutation confers susceptibility to pheochromocytomas in a four-generation family.** *S.K. Flores*<sup>1</sup>, *Z. Cheng*<sup>1</sup>, *A. Jasper*<sup>1</sup>, *R.W. Tothill*<sup>2</sup>, *P.L.M. Dahia*<sup>1</sup>. 1) Department of Medicine, Division of Hematology/Oncology, UT Health San Antonio, San Antonio, TX; 2) Peter McCallum Cancer Centre, Melbourne, Victoria, Australia.

Pathogenic mutations in the von Hippel-Lindau (*VHL*) gene predispose individuals to VHL disease comprising of renal cell carcinomas, pheochromocytomas (PCCs), hemangioblastomas of the central nervous system and other manifestations. Clinical presentation varies remarkably. In VHL disease type 2, PCC risk is higher, with type 2C manifesting PCC only. We report on a four-generation family with a history of PCCs in a pattern consistent with autosomal dominant inheritance. The proband developed a unilateral PCC at age 32. Several of her family members, including her brother, father, paternal aunt and cousin, have also developed unilateral PCCs. Whole exome sequencing of her germline DNA revealed a heterozygous, synonymous mutation (c.414A>G, p.P138P) in *VHL* exon 2. No other candidate genes were identified. Sanger sequencing showed that the mutation segregated with the PCC phenotype in the family. The variant was not observed in population databases (ExAC) whereas ClinVar had 3 entries with conflicting interpretations (2 uncertain significance, 1 likely pathogenic). Nanostring-based Pheo-Type profiling of the proband's archival PCC was consistent with a VHL subtype. In PCC from another relative, loss of the WT allele was observed at the variant locus. PCC cDNA analysis showed absence of the full length VHL transcript and presence of the shorter transcript lacking exon 2 in contrast to other PCCs which expressed both transcripts. Leukocyte cDNA analysis of carrier and WT relatives supported this finding. Another synonymous *VHL* mutation, located at the exon-intron border, has been reported to induce exon 2 skipping and thus alternative splicing and is associated with tumors. *VHL* encodes a tumor suppressor with ubiquitin ligase activity for degradation of hypoxia inducible factors (HIFs). *VHL* exon 2 is critical for the HIF binding domain; predominant expression of the shorter isoform leads to elevated HIF targets associated with oncogenesis. Most genetic screening workflows exclude synonymous variants. Our findings show that synonymous variants in coding regions of susceptibility genes should be taken into consideration as they may have alternative splicing consequences. Based on our findings, the c.414A>G variant is pathogenic and carriers should undergo routine follow-up for early detection. Although this family's clinical profile suggests VHL type 2C disease, further surveillance is recommended as the consequences of this variant are not yet fully defined.

## 673T

**Accurate clinical interpretation of moderate risk breast cancer genes requires inclusion of the significant modifying effects of common genomic variants and family history.** P.A. James<sup>1,3,4</sup>, N. Li<sup>2</sup>, S. McInerney<sup>1</sup>, S. Rowley<sup>2</sup>, D. Goode<sup>2</sup>, R. Scott<sup>5</sup>, L. Devereux<sup>6</sup>, N. Grewal<sup>2</sup>, I.G. Campbell<sup>2,3</sup>. 1) Parkville Familial Cancer Centre, Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; 2) Cancer Genomics Laboratory, Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia; 3) Sir Peter MacCallum Department of Oncology, Melbourne University, Melbourne, Victoria, Australia; 4) Genomic Medicine, Royal Melbourne Hospital, Parkville, Melbourne, Victoria, Australia; 5) Hunter Area Pathology Service, Newcastle, NSW, Australia; 6) LifePool Study, Peter MacCallum Cancer Centre, Melbourne, Victoria, Australia.

Rare variants in several genes are proposed to confer a moderate risk of breast cancer; typically an increased risk between 1.5 and 4 fold. Many of these genes appear on commercial testing panels but the utility of testing for these moderate effects in clinical practice remains unproven. In a large breast cancer case-control study we examined sequence data for 14 known or proposed moderate genes, along with the polygenic risk score and family history to determine whether incorporation of modifying effects could better identify women at actionable levels of breast cancer risk. Method: 5125 women affected by invasive breast cancer, (*BRCA1/BRCA2* excluded), and 4239 healthy controls were screened for variants in potential breast cancer risk genes, and a polygenic risk score (PRS) made up of 74 GWAS-reported SNPs using a custom targeted capture panel. Loss of function and pathogenic missense variants in established risk genes (*PALB2*, *CHEK2*, *ATM*) or proposed candidates (*BRIP1*, *BLM*, *MRE11A*, *NBN*, *FANCM*, *RAD51C*, *RAD51D*, *RAD50*, *BARD1*, *XRCC2*, *ATR*), were analysed together with an individual's PRS and breast cancer family history (FHx) by multiple logistic regression. A contrasting group of very high risk genes (*TP53*, *PTEN*, *STK11*, *CDH1*) were also examined. Results: Analysis included 517 rare pathogenic variants in 9364 women (6.6% cases, 3.9% controls). Polygenic risk and FHx showed the expected association with breast cancer: PRS, HR 1.52 (95% CI 1.46-1.58) per SD, Breast cancer FHx, OR<sub>adj</sub> 1.42 (1.35-1.50). The risk conferred by pathogenic variants in 14 established and proposed moderate genes, but not in rare high risk genes, was significantly modified by the PRS, with no risk observed associated with a low PRS background (low quintile) OR=0.7 (0.5-1.2), and clinically actionable risk associated with the same variants and high PRS, (high quintile) OR=3.7 (2.5-5.6). Defining 'high risk' as a 30% lifetime breast cancer risk, 16% of carriers of pathogenic variants in candidate moderate risk genes would be high risk, 30% moderate risk, and for 54% their estimated risk was not significantly different to population levels. Conclusion: Important SNP-modifying effects affect many suggested moderate risk breast cancer genes, potentially contributing to the conflicting reports of risk for these genes. Combined interpretation of rare variants with PRS data and FHx can significantly improve the accurate identification of high risk individuals.

## 674F

**A retrospective cohort study investigating age and gender specific presentations of Li-Fraumeni Syndrome.** S.P. MacFarland<sup>1</sup>, K. Zelle<sup>1</sup>, J. Long<sup>2</sup>, D. McKenna<sup>2</sup>, J. Powers<sup>2</sup>, B.W. Katona<sup>2</sup>, S.M. Domchek<sup>2</sup>, K.L. Nathanson<sup>2</sup>, G.M. Brodeur<sup>1</sup>, K.N. Maxwell<sup>2</sup>. 1) Children's Hospital of Philadelphia, Philadelphia, PA., USA; 2) University of Pennsylvania, Philadelphia, PA, USA.

**Introduction:** Patients with Li-Fraumeni Syndrome (LFS) have an up to 90% lifetime cancer risk. Although previously considered a pediatric cancer predisposition syndrome, adults with LFS are increasingly ascertained via multi-gene panels. We sought to investigate age- or gender-specific genotype or phenotype correlations in LFS. **Methods:** Patients were identified by query of the electronic medical record from 2007-2017 at the Children's Hospital of Philadelphia and the University of Pennsylvania. Medical records review confirmed the presence of a pathogenic *TP53* mutation, family relationships, and personal and family cancer histories. **Results:** Ninety-eight individuals from 63 families with LFS were identified. Of the 63 families, 60% fit Chompret criteria and 8% had known de novo mutations. Of remaining families (n=20), 85% had LFS-like syndrome, breast cancer under age 40, multiple primary cancers or a pediatric cancer. Comparing 68 females to 30 males, 72% versus 57% had any cancer and 56% vs 67% had an LFS core cancer. Non-LFS core cancers were more common in males, 9% vs 27% (p=0.03). In order to study LFS diagnosed in children versus adults, 25 index cases of LFS under age 18 (pediatric probands) and 33 index cases of LFS over age 18 (adult probands) were identified. There were no significant genotype differences between pediatric and adult probands (DNA binding domain missense in 52% vs 65%, tetramerization domain missense in 10% vs 16% and truncating mutations in 38% vs 19% of pediatric vs adult probands, respectively). Pediatric and adult probands' family histories fit LFS criteria at similar rates (24% vs 30% for Classic and 62% vs 55% for Chompret). Nearly all probands presented with cancer including 96% of pediatric and 94% of adult probands with LFS core cancers found in 88% of pediatric probands and 79% of adult probands. Only non-LFS tumors were marginally more common in adult vs pediatric probands (36% vs 12%, p=0.06). **Conclusion:** Though sample size was limited and included only patients from tertiary care medical centers, this collaborative retrospective study is uniquely positioned to make adult versus pediatric comparisons. In this cohort, LFS-core cancers occurred at similar rates in adult and pediatric probands, and non-LFS cancers were more common in males and adult probands. A prospective longitudinal cohort study is ongoing to enable further genotype-phenotype studies in adult versus pediatric LFS.

## 675W

**Challenges in clinical variant classification in *TP53*: A representative case series for *TP53* c.1000G>C; p.G334R.** J. Powers<sup>1</sup>, K. Zelle<sup>2</sup>, B. Levin<sup>3</sup>, T. Slavin<sup>4</sup>, V. Joseph<sup>5</sup>, J. Weitzel<sup>6</sup>, K. Offit<sup>7</sup>, J. Stopfer<sup>8</sup>, J. Garber<sup>9</sup>, F. Couch<sup>7</sup>, K. Nathanson<sup>1</sup>, S. Domchek<sup>1</sup>, K. Maxwell<sup>1</sup>. 1) University of Pennsylvania, Philadelphia, PA; 2) Children's Hospital of Philadelphia, Philadelphia, PA; 3) MD Anderson Cancer Center at Cooper, Camden, NJ; 4) City of Hope, Duarte, CA; 5) Memorial Sloan Kettering Cancer Center, New York, NY; 6) Dana Farber Cancer Institute, Boston, MA; 7) Mayo Clinic, Rochester, MN.

**Introduction:** Li-Fraumeni syndrome (LFS) is a cancer predisposition syndrome caused by germline mutations in the *TP53* gene. While *TP53* is well-characterized, challenges in variant classification remain due to the predominance of missense mutations, limited research in domains beyond the DNA-binding domain, and phenotypic heterogeneity. In this case series, we present data supporting pathogenicity of a rare *TP53* tetramerization domain missense variant with discordant clinical classifications, c.1000G>C; p.G334R. **Methods:** A retrospective, multi-institutional case review of individuals with *TP53* c.1000G>C; p.G334R was performed in conjunctions with literature and public data review. **Results:** In a research based sequencing study of 278 early onset breast cancer patients, an Ashkenazi Jewish proband with early onset breast cancer and sarcoma was found to carry the *TP53* c.1000G>C; p.G334R variant. Familial analysis indicated the variant segregated with component LFS cancers in third degree relatives. The proband's paternal first-cousin, with early onset breast cancer and glioblastoma, underwent clinical testing confirming c.1000G>C; p.G334R, which was classified as a variant of uncertain significance (VUS). Nine additional c.1000G>C; p.G334R probands were ascertained. Of the ten total cases, five met Chompret, and two met LFS-like criteria. The variant segregated with cancer in third and fourth degree relatives in two families. Of the eight carriers with ancestry data, all reported Ashkenazi Jewish descent; whereas no carriers were identified in 1154 Ashkenazi Jewish control chromosomes or in gnomAD. *In silico* prediction models were consistent with a deleterious effect. Literature review revealed cell-type specific reduction in transactivation capability. Of nine CLIA-CAP laboratories for which variant calls were obtained, five laboratories classify c.1000G>C; p.G334R as a VUS and four classify as likely pathogenic or pathogenic. Loss of heterozygosity and haplotype analyses are pending and will be reported in the near future. **Conclusion:** Our data suggest that *TP53* c.1000G>C; p.G334R is a rare Ashkenazi Jewish founder mutation leading to a Li-Fraumeni-like syndrome. This study demonstrates challenges in variant classification even in well-characterized genes such as *TP53*. Centralized collection and deep phenotyping of multiple families in combination with gene-specific expertise may aid in variant classification and clinical management.

## 676T

**Beyond Lynch syndrome: Thinking about CMMRD.** R. Quero<sup>1,2</sup>, M. Manotas<sup>1,2</sup>, A. Gómez<sup>2</sup>. 1) Pontificia Universidad Javeriana, Bogotá D.C., Colombia; 2) Hospital Universitario San Ignacio.

Lynch syndrome (LS [MIM 609310]) is an adult-onset hereditary cancer syndrome characterized by gastrointestinal and genitourinary cancers. It is caused by monoallelic germline mutations in *MLH1*, *MSH2*, *MSH6*, *PMS2* (MMR genes) or *EPCAM*. In contrast, biallelic mutations in MMR genes result in a distinct disease defined as Constitutional Mismatch Repair Deficiency Syndrome (CMMRD). The proband was referred to Medical Genetics due to colorectal cancer at 39 years old, a daughter with medulloblastoma, who died at 3 years old, and maternal family history of colorectal and gastric cancers. As suspected, a heterozygous germline mutation in *MLH1* gene was found (c.790+1G>A), confirming LS. The patient and his wife reported that their deceased daughter was diagnosed and followed-up as neurofibromatosis type 1 (NF1), due to café-au-lait spots, and the medulloblastoma was considered related to it. At that moment, a complete pedigree of the proband's wife was made, finding a maternal aunt with colorectal cancer at 35 years old and a common ancestor with the proband. The patient's wife was found with the same mutation in *MLH1*. This couple is undergoing surveillance for LS and has a 5-year-old daughter who is awaiting assessment to define evaluation for this specific mutation. CMMRD is characterized by early-onset malignancies: hematological, central nervous system tumors, colorectal and other cancers, typically seen in LS patients at a later age, and features reminiscent of NF1. In this case, it is presumed that the deceased daughter had this syndrome and the evaluation of the alive daughter is expected to determine if she is a *MLH1* mutation biallelic carrier. It is important to suspect and diagnose this rare disease since there are proposals of surveillance protocols for early tumor detection and potential therapeutic interventions.

**Phenotypic variability in familial FH whole gene deletion.** C. Quindipan<sup>1</sup>, S. Thomas<sup>2</sup>, A. Martinez<sup>3</sup>, M. Fox<sup>3</sup>, S.C. Saitta<sup>1,4</sup>. 1) Center for Personalized Medicine, Children's Hospital Los Angeles, Los Angeles, CA; 2) Division of Hematology/Oncology, Children's Hospital Los Angeles, Keck School of Medicine, University of Southern California, Los Angeles, CA; 3) Invitae, San Francisco, CA; 4) Department of Pathology, Keck School of Medicine, University of Southern California, Los Angeles, CA.

*FH* encodes fumarate hydratase, a Krebs cycle enzyme that acts as a tumor suppressor. Germline pathogenic variants in *FH* are seen in autosomal dominant hereditary leiomyomatosis and renal cell cancer (HLRCC) and autosomal recessive fumarate hydratase deficiency. We report a 12-year-old female who presented with abdominal distension, respiratory distress, and altered mental status. A CT scan showed a left adrenal gland mass with pheochromocytoma confirmed by histopathology of the resected tumor. The patient has normal intellectual function and no concern for a metabolic disorder. A 3-generation family history was unremarkable for cancer but the patient's mother required a hysterectomy at age 47 for uterine fibroids and heavy menstrual bleeding. A 14-gene Paraganglioma-Pheochromocytoma Panel identified a pathogenic deletion of the entire coding sequence of the *FH* gene in the proband's peripheral blood. Chromosome microarray then showed a 1.34 Mb deletion of chromosome 1q43 including *FH*. None of the other 10 genes in the deleted interval are associated with human disease. All first-degree family members were tested and the deletion was found only in the proband and in her mother; the unaffected sibling was deletion negative. None of the maternal extended family members are available for testing. Only 1% of patients with pheochromocytoma have germline *FH* mutations. Uterine leiomyomata instead are present in almost every female with HLRCC, presenting with dysfunctional uterine bleeding, though rarely becoming malignant. HLRCC can include multiple cutaneous leiomyomas on the abdomen, shoulders, and extremities, seen in the 2nd-4th decades. Renal tumors are observed in 15% of individuals with HLRCC including type 2 papillary renal cell carcinoma, collecting-duct carcinomas, and Wilms tumor. Neither the patient nor her mother is currently affected with cutaneous or renal tumors. This is, to our knowledge, the first-known familial *FH*-related disorder in a pediatric patient and her parent, presenting with distinct phenotypes. Tumor surveillance for both individuals will now include screening for pheochromocytomas and renal cancer. In addition, abdominal ultrasounds will be performed on the proband every two years to screen for uterine fibroids. This case underscores the importance of family testing for germline cancer predisposition genes and its relevance to developing an appropriate care plan.

**Co-occurrence of neurofibromatosis Type 1 (NF1) and Type 2 (NF2): Common downstream effects on the RAS pathway with implications for tumor burden and potential treatment.** S. Krishnamurthi, J. Fisher, J. Mann. Kaiser Permanente, Clovis, CA.

NF1 and NF2 are two highly penetrant autosomal dominant phakomatoses with an incidence of 1:3000 and 1:33,000 respectively. Somatic mosaicism is known feature of both disorders. The protein products of the associated genes, neurofibromin and merlin, are functionally unrelated but act as tumor suppressors through modulation of the RAS/RAC oncogenic pathways. Neurofibromin is a RAS GTPase activating protein (GAP) which maintains RAS in the inactive GDP form and its loss leads to abnormal activation of RAS and a downstream oncogenic kinase, PAK1, which is involved in several aspects of oncogenesis. Merlin also directly inactivates PAK1 and its dysfunction causes abnormal activation of PAK1. Thus, NF1 and NF2 are genetically distinct disorders with similar phenotypic outcomes resulting from a common effector site at the molecular level. This creates implications for tumor burden in cases of co-occurrence of these two conditions but also provides an opportunity for targeted therapy to combat both disorders simultaneously with use of PAK1 blockers. We report a case of a 54-year female clinically diagnosed at an early age with NF1 with numerous neurofibromas, café au lait macules and lisch nodules who later presented in her 50's with unilateral hearing loss. MRI revealed bilateral vestibular schwannomas meeting clinical criterion for NF2. She has no known family history of NF1 or NF2. Molecular testing for *NF1*, *NF2*, *LZTR1* and *SMARCB1* showed only a pathogenic splicing alteration in the *NF1* gene. Tumor testing has not yet been undertaken. Co-occurrence of NF1 with NF2 has been rarely reported before with a germline variant in one disorder and a somatic mosaicism at a segmental level in the other. About a third of simplex cases of NF2 are found to be mosaic. Two independent germline variants leading to both conditions together in the same individual has never been reported before to our knowledge. Regardless, for any individual meeting criteria both disorders ensuring optimal ongoing surveillance and management, and appropriate recurrence risk counseling is an essential consideration. PAK1 blockers may provide a unique treatment option in the future.

## 679T

**A de novo BRCA2 mutation identified in a woman with breast cancer and strong maternal family history.** R. Drouin<sup>1,2</sup>, W. Pirjamali<sup>3</sup>, L. Provencher<sup>4</sup>, M. Letourneau<sup>1,5</sup>, C. Bouffard<sup>6</sup>, S. Strom<sup>3</sup>, H. Gao<sup>3</sup>. 1) Laval University, Faculty of Medicine, Quebec City, Quebec, Canada; 2) CHUL-CHUQ Université Laval, CHUL, Division of Medical Genetics, Dept of Pediatrics, Quebec City, Quebec, Canada; 3) Fulgent Genetics, Temple City, CA, USA; 4) CHUL-CHUQ Université Laval, Centre des Maladies du Sein Deschênes-Fabia, Hôpital du Saint-Sacrement, Dep of Surgery, Quebec City, Quebec, Canada; 5) CHUL-CHUQ Université Laval, Hospital Hotel-Dieu of Quebec, Division of Radio-Oncology, Dept of Specialized Medicine, Quebec City, Quebec, Canada; 6) Laboatoire de recherche transdisciplinaire en génétique, médecines et sciences sociales, Division of Genetics, Dept of Pediatrics, FMSS, Université de Sherbrooke, Sherbrooke, Quebec, Canada.

A 45-year-old woman was referred to Medical Genetics for investigation of her breast cancer, an infiltrating ductal carcinoma diagnosed at the age of 43. Maternal family history revealed seven cases of breast cancer. The tumor was positive for estrogen and progesterone receptors and negative for amplification of HER2/NEU. The patient had a recurrence risk score of 24 (intermediate risk, Genomic Health / Oncotype DX) and was tested for the following genes at Fulgent Genetics: *APC*, *ATM*, *AXIN2*, *BARD1*, *BMPR1A*, *BRCA1*, *BRCA2*, *BRIP1*, *CDH1*, *CHEK2*, *EPCAM*, *GALNT12*, *GREM1*, *HOXB13*, *MLH1*, *MLH3*, *MRE11A*, *MSH2*, *MSH6*, *MUTYH*, *NBN*, *NF1*, *PALB2*, *PMS2*, *POLD1*, *POLE*, *PTEN*, *RAD50*, *RAD51C*, *RAD51D*, *SMAD4*, *SMARCA4*, *STK11*, *TP53* and *XRCC2*. **Design/Method.** Retrospective case review of a patient with a diagnosis of breast cancer tested with a cancer gene panel at Fulgent Genetics. Genomic DNA from the submitted sample is barcoded and enriched for the coding exons of targeted genes using hybrid capture technology. Prepared DNA libraries are sequenced using a Next Generation Sequencing (NGS) technology. Sequencing results are aligned to the reference sequence and variants are detected in regions with sufficient coverage. In general, 100% of coding regions and splicing junctions are covered to at least 50x by NGS or by Sanger sequencing. Locus specific databases, literature searches, and other molecular biological principles are used to classify variants. To minimize false positive results, any variants that do not meet internal quality standards are confirmed by Sanger sequencing. All genes listed were evaluated for large deletions and/or duplications. Deletions or duplications identified by NGS are confirmed by an orthogonal method (qPCR or MLPA). **Results.** A pathogenic truncating mutation was detected in *BRCA2* (c.9435\_9436del p.Ser3147Cysfs\*2). Parental testing was negative, indicating a de novo mutation. The parent identity testing will be done to confirm that the parents are the parents and that there was no sample swap. **Conclusions.** These results confirm that whenever it is possible, parents should be tested to determine whether a mutation has been inherited or occurred de novo to better tailor the genetic counseling.

## 680F

**Analysis of actionable adult-onset disease risk findings in newborn genomic sequencing.** O. Ceyhan-Birsoy<sup>1,2</sup>, S. Fayer<sup>2</sup>, J.M. Murry<sup>2,4,5</sup>, K. Machin<sup>2,4,5</sup>, C.A. Genetti<sup>6</sup>, T. Schwartz<sup>6</sup>, M.S. LeBo<sup>2,4,5,7</sup>, T.W. Yu<sup>5,6,8</sup>, P.B. Agrawal<sup>5,6,9</sup>, R.B. Paradi<sup>8,10</sup>, R.C. Green<sup>3,5,7</sup>, H.L. Rehm<sup>2,4,5,7,11</sup>, I.A. Holm<sup>5,6</sup>, A.H. Beggs<sup>5,6</sup>. 1) Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY; 2) Laboratory for Molecular Medicine, Partners HealthCare Personalized Medicine, Cambridge, MA; 3) Division of Genetics, Department of Medicine, Brigham and Women's Hospital, Boston, MA; 4) Department of Pathology, Brigham and Women's Hospital, Boston, MA; 5) Harvard Medical School, Boston, MA; 6) Division of Genetics and Genomics, The Manton Center for Orphan Disease Research, Boston Children's Hospital, Boston, MA; 7) The Broad Institute of MIT and Harvard, Cambridge, MA; 8) Department of Neurology, Boston Children's Hospital, Boston, MA; 9) Division of Newborn Medicine, Boston Children's Hospital, Boston, MA; 10) Department of Pediatric Newborn Medicine, Brigham and Women's Hospital, Boston, MA; 11) Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA.

Currently, there is ongoing debate about the risks and benefits of returning adult-onset disease risk findings from genomic sequencing (GS) to children. The BabySeq Project is a randomized controlled trial that explores the use of GS in the clinical care of newborns. Healthy newborns from the well-baby nursery and ill newborns from intensive care units (ICUs) were enrolled and half were randomized to receive GS in addition to standard of care. All families in the GS arm received a report that returned risk and carrier status for childhood-onset diseases as well as pediatrics-related pharmacogenomics findings. In addition, 114 families were consented to receive actionable adult-onset disease risk information for their newborns. To identify genes associated with diseases known to present only during adulthood and for which early knowledge could improve health outcomes, 113 genes that were possibly associated with adult-onset cardiovascular, neurological and endocrine disorders, and hereditary cancers, including the 59 genes recommended by ACMG to be analyzed for secondary GS findings, were curated for validity of disease association, earliest reported age of onset, penetrance, and actionability. Genes that may present during childhood, including 53 ACMG recommended genes, were excluded, as they were assessed during the initial childhood-onset disease risk analysis. Seven genes were determined to present during adulthood only, have at least moderate penetrance, and be medically actionable. *PMS2* and *EPCAM* were excluded from further analysis, as the majority of their pathogenic variation was not expected to be detected by exome sequencing. GS data were filtered and interpreted to identify pathogenic and likely pathogenic variants in *BRCA1*, *BRCA2*, *MLH1*, *MSH2*, and *MSH6* genes. 3/114 (2.6%) newborns had actionable adult-onset disease risk findings. Two newborns that were healthy at the time of enrollment had pathogenic variants in *BRCA2* and *MSH2*, associated with hereditary breast and ovarian cancer and Lynch syndrome, respectively. One newborn with a congenital heart disease enrolled from the ICU had a pathogenic *BRCA2* variant. Testing of parental samples identified parents who also harbored these variants and therefore risk for disease. Results were returned and families were counseled and referred to oncology specialists as appropriate. We continue to explore the medical, behavioral and economic impacts of our GS results on the newborns and their families.

## 681W

**Germline *MSH2* c.-82G>C promoter variant found in Newfoundland patients with mismatch repair deficiency.** A.L. Jacobson<sup>1</sup>, A.S. McFaddin<sup>1</sup>, M. Aronson<sup>2</sup>, A. MacMillan<sup>3</sup>, P. Matthews<sup>4</sup>, G. Boughton<sup>1</sup>, B.A. Fernandez<sup>5</sup>, R.H. Kim<sup>6</sup>, U. Tabori<sup>7</sup>, B.H. Shirts<sup>1</sup>, E.Q. Konnick<sup>1</sup>, C.C. Pritchard<sup>1</sup>. 1) Department of Laboratory Medicine, University of Washington, Seattle, WA; 2) Zane Cohen Centre for Digestive Diseases, Mount Sinai Hospital, Toronto, ON, Canada; 3) Provincial Medical Genetics Program, Eastern Health, St. John's, NL, Canada; 4) James Paton Memorial Regional Health Centre, Gander, NL, Canada; 5) Discipline of Genetics, Memorial University of Newfoundland, St. John's, NL, Canada; 6) Mount Sinai Hospital, Department of Medicine, University of Toronto, Toronto, ON, Canada; 7) Division of Haematology Oncology, The Hospital for Sick Children, Toronto, ON, Canada.

**Introduction:** Pathogenic variants in mismatch repair (MMR) genes cause Lynch syndrome and constitutional mismatch repair deficiency (CMMRD). Very few pathogenic promoter variants have been identified in MMR genes. We identified a rare homozygous germline *MSH2* promoter variant (c.-82G>C) in a child suspected to have CMMRD. The patient had an ultra-mutated brain tumor with *MSH2/MSH6* loss by immunohistochemistry (IHC) that was unexplained by any other variant, prompting a comprehensive review of the variant. This variant is not reported in gnomAD and is reported once in ClinVar as a variant of uncertain significance (ID 231091). **Methods:** We identified carriers of the *MSH2* c.-82G>C germline variant among a series of 10,466 patients ascertained for clinical cancer predisposition testing using a comprehensive NGS cancer panel which includes promoter sequences of the MMR genes. Both germline and paired MMR deficient tumor samples were tested in a subset of cases. **Results:** In our clinical series, we identified four additional patients heterozygous for the *MSH2* c.-82G>C germline variant (Table 1). All patients originated from Newfoundland and were not known to be related. Three of 4 patients had Lynch syndrome-related cancers (2 colorectal, 1 endometrial). We detected IHC loss of *MSH2/MSH6* in all 3 tumors. We also detected *MSH2* promoter methylation in one tumor in which sufficient material was available for this testing (1 of 1 methylated); additional tumor material is being requested for the other *MSH2* c.-82G>C germline carriers to test for *MSH2* methylation. One heterozygous carrier did not have a personal history of cancer and was tested for family history of cancer. **Conclusion:** Our results support that the *MSH2* c.-82G>C variant is likely pathogenic and a likely cause of Lynch syndrome and CMMRD in Newfoundland patients. We hypothesize that this promoter variant may predispose to *MSH2* gene silencing via methylation. Additional work, including segregation studies and additional *MSH2* methylation testing, will help to further characterize this variant.

Case	Clinical history	MMR IHC	Germline MMR	Zygosity	Somatic MMR

Patel<sup>1</sup>, T. Peseran<sup>6</sup>, T. Stockley<sup>2</sup>, A. Tirosh<sup>12</sup>, Y. Wang<sup>7</sup>, S.E. Plon<sup>1</sup>, R.H. Kim<sup>2</sup>, ClinGen VISION VHL Expert Panel. 1) Baylor College of Medicine, Houston, TX, USA; 2) University Health Network, Princess Margaret Cancer Center, Canada; 3) Invitae, San Francisco, CA, USA; 4) McDonnell Genome Institute, Washington University, St. Louis, MO, USA; 5) University Medical Center, Utrecht, NL; 6) Ambry Genetics, Aliso Viejo, CA; 7) GeneDx, Gaithersburg, MD, USA; 8) St. Jude's Children's Research Hospital, Memphis, TN, USA; 9) Children's Hospital of Philadelphia, Philadelphia PA, USA; 10) Prevention Genetics, Marshfield WI, USA; 11) University of Cambridge, Cambridge, UK; 12) National Institutes of Health, Bethesda, MD, USA.

Von Hippel Lindau (VHL) disease is a hereditary tumor predisposition syndrome with multiple subtypes and has a prevalence of ~1/36,000. To date, no concerted effort has been established to share VHL clinical or variant information or develop VHL gene specifications. The Clinical Genome Resource (ClinGen) has convened an Expert Panel (EP) to assess VHL gene-specific criteria for variant interpretation using the American College of Medical Genetics and Genomics (ACMG) guidelines. The VHL Information Sharing International Consortium (VISION) is composed of 27 members across multiple clinical and research disciplines. Our first aim is to review the ACMG evidence codes to determine the needed specifications for VHL, informed by the ClinGen Sequence Variant Interpretation (SVI) guidance. To accomplish this, VISION has divided into three sub-teams as follows: Computational, Functional, Splicing (Team V), Segregation, Allelic, de novo (Team H) and Population-related criteria (Team L). Thus far, we have completed Step 1 of the ClinGen EP Application and are in the process of Step 2 (developing VHL gene specific criteria specifications). We have focused on preliminary specifications for 6 codes (PVS1, PM1, PP1, PP3, BA1 and BS1) and intend to complete all codes that need assessment by Spring 2019. These rules will be piloted on a test set of at least 75 VHL variants. A second aim of VISION is to encourage sharing of VHL clinical and variant information through contribution of VHL variants to ClinVar and consolidation of publicly available variants. To this end, members of VISION collaborated with the crowd-sourced database CIViC (Clinical Interpretations of Variants in Cancer). CIViC possesses the unique capacity of associating deep clinical information with precise genomic information, critical components of VHL variant interpretation. Over 450 VHL variants representing over 1300 cases with clinical phenotyping using HPO terms were deposited into CIViC to date and will provide a dataset for EP use. We have imported this, and additional CIViC VHL curations, into a variant-based pre-curation format that can be reviewed prior to submission into the ClinGen Variant Curation Interface (VCI), where it can be incorporated into the EP variant curation. Collectively, the VISION consortium will work towards facilitating a culture of VHL information sharing, and develop gene specific rules to help resolve challenging VHL variants in an ongoing manner.

**Identifying genetic polymorphisms conferring inverse risk in Alzheimer's and cancer using multivariable association analysis.** G. Pathak, N. Phillips. Department of Microbiology, Immunology & Genetics UNT Health Science Center, Fort Worth, TX.

Worldwide, age demographics are shifting due to the significant expansion of the elderly population. Not surprisingly, this has resulted in an increased prevalence of aging-associated diseases, including Alzheimer's and cancer. Large population studies have reported that individuals with Alzheimer's have a lower risk of cancer history, and individuals with a history of cancer have a lower-than-expected prevalence of Alzheimer's. We hypothesize that the inverse relationship between Alzheimer's and cancer is attributed to genetic variants conferring opposite effects in cancer and Alzheimer's. Therefore, to identify these SNP markers for cancer subtypes and Alzheimer's, a frequentist's multinomial regression (MR) was applied to compare the three disease phenotypes- Alzheimer's, breast and prostate cancer- against controls. This approach increases the power to detect relative risk to Alzheimer's over cancer. QC-filtered genotype data were pooled for of all three disease-affected individuals and conducted PCA analysis to remove population stratification outliers. MR tests were conducted using Trinculo in a total of 4824 individuals with all individuals over the age of 50 and adjusting for age, sex, and first two principal components are covariates. A suggestive threshold of combined  $p < 10^{-4}$  using likelihood ratio test for association of variants across all categories was used to identify significant SNPs. Genetic variants were filtered based on odds-ratio, variants with odds ratio less than 1 in Alzheimer's and higher than 1 for both cancers, and variants conferring high risk in cancer ( $OR > 1$ ) and low risk towards cancer ( $OR < 1$ ). The following genic SNPs exhibited significantly different allelic distributions when comparing all four phenotypes and conferred opposite risk effects when comparing odds ratios for Alzheimer's to odds ratios for cancer (both breast and prostate): rs207906 (XRCC5), rs11893547 (SMYD5), rs2075650 (TOMM40), rs405509 (APOE), rs8106922 (TOMM40), rs224519 (FOXP2). The next for this approach is to stratify the population by sex and identify gender-specific SNP associations for Alzheimer's and cancer. Exploring genetic variant-dependent bidirectional effects in cancer and Alzheimer's holds the potential to identify possible off-target effects of underlying pathology providing a protective effect of one disease over the other.

**Systematic study of chromosomal instability across human cancers.** B.N. Lasseigne, S.J. Cooper, G.M. Cooper, R.M. Myers. HudsonAlpha Institute for Biotechnology, Huntsville, AL, USA.

**Genomic instabilities (GIN) like chromosomal instability (CIN, altered chromosome number and structure) are molecular signatures linked to gross genomic alterations, are an enabling characteristic of the hallmarks of cancer, represent distinct etiologies, and are associated with drug efficacy and patient prognosis. However, studies of copy number burden use different methods like number of breakpoints, number of genes with copy number variation (CNV), percent of bases with CNV, and functional aneuploidy scores. Because there is not consensus on which are most biologically and clinically relevant, our goal was to evaluate CIN metrics across human cancers. Using The Cancer Genome Atlas (TCGA, n=33 cancers) with other public data as validation, we demonstrate CIN metrics are not equivalent and occur at different frequencies in cancers. For example, in clear cell kidney carcinoma (KIRC) the number of breakpoints and number of genes with CNV are correlated ( $\rho=0.20$ ), but represent distinct biological properties like homologous repair defects and selective pressure for CNVs with driver genes, respectively. CIN metrics also had varying associations with clinical characteristics (e.g., number of breakpoints or number of genes with CNV and reduced patient survival in KIRC; Cox  $p=3.62 \times 10^{-7}$  and 0.45, respectively). We also identified molecular features consistently associated with each CIN metric (e.g., 8,831 CpGs associated with number of genes with CNV in KIRC; linear regression with patient age as a covariate, BH-adjusted  $p < 0.05$ ). GO-term, transcription factor occupancy, and proximity to tissue-specific eQTL enrichments for each metric identified pathways and feature sets suggesting mechanisms of disease etiology and progression and potential therapeutic strategies (e.g., targeting purinoceptors in KIRC tumors with a low number of genes with CNV). Additionally, we hypothesized because CIN is linked to widespread DNA hypomethylation and characteristic gene expression changes, it can be inferred from these and other data types. We predicted CIN from each TCGA data type, consistently building models with favorable performance characteristics (e.g., LASSO regression of KIRC high/low number of breakpoints predicted from gene expression, area under curve  $> 0.91$ ). Our study improves CIN signature interpretation, models CIN in other data types, and provides insight into the role of CIN in human cancer etiology, progression, and potential treatment strategies. .**

**685T****Biological networks modulating chemotherapy response in ovarian cancer.**

*D.G. Topouza<sup>1</sup>, J. Choi<sup>1</sup>, S. Nesdoly<sup>2</sup>, Q.L. Duan<sup>1,2</sup>.* 1) Department of Biomedical and Molecular Sciences, Queen's University, Kingston, Ontario, Canada; 2) Queen's School of Computing, Queen's University, Kingston, Ontario, Canada.

Ovarian cancer has the lowest survival rate of all common gynaecological cancers. The gold standard of care for ovarian cancer is surgery and platinum-based chemotherapy; however, more than a third of patients are not responsive to this treatment. The underlying mechanisms of platinum therapy resistance remain poorly understood. In this study, we analyzed RNA sequence data from 190 ovarian serous cystadenocarcinoma patients (The Cancer Genome Atlas) to detect gene expression networks and genomic variants associated with platinum chemotherapy response. Responders (N=111) were cancer-free for one year after the completion of chemotherapy, whereas non-responders (N=79) had a recurrence of cancer less than six months following chemotherapy completion. The aims of this project were to: (i) identify differentially expressed genes using univariate analysis; (ii) identify and characterize gene co-expression networks using multivariate analysis; and (iii) associate genomic variants with platinum chemotherapy response. Preliminary analysis identified 56 differentially expressed genes between platinum responders and non-responders. These included genes contributing to known ovarian cancer regulatory pathways such as the *PI3K-AKT-mTOR* and integrin signaling pathways, as well as novel genes contributing to immune cell regulation pathways. Moreover, we identified a co-expression network associated with chemotherapy response, which was enriched for genes in known cancer development pathways including serine/threonine kinase activity and cyclin D regulation. In addition, this network of genes was enriched for cellular responses to oxidative stress, which is known to be involved in chemotherapy resistance. On-going analysis includes association of tumor and germline variants with chemotherapy response. Our study of the genes and networks associated with chemotherapy response will implicate the underlying mechanisms of platinum therapy resistance. We hope that this will ultimately facilitate genetic testing, promote novel drug development, and improve the efficacy of chemotherapy.

**686F****Genetic risk factors for high-risk human papillomavirus (HPV) infection and persistence among women of African ancestry.**

*C.A. Adebamowo<sup>1,2,3,4</sup>, S.N. Adebamowo<sup>1,2</sup>, A.A. Adeyemo<sup>5</sup> for the H3Africa ACCME Research Group.* 1) Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD, USA; 2) University of Maryland Greenbaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD, USA; 3) Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD; 4) Institute of Human Virology Nigeria, Abuja, Nigeria; 5) Center for Research on Genomics and Global Health, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland, USA.

**Background:** Genetic factors may influence the susceptibility to high-risk human papillomavirus (hrHPV) infection and persistence. We conducted a genome-wide association study (GWAS) to identify variants associated with hrHPV infection and persistence among women of African ancestry. **Methods:** Participants were 522 Nigerian women evaluated at baseline and 6 months follow-up visits for HPV. HPV was characterized using SPF<sub>25</sub>/LiPA<sub>10</sub>. hrHPV infection was positive if at least one carcinogenic HPV genotype was detected in a sample provided at the baseline visit and persistent if at least one carcinogenic HPV genotype was detected in each of the samples provided at the baseline and follow-up visits. Genotyping was done using the Illumina Multi-Ethnic Genotyping Array (MEGA) and imputation was done using the African Genome Resources Haplotype Reference Panel. Association analysis was done under additive genetic models adjusted for age, HIV status and the first 3 principal components of the genotypes. **Results:** The mean ( $\pm$ SD) age of the study participants was 38 ( $\pm$ 8) years, 46% were HIV negative, 24% were hrHPV positive and 10% had persistent hrHPV infections. The GWAS yielded 71 and 107 variants associated with hrHPV infection and persistence, respectively, with suggestive genome-wide significance [ $p$  value  $< 1.0 \times 10^{-3}$ ]. The top variants (rs149473200, rs147344426, rs151071053 and rs572823632) associated with hrHPV infections are in or near *KLF12* [all  $p = 1.5 \times 10^{-6}$ ]. *KLF12* is an important regulator of gene expression during carcinogenesis, and it is highly expressed by human immune cells. In several studies, it was associated with HPV and cervical cancer. The top variants associated with persistent hrHPV infections were 3 variants upstream of *AL450244* (rs143668247, rs12740341, rs2502139), a cluster of 5 intronic variants in *JPH2* (rs116834259, rs74358070, rs11452236, rs79032354, rs6130527) and 2 intronic variants in *GPR39* (rs16832308, rs62167448) [all  $p < 7.0 \times 10^{-7}$ ]. These variants are in enhancer histone marks in several tissues and alter the motifs *Ets*, *GATA*, *NR4A*, *RXR $\alpha$* , which have been associated with several cancers of the female reproductive system and leiomyosarcomas. **Conclusions:** This exploratory GWAS yielded risk loci that provide clues to the pathogenesis of hrHPV infection and persistence in women of African ancestry. Given the limited sample, larger discovery and replication studies are under way to further characterize the reported associations.

## 687W

**Classical HLA alleles are associated with persistent high-risk human papillomavirus (HPV) infection in African women.** S.N. Adebamowo<sup>1,2</sup>, A.A. Adeyemo<sup>3</sup>, C.A. Adebamowo<sup>1,2,4,5</sup> for the H3Africa ACCME Research Group. 1) Department of Epidemiology and Public Health, University of Maryland School of Medicine, Baltimore, MD, USA; 2) University of Maryland Greenebaum Comprehensive Cancer Center, University of Maryland School of Medicine, Baltimore, MD, USA; 3) Center for Research on Genomics and Global Health, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD, USA; 4) Institute of Human Virology, University of Maryland School of Medicine, Baltimore, MD, USA; 5) Institute of Human Virology Nigeria, Abuja, Nigeria.

**Background:** Persistent high-risk human papillomavirus (hrHPV) infection is a necessary cause of cervical cancer. However, the genetic factors underlying its risk are not well understood. We hypothesized that immunogenetic variation plays a role in HPV infection and persistence. Therefore, we conducted a study of classical HLA alleles and their association with hrHPV persistence.

**Methods:** We characterized HPV infection using SPF<sub>22</sub>/LiPA<sub>10</sub> in 522 Nigerian women at baseline and at 6 months follow-up visits in 2014. hrHPV infection was positive if at least one carcinogenic HPV genotype was detected in a sample provided at the baseline visit and persistent if at least one carcinogenic HPV genotype was detected in each of the samples provided at the baseline and follow-up visits. Genotyping was performed with the Illumina Multi-Ethnic Genotyping Array. Classical HLA alleles were imputed from genotypes in the MHC region using the HLA genotype imputation with attribute bagging (HIBAG) algorithm. HLA association tests were conducted under additive genetic models adjusted for age and HIV status. *P*-values were adjusted for multiple comparisons with the false discovery rate (FDR) method. **Results:** The mean ( $\pm$ SD) age of the study participants was 38 ( $\pm$ 8) years, 46% (239/522) were HIV negative, 24% (125/522) were hrHPV positive at baseline and 10% (51/522) had persistent hrHPV infections. HLA-C\*04:01 was the most prevalent MHC I allelic variant (27% of hrHPV negative, 31% of hrHPV positive and 32% of persistent hrHPV positive women), while HLA-DQA1\*01:02 was the most prevalent MHC II allelic variant (40% of hrHPV negative, 38% of hrHPV positive and 32% of persistent hrHPV positive women). HLA-C\*17\*01 was significantly, positively associated with persistent hrHPV infections (OR 2.94; 95% CI: 1.34 – 6.43; adjusted *P*-value 0.04). HLA-DQA1\*02:01 showed borderline positive association with persistent hrHPV infections (OR 2.45; 95% CI: 1.21 – 4.96; adjusted *P*-value 0.07). HLA-DQA1\*02:01 has been shown to be associated with HPV seropositivity in other populations. **Conclusions:** This study, the first to investigate HLA alleles and persistent hrHPV risk in African women, has identified important risk alleles that merit further study. Our findings provide new insights into the risk factors for hrHPV infection in women of African ancestry.

## 688T

**Functional network-based mapping identifies disease genes in polygenic loci unresolved by fine-mapping of cutaneous melanoma GWAS.** M. Artomov<sup>1,2</sup>, A. Loboda<sup>2,3</sup>, H. Tsao<sup>1,2</sup>, M.N. Artyomov<sup>4</sup>, M.J. Daly<sup>1,2</sup>. 1) Massachusetts General Hospital, Boston, MA; 2) Broad Institute, Cambridge, MA; 3) ITMO University, St.Petersburg, Russia; 4) Washington University, St. Louis, MO.

**Background:** GWAS in combination with fine-mapping is the major methodology for studying complex traits. Having made great success in identification of associated loci, GWAS still has limited power to detect associated genes. Numerous associations observed in GWAS imply a limited number of causal functional pathways. Hence, functional interactions network (e.g. Protein-Protein Interactions, Co-expression) could serve a valuable source of information for resolution of polygenic loci. We illustrate this approach with mapping of cutaneous melanoma (CM) GWAS results that identifies novel candidate genes. **Methods:** CM GWAS results from 15,990 CM cases and 26,409 controls (PMID:26237428) were used for construction of the candidate genes list. InWebIM protein-protein interaction network reference (PMID:27892958) was used for assessing functional connectivity. For gene mapping validation we used exome-sequencing dataset of 273 CM cases matched to 7,629 controls (PMID:29522175). **Results:** By fitting beta-uniform distribution to observed *p*-values distribution we created a score for each gene, based on signal (beta-distributed) to noise (uniform) ratio. Genes found within the same locus received equal scores. Using modified prize-collecting Steiner tree algorithm we identified functional module containing genes with the greatest proportion of association signal. We hypothesize that non-relevant for melanoma gene removal from reference network and repeated search for functional module should result in module's cumulative score decrease to be the score of removed gene. By filtering out genes with score drop much smaller than expected and keeping genes with score drop below expectation we selected one candidate gene from each polygenic locus - *ARNT*, *RAD23B*, *CCND1*. With selecting right genes we expect to improve association signal observed in the list of all GWAS genes. We estimated total burden of rare (MAF<0.01%) protein-truncating variants in all GWAS genes using exome sequencing dataset (*p*=0.045; OR=2.12) and compared to the same gene list lacking likely non-relevant genes (*p*=0.016; OR=2.45), gene list lacking likely relevant genes (*p*=0.33; OR=1.42) expectedly contains noise variation. **Conclusions:** Validation shows that predicted non-relevant genes carry small to none signal in rare variation, while relevant genes improve cumulative association signal. These results implicate novel melanoma risk genes and offer usage of this methodology for other complex traits.

**689F**

**Genetic association between *IFITM* gene polymorphisms and cervical cancer susceptibility.** T. Chang<sup>1</sup>, Y. Yang<sup>1,2</sup>, Y. Lee<sup>1,2</sup>, T. Chen<sup>1</sup>, W. Lin<sup>1</sup>, C. Lin<sup>1</sup>. 1) Mackay Memorial Hospital, New Taipei, Taiwan; 2) Taipei Medical University, Taipei, Taiwan.

A small percentage of women with cervical HPV infection progress to cervical cancer, indicating that host genetic makeup could play an important role. Interferon induced transmembrane (IFITM) proteins are highly inducible by interferon and may be crucial factors in carcinogenesis and progression of multiple cancers. This study aims to investigate if variants of the *IFITM* genes are associated with cervical cancer in Taiwanese women. The *IFITM1* rs77537847 A/G, *IFITM2* rs1059091 G/A and rs2031090 G/A, and *IFITM3* rs3888188 C/A polymorphisms were genotyped in 300 cervical squamous cell carcinoma (CSCC) patients and 300 age/sex matched healthy controls. The presence and genotypes of HPV in CSCC patients were also determined. We found no significant association between any polymorphisms or haplotypes examined and CSCC risk. In addition, no significant association was observed between HPV-16 positive CSCC patients and controls. Our findings provide no support for the hypothesis that specific polymorphisms of *IFITM* genes are associated with CSCC susceptibility in Taiwanese women.

**690W**

**Genetic ancestry and the risk of cutaneous squamous cell carcinoma.** H. Choquet<sup>1</sup>, J. Yin<sup>1</sup>, T.J. Hoffmann<sup>2,3</sup>, Y. Banda<sup>2</sup>, M.N. Kvale<sup>2</sup>, C. Schaefer<sup>1</sup>, N. Risch<sup>1,2,3</sup>, M. Asgari<sup>4,5</sup>, E. Jorgenson<sup>1</sup>. 1) Kaiser Permanente Northern California Division of Research, Oakland, CA, USA; 2) Institute for Human Genetics, University of California San Francisco, San Francisco (UCSF), CA, USA; 3) Department of Epidemiology and Biostatistics, UCSF, CA, USA; 4) Department of Dermatology, Massachusetts General Hospital, Boston, MA, USA; 5) Department of Population Medicine, Harvard Pilgrim Health Care Institute, Harvard Medical School, Boston, MA, USA.

**Purpose:** Cutaneous squamous cell carcinoma (cSCC) is one of the most common malignancies in non-Hispanic white individuals. The risk of cSCC is particularly elevated in individuals of northern and western European origin, likely due to fair pigmentation phenotypes (e.g. blue eye, pale skin). Here, we investigate the association between genetic ancestry and cSCC risk in individuals of European origin, and evaluate whether pigmentation phenotypes and known cSCC-associated loci attenuate the ancestry associations. **Methods:** To examine the contribution of genetic ancestry in cSCC risk, we conducted a genetic ancestry analysis in 7,701 cSCC cases and 60,166 controls of non-Hispanic white race/ethnicity from the Kaiser Permanente Northern California Genetic Epidemiology Research in Adult Health and Aging cohort. cSCC cases were identified based on electronic pathology records and systematized nomenclature of medicine codes and were clinically confirmed. We used logistic regression analysis to examine the association of ancestry principal components (PC) with cSCC case/control status, adjusting for age and sex as covariates. We then ascertained whether ancestry associations were explained by predicted pigmentation phenotypes and known cSCC-associated loci. Pigment phenotypes were predicted using HlrisPlex-S, a program that utilizes known pigment genetic variants to generate probabilities of different pigment phenotypes (i.e. for eye, hair, and skin). **Results:** The first two principal components (PC1 and PC2) differentiate geographical clines across Europe, and both were strongly associated with cSCC risk ( $P_{PC1}=1.0 \times 10^{-68}$ ;  $P_{PC2}=2.9 \times 10^{-49}$ ), suggesting that individuals of northern and western European ancestry had greater risk of cSCC. The genetic ancestry associations were attenuated, but still highly significant, after including HlrisPlex-S pigmentation phenotypes in the model ( $P_{PC1}=6.3 \times 10^{-23}$ ;  $P_{PC2}=1.6 \times 10^{-23}$ ). Finally, we incorporated fourteen known cSCC genetic risk variants into the ancestry and HlrisPlex-S model, which further attenuated, but did not eliminate the ancestry signal ( $P_{PC1}=7.3 \times 10^{-22}$ ;  $P_{PC2}=6.2 \times 10^{-21}$ ). **Conclusions:** Our findings reveal that northern and western European ancestry is associated with a greater risk of cSCC in non-Hispanic white populations. Pigmentary traits and cSCC-associated loci explain some of the ancestry associations. However, additional cSCC risk factors that correlate with European ancestry remain to be discovered.

**691T**

**Comparative analysis of the expression of PARKIN, APC and KI67 in colorectal polyps and adenocarcinomas.** C.C.V. da Silva-Camargo, W.A.C.C. Cecílio, L. Noronha, V.S. Sotomaior. Pontifícia Universidade Católica do Paraná, Curitiba, Paraná, Brazil.

Colorectal carcinoma remains the 3<sup>rd</sup> most common cause of cancer in Brazil. The wide spread of screening programs combined with the evolution of molecular biology, applied on the clinical practice, have raised the success rates in the treatment of such neoplasia. Based on the current knowledge of the sequence adenoma-adenocarcinoma, we aimed to analyze comparatively the immune-expression of the tumor suppressor gene *PARK2* (and its protein, PARKIN) with *APC* and *KI67*, in samples of colorectal polyps and adenocarcinomas. We included neoplastic polyps, classified as low dysplasia adenoma, high dysplasia adenoma, sessile serrated polyps, and hyperplastic polyps. Through techniques of tissue microarray, we reviewed by immunohistochemistry, 284 polyps from 222 patients, besides 73 colorectal samples of adenocarcinoma. Due to the fact that more than half of the patients with polyps were found to have more than one lesion, we decided to elaborate a multilevel linear regression statistical model, in order to avoid interpretation bias. The association among quantitative variables was performed by the Person's correlation test, while the comparison between groups was assessed either by the t-test of Student or analysis of variance. There was no significant difference on variables related to patient (sex, age, multiplicity of polyps) and the tissue expression of the proteins. Considering the hierarchical multilevel structure, we only found association to APC and the right side of the colon and type of polyp (sessile serrated). Regarding the level of differentiation, there were found significant correlation ( $p < 0.05$ ) to PARKIN and APC towards the group of carcinomas. The opposite was seen to KI67, *i.e.*, higher levels in polyps with elevated grade of dysplasia. Such findings have similarities in literature, many authors support that PARKIN and APC act on synergism over the colorectal tissue. Although, there are no studies showing overexpression of such proteins in adenocarcinomas, compared to neoplastic polyps, as we have seen here. This findings point out that PARKIN and APC might be involved in later mechanisms of tumor progression control, in the pathway of carcinogenesis.

**Nicotinamide induces mitochondrial-mediated apoptosis through oxidative stress in human cervical cancer HeLa cells.** Y. Feng<sup>1,2</sup>, C. Jiang<sup>1</sup>, Z. Fang<sup>1</sup>, Z. Zhang<sup>1</sup>, W. Jiang\* (Corresponding Author)<sup>1</sup>. 1) Medical Genetics, Zhongshan Medicine School, Sun Yat-sen University, Guangzhou, Guangdong Province, China; 2) Department of Endocrinology, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong Province, China.

**Aims:** Nicotinamide participates in energy metabolism and influences cellular redox status and modulates multiple pathways related with both cellular survival and death. Recent studies have shown that it induced proliferation inhibition and apoptosis in many cancer cells. However, little is known about the effects of nicotinamide on human cervical cancer cells. We aimed to evaluate the effects of the indicated concentrations nicotinamide on cell proliferation, apoptosis and redox-related parameters in HeLa cells and investigated the apoptotic mechanism. **Materials and Methods:** After the treatment of the indicated concentrations nicotinamide, HeLa cell proliferation was evaluated by the CCK-8 assay and the production of ROS (reactive oxygen species) was measured using 2',7'-Dichlorofluorescein diacetate. The apoptotic effect was confirmed by observing the cellular and nuclear morphologies with fluorescence microscope and apoptotic rate of HeLa cell apoptosis was measured by flow cytometry using Annexin-V method. Moreover, we examined the mitochondrial membrane potential by JC-1 method and measured the expression of apoptosis related genes using qRT-PCR and immunoblotting. **Key findings:** Nicotinamide restrained the HeLa cell proliferation and significantly increased the accumulation of ROS and depletion of GSH at relatively high concentrations. Furthermore, nicotinamide promoted HeLa cell apoptosis via the intrinsic mitochondrial apoptotic pathway. The mechanism may related G6PD inhibited by Nicotinamide. **Significance:** Our study revealed that nicotinamide induced the apoptosis through oxidative stress and intrinsic mitochondrial apoptotic pathways in HeLa cell. The results emerge that nicotinamid may be an inexpensive, safe and promising therapeutic agent or a neoadjuvant chemotherapy for cervical cancer patients, as well useful to find new drugs for cervical cancer therapy.

**Array comparative genomic hybridisation of familial prostate cancer tumours identifies a recurrent copy number gain on chr19p13.3 encompassing the EEF2 gene.** L.M. FitzGerald<sup>1</sup>, K. Raspin<sup>1</sup>, J.R. Marthick<sup>1</sup>, R.C. Malley<sup>1,2</sup>, S. Donovan<sup>3</sup>, J.L. Dickinson<sup>1</sup>. 1) University of Tasmania, Tasmania, Australia; 2) Royal Hobart Hospital, Hobart, TAS, 7000, Australia; 3) Hobart Pathology, Hobart, TAS, 7000, Australia.

In a bid to discover genomic features associated with prostate cancer (PrCa) development and progression, copy number variations (CNVs) have been studied in tumour samples. Early comparative genomic hybridisation (CGH) studies led to the identification of many chromosomal regions of loss and gain, with a small number of these shown to be consistent across studies and, significantly, some suggested to be associated with PrCa progression. More recently a small number of studies have applied dense genome-wide SNP array platforms to fresh-frozen prostate tumours to identify recurrent CNVs, however these platforms are not suitable for the more widely available formalin-fixed, paraffin-embedded (FFPE) tumour samples. With the aim of replicating or identifying novel recurrent prostate tumour CNVs and elucidating the underlying genes involved, we applied the Agilent Oligonucleotide array-based CGH (aCGH), with both genome-wide and custom probes, to 12 FFPE prostate tumour DNA samples from a single Tasmanian family, PcTas9. Analysis of these data revealed as little as two to tens of CNVs present in each tumour, the majority of which were gains. In addition, several recurrent CNVs were identified, the most common of which was present on chromosome 19p13.3 and contained only two genes, including EEF2. EEF2 has recently been shown to be overexpressed in various cancer types, including PrCa where it has been suggested to be associated with Gleason score. Currently, we are performing EEF2 gene and protein expression studies in tumour samples from PcTas9 and additional Tasmanian familial and sporadic PrCa cases, and will investigate whether these are associated with Gleason score. Our findings to date suggest that increased EEF2 protein levels observed in prior prostate tumour studies may be due to a copy number gain on 19p13.3. To test this hypothesis, gene and protein expression studies are currently underway and results will be presented at the meeting.

**Pathway-analysis of MAPK/ERK SNPs in gastric cancer.** P. Gonzalez-Hormazabal<sup>1</sup>, M. Musleh<sup>2</sup>, M. Bustamante<sup>3</sup>, J. Stambuk<sup>4</sup>, R. Pisano<sup>4</sup>, V.G. Castro<sup>1</sup>, E. Lanzarini<sup>2</sup>, H. Valladares<sup>2</sup>, J. Rojas<sup>2</sup>. 1) Human Genetics Program, Institute of Biomedical Sciences, University of Chile; 2) Department of Surgery, University of Chile Clinical Hospital; 3) Department of Surgery, School of Medicine at Eastern Campus, University of Chile; 4) San Juan de Dios Hospital.

Background: Chile has one of the world's highest mortality rate from gastric cancer. Activation of MAPK/ERK pathway is key in cancer cell proliferation. Aim: We aimed to assess the association with gastric cancer (GC) of polymorphisms in MAPK/ERK pathway in a case-control study of 242 gastric adenocarcinoma patients and 192 controls. Methods: DNA samples were genotyped using Infinium Global Screening Array (Illumina) and we obtained genotypes of 21 SNPs belonging to *ARAF*, *BRAF*, *GRB2*, *HRAS*, *MAP2K1*, *MAP2K2*, *MAPK1*, *MAPK3*, *RAF1*, *SHC1*, *SOS1* and *SOS2*. Estimates of association under the additive model was obtained from logistic regression, adjusting by population stratification (PC1 and PC2 from PCA analysis implemented in PLINK 1.90). A p-value of 0.0023 was considered significant (Bonferroni correction). Results: Three SNPs was associated with GC: *MAPK1* rs6928 p=0.002, OR=1.57, *RAF1* rs3729931 p=0.002, OR=1.53, and *MAPK1* rs2283792 p=0.002 OR=1.55. An interaction between *H.pylori* infection and *MAP2K2* rs3500912 is suggested (p=0.039). All the associated SNPs are eQTL according to GTEx portal. Conclusions: These findings suggest that *MAPK1* rs6928, *MAPK1* rs2283792, and *RAF1* rs3729931 polymorphisms are associated with GC, and the risk of *MAP2K2* rs3500912 is modified by *H.pylori* infection.

**Impact of next generation sequencing on the analysis of familial breast cancer in African populations.**

Y. Hamdi<sup>1</sup>, M. Boujemaa<sup>1</sup>, N. Mighri<sup>1</sup>, N. Mejr<sup>2</sup>, O. Jaidane<sup>3</sup>, S. Ben Nacer<sup>4</sup>, S. Labidi<sup>2</sup>, J. Ben Hassouna<sup>2</sup>, J. Ayari<sup>2</sup>, H. El Benna<sup>2</sup>, H. Bouazizi<sup>2</sup>, B. Mezghanni<sup>2</sup>, A. Haddaoui<sup>2</sup>, K. Rahhal<sup>2</sup>, H. Boussen<sup>2</sup>, M.S. Boubaker<sup>1</sup>, S. Abdelhak<sup>1</sup>, PEC Consortium. 1) Institute Pasteur of Tunis, Tunis, Tunisia; 2) Abderahmane Mami Hospital, Ariana, Tunisia; 3) Salah Azaiez Hospital, Tunis, Tunisia; 4) Military hospital, Tunis, Tunisia.

A family history of breast cancer (BC) has long been thought to indicate the presence of inherited genetic events that predispose to this disease. Actually, the major challenge of BC molecular genetics is to identify causal variants. Because of important differences in genetic patterns between ethnicities, association studies and haplotype analysis in different populations can help to overcome this challenge. Our present genome-wide-scanning was applied with Affymetrix-Genome-Wide-Human-SNP-Array-6.0 in order to determine allelic frequencies of the known BC associated variants in 135 Tunisians representing the general-population. We constructed and phased haplotypes carried by the studied Tunisian-population. Moreover, we assessed the biological effect of the putative functional variants by conducting eQTL-assays. We also compared BC associated-loci between different HapMap-populations by comparing LD-blocks and by conducting Principle-Component-Analysis. Our haplotype analysis showed that the Tunisian-population is more predisposed to the following at risk loci: 2p24, 4q21, 6q25, 9q31, 10q26, 11q13, 14q32. Four polymorphisms specific to the Tunisian population have also been identified including one on the *ESR1*-gene. Furthermore, we characterized a *BRCA1*-variant that can be considered as a causal polymorphism. In addition, we conducted Whole-Exome-Sequencing in 11 BC patients. In a first BC family, no deleterious mutation have been identified on known BC genes. However, functional annotation showed that *MMS19*, *POLK* and *KATB6* are novel breast cancer candidate genes that seems to be inherited in a family specific model. In a second BC family, we identified 2 cis-deleterious mutations on *BRCA2*. This cis-double heterozygosity have not been reported before and seems to be associated with a distinctive clinical phenotype. In this first WES application on Tunisian BC patients and by combining association, functional and bioinformatics analysis we highlighted the impact of next generation sequencing technologies on the identification of novel breast cancer candidate genes and novel genetic patterns such as the *BRCA2*-cis double heterozygosity. Further genetic analysis on additional African BC cases may bring new insights into the biological mechanisms of breast carcinogenesis which will provide a better clinical management of patients from under-represented populations. .

Baragan<sup>8</sup>, Y. Lu<sup>9</sup>, L. Tamagnone<sup>9</sup>, I. Inoue<sup>9</sup>, X. Li<sup>10</sup>, J. Luo<sup>11</sup>, H. You<sup>11</sup>. 1) Department of Systems Bioinformatics, Graduate School of Medicine Yamaguchi University, Ube, Yamaguchi, Japan; 2) Department of Endocrine and Breast Surgery, The First Affiliated Hospital of Chongqing Medical University, Chongqing, China; 3) Department of Medical Genetics, School of Basic Medical Sciences, Peking University, Beijing, China; 4) Key Laboratory of Birth Defects and Reproductive Health of the National Health and Family Planning Commission, Chongqing Population and Family Planning Science and Technology Research Institute, Chongqing, China; 5) Investigación Clínica y Traslacional del Cáncer, Virgen de la Victoria Hospital, IBIMA, Málaga, Spain; 6) Division of Human Genetics, National Institute of Genetics, Mishima, Japan; 7) The First Affiliated Hospital, Jinan University, Guangzhou, China; 8) Physiology and Pharmacology Department, Karolinska Institute, Snola, Sweden; 9) Department of Oncology, University of Torino, Candiolo, Italy; 10) State Key Laboratory of Agrobiotechnology, College of Biological Sciences, Beijing Advanced Innovation Center for Food Nutrition and Human Health, China Agricultural University, Beijing, China; 11) Affiliated Cancer Hospital & Institute of Guangzhou Medical University, Guangzhou, China.

**Background:** Breast cancer (BC) is the most prevalent malignance among women. Metastasis is one of the major obstacles to BC treatment and is responsible for more than 90% of BC related deceases. Therefore, it is necessary to better understand the genetic and molecular mechanisms leading to BC metastasis. Involvement of Long non-coding RNAs (lncRNAs) in BC has been proposed given their abnormal expression during the occurrence, recurrence and progression of BC. However, the pathophysiological contribution of lncRNAs in BC and specifically in the metastatic stage are still unclear. **Methods:** We examined the differential expression of lncRNAs between five pairs of invasive BC and their corresponding adjacent tissues by Agilent human lncRNA + mRNA Array V3.0. A differentially expressed lncRNA was further validated in 56 additional samples of BC. We also conducted knockdown and over-expression analysed of the lncRNA. **Results:** We identified a differential increase in the expression of 231 lncRNAs and a differential decrease in the expression of 625 lncRNAs in the BC. One of the differentially expressed lncRNA (lncRNA-BCHE) was remarkably upregulated (fold change more than 20, p value = 0.029) in the 56 samples of BC. Knockdown of lncRNA-BCHE inhibited the proliferation of MDA-MB-231 cells in vitro. Over-expression of lncRNA-BCHE promoted the migration and invasion of BC cells. **Conclusion:** All these data suggested that this novel lncRNA is a potential prognostic marker and a target gene therapy in BC.

**An integrative approach for mapping the mutation landscape of DNA repair genes and pathways in prostate cancer.** C. Hicks<sup>1</sup>, T. Mamidi<sup>1</sup>, J. Wu<sup>1</sup>, E. Nicklow<sup>1</sup>, O. Sartor<sup>2</sup>, E. Ledet<sup>1</sup>, W. Liu<sup>1</sup>. 1) Department of Genetics, 533 Bolivar Street, Louisiana State University Health Sciences Center, School of Medicine, New Orleans, LA. 70112; 2) Department of Medicine and Urology, Tulane University, School of Medicine, 150 S Liberty St, New Orleans, LA 70112.

**Background:** Prostate Cancer (PC) is the most diagnosed cancer and the second leading cause of cancer-related deaths among men in the United States. Pathogenic variants in genes involved in the DNA repair process play a role in the pathogenesis of PC. The recent surge of high-throughput sequencing of PC genomes has led to an expanding molecular classification of PC. However, to date, sequence data has not been optimally leveraged and integrated with transcriptome data to map the mutation landscape of DNA repair genes and pathways in indolent and aggressive PC. Here we integrated sequence information with gene expression data to map the mutation landscape of DNA repair genes, molecular networks and biological pathways in indolent and aggressive PC. Our working hypothesis is that genomic aberrations and alterations in genes, molecular networks and biological pathways involved in the DNA repair process could lead to measurable changes affecting therapeutic decision making. **Methods:** We have addressed this hypothesis as follows: We evaluated 311 genes involved in the DNA process for somatic mutations using TCGA data involving 190 men with indolent PC (Gleason score <7) and 304 men with aggressive PC (Gleason score = 8-10). We leveraged mutation information with gene expression data on the same patients and 52 matched normal to discover signatures of mutated genes. We performed network and pathway analysis to generate an atlas of interactive maps and pathways enriched for mutations and their functional connectivity. **Results:** This unbiased approach revealed gene signatures, molecular networks and biological pathways enriched for mutations prevalent in indolent and aggressive PC. Among the mutated genes discovered, 25 were associated with indolent PC and 35 were associated with aggressive PC, with 11 genes common to both disease states. Several genes including *BRCA2*, *BRCA1*, *ATM*, *CHEK2* and *PALB2* and pathways (DNA repair and DNA mismatch repair) contained mutations predicted to be deleterious. The clinical implications of these results is that mutations could be used to identify patients at high risk of developing lethal PC. **Conclusions:** The results show that somatic mutations in genes and pathways mediating the DNA-repair processes are prevalent among men with indolent and aggressive PC and tend to be higher in the latter. Future work will involve both germline and somatic mutations in genes and pathways among men with PC in multiple ethnic populations.

**Genotype/phenotype assessment in male *BRCA1/2* pathogenic variant carriers.** S. Hiraki, L.R. Susswein, P.D. Murphy, M.L. Marshall, K.S. Hruska, R.T. Klein. GeneDx, Gaithersburg, MD.

**Background:** Pathogenic variants in *BRCA1* and *BRCA2* are known to increase the risk of breast and ovarian cancer in women; however, male *BRCA1/2* pathogenic variant carriers are also at increased cancer risk, including prostate and breast cancers. Ovarian cancer risks are known to vary by variant location in *BRCA1/2*, and there is some suggestion that genotype-phenotype correlations also exist for prostate cancer. In this study, we delineated the spectrum of cancers in male *BRCA1/2* pathogenic/likely pathogenic variant (PV) carriers, and investigated whether prostate cancer risks differed by variant location. **Methods:** We reviewed the results of all men tested for *BRCA1/2* at GeneDx as part of a multi-gene panel of 2 to 64 genes between August 2013 and April 2018. Self-reported cancer histories and type of PV identified were reviewed. Based on the location of a majority of PVs, putative *BRCA1/2* prostate cancer cluster regions (PCCR) were defined, and the relative risk of prostate cancer for variants inside versus outside these regions was calculated. Men with more than one PV in any gene were excluded from all analyses, and those with exon-level deletion/duplications were excluded from PCCR analyses. **Results:** Among 353 PVs identified, 63% were in *BRCA2* and 37% were in *BRCA1*. A personal history of cancer was reported in 169/222 (76%) *BRCA2* PV carriers and 65/131 (50%) *BRCA1* PV carriers. Prostate cancer was reported in 23% (52/222) of *BRCA2* PV carriers and 12% (15/131) of *BRCA1* PV carriers. We identified putative PCCRs in *BRCA2* (c.3847-c.6468) and *BRCA1* (c.4035-c.4357). Comparing men who carried a PV inside versus outside the *BRCA2* PCCR, 28/83 (34%) versus 23/134 (17%) had prostate cancer, translating to a relative risk of 1.97 ( $p < 0.01$ ). Comparing men who carried a PV inside versus outside the *BRCA1* PCCR, 4/8 (50%) versus 8/104 (8%) had prostate cancer, but the small sample size of this cohort precluded further analyses. **Conclusions:** Prostate cancer is the most frequently reported cancer in men with *BRCA1/2* PVs. Prostate cancer diagnoses appeared to be more common in men with PVs located within *BRCA2* c.3847-c.6468, defining a potential PCCR. A *BRCA1* PCCR may also exist, however, larger numbers are needed to confirm this association. Further delineation of genotype-phenotype correlations for cancer risk may contribute to more personalized risk assessment and management for male *BRCA1/2* PV carriers.

## 699W

**The incidence of occult ovarian neoplasia and cancer in *BRCA1/2* mutation carriers after the bilateral prophylactic salpingo-oophorectomy (PBSO): A single center prospective study.** R. Janavicius<sup>1,2</sup>, G. Januska<sup>1</sup>, P. Jukna<sup>1</sup>, V. Rudaitis<sup>1,2</sup>. 1) VUH Santaros Klinikos, Vilnius, VNO, Lithuania; 2) State Research Institute Innovative Medicine Center, Vilnius, Lithuania.

**Objective:** to evaluate the incidence of occult neoplasia in specimen collected during PBSO and to determine the significance of this operation in *BRCA1/2* mutation carriers. **Methods:** Between January 2010 and October 2016 a total of 564 new germline *BRCA1/2* mutation positive women were identified at Hereditary Cancer Competence Center Unit of Hematology, Oncology and Transfusion Medicine Center, in Vilnius University Hospital Santaros Klinikos (VULSK). All these patients had undergone oncogenetic counselling, genetic testing, and corresponding cancer risk reduction management in the same institution. Patients were prospectively included in password protected electronic Patients Surveillance System Registry (ONCOGEN). As part of ovarian risk reduction management process, laparoscopic prophylactic bilateral salpingo-oophorectomy (PBSO) was performed for 71 eligible women, who opted for this procedure and were included in this perspective study. Fifty nine women (83.1%) were *BRCA1* and 12 (16.9%) were *BRCA2* mutation carriers; study patients harboured 22 different *BRCA1/2* germline mutations. **Results:** STIC was diagnosed in seven (9.85%; 95% CI 4.58 - 19.26) women and occult ovarian cancer (OC) was found in four (5.6%; 95% CI 1.80 - 14.03) women. The median age of women that were diagnosed with STIC or OC at the time PBSO was 45,9 years ( $\pm 6,68$ ;  $P=0.7314$ ), the youngest patient being 42 and the oldest 64 years. All 11 women who were diagnosed with STIC or OC had *BRCA1* mutations. Interestingly, STIC was detected in 6 carriers (out of 27) of exclusively *BRCA1* c.4035delA mutation (22.2%; 95% CI 10.26 - 41.10), a common Baltic founder mutation. The difference between STIC detected in c.4035delA (6/27) and other mutations carriers (1/44) was statistically significant ( $P=0.0105$ ). The mean follow up time for women being diagnosed with ovarian cancer or STIC was 3.72 years ( $\pm 1.24$ ). The median operating time to perform a laparoscopic PBSO was 45 minutes ( $\pm 9,94$ ) ranging from 25 to 65 minutes. No surgical complications occurred during this operation. **Conclusion:** The detection rate of precursor-only lesions (STIC) in our study (9.85%) was slightly higher than previously reported (5-8%). We found statistically significant enrichment of *BRCA1* c.4035delA mutation carriers in STIC group, which may indicate that c.4035delA mutation carriers may have an increased tumorigenesis rate in fallopian tubes, which can also explain higher STIC detection rate in our series. Grant SEN18/2015.

## 700T

**An association study of genetic variants located in DHSs with the risk of gastric cancer in Chinese population.** Y. Jiang<sup>1,2</sup>, F. Yu<sup>1,2</sup>, T. Wang<sup>1,2</sup>, Q. Qi<sup>1,2</sup>, H. Ma<sup>1,2</sup>, Z. Hu<sup>1,2</sup>, G. Jin<sup>1,2</sup>. 1) Department of Epidemiology and Biostatistics, Nanjing Medical University, Nanjing, Jiangsu, China; 2) Jiangsu Key Lab of Cancer Biomarkers, Prevention and Treatment, Collaborative Innovation Center for Cancer Medicine, Nanjing Medical University, Nanjing, Jiangsu, China.

**Objective:** Deoxyribonuclease I hypersensitive sites (DHSs) are markers of regulatory elements across genome. Genetic loci of diseases or traits identified genome-wide association studies (GWAS) are enriched in DHSs. We explored whether genetic variants in DHSs played an important role in susceptibility to gastric cancer (GC). **Method:** DHSs were defined on the basis of data from 125 tissues and cell lines of ENCODE. Genetic variants in DHSs were evaluated the association with GC risk in 3771 cases and 5426 controls from 4 existing GWAS of Chinese population. Expression quantitative trait loci (eQTL) were analyzed by using genotype and mRNA data from GTEx (170 normal stomach tissues) and TCGA (412 GC tissues) and differential expression analysis was based on TCGA (413 GC tissues and 32 normal tissues). According to the results of association, eQTL, differential expression, GC risk related loci were selected for subsequent validation in 6222 GC cases and 7510 controls by Sequenom and TaqMan assays. **Results:** We found a variant at 7q22.1 was significantly associated with GC risk (per allele: OR=0.85, 95%CI: 0.81-0.90,  $P=2.56 \times 10^{-3}$ ). The genotypes were significantly related to the expression level of *SEMA3D* ( $P=7.16 \times 10^{-3}$ ), and expression of *SEMA3D* was down-regulated in GC tissues (paired samples:  $P=1.50 \times 10^{-5}$ , unpaired samples:  $P=8.97 \times 10^{-3}$ ). **Conclusion:** These results indicate that the genetic variant in DHSs on chromosome 7q21.11 may modulate susceptibility to gastric cancer through regulating the expression of *SEMA3D*, which further highlighted the important role of genetic variants in DHSs in the development of GC.

**The analysis on the mechanism of apoptosis induced by inhibiting G6PD activity in HeLa cells.** *W. Jiang<sup>1</sup>, Y. Feng<sup>1,2</sup>, X. Lin<sup>1</sup>, C. Jiang<sup>1</sup>, P. Du<sup>1</sup>, H. Luo<sup>1</sup>, R. Hassan<sup>1</sup>, J. Yan<sup>1</sup>.* 1) Department of Medical Genetics, Zhongshan Medicine School, Sun Yat-sen University, Guangzhou, Guangdong Province, China; 2) Department of Endocrinology, Guangzhou Women and Children's Medical Center, Guangzhou, Guangdong Province, China.

**Aims:** Glucose-6-phosphate dehydrogenase (G6PD) is a critical rate-limiting enzyme for pentose phosphate pathway (PPP). 5-phosphate ribose that is the nucleotide component and NADPH that is not only to maintain the glutathione (GSH) reduction state, but also function as for biosynthesis are the main metabolites in PPP. G6PD plays an important role in regulating the metabolic reprogramming of tumor cells, which is involved in the processes of apoptosis, proliferation and cell-cycle progression. But the mechanisms remains elusive. We aim to assess the effects of DHEA and nicotinamide on G6PD activity and redox status in HeLa cells and explored the mechanism of DHEA-induced apoptosis of HeLa cells, searching for a new potential cancer therapeutic target. **Methods:** After the treatment of the indicated concentrations DHEA, HeLa cell proliferation was evaluated by the CCK-8 assay and the production of ROS (reactive oxygen species) was measured using 2',7'-Dichlorofluorescein diacetate. The apoptotic effect was confirmed by observing the cellular and nuclear morphologies with fluorescence microscope and apoptotic rate of HeLa cell was measured by flow cytometry using Annexin-V method. Moreover, the mitochondrial membrane potential was examined by JC-1 method and the expression of apoptosis related genes were analyzed using qRT-PCR and immunoblotting. **Key findings:** DHEA inhibited G6PD activity to induce HeLa cell apoptosis via the intrinsic mitochondrial apoptotic pathway. The mechanisms related with the increased intracellular ROS levels, decreased GSH content. G6PD knockdown was associated with cell-cycle arrest during the G0/G1 or S phase, which promoted cell apoptosis. **Significance:** Our study demonstrated that DHEA inhibiting G6PD could induce ROS-mediated apoptosis, indicating the important role of G6PD in HeLa cells of redox regulation to suppress the cervical cancer and provided a new evidence that inhibition of G6PD activity may be useful for cervical cancer therapy.

**The genomic landscape of recurrent ovarian cancer reveals mutational processes and functional mechanisms that drive chemoresistance.** *M.R. Jones<sup>1</sup>, S.G. Coetzee<sup>1</sup>, N.M. Gull<sup>1</sup>, A.L.P. Reyes<sup>1</sup>, J.T. Plummer<sup>1</sup>, B.D. Davis<sup>1</sup>, S. Chen<sup>1</sup>, J.P.B. Govindavar<sup>2</sup>, J. Rutgers<sup>2</sup>, J. Lester<sup>2</sup>, K. Lawrenson<sup>3</sup>, D.J. Hazelett<sup>1</sup>, B.P. Berman<sup>1,4</sup>, B. Karlan<sup>3</sup>, S.A. Gayther<sup>1,4</sup>.* 1) Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA; 2) Dept of Pathology and Laboratory Medicine, Cedars-Sinai Medical Center, Los Angeles, CA; 3) Women's Cancer Program, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA; 4) Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA.

Seventy percent of high grade serous ovarian cancer (HGSOC) patients are diagnosed with late stage disease when 5-year survival rates are ~30%. Patients initially respond to chemotherapies, but tumor recurrence occurs in 80% of cases leading to chemotherapy resistant disease that is ultimately fatal. More than 15% of serous OC patients carry a germline mutation in BRCA1/2, which account for approximately 30% of the heritability of HGSOC. The genomes of HGSOC tumors are highly unstable; BRCA1/2 mutant tumors are deficient in homologous recombination repair while tumors from patients without BRCA1/2 mutations harbor high numbers of foldback inversions. To identify the genomic mechanisms underlying chemoresistance in HGSOC we studied a cohort of 34 patients (13 BRCA1/2 mutation carriers; 21 patients with no identified genetic predisposition) with paired tumor specimens that were chemotherapy naive (from primary debulking surgery) as well as >1 recurrent tumor (chemotherapy resistant). We generated a genomic landscape of the changes that occur as a result of chemoresistance in each tumor (n=73) with whole genome sequencing, whole genome bisulfite sequencing and RNA-Seq. Somatic single nucleotide variant, Indel and structural variant (SV) analysis reveal monoclonal and polyclonal seeding of recurrent tumors by populations of clones from the primary tumor carrying mutations allowing them to survive the purifying selection process of chemotherapy. An range in increased mutational load in the recurrent tumors in each patient (1,069-15,913 SNVs) indicates diverse mutational mechanisms between patients. Mutational signatures in the primary tumor were dominated by BRCA and Age signatures, while recurrent tumors frequently differed from the matched primary and were enriched for Signatures 8 (Breast Cancer; C>A) and 12 (Liver Cancer; T>C). The genes most frequently mutated in recurrent tumors were LINC00969, RUNX1T1, and SEPT9; the candidate ovarian tumor suppressor gene. Two patients (non-BRCA mutation carriers) showed a unique sub-population of clones that were able to leave the peritoneal cavity and metastasize to the brain. Mutations identified across recurrent tumors identify pathways that can be targeted using existing therapies in platinum-resistant patients. To improve survival for women with HGSOC, discovering novel therapeutic opportunities for platinum-resistant disease remains a top priority.

## 703T

**Early lifestyle factors are associated with an increased risk of atopic disorders in lymphoid cancer families.** S.J. Jones<sup>1,2</sup>, S. Stroschein<sup>3</sup>, D. Liu<sup>4</sup>, J. Spinelli<sup>5</sup>, J.M. Connors<sup>6</sup>, A. Brooks-Wilson<sup>2,3</sup>. 1) Medical Genetics, University of British Columbia, Vancouver, British Columbia, Canada; 2) Canada's Michael Smith Genome Sciences Centre, British Columbia Cancer Agency, Vancouver, Canada; 3) Department of Biomedical Physiology and Kinesiology, Simon Fraser University, Burnaby, Canada; 4) Department of Statistics and Actuarial Science, Simon Fraser University, Burnaby, Canada; 5) Cancer Control Research Program, British Columbia Cancer Agency, Vancouver, Canada; 6) Centre for Lymphoid Cancers, BC Cancer Agency, Vancouver, Canada.

The etiology of lymphoid cancers is multifactorial. Research suggests that infectious diseases and immune disorders may influence the risk of lymphoid cancer. The hygiene hypothesis proposes that a lower infectious burden during early life prevents the immune system from maturing optimally and may cause adult-onset immunogenetic disorders. We evaluated birth order and sibship size as indicators of early lifestyle in 192 families with a history of lymphoid cancer. Data was collected from 443 lymphoid cancer cases and 987 unaffected siblings among 341 lymphoid affected sibships. The relationship between lifestyle factors and risk of lymphoid cancer, allergies, and autoimmune conditions were examined using a linear regression with generalized estimating equation to accommodate correlated family data. Odds Ratios (ORs) were adjusted for age and sex. Birth order and sibship size were independently associated with risk of lymphoid cancer. Increasing birth order was inversely associated with risk of cancer for all lymphoid cancers collectively (OR=0.79; 95% CI:0.74-0.85), and separately for multiple myeloma (OR = 0.35; 95% CI:0.15-0.77), non-Hodgkin lymphoma (OR=0.65; 95% CI:0.53-0.79) and chronic lymphocytic leukemia (OR=0.73; 95% CI:0.54-0.98). That is, individuals with an earlier birth order position had a higher risk of lymphoid cancer than later born siblings. Effects of birth order were seen in smaller families with 2 or 3 lymphoid cases but were not observed in families with 4 or more affected. Birth order was also inversely associated with risk of allergies (OR=0.83, 95% CI:0.68-0.99) but not autoimmune disease. The associations between lymphoid cancer and atypical immune function have been explored in small cohort and large population studies, however, there is limited evidence in the familial context. The inverse relationship between birth order and risk of disease has been documented for allergies and some lymphomas, but no association has been reported for autoimmune diseases. The observed inverse relationship between birth order and sibship with risk of lymphoma is supportive of the hygiene hypothesis, and that childhood exposure to infectious disease may play a role in the lymphatic malignancies. The familial nature of these cancers implies a role of shared genetic and/or environmental factors. These effects may be modified by lifestyle factors that correlate with birth order and could identify protective lifestyle factors, even in the familial context.

Lee Moffitt Cancer Center & Research Institute, Tampa, FL, USA; 21) Unit of Nutrition and Cancer, Catalan Institute of Oncology (ICO-IDIBELL), Barcelona, Spain; 22) Population Health Science, Bristol Medical School, MRC Integrative Epidemiology Unit, University of Bristol, Bristol, UK; 23) Institute for Clinical and Translational Research, Baylor College of Medicine, Houston, TX, USA; 24) Lunenfeld-Tanenbaum Research Institute, Sinai Health System, Toronto, ON, Canada.

Individuals with impaired lung function have an increased risk of developing lung cancer. However, since impaired lung function is also an indicator of obstructive pulmonary disease, and a consequence of tobacco smoking, it is unclear whether the observed relationship with lung cancer is causal. To investigate this hypothesis, we developed genetic instruments for each lung phenotype using genome-wide analyses full UK Biobank cohort (UKB), and applied these novel instruments in Mendelian randomization (MR) analyses of 24 studies from the OncoArray collaboration. Lung function was measured as forced expiratory volume in 1 second (FEV<sub>1</sub>), forced vital capacity (FVC), and FEV<sub>1</sub>/FVC, based on reproducible spirometry (within 0.15 L) from European ancestry subjects. GWAS of 15.5 million variants for FEV<sub>1</sub> (n=371,892), FVC (n=369,830), and FEV<sub>1</sub>/FVC (n=367,764) identified over 400 independently associated loci (p<5×10<sup>-8</sup>; r<sup>2</sup><0.05) for each trait. Heritability estimated using LD-Score regression was 18% for FEV<sub>1</sub> and FVC, and 14% for FEV<sub>1</sub>/FVC. After filtering indels and palindromic SNPs, the following instruments were developed: FEV<sub>1</sub> (374 SNPs, 6.1% of variation explained), FVC (318 SNPs, 4.9%), and FEV<sub>1</sub>/FVC (431 SNPs, 8.9%). Causal odds ratios (OR) per 1 standard deviation (FEV<sub>1</sub>, FVC) and 1 unit (FEV<sub>1</sub>/FVC) increase were estimated using summary statistics from 18,806 lung cancer cases (adenocarcinoma: n=7,039; squamous carcinoma: n=4,550) and 14,220 controls (>80% European ancestry). Maximum-likelihood MR estimates indicated that genetic determinants of reduced FEV<sub>1</sub> were associated with increased risk of lung cancer overall (OR=1.26, 1.05-1.50), lung adenocarcinoma (OR=1.32, 1.05-1.67), and squamous cell carcinoma (OR=1.28, 0.97-1.69). These findings were supported by MR Robust Adjusted Profile Scores (OR lung: 1.21, 1.03-1.43; OR adeno: 1.27, 1.01-1.59), and the direction of the causal effect was confirmed by MR Steiger. There was little evidence of heterogeneity among FEV<sub>1</sub> causal effect estimates (Cochrane's Q p-value>0.05). Despite the high genetic correlation between FEV<sub>1</sub> and FVC (r<sub>g</sub>=0.77), no statistically significant associations with lung cancer were observed for FVC or FEV<sub>1</sub>/FVC. Our findings suggest that FEV<sub>1</sub> loci capture distinct pathways that may be implicated in lung cancer susceptibility. However, these results should be interpreted with caution since pleiotropic effects cannot be ruled out, and the contribution of smoking-mediated pathways remains to be clarified.

## 705W

**Genetic polymorphisms in the *SPC25*, *LOC285762* and *NPY* genes are associated with colorectal advanced adenoma in a Korean population.** S. Kang<sup>1</sup>, J. Lee<sup>2</sup>, S. Chung<sup>1</sup>, E. Shin<sup>2</sup>, E. Choe<sup>1</sup>, S. Choi<sup>1</sup>. 1) Seoul National University Hospital Gangnam Center, Seoul, Korea, Republic of; 2) DNA Link, Inc., Seoul, Korea, Republic of.

Colorectal cancer (CRC) is a leading cause of morbidity and mortality in the developed countries. Most CRCs develop from adenomas in a well-described adenoma-carcinoma sequence. Cancer risk of adenoma with advanced features (size more than 1cm, villous elements or high grade dysplasia, and adenoma more than 3) is particularly high compared with non-advanced adenoma. We performed the first genome-wide association study (GWAS) on susceptibility to advanced adenoma in a Korean population. A GWAS was conducted among 7,948 healthy individuals; among these cases, the test set comprised 625 cases and 600 controls, and the replication set comprised 283 cases and 243 controls. Advanced adenoma was diagnosed by colonoscopy during comprehensive medical check-ups, and single-nucleotide polymorphisms (SNPs) related to advanced adenoma were detected with the Affymetrix Axiom™ KORV1.1-96 Array. In total, 6 SNPs were identified in three SNP aggregates in the test set ( $P < 10^{-3}$ , within 200 kb) after adjusting for age and sex. All the SNPs were replicated in the replication set ( $P < 0.05$ ). Two SNPs were near the *SPC25* gene, two SNPs were near the *LOC285762* gene, and two SNPs were near the *NPY* gene. The top SNP associated with colorectal advanced adenoma was rs78127544, located near the *LOC285762* gene [combined set, P-value =  $1.809 \times 10^{-4}$ , odds ratio = 1.556 (95% confidence interval: 1.235-1.961)]. We found 6 novel SNP alleles associated with advanced adenoma that implicated three gene loci, the *SPC25*, *LOC285762*, and *NPY* gene, as being involved in the underlying genetic susceptibility to colorectal advanced adenoma. Our results could provide new genetic insights into the development of advanced adenoma in Asian populations.

**Chromosome 10q24.32 variant increases risk of non-melanoma skin cancer and Bowen's disease in arsenic exposed population.** M.G. Kibriya<sup>1</sup>, F. Jasmine<sup>1</sup>, B.L. Pierce<sup>1</sup>, M. Argos<sup>2</sup>, M.T. Islam<sup>3</sup>, M. Rakibuz-Zaman<sup>3</sup>, A. Ahmed<sup>3</sup>, H. Shahriar<sup>3</sup>, T. Islam<sup>3</sup>, J. Graziano<sup>4</sup>, C.R. Shea<sup>5</sup>, M. Kamal<sup>6</sup>, H. Ahsan<sup>7,8</sup>. 1) Public Health Sciences, University of Chicago, Chicago, IL, USA; 2) Division of Epidemiology and Biostatistics, School of Public Health, University of Illinois, Chicago, IL, USA; 3) University of Chicago Research Bangladesh, Dhaka, Bangladesh; 4) Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University, New York, USA; 5) Department of Dermatology, University of Chicago, IL, USA; 6) Department of Pathology, Bangabandhu Sheikh Mujib Medical University (BSMMU), Dhaka, Bangladesh; 7) Cancer Research Center, University of Chicago, Chicago, IL, USA; 8) Institute of Population and Precision Health, Biological Sciences Division, University of Chicago, Chicago, IL, USA.

**Background:** Non-melanoma skin cancers (NMSC) are the most prevalent malignancy in the US, with an estimated 2 million new diagnoses each year. NMSC includes basal cell carcinoma (BCC) and squamous cell carcinoma (SCC). Bowen's disease (BD) is actually squamous cell carcinoma in-situ. While ultraviolet (UV) light exposure and skin sensitivity are known risk factors for NMSC especially in Caucasians, arsenic (As) exposure through contaminated drinking water or diet may be a risk factor in some populations. Arsenical skin lesion (ASL) is a hallmark of As toxicity. From population-based genome-wide investigations in As exposed individuals, we previously identified six SNPs in chr10q24.32 region (rs1046778, rs11191527, rs11191659, rs4290163, rs4919694 and rs9527) associated with ASL and As metabolism. We also identified a number of CNVs in germline DNA predisposing individuals to develop ASL. In this study, we prospectively examine if those genomic markers are associated with NMSC and BD in As-exposed Bangladeshi population. **Material:** From a large and long-term (96 months) prospectively followed-up cohort, we randomly selected 2171 subjects (m=1032, f=1139) at enrollment and genotyped their whole blood DNA samples at baseline on Illumina SNP chips to generate DNA copy number. We previously reported the SNPs and CNVs that were associated with ASL in this study population. Participants were followed up every 2 years for a total of 8 years, especially for the development of NMSC and BD. Among these subjects, the clinically suspected NMSC were subjected to skin biopsy. Cases were defined as BD, SCC or BCC. **Result:** Out of the 2171 subjects, a total of 416 (M=301, F=115) developed ASL during follow-up and 70 of them (M=37, F=33) were biopsied for suspected BD or NMSC. Histopathology showed that 31 had BD, 2 had SCC and 14 had BCC. Keratosis with dysplasia was seen in 16 and the rest 7 had other dermatological lesions. Individuals with variant allele for SNP rs11191659 near the gene *AS3MT* showed significant association with NMSC and BD cases combined (OR 2.45, 95%CI 1.13 – 5.33). This association remained unchanged (OR 2.44, 95%CI 1.12 – 5.33) even after adjustment for age, gender, and baseline arsenic exposure. None of the other five 10q24.32 SNPs, and none of the CNVs previously showing associations with ASL showed association with NMSC. **Conclusion:** Genomic variation in chromosome 10q24.32 region may have association with NMSC risk in a Bangladeshi population.

**Small RNA sequencing of 441 normal prostate transcriptomes reveals prostate cancer risk-SNP eQTL associations with miRNA expression.** N.B. Larson, S.K. McDonnell, S. Riska, Z. Fogarty, Y. Liu, S. Baheti, M.S. DeRycke, L.S. Tillmans, D.J. Schaid, S.N. Thibodeau. Mayo Clinic College of Medicine and Science, Rochester, MN.

Large genome-wide association studies have to date identified 284 single-nucleotide polymorphisms (SNPs) associated with increased risk of prostate cancer (PRCA). Many of the identified variants are located in intergenic regions of the genome and presumed to be regulatory in nature. Expression quantitative trait loci (eQTL) analyses have been successful in linking PRCA risk SNPs to genes through evidence of transcriptional dysregulation, and prostate-specific eQTL studies have begun to unravel connections between PRCA risk SNPs and protein-coding mRNAs. However, less work has been directed toward non-coding RNAs, including miRNAs. Recent evidence demonstrates that pri-miRNA transcripts are susceptible to the same cis-acting regulatory effects as other long RNAs, and PRCA risk SNPs may confer systemic impacts on the prostate transcriptome through miRNA expression dysregulation. In this study, we performed small RNA sequencing on a large set of normal prostate tissue samples with available genome-wide genotyping and RNA-Seq expression data to investigate the role of miRNAs in the genetic risk of PRCA. Sequencing was performed on an Illumina HiSeq 4000 instrument using NEBNext® Multiplex Small RNA Library Prep Kit with sample multiplexing at up to 48 samples per lane. Sequencing results were processed using the CAP-miRSeq miRNA workflow and trimmed mean of M (TMM) normalization, identifying 605 expressed mature miRNAs ( $\geq 5$  reads in  $>25\%$  of samples) across 441 samples that passed quality control. We then performed a systematic cis-eQTL association study focused on PRCA risk genetics by testing all SNPs in high LD ( $r^2 \geq 0.5$ ) with PRCA risk SNPs, consisting of 5264 total tests (2608 unique SNPs and 82 unique miRNAs). Under a gene-based significance threshold of  $FDR < 0.05$ , we identified two significant cis-eQTL associations: rs1058319 with the miR-941 family ( $P = 4.6E-09$ ,  $B = -0.187$ ) on chromosome 20, and single-base deletion chr10:104317808:1\_CA with mir-1307-3p ( $P = 1.6E-05$ ,  $B = 0.105$ ). Follow-up analysis of transcriptome-wide protein-coding trans-eQTL results for rs1058319 also indicated significant differences in effect estimates between miR-941 target and non-target genes (Wilcoxon  $P = 0.0057$ ) based on TargetScan, with results consistent with the expression silencing mechanism of miRNAs. Future studies aim to further integrate small- and long-RNA expression datasets to better elucidate the complex transcriptomic dysregulation associated with PRCA genetics.

**Novel pathogenic variants for high-risk breast cancer identified from whole exome sequences of Korean BRCAX cases.** J.-Y. Lee<sup>1</sup>, J. Kim<sup>2</sup>, J.W. Lee<sup>2</sup>, S.W. Kim<sup>2</sup>, J. Sung<sup>1</sup>. 1) Seoul National University Graduate School of Public Health, Seoul, Korea, Republic of; 2) Asan Medical Center, Seoul, Korea, Republic of; 3) Daerim St. Mary's Hospital, Seoul, Korea, Republic of.

**Introduction** Genome-wide association studies (GWAS) of BRCAX cases (high-risk cases without pathogenic mutation on *BRCA1/2*) have found several novel candidate loci associated with breast cancer. Common markers identified from GWASs have inborn limitations in that they have limited impacts and the markers are not likely the causative variants. In this study, we aimed to find rare variants associated with BRCAX using whole exome sequencing (WES) data of high-risk breast cancer cases in Korea. **Materials and Methods** We included 172 high-risk breast cancer cases without pathogenic mutation on *BRCA1/2*—early onset ( $<40$ ), with strong family history, with past medical history of other cancer, or bilateral cases from the Korean Hereditary Breast Cancer (KOHBRA) study. A WES analysis was performed with Nextera Rapid Capture Exome and Expanded Exome Kit. WES data were processed using BWA, Picard, and GATK, according to GATK Best Practices. We scanned through all exonic regions and prioritized variants with Variant Effect Predictor (VEP). First, we excluded common variants (minor allele frequency  $>0.1\%$  in the 1KG, ExAC, or gnomAD) and benign variants predicted by SIFT, PolyPhen2, and CADD ( $<15$ ). Then, variants predicted to be involved in protein truncation were retained. Finally, the frequencies of these variants were compared to the Korean Reference Genome ( $N=397$ ). Using all these information, pathogenic or likely pathogenic variants defined by the ACMG guideline were investigated. **Results** For 172 BRCAX cases, 295K variants (on average, 1.7K variants per individual) were called and the mean depth was 42. After filtering common or benign variants, 896 markers with high impact remained and 121 of them were damaging according to multiple prediction tools. We classified 32 variants as likely pathogenic, as they were absent or extremely rare in public databases (PM2) or in control data (PS4), predicted to be deleterious by multiple tools (PP3), and located in mutational hotspot (PM1). Several identified genes were reported from the GWAS or suggested for panel sequencing for breast cancer. Two novel truncating variants located on *PANK4* and *ERCC5* were identified as heterozygous mutations from four and two cases, respectively. **Discussion** We identified novel pathogenic variants, by examining the WES data of BRCAX cases. We suggest two candidate genes associated with high-risk breast cancer, which could be used for screening after validation with larger samples and functional assays.

## 709T

**Identifying candidate genes associated with breast cancer predisposition in *BRCA1/2* mutation-negative individuals.** A.S.G. Lee<sup>1,2,3</sup>, P. Munusamy<sup>1</sup>, G.L. Koh<sup>1</sup>, C.H.T. Chan<sup>1</sup>, E.S.Y. Wong<sup>1</sup>, S.Y. Loke<sup>1</sup>, W.K. Lim<sup>4</sup>, J.X. Teo<sup>5</sup>, M.H. Tan<sup>5,6,7</sup>, Y.S. Yap<sup>8</sup>, P. Ang<sup>8</sup>. 1) Division of Cellular and Molecular Research, National Cancer Centre Singapore, Singapore; 2) Department of Physiology, Yong Loo Lin School of Medicine, National University of Singapore, Singapore; 3) Office of Clinical & Academic Faculty Affairs, Duke-NUS Medical School, Singapore; 4) SingHealth Duke-NUS Institute of Precision Medicine, Singapore; 5) Department of Medical Oncology, National Cancer Centre Singapore, Singapore; 6) Institute of Bioengineering and Nanotechnology, Singapore; 7) Lucence Diagnostics Pte Ltd, Singapore; 8) Oncocare Cancer Centre, Gleneagles Medical Centre, Singapore.

**Purpose:** Hereditary breast and/or ovarian cancer (HBOC) is a cancer predisposition syndrome, associated with mutations in *BRCA1/2* or other genes at a lower frequency. However, mutations are not detected in many high-risk individuals who have undergone multigene panel testing, suggesting that additional genes remain to be discovered. This study aimed to identify novel genes associated with breast cancer (BC) predisposition. **Methods:** Targeted next-generation sequencing for 283 cancer-associated genes, including 25 known or proposed BC susceptibility genes (25-genes) was performed on 239 individuals eligible for *BRCA1/2* genetic testing recruited at the National Cancer Centre, Singapore. Using extensive bioinformatics analysis, we applied multiple variant prioritization approaches to identify likely candidate genes. Case-control association analysis of candidate genes was done using East-Asian controls from the Exome Aggregation Consortium (ExAC). **Results:** Of the 239 subjects, 149 tested negative for 25-genes. From our in-depth analysis of these subjects, likely pathogenic variants in *DDR2* (2.68%), *EMSY* (4.7%), *APC* (6.71%), *AKT3* (2.01%) and *ARAF* (2.01%) were identified. Importantly, subjects who tested positive for the 25-genes did not harbor variants in these five genes. Association analysis revealed significant associations of these five genes with BC susceptibility at  $P < 0.05$ , with odds ratios ranging from 2.37 to 7.92. **Conclusion:** We report pathogenic or likely pathogenic variants in *DDR2*, *EMSY*, *APC*, *AKT3* and *ARAF* in *BRCA1/2* mutation-negative cases. Further studies on additional populations and larger cohorts, as well as segregation and functional studies are warranted.

## 710F

**Cervical cancer in Guatemala: Somatic mutations and molecular analyses of the HPV16 D2 and D3 sub-lineages.** H. Lou<sup>1</sup>, J. Boland<sup>1</sup>, E. Gonzalez<sup>2</sup>, A. Albanez<sup>3</sup>, W. Zhou<sup>1</sup>, M. Steinberg<sup>1</sup>, L. Diaw<sup>2</sup>, D. Roberson<sup>1</sup>, M. Cullen<sup>1</sup>, L. Garland<sup>1</sup>, F. Pinto<sup>3</sup>, S. Bass<sup>1</sup>, R. Burk<sup>3</sup>, M. Yeager<sup>1</sup>, N. Wentzensen<sup>4</sup>, M. Schiffman<sup>4</sup>, L. Mirabello<sup>4</sup>, E. Gharzouzi<sup>5</sup>, M. Dean<sup>2</sup>. 1) NCI-Leidos Biomedical Research Inc., Gaithersburg, MD; 2) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, Leidos Biomedical Research, Inc., National Laboratory for Cancer Research, Gaithersburg, MD; 3) Instituto de Cancerologia, Guatemala City, Guatemala; 4) Laboratory of Cancer Genetics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Gaithersburg, MD USA; 5) Albert Einstein College of Medicine, Bronx, NY.

Cervical cancer (CC) is the most frequent cause of cancer mortality for women living in poverty, and is almost exclusively caused by human papilloma virus (HPV). We have surveyed 665 cases of cervical cancer from Guatemala. The average age is 52 (mean 51), average number of children is 6.0 (mean 5.0), 5.6% report tobacco use; 56% have stage 2 or 3 cancer and 82% of tumors are squamous cell carcinoma. In total 20% of subjects report a family history of any cancer and 6% for CC. Patients with a family history of CC have a younger age of onset (47 years), and were pre-menopausal cancer (57% versus 42% in the entire sample). While tobacco use is low, a high percentage (73%) cook at home with wood, and therefore are exposed to airborne carcinogens. To further understand the somatic mutations, we sequenced 24 tumor DNA samples for 245 cancer-related genes. In total, 11/24 tumors had a mutation in the *PIK3CA* gene (46%) and 58% of tumors had at least one mutation in the PI3K pathway. Other known driver mutations included *TP53*, *RB1*, and *CAPS8*. Mutations in chromatin remodeling genes (*PBRM1*, *EP300*, *SMARCA4*, *KMT2C*, *KMT2D*, *HIST1H3B*, *HIST1H4E*, *HIST1H1E*) were also elevated with 46% of tumors having at least one mutation. Tumors had an average of 18 mutations (median 14), however 4 tumors had high (32-38 mutations) or very high (63-64) mutation load. All hypermutation subjects have *PIK3CA* mutations and are post-menopausal. Mutation signature analysis showed that the highest signature is APOBEC-related mutations (46%) and HPV is known to activate APOBEC. Pre-menopausal patients had a lower mutation load (13 mutations) and a lower fraction of APOBEC-related mutations (40%). Overall, HPV16 accounts for 58% of HPV infections in Guatemala. We have sequenced and variant classified 96 HPV16 + CC and found that the D2 and D3 sub-lineages represented 26% and 29% of the samples, respectively. A total of 65% (62/96) of the samples had integrated HPV16 sequences as determined by HPV DNA Capture on NimbleGen Array and A1 and D2 sub-lineages showed a higher frequency of integration compared to D3. Subjects with HPV16 integration have a significantly younger age, and D2 was observed in younger patients, as compared to A1. In conclusion, Guatemalan cervical tumors have a similar profile of somatic mutations to those in the US, with a high frequency of *PIK3CA* mutations, and a high frequency of the very high-risk HPV16 D2, D3 sub-lineages.

## 711W

**Evaluate a new panel of SNPs to predisposition of development of thyroid cancer in admixture population.** A.D. Luchessi<sup>1</sup>, I.C.C. Santos<sup>1</sup>, J. Genre<sup>2</sup>, D.C.S. Marques<sup>3</sup>, A.M.G. Silva<sup>3</sup>, J.C. Santos<sup>3</sup>, J.N.G. Araujo<sup>3</sup>, V.H.R. Duarte<sup>3</sup>, A.M.A. Carracedo<sup>3</sup>, M. Torres<sup>3</sup>, G.M. Bastos<sup>3</sup>, C.C.F. Ramos<sup>3</sup>, V.N. Silbier<sup>4</sup>. 1) Federal University of Rio Grande do Norte, Natal, Rio Grande do Norte / Natal, Brazil; 2) Department of Clinical and Toxicological Analysis, Federal University of Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil; 3) Centro Nacional de Genotipagem, Santiago de Compostela, La Coruña, Spain; 4) Department of Clinical Analysis and Toxicology of São Paulo University, São Paulo, SP, Brazil; 4) Liga Norte Riograndense Contra o Câncer, Rio Grande do Norte, RN, Brazil.

Thyroid cancer (TC) is the most common endocrine tumor. Genetic predisposition to this cancer might be associated with multiple penetrance genes that interact with each other and with the environment. Genetic variation are becoming useful biomarkers for diagnosis and risk stratification, and as potential treatment targets for aggressive forms of tumor. However, there is limit study of genetic predisposition to TC performed in the admixture population. In this way, the present project aims to evaluate the genetic predisposition of admixture population in Brazil to develop the TC. To this purpose, 580 sample were select, 279 paraffin blocks of the thyroid gland adjacent to the tumor from bank of the LNRCC Pathology Laboratory to compose the study group, and venous blood from 301 health donors from Hemovida Blood Bank as a control group. Genomic DNA from the paraffin blocks and blood samples were extracted and the Genotyping of a panel of 84 SNPs was performed using the MassaiRA<sup>®</sup> iPLEX Gold Mass Spectrometer MALDI-TOF Sequenom<sup>®</sup>. Thirty-six SNPs showed significant differences in their allelic frequencies when compared to cases and controls. Of these, 23 SNPs were associated with the risk of developing CT, mainly variants rs2997312 (OR = 6.33, IC95%: 1.80-22.29, P= 0.00085), rs116909374 (OR = 3.40, IC95%: 1.57-7.40, P= 0.00093), rs7024345 (OR = 2.97, IC95%: 1.05-8.46, P= 0.03032), rs965513 (OR = 2.91, IC95%: 1.62-5.24, P= 0.00020), and rs10788123 (OR = 2.78, IC95%: 1.60-4.82, P= 0.00016), since they confer greater risk to patients. In addition, 13 SNPs were presented as a protective factor for the non-development of this neoplasia, between them rs2651339 (OR= 0.48, IC95%: 0.34-0.69, P= 0.00005), rs34566348 (OR= 0.51, IC95%: 0.34-0.78, P= 0.00148), rs664677 (OR= 0.56, IC95%: 0.40-0.80, P= 0.00135), rs1801516 (OR= 0.57, IC95%: 0.37-0.87, P= 0.00802) and rs13447450 (OR= 0.57, IC95%: 0.40-0.82, P= 0.00186). Thus, we suggest a panel of SNPs that may represent biomarkers of predisposition or protection in the development of CT in brazilian admixture populations.

## 712T

**Characteristics of potentially actionable germline findings identified on tumor-only sequencing: Implications for cancer risk assessment.** K.N. Maxwell, D. Farengo-Clark, J. Powers, D.B. Lieberman, S.M. Domchek, J.J.D. Morrisette, K.L. Nathanson. University of Pennsylvania, Philadelphia, PA.

**Background:** Next-generation sequencing for tumor DNA profiling (tNGS) is increasingly advocated for all cancer patients given potential therapeutic indications. It is critical to understand possible incidental germline findings that may be revealed by tNGS, given the clinical implications for the patient and family. **Methods:** tNGS clinical reports with potentially actionable pathogenic germline variants (PV) were identified by a novel pipeline implemented at the University of Pennsylvania in 2016, with details described separately (Clark et al). Characteristics associated with the tumors and PVs were analyzed.

**Results:** Forty-eight patients identified by the tNGS pipeline from 2016-2018 underwent confirmatory germline testing, and 28/48 (58%) had mutations that confirmed to be germline. Patients were most commonly referred for PVs in *BRCA2* (n=14), followed by *TP53* (n=6), Lynch genes (n=6), *BRCA1* (n=4), *CHEK2* (n=4), *PALB2* (n=4), and *CDH1* (n=3), with germline confirmation rates ranging from 33-79%. Patients with confirmed germline mutations (GPV) were similar in age to patients with somatic-only mutations (SPV) (average 56±13 vs 54±15, p=0.72). The tumor allele frequency (AF) of GPV was modestly higher than SPV (54±16% vs 40±25%, p=0.04); however, the range of AF overlapped in both groups: GPV, 11-86% versus SPV, 2-79%. 46% of GPV and 80% of SPV were found in tumors known to be associated with mutations in that gene. In tumors with estimated tumor purity over 25% (16 of 28 tumors) probable loss of heterozygosity (LOH) was inferred in patients with GPV. LOH was suggested in six of nine (67%) of tumors known to be part of the phenotypic spectrum of the germline finding, but in only one of seven (14%) of tumors outside this group (p=0.06). For example, in confirmed germline *BRCA2* carriers, LOH was suggested by SPV AF>65% in two of three pancreatic cancers, one breast, and one of two prostate cancers. However, two glioblastomas, one cholangiocarcinoma and one colon cancer with confirmed GPV in *BRCA1* or *BRCA2* had the corresponding SPV AF<55%. **Conclusions:** Tumor variant AF, probable LOH, patient age, and personal cancer history are not sufficient to identify all potentially actionable germline findings from tNGS. Highly integrated pathways between genetic testing laboratories, oncologists, and cancer risk genetics professionals are needed to adequately triage potentially actionable germline findings that may be revealed by tumor-only genomic profiling.

**713F**

**eQTL and co-expression network analyses uncover genetic and regulatory mechanisms underlying multiple myeloma.** *H.M. Natrj<sup>1,2</sup>, M. Wilson Sayres<sup>1</sup>, K. Buetow<sup>1</sup>, J. Keats<sup>2</sup>, N. Banovich<sup>2</sup>.* 1) Center for Evolution and Medicine, Arizona State University, Tempe, AZ; 2) Translational Genomics Research Institute, Phoenix, AZ.

Multiple myeloma (MM) is the second most common hematological cancer, accounting for 2% of all cancer deaths. MM remains incurable and nearly all patients experience relapse. To this end, The Multiple Myeloma Research Foundation developed the CoMMpass study. CoMMpass is a longitudinal clinical trial aimed at accelerating the discovery of more targeted treatments for MM. Each of the 1147 newly-diagnosed participants receives a proteasome inhibitor and/or immunomodulatory agent treatment regimen. Clinical parameters and tumor specimens are collected at baseline and through the eight-year observation period. To identify genetic determinants of clinical outcomes, each tumor specimen is characterized by Whole Genome, Exome and Transcriptome sequencing. This work has uncovered a number of somatic mutations and copy number alterations associated with tumor progression and response to therapy as well as a novel classification of MM into 12 distinct subtypes based on gene expression. However, the contribution of germline genetic variation to gene expression changes and clinical phenotypes remains poorly understood. Genome-wide association studies have identified germline variants associated with MM risk, indicating inherited genetic susceptibility. Men are in a higher risk to develop MM than women, and previous studies have reported loss of X or Y chromosomes in up to 40% of MM cases. To better understand the genetic and biological basis of MM predisposition, we utilize a systems genomics approach to examine inherited genetic effects on gene expression and MM subtypes. Data from 616 CoMMpass participants with available low coverage WGS of normal blood samples and RNAseq of baseline tumor specimens were used to map *cis*- and *trans*-acting eQTLs. Modules of co-expressed genes were constructed using a weighted correlation network analysis. Associations between eVariants and MM tumor subtypes were explored to detect genetic effects on gene expression and MM etiology. We have constructed a global transcriptional network connecting coding and regulatory germline variants to clinical phenotypes through regulation of gene expression, providing a comprehensive picture of genetic and regulatory mechanisms underlying MM susceptibility. These and further analyses integrating germline and somatic variants, gene expression, and clinical outcomes will support the development of personalized medicine approaches for better treatment of MM.

**Evaluation of a 94-gene inherited cancer panel across 248 families referred for testing to a reference molecular diagnostic laboratory.** *H. Onay<sup>1</sup>, A.E. Solmaz<sup>1</sup>, L. Yeniyay<sup>2</sup>, E. Gokmen<sup>3</sup>, T. Atik<sup>4</sup>, F. Ozkinay<sup>1,4</sup>.* 1) Medical Genetics Dept, Ege University, Izmir, Turkey; 2) General Surgery Dept, Ege University, Izmir, Turkey; 3) Internal Medicine Dept, Ege University, Izmir, Turkey; 4) Pediatrics Dept, Ege University, Izmir, Turkey.

Cancer is one of the major health problems worldwide with a high rate of morbidity and mortality. Hereditary cancer syndromes, which show extensive clinical and genetic heterogeneity, account for approximately 5–10% of all cancer. Recently, next-generation sequencing genetic testing panels have become clinically available for hereditary cancer, helping to identify genetic etiology more efficiently. This study reports the experience of a reference molecular genetic center which used 94-gene inherited cancer panel on a selected group of 248 families with cancer or cancer susceptible diseases. **METHODS** Two hundred and forty eight families tested for cancer susceptibility genes were selected by experienced clinicians who were able to interpret the genetic counseling data in accordance with the latest literature. Illumina Trusight Cancer panel (including 94 cancer genes) was used as Multi-gene sequencing panel on the Illumina MiSeq platform. Genetic variations were identified using Illumina Variant Studio software and interpreted using the *in silico* prediction tools, such as: SIFT, PolyPhen Mutation Taster. **RESULTS** In 99 (39.9%) of 248 patients tested a mutation were detected in one of the cancer genes included in the panel. Of these, 106 were *BRCA1/2* mutation negative breast cancer patients. Among these 106 patients, 30 (28.3%) carried 31 different mutations in 14 different panel genes. Of the 28 colon cancer patients 22(75%) and of the 6 stomach cancer patients 3 (50%) found to have a mutation in 1 one of 95 genes investigated. In the study twenty six patients were referred for Fanconi molecular analysis and responsible mutations were defined in 16 (61.5%) of them. In 21 patients, the clinical diagnosis was neurofibromatosis and 16 (76.1%) of them had mutations in *NF1* gene. Four (57.1%) of 7 patients analyzed for tuberous sclerosis had a mutation in either *TSC1* or *TSC2* gene. Molecular defects were also detected in two patients with Gorlin syndrome, 1 over cancer patient, 1 GIST patient, 1 retinoblastoma patient, 1 Werner syndrome patient, 1 Bloom syndrome patient and 1 ataxi telangiectasia patient. **CONCLUSION** As a conclusion using 94 cancer gene panel (Trusight Cancer panel by Illumina), molecular diagnosis can be achieved in considerable number of families with inherited cancer or cancer susceptible diseases.

Perturbations of the coding genome and their role in cancer development have been studied extensively. However, the non-coding genome's contribution in cancer is poorly understood, because it is difficult to define the non-coding regulatory regions and the genes they regulate, and because there is limited power owing to the regulatory regions' small size. We try to resolve this by defining modules of coordinated non-coding regulatory regions of genes (Cis Regulatory Domains or CRDs) by using the correlation between histone modifications, assayed by ChIP-seq, in population samples of immortalized B-cells and skin fibroblasts. We screen for CRDs that accumulate an excess of somatic mutations in chronic lymphocytic leukaemia (CLL) and skin cancer, after accounting for somatic mutational patterns and biases. At 5% FDR, we find 90 CRDs with significant excess somatic of mutations in CLL, 60 of which regulate 126 genes, and in skin cancer 59 significant CRDs, 25 of which regulate 37 genes. The genes identified include ones already implicated in tumorigenesis, and are enriched in pathways involved in the respective cancers, like the BCR signalling pathway in CLL and the TGF $\beta$  signalling pathway in skin cancer. We discover that the somatic mutations in the significant CRDs of CLL are hitting bases more likely to be functional than the mutations in non-significant CRDs. Moreover, in both cancers, mutational signatures observed in the regulatory regions of significant CRDs deviate significantly from their null sequences. Both results indicate selection acting on CRDs during tumorigenesis. We find that the transcription factor binding sites that are disturbed by the somatic mutations in significant CRDs are enriched for factors known to be involved in cancer development. Previously we detected genes with putative somatic regulatory drivers in colorectal cancer using perturbations in allele specific expression (Ongen et. al. Nature 2014). We are therefore currently testing the effect of mutations in the CRDs on the expression and the allelic expression of the genes implicated to further confirm their driver potential. Finally, we are conducting cell culture experiments to show the driver potential of the genes identified. This study describes a new powerful approach to discover non-coding regions involved in tumorigenesis in CLL and skin cancer and this approach could be generalized to other cancers.

Lack of effective targeted therapies make parathyroid carcinoma (PC), a rare and diagnostically challenging malignancy, difficult to combat. Typically, if the cancer is not cured by early surgery, elevated parathyroid hormone levels can lead to severe hypercalcemia and ultimately fatal end-organ damage. As the molecular mechanisms of oncogenesis in PC are poorly understood, we established an international collaboration to gain further insights that could lead to improved clinical outcomes. Initial findings on genomic profiles of 24 PC cases from these collective efforts confirmed the importance of driver mutations in *CDC73* (the only established tumor suppressor in PC) and identified several putative drivers and aberrant pathways (Pandya et al., JCI Insight 2017; 2:e92061). To pursue these findings with additional power, we have now expanded our cohort of collected tumor (primary, local recurrence, or metastatic) and normal DNA samples to 73 patients with sporadic PC fulfilling stringent selection by WHO criteria. We used a PC-informed, custom Ion AmpliSeq 16-gene targeted panel to generate DNA sequence data for identifying somatic and germline genetic alterations. We observed 47 samples harboring  $\geq 1$  variant and 24 samples with no variant, corroborating previous findings of a moderate tumor mutation burden in PC. Consistent with earlier studies, we found 41% (30/73) of the patients to harbor loss-of-function (LOF) somatic *CDC73* mutations, with germline inactivating variants in 4 patients. Notably, the PI3K/AKT/mTOR pathway was altered in 12.3% of the 73 cases with known oncogenic hotspots in *PIK3CA* (p. K111E, p.E545K/A & p. H1047R), primarily in tumors without *CDC73* mutations, thereby reinforcing our published novel finding and consideration of this as a clinically actionable pathway in PC. Correlating the genomic and clinical features revealed that patients harboring a *CDC73* LOF mutation tend to have early-onset PC (P-value=0.0002; odds-ratio=7.4; adjusted P-value=0.003) and are likely to suffer from life threatening recurrent/metastatic PC (P-value=0.02; odds-ratio=4.2; adjusted P-value=0.29). Our study, which is the largest cohort of PC samples analyzed at a molecular level to date, facilitates improved understanding of the genomic underpinnings of this rare malignancy and helps to provide a rational basis for individualized treatments.

## 717W

**Segmental odonto-maxillary dysplasia: A mosaic disorder due to missense mutations in *ACTB*.** S. Polubothu<sup>1,2</sup>, A. Thomas<sup>1</sup>, R. Evans<sup>3</sup>, A. Calder<sup>4</sup>, V.A. Kinsler<sup>1,2</sup>. 1) Genetics and Genomic Medicine, University College London Institute of Child Health, London, London, United Kingdom; 2) Paediatric Dermatology, Great Ormond St Hospital for Children, London; 3) Maxillofacial Surgery, Great Ormond St Hospital for Children, London; 4) Paediatric Radiology, Great Ormond St Hospital for Children, London.

Segmental odontomaxillary dysplasia (SOD) is a rare sporadic disorder of unknown aetiology presenting at birth or in childhood with unilateral abnormal maxillary development. This condition is well-known to maxillo-facial and dental specialists, but less well known in other specialties. Affected individuals usually present with colocalised abnormalities such as facial asymmetry, progressive hypertrichosis, increased or decreased pigmentation or erythema, dental anomalies and commissural lip fissures. Here we present detailed phenotypic, histological and radiological data from a cohort of eight patients, and investigate the likely mosaic basis of the disorder in three. Sequencing of DNA extracted directly from paired samples of affected skin and blood demonstrated missense variants in the gene encoding beta-actin (*ACTB*) at mosaic levels in affected tissue but undetectable in blood in all three. Germline GOF and LOF *ACTB* variants cause two distinct inherited disorders, and mosaic *ACTB* variants have previously been identified as the cause of a proportion of Becker's naevi. The exact mechanism of beta-actin action however are not clear. These findings uncover the cause of SOD, and suggest that beta-actin may be intrinsically involved in cross-talk between different colocalised embryonic tissues, as a single cell mutation during embryogenesis could not otherwise explain bony, soft tissue, and skin pathology. In addition, this finding highlights this clinical diagnosis to Clinical Geneticists and Paediatric Dermatologists, where we estimate the disorder is poorly recognised given the frequency in our department.

## 718T

**Whole-exome sequencing identified mutational profiles of squamous cell carcinomas of anus.** S. Shin<sup>1,2</sup>, H-C. Park<sup>1,2</sup>, M.S. Kim<sup>3,4</sup>, S.H. Jung<sup>2,3</sup>, Y-J. Chung<sup>1,2,3</sup>, S.H. Lee<sup>3,4</sup>. 1) Department of Microbiology, The Catholic University of Korea, Seoul, Republic of Korea; 2) Integrated Research Center for Genome Polymorphism, The Catholic University of Korea, Seoul, Republic of Korea; 3) Cancer Evolution Research Center, The Catholic University of Korea, Seoul, Republic of Korea; 4) Department of Pathology, The Catholic University of Korea, Seoul, Republic of Korea.

Anal squamous cell carcinoma (ASCC), either with human papillomavirus (HPV) (+) or (-), is a neoplastic disease with frequent recurrence and metastasis. To characterize ASCC genomes, we attempted to disclose novel alterations of ASCC genomes as well as other genetic features including mutation signatures. We performed whole-exome sequencing and copy number alteration (CNA) profiling for 8 ASCC samples from 6 patients (2 cases with primary and recurrent/metastatic tumors). We found known ASCC mutations (*TP53*, *CDKN2A* and *PIK3CA*) and CNAs (gains on 3q and 19q and losses on 11q and 13q). In addition, we discovered novel mutations in *HRAS* and *ARID1A* and CNAs (gain on 8q and losses 5q, 9p, 10q and 19p) that had not been reported in ASCCs. We identified 4 signature patterns of the mutations (signatures 1 and 2 with deamination of 5-methyl-cytosin, signature 3 with APOBEC and signature 4 with mismatch repair) in the ASCCs. While the signatures 1-3 have been detected in other SCCs, the signature 4 was first identified in ASCCs. In addition, we first found that ASCCs harbored chromothripsis, copy-neutral losses of heterozygosity and focal amplification of *KLF5* super-enhancer. Analyses of primary and recurrent/metastatic pair genomes revealed that driver events in development and progression of ASCC might not be uniform. Our data indicate that ASCCs may have similar mutation and CNA profiles to other SCCs, but that there are unique genomic features of ASCCs as well. Our data may provide useful information for ASCC pathogenesis as well as for developing clinical strategies for ASCC.

## 719F

**Whole exome sequencing to identify genetic markers for trastuzumab-induced cardiotoxicity.** C. Udagawa<sup>1,2,3</sup>, H. Nakamura<sup>4</sup>, K. Tamura<sup>5</sup>, T. Shimo<sup>6</sup>, M. Yoshida<sup>6</sup>, T. Yoshida<sup>7</sup>, H. Okamura<sup>3</sup>, Y. Totoki<sup>4</sup>, T. Shibata<sup>4</sup>, H. Zembutsu<sup>1,2</sup>.

1) Liquid Biopsy Development Group, Cancer Precision Medicine Center, Japanese Foundation for Cancer Research, Tokyo, Japan; 2) Division of Genetics, National Cancer Center Research Institute, Tokyo, Japan; 3) Toyo Kohan Co., Ltd., Tokyo, Japan; 4) Division of Cancer Genomics, National Cancer Center Research Institute, Tokyo, Japan; 5) Department of Breast and Medical Oncology, National Cancer Center Hospital, Tokyo, Japan; 6) Department of Pathology and Clinical Laboratories, National Cancer Center Hospital, Tokyo, Japan; 7) Fundamental Innovative Oncology Core, National Cancer Center Research Institute, Tokyo, Japan.

Trastuzumab is used for the treatment in human epidermal growth factor receptor 2 (HER2) positive breast or gastric cancer patients. However, it is reported in many studies that approximately 5% of the patients treated with trastuzumab alone cause cardiac dysfunction. To identify a genetic marker(s) determining the risk of trastuzumab-induced cardiotoxicity, we performed whole exome sequencing of germline DNA samples from 9 patients with trastuzumab-induced cardiotoxicity, and conducted a case-control association study of 2,258 genetic variants between 9 cases (with trastuzumab-induced cardiotoxicity) and general Japanese population controls registered in Human Genetic Variation Database (HGVD). To further validate the result of the screening study, we carried out a replication study of 10 variants showing  $P_{\text{min}} < 0.001$  in the screening study using 10 cases and 224 controls (without trastuzumab-induced cardiotoxicity). In the replication study, we observed that three variants had effect in the same direction as in the screening study (SNV1 in exon 2 of *HERADR1*, SNV2 in exon 2 of *HERADR2* and SNV3 in exon 44 of *HERLC*). A combined result of the screening and the replication studies suggested an association of a locus on chromosome 6q12 with trastuzumab-induced cardiotoxicity (SNV3 in *HERLC*, combined- $P_{\text{min}} = 0.00056$ , OR = 13.73). *HERLC* protein have signal peptide, predicted cleavage site and multiple EGF-like domains. Moreover, *HERLC* is highly expressed in retina and pineal body according to the gene expression database. These lines of evidence suggest that *HERLC* is a secreted protein and might affect the efficiency of HER2 signal transduction as a ligand for HER2. Although further investigation is required to clarify the effect of *HERLC* on trastuzumab-induced cardiotoxicity, these findings provide new insights into personalized trastuzumab therapy.

## 720W

**Whole-exome case-control association to characterize the contribution of rare coding variants to sarcoma susceptibility.** Y. Yu, F. Hu, J. Chen, P. Scheet, C. Huff. UT MD Anderson Cancer Center, Houston, TX.

Genetic susceptibility has a well-established role in the etiology of sarcoma, but the contribution and effect size of rare genetic variants to sarcoma risk is underexplored. To evaluate the contribution of rare, protein-coding variation to sarcoma risk, we conducted a whole-exome case-control study of individuals with European ancestry involving 219 cases from the Cancer Genome Atlas (TCGA) and a population control set of 3,507 individuals from NDAR. We used XPAT to control for technological stratification biases from heterogeneous platforms. We then used VAAST 2.1 to conduct gene-based association tests for all samples and sub-groups of six soft-tissue sarcoma subtypes: leiomyosarcoma (LMS), dedifferentiated liposarcoma (DLPS), myxofibrosarcoma (MFS), undifferentiated pleomorphic sarcoma (UPS), malignant peripheral nerve sheath tumors (MPNST), and synovial sarcoma (SS). We observed nominally significant association signals for three well-established sarcoma susceptibility genes, *NF1* ( $p=1 \times 10^{-5}$ ), *TP53* ( $p=0.0025$ ), and *RB1* ( $p=0.028$ ). *MSH2*, an HNPCC gene, was also nominally significant ( $p=0.0085$ ); previous studies have suggested that sarcomas may be within the spectrum of HNPCC tumors. We also estimated the effect size estimates for variants in these. The likely-gene disrupting (LGD) variants in these genes exhibit large effect size to sarcoma relative to other cancer types. The ORs of *NF1* and *MSH2* LGD variants were 39.4 (95% CI: 7.1 – 219.3) and 33.0 (95% CI: 2.4 – 462.5), respectively. We observed predicted damaging missense variants with large effect sizes in *RB1* and *TP53* genes, which ORs were 12.0 (95% CI: 2.4 – 59.1) and  $\infty$  (95% CI: 6.7 –  $\infty$ ), respectively. In subtype-specific analyses, we found *NF1* was significantly associated with MPNST and LMS, *RB1* and *MSH2* were significantly associated with LMS, and *TP53* were significantly associated with UPS. Our results indicate that rare coding variants can confer substantial increases in risk for multiple soft-tissue sarcoma subtypes. In conclusion, our results confirm previously established sarcoma susceptibility loci and provide a foundation for future rare-variant association studies in sarcoma.

## 721T

**Integrating of multi-omics data for the prognostic assessment of breast cancer.** C. Yu<sup>1,2</sup>, Y. Jiang<sup>1,2</sup>, J. Dai<sup>1,2</sup>, H. Ma<sup>1,2</sup>. 1) Department of Epidemiology and Biostatistics, Nanjing Medical University, Nanjing, Jiangsu, China; 2) Jiangsu Key Lab of Cancer Biomarkers, Prevention and Treatment, Collaborative Innovation Center for Cancer Medicine, Nanjing Medical University, Nanjing, Jiangsu, China.

**Background:** Breast cancer is the most diagnosed cancer and the leading cause of cancer death among females, and both genetic variants and genes expression have been confirmed to be effective in the prediction of the prognosis of breast cancers. However, only partially breast cancer survival statuses can be explained, suggesting that integrating these factors may contribute the prediction of the prognosis of breast cancer. **Methods:** 810 samples from TCGA data sets are randomly divided into training set (540 subjects) and validation set (270 subjects). We first selected single nucleotide polymorphism (SNPs) and genes associated with breast cancer prognosis in the training set to construct the prognostic prediction model, and then replicated the prediction efficiency in the validation set. Cox proportional hazards models were performed to evaluate the prognostic effect of SNPs and genes. Prognostic index was calculated using HR (Hazard Ratio) weighted method. **Results:** We identified 4 SNPs and 3 genes that associated with the prognosis of breast cancers in the training set, and were incorporated into the prognostic model. The high-risk patients defined by the 4 SNPs and 3 genes signature-based prognostic index, had a statistically significantly worse overall survival (HR=9.43, 95% CI= 3.81 to 23.33,  $P < 0.001$ ), and the C statistics of ROC of the signature-based prognostic index was 0.79. In the validation set, patients in the high-risk group had a significantly worse overall survival (HR= 4.55, 95% CI= 1.50 to 13.88,  $P < 0.001$ ), and the C statistics of ROC of the signature-based prognostic index was 0.76. **Conclusions:** Our findings suggested that integrating multiple omics data could greatly increase the predictive performance of the prognosis of breast cancer survival. This strategy may be useful in identify poor prognosis risk populations for targeted cancer treatment.

## 722F

**Cancer-associated mutations in colorectal adenomatous polyps.** C. Zeng<sup>1</sup>, M.J. Shrubsole<sup>1</sup>, H.J. Murff<sup>1,2</sup>, Q. Cai<sup>1</sup>, Q. Liu<sup>3</sup>, Q. Sheng<sup>3</sup>, A. Madan<sup>1</sup>, R.J.C. Coffey<sup>1,2</sup>, W. Zheng<sup>1</sup>. 1) Department of Medicine, Division of Epidemiology, Vanderbilt Epidemiology, Vanderbilt University Medical Center, Nashville, TN; 2) Department of Veterans Affairs, Tennessee, Valley Healthcare System, Nashville, TN; 3) Center for Quantitative Science, Vanderbilt University, Nashville, TN; 4) Covance Genomics Lab, Redmond, WA.

**Background** Few studies examined the associations of somatic mutation profiles with histologic characteristics of sporadic colorectal adenomatous polyps and risk of adenoma recurrence. We evaluated these associations in a study including 200 patients with sporadic adenomas. **Methods** Study participants were recruited as part of the Tennessee Colorectal Polyp Study from patients who received a colonoscopy at the Vanderbilt University Medical Center and Tennessee Valley Healthcare System Nashville Campus. The 200 participants were selected from among those for whom formalin-fixed paraffin-embedded (FFPE) blocks were available for DNA extraction and had at least one subsequent surveillance colonoscopy. Among these participants, 100 of them had synchronous small (<1 cm) tubular adenomas and the remaining had at least one advanced adenoma ( $\geq 1$  cm or tubulovillous/villous or high-grade dysplasia) with or without the presence of synchronous adenoma. In addition, within each of these subgroups, 50 developed  $\geq 1$  metachronous adenoma and 50 had no future adenomas. For those with synchronous adenomas, the single adenoma that was sequenced was selected in the following order: most dysplastic, most villous, and largest in size. Targeted next generation sequencing for 728 genes was performed to detect somatic mutations in adenoma tissues obtained at the first diagnosis from these patients. We limited our analysis to potential colorectal cancer (CRC) driver genes (n=19) and potential driver mutations (n=65) proposed by previous studies in CRC. **Results** There were considerable inter-person variations in mutational profiles. No single mutation was statistically significantly associated with advanced features of adenomas or risk of recurrence ( $P > 0.01$ ). Patients with APC gene mutations were more likely to have advanced adenomas than those without APC mutations (odds ratio (OR) = 4.3,  $P=0.004$ ). Patients who carried potential driver mutations were more likely to have advanced adenomas (OR for carrying each potential driver mutation = 2.4,  $P=0.0002$ ) and had a higher risk of adenoma recurrence (OR for carrying each potential driver mutation= 1.7,  $P=0.02$ ), comparing with those who did not. **Conclusions** These data suggested that somatic mutations in cancer-associated genes could help identify adenoma patients at a higher risk of recurrence and facilitate personalized surveillance and prevention of CRC.

**723W****Clinical presentation of individuals with mosaic APC variants.** *M.E.*

*Roberts, E.M. Webb, M.M. Marshall, L.R. Susswein, Y. Wang, R.T. Klein, K.S. Hruska. GeneDx, Gaithersburg, MD.*

**Background:** Familial adenomatous polyposis (FAP) is characterized by the presence of many adenomatous polyps and a high risk for colorectal cancer (CRC). Individuals with an attenuated phenotype (AFAP) tend to have fewer polyps, later ages of onset, and/or lower risks for CRC. Pathogenic/likely pathogenic variants (PVs) in *APC* are known to cause FAP/AFAP, yet many cases of polyposis remain unexplained. Mosaic *APC* PVs have been reported to cause a subset of unexplained FAP cases, with mosaicism confirmed in patient leukocytes, lymphocytes, and adenomas. In a large published polyposis cohort, 4% of individuals with a PV in *APC* on germline testing were identified to be mosaic. In a subset of these cases, mosaicism was detected in adenomatous tissue rather than peripheral blood specimens. **Purpose:** We aim to describe the clinical presentation of a series of individuals with mosaic *APC* PVs identified at our clinical diagnostic laboratory. **Methods:** We performed a retrospective review of clinical data from test requisition forms for individuals found to carry a mosaic *APC* PV via multi-gene hereditary cancer panel testing. Testing was performed in peripheral blood and/or fibroblasts, but not in adenomatous polyps/CRCs/other affected tissues. **Results:** In total, 5/289 (1.7%) probands with *APC* PVs were found to be mosaic in peripheral blood. None of these five individuals carried a second PV in *APC* or in another gene and the average age of testing was 48.7yrs (38-55). All individuals identified to have a mosaic PV in *APC* reported phenotypes consistent with AFAP/FAP, with 38 to >100 polyps or CRC reported. Of the five individuals, one reported CRC only, two reported CRC and polyps, and one reported only polyps. Only two individuals reported a family history of CRC or polyps. Two of five individuals had subsequent testing in fibroblasts or targeted variant testing in a child, in which the *APC* PV was also identified, suggesting constitutional mosaicism. **Conclusion:** These data support that mosaic *APC* PVs may explain a subset of unexplained polyposis cases. The presence of phenotypes consistent with AFAP/FAP and supportive fibroblast and/or familial testing results in our cohort suggest that the mosaic PVs may have contributed to polyposis and/or CRC development.

**724T****Using low coverage and off target sequencing for polygenic risk scores and ancestry.** *J.R. Homburger, C.L. Neben, C. Lai, W. Stedden, A. Zimmer, A.Y. Zhou, G. Mishne. Color Genomics, Burlingame, CA., USA.*

Next generation sequencing (NGS) is an integral part of clinical care and management with applications such as targeted multi-gene panels for monogenic diseases. There is an emerging consensus that polygenic risk scores (PRS) also have validity and utility in stratifying disease risk, however, several barriers exist to implementing PRS into clinical practice. For example, PRS has traditionally been performed on genotyping arrays, and therefore assessment for polygenic risk in addition to monogenic risk currently adds additional tests, time, and cost. Recent advancements in NGS have made it possible to provide cost effective assessment of common genetic variation using low coverage sequencing while still maintaining the computational power of a genotyping array. This enables us to develop a single cost-effective assay that combines clinical grade targeted sequencing with low-coverage whole genome sequencing (lc-WGS) to determine monogenic and polygenic risk at the same time. Here, we assess the feasibility of using lc-WGS for genotype imputation and downstream applications including PRS and ancestry. First, similar to previously published studies, we used known control samples to show that 0.5x coverage achieves average imputation  $r^2$  of > 0.9 of imputed dosages to true genotypes at common genetic variants ( $MAF > 0.05$ ), demonstrating non-inferiority to array-based imputation. Second, we created a method for low coverage PRS, which uses imputed genotype dosages from lc-WGS data as inputs to polygenic risk algorithms developed from summary statistics using the LDpred approach. We found that our low coverage PRS, which combines both a high-coverage targeted panel and off target reads with a mean coverage of 0.3x, is a significant predictor of self-reported breast cancer (OR 1.43 per score standard deviation,  $p < 10^{-16}$ ) after adjusting for age, gender, family history, and age at menarche. Third, we found that lc-WGS can be used for accurate continental and subcontinental ancestry determination, an important covariate in current polygenic risk approaches. In conclusion, we demonstrate that at certain coverages, lc-WGS is equivalent to genotyping arrays and may be an attractive option for PRS and ancestry assessment. Importantly, the accuracy of lc-WGS-based methods is highly dependent upon coverage and trait genetic architecture, indicating that strict quality metrics will need to be developed before clinical implementation.

**725F****Characterizing known risk loci for colorectal cancer in African Americans.** *H. Wang<sup>1</sup>, C. Haiman<sup>2</sup>, T. Burnett<sup>1</sup>, I. Kato<sup>3</sup>, T. Keku<sup>4</sup>, W. Blot<sup>5</sup>, M. Pande<sup>6</sup>, K. Zanetti<sup>7</sup>, C. Harris<sup>8</sup>, J. Palmer<sup>9</sup>, S. Berndt<sup>10</sup>, P. Newcomb<sup>11</sup>, D. West<sup>12</sup>, L. Wilkens<sup>1</sup>, R. Haile<sup>13</sup>, D. Stram<sup>2</sup>, L. Le Marchand<sup>1</sup>.*

D. Anderson Cancer Center, Houston, TX; 7) Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Bethesda, MD; 8) Laboratory of Human Carcinogenesis, National Cancer Institute, National Institutes of Health, Bethesda, MD; 9) Slone Epidemiology Center at Boston University, Boston, MA; 10) Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Bethesda, MD; 11) Fred Hutchinson Cancer Research Center, Seattle, WA; 12) Cancer Prevention Institute of California, Fremont, CA; 13) Cedars-Sinai Medical Center, Los Angeles, CA.

Genome-wide association studies of colorectal cancer, mostly conducted in Europeans and East Asians, have identified over 70 risk SNPs in 50 susceptibility regions. Re-assessment of these susceptibility regions in African Americans with a more diverse haplotype background can help identifying the best risk-defining variants and understanding the risk predicting ability of these known variants in this population. We previously performed a fine-mapping study for 21 of the risk regions (250kb on both sides of the index SNPs) using 6,597 African Americans (1,894 cases and 4,703 controls) imputed into the 1000 Genomes Project (phase 1). Here, we are updating the results with an additional 1,609 sample from 4 participating studies (652 cases, 957 controls) genotyped on OncoArray BeadChip and imputed into the Consortium on Asthma among African-ancestry Populations in the Americas (CAAPA) haplotype reference panel with 31 million markers. In addition, we will quantify the risk increment associated with a polygenic risk score, summarizing the effects of all known variants, and estimate the proportion of the familial colorectal cancer risk attributable to these SNPs. These data represent the largest genome-wide association study on colorectal cancer in African Americans and the findings would provide valuable insight into the genetic architecture of this complex disease.

**726W****Co-localization of chromatin QTLs and expression QTLs to establish functional mechanisms at ovarian cancer risk loci.** *M.K. Freund<sup>1</sup>, J. Plummer<sup>2</sup>, F. Abbas<sup>3</sup>, N. Mancuso<sup>4</sup>, C. Giambartolomei<sup>4</sup>, M. Roytman<sup>5</sup>, B. Davis<sup>2</sup>, P. Pharoah<sup>6</sup>, A. Gusev<sup>7</sup>, B. Pasaniuc<sup>1,4,5</sup>, S.A. Gayther<sup>6</sup>, K. Lawrenson<sup>2,3</sup>.*

1) Department of Human Genetics, David Geffen School of Medicine, UCLA, Los Angeles, CA; 2) Center for Bioinformatics and Functional Genomics, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA; 3) Program at the Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA; 4) Department of Pathology and Laboratory Medicine, David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA; 5) Bioinformatics Interdepartmental Program, University of California Los Angeles, Los Angeles, CA; 6) Department of Public Health and Primary Care, Department of Oncology, University of Cambridge, UK; 7) Dana-Farber Cancer Institute, Harvard Medical School, Boston, MA.

Epithelial ovarian cancer is a rare but highly lethal malignancy, expected to cause ~14,000 deaths in the US in 2018. Though recent studies have provided insight into the mechanisms of ovarian cancer risk, the specific regulatory pathways in ovarian surface epithelial cells, an ovarian cancer precursor cell type, are still largely unknown. Here, we examine the largest ovarian cancer precursor cell dataset to date, comprising H3K27ac ChIP-seq, RNA-seq, and GWAS genotyping data in primary normal ovarian surface epithelial cells from 54 patients. We first identify novel tissue-relevant H3K27ac chromatin QTLs (cQTLs) and expression QTLs (eQTLs). In combination with transcriptome wide association scans to identify candidate target genes associated with ovarian cancer risk loci, we then identify ovarian cancer risk regions with eQTL associations, cQTL associations, and regions where both eQTL and cQTL associations are co-localized. Preliminary results identify 29 ovarian cancer risk regions with significant cQTL associations. In parallel, HiChIP analysis in ovarian normal and cancer cell lines to characterize the 'interactome' in these tissues is ongoing, to validate the putative eQTL-cQTL interactions and discover additional novel transcript-histone modification interactions. In addition to providing insight into the regulatory landscape of healthy ovarian surface epithelial cells and identifying putative tissue-specific ovarian cancer pathways, these results can be contrasted to similar QTL analyses in ovarian tumors to pinpoint the major changes in gene regulation and pathway activation that occur during neoplastic transformation.

**Rare disruptive coding variants and prostate cancer risk in men of African ancestry.** *M. Matejic<sup>1</sup>, Y. Patel<sup>1</sup>, L. Lilyquist<sup>2</sup>, F.J. Couch<sup>2,3</sup>, D.V. Conti<sup>1</sup>, C.A. Haiman<sup>1</sup>.* 1) Department of Preventive Medicine, University of Southern California, Los Angeles, CA; 2) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, Minnesota; 3) Department of Health Sciences Research, Mayo Clinic, Rochester, Minnesota.

We explored the contribution of rare coding variation to risk of PCa in men of African ancestry by sequencing a panel of 19 DNA repair and known cancer susceptibility genes in 2,098 cases and 1,481 controls of African ancestry (2,442 African American men and 1,137 Ugandan men). Variants with minor allele frequency <1% were annotated based on their functional consequence and pathogenic effect according to CAVA, ClinVar and five prediction algorithms (Polyphen2-HumDiv, PolyPhen2-HumVar, LRT, Mutation Taster, and SIFT). Analyses were performed at single variant and gene burden level to test individual and aggregate effects of rare coding variation on overall PCa risk as well as by disease aggressiveness. We identified 85 loss-of-function (Tier 1: frameshift insertion/deletions, stop gain and essential splice site changes) and 600 missense (Tier 2: non-synonymous and exon start/end codon changes) variants meeting the criteria for being deleterious. Of these, 153 (22.3%) were not previously reported in either gnomAD or ClinVar. The strongest single variant association with PCa risk was observed for three missense (Tier 2) variants in *MSH2* (Gln170Glu,  $p=0.00308$ ), *MRE11A* (Leu7Phe,  $p=0.00363$ ) and *ATM* (Glu1991Gly,  $p=0.0078$ ), which were replicated in Ugandans ( $p=0.01279$  for Gln170Glu,  $0.02082$  for Leu7Phe and  $0.0156$  for Glu1991Gly). In gene-burden testing with Tier 1 variants, significant associations were observed for *BRCA2* ( $p=0.00196$ ), *ATM* ( $p=0.0282$ ) and *PALB2* ( $p=0.03395$ ) in the overall study population and for *BRCA2* ( $p=0.00364$ ), *ATM* ( $p=0.02495$ ) and *MSH6* ( $p=0.03027$ ) in Ugandans. These associations were stronger in high-aggressive cases ( $n=988$ ) compared to controls ( $p=0.00017$  for *BRCA2*,  $0.01749$  for *PALB2*,  $0.03224$  for *ATM*). In Tier 2 gene-burden testing, *PTEN* was significantly associated with PCa risk in the overall ( $p=0.01326$ ) and African American ( $p=0.01522$ ) populations. The aggregation of Tier 1 variants by DNA-repair pathways in the overall study population showed a significantly increased risk associated with genes involved in the Fanconi anemia ( $p=0.00168$ ) and homologous recombination ( $p=0.00438$ ) signalling networks, with a stronger effect size in Ugandans ( $p=0.00221$  and  $0.0005$ , respectively). Our findings suggest that rare coding variation may have appreciable effects on disease risk in men of African ancestry, especially in Ugandans, which highlights the importance of sequencing in diverse populations for a more efficient screening of high-risk patients. .

**GWAS identifies the first risk loci for gastroesophageal reflux disease, with most influencing risk of Barrett's esophagus and/or esophageal adenocarcinoma.** *J. An<sup>1</sup>, P. Gharahkhani<sup>1</sup>, M.H. Law<sup>1</sup>, J.S. Ong<sup>1</sup>, X. Han<sup>1</sup>, I. Tomlinson<sup>2</sup>, T.L. Vaughan<sup>3</sup>, M.F. Buas<sup>3,4</sup>, R.C. Fitzgerald<sup>5</sup>, J. Schumacher<sup>6</sup>, C. Palles<sup>7</sup>, D.C. Whiteman<sup>7</sup>, S. MacGregor<sup>1</sup>.* 1) Statistical Genetics, QIMR Berghofer Medical Research Institute, Brisbane, QLD, Australia; 2) Institute of Cancer and Genomic Sciences, University of Birmingham, Birmingham, UK; 3) Division of Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, USA; 4) Department of Cancer Prevention and Control, Roswell Park Cancer Institute, Buffalo, New York; 5) Medical Research Council (MRC) Cancer Unit, Hutchison-MRC Research Centre and University of Cambridge, Cambridge, UK; 6) Institute of Human Genetics, and Department of Genomics, Life & Brain Center, University of Bonn, Bonn, Germany; 7) Cancer Control, QIMR Berghofer Medical Research Institute, Brisbane, QLD, Australia.

Gastroesophageal reflux disease (GERD) is a very common chronic disease where stomach acid flows back up into the esophagus. GERD causes mucosal damage and complications in the upper digestive system and is associated with Barrett's esophagus (BE) and esophageal adenocarcinoma (EA). We conducted a case-control GWAS in UK Biobank with cases defined in terms of a) GERD status or b) GERD medication history. Results were replicated in an independent case-control cohort (QSKIN - Australia). Concordance in terms of GWAS effect sizes between GERD status and GERD medication history was very high, justifying merging to maximize power. Taken together, 72,334 cases and 263,352 controls had genome-wide data. We identified 28 independent loci for GERD, the first genome-wide significant loci to be identified for this condition. We then investigated the effect of these GERD loci in GWAS data on Barrett's esophagus (BE; 6,167 cases, 17,159 controls) and esophageal carcinoma (EA; 4,112 cases, 13,663 controls). The vast majority of the trait increasing alleles at the GERD loci also increased risk of BE and/or EA. Three of the 28 GERD loci overlapped with those previously implicated in BE and/or EA at  $P<5e-8$ . The majority of the loci implicated in our GERD analysis and showed  $P<0.05$  for BE and/or EA, including SNPs in our HIST1H3J, ZSCAN12 and SLC9A3. Finally, using LD-Score regression, we identified strong genetic correlations between GERD and BMI, and GERD and depression.

**Genome-wide interaction analysis of menopausal hormone therapy and breast cancer risk.** X. Wang<sup>1,2</sup>, P. Middha<sup>3</sup>, P. Auer<sup>4</sup>, R. Milne<sup>5,6</sup>, P. Kraft<sup>7,8</sup>, J. Chang-Claude<sup>3</sup>, S. Lindström<sup>1,2</sup>, *Breast Cancer Association Consortium (BCAC)*. 1) Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Department of Epidemiology, University of Washington, Seattle, WA; 3) Division of Cancer Epidemiology, German Cancer Research Center, Heidelberg, Germany; 4) Department of Biostatistics, School of Public Health, University of Wisconsin Milwaukee, Milwaukee, WI; 5) Cancer Epidemiology and Intelligence Division, Cancer Council Victoria, Melbourne, Vic, Australia; 6) Centre for Epidemiology and Biostatistics, Melbourne School of Population and Global Health, the University of Melbourne, Melbourne, Vic, Australia; 7) Department of Epidemiology, Harvard Chan T. School of Public Health, Boston, MA; 8) Department of Biostatistics, Harvard Chan T. School of Public Health, Boston, MA.

**Background:** Use of menopausal hormone therapy (MHT) has been associated with higher risk for breast cancer. However, the relevant mechanisms and its interaction with genetic variants are not fully understood. **Methods:** We conducted a genome-wide interaction analysis between current MHT use and genetic variants for breast cancer risk among 20,872 cases and 26,550 controls from 21 observational studies. All women were post-menopausal and of European ancestry. Multivariate logistic regression models were used to test for multiplicative interactions between SNP and current MHT, adjusting for main effects of SNPs and current MHT use, age, study, former use of MHT and principal components. We considered interaction p-values  $< 5 \times 10^{-8}$  as genome-wide significant. **Results:** Among the total of ~10 million SNPs tested for SNP-MHT interactions, none reached genome-wide significance level. 33 SNPs had p-values  $< 1 \times 10^{-6}$ . The most significant SNP rs190966839 (p-value:  $1.13 \times 10^{-6}$ ) was close to the tumor suppressor candidate 1 (*TUSC1*) gene, on chromosome 9. **Conclusions:** In this genome-wide SNP-MHT interaction study of breast cancer, we identified suggestive variants that potentially interact with MHT use; however, no SNP reached genome-wide significance. Our next step is to replicate these results in similar-sized independent datasets that are currently under preparation.

**730T**

**Whole genome sequencing identifies candidate germline variants leading to familial non-medullary thyroid cancer.** Y. Wang<sup>1</sup>, S. Liyanarachchi<sup>1</sup>, K.E. Miller<sup>2</sup>, T.T. Nieminen<sup>1</sup>, D.F. Comiskey<sup>1</sup>, W. Li<sup>1</sup>, P. Brock<sup>3</sup>, H. He<sup>1</sup>, D.C. Koboldt<sup>4</sup>, A. de la Chapelle<sup>1</sup>. 1) Comprehensive Cancer Center, The Ohio State University, Columbus, OH; 2) Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH; 3) Department of Internal Medicine, The Ohio State University Comprehensive Cancer Center, The Ohio State University, Columbus, OH.

Thyroid cancer is the most common malignancy of the endocrine system. Based on the data from National Cancer Institute for 2018, the estimated number of new thyroid cancer patients is 53,990 in the United States. It has been reported that familial non-medullary thyroid cancer (FNMT) demonstrates more aggressive features than sporadic non-medullary thyroid cancer. FNMT constitutes only 3-9% of all thyroid cancers. Its predisposition pattern is complex and most likely due to multiple mutations. To identify rare pathogenic variants in non-medullary thyroid cancer (NMTC) families, here we performed whole genome sequencing (WGS) on 57 samples from 17 NMTC families. Blood DNA samples from at least 3 patients within each family were sequenced by Novogene using Illumina HiSeq platform. We also performed whole genome linkage analysis using Illumina HumanCytoSNP-12 BeadChip in a total of 106 samples including unaffected family members. Variants were analyzed using MendelScan v1.2.3. Candidate variants were selected based on the maximum allele frequency in gnomAD population data, functional prediction score using Varsome, and the evidence of constraint in ExAC database. Alternatively and additionally, to avoid missing important truncating variants caused by algorithm bias, variants from the same VCF file were further analyzed by using Baseplayer (1.0.0). A list of rare variants possibly causing FNMT was generated including the variants identified by both methods. All these variants were shared by every WGS tested individuals within each family. We identified a total of 86 candidate variants, comprising 71 single nucleotide variants (49 missense, 12 nonsense, and 10 splice site variants) and 15 frameshift variants. Among all the variants, 51% (44/86) were novel and have not yet been reported in gnomAD database. Furthermore, Sanger sequencing validation within all family members with DNA available has confirmed complete cosegregation with NMTC in 11 of 26 variants tested so far. Functional validation experiments will be performed to prove the roles of these rare variants in FNMT predisposition. Our study identified a group of rare germline variants that may play a putative role in creating familial thyroid cancer risk.

**Characterizing the spectrum of low-penetrance variants predisposing to papillary thyroid cancer.** D.F. Comiskey, H. He, S. Liyanarachchi, L.K. Genu-tis, P. Brock, A. de la Chapelle. The Ohio State University, Columbus, OH.

Papillary thyroid cancer (PTC) arises from thyroid follicular epithelial cells and accounts for over 90% of all thyroid cancer diagnoses. PTC demonstrates high heritability and a low somatic mutation burden relative to other cancers. To understand the genetic basis of PTC many have taken to using both case-control studies and genome-wide association studies (GWAS) in order to identify low-penetrance germline variants. Recently, a meta-GWAS in PTC patients and controls of European descent yielded five new loci at 1q42, 3q26, 5q22, 10q24, and 15q22 genome-wide significantly associated with PTC. The underlying mechanisms of many of the PTC risk loci is unknown, however the sentinel single nucleotide polymorphisms (SNPs) are located adjacent to promoter and enhancer elements. Overall, our data support a hypothesis that SNPs in these loci alter the transcriptional activity of genes relevant to thyroid cancer pathogenesis. Here we report the characterization of three loci. SNP rs6793295 at 3q26 is a missense variant that lies within exon 7 of *LRRC34* and shows allele-specific expression in normal thyroid tissue. Mass spectroscopy of *LRRC34* indicates that this protein has functions related to protein folding, chromatin regulation, and cellular metabolism. We have also detected another region in the promoter of *LRRC34* that also shows association with PTC risk. SNP rs12129938 at 1q42 is located in a 16 kilobase haplotype in the first intron of *PCNXL2*. This block is a promoter-flanking region in the vicinity of several expression quantitative trait loci (cis-eQTL) for thyroid tissue. *PCNXL2* is modestly expressed in thyroid and its expression is two-fold higher in PTC tumor as compared to normal tissue. Finally, SNP rs73227482 at 5q22 lies within an intron of a non-coding transcript of *EPB41L4A*. *EPB41L4A* is highly expressed in thyroid and this SNP shows allele-specific expression in normal thyroid tissue. However, it does not show differential expression between normal and PTC tumor tissue. To understand the functions of these genes we have performed a combination of luciferase assays, mass spectroscopy, overexpression, and knockdown followed by transcriptome profiling in PTC cell lines. In the era of GWAS it is often difficult to extrapolate functional genetic variants from statistical association. The strength of our studies lies in the functional validation of these loci, which will allow us to better understand genetic risk and network of genes involved in PTC.

**Genome-wide association study to identify novel biomarkers for trastuzumab-induced cardiotoxicity.** M. Hara<sup>1,2</sup>, C. Udagawa<sup>1</sup>, A. Shimo<sup>2</sup>, Y. Kojima<sup>2</sup>, R. Yoshie<sup>2</sup>, H. Zaha<sup>3</sup>, N. Abe<sup>3</sup>, T. Motonari<sup>3</sup>, M. Unesoko<sup>3</sup>, K. Tamura<sup>4</sup>, T. Shimo<sup>5</sup>, M. Yoshida<sup>5</sup>, T. Yoshida<sup>6</sup>, T. Mushiroda<sup>7</sup>, K. Tsugawa<sup>2</sup>, H. Zembutsu<sup>1,8</sup>. 1) Cancer Precision Med. Ctr. JFCR, Tokyo, Japan; 2) Dept. Breast and Endocrine Surg., St. Marianna Univ., Sch. of Med. Kanagawa, Japan; 3) Dept. Breast Surg., Nakagami Hosp. Okinawa, Japan; 4) Dept. Breast and Med. Oncology, Natl. Cancer Ctr. Hosp. Tokyo, Japan; 5) Dept. Pathol, Natl. Cancer Ctr. Hosp. Tokyo, Japan; 6) Fund. Innov. Oncol. Core, Natl. Cancer Ctr. Res. Inst. Tokyo, Japan; 7) RIKEN Ctr. Integrative Med. Sci. Kanagawa, Japan; 8) Div. Genetics, Natl. Cancer Ctr. Res. Inst. Tokyo, Japan.

To identify a novel genetic marker(s) determining the risk of trastuzumab-induced cardiotoxicity, we carried out a genome-wide association study (GWAS) using 11 cases (with trastuzumab-induced cardiotoxicity) and 257 controls (showing no sign of trastuzumab-induced cardiotoxicity). Top 100 single nucleotide polymorphisms (SNPs) which revealed smallest *P* value in GWAS ( $P = 1.61 \times 10^{-7} - 2.30 \times 10^{-3}$ ) were further examined using replication samples consisted of 14 cases and 199 controls. The combined analysis of the screening and replication study indicated 5 loci showing stronger association with trastuzumab-induced cardiotoxicity than GWAS phase (SNP A on chromosome 13;  $P_{\text{combined}} = 6.00 \times 10^{-6}$ , SNP B on chromosome 4;  $P_{\text{combined}} = 8.60 \times 10^{-5}$ , SNP C on chromosome 15;  $P_{\text{combined}} = 1.01 \times 10^{-4}$ , SNP D on chromosome 17;  $P_{\text{combined}} = 1.07 \times 10^{-4}$  and SNP E on chromosome 15;  $P_{\text{combined}} = 1.60 \times 10^{-4}$ ). Of the above 5 loci, non-coding RNAs were included on Chr 13 and 15, and a secreted protein was also included on Chr 15. These findings provide new insights into personalized trastuzumab therapy for patients with human epidermal growth factor receptor 2 (HER2)-positive cancer.

**Background:** High-dose methotrexate (HD-MTX) is a cornerstone agent in the chemotherapeutic treatment of patients with osteosarcoma. Due to inter-individual variation in MTX metabolism, patients often develop HD-MTX-induced toxicities which cannot always be prevented by MTX plasma level monitoring. We aim to identify determinants of HD-MTX-induced toxicities in osteosarcoma patients, by investigating the relation between MTX plasma levels and toxicities, and the contribution of genetic variants in genes related to drug absorption, distribution, metabolism and elimination (ADME). **Methods:** A cohort of 114 osteosarcoma patients was genotyped for 1,931 variants in 231 genes using the Drug Metabolism Enzymes and Transporters (DMET) Plus array. Laboratory results during treatment concerning renal function, liver damage and myelopoiesis were obtained to evaluate toxicity. Associations were tested between toxicity data, 48-hour MTX plasma levels, and ADME genetic variants by performing generalized estimating equation analyses to take repeated measurements into account. **Results:** Analyses of data concerning 1,238 HD-MTX courses identified no association between 48-hour MTX plasma levels and related toxicities. Three of the tested genetic variants were significantly associated with HD-MTX induced toxicities. We found an association between a variant in *CYP2F1* (rs58285195) and decreased neutrophil count (coef -0.600 [95% CI -0.753–0.448];  $p=1.40 \times 10^{-4}$ ). Also, a variant in *CYP4F2* (rs3093153) was significantly associated with increased alanine transaminase levels (coef 0.813 [95% CI 0.469–1.157];  $p=3.67 \times 10^{-6}$ ) and a variant in *CYP4F8* (rs4808326) was associated with a protective effect on platelet count (coef 0.198 [95% CI 0.105–0.291];  $p=2.91 \times 10^{-6}$ ) in our cohort. **Conclusions:** Our study identified three variants in genes involved in drug processing to be strongly associated with HD-MTX-induced toxicities. To date, the variants in these genes were not known to play a role in MTX metabolizing pathways and were also not previously found to have an influence of the development and severity of bone marrow suppression or liver damage. Further functional investigation of variants in the identified genes is ongoing to study if and how they affect the development of HD-MTX-induced toxicities.

## 734F

**Optimizing cisplatin chemotherapy through *SNAIL* pathway expression regulation implicates *S100P* as potential target.** *C. Del Greco, L. Mortensen, A.L. Stark.* University of Notre Dame, Notre Dame, IN.

Cisplatin is a common platinum chemotherapy treatment given to breast cancer patients, but it is plagued with non-response and resistance. Much research has been focused on trying to understand and improve therapy hurdles. One promising avenue is the *SNAIL* pathway, which has complex roles throughout the cell. Given the knowledge of the cisplatin mechanism, we hypothesized that gene expression changes seen after *SNAIL* upregulation would be reversed after cisplatin treatment. In order to investigate this prediction, we analyzed gene expression in MCF-7 cells in response to upregulated *SNAIL* as found in the Expression Atlas. The fourteen genes with the lowest p-values for expression changes in response to *SNAIL* overexpression ( $p=1.88e-8$ ) were then researched to prioritize the most promising targets for cisplatin therapy modification. Genes selected for initial study were *THBS1*, *S100P*, *LDHB*, *DECR1*, *TSPYL5*, and *TMEM47*. qPCR was performed to assess the expression changes in each gene when cells are exposed to 5  $\mu$ M cisplatin treatment for 24 and 48 hours. Most of the genes showed very modest expression changes after both time points of cisplatin exposure, suggesting they may not be affected by cisplatin therapy. However, *S100P* expression increased by a log fold of 4.47 ( $p=5.70359e-6$ ) after 24 hours of exposure to cisplatin treatment, and increased by a log fold of 14.34 ( $p=4.98091e-5$ ) after 48 hours of exposure to cisplatin treatment. This is especially relevant given that *S100P* has not only been observed to decrease cell adhesion while increasing invasion and metastasis, but has also been known to interact with, and in some cases desensitize cells to, therapies such as cisplatin. Future research will be therefore aimed towards assessing the effects of inhibiting *S100P* in cisplatin-treated cells on cellular growth with the hope of optimizing cisplatin chemotherapy outcomes.

## 735W

**Association between imputed pancreatic gene expression profiles and the development of L-asparaginase-induced pancreatitis.** *B.I. Drogemoller<sup>1,2</sup>, G.E.B. Wright<sup>2,3</sup>, S. Ito<sup>4</sup>, B.C. Carleton<sup>2,5,6</sup>, C.J.D. Ross<sup>1,2</sup>*, *The Canadian Pharmacogenomics Network for Drug Safety Consortium*. 1) Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; 2) BC Children's Hospital Research Institute, University of British Columbia, Vancouver, BC, Canada; 3) Department of Medical Genetics, Centre for Molecular Medicine and Therapeutics, University of British Columbia, Vancouver, BC, Canada; 4) Clinical Pharmacology and Toxicology, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada; 5) Division of Translational Therapeutics, Department of Pediatrics, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada; 6) Pharmaceutical Outcomes Programme, BC Children's Hospital, Vancouver, BC, Canada.

L-asparaginase is highly effective in the treatment of pediatric acute lymphoblastic leukemia. Unfortunately, the use of this treatment is limited by the occurrence of pancreatitis, a severe and potentially lethal adverse drug reaction, which occurs in 2-18% of patients. As previous studies have been unable to identify strong associations between clinical variables and susceptibility to L-asparaginase-induced pancreatitis, genetic factors are expected to play an important role in the development of this adverse drug reaction. To uncover these genetic factors, a total of 284 patients treated with L-asparaginase were recruited from 13 pediatric oncology units across Canada. Extensive demographic and clinical data were collected for all patients and genotyping was performed using the Illumina HumanOmniExpress array. Pancreatic gene expression profiles were imputed using GTEx v7 and S-PrediXcan. Genes that were predicted to be differentially expressed in cases and controls ( $P < 0.01$ ) were included in overrepresentation enrichment analyses using the WEB-based GENE SeT AnaLysis Toolkit. S-PrediXcan analyses identified one gene, *SLC39A13*, which exhibited significantly higher imputed expression levels in individuals with L-asparaginase-induced pancreatitis ( $P = 1.2 \times 10^{-5}$ ). WEB-based GENE SeT AnaLysis Toolkit analyses revealed an enrichment of genes (*HLA-DQB1*; *HLA-DRB5*) that have previously been associated with drug-induced toxicity (adjP=0.02). In conclusion, this study has uncovered associations with L-asparaginase-induced pancreatitis and predicted gene expression levels of (i) *SLC39A13* - a gene involved in Ehlers-Danlos syndrome, a condition in which pancreatitis has been reported to occur, and (ii) *HLA* genes - mirroring previous associations with the *HLA* region and pancreatitis caused by other drugs. These findings have provided additional insight into the genetics factors that are involved in the development of L-asparaginase-induced pancreatitis, the results of which will facilitate future replication and validation studies.

## 736T

**Elucidating the relationship between ER stress and cisplatin on gene regulation in colorectal cancer cells.** *A.P. Hubert, R. Georgiadis, A. Stark*. College of Science, University of Notre Dame, Notre Dame, IN.

The chemotherapeutic agent cisplatin has been shown to increase survival rates in colorectal cancer patients. It produces a cytotoxic environment inside cells, initiating several death pathways while producing ER stress. Impacts of cisplatin treatment on gene expression could help characterize cellular responses to the drug and identify important genes to therapy response. Utilizing the Expression Atlas, expression profiles of HCT116 colorectal cells with induced ER stress by Brefeldin A identified genes with large expression changes. Over 800 genes were identified with expression changes  $p < 0.00011$ , which was unsurprisingly due to the importance of the ER stress pathway in the cell. Based on their large fold change, three genes were initially selected for examination with cisplatin treatment: MALAT1 ( $p = 5.624 \times 10^{-5}$ ), SLC7A11 ( $p = 1.04 \times 10^{-4}$ ) and SPX ( $p = 2.827 \times 10^{-5}$ ). Due to the expression fold changes observed under ER stress (6), our hypothesis is that during cisplatin treatment, cells would upregulate the expression of all three genes. HCT116 colorectal cancer cells were treated with 5  $\mu$ M cisplatin for 24 hours and 48 hours. Quantitative PCR was run on cDNA to determine the effect on expression of the genes in question. All three genes showed evidence of significant down-regulation. MALAT1 is a gene normally upregulated in cancer cells and the observed downregulation suggests that this gene may play a role in cisplatin response. High expression of SLC7A11 has been observed in the literature in cisplatin resistant cell lines in several cancers including lung and bladder cancer. However, the observed downregulation suggests tissue specificity. SPX is a gene which is involved maintaining homeostasis and further work needs to be done to understand its role in cisplatin treatment. Overall, these genes were expected to show increased expression due to cisplatin induced ER stress, however, because they did not, further work needs to be done to understand the role of ER stress in colorectal cancer cells cisplatin response. Ultimately, understanding the mechanistic similarities between ER stress and cisplatin treatment in colorectal cells will pinpoint future therapy strategies for more effective treatment.

## 737F

**Genome-wide association study of anthracycline-induced cardiotoxicity in adult cancer patients.** E.N. Scott<sup>1,2</sup>, B.I. Drögemöller<sup>2,3</sup>, G. Wright<sup>1,2</sup>, K. Gelmon<sup>4</sup>, D. Villa<sup>4</sup>, J.N. Trueman<sup>5</sup>, B.C. Carleton<sup>5,6</sup>, C.J.D. Ross<sup>1,2,3</sup>. 1) Department of Medical Genetics, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada; 2) BC Children's Hospital Research Institute, Vancouver, BC, Canada; 3) Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada; 4) Division of Medical Oncology, BC Cancer, Vancouver, BC, Canada; 5) Pharmaceutical Outcomes Programme, BC Children's Hospital, Vancouver, BC, Canada; 6) Division of Translational Therapeutics, Department of Pediatrics, Faculty of Medicine, University of British Columbia, Vancouver, BC, Canada.

**Background** Anthracycline agents, such as doxorubicin and epirubicin, are commonly prescribed for a variety of cancers and contribute largely to the survival of patients. Nevertheless, up to 18% of adult patients develop severe life-threatening anthracycline-induced cardiotoxicity (ACT). Clinical risk factors include cumulative anthracycline dose, age, prior thoracic radiotherapy, and pre-existing cardiac disease. Germline genetic variants associated with a higher ACT risk in adults have not yet been identified. The objective of this study is to replicate previous, and discover new, ACT-associated genetic variants in adult cancer patients in order to improve our understanding of the genetic causes of ACT. **Methods** Genotyping of 1.7 million variants has been performed on 175 adult cancer patients (59 cases, 116 controls) treated with anthracyclines, recruited from academic health centres in Vancouver, and rigorously assessed for ACT. Targeted analyses will examine genetic variants in 25 genes that have been previously implicated in ACT and identified through an extensive literature review. Genome-wide analyses will identify novel variants associated with ACT. Targeted and genome-wide analyses will be performed using logistic regression, including significantly-associated clinical variables as covariates. Functional and biological relevance of candidate variants will be examined using various computational annotation tools, such as VEP, GTEX, and CADD, and associated genes will be investigated for enrichment in specific pathways. **Results** An extensive review of the literature has identified 25 genes that have been previously associated with ACT, the role of which will be validated in our cohort through a targeted analysis. We will present the top candidate variants that reach statistical significance in both targeted and genome-wide analyses. **Conclusions** The results from this study will enable the development of genetic tests that can be used to determine which patients are at high risk of experiencing ACT. In addition, the identification of genetic variants associated with ACT will play an important role in improving the safety of anthracyclines and, ultimately, in reducing the burden on the healthcare system as well as affected patients.

## 738W

**The alkylating drug Irofulven shows potent tumor inhibition in an ERCC3 mutant background.** S. Topka<sup>1,2</sup>, S. Khalil<sup>3</sup>, Z. Steinsnyder<sup>1,2</sup>, V. Ravichandran<sup>1,2</sup>, M. Winkel Madsen<sup>5</sup>, E. De Stanchina<sup>4</sup>, J. Vijai<sup>1,2,7</sup>, K. Offit<sup>1,2,6,7</sup>. 1) Department of Medicine, Memorial Sloan Kettering Cancer Center, New York, NY; 2) Cancer Biology and Genetics Program, Memorial Sloan Kettering Cancer Center, New York, NY; 3) Gerstner Sloan Kettering Graduate School of Biomedical Sciences, New York, NY; 4) Antitumor Assessment Core Facility, Molecular Pharmacology Program, Memorial Sloan Kettering Cancer Center, New York, NY; 5) Oncology Venture ApS, Horsholm, Denmark; 6) Clinical Genetics Service, Department of Medicine, Memorial Sloan Kettering, New York, N.Y.; 7) Department of Medicine, Weill Cornell Medical College, New York, N.Y.

The ATP dependent helicase ERCC3 plays a crucial role in normal basal transcription and nucleotide excision repair. A recurrent Ashkenazi Jewish founder mutation in ERCC3 (p.R109X) has been shown to confer risk for multiple cancer types. Modeling of this mutation in mammary epithelial cell lines via CRISPR/Cas9 showed a consistent pattern of reduced expression of the protein and concomitant hypomorphic functionality when treated with the DNA alkylating agent IlludinS. A derivative of IlludinS- Irofulven- has previously been evaluated as an antitumor agent in multiple clinical trials and has shown high antitumor activity. Higher effective doses of this drug have been shown to give rise to side effects, including retinal toxicity. Based on the observation that ERCC3 mutant cell lines are sensitive to lower doses of IlludinS we aimed to explore the IlludinS-derivative Irofulven as a potential therapeutic agent to treat patients with hypomorphic ERCC3 mutations. We tested the efficacy of Irofulven in isogenic WT and ERCC3 mutant mammary epithelial cell lines *in vitro* and in xenograft models. *In vitro*, cells were treated with various doses of Irofulven and cell viability was assessed at 72h following treatment. For generation of xenograft models hRAS-V12 expressing genetically engineered ERCC3 mutant as well as isogenic ERCC3 wild-type cell lines were injected into flanks of nude mice and treated with different doses of Irofulven. Tumor volumes were measured over the course of treatment and tumors excised after termination of treatment for final weighing and for histological and subsequent molecular-genetic analysis. *In vitro* studies showed an increased sensitivity of the ERCC3 mutant cells towards the drug Irofulven, while no difference was observed for other commonly used drugs such as PARP inhibitors or platinum-based agents. Xenograft experiments showed enhanced *in vivo* sensitivity in the ERCC3 mutant background. Additional experiments are ongoing including RNA sequencing of tumor tissue and exploration of combinatorial therapies. Similar to tumors arising in the background of homologous repair defects, mutations in nucleotide excision repair genes such as ERCC3 could constitute potential therapeutic targets in a subset of cancers. The present study provides a potential pre-clinical approach to a subset of cancer cases with an inherited mutation of a nucleotide excision repair pathway gene, demonstrating sensitivity to the DNA alkylating agent Irofulven.

**Application of human genetics to launch and guide the discovery of a novel cancer immunotherapy.** J. Hutz, C. Zhang, Y. Huang, D. Chandra, A. Endo, K. Huang, X. Bao. Eisai, Andover, MA.

Though it has been shown that human genetics is useful for the identification of drug targets, less has been shared to show how human genetics can continuously impact drug discovery and development after target identification. We present an example that highlights the many contributions of human genetics to the discovery of E7766, a small molecule agonist of STING for the treatment of cancer. First, STING (encoded by *TMEM173*) was chosen as a promising target based on both GWAS and Mendelian support. Linked SNPs in the *TMEM173* locus had been associated with higher esophageal cancer risk and lower interferon alpha production. Additionally, gain-of-function mutations in *TMEM173* had been shown to cause a rare type 1 interferonopathy (SAVI). The combination of these findings suggested that STING-induced interferon production could be beneficial for the treatment of cancer. Based in part on this information, chemistry and pharmacology efforts were initiated and resulted in the discovery of E7766, a potent STING agonist. Second, human genetics played a critical role in outlining a pharmacogenomic basis for differentiation of E7766 from other STING agonists. Five common *TMEM173* haplotypes exist worldwide. In collaboration with a consumer genetics company, we involved sequenced research participants in a study and demonstrated that PBMCs carrying all common genotypes responded to E7766 *in vitro* but that other STING agonists may benefit from pharmacogenomic testing. Understanding the geographic frequencies of these genotypes supported selection of clinical trial sites that can test clinical efficacy in all genotypes. Third, human genetics provided a clear set of biomarkers to be tested in clinical trials. SAVI patients demonstrate increased expression of a type 1 interferon gene signature. We confirmed that E7766 induces similar but temporary gene expression changes in mice and human primary cells and may test expression of these genes to confirm activity of E7766 in treated patients. Finally, reports have emerged of successful treatment of SAVI patients using JAK inhibitors, which may be useful in considering how to address unexpected adverse events in clinical trials of STING agonists. Though it is unknown whether E7766 will eventually become an approved therapy for patients with cancer, its discovery and future development provide useful insight on how human genetics can guide therapeutic development.

**Exploring function of genetic variants in lung adenocarcinoma by integrated association analysis of multi-omics data.** J.B. Chen, S.S. Dong, Y. Rong, X.F. Chen, H. Wu, Y.J. Zhang, Y. Guo, T.L. Yang. Key Laboratory of Biomedical Information Engineering of Ministry of Education, School of Life Science and Technology, Xi'an Jiaotong University, Xi'an, Shannxi, China.

Previous genome-wide association studies (GWASs) have identified many single nucleotide polymorphisms (SNPs) associated with human complex traits. Expression quantitative trait loci (eQTL) analysis were then used to explore how these genomic variants influence gene expression and associated traits. However, most of SNPs are located in genome's noncoding regions such as intergenic or intron regions, which may regulate gene expression rather than change gene expression levels directly, therefore, could not be identified by eQTL analysis. Here, for interpreting how these genomic variants associated with human complex traits, we performed association analyses of genotype data with matched transcriptomic (gene expression, alternative splicing and back-splicing), epigenomic (DNA methylation) and proteomic (RPPA) data in lung adenocarcinoma (LUAD) samples from The Cancer Genome Atlas (TCGA). After quality control and analyzing covariates, 12,336 cis-eQTLs, 61,926 cis-splicing quantitative trait loci (sQTLs), 81,552 DNA methylation quantitative trait loci (mQTLs) and 1,215 protein quantitative trait loci (pQTLs) were identified with the significance threshold of false discovery rates (FDR) <0.05. Importantly, we introduced circRNA quantitative trait loci (cQTLs) as the association of genotype with circRNA expression levels which focused on gene expression regulatory network by genomic variants via back-splicing events. Finally, we identified 33,442 cQTLs in LUAD samples. A large portion of known lung adenocarcinoma genes such as *AKT1/2*, *BRAF* and *EGFR* were included in these QTLs genes, especially for cQTL, mQTL and sQTL genes that overlapped with more than half of known genes respectively. Among the top QTL genes with large numbers of SNPs out of known cancer genes, *ANXA2*, *COL1A1*, *PIN4* and *YWHAZ* were further validated by survival analysis, indicating their role of candidate lung cancer genes. For sQTLs, skipped exons (SE) event harbored the most sQTLs and some known lung cancer genes such as *AKT1/2*, *ERBB2* and *TPM3* had complex splicing events. A large number of skipped exons were matched with circularized exons that also validated the exon-skipping model of circRNAs formation. Totally, these QTLs overlapped with 22% of GWAS SNPs. Our research that integrating various dimension of data resources will be helpful to obtain a more comprehensive map of the cancer genomic landscape and investigate the regulating mechanisms of these QTLs in lung adenocarcinoma pathology.

**A meta-analysis of more than 237,380 men of diverse ancestries identifies 40 new risk loci for prostate cancer.** D.V. Conti<sup>1</sup>, L.C. Moss<sup>1</sup>, X. Sheng<sup>1</sup>, S.K. Van Den Eeden<sup>2</sup>, H. Nakagawa<sup>3</sup>, J. Witte<sup>4,5</sup>, R.A. Eeles<sup>6</sup>, Z. Kote-Jarai<sup>6</sup>, C.A. Haiman<sup>1</sup>, PRACTICAL Consortium. 1) Preventive Medicine, University of Southern California, Los Angeles, CA., United States of America; 2) Division of Research, Kaiser Permanente Northern California, Oakland, California, United States of America; 3) Laboratory for Genome Sequencing Analysis, RIKEN Center for Integrative Medical Sciences, Tokyo, Japan; 4) Department of Epidemiology and Biostatistics, University of California, San Francisco, California, United States of America; 5) Institute for Human Genetics, University of California, San Francisco, California, United States of America; 6) The Institute of Cancer Research, London, United Kingdom.

Although genome-wide association studies (GWAS) have identified over 150 independent loci associated with prostate cancer risk, these novel discoveries were primarily in populations of European ancestry. In order to identify additional prostate cancer risk loci, we conducted a meta-analysis of ~30 million genotyped and imputed SNPs in 110,406 prostate cancer cases and 126,974 controls consisting of individuals of African, European, Asian, and Latino ancestry. After excluding known prostate cancer risk loci ( $\pm$  800kb of index marker), our meta-analysis identified over 40 novel loci associated with overall prostate cancer risk ( $P$  value  $< 5 \times 10^{-8}$ ). We examine the polygenic risk score, heritability and proportion of familial relative risk within and between populations captured by our novel loci, as well as previously reported regions. These findings demonstrate the value of combining populations with individuals of diverse ancestry for both novel discovery and improving risk prediction. Additionally, these results will further guide future research into understanding the biological mechanisms underlying prostate cancer susceptibility.

Rabin<sup>2</sup>. 1) Department of Preventive Medicine, University of Southern California, Los Angeles, CA; 2) Baylor College of Medicine, Houston, TX; 3) Duke University, Durham, NC; 4) University of Texas Southwestern Medical Center, Dallas, TX; 5) Ohio State University, Columbus, OH; 6) University of Alabama Birmingham, Birmingham, AL; 7) Johns Hopkins Hospital, Baltimore, MD; 8) University of Washington Medical Center, Seattle, WA; 9) New York University, New York, NY; 10) University of Utah Huntsman Cancer Institute, Salt Lake City, UT; 11) University of Pittsburgh, Pittsburgh, PA; 12) St. Jude Children's Research Hospital, Memphis, TN; 13) University of Florida, Gainesville, FL; 14) University of Montreal, Montreal, QC, Canada; 15) Children's Hospital of Philadelphia, Philadelphia, PA; 16) University of California San Francisco, San Francisco, CA; 17) Emory University, Atlanta, GA; 18) University of California Berkeley, Berkeley, CA; 19) Yale School of Public Health, New Haven, CT; 20) Fred Hutchinson Cancer Research Center, Seattle, WA.

Down syndrome (DS) is one of the strongest risk factors for acute lymphoblastic leukemia (ALL), the most common pediatric malignancy, as children born with trisomy 21 have an approximately 20-fold increased risk of disease. ALL in children with DS (DS-ALL) is associated with inferior outcomes and unique somatic characteristics, including a high frequency of CRLF2 overexpression. However, the role of inherited genetic variation in DS-ALL is unknown. To this end, we performed the first genome-wide association study (GWAS) of DS-ALL, including four independent case-control studies comprising 542 DS-ALL cases and 1192 DS controls. We carried out genome-wide imputation of autosomal and disomic single nucleotide polymorphisms (SNPs), and combined results from all studies using fixed effects meta-analysis. Genome-wide significant SNPs were identified at four loci previously associated with non-DS ALL, including: rs58923657 near *IKZF1* (odds ratio [OR] = 2.02,  $P_{\text{meta}}=5.32 \times 10^{-15}$ ), missense SNP rs3731249 in *CDKN2A* (OR=3.63,  $P_{\text{meta}}=3.91 \times 10^{-10}$ ), rs7090445 in *ARID5B* (OR=1.60,  $P_{\text{meta}}=8.44 \times 10^{-9}$ ), and rs3781093 in *GATA3* (OR=1.73,  $P_{\text{meta}}=2.89 \times 10^{-9}$ ). Case-case analyses comparing the frequency of ALL risk alleles (at *IKZF1*, *CDKN2A*, *ARID5B*, *GATA3*, *CEBPE*, *BMI1*, and *PIP4K2A*) in DS-ALL versus non-DS ALL ( $n = 3082$  cases) revealed significantly higher risk allele frequencies in DS-ALL cases for SNPs in *CDKN2A* (OR=1.58,  $P_{\text{meta}}=4.08 \times 10^{-4}$ ), *GATA3* (OR=1.34,  $P_{\text{meta}}=4.38 \times 10^{-5}$ ), and *IKZF1* (OR=1.18,  $P_{\text{meta}}=0.015$ ). Genetic risk scores (GRS) calculated from the seven susceptibility loci were also significantly higher in DS-ALL cases than in non-DS ALL cases (weighted GRS,  $P=3.33 \times 10^{-6}$ ), indicating that DS-ALL cases harbor significantly more risk alleles than non-DS cases. Furthermore, among controls without ALL, neither the GRS nor any individual ALL risk alleles were associated with DS status, suggesting that the higher risk allele frequencies in DS-ALL cases represents a larger magnitude of effect for known ALL risk loci in the genetic background of trisomy 21. Finally, shRNA knockdown of *IKZF1* in lymphoblastoid cell lines (LCLs) revealed significantly higher proliferation rates in DS LCLs versus non-DS LCLs, as measured by serial counts ( $P<0.05$ ) and proportion of cells in S-phase ( $P<0.05$ ). Our results support a higher penetrance of ALL susceptibility loci in the DS population, and may inform surveillance strategies for children with DS who are at the greatest risk of developing ALL.

**Multi-omics analysis of Ashkenazi Jewish melanoma patients reveals novel genetic markers of melanoma recurrence.** A. Archambault<sup>1</sup>, D. Simpson<sup>1</sup>, T. Hekal<sup>1</sup>, R. Ferguson<sup>1</sup>, E. Kazlow<sup>1</sup>, U. Moran<sup>2</sup>, Y. Lee<sup>2</sup>, A. Izsak<sup>2</sup>, M. Wilson<sup>2</sup>, R. Shapiro<sup>2</sup>, A. Pavlick<sup>3</sup>, I. Osman<sup>3</sup>, T. Kirchoff<sup>4</sup>. 1) Perlmutter Cancer Center, NYU Langone Health, New York, NY; 2) Department of Dermatology, NYU Langone Health, New York, NY; 3) Department of Surgery, NYU Langone Health, New York, NY; 4) Department of Medicine, NYU Langone Health, New York, NY.

A challenge in clinical management of cutaneous melanoma (CM) is the limited predictability of recurrence and hence the progression to advanced stages that associate with less favorable outcomes. Aggressive follow-up care and novel adjuvant therapy strategies in early-stage patients with high-risk of recurrence would likely improve CM-specific survival and reduce mortality. We developed a genome-wide approach to identify germline genetic determinants of melanoma prognosis as putative personalized biomarkers for patients at risk of CM recurrence. Exploring both the coding and non-coding transcribed genome we performed germline whole genome sequencing (WGS) and tumor RNA-seq on 96 CM patients with tumor/blood matched specimens. All patients were of primary stages I-IIb and of Ashkenazi Jewish ancestry to reduce genetic heterogeneity. We compared 48 patients that recurred in <4 years versus 48 patients with recurrence in > 6 years. Univariate and multivariate logistic regression, gene-burden analysis (SKAT), and differential expression analyses of both mRNA and long non-coding RNA (lncRNAs) were used to identify germline regions associated with melanoma recurrence. Several gene regions were associated with melanoma recurrence, with NEGR1 and MGST3 both passing SKAT levels of significance ( $p < 1e-05$ ), and logistic regression analysis on common WGS variants found over 100 variants with significance  $p < 1e-03$ . In addition, we found 200 differentially expressed putative lncRNAs ( $p < 0.05$ ). The analysis of germline WGS found rs199818927, a 1bp insertion previously associated with both NEGR1 and lncRNA LINC01360, among our top 5 most significant regression results (OR=9.107  $p=2.31e-05$ ). This initial phase of our large scale whole genome scan has uncovered germline variants in several coding loci and putative lncRNAs that associate with melanoma recurrence. Most notably, we identified germline variation in a lncRNA near NEGR1, a putative tumor suppressor that has been shown to be under-expressed in advanced cancers, indicating its putative role in cancer progression to metastatic stages. We are currently expanding the patient cohorts and validating these results.

**Association of non-homologous recombination genes with ovarian cancer using clinical exomes as controls.** K. Arvai, R. Torene, L. Susswein, M. Roberts, M. Marshall, Z. Zhang, K. Retterer, K. Hruska. GeneDx, Gaithersburg, MD.

The decreasing cost of next generation sequencing (NGS) has allowed clinical laboratories to expand hereditary cancer panels to include newer genes in addition to well-established cancer predisposition genes like *BRCA1* and *BRCA2*. The associations of newer genes with ovarian cancer have been inconsistently reported in the literature. While recent case-control studies have successfully leveraged publicly available genetic data to estimate various cancer associations these data are limited by lack of phenotype information. We aimed to improve ovarian cancer association estimates by using unaffected females as controls and including age as a covariate in a case-control study to estimate ovarian cancer association with pathogenic variants (PV) in *ATM*, *BARD1*, *BRCA1*, *BRCA2*, *BRIP1*, *CHEK2*, *NBN*, *PALB2*, *RAD51C*, and *RAD51D*. Cases were women with ovarian cancer referred for hereditary cancer multi-gene panel testing. Controls were mothers with no reported family history of cancer selected from a genotyped cohort of 10,138 complete trios who were referred for exome sequencing. Both cases and controls were limited to those of European ancestry. Classification of sequence variants in cases and controls was based on the AMP/ACMG guidelines. Individuals with multiple PVs were excluded. We performed simple and multiple logistic regression to generate crude and adjusted odds ratios (OR). The sample population consisted of 6,220 unique cases and 5,629 controls. The mean age of diagnosis in cases (58.7y) and age of testing in controls (41.8y) were significantly different (t-test,  $p < 0.05$ ). The PV carrier frequency in the controls ranged from 0.04% in *BARD1*, *RAD51C*, and *RAD51D* to 1.0% in *CHEK2*. The PV carrier frequency in the cases ranged from 0.08% in *BARD1* to 3.7% in *BRCA1*. Associations in *BRIP1* and *PALB2* have previously been reported with ovarian cancer. Both genes had 95% confidence intervals (CI) >1.0 by crude OR ( $p=0.01$ ,  $p=0.04$ ), but adjusted CI were <1.0 ( $p=0.99$ ,  $p=0.20$ ), indicating no association with ovarian cancer. We show that case-control studies using internal controls from clinical labs provide valuable information for genotype-phenotype associations. Using a statistical model, we were able to reproduce moderate to strong associations in genes that have been reported with ovarian cancer such as *BRCA1*, *BRCA2*, *RAD51C*, and *RAD51D*. Results from our novel approach provide reliable evidence suggesting that *BRIP1* and *PALB2* are not associated with ovarian cancer.

**745T**

**Validation of a prostate cancer genetic risk score for clinical use.** *M.H. Black<sup>1</sup>, S. Li<sup>1</sup>, H. LaDuca<sup>1</sup>, J. Chen<sup>1</sup>, R. Hoiness<sup>1</sup>, S. Gutierrez<sup>1</sup>, B. Tippin Davis<sup>1</sup>, H.M. Lu<sup>1</sup>, M. Gielzak<sup>2</sup>, K. Wiley<sup>2</sup>, Z. Shi<sup>2</sup>, H. Yu<sup>2</sup>, B.T. Helfand<sup>2</sup>, W. Isaacs<sup>3</sup>, J. Xu<sup>2</sup>.* 1) Ambry Genetics, Aliso Viejo, CA; 2) Northshore University Health System, Evanston, IL; 3) Johns Hopkins University, Baltimore, MD.

**Background:** Genome-wide association studies (GWAs) have identified over 100 common single nucleotide polymorphisms (SNPs) associated with prostate cancer (PrCa) risk. While the risk associated with each SNP is modest, a genetic risk score (GRS) based on their combined genotypes may have substantial predictive value for risk stratification. The overarching goal of this study is to provide evidence for the analytical and clinical validity, as well as clinical utility, of a PrCa GRS in the patient care setting. **Methods:** We genotyped 73 PrCa-associated SNPs using next-generation sequencing in order to examine whether a risk score based on these SNPs was predictive of PrCa in 3,148 Caucasian men (1,731 cases who had previously undergone radical prostatectomy and 1,417 controls unaffected with PrCa) from a large, multi-site collaborative study. We constructed a population-standardized GRS, with each SNP weighted by per-allele relative risks in Caucasians from large GWAs and population-specific allele frequencies, and tested GRS association with PrCa using multivariate logistic regression models adjusted for age alone, as well as age and family history of PrCa. **Results:** Mean±SD age of PrCa cases at diagnosis and age of controls at the time of testing or last clinic visit was 59.0±6.7 and 55.7±11.1 years, respectively. Among cases, 58.5% had Gleason score ≤6, while 41.5% had Gleason ≥8. In addition, 38.1% of cases and 16.5% of controls had ≥1 first- or second-degree relative with PrCa, and 6.4% of cases and 3.9% of controls tested positive for mutations in PrCa predisposition genes. The GRS was significantly higher in cases than controls (mean±SD 1.79±2.97 vs. 1.01±0.46,  $p<0.0001$ ). Compared to men in the 1<sup>st</sup> quartile of age-adjusted GRS, those in the 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> quartile were 1.66 (95% CI: 1.35-2.04), 2.34 (95% CI: 1.90-2.88) and 3.77 (95% CI: 3.04-4.69) times as likely to have PrCa (all  $p<0.0001$ ). Additional adjustment for family history among the subset of patients with this information yielded similar results. GRS predictive performance was consistent with prior literature (AUROC=0.64, 95% CI: 0.62-0.66). **Conclusions:** These data suggest that a 73-SNP GRS is predictive of PrCa. Our ongoing analyses will include GRS association with clinical features of PrCa, validation in non-Caucasian populations, and interaction with high- and moderate-penetrance PrCa predisposition genes, as well as clinical utility for personalized PrCa screening.

**Evaluation of the impact of rare-variants on adrenocortical carcinoma susceptibility.** *R.J. Bohlender, Y. Yu, C. Huff.* Epidemiology, University of Texas MD Anderson Cancer Center, Houston, TX.

Evaluation of the Impact of Rare-Variants on Adrenocortical Carcinoma Susceptibility Authors: Ryan Bohlender, Yao Yu, Chad Huff Adrenocortical Carcinoma (ACC) is a rare form of cancer, with an incidence estimate as low as 1 to 2 per million per year. As a rare disease, epidemiological data is lacking and the underlying etiology of the disease, both environmental and genetic, is poorly understood. We conducted a whole-exome sequencing case-control study involving 75 ACC cases of European ancestry from The Cancer Genome Atlas (TCGA) and 3507 controls of European ancestry from the National Database for Autism Research (NDAR) to investigate sources of risk. We used the Variant Annotation, Analysis, and Search Tool (VAASST) to conduct a case-control association analysis. VAASST is a gene-based test, which leverages variant level information about phylogenetic conservation and amino acid substitution to prioritize variants likely to influence protein function. Due to differences in sequencing platforms, laboratory preparation, and capture technologies, we initially observed high levels of Type I error inflation. We used the Cross Platform Association Toolkit (XPAT), which is designed to control for cross-platform artifacts in association studies with heterogeneous sequencing datasets. Using XPAT, we observed consistency between empirical and observed p-values to alpha levels of 0.005. Application of Phevor2, which leverages phenotype ontology databases to reorder gene rankings establishes *KCNJ10* and *NF1* as the first and second ranked genes. We find *NF1* to be nominally significant in VAASST ( $p=0.00122$ ), and its associated syndrome Neurofibromatosis Type 1, has been previously associated with ACC susceptibility. To estimate the additional risk of ACC contributed by mutations in *NF1*, we calculated gene-level odds ratios. Rare coding variants in *NF1* result in an estimated 3.4-fold (1.2, 8.0) increase in relative risk. The gene *KCNJ10* has not been previously associated with ACC, but is nominally significant in the VAASST analysis ( $p=0.00041$ ), and results in an estimated 6.1-fold (1.5, 17.9) increase in relative risk. *KCNJ10* is involved in SeSAME Syndrome, which causes, e.g., epilepsy and deafness. .

**A novel statistical model for GWAS to identify somatic mutation effects using matched data.** *Y. Bu, M. Chen.* The University of Texas at Dallas, Richardson, TX.

Genome-wide association studies (GWAS) has emerged as a useful tool to identify common genetic variants that are linked to complex diseases. Conventional GWAS are based on the case-control design where the individuals in cases and controls are independent. In cancer research, matched pair designs, which compare tumor tissues with normal ones from the same subjects, are becoming increasingly popular. Such designs succeed in identifying somatic mutations in tumors while controlling both germline and environmental factors. Somatic variation is one of the most important cancer risk factors that contribute to continuous monitoring and early detection of various cancers. However, most GWAS analysis methods, developed for unrelated samples in case-control studies, cannot be employed in the matched pair designs. A novel framework is proposed in this manuscript to accommodate for the particularity of matched-data in association studies of somatic mutation effects. In addition, we develop a Bayesian model to combine multiple markers to further improve the power of mapping genome regions to cancer risks.

**Variants in the PSCA gene associated with risk of cancer and non-neoplastic diseases: Systematic research synopsis, meta-analysis and epidemiological evidence.** *H. Cui<sup>1</sup>, M. Zhang<sup>1</sup>, M. Tang<sup>1</sup>, S. Chen<sup>1</sup>, Y. Fang<sup>1</sup>, S. Liu<sup>1</sup>, Z. Zeng<sup>1</sup>, Z. Shen<sup>1</sup>, J. Lu<sup>2</sup>, D. Gu<sup>1</sup>, B. Zhang<sup>1,2,3</sup>.* 1) Department of Epidemiology and Biostatistics, First Affiliated Hospital and Southwest School of Medicine, Army Medical University, Chongqing, 400038, China; 2) Department of Epidemiology, School of Public Health, Institute for Chemical Carcinogenesis, Guangzhou Medical University, Guangzhou, 510182, China; 3) Department of Epidemiology, School of Public Health, Shanghai Jiaotong University School of Medicine, Shanghai, 200025, China.

Variants in the *PSCA* gene have been linked with risk of multiple cancers and other diseases, yet with generally inconsistent results. We did a comprehensive research synopsis and meta-analysis to evaluate associations between variants in the *PSCA* gene and cancer and non-neoplastic diseases risk based on 54 articles including 81 657 cases and 442 693 controls. Venice criteria and false-positive report probability tests were used to grade the cumulative evidence of significant associations. Six variants showed a significant association with assessed diseases ( $P < 0.05$ ). Cumulative epidemiological evidence of an association was graded as strong for rs2294008 [odds ratio (OR) = 1.32,  $P = 5.10 \times 10^{-33}$ ], rs2976392 (OR = 1.30,  $P = 7.39 \times 10^{-12}$ ), rs9297976 (OR = 0.75,  $P = 1.36 \times 10^{-7}$ ), and rs138377917 (OR = 0.53,  $P = 0.008$ ) with gastric cancer, rs2294008 with bladder cancer (OR = 1.15,  $P = 1.50 \times 10^{-16}$ ), duodenal ulcer (OR = 1.49,  $P = 2.23 \times 10^{-61}$ ), gastric ulcer (OR = 1.13,  $P = 6.36 \times 10^{-7}$ ), and gastritis (OR = 1.35,  $P = 1.19 \times 10^{-5}$ ). Moderate evidence was graded for rs12155758 (OR = 1.19,  $P = 0.002$ ) and rs2976391 (OR = 1.38,  $P = 6.07 \times 10^{-5}$ ) with gastric cancer. Functional annotation suggested these variants might fall in a region with strong enhancer activity. Our study provides summary evidence that variants in *PSCA* gene are associated with risk of gastric, bladder, and non-neoplastic disease and highlights its significant role in the pathogenesis of these diseases.

## 749F

**Using germline variants to predict glioma risk and identify glioma subtype pre-operatively.** J. Eckel-Passow<sup>1</sup>, P. Decker<sup>1</sup>, M. Kosel<sup>1</sup>, T. Kollmeyer<sup>1</sup>, A. Molinaro<sup>2</sup>, T. Rice<sup>2</sup>, A. Caron<sup>1</sup>, K. Drucker<sup>1</sup>, C. Praska<sup>1</sup>, M. Pekmezci<sup>2</sup>, H. Hansen<sup>2</sup>, L. McCoy<sup>2</sup>, P. Bracci<sup>2</sup>, B. Erickson<sup>1</sup>, J. Wiemels<sup>2</sup>, J. Wiencke<sup>2</sup>, M. Bondy<sup>2</sup>, B. Melin<sup>4</sup>, T. Burns<sup>1</sup>, C. Giannini<sup>1</sup>, D. Lachance<sup>1</sup>, M. Wrensch<sup>2</sup>, R. Jenkins<sup>1</sup>. 1) Mayo Clinic, Rochester, MN; 2) University of California, San Francisco, CA; 3) Baylor College of Medicine, Houston, TX; 4) Umea University, Umea, Sweden.

**Background:** Twenty-five single nucleotide polymorphisms (SNPs) are associated with overall glioma risk or with risk of specific subtypes of glioma. We hypothesized that the inclusion of these 25 SNPs with age at diagnosis and sex could predict risk of glioma as well as identify glioma subtypes. **Methods:** Case-control design and multinomial logistic regression were used to develop models to estimate the risk of glioma development while accounting for histologic and molecular subtypes. Case-case design and logistic regression were used to develop models to predict IDH mutation status. Each model included all 25 glioma risk SNPs, patient age at diagnosis and sex. A total of 1273 glioma cases and 443 controls from Mayo Clinic were used in the discovery set, and 852 glioma cases and 231 controls from UCSF were used in the validation set. All samples were genotyped using a custom Illumina OncoArray. **Results:** Patients in the highest 5% of the risk score had more than a 14-fold increase in relative risk of developing an IDH-mutant glioma. Large differences in lifetime absolute risk were observed at the extremes of the risk score percentile. For both IDH-mutant 1p/19q non-codeleted glioma and IDH-mutant 1p/19q-codeleted glioma, the lifetime risk increased from almost null to 2.3% and almost null to 1.7%, respectively. The SNP-based model that predicted IDH mutation status had a validation c-index of 0.85. **Conclusions:** These results suggest that germline genotyping has the potential to provide a new tool for clinicians for the initial management of newly-discovered brain lesions. Specifically, given the low lifetime risk of glioma, SNP-based risk scores should not be useful for population screening. However, they may be useful in certain clinically-defined high-risk groups.

## 750W

**Immuno-modulatory pathways impact genetic susceptibility to the development of multiple primary melanomas.** R. Ferguson<sup>1</sup>, A. Archambault<sup>1</sup>, D. Simpson<sup>1</sup>, E. Kazlow<sup>1</sup>, R. Lax<sup>1</sup>, U. Moran<sup>2</sup>, M. Wilson<sup>3</sup>, R. Shapiro<sup>4</sup>, A. Pavlick<sup>2</sup>, I. Osman<sup>2</sup>, D. Polsky<sup>2</sup>, T. Kirchhoff<sup>1</sup>. 1) Perlmutter Cancer Center, NYU Langone Health, New York, NY; 2) Department of Dermatology, NYU Langone Health, New York, NY; 3) Department of Medicine, NYU Langone Health, New York, NY; 4) Department of Surgery, NYU Langone Health, New York, NY.

During their lifetime about 8% of patients with single primary cutaneous melanoma (SPM) will develop multiple primary melanomas (MPM), which are associated with significantly higher mortality compared to patients with SPM. Based on the evidence that the immune system plays a role in regulating melanoma progression we explored whether germline genetic variants controlling the expression of immunomodulatory genes (immunomodulatory quantitative trait loci, eQTLs) discern risk of MPM compared to patients with SPM or healthy controls. Previously, we identified 50 eQTLs significantly associated with the expression of 265 immunomodulatory genes using the MuTHER twin cohort. These 50 SNPs were genotyped in 837 SPM and 104 MPM individuals using MassARRAY system. 1047 healthy controls were obtained from a publically available GWAS on CM ascertained at MD Anderson (phs000187.v1.p1). We employed multivariate logistic regression to test the association of SNPs with MPM vs cancer-free controls and MPM vs SPM. When comparing MPM vs SPM, rs2071304, previously linked to expression of *SPI1* in MuTHER data, showed a strong association with reduction of MPM risk (OR= 0.60; 95% CI=0.45-0.81; p=0.0007). Intriguingly, this variant also trended toward significance when comparing MPM vs controls (OR=0.61; 95% CI: 0.44-0.85; p=0.003). Finally, our most significant association when comparing MPM to controls was for rs2276645 (OR= 0.60; 95% CI=0.45-0.81; p= 0.0008), an eQTL associated with *Zap-70* expression. Our data, for the first time, indicate that the inherited host immunity impacts risk of MPM in individuals with SPM, highlighting an importance of immune involvement in melanoma progression. The MPM risk-predicting genetic variants identified here or in expanded efforts, currently underway, may eventually lead to a diagnostic tool allowing for enhanced screening and clinical management of patients at risk of MPM, hence reducing elevated MPM-associated mortality. Additionally, our results further support that MPM and SPM may have different genetics underpinnings and should be treated as separate clinical entities.

## 751T

**PSCA in multiple cancer types: Association with cancer risk and survival.** O. Florez-Vargas<sup>1</sup>, C. Tanikawa<sup>2</sup>, W. Yan<sup>1</sup>, K. Matsuda<sup>2</sup>, L. Prokunina-Ols-son<sup>1</sup>. 1) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, US National Institutes of Health, Bethesda, Maryland, USA; 2) Laboratory of Molecular Medicine, Human Genome Center, Institute of Medical Science, University of Tokyo, Tokyo, Japan.

A common single nucleotide polymorphism (SNP) rs2294008 in the Prostate Stem Cell Antigen (*PSCA*) gene has been associated with susceptibility to bladder and gastric cancer in genome-wide association studies. Here, we performed a comprehensive analysis of association of rs2294008 in multiple cancer types. A logistic regression analysis was performed for this SNP to calculate odds ratios and 95% confidence intervals controlling for age and sex in Europeans (20K cases representing 11 cancer types and 13K controls) and Japanese (34K cases representing 14 cancer types and 138K controls). We also evaluated *PSCA* expression in relation to this SNP in 9877 samples representing 46 normal tissue types in the Genotype-Tissue Expression (GTEx) project, and in 8510 tumor samples in 33 cancer types in The Cancer Genome Atlas (TCGA). Of cancers explored both in Europeans and Japanese, rs2294008 was significantly ( $p < 0.05$ ) associated with risk of bladder cancer and suggestively, with ovarian cancer. Additionally, rs2294008 was associated with risk of kidney, pancreatic and prostate cancer in Europeans and gastric and lung cancer in Japanese. In GTEx, *PSCA* expression was increased with the risk rs2294008-T allele in 35 of 46 normal tissue types, whereas in TCGA, increased *PSCA* expression was significantly ( $p < 0.05$ ) associated with rs1045574-A allele (a proxy of the risk rs2294008-T allele;  $R^2 = 0.99$  and  $D' = 0.98$ ) in 23 out of 33 cancer types based on 5000 permutations and controlling for relevant covariates. A multivariate Cox regression survival analysis was carried out in the TCGA dataset for gene expression categorized in terciles and genotype according to dominant model. We showed that patients with the highest compared to the lowest *PSCA* gene expression (third vs. first tercile) had significantly lower survival of breast, kidney and pancreatic cancer, acute myeloid leukemia, mesothelioma, sarcoma, and thymoma, and better survival of bladder cancer. The risk rs2294008-T allele was associated with decreased survival of kidney cancer, mesothelioma, adrenocortical carcinoma and increased survival of rectum adenocarcinoma. Taken together, these results suggest that the rs2294008-T allele in *PSCA* is a multi-cancer susceptibility variant, which significantly increases the mRNA expression of *PSCA* in multiple normal and cancer tissue types. In addition, both *PSCA* mRNA expression and SNP contribute to survival of patients with multiple cancer types.

## 752F

**Association of race, socioeconomic status and stress with Decipher® genomic classifier risk scores and gene expression: Implications on prostate cancer personalized treatments.** A. Grover, S. Greenfield, S. Kaplan, R. Stevenson, E. Uchio. University of California, Irvine, Irvine, CA.

**Introduction:** The Decipher® genomic classifier risk prediction model was developed to predict early metastasis in prostate cancer patients. It was recently incorporated into the National Comprehensive Cancer Network clinical practice guidelines for prostate cancer prognostication and treatment decisions in patients on active surveillance. Decipher scores range from 0 to 1 and are categorized as: 0-0.45, 0.45-0.6, and 0.6-1 indicating low, intermediate, and high-risk of metastasis, respectively. Various factors (race, socioeconomic status (SES) and stress) might influence these predictions. Additionally, gene expression markers like *EZH2*, *GSTP1* and *TOP2A* (included in Decipher gene expression panel) are associated with DNA methylation changes and elevated risk of metastasis in prostate cancer. Decipher scores and gene expression markers were not previously studied for their association with race, SES and stress levels prospectively and therefore, we intended to study these associations in a prospective cohort study. **Methods:** We analyzed the mean Decipher scores and gene expression markers in different races, SES levels (defined by years of education) and stress (composite measure of self-reported long term stress) using one way analysis of variance and linear regression respectively, with adjustment for confounders (age, race and marital status).

**Results:** We found that out of 108 prostate cancer patients from five different hospitals in Southern California, there were 56 Whites, 35 Blacks, 5 Hispanics, 6 Asians, 3 mixed race and 3 other races who had mean Decipher scores of  $0.39 \pm 0.22$ ,  $0.44 \pm 0.22$ ,  $0.55 \pm 0.10$ ,  $0.59 \pm 0.13$ ,  $0.41 \pm 0.31$ ,  $0.45 \pm 0.32$  respectively ( $p = 0.05$ ). There was a 0.5% increase in 5-year predicted metastasis risk with every additional year of education. African Americans and higher SES individuals had higher levels of stress as compared with Whites ( $p = 0.006$ ) and lower SES individuals ( $p = 0.005$ ). Patients with high stress had higher Decipher scores ( $p = 0.04$ ) independent of race and SES. There was a differential gene expression of *EZH2*, *GSTP1* and *TOP2A* in African Americans and patients with high SES and stress. **Conclusions:** These results could provide an epigenetic molecular framework to understand potential influences of race, SES and stress levels on Decipher scores and risk of metastasis in prostate cancer patients. These associations could help formulate predictive models for prostate cancer outcomes and personalized treatments.

## 753W

**COMT modifies vitamin E effects in cancer prevention: Gene-supplement interactions in two randomized clinical trials.** K. Hall<sup>1,2</sup>, J. Buring<sup>1,2</sup>, K. Mukamal<sup>2,3</sup>, V. Moorthy<sup>1</sup>, P. Wayne<sup>1,2</sup>, T. Kaptchuk<sup>2,3</sup>, E. Battinelli<sup>1,2</sup>, P. Ridker<sup>1,2</sup>, H. Sesso<sup>1,2</sup>, S. Weinstein<sup>4</sup>, D. Albanes<sup>4</sup>, N. Cook<sup>1,2</sup>, D. Chasman<sup>1,2</sup>. 1) Brigham and Women's Hospital, Boston, MA; 2) Harvard Medical School, Boston, MA; 3) Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA; 4) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Bethesda, MD.

**Background:** Vitamins are among the most frequently used supplements (48% of US adults). However, little is known about contributions of genetic variation to their efficacy and safety. Multiple pathways link catechol-O-methyltransferase (COMT) to vitamin E (alpha-tocopherol) and cancer. **Methods:** Here we determined if COMT exerted pharmacogenetic effects on cancer prevention in two randomized trials of vitamin E supplementation. Pharmacogenetic effects of common COMT rs4680 (val158met), which encodes a non-synonymous valine-to-methionine substitution, were examined in trial and 10-year post-trial follow-up periods of The Women's Genome Health Study (WGHS, N=23,294), a 10-year vitamin E and aspirin trial with 10 years post-trial follow-up. Results were validated in a case (N=2396)/control (N=2235) subset of the Alpha-Tocopherol Beta-Carotene Cancer Prevention Study (ATBC, N=29,133). The primary outcome was total cancers in the overall period (trial plus 10-year posttrial). Rates of cancer types prevalent in women (colorectal, breast, lung, uterine, and lymphoma/leukemia) were also examined. **Results:** Random-effects meta-analysis of rs4680 genotype strata, in WGHS and ATBC overall periods, revealed differential vitamin E effects compared to placebo: met/met (HR, 0.88; 95% CI, 0.80-0.97; P=0.01); val/met (HR, 0.99; 95% CI, 0.92-1.06; P=0.74) and val/val (HR, 1.18; 95% CI, 1.06-1.31; P=0.002) with a significant COMT-by-vitamin E interaction (Pinteraction=6E-05). Timing of effects differed, with stronger effects in WGHS trial and ATBC post-trial periods. **Conclusion:** Pharmacogenetic analysis of COMT and cancer prevention in two large randomized trials revealed significant COMT-by-vitamin E interactions, such that vitamin E was beneficial among rs4680 met-allele (28%), but not val-allele (22%) homozygotes. These results suggest genetic testing may be helpful in guiding use of over-the-counter supplements like vitamin E for cancer prevention.

## 754T

**Deep targeted tumor sequencing of colorectal cancer cases to study associations of molecular subtypes with clinical, genetic, and lifestyle risk factors.** T.A. Harrison<sup>1</sup>, S. Zaidi<sup>2</sup>, A.I. Phipps<sup>1</sup>, R. Steinfeld<sup>1</sup>, Q.M. Trinh<sup>2</sup>, B.L. Banbury<sup>1</sup>, P. Hofer<sup>2</sup>, S. Brezina<sup>2</sup>, C. Grasso<sup>4</sup>, M. Giannakis<sup>5</sup>, M. Quist<sup>1</sup>, C.S. Fuchs<sup>6</sup>, L.A. Garraway<sup>6</sup>, L. Hsu<sup>1</sup>, L. Stein<sup>2</sup>, A. Gsur<sup>8</sup>, S. Ogino<sup>7</sup>, S. Gallinger<sup>6</sup>, P.A. Newcomb<sup>1</sup>, P.T. Campbell<sup>9</sup>, W. Sun<sup>1</sup>, T.J. Hudson<sup>2</sup>, U. Peters<sup>1</sup>. *Deep targeted tumor sequencing in a sizeable set of colorectal cancer cases and associations of tumor.* 1) Fred Hutchinson Cancer Research Center, Seattle, WA; 2) Ontario Institute for Cancer Research, Toronto, ON, Canada; 3) Medical University of Vienna, Vienna, Austria; 4) University of California, Los Angeles, CA; 5) Dana Farber Cancer Institute, Boston, MA; 6) Yale Cancer Center, New Haven, CT; 7) Harvard Medical School, Boston, MA; 8) Mount Sinai Hospital, Toronto, ON, Canada; 9) American Cancer Society, Atlanta, GA.

Colorectal cancer (CRC) has considerable intertumoral heterogeneity, and while sequencing has enabled improved characterization and definition of subtypes, the relationship of CRC subtypes to patient survival, genetics, and epidemiologic risk factors has not been comprehensively studied in a sizeable population. We sequenced nearly 2,400 CRC tumors and matched normal tissue from the Colon Cancer Family Registry (CCFR) and Genetics and Epidemiology of Colorectal Cancer Consortium (GECCO) using a targeted AmpliSeq panel of CRC related genes and genomic regions, as well as homopolymer repeats to evaluate microsatellite stability. Mean coverage was 740x for DNA from FFPE tumor and 240x for matched normal samples. We used Strelka and MuTect to call somatic single nucleotide variants, VarScan2, VarDict and Strelka to call indels, and GATK to identify copy number alterations. We identified non-silent mutations in genes belonging to the WNT (77%), p53 (44%), IGF2/PI3K (22%), RTK-RAS (47%), and TGF-beta (26%) signaling pathways. Among the 15% of hypermutated tumors, 39% exhibited non-silent mutations in *MLH1*, *MLH3*, *MSH2*, *MSH6*, and *PMS2* and 41% exhibited non-silent mutations in *POLE* and *POLD1*. In a subset of studies with clinical outcomes data, we used Cox proportional hazards regression to estimate adjusted hazard ratios (HRs) and 95% CIs for the association of mutated genes and pathways with CRC-specific survival (CSS) and overall survival (OS). As expected, OS and DSS were significantly more favorable among individuals with hypermutated vs. non-hypermutated tumors, regardless of *POLE* mutations (HR=0.80, 95% CI: 0.63-1.01, p=0.04 and HR=0.36, 95% CI: 0.22-0.59, p=2x10<sup>-6</sup>, respectively). There was no significant association of mutations in WNT, p53, IGF2/PI3K, RTK-RAS, or TGF-beta pathways with survival outcomes. We are further analyzing tumor features defined from our targeted sequencing data in relation to germline genetics and epidemiologic risk factors. Comprehensive molecular characterization of this sizeable set of CRC cases, and analyses relating tumor subtypes to CRC survival and risk factors will help to better elucidate the underlying carcinogenic mechanisms that drive CRC survival and risk.

**Application of a joint longitudinal mixed model and survival model to genetic analysis of advanced neoplasia in a colonoscopy screening cohort.** E.R. Hauser<sup>1,2</sup>, X. Qin<sup>1,2</sup>, T. Hyslop<sup>1,2</sup>, Y. Li<sup>2</sup>, K.J. Sims<sup>1</sup>, A. Stone<sup>3</sup>, M.C. O'Leary<sup>1</sup>, T.S. Redding IV<sup>1</sup>, Z.F. Gellad<sup>1,2</sup>, A. Madison<sup>1</sup>, B. Sullivan<sup>1,2</sup>, D. Lieberman<sup>4,5</sup>, D. Provenzale<sup>1,2</sup>. 1) Durham VA Health Care System, Durham, NC, USA; 2) Duke University, Durham, NC, USA; 3) Central Arkansas Veterans Health System, Little Rock, AR, USA; 4) Portland VA Medical Center, Portland, OR, USA; 5) Oregon Health and Science University, Portland, OR, USA.

Repeated measures of a phenotype may provide additional information about the presence of germline susceptibility variants for complex traits. Cohort studies following participants over time and making multiple phenotypic measurements provide such data, however, such studies also suffer from loss to follow-up and death of participants. Our goal in this work is to evaluate a Bayesian joint model that fits a mixed random effects model to the longitudinal binary outcomes along with a survival model in a colorectal cancer (CRC) screening study. The Department of Veteran Affairs (VA) Cooperative Study 380 is a longitudinal study of 3121 asymptomatic and otherwise healthy participants aged 50-75 from 13 VA Medical Centers who had a screening colonoscopy between 1994-1997. Participants were followed over 10 years capturing the histopathological outcomes for all colonoscopies or other colon cancer screening tests along with ascertainment of vital status from the National Death Index and the VA Electronic Medical Record (EMR). Advanced neoplasia (AN) at each colonoscopy was defined using pathology reports indicating at least one polyp with tubular adenoma  $\geq 10$  mm, adenoma with villous histology, adenoma with high-grade dysplasia or invasive cancer. Time to death from all causes or time to last visit was recorded. A total of 612 individuals were genotyped on the Illumina Infinium Omni2.5-8 v1.3 Beadchip with 2,369,593 (99.8%) high-quality markers for analysis. In this study we analyzed the European-American participants and selected SNPs with MAF  $> 0.05$ . We concentrated on 135 candidate SNPs associated with CRC or AN in other studies. We fit a mixed random effects model to all colonoscopies including SNP genotype along with age and two genetic principal components (PCs). We also fit a Cox proportional survival model to time to death including SNP genotype along with age, comorbidity count and 2 PCs. We then fit the Bayesian joint model (R package JMBayes) that joins the mixed and survival models. We compared results from the input longitudinal model to the result for AN risk from the joint model. The effect size estimates were in excellent agreement ( $\rho=0.99$ ); however, the standard errors from the joint model were much smaller potentially resulting in anti-conservative detection p-values. We successfully implemented the joint model in this genetic analysis; however, more work is required to correctly calibrate the results for gene discovery.

**756W**

**Genetic interaction analysis among oncogenesis-related genes revealed novel genes in lung cancer development.** Y. Li<sup>1</sup>, X. Xiao<sup>2</sup>, I. Gorlov<sup>1</sup>, Y. Han<sup>1</sup>, R. Hung<sup>3</sup>, C. Amos<sup>2</sup> *OncoArray Consortium*. 1) Biomedical Data Science Department, Dartmouth Geisel School of Medicine, Lebanon, NH 03756; 2) Baylor College of Medicine, Institute of Clinical and Translational Research, One Baylor Plaza, Houston, TX 77030; 3) Prosserman Centre for Population Health Research, Lunenfeld-Tanaka Research Institute, Sinai Health System, Toronto, ON M5T 3L9.

Cancer is driven by the accumulation of many genetic variants that may act epistatically. We hypothesize that there are substantial interactions among oncogenesis-related genes in the early development of cancer. To explore epistasis among oncogenesis-related genes in lung cancer development, we conducted a filtered pairwise genetic interaction analysis among 35,031 SNPs from 2027 oncogenesis-related genes selected from cancer gene catalogs. To provide sufficient power for the proposed analysis, we collected the genotype data from 44,438 individuals, including 20,401 controls and 24,037 cases, from three independent cohorts. We first conducted an efficient epistasis analysis using 'fast-epistasis' option in PLINK and then validated the signals using standard logistic regression interaction analysis in a discovery cohort comprising of 18,401 cases and 14,260 controls from OncoArray lung cancer consortium. Candidate SNP pairs were further submitted to replication study including 5,636 cases and 6,141 controls from two independent genome-wide association studies. SNP pairs with interaction p value  $< 5 \times 10^{-10}$  in joint analysis were reported as significant signals. Genetic interactions in *RGL1:RAD51B* (OR=0.44, p value= $3.27 \times 10^{-11}$  in overall lung cancer and OR=0.41, p value= $9.71 \times 10^{-11}$  in non-small cell lung cancer), *SYNE1:RNF43* (OR=0.73, p value= $1.01 \times 10^{-12}$  in adenocarcinoma) and *FHIT:TSPAN8* (OR=1.82, p value= $7.62 \times 10^{-11}$  in squamous cell carcinoma) gene pairs were identified in our analysis. None of these genes have been identified from previous main effect association studies in lung cancer. The candidate gene pairs with suggestive evidence (p value  $< 0.05$ ) in replication study were further submitted to gene set enrichment analysis using the Ingenuity Pathway Analysis program. Potential pathways and gene networks underlying the identified genetic interactions were revealed in lung cancer development. The identified adenocarcinoma- and squamous cell carcinoma- specific genetic interactions also suggested differences in epistasis and signaling pathways involved in lung cancer subtype tumorigenesis and enhance our understanding of the molecular mechanisms underlying different subtype of lung cancer diseases. Our results provide evidence that genetic epistasis is an important mechanism involved in lung tumorigenesis and several latent genes may contribute to lung cancer development by interacting with other modifier genes.

## 757T

**A pan-cancer GWAS of metastasis identified a novel metastasis susceptibility loci.** M. Machado<sup>1</sup>, M. Dean<sup>1</sup>, M. Yeager<sup>1,2</sup>, E. Karlins<sup>2</sup>, N. Chatterjee<sup>2</sup>, N. Freedman<sup>1</sup>, W. Huang<sup>1</sup>, S. Chanock<sup>1</sup>, N. Caporaso<sup>1</sup>, L. Mirabello<sup>1</sup>. 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, NIH, Bethesda, MD, USA; 2) Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD, USA; 3) Department of Biostatistics, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA.

Metastasis is responsible for about 90% of cancer deaths. Discovering new genes and biological pathways in metastasis is critical to understanding its process and developing new strategies for treatment. Although the clinical course for each type of cancer occurs with distinct kinetics and favors unique organ sites, it is possible that shared inherited variation in genes that accelerate or retard cellular activities critical to the complex process of metastasis may impact the clinical onset of metastatic disease for solid tumors in general. The contribution of germline genetic variation to metastasis susceptibility is unknown. Therefore, to determine if germline genetic variation contributes to risk of metastatic disease across solid cancers, we performed the first pan-cancer metastasis GWAS of 13,153 cancer cases, including nine cancer types (lung, breast, ovarian, kidney, pancreas, stomach, testis, endometrial, and prostate). Genotype data was combined for a common set of SNPs from ten distinct GWAS studies conducted at the Division of Cancer Epidemiology and Genetics (DCEG), National Cancer Institute. The clinical phenotype data was carefully harmonized across all studies based on information on the TNM staging system and disease stage to define metastasis. We compared 2,725 cancer cases with advanced stage IV, metastatic disease, to 10,428 cases with early stage, localized disease, using Plink software adjusting for relevant covariates. Case data was pooled for a combined association analysis and also each cancer type was analyzed separately and combined using the statistical tool ASSET, which is able to test association to a subset of the studies and allows opposing effects on different phenotypes. Our preliminary combined results identified a novel locus in a gene desert at 13q33 significantly associated with metastatic disease across cancers (OR=1.72, 95% CI, Padj=2.2x10<sup>-7</sup>). Several other compelling loci were significantly associated in subsets of cancers with risk of metastasis and with site of metastatic disease (e.g., metastasis to the liver). We have assembled a replication set of approximately 30k additional solid cancer cases with information on metastatic disease to validate our findings. Our data suggest that novel germline loci are associated with shared metastasis susceptibility across multiple solid cancer types, and if our findings replicate, this could have importance as a prognostic marker with potential to improve patient management.

## 758F

**IFNL4-DG allele is associated with an interferon signature in tumors and survival of African-American men with prostate cancer.** L. Prokunina-Olsson<sup>1</sup>, W. Tang<sup>2</sup>, T. Wallace<sup>2</sup>, M. Yi<sup>2</sup>, C. Magi-Galluzzi<sup>4</sup>, T. Dorsey<sup>2</sup>, O. Onabajo<sup>1</sup>, A. Obajemu<sup>1</sup>, S. Jordan<sup>2</sup>, S. Loffredo<sup>2</sup>, C. Stephens<sup>2</sup>, R. Silverman<sup>1</sup>, G. Stark<sup>4</sup>, E. Klein<sup>4</sup>, S. Ambbs<sup>2</sup>. 1) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics (DCEG), NCI, NIH, Bethesda, MD, USA; 2) Laboratory of Human Carcinogenesis, Center for Cancer Research (CCR), NCI, NIH, Bethesda, MD, USA; 3) Advanced Biomedical Computing Center, Leidos Biomedical Research, NCI, Frederick, MD, USA; 4) Pathology, Lerner Research Institute, and Glickman Urological and Kidney Institute, Cleveland Clinic, Cleveland, OH, USA; 5) Cancer Prevention and Control Program, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC, USA.

Men of African ancestry experience an excessive prostate cancer mortality which could be related to an aggressive tumor biology. We previously described an immune-inflammation signature in prostate tumors of African-American patients. Here, we further deconstructed this signature and investigated its relationships with tumor biology, survival, and a common germline variant in the interferon lambda 4 (*IFNL4*) gene. We analyzed gene expression in prostate tissue datasets and performed genotype and survival analyses. We also overexpressed *IFNL4* in human prostate cancer cells. We found that a distinct interferon signature that is analogous to the previously described "Interferon-related DNA Damage Resistance Signature" (IRDS) occurs in prostate tumors. Evaluation of two independent patient cohorts revealed that IRDS occurs about twice as often in prostate tumors of African-American than European-American men. Furthermore, analysis in The Cancer Genome Atlas (TCGA) showed an association of IRDS with early recurrence of prostate cancer. To explain these observations, we assessed whether IRDS is associated with a germline variant within the *IFNL4* gene (rs368234815-ΔG) that controls production of IFNL4, a type-III interferon, and is most common in subjects of African ancestry. We show that the *IFNL4* rs368234815-ΔG allele was significantly associated with increased IRDS in prostate tumors and overall survival of African-American patients. Moreover, *IFNL4* expression in 22Rv1 and PC-3 human prostate cancer cells induced IRDS. Our study links a germline variant that controls production of IFN-λ4 to the occurrence of a clinically relevant interferon signature in prostate tumors that may predominantly affect men of African ancestry. Taken together, these observations indicate that IRDS and *IFNL4*-dG allele may have an important function in the tumor biology and survival of African-American patients, and may influence immune therapy outcomes, which should be examined in future studies.

## 759W

**Height and body mass index as modifiers of ovarian cancer risk in 22,588 carriers of BRCA1 or BRCA2 mutations: A Mendelian randomization study.** F. Qian<sup>1</sup>, M.A. Rookus<sup>2</sup>, G. Leslie<sup>3</sup>, C. Engel<sup>4</sup>, K. Kast<sup>5</sup>, O.I. Olopade<sup>6</sup>, G. Chenevix-Trench<sup>6</sup>, T. Rebbeck<sup>7</sup>, D. Huo<sup>8</sup> on behalf of The Consortium of Investigators of Modifiers of BRCA1/2 (CIMBA). 1) Department of Medicine, University of Chicago, Chicago, IL; 2) Department of Epidemiology, Netherlands Cancer Institute, Amsterdam, The Netherlands; 3) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge, Cambridge, UK; 4) Institute for Medical Informatics, Statistics and Epidemiology, University of Leipzig, Leipzig, Germany; 5) Department of Gynecology and Obstetrics, Technical University of Dresden, Dresden, Germany; 6) Department of Genetics, QIMR Berghofer Medical Research Institute, Brisbane, Australia; 7) Department of Epidemiology, Dana Farber Cancer Institute, Boston, MA, USA; 8) Department of Public Health Sciences, University of Chicago, Chicago, IL, USA.

**Background** Lifetime risk of ovarian cancer in BRCA1/2 mutation carriers is substantial, though this relationship is likely modified by lifestyle, reproductive, and genetic factors. Anthropometric characteristics such as height and body mass index (BMI) were shown to increase ovarian cancer risk in the general population, but it remains unclear whether these relationships are causal.

**Methods** We applied a Mendelian randomization approach to assess the association between height/BMI and ovarian cancer risk in the Consortium of Investigators for the Modifiers of BRCA1/2 (CIMBA), consisting of 14,676 BRCA1 and 7,912 BRCA2 mutation carriers, with 2,923 cases of ovarian cancer. We created a height genetic score (height-GS) using 586 height-associated variants and a BMI genetic score (BMI-GS) using 93 BMI-associated variants. Associations were assessed using Cox models, with adjustments for principal components, birth cohort, mutation status, menopausal status, and country of enrollment. **Results** Height-GS explained 13.4% of the variation in height and the BMI-GS explained 2.6% of variation in BMI. We found that observed height was not associated with ovarian cancer risk (hazard ratio [HR]: 1.06 per 10 cm increase in height, 95% confidence interval [CI]: 0.93 – 1.22). Height-GS was not associated with ovarian cancer risk, either (HR: 1.03 per 10 cm increase in genetically determined height, 95% CI: 0.85 – 1.24). Observed BMI and BMI-GS were not statistically associated with ovarian cancer risk – HR: 1.04, 95% CI: 0.95 – 1.14 and HR: 1.10 per 5 kg/m<sup>2</sup> increase in genetically determined BMI, 95% CI: 0.86 – 1.42, respectively. However, we found a significant interaction between BMI or BMI-GS and menopausal status ( $P_{\text{interaction}} = 0.036$  and 0.002 for observed BMI and BMI-GS, respectively). Higher BMI conferred elevated ovarian cancer risk in premenopausal women (HR for observed BMI 1.26, 95% CI: 1.04 – 1.53; HR for BMI-GS 1.99, 95% CI: 1.24 – 3.20), but not in postmenopausal women (HR for observed BMI 1.00, 95% CI: 0.90 – 1.11; HR for BMI-GS 0.84, 95% CI: 0.62 – 1.12). **Conclusion** We did not observe statistically significant relationships between observed or genetically predicted height or BMI with ovarian cancer risk, although the relative risk estimates were consistent with effect sizes observed in the general population. The significant relationship between BMI and ovarian cancer risk in premenopausal women warrants further research.

## 760T

**Genetic association analysis of longitudinal colonoscopies in a colonoscopy screening cohort in the VA Medical System.** X. Qin<sup>1,2</sup>, T. Hyslop<sup>1,2</sup>, K.J. Sims<sup>1</sup>, A. Stone<sup>3</sup>, W.C. Carter<sup>3</sup>, D. Humphries<sup>4</sup>, M.C. O'Leary<sup>1</sup>, T.S. Redding IV<sup>1</sup>, Z.F. Gellad<sup>1,2</sup>, A. Madison<sup>1</sup>, B. Sullivan<sup>1,2</sup>, D. Lieberman<sup>5,6</sup>, D. Provenzale<sup>1,2</sup>, E.R. Hauser<sup>1,2</sup>. 1) Durham VA Health Care System, Durham, NC, USA; 2) Duke University, Durham, NC, USA; 3) Central Arkansas Veterans Health System, Little Rock, AR, USA; 4) VA Boston Healthcare System, Boston, MA, USA; 5) Portland VA Medical Center, Portland, OR, USA; 6) Oregon Health and Science University, Portland, OR, USA.

Repeated measures of disease activity or recurrences over time may identify a wider spectrum of phenotypic severity across individuals and should allow better characterization of the association between complex disease phenotypes and genetic variants. We hypothesized that multiple outcomes across colonoscopies over 10 years would provide additional power to detect genetic association with the colorectal cancer (CRC) precursor phenotype of advanced neoplasia (AN) when compared to a cumulative, binary outcome assessment of 'ever' vs 'never' having been diagnosed with AN. The Veteran Affairs (VA) Cooperative Study 380 is a longitudinal study of 3121 asymptomatic and otherwise healthy participants aged 50-75 from 13 VA Medical Centers who had a screening colonoscopy between 1994-1997. The biorepository includes 815 individuals with blood, serum, DNA or normal rectal tissue samples, with additional frozen and FFPE samples from removed polyps. Using the VA EMR we identified all colonoscopies performed from the start of the study to 10 years after baseline. AN at each colonoscopy was defined using pathology reports indicating at least one polyp classified as either an adenoma  $\geq 10$  mm, adenoma with villous histology, adenoma with high-grade dysplasia, or invasive cancer. A total of 612 individuals were genotyped on the Illumina Infinium Omni2.5-8 v1.3 Beadchip with 2,369,593 (99.8%) high-quality markers for analysis. In this study we analyzed the 500 European-American participants and selected SNPs with MAF > 0.05. We analyzed the data using a case-control GWAS as implemented in PLINK with case status defined as AN at any colonoscopy. We then applied a mixed random effects model to include AN at each of the 1220 colonoscopies for the 500 individuals. In both analyses we adjusted for age at baseline and two genetic principal components. We concentrated on 135 SNPs previously associated with CRC or AN. We compared effect size estimates and p-values for the results of the two models for each SNP. The Spearman rank correlation coefficient for the two sets of p-values from each model across all SNPs was 0.86 ( $p < 0.01$ ), suggesting good agreement in the relative ranks of the SNPs. No candidate SNP met a corrected significance level of 0.0003. The top SNPs from the mixed model analysis were rs11886781, rs1493383 and rs6105057 ( $p < .02$ ). Larger genetic analyses of repeated outcomes over time may enhance discovery of genes involved in the progression from AN to CRC.

**Interconnections between knock-down genes, cancer types, and landmark genes.** *M.B. Rao, S. White, T. Guan, M. Medvedovic, J. Reichard.* Environmental Health, University of Cincinnati, Cincinnati, OH.

An experiment is conducted to examine how a gene knocked-down from a cell line of a cancer tissue affects expressions of a set of landmark genes. 1. Cancers considered (7): skin; lung; kidney; liver; intestine; breast; prostate. 2. Number of genes considered for the knock-down experiment: 2024 3. Number of landmark genes examined: 978 Experiment: Take cancer cell lines derived from a specific tumor type. Select a gene G from the knock-down list. Knock-down the gene G from a subset of the cell lines and the remaining cells serve as controls. From each cell line, determine expressions of the genes from the landmark genes list. Compare (Z-statistic or t-statistic) the expressions of each of the landmark genes using the expression data collected. Using the Z-statistic values, the top 50 genes (up-regulated) are identified by +1, bottom 50 genes (down-regulated) are identified by -1, and the remaining 878 genes are denoted by 0. Repeat the experiment with every cancer cell line in the list and every gene on the knock-down list. Data: Our work begins with the data so collected. The data look like a contingency table of dimensions 2024\*7\*978. There is a difference. The entries in a contingency table are counts. In our case, the entries are categorical with categories +1, 0, or -1. Finding patterns in such a data is challenging. Building a multinomial regression model for a gene in the landmark list with responses +1, 0, -1 with categorical predictors knock-downs and cancers is computationally challenging. We pursued a number of existing methods and developed new methods to elicit patterns in the three-dimensional data. Methods: 1. Bi-clustering methods: These methods are applicable when we have two-dimensional categorical data. For every cancer fixed, we will identify sub-matrices defined by a subset of genes in the knock-down list and a subset of genes in the landmark list in which every entry is +1, -1, or 0. 2. Tri-clustering methods: This is a new method, which will strive to identify a three-dimensional sub-matrix in which every entry is +1, -1, or 0. 3. Reduce the three-dimensional 2024\*7\*978 categorical data to two dimensions by summing or counting over the third dimension and then apply two-dimensional methods. In summary: A number of methods, known and new, will be tried to elicit hidden patterns in the data and our presentation will touch upon the trials and tribulations we underwent in the course of our sojourn.

**Pathogenic germline mutations in lung cancer in the Clinical Cancer Genomics Community Research Network.** *K.L. Reckamp<sup>1</sup>, T. Slavin<sup>2</sup>, S.W. Gray<sup>2</sup>, D. Castillo<sup>2</sup>, J. Herzog<sup>2</sup>, S. Sand<sup>2</sup>, S. Mach<sup>1</sup>, A. Abing<sup>1</sup>, T. Tsou<sup>1</sup>, R. Mejia<sup>2</sup>, J. Wang<sup>3</sup>, S. Tao<sup>3</sup>, J. Weitzel<sup>3</sup>.* 1) Medical Oncology, City of Hope, Duarte, CA; 2) Clinical Cancer Genomics, City of Hope, Duarte, CA; 3) Sequencing Core, City of Hope, Duarte, CA.

**Background:** Lung carcinoma (LC) is the leading cause of cancer death and 10-15% occurs in never smokers. Little is known about germline genetic predisposition to LC. **Methods:** Germline DNA from LC patients (N=177) enrolled in Clinical Cancer Genomics Community Research Network was sequenced and analyzed for coding mutations using a custom-designed Agilent SureSelect targeted gene capture kit. The bait design included full exon, 5' and 3' untranslated regions, and splicing region coverage for 789 genes. Genes suspected to be involved in LC susceptibility on the panel included: *EGFR*, *TP53*, *YAP1*, *CLPTM1L*, *FASLG*, *CASP8*, *DLEC1*, *ERBB2*, *ERCC6*, *RASSF1*, and *PPP2R1B*. The panel also included other candidate predisposition and known hereditary cancer genes. After library preparation, reaction products were evaluated using paired-end sequencing at an average of 100x coverage depth. Variants with an allele fraction  $\geq 35\%$  and read depth  $\geq 5$  were annotated using Ingenuity Variant Analysis using American College of Medical Genetics Guidelines. **Results:** Participants characteristics: 62% Caucasian, 23% Asian, 16% Hispanic, and 3% African-American; 73% female; 90 (51%) never smokers. Of the 77 smokers, mean pack year was 24 (median 20 (0.5-50)). Thirty-two percent had between 1-3 first degree relatives with LC, 22% had between 1-4 second degree relatives with LC, 53% had no family history of LC. Somatic mutations included: 94 *EGFR*, 28 *TP53*, 7 *ALK*, 7 *MET*, 4 *ROS*, 3 *BRCA1*, 3 *BRCA2*, 2 *BRAF*, and 1 *KRAS*. Germline cancer predisposition pathogenic/likely pathogenic variants (PV) were seen in 15 individuals (8.5%) in: 1) known LC associated genes: 2 *EGFR* (p.T790M and p.R776H); 2 *TP53*; and, 2) known cancer associated genes: 2 *ATM*, 2 *BRCA2*, 2 *BRIP1*, 2 *MLH1*, *NBN*, *RAD51C*, *PMS2*. Three individuals had PVs in *DLEC1*, a strong candidate predisposition gene for LC. PVs were also identified in other candidate genes: 2 *BLM*, *FANCM*, *MAP3K6*, and 2 *RAD50*. Both *EGFR* germline mutation carriers had multiple relatives with LC. Neither *BRCA2* carriers had breast/ovarian cancer. Both *TP53* carriers had multiple primary cancers but did not meet Li-Fraumeni Syndrome criteria. **Conclusions:** Our cohort had a greater prevalence of hereditary predisposition gene mutations than expected in the general population. Mutations were identified in known LC association genes, established cancer risk genes, and strong candidate LC predisposition genes. Our findings support the need for further LC predisposition research.

## 763T

**Clinical and molecular characteristics of somatic NF1 mutations identified on hereditary cancer multi-gene panels.** A. Safonov<sup>1</sup>, J. Dolinsky<sup>2</sup>, V. Speare<sup>2</sup>, Z. Powis<sup>2</sup>, M. Pronold<sup>2</sup>, A. Yussuf<sup>2</sup>, C. Gau<sup>2</sup>, H. Laduca<sup>2</sup>, S. Li<sup>2</sup>, K. Allen<sup>2</sup>, A. Yussuf<sup>2</sup>, K. Nathanson<sup>1</sup>. 1) Abramson Cancer Center, Hospital of University of Penn, Philadelphia, PA; 2) Ambry Genetics, Aliso Viejo, CA.

**Background:** Evaluation of patients with clinical features of Neurofibromatosis type 1 (NF1) has led to the longstanding clinical observation of a high rate of somatic mosaicism in NF1. Somatic mutations of NF1 also have been shown to play a role in several tumor types. We explored the clinical and genetic features of patients with NF1 mutations identified through multi-gene panel cancer susceptibility testing (MGPT). **Methods:** Results from a cohort of 118,768 patients who underwent MGPT were queried to identify probands with a NF1 pathogenic/likely pathogenic variant (mutation). Next generation sequencing was performed on panels of 2-67 hereditary cancer genes. Review of test requisition s and available medical records/pedigree was performed. NF1 cases were defined by concordance with NIH criteria. Putative mosaic cases were identified as variant allele frequency (VAF) < 0.30; these cases were subsequently confirmed by Sanger sequencing. **Results:** 276 total patients were identified. 153 (55.1%) patients had a reported clinical diagnosis of NF1; 123 (44.9%) had a mutation in NF1 but were not reported as having NF1. Cancer history was generally similar between groups with a few exceptions. Patients with clinical NF1 were diagnosed with cancer earlier (44.2 vs 53.1 years,  $p = 5.1 \times 10^{-8}$ ), were more likely to have sarcoma (OR 4.8,  $p = 0.038$ ), and; GI malignancies (colon and gastric cancer) (OR 0.12,  $p = 0.004$ ). Putative mosaicism was associated with bilateral breast cancer (OR 4.25,  $p = 0.034$ ). Mutations in other cancer susceptibility genes were present in 7.1% of patients with clinical NF1 and 8.9% of NF1 mutation only cases. When considering patients with multiple mutations, 90% of patients with clinical NF1 and 100% of NF1 mutation only cases met NCCN guidelines for high-risk gene testing. **Conclusions:** Our data did not reveal significance evidence of a "milder" oncologic phenotype in putative mosaic NF1 patients, as compared to heterozygous cases. These results, along with the findings of more frequent bilateral breast cancer suggest that mosaic NF1 may be associated with breast cancer susceptibility. Potential explanations of low VAF of the NF1 gene include somatic mosaicism, circulating tumor, or clonal hematopoiesis of indeterminant potential (CHIP). Additionally, our data suggests MGPT in the NF1 patient population may be reserved for cases in which personal and family history is indicative of an additional hereditary cancer syndrome.

**Frequent basal cell cancer development is a clinical marker for inherited cancer susceptibility and DNA repair defects.** K. Sarin<sup>1</sup>, H. Cho<sup>1</sup>, K. Kuo<sup>1</sup>, S. Li<sup>1</sup>, I. Bailey<sup>1</sup>, S. Aasi<sup>1</sup>, A. Chang<sup>1</sup>, A. Oro<sup>1</sup>, E. Epstein<sup>2</sup>, J. Tang<sup>1</sup>. 1) Dermatology Department, Stanford University, Stanford, CA; 2) Childrens Hospital Oakland Research Institute, Oakland, CA.

Innate DNA repair mechanisms play a critical role in protecting skin keratinocytes from ultraviolet mutagenesis and skin cancer development. We hypothesized that individuals who develop frequent skin cancers may harbor germline defects in DNA repair genes and have increased predisposition to internal malignancies. We enrolled 61 patients with unusually frequent BCC development seen at Stanford Hospital and Clinics from January 2005 until December 2015, for germline analysis of 29 DNA repair genes. In parallel, a case-control retrospective review was performed to interrogate the association of malignancies with frequent BCC development in a large U.S. medical insurance claims database (Truven), which included 13,264 individuals with 6 or more BCCs during 2007-2011. 19.7% of the frequent BCC cohort (N=12) harbored pathogenic mutations in DNA repair genes: APC, BARD1, BRCA1, BRCA2, CDH1, CHEK2, MLH1, MSH2, MSH6, MUTYH, NBN, and PALB2. Individuals with 6 or more BCCs had an increased risk of other malignancies, with a 3.5-fold increase in frequent BCC cohort and a 3.2-fold increase in the Truven database. Individuals who developed frequent BCCs have an increased prevalence of germline mutations in DNA repair genes and increased malignancy risk. Our data implicate frequent BCC development as an external marker of inherited cancer risk.

## 765W

**Sex differences in gene coexpression across the cancer genome atlas studies.** A.D. Skol<sup>1,2,3</sup>, R.L. Grossman<sup>3</sup>, B.E. Stranger<sup>1,2</sup>. 1) Section of Genetic Medicine, Department of Medicine, University of Chicago, Chicago, IL; 2) Institute for Genomics and Systems Biology, University of Chicago, Chicago, IL; 3) Center for Data Intensive Science, University of Chicago, Chicago, IL.

Sex is an important clinical variable known to be associated with incidence, age of onset, and disease severity in many cancers. Thyroid cancer, for example, is 2.5x more common in women than men, whereas bladder cancer is 4x more common in men. Previous studies have shown sex-specific differences in levels of tumor mRNA and miRNA expression, methylation, and somatic mutations in a subset of The Cancer Genome Atlas (TCGA) cancers. Few studies have examined sex differences in gene coexpression, which can help reveal broader functional consequences than gene-level investigations. Using TCGA cancers, we employed three statistical methods to search for significant coexpression differences between male and female cancer patient tumors. The three methods employed, Weighted Gene Coexpression Network Analysis (WGNCA), Algorithm for the Reconstruction of Accurate Cellular Networks (ARACNE), and Bayesian Biclustering (BicMix), identify gene coexpression networks in distinct ways, and thus not surprising, reveal varied results. However, the genes identified by all methods can be revealing. For example, when studying the 340 liver hepatocellular carcinoma tumor samples (107 female, 233 male), BicMix identified 255 pairs of genes that are coexpressed in one sex, but not the other (112 unique to females patients and 143 unique to male patients). Of the genes identified in coexpression networks unique to females, the ARACNE results revealed that three were transcription factors (TFs) that had significantly fewer coexpressed target genes in males than females, including SIM2 (prostate cancer), MITF (renal cancer, melanoma), and THRB (renal cancer). Of the 143 genes pairs found in uniquely male coexpression networks, ARACNE found that five were TFs with significantly fewer coexpressed target genes in females. These include HLF (lung, renal, head and neck), HNF4A (liver, colon), NR1H4 (liver, colorectal), MLXIPL, and KLF15 (breast, renal). Three of these genes, HNF4A, NR1H4, and MLXIPL were also found in sex-distinct WGNCA defined gene modules. These results suggest that sex-specific differences in loss of regulatory control may play a role in clinical differences observed between men and women. Our hope is that by learning more about the disruption of gene regulation, and other cancer-specific genomic differences between men and women, we will gain an improved understanding of how sex-specific genetic differences leads to disparities in clinical measures and outcomes.

**Background** Lipid traits have been suggested as non-Hodgkin lymphoma (NHL) risk factors, but results are inconclusive. Currently, single nucleotide polymorphisms (SNPs) associated with lipid traits explain 8-11% of the total variation in lipid traits in populations of European ancestry. Here we apply a Mendelian randomization (MR) analysis to examine the possibility of causal relationship between lipid traits and the risk of diffuse large B-cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL), follicular lymphoma (FL), and marginal zone lymphoma (MZL). **Methods** GWAS data from the InterLymph Consortium were available for 2661 DLBCLs, 2179 CLLs, 2142 FLs, 824 MZLs, and 6221 controls. SNPs associated ( $P < 5 \times 10^{-8}$ ) with high-density lipoprotein (HDL,  $N=206$ ), low-density lipoprotein (LDL,  $N=160$ ), total cholesterol (TC,  $N=204$ ), and triglyceride (TG,  $N=169$ ) were used as instrumental variables (IV). SNPs were not in strong linkage disequilibrium ( $r^2 < 0.2$ ). MR estimates for the association between each lipid trait and NHL subtype were calculated using the inverse variance-weighted method, after testing for pleiotropy evidence using MR-Egger regression to examine for violation of the standard IV assumptions. Associations were reported as odds ratios (OR) per standard deviation increase in the genetic risk score along with 95% confidence intervals (CI). A conservative Bonferroni-corrected threshold of  $P < 0.003$  was used. **Results** Except for a nominally significant association of TC with DLBCL ( $P=0.02$ ), there was no evidence of violation of the assumptions for any of the associations tested using MR-Egger regression. TG was inversely associated with risk of CLL (OR=0.86, CI: 0.74-0.98) with nominal significance ( $P=0.03$ ). A positive trend was observed for TC with risk of FL (OR=1.07, CI: 0.99-1.17;  $P=0.1$ ), and an inverse trend for LDL with risk of MZL (OR=0.89, CI: 0.79-1.01;  $P=0.07$ ). None of the associations were noteworthy after adjusting for multiple testing. **Conclusions** Our relatively large study did not find evidence of a causal association of these lipid traits and the most common NHL subtypes. The amount of variance accounted by these SNPs for the lipid traits is larger than in many MR studies, and these IVs have been previously linked to colorectal and prostate cancers. Our results are in agreement with most studies that assessed history of hyperlipidemia or statin use with risk of NHL, and suggests positive associations may be due to reverse causality or confounding.

**Pathogenic germline variants associated with young onset colorectal cancer.** T.P. Slavin<sup>1</sup>, I. Solomon<sup>1</sup>, B. Nehoray<sup>1</sup>, D. Castillo<sup>1</sup>, J. Herzog<sup>1</sup>, K. Tsang<sup>1</sup>, K. Blazer<sup>1</sup>, S.L. Neuhausen<sup>1</sup>, K. Yang<sup>1</sup>, J. Wang<sup>1</sup>, S. Tao<sup>1</sup>, S. Manjarrez<sup>1</sup>, P. Rice<sup>2</sup>, K. Blankstein<sup>3</sup>, P. Mora<sup>4</sup>, M. Purdy<sup>5</sup>, C. Hake<sup>6</sup>, D. Margileth<sup>7</sup>, K. Bobolis<sup>8</sup>, J.N. Weitzel<sup>1</sup>, *Clinical Cancer Genomics Community Research Network.* 1) Clinical Cancer Genomics, City of Hope National Medical Center, Duarte, CA; 2) Frederick Memorial Hospital, Frederick, MD; 3) Hunterdon Cancer Center, Flemington, NJ; 4) Instituto Nacional de Enfermedades Neoplásicas (INEN), Lima, Peru; 5) Lovelace Cancer Center, Albuquerque, NM; 6) ProHealth Care Research Institute, Waukesha, WI; 7) St. Joseph Hospital, Orange, CA; 8) Sutter Cancer Center, Roseville, CA.

**BACKGROUND** Colorectal cancers (CRC) generally occur with advanced age; however, diagnoses are rising in the young. Early onset CRC has been associated with genetic predisposition. Our goal was to discover new, and evaluate known, genetic predisposition variants in young-onset CRC. **METHODS** Individuals diagnosed with colorectal adenocarcinoma  $\leq 40$  years ( $n=252$ ) were selected from the Clinical Cancer Genomics Community Research Network registry. For those without a previously identified hereditary predisposition mutation from commercial testing next generation sequencing was completed using an Agilent SureSelect hybrid capture research panel of 767 known and candidate cancer predisposition genes. Variants with a call quality of  $\geq 20$ , a read depth of  $\geq 10$ , and allele fraction of between 30-70% were classified using the American College of Medical Genomics guidelines. Copy number variation was completed using in silico algorithms. **RESULTS** Average age of diagnosis was 33 years (range 17-40); 56% were female; 52% non-Hispanic Caucasian; 43% stage III/IV; only 11% met Amsterdam I or II criteria. Seventy-one (28%) were identified with an actionable colon cancer predisposition gene likely pathogenic or pathogenic variant (PV) by either commercial ( $n=55/153$ ) or research testing (16/196) (45 Lynch syndrome, 16 *APC*, 3 *TP53*, 2 *CHEK2*, and 1 *BRMP1A*). An additional 25 candidate gene PV's were also identified, including 7 (2.7%) in Fanconi Anemia genes: *BRCA2*, *FANCA*, *FANCD2* (3 mutations), *FANCI*, and *FANCL*. **CONCLUSION** In a young CRC cohort, mutations across multiple actionable genes appear common, supporting the use of diagnostic multigene panels. Fanconi Anemia gene PV's also appear enriched in this population. Tumor and case control analyses to support causality are ongoing.

## 768W

**Colorectal cancer susceptibility loci and influence on survival.** N. Song<sup>1</sup>, K. Kim<sup>2</sup>, A. Shin<sup>1,3,4</sup>, J.W. Park<sup>5,6</sup>, H.J. Jang<sup>6</sup>, J. Shi<sup>7</sup>, Q. Cai<sup>7</sup>, D.Y. Kim<sup>8</sup>, W. Zheng<sup>7</sup>, J.H. Oh<sup>6</sup>. 1) Cancer Research Institute, Seoul National University College of Medicine, Seoul, Seoul, Korea; 2) Division of Epidemiology and Biostatistics, University of Illinois at Chicago School of Public Health, Chicago, IL, USA; 3) Department of Preventive Medicine, Seoul National University College of Medicine, Seoul, Korea; 4) Molecular Epidemiology Branch, National Cancer Center, Goyang, Korea; 5) Department of Surgery, Seoul National University College of Medicine and Hospital, Seoul, Korea; 6) Center for Colorectal Cancer, National Cancer Center, Goyang, Korea; 7) Division of Epidemiology, Department of Medicine, Vanderbilt University School of Medicine, Nashville, TN, USA.

Genome-wide association studies (GWAS) have identified multiple single-nucleotide polymorphisms (SNPs) associated with colorectal cancer risk. To evaluate the potential influence of colorectal cancer susceptibility SNPs on disease prognosis, we investigated whether GWAS-identified colorectal cancer risk SNPs and polygenic risk scores (PRSs) might be associated with survival among colorectal cancer patients. A total of 1,374 colorectal cancer patients were recruited from the Korean National Cancer Center. For genotyping, 30 colorectal cancer-susceptibility SNPs previously identified by GWAS were selected. The Cox proportional hazard model was used to evaluate associations of these risk SNPs and PRSs with disease-free survival (DFS) and overall survival (OS). The prognostic values were compared between genetic and non-genetic models by using Harrell's *c* index. During the follow-up period (median: 88, 91 months for DFS, OS), 570 DFS (41.5%) and 487 OS (35.4%) events were observed. We found that 5 SNPs were significantly associated with DFS or OS among colorectal cancer patients at  $P < 0.05$ : rs10936599 at 3q26.2 (*MYNN*), rs704017 at 10q22.3 (*ZMIZ1-AS1*), rs11196172 at 10q25.2 (*TCF7L2*), rs3802842 at 11q23.1 (*COLCA1-2*), and rs9929218 at 16q22.1 (*CDH1*). The PRSs constructed using these 5 SNPs were associated with worse survival (DFS:  $P_{\text{trend}}=0.02$  un-weighted PRS,  $P_{\text{trend}}=0.01$  weighted PRS, OS:  $P_{\text{trend}}=3.7 \times 10^{-3}$  un-weighted,  $P_{\text{trend}}=0.02$  weighted PRS). Furthermore, the performance of the genetic prognostic models including survival SNPs were significantly improved compared with the non-genetic models ( $P=0.03$  for DFS,  $P=0.04$  for OS). Our results suggest that several colorectal cancer susceptibility SNPs could be also related to survival by influencing disease progression.

**Breast cancer and ovarian cancer risk genes: Meta-analysis of sequencing results of NGS multi-gene panels.** M. Suszynska, K. Klonowska, P. Kozłowski. Department of Molecular Genetics, Institute of Bioorganic Chemistry, Polish Academy of Sciences, Poznan, Poland.

**Background:** Germline mutations occurring in highly penetrant genes *BRCA1* and *BRCA2* are responsible for only 16-40% of familial breast cancer (BC) and ovarian cancer (OC) cases, thus several other genes are considered as potential BC and/or OC risk factors. However, the predisposing role of the most of the candidate genes is still elusive, lacking statistically significant and convincing proof. **Methods:** To estimate a reliable BC and OC risk associated with pathogenic variants in the selected candidate BC/OC predisposition genes, a comprehensive meta-analysis of 48 NGS multi-gene panels based studies, analyzing BC and/or OC patients, was conducted. The role of 37 genes was evaluated, comparing in total, the mutation frequency of ~120,000 BC/OC cases and ~120,000 controls, summarized in GnomAD database, what guaranteed strong statistical support with high confidence to most analyzed genes. **Results:** 13 and 11 of analyzed genes were significantly associated with an increased BC and OC risk, respectively. Genes contributed to the (i) high, (ii) moderate, and (iii) low BC risk were as follow: (i) *BRCA1*, *BRCA2*, *CDKN2A*, *PALB2*, *PTEN*, *TP53*, (ii) *ATM*, *BARD1*, *CDH1*, *MSH6*, and (iii) *BRIP1*, *CHEK2\**, *MSH2*. In relation to OC, (i) *BRCA1*, *BRCA2*, *BRIP1*, *MSH2*, *MSH6*, *PTEN*, *RAD51C*, *RAD51C*, *TP53*, and (ii) *ATM*, *NBN*, *PALB2* were classified as high-, and moderate-risk genes, respectively. **Conclusions:** Our study defines which of frequently analyzed NGS multi-panel genes, are associated with the low, moderate, and high BC and OC risk as well as excludes the role of others. Mutations in a few genes are attributed to high BC risk, at the level similar to *BRCA2* mutations, especially in *CDKN2A*, earlier not often mentioned gene in the context of BC predisposition. The profiles of genes contributing to either BC or OC risk differ, as several genes much more strongly predispose to OC than BC.

**Penetrance for carriers of a DNA mismatch repair gene specific variant.**

A.K. Win<sup>1,2</sup>, J.G. Dowty<sup>1</sup>, D.D. Buchanan<sup>2,3</sup>, J.C. Reece<sup>1</sup>, G. Lee<sup>1</sup>, G. Moslein<sup>4</sup>, R.W. Haile<sup>5</sup>, F.A. Macrae<sup>6,7</sup>, I.M. Winship<sup>2,7</sup>, M.A. Jenkins<sup>1</sup>, *International Mismatch Repair Consortium (IMRC)*. 1) Centre for Epidemiology & Biostatistics, The University of Melbourne, Parkville, Victoria, Australia; 2) Genetic Medicine, Royal Melbourne Hospital, Parkville, Victoria, Australia; 3) Colorectal Oncogenomics Group, Genetic Epidemiology Laboratory, Department of Pathology, The University of Melbourne, Parkville, Victoria, Australia; 4) Helios St. Josefs Hospital Bochum-Linden, Linden, Germany; 5) Cedars-Sinai Medical Center, Los Angeles, CA, USA; 6) Colorectal Medicine and Genetics, Royal Melbourne Hospital, Parkville, Victoria, Australia; 7) Department of Medicine, The University of Melbourne, Parkville, Victoria, Australia.

**Background:** Lynch syndrome is a cancer predisposition caused by inherited mutations in mismatch repair genes *MLH1*, *MSH2*, *MSH6* and *PMS2*, or *EPCAM*. Previous estimates of colorectal cancer risk are averages over hundreds of different mutations in these genes. There is statistical evidence of a substantial heterogeneity in these average risks with some carriers at low risk of colorectal cancer and others at high risk. A possible reason for this risk heterogeneity is that risk varies by specific variants in each gene. **Methods:** We estimated colorectal cancer risk for a single specific variant in *MSH2* using 234 families of *MSH2* c.942+3A>T variant. Pedigree data was provided by clinicians and researchers to the International Mismatch Repair Consortium (IMRC) (<http://www.sphinx.org.au/imrc>). For carriers of this specific variant, we estimated the age-specific cumulative risks (penetrance) and 95% confidence intervals using a modified segregation analysis with appropriate conditioning depending on ascertainment and allowing for risk to vary between families by fitting a polygenic effect. **Results:** The estimated average cumulative risks to age 70 years (95% confidence intervals), were 56% (38%-78%) for male carriers and 45% (28%-67%) for female carriers of *MSH2* c.942+3A>T variant. However, the lifetime risks for different people were estimated to vary widely about these average risks ( $p=0.001$ ). For carriers of this specific variant, 26% of males and 16% of females had colorectal cancer risk less than 20%; and 24% of males and 37% of females had risk greater than 70%. **Conclusions:** These findings suggest that even for a specific variant in a DNA mismatch repair gene, there is a wide range of colorectal cancer risks. This is consistent with the existence of strong modifiers of risk, that if known, could be used to provide personalized risk of colorectal cancer for Lynch syndrome.

**Background** Gene-environment (GxE) interaction studies help identify novel loci and biological interactions that give insight to the pathogenesis of colorectal cancer (CRC), as single variants discovered by genome-wide association studies only explain a small fraction of total heritability. Body mass index (BMI), an indicator of obesity and well known risk factor for CRC, is a complex phenotype that might interact with genetic variants to act on CRC risk. As statistical power remains a major concern, incorporating functional genomic information may improve power and help to interpret the underlying biology. **Methods** Genetically determined gene expression levels were tested for interaction with BMI on CRC risk among 26,017 incident cases and 20,692 controls from Genetics and Epidemiology of Colorectal Cancer Consortium (GECCO), Colon Cancer Family Registry (CCFR), and Colorectal Transdisciplinary (CORECT) Study. Using PrediXcan, we imputed the gene expression levels of colon tissues (transverse only) from the Genotype-Tissue Expression (GTEx) Project (n=169) for all genes with sufficient heritability ( $\geq 1\%$ ). We used a mixed-effects model to assess the GxE effects by modeling the interaction between predicted gene expression and continuous measurement of BMI (per 5kg/m<sup>2</sup>) (fixed effects), and residual variant-specific GxE effects that are not accounted for (random effects). The study was stratified by sex as BMI-CRC associations differ by sex. False discovery rate (FDR) was used to account for multiple comparisons, with FDR<0.2 considered genome-wide significant. **Results** Among the 4839 genes tested, *FOXA1* ( $p_{\text{interaction}}=1.94 \times 10^{-5}$ ), *PSMC5* ( $p_{\text{interaction}}=9.96 \times 10^{-5}$ ) and *CD33* ( $p=1.28 \times 10^{-4}$ ) significantly modified the effect of BMI on CRC risk among males, and *KIAA0753* ( $p_{\text{interaction}}=2.80 \times 10^{-5}$ ) and *SCN1B* ( $p_{\text{interaction}}=6.33 \times 10^{-5}$ ) had a significant interaction with BMI on CRC risk among females. The *FOXA1* gene encodes hepatocyte nuclear factors, which has been found to be highly correlated with some protein expression in breast cancer; *CD33*, a transmembrane receptor expressed on myeloid and lymphoid cells, is the target for the treatment of acute myeloid leukemia. **Conclusions** Incorporating functional information, we discovered some novel genes that may interact with BMI on CRC risk. Independent replication and functional follow up of these findings will add additional evidence.

**Background:** Common variants can explain a substantial fraction of familial aggregation of several cancers; however, the proportion of heritability explained by known discoveries in current GWAS varies widely across cancers due to differences in sample sizes. Estimation of underlying effect size distributions of variants can allow an assessment of the diversity of genetic architecture across cancers and a roadmap of future studies. **Methods:** We obtained summary-level data for variant relative risk estimates across GWAS for ten cancer sites with 6,000 to 44,000 cases, plus controls. We applied GENESIS, a method we recently developed, to characterize the effect size distribution of common variants in terms of the proportion of susceptibility variants (polygenicity) and using normal mixture models for their effects. We compared cancers within three groups with similar sample sizes as size can affect the estimation of polygenicity: 1. head and neck, endometrial, glioma, melanoma and renal (<15,000 cases); 2 colorectal and ovarian (15,000-30,000 cases); and 3. breast, prostate and lung (>30,000 cases). **Results:** According to our model, all cancers were highly polygenic with important differences in the degree and nature of polygenicity across sites. In group 1, head and neck cancer had a much higher polygenicity (~6,000 susceptibility variants) than others (~1,000-2,000), and melanoma had susceptibility variants with an average effect size 2-4 fold higher than others. Cancers in group 2 had similar genetic architecture with ~1,000-1,500 variants each. In group 3, prostate cancer had the smallest number of variants (~3,000) with the largest average effect sizes. For all cancers except head and neck, a two-component normal mixture model fitted much better than a single-component model, indicating the presence of clusters of variants with larger effects than the rest. We estimated that sample sizes required to explain 80% of GWAS heritability vary from 100,000 (melanoma) to 1,000,000 (lung) cases and comparable numbers of controls. The projected trajectories for future discoveries showed points of inflections that can inform optimal study designs. Analysis of additional cancers and absolute risk projections are ongoing. **Conclusion:** Increasing the size of GWAS has the potential to explain most of the genetic architecture of cancers. Optimal sample sizes could be achieved in near term for common cancers, while it will take longer for less common cancers.

## 773F

**A mixed-model approach for powerful testing of genetic associations with cancer risk incorporating tumor characteristics.** H. Zhang<sup>1,2</sup>, N. Zhao<sup>1</sup>, T. Ahearn<sup>2</sup>, M. Garcia-Closas<sup>2</sup>, N. Chatterjee<sup>1,3</sup>. 1) Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 2) National Cancer Institute, Division of Cancer Epidemiology and Genetics, Rockville, MD; 3) Department of Oncology, School of Medicine, Johns Hopkins University, Baltimore, MD.

**Background:** Cancers of many sites are composed of clinically distinct subtypes characterized by various factors, including histo-pathological characteristics and molecular markers, such as gene expression and somatic mutation signatures. While it has been shown that incorporation of subtype information can potentially lead to discovery of new genetic loci, it is not evident what is the optimal strategy for handling correlated markers, missing data and increased degrees-of-freedom/multiplicity in the underlying tests of associations.

**Method:** We propose a score test for genetic association using a mixed-effect two-stage polytomous model (MTOP). In the first stage, a standard polytomous model is used to specify a model for genetic association across all possible subtypes defined by the cross-classification of different markers. In the second stage, the subtype-specific case-control odds ratios are specified using a more parsimonious model based on the case-control odds ratio parameter for a baseline disease subtype, and the case-case parameters associated with the individual tumor markers. Further, to reduce the degrees-of-freedom of the model, we specify case-case parameters for exploratory markers using a random-effect model. We account for missing data on tumor markers using an EM algorithm. The score-test and its distribution theory are developed borrowing analogous techniques developed for group-based association tests for rare variants. We illustrated the use of the model using data from the Polish Breast Cancer Study (PBCS) with genome-wide genotyping data on 2,078 breast cancer cases and 2,219 controls; and information on estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (HER2) and grade on the tumors. **Results:** Large-scale simulations across a wide range of realistic scenarios show that MTOP has the correct type one error and robust power. In the PBCS, both MTOP and standard logistic regression methods identified a well-known susceptibility variant in the *FGFR2* locus at  $P < 5 \times 10^{-8}$ . Further, MTOP identified a second known susceptibility locus in chromosome 11 (*CCND1*) at  $P < 5 \times 10^{-8}$  that showed evidence for heterogeneity by ER ( $P = 0.005$ ) and grade ( $P = 0.032$ ). This locus was not genome-wide significant in standard analyses using logistic or polytomous models. **Conclusion:** MTOP is a robust method for testing genetic association in the presence of disease subtype heterogeneity defined by multiple disease characteristics.

Chan School of Public Health, Boston, MA, USA.

Pancreatic cancer is currently the third leading cause of cancer-related deaths in United States with a 5-year survival rate of only 8%. Inherited predisposition plays an important role in pancreatic cancer risk. Rare, moderately to highly penetrant mutations in hereditary cancer and pancreatitis genes, identified in families with a high incidence of disease, account for a small fraction of cases. At the other end of the spectrum, common risk variants of low penetrance have been discovered through genome-wide association studies (GWAS). Currently, over 20 common pancreatic cancer risk signals have been identified through GWAS in populations of European ancestry. However, these loci explain a small fraction of genetic heritability for pancreatic cancer, and the causal genes for the large majority of these loci are unknown. Most susceptibility alleles discovered through GWAS are located in noncoding regions of the genome, and are likely to function through allele specific regulation of gene expression. Transcriptome-wide association studies (TWAS) build on this premise by inferring genetically regulated gene expression levels into GWAS datasets to discover genes whose *cis*-regulated expression is associated with complex traits. To apply this approach to pancreatic cancer, we used two reference datasets generated from normal-derived pancreatic tissue samples from individuals of European ancestry, the DCEG/LTG ( $n = 95$ ) and Genotype-Tissue Expression (GTEx v7,  $n = 174$ ) datasets, to build robust predictors for gene expression, using 5 different models (bslmm, blup, lasso, enet and top1) in FUSION. We then applied these predictors to pancreatic cancer GWAS summary statistics from 9,040 pancreatic cancer cases and 12,496 controls (from PanScan I-III and PanC4), to identify associations between genes and the trait. We discovered 4 genes whose genetically predicted expression is significantly associated with pancreatic cancer risk ( $FDR < 0.1$ ), including 3 novel genes. The most significant TWAS gene identified in this study was *ABO* ( $P = 1.43 \times 10^{-13}$ ), whose expression is positively associated with pancreatic cancer risk. Results from the TWAS and ongoing functional experiments for some of the novel genes will be presented. Our findings showcase the utility of integrating multiple datasets to unravel regulatory impact of genetic variants on complex traits such as pancreatic cancer.

**Differences in germline *TP53* variant classifications affect the estimates of population prevalence of Li-Fraumeni syndrome: A gnomAD-based analysis.** *KC. De Andrade*<sup>1,2</sup>, *MN. Frone*<sup>1</sup>, *T. Wegman-Ostrosky*<sup>1,3</sup>, *PP. Khincha*<sup>1</sup>, *J. Kim*<sup>1</sup>, *A. Amadou*<sup>1</sup>, *KM. Santiago*<sup>2</sup>, *FP. Fortes*<sup>2</sup>, *N. Lemmonnier*<sup>4</sup>, *L. Mirabello*<sup>1</sup>, *DR. Stewart*<sup>1</sup>, *P. Hainaut*<sup>1</sup>, *LP. Kowalski*<sup>5</sup>, *SA. Savage*<sup>1</sup>, *MI. Achatz*<sup>1,6</sup>.

1) Clinical Genetics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institutes of Health, Department of Health and Human Services, Bethesda, MD, USA; 2) International Research Center, A.C. Camargo Cancer Center, São Paulo, Brazil; 3) Division of Research, National Cancer Institute, Mexico City, Mexico; 4) Institute for Advanced Biosciences, Inserm U 1209 CNRS UMR 5309 Université Grenoble Alpes, Site Santé, Allée des Alpes, 38700 La Tronche, France; 5) Department of Head and Neck Surgery and Otorhinolaryngology, AC Camargo Cancer Center, São Paulo, Brazil; 6) Institute for Research and Teaching, Sírio-Libanês Hospital, São Paulo, Brazil.

Recent suggestions of a variable Li-Fraumeni syndrome (LFS) phenotype have raised questions regarding the true disease prevalence. Our previous report on a higher-than-expected population prevalence of pathogenic and likely pathogenic germline *TP53* variants, the primary cause of LFS, was partly attributable to two specific controvertible variants, p.N235S and p.R290H. This study aims to further evaluate germline *TP53* variant prevalence estimates in the gnomAD database, which comprises germline variation from over 130,000 individuals. Variants were selected and classified based on our previously published algorithm. In addition, we provide alternative estimates based on three other classifications databases, ClinVar, HGMD, and the UMD\_TP53 website. Conservative estimates of pathogenic and likely pathogenic germline *TP53* variant prevalence are within the range of one carrier in 3,500-5,700 individuals. Less stringent classification increased approximate estimated prevalence to one carrier in every 400-900 individuals mainly due to the inclusion of the p.N235S, p.V31I, and p.R290H variants. We observed that the population prevalence of pathogenic and likely pathogenic variants may be higher than previously described. However, it can vary widely due to differences in variant classification. Comprehensive approaches are needed to better understand the interplay of germline *TP53* variant classification, prevalence estimates, cancer penetrance and phenotype of LFS.

## 776F

**Evaluating segregation evidence from multiple extended high-risk pedigrees.** *R.G. Waller*<sup>1</sup>, *T.M. Darlington*<sup>2</sup>, *M.J. Madsen*<sup>2</sup>, *N.J. Camp*<sup>2</sup>. 1) Biomedical Informatics, University of Utah, Salt Lake City, UT; 2) Psychiatry, University of Utah, Salt Lake City, UT; 3) Huntsman Cancer Institute, University of Utah, Salt Lake City, UT.

High-risk pedigrees (HRPs) are a key design in mapping rare and highly-penetrant genes in Mendelian-like diseases. However, success with the HRP design in complex diseases has been modest, in part because standard methods do not adequately address genetic heterogeneity. Novel methods are needed to re-invigorate HRP designs for gene-discovery in complex diseases. Extended high-risk pedigrees can contain sufficient meioses to gain power for gene mapping as single pedigrees; however, intrafamilial heterogeneity may still exist. We previously described Shared Genomic Segment (SGS), a large pedigree mapping method that identifies subsets of cases within an extended pedigree that share segregating chromosomal regions. Here, we have expanded this strategy to incorporate evidence from multiple large, HRPs while maintaining statistical rigor. Briefly, using a dense, genome-wide map of single nucleotide polymorphisms (SNPs), excessively long runs of identical-by-state SNPs are identified. Chance occurrence is established empirically using gene-drop simulations. All non-trivial subsets of cases are considered within the pedigree. In the multi-pedigree SGS version, the best region/case-subset at each locus is optimized across pedigrees. Statistical significance for SGS segments at the same genomic location across pedigrees are combined using Fisher's method. Genomewide significance thresholds are determined through distribution-fitting and the Theory of Large Deviations based on the multi-pedigree optimized results. We applied our multi-pedigree strategy to 11 extended, multiple myeloma (MM) HRPs. One genomewide significant region was identified at 18q21.33. This region contains one gene, *CDH20*, that facilitates cell-cell adhesions to form cadherin junctions. Three genomewide suggestive regions were identified at 6q26, 18p11.22, and 7p14.3. Together these regions contain 10 genes: *PARK2*, *TWSG1*, *RALBP1*, *PPP4R1*, *RAB31*, *ADCYAP1R1*, *NEUROD6*, *CCDC129*, *PPP1R17*, and *PDE1C*. Our results provide statistically compelling risk loci for MM with evidence from multiple high-risk pedigrees. Further analyses will interrogate exome sequencing in these regions for functional variants in the SGS carriers and high-risk and sporadic cases. **Table. Significant and suggestive regions with evidence from 2 HRPs.**

Site	Region	Length (Mb)	p-value
18q21.33	58,208,260-59,059,262	0.9	6.1x10 <sup>-9</sup>
6q26	162,474,893-162,676,564	0.2	1.3x10 <sup>-8</sup>
18p11.22	9,285,824-9,751,587	0.5	3.3x10 <sup>-8</sup>
7p14.3	31,091,235-31,806,797	0.7	5.4x10 <sup>-8</sup>

**A Bayesian framework to detect differentially methylated loci in both mean and variability with next generation sequencing.** *H. Xu<sup>1</sup>, S. Li<sup>2</sup>, D. Ryu<sup>3</sup>, V. George<sup>1</sup>.* 1) Augusta University, Augusta, GA; 2) University of Texas Medical Branch, Galveston, TX; 3) North Illinois University, DeKalb, IL.

DNA methylation at CpG loci is the best known epigenetic process involved in many complex diseases including cancer. In recent years, next-generation sequencing (NGS) has been widely used to generate genome-wide DNA methylation data. Although substantial evidence indicates that difference in mean methylation proportion between normal and disease is meaningful, it has recently been proposed that it may be important to consider DNA methylation variability underlying common complex disease and cancer. We introduce a robust hierarchical Bayesian framework with a Latent Gaussian model which incorporates both mean and variance to detect differentially methylated loci for NGS data. To identify methylation loci which are associated with disease, we consider Bayesian statistical hypotheses testing for methylation mean and methylation variance using a twodimensional highest posterior density region. To improve computational efficiency, we use Integrated Nested Laplace Approximation (INLA), which combines Laplace approximations and numerical integration in a very efficient manner for deriving marginal posterior distributions. We performed simulations to compare our proposed method to other alternative methods. The simulation results illustrate that our proposed approach is more powerful in that it detects less false positives and it has true positive rate comparable to existing methods.

**Functional annotation enrichment based weights for multiple comparisons correction in genome-wide gene-environment interaction studies.** *C.B. Haas<sup>1,2</sup>, X. Wang<sup>1,2</sup>, H. Chen<sup>1</sup>, P. Auer<sup>3</sup>, S. Lindstrom<sup>1,2</sup>.* 1) Department of Epidemiology, University of Washington, Seattle, WA; 2) Fred Hutch Cancer Research Center, Seattle, WA; 3) Department of Biostatistics, School of Public Health, University of Wisconsin Milwaukee, Milwaukee, WI.

Bonferroni correction assumes equal prior probability of association for all variants tested in a genome-wide association study (GWAS), limiting power to detect true but weak associations. This is especially a concern for gene-environment (GxE) interaction studies, which require even larger sample sizes. Existing methods for multiple comparison adjustment often penalize each variant equally, ignoring any prior information about the biological importance of a specific variant. A weighted Bonferroni adjustment based on enrichment has been shown to increase power compared to standard Bonferroni correction in GWAS, but this has not been applied to genome-wide GxE interaction studies. We performed a case-only genome-wide GxE interaction analysis of age at menarche in 12,366 breast cancer cases from the UK Biobank. We leveraged results from a recent large-scale GWAS of breast cancer in the Breast Cancer Association Consortium (BCAC) to estimate functional enrichment of breast cancer associations across six functional categories: coding, DNaseI Hypersensitive Sites (DHS), intronic, promoter, UTR, and other. Enrichment estimates were calculated using a p-value thresholds of  $10^{-8}$ . Annotation-specific enrichments were 2.58 (coding), 2.14 (UTR), 1.88 (DHS), 1.46 (intronic), 1.37 (promoter) and 0.87 (other). We then applied the annotation-specific enrichments to the results obtained from the GxE interaction scan. In total, we tested 610,758 variants for their interaction with age at menarche. In the UK Biobank results, 4.2% of SNPs were categorized as coding, 22.1% as DHS, 23.5% as intronic, 1.8% as promoters, 1.2% as UTR, and the remaining 47.1% as other. No SNP reached genome-wide significance at a threshold of  $5 \times 10^{-8}$ . We observed nine variants that had a p-value  $< 10^{-5}$  of which one was a coding variant, two were located in DHS, three were located in introns and three were other. Adjustment for multiple comparisons using weighted p-values based on enrichment with a threshold of  $10^{-8}$  promoted two additional variants, one intronic variant and one variant located in DHS. As next step, we will pursue replication of these variants in independent datasets. Our results shows the feasibility of incorporating functional annotations into GxE interaction studies to capture potentially interesting variants that do not reach conventional thresholds for genome-wide significance.

**Fine-mapping of loci in polyunsaturated fatty acid metabolism genes.**

N.K. Khankari<sup>1</sup>, J.N. Hellwege<sup>1,2</sup>, H.J. Murff<sup>1</sup>, M.J. Shrubsole<sup>1</sup>, Q. Cai<sup>1</sup>, J.C. Denny<sup>2,3</sup>, T.L. Edwards<sup>1,2</sup>, W. Zheng<sup>1</sup>. 1) Division of Epidemiology, Vanderbilt University Medical Center, Nashville, TN; 2) Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN; 3) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN.

**Background:** Metabolism of arachidonic acid results in production of the inflammatory eicosanoid, prostaglandin E2 (PGE2), which has been implicated in colorectal cancer. Levels of arachidonic acid, and other polyunsaturated fatty acids are influenced by the fatty acid desaturase (*FADS1* and *FADS2*; Chromosome 11) and elongase (*ELOVL2*; Chromosome 6) genes. In this analysis, fine-mapping of loci involved in polyunsaturated fatty acid metabolism was conducted in order to identify additional variants that may be associated with red blood cell polyunsaturated fatty acids levels. **Methods:** This study utilized resources from the Tennessee Colorectal Polyp Study (TCPS), a colonoscopy-based case-control study. A total of 1,784 white participants were available for this fine-mapping analysis. These participants had available genotype data for 23 variants in loci related to polyunsaturated fatty acid metabolism (i.e., *FADS1*, *FADS2* and *ELOVL2*), and had red blood cell polyunsaturated fatty acid levels measured. Variants were phased and imputed (via SHAPEIT/IMPUTE2) in these loci using the 1000 Genomes Phase 3 Reference Panel. A total of 716 variants were imputed and used for association analysis after filtering on imputation quality (quality score  $\geq 0.3$ ). Association tests were conducted using SNPTTEST to identify statistically significant associations with red blood cell polyunsaturated fatty acid levels measured as a percentage of total membrane-bound fatty acid content. **Results:** After Bonferroni correction for multiple comparisons, several variants in the *FADS1* and *FADS2* locus were associated with linoleic acid [ $n = 115$ , percent variation explained (%VE) = 3.18], arachidonic acid ( $n = 53$ , %VE = 0.68),  $\alpha$ -linolenic acid ( $n = 23$ , %VE = 7.67), and eicosapentaenoic acid ( $n = 5$ , %VE = 21.6). No variants reached the Bonferroni threshold for statistical significance for the *ELOVL2* locus. The index variants associated with each of the traits were rs102275 for linoleic acid (T allele,  $\beta = 0.61$ ,  $p = 3.6 \times 10^{-11}$ ), rs174562 for arachidonic acid (A allele,  $\beta = -0.18$ ,  $p = 7.3 \times 10^{-7}$ ), rs187598088 for  $\alpha$ -linolenic acid (C allele,  $\beta = 10.6$ ,  $p = 9.2 \times 10^{-79}$ ), and rs189781536 for eicosapentaenoic acid (G allele,  $\beta = 27.7$ ,  $p = 2.3 \times 10^{-224}$ ). **Conclusions:** This study suggests that several variants surrounding the *FADS1* and *FADS2* loci are likely involved in polyunsaturated fatty acid metabolism, in particular for linoleic, arachidonic,  $\alpha$ -linolenic, and eicosapentaenoic acids.

## 780W

**Characterization of candidate functional variants in CASP8 from a melanoma locus at chr2q33-q34.** H. Kong, J. Choi, T. Zhang, M. Kovacs, A. Vu, M. Xu, K.M. Brown. Division of Cancer Epidemiology and Genetics, National Cancer Institute, National Institute of Health, Bethesda, MD.

Previous genome-wide association studies have identified a melanoma susceptibility locus at 2q33-34 near *CASP8*. This region appears to be a multi-cancer risk locus, as a similar association signal has been observed in this region for susceptibility to cutaneous basal cell carcinoma, breast cancer, esophageal squamous cell carcinoma, and chronic lymphocytic leukemia. To perform an eQTL analysis for this locus in a melanoma-relevant tissue, we collected primary cultures of human melanocytes from 106 newborn males, measured transcript levels via RNA sequencing, and assessed genotypes by direct genotyping and imputation. *CASP8* is a significant expression quantitative trait locus (eQTL) gene for this locus, with the risk-associated allele (rs7582362[A]) correlated with lower *CASP8* levels ( $P = 4.43 \times 10^{-6}$ ) in melanocytes. No significant *cis*-eQTL of other genes with the melanoma lead SNP was observed. An association between this locus and *CASP8* is also found in 21 out of 44 the Genotype-Tissue Expression (GTEx) Project tissues, however the direction of effect appears to be opposite that observed in melanocytes for four GTEx tissues (19%). In order to identify potentially functional risk-associated sequence variants with allele-specific transcriptional activities, we performed a massively parallel reporter assay (MPRA) in UACC903 melanoma cells. As a part of a larger MPRA assay, we chose 21 high-LD variants ( $r^2 > 0.4$  with the lead SNP, rs7582362) with promoter/enhancer-relevant ENCODE annotations in either primary melanocytes or melanoma cells. MPRA confirmed that two sequence variants had FDR-significant allele-specific transcriptional activity (rs1861270, FDR =  $1.40 \times 10^{-6}$ ; rs3769823, FDR =  $3.73 \times 10^{-4}$ ), however rs1861270 failed to replicate in an independent assay, and the observed direction of effect for rs3769823 was opposite the direction of the melanocyte eQTL. We are presently evaluating rs3769821 (FDR = 0.07), which also showed allelic differences in activity as a potential causal SNP for melanoma. We have also performed splice QTL analysis of our melanocyte eQTL data using LeafCutter, and have found that the protective allele of a melanoma-associated SNP (rs10804111[T];  $r^2 = 0.65$  to rs7582362) is correlated with usage of an alternative splice donor for exon 8, resulting in a potentially non-functional *CASP8* transcript. We are presently testing associated sequence variants for an effect on gene splicing using a minigene assay.

**Pathway-based analysis of prostate cancer integrating eQTL data and GWAS summary statistics from the UK Biobank.** *T.J. Meyers<sup>1</sup>, S.R. Rashkin<sup>2</sup>, J.S. Witte<sup>1,2</sup>.* 1) Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, USA; 2) Institute for Human Genetics, University of California, San Francisco, San Francisco, CA, USA.

Genome-wide association studies (GWAS) have reported approximately 170 risk variants for prostate cancer. However, the functional mechanisms relating these associations to disease development are not well described. Pathway-based analyses offer potential insight into these mechanisms and confer an advantage when associations of individual variants or genes are modest. Here, we related gene pathways to prostate cancer susceptibility by integrating GWAS summary statistics estimated from the UK Biobank, expression quantitative trait loci (eQTL), and known gene sets using the weighted adaptive sum of powered score pathway-based test ('aSPUPath2'). The UK Biobank study population includes 7,441 prostate cancer cases and 169,970 cancer-free controls, and summary statistics include typed SNP's and those imputed to the Haplotype Reference Consortium (HRC), UK10K, and 1000 Genomes panels. The aSPUPath2 program performs the weighted sum test of the gene variants on gene expression, then tests the association of each gene pathway with the trait by combining associations across the genes. Furthermore, the program is robust to pathways containing genes or SNPs with associations that may be weak and/or in different directions. We obtained eQTL weights from prostate tissue from the GTEx program website and gene sets from the Molecular Signatures Database version 6.1. Results from this analysis will be presented. By leveraging GWAS summary statistics and eQTL data, we can detect biological pathways implicated in prostate cancer development.

**Analysis of the *CDKN2A* gene in FAMMM syndrome families reveals early age of onset for additional syndromic cancers.** *C.D. Middlebrooks<sup>1</sup>, M. Stacey<sup>2</sup>, Q. Li<sup>1</sup>, C. Snyder<sup>2</sup>, T. Shaw<sup>2</sup>, M. Rendell<sup>3</sup>, C. Ferguson<sup>2</sup>, T. Townley<sup>4</sup>, P. Silberstein<sup>5</sup>, M.J. Casey<sup>2,6</sup>, S. Lanspa<sup>7</sup>.* 1) National Human Genome Research Institute, Baltimore, MD; 2) Hereditary Cancer Center, Creighton University, Omaha, NE; 3) The Rose Salter Medical Research Foundation, Newport Coast, CA; 4) Internal Medicine Department, Creighton University, Omaha, NE; 5) Department of Hematology/Oncology, Creighton University, Omaha, NE; 6) Department of Obstetrics and Gynecology, Creighton University, Omaha, NE; 7) Internal Medicine Department - Gastrointestinal Division, Creighton University, Omaha, NE.

Familial atypical multiple mole melanoma (FAMMM) syndrome is a familial cancer syndrome that results from mutations in several genes including the *CDKN2A* gene. The syndrome is currently comprised of dysplastic nevi as well as melanoma, breast, pancreatic and lung cancer which are referred to as "concordant" cancers. As families with known *CDKN2A* mutations have been studied longitudinally, clinicians observed an abundance of other cancers or "discordant cancers." However, it was unknown whether these cancers were related to the syndrome. We sought to determine whether these discordant cancers also occur at higher frequencies and at earlier age of onset in carriers than non-carriers. We studied 10 FAMMM syndrome families (N = 1085 individuals) in which a causal mutation in the *CDKN2A* gene was identified. We performed survival analysis as well as a mixed effects cox regression with age at follow-up or cancer event as our time variable and presence or absence of a concordant or discordant cancer as our censoring variable. The survival curves showed a significant age effect with carriers having a younger age at cancer onset for concordant (as expected) as well as discordant cancers than that of non-carriers. The cox regression models were also highly significant (P = 1.24E-27 and P = 5.00E-13 for the concordant and discordant cancers, respectively). As melanoma screening in these high risk families will identify non-melanoma skin cancers but not the other discordant cancers observed here, we sought to determine if there was evidence that new sites should also be commonly screened. Hence, we repeated the discordant cancer analysis with non-melanoma skin cancers removed to ensure that this group was not driving the effects seen. The result was still highly significant. These analyses support the hypothesis that carriers of mutations in *CDKN2A* in FAMMM syndrome have increased risk for early onset of several additional cancer types, suggesting that early screening for these cancers would be beneficial to carriers and clinical guidelines may need to be updated. Based on the data and results, we also recommend that genetic counseling with intensive cancer screening education should be offered to family members beyond the usual first-degree relatives.

**Integrative latent unknown cluster assignment using multi-omics data with phenotypic traits.** C. Peng<sup>1</sup>, J. Wang<sup>1</sup>, I. Asante<sup>2</sup>, S. Louie<sup>2</sup>, G. Casey<sup>1</sup>, D.C. Thomas<sup>1</sup>, D.V. Conti<sup>1</sup>. 1) Department of Preventive Medicine, Keck School of Medicine, University of Southern California, Los Angeles, CA; 2) School of Pharmacy, University of Southern California, Los Angeles, CA.

Epidemiologic, clinical, and translational studies are increasingly generating multiplatform omics data, such as chemical profiles, metabolomes, transcriptomes, genomes and epigenomes. Methods that can integrate across multiple high-dimensional data types while accounting for differential patterns are critical for uncovering novel associations and underlying relevant subgroups. We propose an integrative model to estimate latent unknown clusters (LUCid) that aims to both distinguish unique genotypes and informative biomarkers/omic effects while jointly estimating subgroups relevant to the outcome of interest. Leveraging ideas from the theory of exposure measurement error, the conceptual framework for the integrated analysis views measured omic data as flawed measurements of currently unobserved, latent subgroups. In turn, these subgroups are both influenced by long-term factors (i.e. genotypes or previously encountered exposures) and are related to the outcome. To estimate the overall integrated model, we treat subtype estimation as a missing data problem, where we can use the Expectation-Maximization (E-M) algorithm for estimation with the E-step using the conditional probabilities, and M-step using the expected log-likelihood from the E-step maximized with respect to the parameters. We have implemented this model in an R package *LUCid* (<https://github.com/USCbiostats/LUCid>) capable of analyzing a large number of measured omic data and exposure or genotypes with either a continuous or dichotomous outcome. To accommodate high dimensional omics data, we use regularized regression techniques to obtain sparse estimates for the corresponding coefficients. Simulation results indicate that we can obtain consistent estimates reflective of the true simulated values and we can estimate subgroups and recapitulate subgroup-specific effects. We apply this approach to real data with measured folate biomarkers among colorectal cancer (CRC) cases and controls. We identify four latent subgroups with one noteworthy group having high CRC risks (OR=6.7) and characterized by high levels of pyridoxal and homocysteine (HCY) in the methionine cycle and low levels of 5-MTHF in the folate cycle. The proposed method offers a promising solution to identify factors and estimate molecular subtypes of disease for efficient targeted treatments and successful personalized medicine.

*BRA-STRAP* is performing targeted-sequencing of 24 genes commonly included on panel tests for breast cancer predisposition in 30,000 Australian women of all ages across the cancer risk spectrum, affected and unaffected with breast cancer, and their families. Contributing to *BRA-STRAP* are i) large research cohorts of aging populations and of women above population risk, and ii) the clinical genetics community and women found negative for *BRCA1* and *BRCA2* mutations following testing in an Australian Familial Cancer Centre (FCC) over the last 2 decades. *BRA-STRAP* is also engaged with other similarly designed studies set outside of Australia (e.g. BRIDGES and CARRIERS). Data on this scale represents the spectrum of genetic variation observed in these genes and exemplifies the opportunities and challenges for realizing precision medicine and precision public health for breast cancer. To date, *BRA-STRAP* has identified over 240 women carrying genetic variants in genes supported by Australian best practice guidelines: 133/2,744 (4.8%) in the Australian Breast Cancer Family Registry (ABCFR) and 106/4,911 (2.1%) in the participating FCCs. These genetic variants include pathogenic variants in *BRCA1* and *BRCA2* (as classified by *ENIGMA*), truncating variants in *PALB2* and *TP53*, and *ATM:c.7271T>G* (p.Val2424Gly). Women found to carry these variants have the opportunity to receive this information, free of charge, to inform their risk management, treatment options and enable predictive testing in family members. In the other genes, *BRA-STRAP* has so far identified 49/1,189 (4.1%) and 238/4,911 (4.8%) carriers of truncating variants in affected women participating in the ABCFR and women attending an FCC, respectively. A comprehensive analysis of the data generated to date is underway. A large number of genetic variants will need further study to determine their clinical utility. These include variants in genes that are not well characterized outside a specific cancer syndrome or for which there is currently insufficient evidence to be called *bona fide* breast cancer susceptibility genes, and variants of uncertain clinical significance in known breast cancer susceptibility genes. For instance, we have observed 85/7,655 (1.1%) carriers of rare (MAF <0.1%) missense variants in *PALB2* that are predicted to be deleterious by multiple prediction tools. More information is urgently required so these variants can be included in evidenced-base clinical management and genetic counselling.

**Fine-mapping of 150 breast cancer susceptibility regions to single-variant resolution and prediction of target genes.** J. Beesley<sup>1</sup>, L. Fachal<sup>2</sup>, J. Allen<sup>2</sup>, S. Karr<sup>2</sup>, D. Barnes<sup>2</sup>, H. Aschard<sup>3</sup>, V. Kristensen<sup>4</sup>, A. Lemaçon<sup>5</sup>, A. Antoniou<sup>6</sup>, J. Simard<sup>6</sup>, P. Kraft<sup>6</sup>, D.F. Easton<sup>2</sup>, G. Chenevix-Trench<sup>1</sup>, A.M. Dunning<sup>2</sup>. 1) QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia; 2) Centre for Cancer Genetic Epidemiology, Department of Oncology, University of Cambridge, Cambridge, UK; 3) Program in Genetic Epidemiology and Statistical Genetics, Harvard T.H.Chan School of Public Health, Boston, MA, USA; 4) Department of Cancer Genetics, Institute for Cancer Research, Oslo University Hospital Radiumhospitalet, Oslo, Norway; 5) Genomics Center, Centre Hospitalier Universitaire de Québec Research Center, Laval University, Québec City, QC, Canada; 6) Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, USA.

Genome-wide Association Studies (GWAS) have identified breast cancer risk alleles at 150 genomic regions. Here, we use dense genotyping and imputation to fine-map all these regions to identify independent risk signals, reduce the number of candidate causal variants (CCVs), and predict target genes. Using stepwise multinomial logistic regression with genotype data for >90,000 cases and 95,000 controls from 147 studies contributing to the Breast Cancer Association, Discovery, Biology, and Risk of Inherited Variants in Breast Cancer, and Investigators of Modifiers of *BRCA1/2* Consortia, we identify 352 independent risk signals comprising 7,394 CCVs, defined as variants with marginal *P* values within two orders of magnitude of the most significant SNP. We find 28 signals with a single CCV, and 96 signals with less than ten. Sixty six signals are more strongly associated with risk of estrogen receptor positive (ER+) and 29 with ER- disease. Enrichment analysis reveals significant overlap of CCVs in cistromes of transcription factors (TFs) associated with estrogen signalling with far larger effect sizes observed for ER+ variants. Significant overlap of ER+ CCVs is further supported by localisation of variants to corresponding TF recognition motifs. We use Integrated expression Quantitative trait and In Silico prediction of GWAS Targets (INQUISIT) to predict target genes finding 1,355 unique targets for 93% signals. The 155 most robustly predicted targets are strongly enriched for known breast cancer driver genes ( $P < 10^{-6}$ ) but also include many genes with no previously known role in breast cancer. Modelling the number of signals per gene by negative binomial versus Poisson regression suggests that a larger than expected number of genes are impacted by >1 independent signal at proximal genomic regions (likelihood ratio test  $P = 10^{-3}$ ). Pathway analysis using high confidence target gene predictions reveals specific themes for ER+ candidate targets including Ephrin signalling, and FOXM1 signalling for ER- risk genes. These results provide logical prioritization of risk loci for functional follow-up to unequivocally identify target genes and elucidate the molecular and cellular mechanisms underlying the genetic basis of breast cancer. 1. Michailidou *et al.*, Association analysis identifies 65 new breast cancer risk loci. *Nature* 2017.

**Judging genetic loci by the company they keep: Comparing network-based methods for biomarker discovery in familial breast cancer.** H. Climente-González<sup>1,2,3</sup>, C. Lonjou<sup>3,1,2</sup>, F. Lesueur<sup>3,1,2</sup>, D. Stoppa-Lyonnet<sup>4,5</sup>, N. Andrieu<sup>3,1,2</sup>, C.-A. Azencott<sup>2,1,3</sup>, GENESIS investigators. 1) Institut Curie, PSL Research University, F-75005 Paris, France; 2) MINES ParisTech, PSL Research University, CBIO-Centre for Computational Biology, F-75006 Paris, France; 3) INSERM, U900, F-75005 Paris, France; 4) Service de Génétique, Institut Curie, Paris, France; 5) Inserm, U830, Université Paris Descartes, Paris, France.

In this work we explore and evaluate the ability of network-based methods to find genetic markers for complex diseases. The three surveyed algorithms (PINBPA, dmGWAS and SConES) leverage on prior knowledge to overcome the lack of power of GWAS studies. We explore the GENESIS case-control dataset, composed of 1,282 French women affected by familial breast cancer, and 1,272 unaffected women from the general population. Genotyping data were obtained using the iCOGS SNP array (200,000 SNPs). Network methods found biomarkers that showed high, albeit non-significant, scores of association with the disease, while being connected in a network that represents the underlying biology. Most of them are in or close to genes well known to be related to breast cancer susceptibility (such as *FGFR2*, *TOX3*, *NEK10*) We compared our results to those reported for European populations by the Breast Cancer Association Consortium (BCAC), who have performed the most exhaustive meta-GWAS of breast cancer. Network methods retrieved 23 and 7% of BCAC significant SNPs and genes respectively with a hundredth of the sample size. On top of that, they recovered 211 SNPs and 12 genes candidates to be specific for the French population. While all three algorithms successfully leverage prior knowledge on our data set, they differ in their methodology, aim, and results. PINBPA and dmGWAS require combining SNP scores into gene scores. They output a list of ranked subnetworks of the provided gene-gene network, where strongly associated genes are interconnected through other genes, if not directly. By contrast, SConES returns a single list of SNPs and works directly on genotypes, using a SNP-based network. We explored three SNP-network architectures: genome structure, gene membership and a network derived from the protein-protein interaction network we used for PINBPA and dmGWAS. Two challenges all three tools have in common are the choice of their parameters, which can notably alter their output, and the visualization of the results. In summary, dmGWAS, PINBPA, and the three variants of SConES all give different importance to gene-gene interactions. We found that although the multiplicity of subnetworks from PINBPA and dmGWAS makes interpretation more challenging, it provides useful complementary information. We conclude that dmGWAS and PINBPA are interesting for generating hypotheses about the etiology of the disease, while SConES' strength is biomarker discovery.

## 787T

**Phenotype-driven burden testing for identifying rare and common variants influencing the somatic mutation landscape in 2,642 cancer genomes.** *F.M. De La Vega<sup>1,2</sup>, S. Nohzadeh Malakshah<sup>3</sup>, S. Flygare<sup>3</sup>, B. Moore<sup>3</sup>, E. Hernandez<sup>3</sup>, E. Kiruluta<sup>1</sup>, C.D. Bustamante<sup>2</sup>, M. Yandell<sup>3</sup>.* 1) Fabric Genomics, Oakland, CA; 2) Stanford University School of Medicine, Stanford, CA; 3) University of Utah School of Medicine, Salt Lake City, UT.

Whole-genome and whole-exome sequencing (WGS/WES) are increasingly used to identify rare genetic variants involved in the etiology of complex disease and novel drug targets. Analysis of such datasets requires specialized statistical methods that need to deal with allelic and locus heterogeneity and the scale of the data. To address these needs, we have developed an integrated pipeline that includes an improved version of the VAAST algorithm, which implements a gene-level burden test statistic and provides empirically calculated  $p$ -values for every gene-hit. The pipeline starts from variant calls in VCF format, bundles clean-up and normalization steps, scores variants with a new algorithm (VVP), performs the VAAST burden test, and then optionally runs Phevor, a phenotype-driven method that leverages prior knowledge from the Human Phenotype and Gene Ontologies to increase power. To validate our pipeline, we spiked known disease variants from ClinVar into WES data from 2,000 controls from unrelated studies. Variants were spiked on a range of allele frequencies, carrier rates, inheritance models, and allelic heterogeneities. We also benchmarked our software against the commonly used SKAT-O method. Our methods consistently identified known disease-genes with genome-wide significance and delivered more power than SKAT-O, alongside fast compute times. We applied our pipeline to a dataset of 2,642 cancer patients across 39 cancer types, where their germline and cancer genomes were sequenced as part of the Pan-Cancer Analysis of Whole-Genomes ICGC project. Since this cohort does not include non-cancer control samples, for analysis we split samples with different mutational signatures, different germ layers, or used external WGS controls. Previous analysis uncovered germline variants in *APOBEC3B* associated with somatic mutational signatures derived from this enzyme activity; however, even when the analysis was limited to 298 candidate cancer genes, other analyses were underpowered. Our pipeline is applied to replicate the previous finding with *APOBEC3B*, and additional associations with *BRCA1/BRCA2* in ovarian and breast cancer, respectively, and *POLK* in lymphoma, without limiting to candidate genes. Our results show an increased power to identify genes associated with complex traits in the presence of allelic and locus heterogeneity with modest sample sizes, suggesting our pipeline could be valuable to analyze large prospective and case/control cohorts.

Bailey-Wilson<sup>1</sup>.* 1) Computational and Statistical Genomics Branch, National Human Genome Research Institute, National Institutes of Health, Baltimore, MD; 2) Laboratory of Medical Genetics, Harbin Medical University, Harbin, China; 3) Geisel School of Medicine, Dartmouth College, Lebanon, NH; 4) Mayo Clinic, Rochester, MN; 5) Department of Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 6) Department of Medicine, University of Toledo Dana Cancer Center, Toledo, OH; 7) Medical College of Wisconsin, Milwaukee, WI; 8) Institute for Genomic Medicine, Nationwide Children's Hospital, Columbus, OH; 9) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 10) Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, OH; 11) Baylor College of Medicine, Houston, TX; 12) Division of Oncology, Washington University School of Medicine, St. Louis, MO.

Lung cancer (LC) kills more people in the United States than any other cancer; it is responsible for 25% of all cancer deaths nationwide. LC risk is known to be increased by a variety of environmental factors, especially tobacco smoking, however the disease has a significant genetic component as well. We performed whole exome sequencing (WES) on 204 individuals from 25 extended families. These families have a strong history of LC and are highly aggregated for the lung cancer phenotype. Individuals from each family were chosen for sequencing to maximize information in a genetic linkage analysis. The WES was recalled with PICARD and GATK and standard quality controls on depth, genotype quality, missingness and Mendelian errors were performed. We also calculated identity-by-descent (IBD) values to confirm all familial relationships. After quality control, we were left with approximately 500,000 SNVs and indels per family for subsequent analysis. We performed two-point parametric linkage analysis on LC and the WES data including phenotype data for both sequenced and unsequenced family members (493 total) using an autosomal dominant model with disease allele frequency of 1%, 10% penetrance for carriers and a 1% phenocopy rate. Our analyses were affected only analyses, meaning individuals that were affected were coded as cases, all others were coded as having unknown (or missing) phenotypes. We performed linkage analysis both on the individual markers (SNVs or indels) and on individual genes. The gene-based markers were constructed from haplotypes of the rare variants (MAF < 0.01) located in each gene. Two-point linkage was then performed on each gene-based marker. Initial analyses found multiple significant gene-based linkages. The highest HLOD scores centered on chromosome 1q. The significant HLOD scores clustered around known cancer genes, including the implicated genes *OBSCN* and *RYR2*. The signals also centered on five genes in the neuroblastoma breakpoint family (NBPF) genes, a cluster of recently duplicated genes that have been found to be associated with a variety of cancers, including lung cancer. We have an additional 200 individuals from additional extended families that are currently being recalled and will be ready for analysis shortly. These individuals will be analyzed as well to increase power on our current findings and possibly identify new linked regions.

**Multivariable Mendelian randomization study of adiposity measures, puberty onset, and prostate cancer risk.** C. Zhang<sup>1</sup>, L. Kachuri<sup>1</sup>, S. Rashkin<sup>1</sup>, T.J. Meyers<sup>1</sup>, K.M. Walsh<sup>2</sup>, J.S. Witte<sup>1</sup>. 1) University of California, San Francisco, San Francisco, CA; 2) Duke University, Durham, NC.

Observational studies suggest links between adiposity measures and prostate cancer risk, including lower risk with elevated body mass index (BMI) and, paradoxically, higher risk with greater BMI-adjusted waist hip ratio (whradjBMI). However, Mendelian randomization studies do not support the effect of genetically elevated BMI or whradjBMI on prostate cancer. Furthermore, some of the genetic variants associated with the two adiposity measures are pleiotropic, i.e. associated with both BMI and whradjBMI, which violates the assumptions of traditional univariable MR. A previously described protective effect of delayed puberty onset on prostate cancer risk has been attributed to reduced androgen levels, which has also been suggested as the underlying mechanism for the protective effect of obesity on prostate cancer risk. To explore these hypotheses, we performed a *multivariable* MR analysis of the independent causal effects of BMI, whradjBMI, and puberty onset (based on the Tanner scale) using GWAS summary statistics for prostate cancer risk from the UK Biobank (cases=7,441), and previously published GWAS data on the three risk factors. Results from univariable MR show a weak protective effect of increased BMI on prostate cancer risk (odds ratio (OR)=0.87, 95% confidence interval (CI)=0.71-1.05), a weak protective effect of later puberty onset (OR=0.76, 95% CI=0.47-1.22), and a weak risk effect of higher whradjBMI (OR=1.25, 95% CI=0.93-1.67). In a multivariable MR analysis that included all three factors, the inverse associations for BMI and puberty onset strengthened, reaching statistical significance: OR=0.77 (95% CI=0.63-0.95) and OR=0.77 (95% CI=0.60-0.99), respectively, while the multivariable MR estimate for whradjBMI revealed a non-significant protective effect of greater BMI-adjusted waist hip ratio on prostate cancer risk (OR=0.84, 95% CI 0.65-1.09). These results suggest that BMI and puberty onset exert independent causal effects on prostate cancer but does not exclude the possibility that both operate via the effect of diminished androgen exposure during discrete phases of life. Multivariable MR analysis can be useful in evaluating the role of multiple exposures on disease risk when these exposures share overlapping genetic architecture.

**Re-interpreting PAM50: Intrinsic tumor dimensions, prognosis and response to paclitaxel.** N.J. Camp<sup>1,2</sup>, M.J. Madsen<sup>1</sup>, J.H. Valera<sup>3</sup>, E. Carrasco<sup>3</sup>, R. Caballero<sup>3</sup>, M. Martin<sup>4</sup>, P.S. Bernard<sup>1,5</sup>. 1) Huntsman Cancer Institute, University of Utah, Salt Lake City, USA; 2) Department of Internal Medicine, University of Utah, Salt Lake City, USA; 3) Spanish Breast Cancer Research Group, GEICAM, Madrid, Spain; 4) Department of Medical Oncology, Hospital General Universitario Gregorio Marañón, Madrid, Spain; 5) Department of Pathology, University of Utah, Salt Lake City, USA.

**Background.** We recently showed that PAM50 gene expression data can be represented by five quantitative, orthogonal, multi-gene breast tumor traits. These novel tumor 'dimensions' were superior to intrinsic subtypes for differentiating tumors from high-risk breast cancer pedigrees, indicating potential to represent underlying genetic susceptibilities and biological pathways. Here we explore the prognostic and predictive utility of these tumor dimensions in a sub-study of GEICAM/9906, a Phase III randomized prospective clinical trial of the addition of paclitaxel in breast cancer. **Methods.** Intrinsic tumor dimensions PC1 – PC5 were calculated using pre-defined coefficients. Univariable and multivariable Cox proportional hazards (PH) models, Kaplan-Meier curves and log-rank tests for disease-free survival (DFS) were used to identify associations between dimensions and prognosis or response to the addition of paclitaxel. **Results.** Dimensions PC1 and PC5 were associated with DFS (Cox PH  $p=6.7 \times 10^{-7}$  and  $p=0.036$ ), remaining significant after correction for standard clinical-pathologic prognostic characteristics. Both dimensions were selected in the optimal multivariable model, together with nodal status and tumor size (Cox PH  $p=1.4 \times 10^{-12}$ ). Interactions with treatment were identified for PC3 and PC4. Response to addition of paclitaxel was restricted to tumors with low PC3 and PC4 (log-rank  $p=0.0021$ ). Women with tumors high for PC3 or PC4 showed no survival advantage. **Conclusions.** Intrinsic dimensions illustrate clinical utility beyond standard clinical-pathologic characteristics for prognosis and predicting chemotherapy response in locally-advanced breast cancer patients. The consideration of expression data as quantitative tumor dimensions offers new potential to identify clinically-important patient subsets, increase power in clinical trials and improve precision medicine.

**791F**

**Mosaic Y loss and incident cancer risk in the UK Biobank.** *M.J. Machie-la<sup>1</sup>, E. Lofffield<sup>1</sup>, W. Zhou<sup>1,2</sup>, M. Yeager<sup>1,2</sup>, S.J. Chanock<sup>1</sup>, N.D. Freedman<sup>1</sup>.* 1) Division of Cancer Epidemiology and Genetics, National Cancer Institute, Rockville, MD; 2) Cancer Genomics Research Laboratory, Frederick National Laboratory for Cancer Research, Leidos Biomedical Research, Inc., Frederick, MD, USA.

Mosaic loss of the Y chromosome (mLOY) in peripheral leukocytes is a somatically occurring event in which a fraction of leukocytes lacks the entire Y chromosome. The frequency of mLOY is higher among cigarette smokers and increases with age, with mLOY commonly observed in men over age 50. mLOY may reflect poor genomic maintenance as well as clonal imbalances in normal immune function, making mLOY an attractive candidate marker for cancer risk. Some, but not all, previous studies have suggested that mLOY may be associated with higher risk of solid tumors. Therefore, we investigated the relationship between mLOY and incident cancer in a large sample of 207,603 cancer-free men from the UK Biobank. We identified mLOY by scanning for deviations in genotyping array log R intensity ratios (LRR) across the male-specific chromosome Y region, classifying mLOY into low (median LRR < -0.15, ~10%) and high (median LRR < -0.40, ~24%) proportions of cells affected. In total, 14,947 men developed an incident cancer during follow-up with prostate (N=4,345), colon (N=848) and lung (N=783) being the most common incident non-cutaneous solid tumors. Overall, we detected low proportions of cells with mLOY in 3,358 (1.6%) men and high proportions of mLOY in 524 (0.3%) men. Adjusting for age, comprehensive smoking history, ethnicity, body mass index, alcohol consumption and education, we found no association of mLOY with overall cancer incidence using either the low or high mLOY thresholds (HR<sub>low</sub>=1.05, 95% CI<sub>low</sub>=0.96-1.16, P-value<sub>low</sub>=0.31; HR<sub>high</sub>=1.22, 95% CI<sub>high</sub>=0.99-1.51, P-value<sub>high</sub>=0.07), but we did observe associations for two smoking-related cancers: bladder (HR<sub>low</sub>=1.67, 95% CI<sub>low</sub>=1.07-2.59, P-value<sub>low</sub>=0.02) and lung (HR<sub>high</sub>=1.97, 95% CI<sub>high</sub>=1.19-3.24, P-value<sub>high</sub>=0.008) cancer. Stronger associations were observed without adjustment for smoking, suggesting that smoking may be an important confounder. Alternatively, mLOY may mediate, at least to some extent, the association of cigarette smoking to these cancers. In summary, mLOY was not a strong risk factor for incident solid tumors in adult men in the UK Biobank. Modest associations were observed for bladder and lung cancer, although these findings may reflect residual confounding by smoking.

**Association testing in admixed populations using aggregated data.** *E. Ziv<sup>1</sup>, D. Hu<sup>1</sup>, J. Weitzel<sup>2</sup>, S. Neuhausen<sup>2</sup>.* 1) Medicine, University of California San Francisco, San Francisco, CA; 2) Beckman Research Institute, City of Hope, Duarte, CA.

Modern sequencing studies often depend on the use of aggregate data for controls, such as ExAC and gnomAD. However, a significant limitation of this approach, particularly in admixed populations, is that genetic ancestry is not known for individual participants and therefore there is no method to adjust for ancestry differences between cases and controls. Here we develop a method to adjust for ancestry differences between cases and controls using aggregate data. The components required include (a) an estimate of the overall genetic ancestry in the aggregate dataset/s and (b) an estimate of the allele frequency in each ancestral population for each allele tested. Methods for the former have previously been developed and can be implemented as long as a fraction of the variants have also been genotyped in ancestral populations. For the latter, estimation of allele frequencies in the ancestral populations, we develop a method that uses several admixed populations to infer the ancestral allele frequencies. We show that as long as for any N admixed populations derived from M ancestral populations with different proportions, as long as N≥M, we can infer ancestral allele frequencies for any variant typed in all N populations. This inferred allele frequencies can then be used as part of a likelihood ratio test conditional on the overall ancestral proportions in cases and controls. We demonstrate the method avoids bias due to population stratification using simulations. We also utilize the approach to test for allele frequency differences between Latina breast cancer cases and Latino controls from ExAC and gnomAD.

## 793T

**TWO-SIGMA-geneset: TWO-component SInGle cell Model-based Association method for Gene Set Testing.** E. Van Buren, Y. Li, D. Wu. University of North Carolina at Chapel Hill, Chapel Hill, NC.

Gene set testing (GST) methods allow omnibus testing for a pre-specified set of genes, often by assigning an overall  $p$ -value to the set of genes. By considering such sets of genes, GST methods can improve statistical power and help to understand how genes in a common pathway jointly regulate biological processes. There are many GST methods for bulk RNA-seq data, however no such methods are specifically designed for use with single-cell RNA-seq data, which often exhibits excess zeros and overdispersed counts compared to traditional bulk RNA-seq data. Here, we propose TWO-SIGMA-geneset to conduct gene set testing using single-cell RNA-seq data. We utilize our previously developed TWO-SIGMA, a flexible TWO-component SInGle cell Model-based Association method. The first component of TWO-SIGMA models the “drop-out” probability with a mixed effects logistic regression, and the second component models the (conditional) mean read count with a log-linear negative binomial mixed-effects regression. TWO-SIGMA accommodates excess zeros and overdispersed counts, and can, using random effects, explicitly account for the possible dependency introduced by measuring multiple single cells from the same sample. The focus of TWO-SIGMA-geneset is on conducting competitive gene set testing, in which the genes in a given set are compared to the remaining collection of genes. Each gene in the set is assigned an individual statistic, such as a likelihood ratio statistic from the joint test of both components, produced from TWO-SIGMA. These gene-level statistics are then combined into one set-level statistic, with options including the average, median, or sum of the ranks. Finally, the set-level statistic is compared to the complement set of genes using, for example, the t-test, Wilcoxon rank-sum test, or a Monte Carlo  $p$ -value. Simulation studies show that type-I error is well controlled in a variety of representative scenarios. Power is improved over state-of-the-art methods, including CAMERA, for a variety of scenarios consistent with real single-cell RNA-seq data, including when varying: gene set sizes, the scales of the differential expression, the proportion of drop-out events, or the presence of individual-level random effects. Extensions to allow for inter-gene correlation are discussed. We demonstrate our method with an application to a real dataset consisting of 36,849 single cells from 10 mice and gene sets from the Molecular Signatures Database.

## 794F

**Genome partitioning with region-based analysis adapted to linkage disequilibrium (LD) structure in lung cancer case-control association analysis.** M. Brossard<sup>1</sup>, S.A. Kim<sup>2</sup>, D. Roshandel<sup>3</sup>, Y. MacMillan<sup>1</sup>, A.D. Paterson<sup>3,4</sup>, R. Hung<sup>1,4</sup>, Y.J. Yoo<sup>2</sup>, S.B. Bull<sup>1,4</sup>. 1) Lunenfeld-Tanenbaum Research Institute, Sinai Health System, Toronto, ON, Canada; 2) Seoul National University, Seoul, Korea; 3) Hospital for Sick Children Research Institute, Toronto, ON, Canada; 4) Dalla Lana School of Public Health, University of Toronto, Toronto, ON, Canada.

To improve region discovery in genome-wide association studies of complex traits, we investigate a novel haplotype block detection method (BigLD, Kim 2017) to identify non-overlapping, quasi-independent LD block regions for subsequent region-based testing. When individual effects are too small to be detected by conventional single-SNP analysis, global region tests can improve power to identify genomic regions that harbor multiple SNPs with joint effect on disease risk (Yoo 2017). We investigated a region-based approach in chromosome 8 data from the Toronto site (1359 cases/949 controls) of the ILCCO large scale meta-analysis of lung cancer case-control studies (McKay, Nat Gen 2017), based on a reported *NRG1* susceptibility locus. We applied BigLD on 335K 1000Genomes (1KG)-imputed SNPs ( $MAF \geq 0.05$ ) and assessed sensitivity to the BigLD input parameters and the source population. Because cases may have different LD structure than controls, we recommend that control samples be used for block construction; blocks identified in controls showed good agreement with recombination hotspots and with blocks identified in 1KG European samples. In controls, BigLD identified 5266 blocks with a variable number of SNPs per block (median:15, range: 2-1071); pairwise SNP correlation was high within- and low between-blocks (mean: 0.60 and 0.33 respectively). We found BigLD to be robust to clustering parameter values within the neighborhood of the default value. In each of the BigLD blocks, we compared three regression-based tests to assess global association with lung cancer risk: the generalized Wald test with df equal to the number of SNPs in region and two reduced df tests adapted to local correlation structure. The multiple linear combination test (MLC, Yoo 2017) constructs a constrained test statistic from regression coefficients with df equal to the number of correlated SNP clusters. The regression of SNP principal components (PC80, Gauderman 2007) first reduces the number of regression variables and then constructs a Wald test. MLC and PC80 reduce df of region-based tests (reduction of Wald-df by mean factor of 3 and 5 respectively (ranges 1-13, 1-65)) and provide similar test results (Pearson correlation of  $-\log_{10}$  P-values of 0.84). Because LD varies across the genome, LD-defined region size is right-skewed and high-df global tests tend to become conservative as region sizes increase, suggesting the need for additional dimensional reduction methods in very large regions.

**iMEM: A novel data statistical method for integrating mutation, gene expression and methylation with an application to a paired oral cancer dataset.** S. Das<sup>1</sup>, P.P. Majumder<sup>2</sup>, I. Mukhopadhyay<sup>1</sup>. 1) Human Genetics Unit, Indian Statistical Institute, Kolkata, West Bengal, India, PIN 700108; 2) National Institute of Biomedical Genomics, P.O.: N.S.S., Kalyani, West Bengal, India, PIN 741251.

Alteration in regulatory activities of a gene may be attributed to various genetic and epigenetic factors, like, mutation in DNA, methylation at various CpG sites etc. Traditional methods of analysing omics data separately would incur loss of essential information that might be beneficial in differentiating between the genetic code of a tumor and a normal sample. Recently data integration through joint analysis of various omics data is focused to obtain robust inferences. But it is imperative to understand and include the available downstream information and use more practical assumptions in the model development, in order to capture the diversity in the genomic profiles of patients. Using the idea of analysis of covariance, we propose a general statistical method that identifies the regulators affecting the expression of a gene, through integration of three omics data viz. somatic mutation, gene expression, and methylation. In our model, we consider various downstream categories of mutation classified according to their functional severity that is induced by change in the amino acid and subsequent alteration in the protein. On the other hand, methylation values at adjacent CpG sites are strongly correlated and this correlation weakens as the methylation sites move apart. Our model summarises hundreds of methylation values in the vicinity of the gene incorporating the correlation structure among the methylation sites. Thus our method includes a biological insight from mutation and methylation to assess its effect on the gene expression based on tumor-normal paired sample. We also derive the asymptotic distribution of our test statistic to calculate p-values fast. We perform extensive simulations to analyse the performance of our method mainly in terms of size and power of the test. The type I error rate, calculated on the basis of the distribution of the test statistic, is controlled at 5% level of significance. Our proposed method is powerful and consistent as the power of the test increases with the increase in sample size. Our method is robust as it shows consistent results for different genetic models that we consider in our simulation study. Application to real dataset identifies some significant genes, of which a few are already reported. Based on the results obtained from simulated and real data on oral cancer, our method looks very promising in differentiating gene expression profiles of patients through integrated analysis of three omics data.

**796T**

**Polygenic prediction of breast cancer: Comparison of genetic predictors and implications for screening.** K. Läll<sup>1,4</sup>, M. Lepamets<sup>1</sup>, M. Palover<sup>1</sup>, T. Esko<sup>2</sup>, A. Metspalu<sup>1</sup>, N. Tõnisson<sup>1</sup>, P. Padrik<sup>2,3</sup>, R. Mägi<sup>1</sup>, K. Fischer<sup>1</sup>. 1) Estonian Genome Center, Institute of Genomics, University of Tartu, Tartu, Tartumaa, Estonia; 2) Institute of Clinical Medicine, University of Tartu, Estonia; 3) Cancer Center, Tartu University Hospital, Tartu, Estonia; 4) Institute of Mathematics and Statistics, University of Tartu, Estonia.

As the heritability of breast cancer (BC) is known to be around 20-30%, but only small fraction of BC cases has rare inherited component identified, the ability to predict BC polygenic forms may improve current screening and risk assessment strategies. We compare four genetic risk scores (GRS): two (GRS<sub>70</sub>, GRS<sub>75</sub>) have been recommended by previous publications and include less than 100 single-nucleotide polymorphisms (SNPs) and two newly developed GRSs (GRS<sub>ONCO</sub> and GRS<sub>UK</sub>) based on available summary statistics of two large-scale GWAS analyses. Two cohorts - Estonian biobank with 32557 women and a subset of 46,984 women from the UK Biobank cohort- were used to study associations between GRSs and BC. We show that combining GRS<sub>ONCO</sub> and GRS<sub>75</sub> into one metaGRS produces the score with strongest association with prevalent disease in both cohorts. Women in the top 5% metaGRS category have 4.2 times higher hazard (95% CI 2.8-6.2,  $p = 8.1 \times 10^{-12}$ ) for incident breast cancer than women in the lowest 50% of metaGRS and almost 3 times higher hazard (HR=2.73, 95% CI 1.92-3.9) of developing BC compared to the rest of the population in the Estonian Biobank. While the overall BC incidence in the Estonian population reaches 5% by the age of 70, women in the highest 5% of the metaGRS reach the same risk level almost 20 years earlier. We also show that GRSs that are based on summary statistics of different GWASs are only moderately correlated with each other and discuss the possible implications of that to personalized genetic feedback.

**797F**

**Quantifying uncertainty in causal biological networks.** *E.A. Martin, A.Q. Fu.* Bioinformatics and Computational Biology, University of Idaho, Moscow, ID.

Introduction: Many methods have been developed to infer a causal network under the principle of Mendelian randomization (PMR), by jointly analyzing genotype and gene expression data. In particular, MRPC, our recently developed algorithm, is one such method and outperforms similar methods in inference accuracy. Due to noise in the data, however, not all edges in the inferred network have the same level of confidence, and none of the existing methods quantifies the uncertainty in the inferred edges. Methods: With the causal network inferred by MRPC, we develop a genetic algorithm (GA) to estimate for each inferred edge the probability of the (directed or undirected) edge being correctly identified. The fitness is the log likelihood of the graph given the orientation of the edges and the data. Our algorithm starts by generating a population of individuals, whose 'DNA' are the inferred edges, with their directions randomly assigned. In each generation of the GA a winner and loser are selected from two subsets of the population. The winner is the individual who has the highest fitness among the first subset of individuals. The loser is the individual who has the lowest fitness among the second subset of individuals. The fitness is the log likelihood of the graph given the orientation of the edges and the data. After the winner and loser are selected the DNA of the winner is copied, mutated (reversing edge direction), and then replaces the DNA of the loser. The GA is run until most of the individuals in the population have a similar likelihood. We next count the number of times each direction occurs in the population and divide it by the population size. This gives a probability of an inferred edge being correct. Conclusions: We have simulated data under multiple graphs with different numbers of nodes and edges. In the initial results the probabilities of the edges are what we would expect even accounting for Markov equivalent graphs, which have different topologies but the same likelihood. With these promising results we will continue to expand the algorithm to include more data types (eg genetic variants, different distribution models, etc.) and test it on larger graphs.

**Using Bayes model averaging for admixture mapping.** *L.C. Moss, X. Sheng, C.A. Haiman, D.V. Conti.* *African Ancestry Prostate Cancer Consortium and the Ellipse Game-On Consortium.* Preventive Medicine, University of Southern California, Los Angeles, CA.

Admixture mapping is typically performed in recently admixed populations to detect genetic risk loci for diseases that have differential risk by ancestry. Admixture mapping relies on the deviation of local ancestry, alleles inherited from one ancestral population at a particular locus, from global ancestry, the proportion of the entire genome inherited from one ancestral population. The approaches most commonly used are case-only or case-control models which respectively compare ancestry deviations in cases only or test the effect of the deviation between cases and controls on the disease outcome. Although the case-only approach has potentially more power than the case-control approach, the case-only approach is prone to spurious associations when deviations of ancestry are not solely due to noise within controls. In this study, we Bayes model averaging from estimates obtained from case-only and case-control models to yield a novel statistical test for admixture mapping. The novel approach offers more power than a case-control method while remaining robust in scenarios where the case-only method is most susceptible to false positives. We use simulations to demonstrate that our approach detects admixture signals with increased power and robustness over case-control and case-only methods and illustrate the approach in the African Ancestry Prostate Cancer (AAPC) and the Ellipse Game-On Consortia.

**799T**

**Classification of variants without prior penetrance estimates and the effect of ascertainment bias on classification.** *J. Ranola, G. Tsai, B. Shirts.* University of Washington Laboratory Medicine, Seattle, WA.

Classification of variants of unknown significance is an increasingly important aspect of personalized medicine. Current methods require a penetrance estimate for a gene prior to classification of a new variant in that gene. When available, these penetrance estimates are often based on highly deleterious variants binned together under the assumption that they all have the same pathogenic effect. New variants are then classified according to whether they more closely resemble this set of pathogenic variants or benign ones. The assumption that all pathogenic variants in a gene have the same effect is problematic when classifying new variants. Requiring the penetrance of a similar variant in order to determine the pathogenicity of a new variant is paradoxical. The problem of penetrance assumptions can be exacerbated by the fact that initial penetrance estimates are often from selected families leading to biased over estimates of penetrance. These assumptions put limits on the type of variants that can be correctly classified. Variants with low to moderate risk could never be correctly classified regardless of the amount of data. Likewise, protective variants would be misclassified. As a solution to this problem, we present a new variant assessment method for hereditary cancer risk genes that uses family data and SEER cancer incidence data, which is readily available. The method, based on the Poisson binomial model, compares incident cancers in a family with expected incident cancers while utilizing information from both genotyped and ungenotyped relatives. The model may facilitate information sharing and ongoing improvement of estimates as identifiable pedigree information no longer needs to be shared to combine variant-specific penetrance estimates. Our method, like previous methods, takes into account the ascertainment bias inherent in the proband and can also account for known bias in ascertainment of other relatives. This method can also be used to detect bias in a control dataset when making initial risk estimates. We apply this method to classify hypothetical variants in simulated families across a range of risk while varying the percent of individuals genotyped. We also evaluate actual families tested for hereditary cancer University of Washington database and show the magnitude of clinical bias in ascertaining cancer families. .

**Rare variant tests for association in affected sib pairs with application to breast cancer.** *R.G. Romanescu<sup>1</sup>, G. Gos<sup>1</sup>, I.L. Andrulis<sup>1,2</sup>, S.B. Bull<sup>1,3</sup>.* 1) Lunenfeld-Tanenbaum Research Institute, Toronto ON, Canada; 2) Department of Molecular Genetics, University of Toronto, Toronto ON, Canada; 3) Dalla Lana School of Public Health, University of Toronto, Toronto ON, Canada.

Recent progress in sequencing technologies has made it possible to investigate the role of rare variants (RVs) in disease etiology. Compared to case-control designs, tests based on affected sib pairs (ASPs) can be more powerful, as RVs tend to be enriched in families. With the aim of discovering novel breast cancer susceptibility genes, we conducted a whole exome sequencing (WES) study of sisters with early onset breast cancer (proband age-at-onset <45 years). The sisters, ascertained from high-risk families in the Ontario Familial Breast Cancer Registry, screened negative for known susceptibility genes (including *BRCA1/2* and *CHEK2\*1100delC* variants), thereby increasing the chances of finding rare familial mutations. Candidate genes identified in the ASP study are deemed eligible for potential validation in large case-control consortia. Our objective is to develop tests of association for RVs at the single region, as well as the pathway level, a feature which is expected to improve power and biological interpretability. The key idea is that RVs will be found preferentially on haplotypes shared identical by descent (IBD) versus haplotypes not shared IBD. We construct two test statistics which measure the departure of the joint distribution of RV allele count for the pair and their IBD state (0-2) under ascertainment compared to expectation under simple Mendelian transmission. To mimic the motivating study design, we evaluate our methods on simulated sister pair data under early age-at-onset ascertainment. We assume a genetic model that reflects a scientific hypothesis of locus heterogeneity, i.e., that different families tend to harbor different susceptibility variants. We demonstrate good type I error properties for the tests under a null scenario in which the ASPs do not share causal RVs captured in the test statistic, because they are sporadic cases or because they share a causal RV not included in the test. Under the alternative hypothesis that 15% of RVs captured in the test are causal, we show that the proposed tests are as, or more powerful than existing methods for testing association in ASPs. Finally we apply our tests to sets of variants classified as rare in our sister pairs data, and compare the results to those of a conventional filtering approach we applied in these data that prioritized variants based on mutation type, gene function, and pathway membership.

**Y-chromosome lineages and its contribution to prostate cancer in Mestizo population from Mexico City.** *E. Álvarez-Topete<sup>1</sup>, R. Gómez<sup>1</sup>, L. Torres-Sánchez<sup>2</sup>, S.J. Trujillo-Cáceres<sup>2</sup>.* 1) Departamento de Toxicología, Cinvestav, Mexico City, Mexico; 2) Instituto Nacional de Salud Pública, Centro de Investigación en Salud Poblacional, Cuernavaca, Morelos, Mexico.

Prostate cancer (PC) is the second most common malignant neoplasm in males worldwide and the fifth leading cause of death for cancer in men. Risk factors such as age, diet, smoking, and the genetic background are keystones in this malignant hyperplasia. Y-chromosome genes play a meaningful role in male-specific organs such as prostate glands and have been related to incidence and PC progression. Certain paternal lineages have also been related to PC development and prognosis in different populations. Nonetheless, the Y-chromosome haplogroups have been poorly studied in this context in the Mexican population, which presents a complex genetic architecture related to the historical migrations of the last 500 years. The tremendous diversity within the Mexican paternal lineages provides a unique opportunity to investigate the contribution of Y-chromosome haplogroups and the PC in a multi-ethnic population. Therefore, the non-recombining region of Y-chromosome (NRY) of 533 unrelated mestizo men (150 PC incident cases and 383 population controls) was genetically characterised with seventeen-Y-STRs through capillary electrophoresis. Each individual signed an informed consent validated by the Ethics Committee of National Public Health Institute. The Native American lineage (Q) was the most prominent (~ 42%), followed by R1b (~ 30%) and E1b1b (~ 8%) haplogroups. Of note, the E1b1b carriers exhibited a marginal association of twice risk to PC (OR = 1.80; CI95% 0.965 - 3.998,  $p = 0.06$ ) than the rest of the haplogroups. Stratifying the carriers of this lineage by age-onset and PC aggressiveness degree, a significant association was found (OR = 2.30; CI95% 1.06 - 4.97,  $p = 0.03$ ) for late-onset PC ( $\geq 60$  years old) and Gleason  $\leq 6$  at PC diagnosis (OR= 4.96; CI95% 1.6 - 15.5,  $p = 0.006$ ). Our results suggest a possible contribution of E1b1b with PC, reinforcing previous findings in Ashkenazi Jewish ancestry, and African ancestry where this haplogroup is highly prominent. Our preliminaries results suggest a potential role of Y-chromosome in late-onset PC with a slowly growing grade in the Mexican population.

**A survey of germline mutations with epithelial ovarian cancer in Japanese patients.** *A. Abe<sup>1</sup>, I. Imoto<sup>2</sup>, M. Nishimura<sup>1</sup>, M. Irahara<sup>1</sup>.* 1) Tokushima university, Tokushima, Japan; 2) Aichi Cancer Center Hospital, Aichi, Japan.

**Objectives:** In Japan, the number of BRCA testing is increasing annually. But, till recently, genetic counselling for epithelial ovarian cancer (EOC) has not been generalized according to hereditary breast and ovarian cancer (HBOC). We investigated the awareness survey and the rate of gBRCA1/2 mutation with EOC, regardless of their family histories. **Methods:** 127 patients with EOC who had treated at our hospital were enrolled for 2years. After genetic counselling, Three patients refused result disclosure of gBRCA1/2 testing because of no relatives or depression. For 108 patients, analyses for gBRCA1/2 test were performed. DNA was extracted from whole blood, and all coding exons and their flanking intron regions of 11 genes included BRCA1 and BRCA2 were sequenced with next-generation sequencing in our laboratory. **Results:** 99 patients (80%) wished for gBRCA1/2 result disclosure, and other 21 patients did not wish to know that result because of worrying. Seventeen of the 108 patients (15.7%); 6 patients in gBRCA1 mutation, 10 patients in gBRCA2 mutation, and one patient in gRAD51C mutation. 10 of 16 with gBRCA1/2 mutation were high grade serous carcinoma, two; adenocarcinoma, and 2; others. **Conclusion:** Almost patients with EOC wanted to know genetic risk after genetic counselling. The rate of gBRCA1/2 mutation in tested Japanese EOC patients with an inherited risk, regardless of a family history, was 15.7%. This finding indicates that the cooperation of genetic counselling with other department would be important for patients with ovarian cancers.

**Quantifying the varying selective processes of pre-tumor and tumor evolution from high-coverage sequence data.** A. Ang Houle<sup>1,2</sup>, K. Skead<sup>1</sup>, D. Soave<sup>1</sup>, P. Mehanna<sup>1,3</sup>, M. Agbessi<sup>1,3</sup>, V. Bruat<sup>1,3</sup>, J. Bartlett<sup>4</sup>, P. Boutros<sup>1,5</sup>, S. Wright<sup>6</sup>, L. Stein<sup>1,2</sup>, P. Awadalla<sup>1,2</sup>. 1) Computational Biology, Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 2) Molecular Genetics, University of Toronto, Toronto, Ontario, Canada; 3) Montreal Heart Institute, Montreal, Quebec, Canada; 4) Diagnostic Development, Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 5) Medical Biophysics, University of Toronto, Toronto, Ontario, Canada; 6) Ecology and Evolutionary Biology, University of Toronto, Toronto, Ontario, Canada.

Cancer progression is an evolutionary process: somatic mutations can confer selective advantages to certain cells, eventually causing them to abnormally proliferate. Important aspects to consider when studying the evolutionary processes of cancer include the accurate characterization of somatic mutations. While positively selected alleles may lead to selective sweeps within the cancer population, and reduce the diversity of somatic variation, damaging mutations may occur and be swept along during the process. The signature of the selective sweeps may hinder the detection of negative selection within the cancer cell population. Our ability to capture these evolutionary signatures is dependent on sample size, which we infer from the depth of sequence coverage in the cases of tumor evolution within a single patient. Average sequencing depths are often insufficient to detect mutations found at low variant allele frequency within a population of cancer cells, and sequencing at higher depths of coverage allows for a more complete picture of the full evolutionary spectrum. Here, we aim to accurately identify evolutionary processes in 1735 cancer and pre-cancer samples sequenced with a minimal coverage of 100x from 5 cancer types. Using the read depth of somatic mutations to quantify the allelic frequency of a mutation within each population of cancer cells, we employ an Approximate Bayesian Computation framework to quantify the proportions of beneficial and deleterious mutations, and the timing of driver and passenger events throughout the life of a cancer. Owing to the absence of programmed recombination allowing for the exchange of alleles, non-recombining evolutionary models may be applied to cancer cells, and the richness of high coverage cancer data provides a unique opportunity to accurately quantify evolutionary processes in non-recombining systems. Using these same models, we can capture the impact of ploidy changes on evolutionary inferences. Interestingly, by applying these models, and stratifying the mutational spectrum within patient samples, we capture non-neutral evolutionary processes previously undetected in tumors. We show varying rates of damaging as well as beneficial mutations accumulating across patients within many tumor types. Our work demonstrates the heterogeneity of evolutionary processes within a cancer type, and further outlines the possibility of dubious inferences of cancer evolutionary processes caused by low sequencing depth.

**Genetic testing for the Tier 1 genomic conditions in a population-level cohort.** C.L. Neben, A. Zimmer, W. Stedden, J. Van den Akker, A.Y. Zhou. Color Genomics, Burlingame, CA.

An estimated 2 million people in the United States are at increased risk for the Tier 1 genomic conditions hereditary breast and ovarian cancer (HBOC), Lynch syndrome (LS), and familial hypercholesterolemia (FH). Recently, there has been momentum in the field towards offering genetic testing for these conditions at the population-level because such screening leads to early detection and intervention. Color Genomics has been partnering with organizations to offer genetic testing for these conditions as an employer-sponsored, voluntary, confidential employee health benefit. Here, we report the frequency and spectrum of pathogenic variants in HBOC (*BRCA1*, *BRCA2*), LS (*MLH1*, *MSH2*, *MSH6*, *PMS2*, *EPCAM*), and FH (*APOB*, *LDLR*, *PCSK9*) in employees who represent an average-risk population-level cohort. This cohort was almost equal parts men (5735, 47.5%) and women (6351, 52.5%), the majority of which were under age 40 (6854, 56.7%). Nearly half of individuals were non-Caucasian (5566, 46.1%) with Asians accounting for 25.1% (3028). Only 0.7% (90/12,073) of individuals reported a personal history of breast, ovarian, colorectal, or endometrial cancer, and 21.3% (342/1605) reported having high cholesterol. These demographics are in stark contrast to typically studied multi-gene panel cohorts of women, over age 50, with high clinical risk. In this cohort, we identified 122 pathogenic variants in HBOC or LS genes in 12,073 individuals for a pathogenic frequency of 1.01% and 7 pathogenic variants in FH genes in 1605 individuals for a pathogenic frequency of 0.44%. Thus, we estimate an overall pathogenic frequency for the Tier 1 genomic conditions of 1.45%. This frequency is double the estimated prevalence from previous studies, but closely matches that from the recent Geisinger MyCode cohort (1:78, 1.28%). In our cohort, of those with a pathogenic variant in HBOC or LS genes, only 2.5% (3) of individuals had a personal history of cancer, which is likely attributed to a younger age. Furthermore, only 50.0% (61) of individuals would have met NCCN criteria for genetic testing, which is consistent with recently published findings in population-level testing. Taken together, these data suggest that twice as many people are at increased risk for HBOC, LS, and FH and that carriers may be missed by current guidelines. Identifying these individuals by population screening at a young age, such as through an optional employee benefit, can improve health outcomes and prevent disease.

**Quantifying the evolutionary parameters of age-related clonal hematopoiesis (ARCH).** K. Skead<sup>1,2</sup>, A. Ang Houle<sup>1,2</sup>, D. Soave<sup>1</sup>, S. Abelson<sup>3</sup>, M. Agbessi<sup>1</sup>, P. Mehanna<sup>1</sup>, M. Minden<sup>3,4</sup>, L. Shlush<sup>3,5</sup>, J.E. Dick<sup>2,3</sup>, S. Wright<sup>6</sup>, P. Awadalla<sup>1,2</sup>. 1) Department of Computational Biology, Ontario Institute for Cancer Research, Toronto, Ontario, Canada; 2) Department of Molecular Genetics, University of Toronto, Toronto, Ontario Canada; 3) Princess Margaret Cancer Centre, Toronto, Ontario, Canada; 4) Department of Medical Biophysics, University of Toronto, Toronto, Ontario, Canada; 5) Weizmann Institute of Science, Rehovot, Israel; 6) Department of Ecology & Evolutionary Biology, University of Toronto, Toronto, Ontario, Canada.

Cancers share common traits that are thought to accumulate progressively as a function of somatic evolution. We have a limited understanding of how these mutations accumulate and the evolutionary forces which catalyze the transition of a cell from a healthy to a cancerous state. Multiple studies reveal that hematopoietic stem cells (HSCs) accumulate somatic mutations as a function of regular aging in a process referred to as Age-Related Clonal Hematopoiesis (ARCH). Some of these acquired mutations are believed to confer a slight fitness advantage causing particular HSCs to undergo clonal expansions and contribute disproportionately more to the mature blood cell pool. However, ARCH has been found to associate with blood-based cancers and cardiometabolic conditions and, accordingly, as a pre-disease state, affords us the unique opportunity to capture and characterize the evolutionary forces contributing towards disease development. Here, we develop computational models to characterize tumour evolution by repurposing classic population genetic tools, and explore their utility in quantifying the evolutionary parameters associated with ARCH development. To test our models, we use longitudinal deep-coverage sequencing data and paired clinical outcomes from 100 pre-AML samples and 400 age-matched controls. We employ a comparative Bayesian approach to simulate a quantitative framework to ascertain which models and selection parameters shape the intra-individual accumulation of somatic mutations. Our simulation parameters are modelled on observed hematopoietic stem cell niche characteristics and we vary probabilities of mutations being beneficial, rates of selection and the distribution from which they are drawn. We are able to identify instances in both pre-AML and control samples where evolutionary parameters: 1) depart from neutrality, 2) are characteristic of deleterious selection, and 3) calibrate the rate and timing of driver mutations and their association with cancer outcomes. These models will be used to inform analytical approaches in deep coverage sequencing, and provide a richer description of temporal evolutionary processes so as to predict which clinical outcome a sample is destined towards. Our work establishes a paradigm for determining the mutational and deterministic forces shaping tumour evolution and stands to transform diagnostic pipelines through facilitating the incorporation of evolutionary analyses into standard clinical practice.

**Intratumor heterogeneity of non-small-cell lung cancer with EGFR mutations.** X. Zhao<sup>1</sup>, S. Qiao<sup>1</sup>, X. Zhou<sup>1</sup>, Y. Zhang<sup>2</sup>, L. Zhang<sup>2</sup>, K. Wu<sup>1</sup>. 1) BGI-Shenzhen, Shenzhen, China; 2) Sun Yat-sen University Cancer Center, Guangzhou, China.

The mutation frequency of epidermal growth factor receptor (EGFR) is approximately 40% among Asian patients with NSCLC. Guidelines for the diagnosis and treatment of primary lung cancer in China recommended epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) as a first-line therapy for advanced NSCLC patients carrying EGFR mutation including exon 19 deletion (19Del) and L858R mutation on exon 21 (L858R). Although survival periods in clinical practice of EGFR-TKIs treatment have been getting longer, the patients with different subtype of EGFR mutations exhibited diverse drug response to EGFR-TKIs. The reasons why are still unclear. In this study, we performed whole genome and panel sequencing of 239 spatially distinct regions from 42 lung adenocarcinoma of Chinese patients, of which 14 patients carried EGFR 19del mutation (EGFR<sup>19del</sup>), 15 patients carried L858R mutation (EGFR<sup>L858R</sup>) and 13 patients did not carry any of these two mutation types (Control). We found the intra-tumor heterogeneity (ITH) levels were significantly higher in EGFR-mutant patients compared with control (P<0.05). Average fraction of non-ubiquitous mutation was 93.63%, 93.87% and 71.34% in EGFR<sup>19del</sup>, EGFR<sup>L858R</sup> and Control, respectively. Moreover, EGFR<sup>19del</sup> patients showed slightly higher ITH levels than EGFR<sup>L858R</sup> which non-silent mutations were considered as a unique parameter. Remarkably, two distinct evolutionary patterns were observed in the EGFR mutant subtypes. Cell locomotion and biological adhesion promoted oncogenesis and progression in EGFR<sup>19del</sup> and the mutant of CTNNB1, COL2A1 and SMAD4 were the later driver events. Correspondingly, the evolutionary model of EGFR<sup>L858R</sup> showed a diversity driver events in our cohort. These preliminary results suggested that intratumor genetic diversity provided a substrate for tumor adaptation and evolution in the subtype of EGFR mutation. It could provide genetic basis for diagnosis and prognosis in EGFR-TKIs therapeutic response and to guide stratification of lung cancer treatment and clinical research in future.

**ScaR - A tool for sensitive detection of known fusion transcripts: establishing prevalence of fusions in testicular germ cell tumors.** *A.M. Hoff, S. Zhao, J.M. Strømme, R.I. Skotheim.* Institute for Cancer Research, Oslo University Hospital, Oslo, Norway.

Bioinformatics tools for detection of fusion transcripts from RNA-sequencing data are in general developed for identification of novel fusions, often from data with a high level of background noise. Therefore, these demand a high number of supporting reads and strict filters are applied to ensure high specificity and low false discovery rate. However, as our knowledge of bona-fide fusion genes become more saturated and these are also implicated as biomarkers in cancer, there is a more pressing need to pinpoint the presence and prevalence of these fusion transcripts with high sensitivity. Here, we report the development of *ScaR*, using a scaffold realignment approach for sensitive fusion detection in RNA-seq data. We show that *ScaR* detects a set of 50 synthetic fusion transcripts from simulated data at a higher sensitivity compared to the established fusion finders deFuse and FusionCatcher. We further apply *ScaR* to explore on previously established fusion genes in testicular germ cell tumours (TGCTs) in larger cohorts. From RNA-sequencing data of 150 TGCTs, available from The Cancer Genome Atlas, *ScaR* detects the fusion transcripts *RCC1-ABHD12B* and *CLEC6A-CLEC4D* in 9% and 28% of the samples, respectively. In comparison, none out of 198 normal testis tissue samples were positive for the fusion transcripts, using RNA-sequencing data from the GTEx consortium. Thus, we demonstrate high prevalence of the *RCC1-ABHD12B* and *CLEC6A-CLEC4D* fusion transcripts in clinical TGCT samples, and that they are highly cancer specific. Further, within TGCTs, we find that *RCC1-ABHD12B* and *CLEC6A-CLEC4D* are predominantly expressed in the seminoma and embryonal carcinoma histological subtypes. In conclusion, we have developed an approach for sensitive detection of fusion transcripts from RNA-seq data, *ScaR*, which will be useful for establishing the frequency of known fusion transcripts in larger data sets and detecting clinically relevant fusion transcripts with high sensitivity.

**808T**

**Isoform expression signatures associated with epigenetic interactions between miRNA and DNA methylation in bladder cancer.** *M. Shivakumar<sup>1</sup>, S. Han<sup>2</sup>, Y. Lee<sup>2,4</sup>, D. Kim<sup>1,3</sup>.* 1) Biomedical and Translational Informatics Institute, Geisinger Health System, Danville, PA; 2) Department of Biomedical Informatics, University of Utah, University of Utah School of Medicine, Salt Lake City, UT; 3) The Huck Institutes of the Life Sciences, The Pennsylvania State University, University Park, PA; 4) Huntsman Cancer Institute, University of Utah, Salt Lake City, UT.

Various epigenetic factors are responsible for the non-genetic regulation on gene expression. The epigenetically dysregulated oncogenes or tumor suppressors by miRNA and/or DNA methylation are often observed in cancer cells. Each of these epigenetic regulators has been studied well in cancer progressions; however, their mutual regulatory relationship in cancer still remains unclear. In this study, we propose an integrative framework to systematically investigate epigenetic interactions between miRNA and methylation at the alternatively spliced mRNA level in bladder cancer, which is a way of a higher resolution for interpreting miRNA's regulation at the mRNA level. DNA methylation, miRNA, and RNA-seq datasets for bladder cancer were retrieved from TCGA and analyzed using a rMAT tool to identify alternatively spliced events. Then, a likelihood-ratio test was used to determine if the interaction terms between miRNA and methylation for the evaluated models were statistically significant (Bonferroni corrected  $P < 0.05$ ). Cox regression adjusting for age and gender was performed on statistically significant pairs. We identified 125 significant isoform signatures (103 genes) associated with epigenetic interactions as well as overall survival. As intragenic DNA methylation may have a different molecular function by their specific location in gene, we classified the interaction pairs according to the regions of DNA methylation (i.e., promoter, exon, intron, and 3' UTR). We observed that the methylation status is more dominant regulators than miRNAs in all interaction pairs. Additionally, we found that there were more genes in the intron region showing significant associations with overall survival. Our study provides a higher resolution of molecular insight into the crosstalk between two epigenetic factors, DNA methylation and miRNA. Furthermore, our work will be an addition to our knowledge on how intragenic methylation may play with miRNA for the mRNA regulation.

**Isoform expression analysis reveals distinct subset of cancer: Role of alternative splicing patterns of *LARS* in colon adenocarcinoma.** H. Song<sup>1,2</sup>, N.H. Kwon<sup>3</sup>, H.S. Yun<sup>4</sup>, S.S. Yoon<sup>1,5</sup>, S. Kim<sup>3</sup>, Y. Koh<sup>2,5</sup>. 1) Cancer Research Institute, Seoul National University, Seoul, South Korea; 2) Center for Medical Innovation, Seoul National University Hospital, Seoul, South Korea; 3) Medical Bioconvergence Research Center, Seoul National University, Seoul, South Korea; 4) Department of Bioinformatics, Seoul National University Hospital, Seoul, South Korea; 5) Department of Internal Medicine, Seoul National University Hospital, Seoul, South Korea.

Aminoacyl tRNA synthetases are essential enzymes for attaching appropriate amino acids to its tRNAs. Leucyl-tRNA synthetase (*LARS*) functions as an intracellular leucine sensor; when it senses sufficient amounts of leucine, it activates mammalian target of rapamycin (mTOR) pathway that regulates protein translation, cell size, and autophagy. We searched for alternative splicing in *LARS* gene in colon cancer samples. We aligned 46 whole transcriptome sequencing (WTS) data of TCGA colon adenocarcinoma (COAD) using STAR algorithm and quantified expression using RSEM algorithm. We used isoform-level expression of 16 isoforms followed by StringTie and Ballgown to re-assemble, merge, and quantify exon-level expression to explore unique expression pattern of *LARS*. We first performed unbiased clustering using 16 *LARS* isoform-level expression values and then performed another clustering based on the differentially expressed genes (DEG) from whole human gene set. CMScaller was used to annotate the samples in terms of the consensus molecular subtypes (CMSs) of colon cancer. We first classified 46 COAD samples into 4 clusters (A, B, C, and D) by *LARS* isoform expression, and identified that 5 samples in cluster A define a separate group. In order to verify consistency of the classification, we applied this cluster group annotation to the second clustering (DEG). As a result, we have found that in cluster A, six samples are clustered adjacent to each other in terms of distance between each sample. Interestingly, we noticed that these samples belong to either CMS 2 or CMS 4 which has high somatic copy number alterations. In addition, we found that these samples have mutations of *ATRX* (essential in normal development) and *STAG2* (a tumor suppressor) in common. Survival analysis revealed a tendency for short survival in *cluster A* compared to the other clusters. In conclusion, we demonstrated that the clustering by *LARS* isoform expression distinguishes certain biological similarities and distinct subsets in colon adenocarcinoma.

**810W**

**Analysis of gene fusions and simple nucleotide variants using molecular bar coded chemistry.** J. Balan, A. Nair, J. Voss, E.B. Fritcher, C. Zysk, T. Kollmeyer, N. Mattson, R. Gonzalez, E. Kischell, C. Ross, A. Raghunathan, C. Ida, B. Kipp, C. Giannini, R. Jenkins, E. Klee. Mayo Clinic, Rochester, MN.

Cancer is a result of tumor accretion resulting from genomic mutations, genomic rearrangements and epigenetic alterations. Detecting these alterations in the driver oncogenes is pivotal for clinical therapy. The developments in the Next Generation Sequencing (NGS) analysis technologies provide excellent means to study such alterations. Most sequencing techniques designed to study the driver oncogenes involve Polymerase Chain Reaction (PCR)-based sequencing methods that makes it challenging to identify true events over PCR bias artifacts. However, adding molecular bar codes (MBCs) to each DNA/RNA molecule permits traceability of PCR artifacts/duplicates. We have developed a neuro-oncology assay that utilizes the QIAseq (Qiagen Inc., Germantown, MD) targeted chemistry and Illumina sequencing. In our neuro-oncology assay, we target 150 genes for the DNA panel and 80 genes in the RNA panel to detect simple nucleotide variants (single nucleotide polymorphisms and small indels less than 50 base pairs in length) and gene fusions, respectively. We have developed UMIDNA and UMIFUSION pipelines to detect these simple nucleotide variants and fusions. UMIFUSION (a Cromwell/WDL based pipeline) uses an approach that involves denovo assembly of the targeted reads using CAP3, mapping the assembled contigs to human genome reference using BLAT, a second pass alignment using BWA-mem, false positive filtering module, annotation module and calculation of unique molecules that support the fusions. The UMIDNA pipeline involves trimming the reads to remove non-reference bases, alignment and variant calling using CLC and a post processing step that annotates variants with unique molecules that support the variant. Using these pipelines, we have analyzed 52 DNA samples and 61 RNA samples in neuro-oncology assay verification studies. For DNA samples, we achieved >98% concordance to an alternative method (Ion Torrent with QIAseq chemistry, other NGS Illumina chemistries, and Sanger) for detecting simple nucleotide reportable variants. For RNA data samples, we achieved 100% concordance to alternative confirmatory methods (RT-PCR/Sanger, other NGS Illumina chemistries and FISH) in detecting gene fusions. Leveraging the chemistry with the MBCs and pipelines that handle the MBCs, we have established high sensitivity of the DNA and RNA assays. Importantly, the simple variants and fusion data from DNA and RNA of a patient helps us advance the clinical diagnosis of cancer.

## 811T

**Deep learning approach to automate somatic variant refinement.** *E.K. Barnell<sup>1</sup>, B.J Ainscough<sup>1,2</sup>, K.M. Campbell<sup>1</sup>, T.E. Rohan<sup>3</sup>, R. Govindan<sup>1,2</sup>, M. Griffith<sup>1,2,4,5</sup>, E.R. Mardis<sup>6,7</sup>, S.J. Swamidass<sup>8</sup>, O.L. Griffith<sup>1,2,4,5</sup>.* 1) McDonnell Genome Institute, Washington University School of Medicine, St. Louis, MO, USA; 2) Siteman Cancer Center, Washington University School of Medicine, St. Louis, MO, USA; 3) Department of Epidemiology and Population Health, Albert Einstein College of Medicine, New York, NY, USA; 4) Division of Oncology, Department of Medicine, Washington University School of Medicine, St. Louis, MO, USA; 5) Department of Genetics, Washington University School of Medicine, St. Louis, MO, USA; 6) Institute for Genomic Medicine, The Research Institute at Nationwide Children's Hospital, Columbus, USA; 7) Department of Pediatrics, The Ohio State University College of Medicine, Columbus, USA; 8) Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, Missouri, USA.

**Introduction:** Cancer genomic analysis requires accurate identification of somatic variants in sequencing data. Manual review to refine somatic variant calls is required as a final step after automated processing. However, manual variant refinement is time-consuming, costly, poorly standardized, and non-reproducible. Here we describe a systematized and standardized method for somatic variant refinement using a machine learning approach. **Methods:** A deep learning model was developed using 41,000 variants from nine tumor subtypes including both hematologic tumors and solid tumors. Data was derived from multiple different sequencing platforms (whole-exome-, whole-genome-, and capture-sequencing) and variants were called by a variety of automated variant callers (VarScan, Strelka, etc.). Model performance was analyzed by using internal cross-validation, comparing model predictions to orthogonal sequencing data, and comparing model predictions to manual review calls on independent testing sets. **Results:** Internal cross-validation showed a receiver operating characteristic (ROC) area under the curve (AUC) of 0.96. When the model was employed on a set of 192,241 putative somatic variants derived from a single AML case with orthogonal sequencing data, the model attained a ROC AUC of 0.96. When the model was employed on a cohort of 17,356 variants derived from 11 lung carcinomas, 14 follicular lymphomas, 19 oral squamous cell carcinomas, and 1 breast cancer cell line, the model recapitulated manual review labels with a slightly reduced accuracy (ROC AUC range = 0.72-0.92). Reduction in accuracy was attributed to batch effects associated with the new data features including: different manual reviewers, new somatic variant callers, unseen tumor subtypes, and updated sequencing platforms. When retraining a new model that incorporated ~250 data points from the independent testing sets, model accuracy was recovered (ROC AUC >0.9). **Conclusions:** The deep learning model for somatic variant refinement (DeepSVR) provides an unbiased method for identifying true somatic variants to avoid observed high inter-reviewer variability. It also reduces the existing annotation bottleneck hindering widespread adoption of genomic analysis for every tumor workflow. The described model and methods for customizing a new model have been made publicly available at <https://github.com/griffithlab/DeepSVR>.

## 812F

**Bioinformatics and DNA-extraction strategies to reliably detect genetic variants from FFPE breast tissue samples.** *A.V. Bhagwate, S. Winham, S. McDonough, M. Stallings-Mann, J.M. Cunningham, E.P. Heinzen, J. Davila, R.A. Vierkant, D.C. Radisky, A.C. Degnim, C. Wang.* Mayo Clinic, Rochester, MN.

Archived FFPE samples are valuable clinical resources to examine tissue features (including protein expression and genetic changes) associated with clinical outcomes. However, the DNA quality and quantity from FFPE samples are sub-optimal and degraded, and resulting NGS-based genetics variant detections are prone to false positives. With the advancement of new NGS protocols for FFPE DNA, an overall evaluation of wet-lab and bioinformatics approaches are needed to optimize variant detection from FFPE samples. Focusing on breast tissue samples as pilot study, we designed within-subject replicates consisting of DNA derived from four paired FFPE and fresh frozen samples to highlight FFPE-specific artifacts. We tested two FFPE DNA extraction methods to determine the impact of wet-lab procedures on variant calling: Qiagen QIAamp DNA Mini Kit ("QA"), and Qiagen GeneRead DNA FFPE kit ("QGR") containing a repair step, resulting in a total of four triplicates (N=12 samples). The fresh frozen samples were prepared using Qiagen Genra Puregene Kit ("QGP"). Additionally, we used one negative control sample (NA12891) and one positive control sample (Horizon Discovery) with known mutations. All DNA sample libraries were prepared for NGS according to QIAseq Human Breast Cancer Targeted DNA Panel protocol as per vendor's instructions, and sequenced on the HiSeq 4000, 150bp per lane, 12 samples multiplexed per lane. The variant calling was performed using Qiagen Gene Globe Data Portal, following which variant concordance comparisons were carried out within replicates. In this study, we found more variants on average called with FFPE samples (QGR=1119; QA=9592 variants), compared to their paired fresh-frozen tissue samples (QGP=273 variants), even after applying molecular barcoding error-correction and default bioinformatics filtering recommended by the vendor. We also found that an optimized FFPE-DNA extraction approach (QGR) leads to much fewer false variants. Approximately 92% of the uniquely called FFPE variants were of low allelic frequency range (<5%), and collectively shared a "C>T|G>A" mutational signature known to be representative of FFPE artifacts. Based on control samples and replicates, we derived effective filtering strategy with associated empirical false-discovery estimates. Through this study, we demonstrated the feasibility of calling genetic variants from FFPE samples, and recommend a FFPE-fresh frozen paired design for controlling false variants.

**813W****Integration of biological information into the CIViC database cancer**

**variant representation.** A. Danos, K. Krysiak, A. Wagner, S. Kiwala, J. McMichael, A. Coffman, E. Barnell, C. Ramirez, M. Griffith, O. Griffith. McDonnell Genome Institute, Washington University, Saint Louis, MO.

With the growing availability of clinical cancer genome sequencing coupled with growing knowledge on the vast array of cancer variants, there is great need for data resources focusing on the subset of clinically important cancer variants. The Clinical Interpretations of Variants in Cancer (CIViC, [www.civicdb.org](http://www.civicdb.org)) database is designed to meet this need. As construction of large datasets requires massive amounts of curation effort, some databases maintain this curated knowledge behind a paywall, presumably using fees for this curation. In contrast, CIViC's approach is to crowdsource and expertly moderate curation effort, which allows it to be a completely free, open-access public resource, able to quickly respond to new directions in the field as the active user base grows. To date CIViC has built a community of over 100 contributors and over 16,000 clinical and research users worldwide. The fundamental unit of knowledge in CIViC is the evidence item (EID). The EID associates a clinically relevant statement to a specific variant in a specific cancer type using evidence derived from peer-reviewed publications and linked to a PubMed ID. EIDs are used to build summary clinical assertion statements for a variant in a specific cancer context, to which an AMP Tier and Level is associated. Here we introduce a new EID type called Biological Evidence. The CIViC EID currently consists of Predisposing, Predictive, Diagnostic or Prognostic evidence, and variants that are known to play an important role in cancer, but do not have directly actionable clinical information associated to them, are not admissible in CIViC. Upon user request for CIViC to be able to handle this type of evidence, and internal desire to expand the data model, Biological EIDs will be added to CIViC. This new evidence type will allow CIViC to gather information on important cancer driver mutations, and furthermore admit important new functionality enabling classification of AMP Tier III (VUS) and AMP Tier IV (known benign) variants. Additionally, Biological Evidence allows CIViC EIDs to incorporate PM1, PM4 and PM5 codes from the ACMG guidelines for assessment of variant pathogenicity at the assertion level. Current debates are underway regarding methods for assessment of somatic cancer variant oncogenicity, and integration of biological evidence will allow CIViC's evolving conception of the cancer variant to incorporate and help establish new standards for variant representation as they emerge.

**814T****GCC-Calc, a method and tool to identify, compare, normalize and interpret genomic copy number variation in longitudinal bone metastases and xenografts.**

T. Gaasterland<sup>1,2,3</sup>, M.T. Muldong<sup>4,5</sup>, A.A. Kulidjian<sup>6</sup>, C.J. Kane<sup>4</sup>, C.A.M. Jamieson<sup>4,5</sup>. 1) Institute for Genomic Medicine, University of California, San Diego, La Jolla, CA; 2) Scripps Institution of Oceanography, University of California, San Diego, La Jolla, CA; 3) Bioinformatics & Systems Biology Program, University of California, San Diego, La Jolla, CA; 4) Department of Urology, University of California, San Diego, La Jolla, CA; 5) Moores Cancer Center, University of California, San Diego, La Jolla, CA; 6) Department of Orthopaedic Surgery, University of California, San Diego, La Jolla CA.

**Rationale:** Prostate cancer (PrCa) metastasizes to bone in 50-90% of patients with advanced disease yet little is known about genome-wide alterations in the bone metastases. To identify changes that may lead to progressive therapy resistance, we measured genome variation and gene expression in a longitudinal series of surgical PrCa bone metastasis samples and xenografts derived from one patient. To interpret the data, we developed methods to compare copy number variants across samples and measurement platforms, determine gene structures impacted over time, and assess expression changes. **Data:** Surgical samples from one patient's serial metastasis events during 3 years were saved as flash-frozen tissue and dissociated cells. Xenograft models were generated from the cells and subjected to the patient's treatments. Blood provided a baseline genome. Healthy bone marrow provided baseline gene expression. Data from each sample included copy number variant (CNV) regions measured with the Oncoscan CNV platform, whole exome sequencing (WES), and gene expression measured with the GeneChip RNA platform. Exome data were analyzed to compute CNV regions using CNVkit and single nucleotide polymorphism (SNP) sites with samtools and GATK. **Approach:** We developed a method to generate a merged CNV profile for a given sample. It compares CNV regions measured with different platforms in the same sample, determines concordances and differences, and generates a consistent CNV profile. The method then compares CNV profiles across serial samples, determines emerging variants, and associates new variants with genes. Gene expression data is then queried to assess expression patterns for genes affected by CNVs. The methods address the following data challenges: normalization of CNV gain scores across samples, resolving lower-confidence CNVs in patient samples with differing proportions of normal and diseased cells, and distinguishing true CNV gains and losses from mis-measurement. A tool suite, GCC-Calc (Gene Copy Comparison Calculator), accepts tables of CNV regions for serial samples and reports affected genes and expression changes. **Results:** With GCC-Calc, merged, serial CNV profiles revealed a therapy resistant sub-clone present at low levels in the early patient bone metastasis. GCC-Calc provides a foundation to profile genomic diversity in recurrent bone metastatic cancers. It enables comparison of CNV platforms and resolves differences in CNV profiles obtained for one sample.

**A sensitive and robust pipeline for analyzing 5hmC patterns from low coverage oxidative bisulfite sequencing.** *R.L. Goldfeder, A.C. Lau, C. Wei.* The Jackson Laboratory for Genomic Medicine, Farmington, CT.

Over 600,000 Americans die each year of cancer. Cancer is so deadly because it often cannot be identified until symptoms are very advanced, when the cancer has likely metastasized and treatment is less successful. Liquid biopsy is a new, non-invasive technique that enables early cancer detection, thereby facilitating earlier life-saving treatment. This technique involves simply drawing blood, sequencing the cell-free DNA (cfDNA) in the blood, and analyzing the DNA for biomarkers that indicate the presence of cancer. Until recently, cfDNA analysis has focused on sequence mutations or patterns of 5-methylcytosine (5mC). Now, researchers are beginning to investigate 5-hydroxymethylcytosine (5hmC), a tissue-specific epigenetic mark that has been linked to cancer. This mark can be assayed from bisulfite and oxidative bisulfite sequencing. Our group and others aim to study 5hmC patterns from cfDNA and solid tumor biopsy; our goal is to identify patterns in cfDNA that recapitulate the patterns seen in tumor biopsy so that 5hmC can be utilized as a biomarker in liquid biopsies for early cancer detection. cfDNA is fragmented, in low abundance, and is a representation of the tumor-derived tissue as well as other tissues in the body, creating several challenges with sequencing and analysis. Currently, the available tools for detecting 5hmC rely on high coverage datasets or are inappropriate for meeting the challenges that arise with cfDNA. For example, we see short sequence reads with paired ends that overlap and high duplication rates that ultimately lead to low coverage and low quality 5hmC calls. Additionally the mapping rate is low due to the nature of bisulfite sequencing. To address these challenges, we present Convinced, a sensitive and robust pipeline for detecting 5hmC patterns from oxidative bisulfite sequencing. We evaluate Convinced using publically available data and benchmark against a commonly used pipeline for analyzing 5hmC, BsExpress. We find that Convinced provides a higher mapping rate and more accurate 5hmC calls. Our pipeline improves 5hmC detection from bisulfite and oxidative bisulfite sequencing libraries. This will ultimately enable researchers and physicians to use 5hmC patterns from liquid biopsies to aid in the non-invasive early detection of cancer.

**Development and analytical validation of highly customizable next-generation targeted sequencing technology for the detection of gene fusions at a very low frequency.** *R.K. Gottimukkala, N. Li, Y. Fu, A.G. Hatch, C. Van Loy, C. Bai, A. Erwing, D.J. Mazur, F.M. Hyland.* Thermo Fisher Scientific, South San Francisco, CA.

Gene fusions caused by chromosomal rearrangements play an important role in oncogenesis, the progression of cancer and the selection of guided targeted therapies. Next-generation sequencing enables sensitive, specific and precise detection of particular fusion isoforms for defined gene pairs. AmpliSeq™ HD technology is new targeted sequencing chemistry that allows highly sensitive variant detection down to  $\leq 0.1\%$  mutant allele fractions in both blood and FFPE samples. We developed cloud-based software to support the design of a custom AmpliSeq™ HD gene fusion panel, comprising 1 to 523 fusion isoform assays and any gene expression assays for normalization. These include high quality curated and annotated fusion isoforms involving ALK, RET, ROS1, NTRK1 and other genes. We designed AmpliSeq™ HD primer pairs for each of these fusions using advanced assay design algorithms. We developed cloud-based analysis software to analyze the BAM file resulting from amplification and sequencing of custom AmpliSeq™ HD fusion panels on an Ion GeneStudio™ S5 sequencer. The sequencing reads generated using this chemistry contain unique molecular tags that allow identification of reads which originated from the same molecule. We developed an algorithm that models errors accumulated during amplification and sequencing, and accurately reconstructs the sequence of original molecules based on these reads. We developed a Fusions calling method that uses the reconstructed sequences to enable accurate detection of gene fusions. To validate the AmpliSeq™ HD chemistry and the analysis workflow for the detection of gene fusions, we created three custom panels: Panel 1 with 95 fusion isoform assays and 4 gene expression assays, panel 2 with 40 fusion isoforms assays and 19 gene expression assays and panel 3 with 17 fusion isoform assays and 19 gene expression assays. We sequenced the Total RNA from Tri-Fusion control sample diluted to  $\leq 1\%$  with the background of wild-type RNA, using all the three panels and detected all the expected fusions; EML4-ALK, SLC34A2-ROS1, and CCDC6-RET with 100% specificity. We sequenced the Seracare FFPE samples using panel 2 and detected all the 8 expected fusions with 100% sensitivity and specificity. We also sequenced the negative FFPE samples using panel 2 and as expected, detected no fusions. This technology enables researchers to create large multiplex custom FFPE and cfDNA panels to detect gene fusions at an ultra-low frequency with high accuracy.

**Combining single-cell RNA and DNA sequencing analysis to measure genomic instability at individual clone resolution in gastric cancer.** S.M. Grimes<sup>1</sup>, N. Andor<sup>2</sup>, B.T. Lau<sup>1</sup>, H.P. Ji<sup>1,2</sup>. 1) Stanford Genome Technology Center, Stanford University, Palo Alto, CA; 2) Division of Oncology, Department of Medicine, Stanford University School of Medicine, Stanford, CA.

Genomic instability is a hallmark of cancer and gives rise to the diversification which allows tumors to evolve into multiple genetically distinct subclones. Traditional bulk sequencing analysis averages out the signals from the individual clones, and therefore is often unable to distinguish the unique markers which characterize smaller clones. These unidentified clones may be resistant to prescribed treatment, leading to subclonal expansion and tumor growth. To help decipher intratumor heterogeneity we present a method to measure genomic instability at the individual clone resolution, using a combination of single cell DNA and RNA sequencing analysis. Copy number variation (CNV) and clustering of cells in G0G1 cell cycle phase with similar CNV profiles, is performed using both techniques. For scDNA the cell cycle was inferred by analysis of cell ploidy and breakpoints; CNV calls were made by standard open-source software and clustering was based on CNV segmentation. For scRNA the cell cycle was determined by the activity of pathways related to the different phases of the cell cycle, copy number was inferred by gene expression across the transcriptome and clustering was based on consolidated gene expression across large (>10Mb) segments of the genome. This methodology was validated on several gastric cancer cell lines, and resulted in good correlation between number and size of clones identified independently by scDNA and scRNA on the same samples. This method was then used to analyze a primary gastric tumor sample, with scDNA enabling a more granular identification of clones and phylogeny, and scRNA categorizing clones in more detail via cell surface markers and pathway analysis. The ability to interrogate both the genome and transcriptome of single cells and identify clonal characteristics provides a very powerful analysis tool with regard to tumor evolution and cell fitness, enabling potential identification of new therapeutic targets.

**Exome-wide analysis of bi-allelic alterations identifies a Lynch phenotype in the Cancer Genome Atlas.** O. Harismendy<sup>1</sup>, A.R. Buckley<sup>2</sup>, T. Ideker<sup>1</sup>, H. Carter<sup>1</sup>, N.J. Schork<sup>1,2,3</sup>. 1) UC San Diego, San Diego, CA; 2) J. Craig Venter Institute, La Jolla, CA; 3) The Translational Genomics Research Institute, Phoenix, AZ.

Cancer susceptibility genes generally require the somatic alteration of the remaining allele to drive oncogenesis and, in some cases, tumor mutational profiles. Whether combined germline and somatic bi-allelic alterations are universally required for germline variation to influence tumor mutational profile is unclear. Here we performed an exome-wide analysis of the frequency and functional effect of bi-allelic alterations in The Cancer Genome Atlas (TCGA). We integrated germline variant, somatic mutation, somatic methylation, and somatic copy number loss data from 7,790 individuals from TCGA to identify germline and somatic bi-allelic alterations in all coding genes. We used linear models to test for association between mono- and bi-allelic alterations and somatic microsatellite instability (MSI) and somatic mutational signatures. We discovered significant enrichment of bi-allelic alterations in mismatch repair (MMR) genes, and identified 6 bi-allelic carriers with elevated microsatellite instability (MSI), consistent with Lynch syndrome. In contrast, we find little evidence of an effect of mono-allelic germline variation on MSI. Using MSI burden and bi-allelic alteration status, we reclassify two variants of unknown significance in *MSH6* as potentially pathogenic for Lynch syndrome. Extending our analysis of MSI to a set of 127 DNA damage repair (DDR) genes, we identified a novel association between methylation of *SHPRH* and MSI burden. We find that bi-allelic alterations are infrequent in TCGA, but most frequently occur in *BRCA1/2* and MMR genes. Our results support the idea that bi-allelic alteration is required for germline variation to influence tumor mutational profile. Overall, we demonstrate that integrating germline, somatic, and epigenetic alterations provides new understanding of somatic mutational profiles.

**Identification of critical cis-regulators of differential gene expression between EGFR mutant and wild-type lung adenocarcinomas.** *H. Ho<sup>1</sup>, S. Yuan<sup>1</sup>, G. Chang<sup>2,3,4</sup>, S. Yu<sup>5</sup>, K. Li<sup>1,6</sup>.* 1) Institute of Statistical Sciences, Academia Sinica, Taipei, Taiwan; 2) Division of Chest Medicine, Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan; 3) Faculty of Medicine, School of Medicine, National Yang-Ming University, Taipei, Taiwan; 4) Institute of Biomedical Sciences, National Chung Hsing University, Taichung, Taiwan; 5) Department of Clinical Laboratory Sciences and Medical Biotechnology, College of Medicine, National Taiwan University, Taipei, Taiwan; 6) Department of Statistics, University of California, Los Angeles, USA.

**Introduction** Lung cancer is the most common cause of cancer deaths worldwide with lung adenocarcinomas being its predominant subtype. EGFR-activating mutation is the most common driver mutation for lung adenocarcinomas in East Asia and also has a high carrier frequency in the West. Several studies have established that EGFR-TKIs are in general more effective for EGFR mutant (MT) patients than wild-type (WT) patients. The cause of the response heterogeneity at the molecular level remains unclear. We hypothesized that a better understanding of the heterogeneity of the gene regulation between EGFR MT/WT tumors may help understand the response heterogeneity. In cancer genome, gene expression is regulated by factors at multiple molecular levels, including point mutation, indels and copy number alteration (CNA) at the DNA level; transcription factor and miRNA at the RNA level; and methylation at the epigenetic level (hereinafter referred to as “regulators”). Integrating multi-level molecular profiling is urgently needed for studying gene regulation. **Methods** Multi-level molecular profiling, including MASS spectrometry for EGFR mutation, array CGH for CNA, gene expression array and real-time PCR for miRNA expression was performed on a cohort of 177 lung adenocarcinomas from National Taiwan University Hospital and Taichung Veterans General Hospital. We proposed a modified liquid association score to quantify the strength of differential regulations (DR) between EGFR MT/WT lung adenocarcinomas. We derived a novel statistical framework combining differential expression (DE) analysis and DR analysis to form an enrichment test for identifying the critical regulators of the DE genes. **Results** Through the DE analysis, we identified 507 DE genes between EGFR MT/WT patients. By utilizing our approach, we found that four DE genes were differentially regulated by cis-CNAs and 109 DE genes were differentially regulated by seven DE miRNAs. In total, 22% of the DE genes were regulated to at least one critical cis-regulators. Among them, five critical cis-regulators were associated with patient’s overall survival. **Conclusions** Integrative analysis of multi-level molecular profiling shed light on the critical regulatory disparity between EGFR MT/WT lung adenocarcinomas associated with patient’s outcome. Our finding provides a better understanding of the heterogeneity of gene regulation between EGFR MT/WT patients and may help improve patient management in lung adenocarcinoma.

**Deconvoluting pathway dynamics using big data.** *S.Chloe. Jang, B. Han.* Department of Medicine, Seoul National University College of Medicine, Seoul, South Korea.

Complex diseases such as cancer are usually the result of a combination of various biological pathways consisting of sets of genes. It is potentially invaluable to identify causal pathways of diseases, as they give understanding of pathogenesis of diseases. For this reason, pathway analysis has become a popular method for revealing new insight into the underlying biology of differentially expressed genes, as it identifies functional associations among genes. The current pathway datasets include the snapshot of each pathway that consists of the genes in the pathways (nodes) and the relation between them (edges). The limitation of these datasets is that they give only the static snapshot, and not the dynamics under different conditions. For example, a subset of edges may be “open” under specific conditions and “closed” under different conditions. The existing datasets lack this information because the edges in the pathway were confirmed by many different experiments that differ by time, cell type, and condition. This study proposes a new approach that decomposes the biological pathways into subgroups that dynamically act together by using big expression data. Specifically, we assess how pathway relations (edges) are associated and correlated using the datasets from Gene Expression Omnibus (GEO) and The Cancer Genome Atlas (TCGA) data sets. Colorectal Cancer(CRC) is one of the most frequent cancers and accounts as the second leading cause of death from cancers in the world. We investigated CRC expression data from 24 gene expression datasets derived from GEO and TCGA. We parsed all the human pathway data in major public repository, Kyoto Encyclopedia of Genes and Genomes (KEGG), and filtered out the cancer-related pathways. We then assessed the correlation between genes denoting edges in the pathways. We confirmed that the correlations of the edges were higher than the null subsets (random 1000 gene sets) as expected. Then we analyzed the dynamics of the edges in each pathway by calculating associations between the correlation coefficients of edges and applying clustering algorithms. We found that many pathways show clustering that may give clue how edges act together under different conditions. We expect that our findings may give exploration of the effective subnetworks of pathways, which may reduce the complexity in pathway mapping analysis and increase power to detect sub-pathways that contain genetic signals associated with complex diseases.

**PathoMAN: An automated germline cancer variant classification tool for pathogenicity and clinical actionability.** V. Joseph<sup>1</sup>, V. Ravichandran<sup>1</sup>, Z. Shameer<sup>1</sup>, Y. Kemel<sup>1</sup>, M. Walsh<sup>1</sup>, K. Cadoo<sup>1</sup>, S. Lipkin<sup>2</sup>, D. Mandelker<sup>1</sup>, L. Zhang<sup>1</sup>, Z. Stadler<sup>1</sup>, M. Robson<sup>1</sup>, K. Offit<sup>1</sup>. 1) Medicine, MSKCC, New York, NY., USA; 2) Weill Cornell Medical College, New York, N.Y., 10065, USA.

Clinical Cancer Gene testing is one of the cornerstones of cancer prevention. Cancer Genetics testing has transformed from single gene test to multiplexed gene panel testing that extend beyond traditionally tested cancer types. The trend towards complex gene panels to exomes is unmistakable. While, data generation is rapid, the data interpretation has lagged behind. Even identifying known gene mutations is usually tenuous for many end-users. There is demand for a germline genomics platform that can perform high throughput variant interpretation and gene discovery. Similarly, there is no other algorithm that can perform variant classification in a uniform, rapid, unbiased fashion for key cancer genes. PathoMAN, a variant classification system, is perhaps the only system that brings rich germline cancer genetics domain expertise, intuitive ease of use and clear interpretation in the same application. PathoMAN delivers variant classification and interpretation with high concordance and low discordance to those curated by domain experts. It provides these classifications in six categories: Pathogenic (P), Likely-Pathogenic (LP), Benign (B), Likely-Benign (LB), Risk Factor (RF) and Variant of Uncertain Significance (VUS). In addition, it also tags select variants as a founder mutation in certain population such as the Ashkenazi Jews. We compared expert manually curated variant data from studies on (i) prostate cancer (ii) breast cancer and (iii) ClinVar to assess performance. PathoMAN achieves high concordance (83.1% pathogenic, 75.5% benign) and negligible discordance (0.04% pathogenic, 0.9% benign) when contrasted against expert curation. Some loss of resolution (8.6% pathogenic, 23.64% benign) and gain of resolution (6.6% pathogenic, 1.6% benign) was also observed. We propose new literature mining features and functional evidence for mutations from saturation mutagenesis studies that is used in the variant classification. Discovery mode enables users to perform gene burden test against ExAC population. PathoMAN will reduce the manual workload of domain level experts. It provides a substantial advance in rapid classification of genetic variants by generating robust models using a knowledge-base of diverse genetic data. <https://pathoman.mskcc.org>.

**Improving variant detection with unique molecular index technology: The case of biomedical genomics workbench.** F. Lescai<sup>1</sup>, B.J. Vilhjalmsson<sup>1</sup>, A.M. Hein<sup>1</sup>, D. Kamaev<sup>1</sup>, M.M. Johansen<sup>1</sup>, L. Husted<sup>1</sup>, R. Samara<sup>2</sup>, T. Rask<sup>1</sup>, R.G. Madsen<sup>1</sup>, Z. Etches<sup>1</sup>, V. Gregersen<sup>1</sup>, S. Tian<sup>2</sup>, E. Lader<sup>2</sup>, L. Schausser<sup>1</sup>, M. Simonsen<sup>1</sup>. 1) QIAGEN, Aarhus, Denmark; 2) QIAGEN, Frederick, MD, United States.

In numerous applications, and particularly in detecting somatic mutations at low allele fractions, the capability to distinguish between sequencing or amplification errors and real variants is crucial. Unique Molecular Indices (UMIs), also known as molecular barcodes, address these challenges and allow an unbiased estimation of allele-fractions, by providing a one-to-one representation of the originally captured sample DNA molecules. However, bioinformatics functionality capable of exploiting the added value of molecular barcodes is needed. To provide a sample-to-insight solution, QIAGEN combines a powerful chemistry based on UMIs and a UMI-aware bioinformatics workflow in the Biomedical Genomics Workbench. We assess the impact of UMI information on the sensitivity and precision of variant detection at several coverage levels. We prepared artificial mixtures of Genome-in-a-Bottle and Horizon reference DNA standards to evaluate performances in validated high confidence regions, and in known difficult-to-detect-variants regions. Our analysis quantifies the effect of integrating UMI data into the variant calling pipeline: at 1000X UMI-coverage, the sensitivity in detecting variants with expected allele fraction >5% is 100% when using UMIs, while is 93.3% if UMI information is not used; when detecting variants with expected allele fraction >1%, the sensitivity in UMI-aware workflow is 90.9% and 83.3% without UMI. At 2000X, the precision with UMI variant calling is 99.45% and only 81.55% if UMIs are not used, highlighting their value when analysing high-coverage datasets, crucial in applications like liquid biopsy. Our analysis further investigates this effect in relationship to coverage, and provides evidence of the benefits of combining this new barcoding technology with specifically designed bioinformatics solutions, such as the one offered in QIAGEN Biomedical Genomics Workbench. Finally, we provide suggestions on appropriate sequencing coverage levels in order to reach optimal calling accuracy, and we compare the performance of the Biomedical Genomics Workbench's resequencing workflow with other state-of-the-art pipelines.

**Ensemble machine learning for identifying the important biomarkers in proteogenomics cancer study.** *Y. Liang<sup>1</sup>, A. Gharipour<sup>2</sup>, A. Kelemen<sup>3</sup>, A.L. Kelemen<sup>4</sup>.* 1) Family and Community Health, University of Maryland, Baltimore, Baltimore, MD; 2) School of Information and Communication Technology, Griffith University, Gold Coast campus, Queensland 4222, Australia; 3) Department of Organizational Systems and Adult Health, University of Maryland, Baltimore; 655 W. Lombard Street, Baltimore, MD 21201; 4) Department of Computer Science, University of Maryland, College Park, MD.

Identification of important biomarkers such as proteins is essential for medical diagnosis and prognosis. Accurate biomarker or disease signature selection is critical for drug targets in common diseases such as cancer. Standard statistical models with single feature selection involve the multi-testing burden of low power if the limited samples available. Furthermore, high correlations among the proteins with high redundancy lead to unstable selections and may cause reproducibility issues based on *p* values. The ensemble feature selection approach incorporates stability consideration into the algorithm design stage and has the advantage to alleviate and compensate such drawbacks. It aims at identifying a stable set of disease signatures or biomarkers that could improve the prediction performance of classification models, and thereby also simplify their interpretability. Mass spectrometry based proteomic technologies have enabled protein global expression profiling in order to examine the linkages between mRNA, proteins, and disease status (i.e. ovarian cancer). In this work, we developed and conducted two stage Ensemble Machine Learning approaches for both identifying biomarkers and predicting binary outcomes (putative homologous recombination deficiency, HRD positive or negative) and multiple mRNA classes (differentiated, proliferative, immunoreactive, mesenchymal, and unknown) using ovarian cancer proteogenomics data. In stage one, a homogeneous ensemble biomarker selection with data perturbation based on random forests (RF) approach is developed and implemented to identify important biomarkers. In stage two, we utilized the selection result of stage 1, and compared various ML methods (gaussprLinear, gaussprRadial, LogitBoost, MLP, MLPML, parRF, RF, SVM, treebag, WSRF) for predicting binary HRD, and multiple mRNA classes. Results show that our ensemble approach identifies the consistent and reproducible set of important markers out of 9606 proteins linked to the binary HRD status, and with good prediction accuracy, i.e. Treebag provided 83% prediction accuracy (85% sensitivity and 81% specificity); while for mRNA multi-classes, RF provided 81% prediction accuracy. One drawback of the proposed ensemble approach is that it is computationally expensive (i.e. in the ensemble of RF with homogeneous feature selection algorithm using 10000 trees), therefore requiring constant tuning of the model parameters for an improved performance.

**824F**

**Amplicon Reconstructor: Optical mapping aids the reconstruction of complex, large cancer genome rearrangements.** *J. Luebeck<sup>1</sup>, V. Deshpande<sup>2</sup>, C. Coruh<sup>3</sup>, D. Pai<sup>4</sup>, S. Wu<sup>5</sup>, C. Zhang<sup>1</sup>, K. Turner<sup>5</sup>, J. Law<sup>2</sup>, P. Mischel<sup>5</sup>, V. Bafna<sup>2</sup>.* 1) Bioinformatics & Systems Biology Graduate Program, UC San Diego, La Jolla, CA; 2) Department of Computer Science, UC San Diego, La Jolla, CA; 3) Salk Institute for Biological Studies, La Jolla, CA; 4) BioNano Genomics, San Diego, CA; 5) Ludwig Institute for Cancer Research, UC San Diego, La Jolla, CA.

Focal amplifications (< 5 Mb) are a hallmark of the cancer genome, and differ from large scale chromosomal aneuploidy or simple segmental tandem duplication. Focal amplifications have been shown to reside not only on the linear chromosomes as homogeneously staining regions (HSR), but also as circular extrachromosomal DNA (ecDNA). ecDNA amplicons show high copy count variation, ranging from 10 to 100+ (Turner, Nature 2017). Extrachromosomal structures tend to be highly rearranged and may include segments from multiple chromosomes. Recent estimates suggest ecDNA may be found in ~40% of cancers (Turner). Previously, we developed a tool, Amplicon Architect (AA) that combines coverage and breakpoint information from short reads to output a breakpoint graph containing possible amplicon structures. Due to the complexity of the breakpoint graph, it is often impossible to reconstruct the complete architecture using short reads alone. Optical mapping provides long restriction maps (map length ~200kb) which can be assembled into ultra-long contigs (assembly N50 ~2.5Mb). While useful for ordering large segments of DNA, optical maps struggle to map smaller fragments individually. We developed a method, Amplicon Reconstructor (AR) that uses BioNano optical mapping to scaffold segments in AA-reconstructed breakpoint graphs from NGS data, disambiguating amplicon architecture. AR uses multiple algorithmic strategies (contig recruitment, graph matching and dynamic programming) to obtain candidate reconstructions. AR also maps possible integration sites of ecDNA into chromosomal DNA, and calls structural heterogeneity of amplicons. On five samples with cytogenetically validated ecDNA or HSR amplicons, AR revealed the structure of ecDNA in 3 glioblastoma samples, and identified sites where ecDNA had reintegrated back into chromosomal DNA. In one sample, AR reported structurally heterogeneous ecDNA reconstructions with differing status of EGFRV8 mutation. In a hematopoietic cell line, AR produced the first complete reconstruction of a Philadelphia chromosome (BCR-ABL gene fusion), involving segments from three chromosomes. Additionally, it enabled the first scaffolding of a breakage fusion bridge (BFB), in a lung cancer cell line, by identifying assembled optical map contigs spanning multiple junctions found in the 18.3 Mb BFB structure. Thus we demonstrated a combination of optical mapping and NGS in concert with AR produces unambiguous reconstruction of complex structures.

**Classification of prostate cancer patients as indolent or aggressive using machine learning approach.** *T. Mamidi, C. Hicks, J. Wu, E. Nicklow.* Department of Genetics, Louisiana State University Health Sciences Center, School of Medicine, 533 Bolivar Street, New Orleans, LA 70112.

**Background:** Prostate cancer (PCa) is the second most common cancer in men in the US. Many PCas are indolent and do not result in cancer mortality, even without treatment. However, a significant proportion of patients with PCa have aggressive tumors that progress rapidly to metastatic disease and are often lethal. Currently, treatment decisions for PCa patients are guided by various stratification algorithms. Among these parameters, the most potent predictor of PCa mortality is the Gleason score (ranges from 6-10). Although current risk stratification tools are moderately effective, limitations remain in their ability to distinguish truly indolent from aggressive and potentially lethal disease. Here we propose the use of machine learning (ML) for classification of PC patients as having either indolent or aggressive tumors using transcriptome data. We hypothesize that genomic alterations could lead to measurable changes distinguishing indolent from aggressive tumors. **Method:** We used gene expression data and clinical information on 546 samples (494 tumors and 52 normal) from The Cancer Genome Atlas (TCGA). Tumor samples were distributed according to Gleason score (indolent 45, Gleason score = 6; intermediate grade 245, Gleason score 7 and aggressive 204, Gleason score 8-10). Because intermediate grade has more variable clinical course, we classified it as either indolent (3+4) or aggressive (4+3) based on current treatment protocol. We performed supervised analysis to discover genes distinguishing the two patient groups. We selected a small subset of significantly differentially expressed genes for use as classifiers. We used three ML algorithms including Bayes classifier, Logistic model tree (LMT) and Hoeffding tree classifiers and evaluated their performance and classification accuracy. **Results:** Preliminary results have shown that using current classification protocol of 3+4 for indolent or 4+3 for aggressive, for patients with intermediate Gleason grade 7, patients were misclassified by ~50% by all the three classifiers. We plan to develop new classification algorithms that integrate transcriptome data with mutation information for accurate classification of patients as having indolent and aggressive tumors using ML. **Conclusion:** These results show that current classification protocol could misclassify PC patients and that ML algorithms could be used to accurately classify PCa patients to indolent or aggressive using transcriptome data.

**826T**

**Analysis of targeted sequencing data of hereditary lung cancer families identifies germline copy number variations (CNVs) in multiple genes.** *D. Mandal<sup>1</sup>, D. Tran<sup>1</sup>, K.W. Termine<sup>1</sup>, T. Mamidi<sup>1</sup>, A. Musolf<sup>2</sup>, M. Baddoo<sup>3</sup>, M. de Andrade<sup>4</sup>, C. Gaba<sup>5</sup>, P. Yang<sup>6</sup>, M. You<sup>6</sup>, M.W. Anderson<sup>7</sup>, A.G. Schwartz<sup>8</sup>, S.M. Pinney<sup>9</sup>, C.I. Amos<sup>9</sup>, J.E. Bailey-Wilson<sup>9</sup>.* 1) Genetics, LSU Health Sciences Center, New Orleans, LA; 2) National Human Genome Research Institute, National Institutes of Health, Baltimore, MD; 3) Tulane Cancer Center, New Orleans, LA; 4) Mayo Clinic, Rochester, MN; 5) University of Toledo Dana Cancer Center, Toledo, OH; 6) Medical College of Wisconsin, Milwaukee, WI; 7) University of Cincinnati College of Medicine, Cincinnati, OH; 8) Karmanos Cancer Institute, Wayne State University, Detroit, MI; 9) Baylor College of Medicine, Houston, TX.

About 10% of lung cancer (LC) cases (22,000 cases per year) in the U.S. have at least one first-degree relative affected with LC, and 25% of cases have at least one first- or second-degree affected relative. Previous multipoint linkage analyses of hereditary lung cancer (HLC) families ( $\geq 3$  LC/family) collected by the Genetic Epidemiology of Lung Cancer Consortium detected significant linkage to 6q25. To aid in further investigation, targeted sequencing of 6q23-6q27 was obtained and we analyzed these data to identify germline copy number variations (CNVs). CNVs have been reported on lung cancer cell lines and somatic samples; however, no germline specific CNVs have been reported in HLC families. The objective of the present study is to detect germline CNVs from the targeted sequencing data in HLC families that might be responsible for increased susceptibility to LC in these high-risk families. The nine most strongly linked HLC families ( $\geq 4$  LC cases/family) on whom we have targeted sequencing data included 25 affected and 55 informative unaffected family members. Phenotype, genotype, and smoking data are available on all family members. Two CNV-specific algorithms as incorporated in CANOES (<http://www.columbia.edu/~ys2411/canoes/>) and XHMM (<https://atgu.mgh.harvard.edu/xhmm/>) were used in order to successfully call and identify germline CNVs. To confirm, CNVs were then visualized independently using Integrative Genomics Viewer (IGV). Using both CANOES and XHMM we have identified CNVs in more than 30 genes that are deleted or duplicated in multiple families. Of those, CNVs in four cancer related genes (RGS17, SASH1, ARID1B, and PARK2) are present in more than three families and are detected by both algorithms. These genes were identified previously as candidates using either linkage analysis of the HLC families or by targeted sequencing analysis of 6q23-27. CNVs in three other cancer related genes, PACRG, RPS6KA2, and ESR1 were identified by both algorithms in five or more families. Detection of these genes by both CNV calling algorithms in multiple HLC families warrants further investigation in additional HLC families. In addition to identifying CNVs, transmission of germline CNVs in these families in multiple generations, including both affected and informative unaffected family members, will be useful for biomarker identification for prevention and early detection of LC in high-risk individuals.

**A high throughput software pipeline for NGS-based association studies: From assembly to candidate variants and their effect on 3D protein structures.** *K. Maxfield, S. Baldwin, D. Nash, M. Larson, M. Keyser, S. Darnell, T. Durfee.* DNASTAR, Inc., Madison, WI.

Advances in DNA sequencing have made identifying genetic variation from any individual routine and allowed variation across populations or cohorts to be analyzed for candidate mutations causing diseases or traits of interest. However, the computational complexity of the analysis together with the enormous amount of data pose daunting challenges in terms of bioinformatics, data management and computing resources that are beyond all but the most well equipped laboratories. We have developed a seamlessly integrated software pipeline to address this problem. NGS sequencing reads from each sample are aligned to a reference genome using SeqMan NGen, a fast non-memory bound assembler for data sets of any size. A Bayesian modeled probabilistic variant caller analyzes the gapped alignments in-stream to produce high accuracy single nucleotide variant (SNV) and small indel calls for each sample. Assemblies can be done on standard desktop computers or on the DNASTAR Cloud which allows the samples to be processed in parallel. Variant profiles from each sample are automatically combined into a single project file for analysis in ArrayStar where various searching and statistical methods are available for identifying candidate genes and/or variants of interest. ArrayStar also allows gene and variant level annotations to be added aiding in the identification and prioritization of candidates. Further, for genes with known 3D protein structures, the effect of candidate missense mutations can automatically be predicted through integration our molecular structure visualization and analysis module, Protean 3D. As a demonstration of the pipeline, we will present results from the reanalysis of 96 targeted resequencing samples from a Chinese cohort with lung squamous cell carcinomas (LSCC, Li et al., *Sci Rep.* 2015. 5:14237). Results will be compared to the published observations highlighting new candidate genes/variants that may have been initially missed. We will also show examples of how predicted protein structure changes caused by missense mutations can aid in prioritizing variants of interest.

**828W**

**Expanding GEMINI to annotate and prioritize subclonal mutations in heterogeneous tumors.** *T. Nicholas<sup>1,2</sup>, B. Pedersen<sup>1,2</sup>, Y. Qiao<sup>1,2</sup>, X. Huang<sup>1,2</sup>, G. Marth<sup>1,2</sup>, A. Quinlan<sup>1,2</sup>.* 1) Human Genetics Department, University of Utah, Salt Lake City, UT; 2) USTAR Center for Genetic Discovery, University of Utah, Salt Lake City, UT.

DNA sequencing has unveiled extensive tumor heterogeneity in several different cancer types, with many exhibiting substantial clonal substructures. Considerable genetic variation exists within individual tumors and between metastatic sites from shared phylogenies, highlighting ongoing tumor growth and evolution. These differences can be further magnified over time by selective pressures introduced by different treatments. Properly identifying and tracing this variation throughout the expansion and progression of a tumor represents a significant challenge. Furthermore, being able to prioritize and focus on mutations most likely to contribute to tumor evolution or that could serve as potential therapeutic targets represents an ongoing problem, but is crucial towards determining possible clinical care. GEMINI is an effective tool for exploring genetic variation by enabling the querying of multiple genome annotations into a single database. Here we describe our progress towards an adaptation to the GEMINI framework that is more ideally suited for the complex patterns of genetic variation inherent to the study of changes in tumor heterogeneity across multiple biopsies over the course of treatment. This is accomplished by enhancing GEMINI variant annotation to include tumor clonal specifications and allowing for filtering methods that reflect specific tumor properties. Additionally, by incorporating existing tools and databases that facilitate the interpretation of cancer mutations (e.g., CIViC, DGIdb, CRAVAT) into the GEMINI framework, the identification of mutations that may be driving clonal evolution is simplified. The advances to the GEMINI framework that we are developing will better enable cancer scientists and research oncologists to discern genetic details, at a clonal level, of how a tumor evolves over time, and better interpret these mutations in the context of potential patient care.

**829T****Identification of disruptive germline and somatic variants in intronic splicing sequences and their confirmation by RNA expression in 2,489 cancer patients.**

A. Polley<sup>1</sup>, J. Little<sup>1</sup>, S.C. Benz<sup>1</sup>, S. Rabizadeh<sup>2</sup>, J.Z. Sanborn<sup>1</sup>. 1) NantOmics, LLC., Santa Cruz, CA; 2) NantOmics, LLC., Culver City, CA.

Pre-mRNA splicing is a complex process involving conserved sequence elements within the intron. The 5' and 3' splice sites are critical for proper splicing and their consensus sequences are highly conserved. Variants at these sites can result in disruptive events such as exon loss and intron retention, and are consequently implicated in many human cancers and diseases. Intronic sequences upstream of the 3' acceptor splice site, including the polypyrimidine tract (PPT) and branch point (BP) region, also play a critical role in the splicing reaction. However, the consequences of variants within these regions are less predictable due to lower sequence conservation in the human genome. We have developed a pipeline to study the impact of splice site mutations in both germline and somatic DNA, detect and investigate intronic mutations adjacent to the 3' splice site, and confirm their downstream effect on RNA splicing and expression. We ran 2,489 cancer patients' germline and somatic DNA and tumor RNA sequencing data through the pipeline against 328 cancer genes, including a subset of 22 cancer predisposition genes. Germline splice site variants were identified in cancer genes in almost all patients, and somatic variants in over 15% of patients. Additionally, 15% of patients had germline splice site mutations in the subset of cancer predisposition genes. Low RNA exon coverage was detected for splice site mutations in 5 patients, with a confirmed exon 16 deletion in the *ERBB2* gene of a patient with breast cancer. We identified the cause of this event to be a 3' splice site mutation (c.1854-2A>G). To estimate which intronic sequences could function as the BP and PPT, we created and searched for characteristic sequence identifiers in the reference genome and used this data to rank the strength of potential BPs in the set of cancer genes. We identified over 25,000 potential BPs, which we observed in 90% of genes in our set. Around 15% of the predicted BPs were categorized as being high-confidence. We then investigated variation in the high-confidence sequences and their impact on splicing. Our analysis demonstrates that the prediction of intronic splicing elements is an important supplement to a full splice site mutation analysis. Additionally, we highlight the benefit of using RNA exon coverage data to confirm abnormal splicing, which is an important driver of oncogenesis and plays an under-appreciated role in human disease.

**830F****Beyond BRCA: Discovery of novel drivers of homologous recombination deficiencies.**

N. Sahnji<sup>1</sup>, D.J. Mcgrail<sup>2</sup>, Y. Li<sup>3</sup>, B. Feng<sup>3</sup>, L. Hu<sup>2</sup>, G.B. Mills<sup>2</sup>, S.Y. Lin<sup>2</sup>, S. Yi<sup>4</sup>. 1) MD Anderson cancer center, Houston, TX. Baylor College of Medicine, Houston; 2) MD Anderson cancer center, Houston, TX; 3) TESARO Inc, Waltham, MA; 4) Dell Medical School, The University of Texas at Austin TX.

**Introduction:** In the two decades since the discovery of *BRCA1* and *BRCA2* mutations as risk factors for breast cancer, our knowledge of their function in maintaining genomic integrity through homologous recombination (HR) DNA repair and other pathways has greatly advanced, ultimately culminating in development of PARP inhibitors that can specifically target patients who harbour these mutations. However, BRCA mutations have only shown relevance in a subset of cancers and the discovery of additional drivers of HR deficiencies across cancers remains minimal. **Methods:** We integrated large-scale omics data from The Cancer Genome Atlas across 18 cancer types that display genomic evidence of HR defects to elucidate novel genomic drivers. Using network analysis, we predicted novel drivers of HR defects and experimentally validated these predictions across multiple experimental systems including HR reporter assays and Rad51 foci formation. **Results:** In addition to prediction of classical HR genes such as *BRCA1*, *BRCA2*, and *PALB2*, our analysis indicates that over half of HR deficiencies originate outside of canonical DNA damage response genes. Notably, the novel identified drivers were particularly enriched for genes involved in RNA splicing and processing. The predicted candidates were significantly enriched for cancer risk loci, over half of which were related to RNA processing. Experimental techniques validated over 90% of our predictions in a panel of 50 genes tested by siRNA as well as 31 additional engineered mutations identified from TCGA patients. **Discussion:** Taken together, our integrated computational analysis identified and validated over 50 drivers of HR deficiencies across numerous lineages. These novel drivers may serve as important biomarkers to help understand what patients may benefit from targeted therapies such as PARP inhibition. Moreover, this work may enable better understanding of cancer etiology, and advance screening approaches aimed at identifying individuals at risk for developing malignancies.

**An integrated systems analysis of miRNA target network associated with natural killer cell activation.** G. Thillaiyampalam<sup>1</sup>, K. Bednarska<sup>1</sup>, Q. Cui<sup>1</sup>, F. Vari<sup>1,3</sup>, M. Gandhi<sup>1,2</sup>, A. Cristino<sup>1</sup>. 1) University of Queensland Diamantina Institute, Translational Research Institute, University of Queensland, Brisbane, QLD, Australia; 2) Princess Alexandra Hospital, Brisbane, QLD, Australia; 3) QIMR Berghofer Medical Research Institute.

Natural killer (NK)-cells are immune effector cells that have the ability to kill cancer cells without prior sensitization. A number of cell surface receptors and transcriptional factors are known to control NK-cell activation. However little is known about the regulatory molecules involved in NK-cell activation. microRNAs (miRNAs) are regulatory RNAs (19 – 24 nt) critical for the control of gene expression via direct binding to 3'UTR of messenger RNAs (mRNAs) to suppress the protein synthesis. In this study we used the human NK-cell lines as a model system to identify the regulatory miRNAs by comparing the transcriptome of resting NK cells and two activation systems: direct cytotoxicity and antibody-dependent cell-mediated cytotoxicity. We identified genes involved in ER stress (XBP1), cell motility (XIRP1) and checkpoint receptors (PD1) up-regulated during activation. Our transcriptomic analysis revealed 83% of mRNA transcripts were up regulated while 81% of miRNAs were down regulated during both activation conditions which resulted in a putative miRNA - mRNA network. miR-34a-5p has been identified as a regulatory hub binding to 3'UTR of genes including XBP1, XIRP1 and PD1. We validated the direct binding of miR34a-5p to the predicted target sites in these genes by a dual-luciferase reporter system and the *in vivo* regulation over PD1 protein was validated by flow cytometry of NK cells transfected with mimics miR-34a-5p. Our findings provide detailed characterization of a miRNA regulatory network underpinning NK-cell activation against cancer cells and could open new avenues for miRNA-based therapeutics to enhance NK cell anti-tumoural function.

**Coordinating variant interpretation knowledgebases improves clinical interpretation of genomic variants in cancers.** A. Wagner<sup>1</sup>, B. Walsh<sup>2</sup>, G. Mayfield<sup>2</sup>, D. Tamborero<sup>2</sup>, D. Sonkin<sup>4</sup>, K. Krysiak<sup>1</sup>, J. Deu Pons<sup>2</sup>, R. Duren<sup>2</sup>, J. Gao<sup>2</sup>, J. McMurry<sup>2</sup>, S. Patterson<sup>7</sup>, C. Del Vicchio Fitz<sup>2</sup>, S. Li<sup>2</sup>, D. Ritter<sup>2</sup>, R. Dienstmann<sup>10</sup>, D. Chakravarty<sup>6</sup>, J. Beckmann<sup>11</sup>, M. Baudis<sup>12</sup>, M. Haendel<sup>2</sup>, M. Lawler<sup>13</sup>, S. Mockus<sup>2</sup>, O. Elemento<sup>14</sup>, N. Schultz<sup>2</sup>, N. Lopez-Bigas<sup>3</sup>, J. Goecks<sup>2</sup>, A. Margolin<sup>2</sup>, M. Griffith<sup>1</sup>, O. Griffith<sup>1</sup>. 1) Washington University School of Medicine, St. Louis, MO; 2) Oregon Health and Science University, Portland, OR; 3) Institute for Research in Biomedicine, Barcelona, Spain; 4) National Cancer Institute, Rockville, MD; 5) Molecular Match, Houston, TX; 6) Memorial Sloan Kettering Cancer Center, New York, NY; 7) The Jackson Laboratory for Genomic Medicine, Farmington, CT; 8) Dana-Farber Cancer Institute, Boston, MA; 9) Baylor College of Medicine, Houston, TX; 10) Vall d'Hebron Institute of Oncology, Barcelona, Spain; 11) University of Lausanne, Lausanne, Switzerland; 12) University of Zurich, Zurich, Switzerland; 13) Queen's University Belfast, Belfast, Northern Ireland; 14) Cornell University, Ithaca, NY.

The promise of precision medicine in which a cancer patient's treatment is tailored to their specific cancer variants requires concise, standardized, and searchable clinical interpretations: biomarker-disease associations that provide therapeutic or prognostic value. While many institutions curate interpretations for clinically relevant cancer variants, these efforts are siloed and non-interoperable. We formed the Variant Interpretation for Cancer Consortium (VICC, [cancervariants.org](http://cancervariants.org)) as a Driver Project of the Global Alliance for Genomics and Health (GA4GH, [ga4gh.org](http://ga4gh.org)), and assessed six established resources of cancer variant interpretations (CIVIC, OncoKB, JaxCKB, MMatch, PMKB, CGI). We compared the coverage of the biomedical literature between them, finding that 87% of the 6034 publications from the six resources were unique across the collective. This illustrates both the value gained from aggregating the knowledge of these resources and the enormity of the biomedical literature describing cancer variants. We integrated guidelines and ontologies describing genes, variants, diseases, drugs, and evidence to harmonize clinical interpretations of cancer variants. From this, the VICC collectively established a set of minimum elements required for describing a cancer variant interpretation, and used them to harvest and harmonize knowledge from the six founding resources. Our results demonstrate that the knowledge from the constituent resources of the VICC are highly heterogeneous across every element defining these interpretations (genes/variants, drugs, diseases, evidence). To address this, we have developed a harmonized database and a prototype web interface for exploring and querying this breadth of knowledge. We evaluated 110,320 somatic mutations of 17,005 patient donors in the AACR Project GENIE cohort against our VICC aggregate interpretation database. When stratified by evidence level (as described by the joint consensus recommendation of the Association for Molecular Pathology, American Society of Clinical Oncology, and College of American Pathologists), the interpretations within the VICC aggregate knowledgebase provided 2-4x breadth of coverage across each level of evidence when compared to the median coverage from the constituent resources. Finally, we demonstrated how the clinically actionable interpretation of a patient mutation may change dramatically when considering the knowledge from the VICC resources in aggregate instead of individually.

**Machine learning-based genome-wide interrogation of copy number aberrations in circulating tumor DNA for non-invasive detection of early-stage hepatocellular carcinoma.** Q. Wei<sup>1</sup>, Z. Bian<sup>2</sup>, Z. Ye<sup>3</sup>, Y. Wang<sup>2</sup>, C. Wang<sup>3</sup>, C. Yin<sup>2</sup>, K. Tao<sup>2</sup>, H. Yang<sup>3</sup>, B. Li<sup>1</sup>, J. Xing<sup>2</sup>. 1) Department of Molecular Physiology and Biophysics, Vanderbilt University, Nashville, TN; 2) State Key Laboratory of Cancer Biology and Experimental Teaching Center of Basic Medicine, Fourth Military Medical University Xi'an, China; 3) Department of Medical Oncology, Thomas Jefferson University, Philadelphia, PA.

Hepatocellular carcinoma (HCC) is a leading cause of cancer death worldwide. For HCC patients, detecting them in early-stage is a much higher prognosis. Recently the discovery of ctDNA (circulating tumor DNAs) in cancer patients makes it possible to develop blood-based non-invasive approaches of cancer detection. In this study, we carried out low-depth (5X) whole-genome sequencing (WGS) to analyze somatic copy number aberration (SCNA) profiles in 392 plasma samples of hepatitis B virus (HBV)-related HCC and cancer-free HBV patients, using three different cohorts, and developed a machine learning-based early-detection model to detect the HCC patients in early-stage. In a discovery cohort of 209 samples, leveraging the model we achieved an overall area under curve (AUC) of 0.894 (0.842 for stage I and 0.934 for stage II-IV). We then assessed the performance of our model in two independent validation cohorts with 78 and 105 samples respectively, consisting of mostly stage I patients (75%). Our model exhibited a robust predictive performance, with AUC of 0.898 and 0.788 in validation cohort 1 and 2, respectively. Meanwhile to increase the detection accuracy for early-stage HCC, we incorporated prior knowledge derived from external genomics data into the framework and improved the model performance in validation cohort 2. Overall, we developed an SCNA-based, machine learning-driven model in the non-invasive detection of early-stage HCC and demonstrated its performance through strict independent validations.

**Breast cancer type classification using machine learning approach.** J. Wu<sup>1</sup>, T. Mamidi<sup>1</sup>, L. Zhang<sup>2</sup>, E. Nicklow<sup>1</sup>, H. Hicks<sup>1</sup>. 1) Department of Genetics, Louisiana State University Health Sciences Center, New Orleans, LA; 2) Louisiana Tumor Registry, Louisiana State University Health Sciences Center, New Orleans, LA.

Background: Breast cancer (BC) is the most diagnosed cancer and the second leading cause of cancer-related death among women in the US. Majority of BC are ER positive (ERPBC) and respond to endocrine or targeted therapies. However, a significant proportion of BC are triple negative breast cancer (TNBC) the most aggressive form of BC with poor survival rates and poor clinical outcomes. Although current classification based on the three receptor markers (lack of estrogen receptor, progesterone receptor and lack of HER-2 amplification) is relatively effective in identifying patients with TNBC, significant challenges remain. BC is inherently a heterogeneous disease and accurate stratification of BC patients based on the molecular type remains a challenge for clinicians and oncologists. Accurate classification of breast cancer types could guide therapeutic decision making. Advances in high-throughput sequencing of BC genomes has led to an expansion in molecular classification of types of BC. Here we propose the use of machine learning (ML) for classification of BC patients as either having TNBC or ERPBC. We hypothesize that genomic alterations in individual patients with either TNBC or ERPBC could lead to lead to measurable changes distinguishing the two patient groups, and that this could be accomplished using ML. Methods: Our proposed classification method uses information from gene expression and clinical data we downloaded from The Cancer Genome Atlas (TCGA) consisting of 110 TNBCs, 922 ERPBCs and 53 control samples. We performed whole genome analysis comparing gene expression levels between the two patient groups (TNBC vs ERPBC) to discover significantly differentially expressed genes. From the significantly differentially expressed genes, we selected a small subset of genes for use as classifiers. We used two classification approaches, k-nearest neighbors (kNNs) and decision-trees (DTs) and evaluated their performance and classification accuracy. Results: The two methods accurately classified the patients as either TNBC or ERPBC, suggesting that ML could be used to accurately classify BC into the two types of BC. The overall classification accuracy was higher than 95% for both ML methods. Conclusions: The result demonstrate that ML could be used to accurately classify BC patients as either TNBC or ERPBC type using molecular markers from transcription profiling. Future work will involve mutation-based classification of BC into TNBC or ERPBC using ML. .

**835T**

**Comprehensive analysis of genetic variations in patients with acute lymphoblastic leukemia.** *W. Yun<sup>1</sup>, B. Kim<sup>2</sup>, S.T. Lee<sup>2</sup>, J.R. Choi<sup>2</sup>.* 1) Brain Korea 21 PLUS Project for Medical Science, Yonsei University; 2) Department of Laboratory Medicine, Yonsei University College of Medicine, Seoul, Korea.

**Background** Researches on genetic variations in patients with B-cell and T-cell acute lymphoblastic leukemia (ALL) are ongoing, but a comprehensive analysis of genetic variations including chromosomal and genic copy number variations is rarely reported. **Methods** We developed and applied next-generation sequencing (NGS)-based targeted gene panel and bioinformatics pipeline to profile the genetic changes in patients with acute lymphoblastic leukemia. We analyzed 185 genes in 87 patients with B-cell ALL (n=72) and T-cell ALL (n=15). Thirty five adults and 53 pediatric patients were included.

**Results** Among 72 patients with B-ALL, 33 has chromosomal abnormality such as hyperdiploidy. A total of 197 genetic variants were detected and 149 of these were deletion or duplication of genes (75.6%). *CDKN2A/B* and *IKZF1* genes were most frequently deleted. Among single nucleotide variants and small indels, those of *TP53*, *RAS* and *PTPN11* were most frequently detected. Among 15 patients with T-cell ALL, variations in *PTEN*, *PHF6* genes were frequently observed along with *CDKN2A* deletion. Deletions of genes indicating poor prognosis, such as *IKZF1* and *EBF1* deletion was more frequent in adult patients. **Conclusion** Using NGS-based gene panel which can assess copy number variations as well as sequence variations, genetic variations of lymphoblastic leukemia could be better understood. Further study would be needed to connect the genetic variations to the clinical outcomes.

**836F**

**Reconstruct pseudogene regulatory networks using natural language processing for novel drug target prediction.** *Y. Zhang<sup>1</sup>, S. Tan<sup>1,2</sup>, X.-M. Mo<sup>1</sup>.* 1) Department of Biomedical Informatics, College of Medicine, The Ohio State University, Columbus, OH; 2) School of Information Engineering, Hubei University of Economics, Wuhan, Hubei, China.

**Background:** Pseudogenes are non-coding DNA segments that are homologous to the coding genes. Although they have been thought of as "genomic fossils", recent studies have shown that a considerable number of pseudogenes are transcribed and some can even regulate gene expression. Some of the pseudogenes can regulate the parental genes' expression by competitively binding to microRNAs. Some others can generate competitive endogenous RNAs (ceRNAs) that can bind to the 3' UTR of the parental gene thus regulate gene expression. One of the regulatory pseudogenes includes PTENP1. The selective loss of PTENP1 can result in aberrant activation of PI3K/AKT signaling pathway and is associated with tumorigenesis in human. All these show that pseudogenes make a new class of modulators of gene expression. However, they are still understudied and there is a lack of functional annotations of pseudogenes. **Results and Conclusion:** We extract information about regulatory pseudogenes by analyzing literature using natural language processing (NLP) techniques. Based on this information, we reconstructed the regulatory networks involving pseudogenes and target genes with disease and tissue-specific annotation. We performed pathway analysis on the networks, based on which we were able to annotate the regulatory pseudogenes with enriched functional impact. We also overlaid drug-target network onto this regulatory network, and predict the potential treatment mechanisms that the pseudogenes are involved in. This not only filled the gap for functional annotation of pseudogenes but also can be used as a ground truth, upon which we can develop computational methods for pseudogene function prediction and cross-validation.

**837W**

**Integrating genetic information with machine learning to predict which prostate cancer cases should not be immediately treated.** *T.B. Cavazos<sup>1</sup>, N.C. Emami<sup>1</sup>, J.E. Cowan<sup>2</sup>, M.R. Cooperberg<sup>2,3</sup>, J.M. Chan<sup>2,3</sup>, P.R. Carroll<sup>2</sup>, J.S. Witte<sup>2,3</sup>.* 1) Program in Biological and Medical Informatics, University of California, San Francisco, San Francisco, CA; 2) Department of Urology, University of California, San Francisco, San Francisco, CA; 3) Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA.

Advances in screening and treatment have greatly improved five-year survival for prostate cancer. Approximately 90% of men diagnosed with prostate cancer are characterized as having low-risk disease. Although important strides have been made towards accurate patient stratification, less has been done to help guide treatment decisions for this low risk group. While some patients may experience upgrading or upstaging (UGUS) of their tumor and benefit from more invasive treatments such as radical prostatectomy, others may have slower growing tumors that are unlikely to result in any increased risk of morbidity or mortality due to this disease. In this case, active surveillance may be the best treatment option as surgery or radiotherapy have a number of potential side effects. To better stratify and guide the medical decisions of low-risk prostate cancer patients, we created a random forest (RF) classifier to predict the likelihood of future UGUS of prostate cancer at diagnosis and prioritize germline variants associated with this phenotype. We analyzed genetic and clinical data from a cohort of 864 low-risk prostate cancer patients whom underwent radical prostatectomy 6 months after initial diagnosis. At radical prostatectomy, 448 patients did not experience a change in tumor stage or grade. The patients were split into a training (n = 690) and validation (n = 174) cohort. With clinical factors alone, including Gleason score and prostate specific antigen levels (PSA), UGUS was predicted with 70% accuracy using a generalized linear model. To identify prognostic signals independent of clinical factors, approximately 700,000 single nucleotide polymorphisms (SNPs) were genotyped in these subjects. Due to the large number of features and small sample size of this study, RF is an appropriate method for analysis given its ensemble learning approach that helps prevent model overfitting. By integrating genetic information and using a RF classifier, we will show the potential increase in prediction accuracy over the clinical model alone.

**838T**

**Clinically actionable fusion genes and their detection through whole transcriptome sequencing (RNASeq™) from FFPE solid tumor biopsies.** *H.K. Chandok, K. Kelly, D. Bergeron, G. Ananda, H.V. Reddi.* The Jackson Laboratory for Genomic Medicine, Farmington, CT., 06032.

**Introduction:** Fusion genes have played a major role in tumor initiation and progression. A number of Next Generation Sequencing (NGS) technologies have enabled detection of fusions from both DNA and RNA. Transcriptome analysis allows improved detection of expression changes, somatic aberrations and gene fusions. Here we describe the development of an in-house RNAseq-based approach for detection of a larger number of gene fusions in solid tumors as an upgrade to our current 53 gene assay. **Methods:** 13 FFPE tumor samples with known fusions were selected, which included both pure cell lines and synthetic controls. Libraries were prepared from purified RNA using the KAPA RNA HyperPrep Kit with RiboErase (HMR) and were subsequently sequenced using the Illumina NextSeq. Sequencing data was processed through in-house bioinformatics pipeline including tools such as SOAPfuse, FusionCatcher, and EricScript for the detection of fusion transcripts. Samples were subjected to clinical quality control (QC) monitoring through the various sequencing and analysis steps. The fusion transcript detection algorithms were evaluated for their precision, recall trade-off, and computational cost. **Results:** Evaluation of QC metrics revealed that all 13 samples prepped using the developed protocol passed clinical quality cut-offs for library preparation, sequencing, and bioinformatics analysis. The samples had ~53-70M reads of which 39-55M reads were of high quality. FusionCatcher outperformed the others by providing the highest sensitivity of 87% compared to 40% and 47% by SOAPfuse and EricScript respectively. FusionCatcher was able to successfully identify 21 of the 23 known clinically actionable fusions in the samples tested. Additionally, the tool called 125-320 unknown fusions per sample. We imposed a series of filters to eliminate false positives and non-cancerous fusions such as gene fusions present in population databases, predicted effect in coding sequence regions, reads supporting spanning and junction regions etc., and the unknown fusions which passed out filters are currently under validation. **Conclusion:** Analyzing high quality data produced by RNAseq libraries through our robust pipeline allows for the detection of clinically relevant gene fusions as good targets for therapeutic applications and personalized medicine. With gene fusions implicated in a variety of cancer types, offering high quality, low cost molecular testing services will serve to best benefit the patient.

**Predicting melanoma survival with deep neural networks.** *L. Cordeiro, O. Lupi.* UNIRIO, Rio de Janeiro, Brazil.

The worldwide incidence of cutaneous melanoma has been increasing at a rate higher than the rate of any other tumor over the last several decades. While novel systemic therapies have revolutionized melanoma treatment in the past few years and five-year survival rates have been improving, survival can be lower than 10% in advanced cases. Since the early prognostic models of Clark and Breslow, several attempts to develop accurate survival models have met with limited success. Recent models incorporating different omics datasets and employing standard machine learning algorithms have achieved mixed performance. Deep learning is a novel class of machine learning algorithms that found many applications in medicine recently. The objective of this study is to experiment with this technique and develop a predictive survival model for melanoma using public gene expression data. We developed a semi-supervised learning model, i.e., one that learns representative features from unlabeled data – without survival information – and uses this representation to train a supervised model to try and predict clinical outcomes of interest. We constructed the unlabeled dataset by systematically mining public gene expression data and building a unique dataset of over 650 samples of normal skin and primary and metastatic melanoma. The unlabeled dataset was used to train a deep stacked autoencoder which fed a three-layer classifier. We used TCGA data as the labeled dataset in the supervised learning task. Based on available survival data, we categorized each sample as “deceased” or “alive” in five discrete time horizons – from one to five years – to try and predict whether a patient would be alive at a particular time horizon, given the global expression profile of her tumor at the moment of diagnosis. To assess model performance, we performed 1000 iterations of a repeat cross-validation procedure. All computations were done in MATLAB. Prediction performance was poor in shorter horizons, most likely due to severe class unbalance, though in longer time horizons it reached accuracy levels currently seen in the literature. Model accuracy hovered around 65% in T = 4 and T = 5 years, with sensitivity and specificity in the 63%–65% range. Further modeling will integrate deep autoencoders with more sophisticated techniques such as regularized Cox regressions and random survival forests, allowing us to identify features that significantly impact survival.

**Immune cell tumor infiltration in TCGA: A genome-wide association study.** *E.A. Daly, A. Mitchell, J. Hutz.* Human Biology and Data Science, Eisai Pharmaceuticals, Andover, MA.

Immunotherapy is a promising new treatment for many types of cancer that have not responded well to chemotherapy or traditional drugs. However, patient response to immunotherapy is still difficult to predict, and understanding underlying differences among these cancers is key to improving our treatment of them. In recent literature, infiltration of different immune cell types has been associated with mutation load and survival in multiple cancers. We sought to explore using GWAS whether there is a heritable contribution to an individual's immune response to cancer. We have explored through quantitative infiltration data generated by TIMER <<https://cistrome.shinyapps.io/timer/>> and germline genetic data from TCGA <<https://cancergenome.nih.gov/>> genetic variations in cancer patients leading to unusually high or low infiltration in six immune cell types: macrophages, neutrophils, dendritic cells, CD4 T-cells, CD8 T-cells, and B-cells. We utilized a standard pipeline including filtering for rare alleles (minor allele frequency > 0.02), missing genotyping rate < 0.02, missing rate for loci < 0.05, and Hardy-Weinberg equilibrium p-value > 1e-6, greatly reducing the noise in the results. As a positive control, we expected to see variants in the MHC controlling some variation in immune cell presence in tumors. Results for B-cells showed this most prominently with three variants in the MHC region with a p-value < 1e-5, but scattered signal for the MHC was present in all immune results, providing a level of confidence in the findings. Dendritic cell infiltration, which has been associated with mutation load in breast cancer, had a strong association with two SNPs very close in the same region of chr15 (99827439 and 99827447). Additionally, dendritic cell findings were very closely replicated in CD8 T-cell findings. This analysis is exploratory, but has promise in gaining a better understanding of the role of immune cells in cancer and the genetic profile of different tumors. We seek to replicate these findings using other methods of calculating tumor infiltration (outside of TIMER). With a better picture of genetic effects on immune cell infiltration in various cancer types, we may be able to better predict how patients will respond to immunotherapy.

**Multiscale mapping of the functional architecture of cancer systems.** *M. Flagg*<sup>1,3</sup>, *F. Zheng*<sup>1,3</sup>, *M. Yu*<sup>1,3</sup>, *K. Ono*<sup>1,3</sup>, *M. Kim*<sup>2,3</sup>, *D. Swanney*<sup>2,3</sup>, *B. Demchak*<sup>1,3</sup>, *J. Kreisberg*<sup>1,3</sup>, *N. Krogan*<sup>2,3</sup>, *T. Ideker*<sup>1,3</sup>. 1) Department of Medicine, University of California San Diego, La Jolla, CA; 2) Department of Cellular and Molecular Pharmacology, University of California, San Francisco, CA; 3) The Cancer Cell Map Initiative (CCMI), La Jolla and San Francisco, CA.

The modular, interdependent multi-gene systems which govern cancer remain poorly understood. It is well-established that any given cancer gene operates in multiple distinct cellular contexts. However, it remains unclear how to represent these diverse roles in a single comprehensive model with predictive capabilities and robust multi-omic data integration. To that end, we integrate many physical and functional networks from a wide range of molecular studies, assembling a comprehensive multiscale map of human cancer's functional systems. This map organizes protein complexes, signaling pathways, and inter-pathway crosstalk in a single hierarchy of cellular subsystems. The model's many uncharacterized modules offer intriguing hypotheses with robust data support; in examining these modules, we predict novel functional roles for hallmark cancer genes, established biomarkers of unclear function, and wholly uncharacterized genes. Applied to somatic mutation profiles in The Cancer Genome Atlas (TCGA) patients, this map reveals patterns of subsystem alteration, identifying systems targeted by mutations at multiple scales above the individual gene. This map facilitates interpretation of omics data in terms of affected subsystems; we integrate new protein-protein interactions identified with AP-MS to elucidate the selective rewiring of these modules in multiple breast cancer cell lines. This map also enables integration of mutation and clinical data in TCGA patients across many cancer types, bridging genotype and phenotype to connect patient survival, treatment resistance, and tumor histology to subsystem alteration. By linking clinical course to underlying biology through the lens of this model, we identify novel cancer subtypes, offering a framework for personalized medicine approaches. To facilitate model interpretation, we created HiView, a web-based hierarchy browsing tool, which allows users to visualize and navigate hierarchies, contextualizing each module by displaying the underlying data and relevant entries in gold-standard databases.

**Tumor gene expression profiles segregate across primary sites.** *F.G. Frost*<sup>1</sup>, *D. Condon*<sup>1</sup>, *P. Cherkuri*<sup>1</sup>, *L. Charnichael*<sup>1</sup>, *M. Dogramaci*<sup>2</sup>, *S. Milanovich*<sup>1</sup>, *C. Boerkoel*<sup>1</sup>, *UCSC Treehouse Childhood Cancer Initiative*. 1) Sanford Imagenetics, Sioux Falls, SD; 2) Sanford Children's Hospital, Sioux Falls, SD.

**Background:** Cancer classification according to tumor primary site and histopathology have helped define tumor treatment and prognosis for over 200 years. With increasing knowledge and improving technology, many tumors are now subdivided according to histopathology as well as by protein and/or nucleic acid biomarkers. The latter has shown that tumors of apparently disparate histopathology can have similar gene expression signatures, and that tumors with similar histopathology can have distinct gene expression signatures. Based on either the Cancer Stem Cell (CSC) or the Dedifferentiation Theories of tumorigenesis, one might postulate that there are a finite number of ways for cancer to develop and that these mechanisms act across multiple primary tissue types. **Remaining Question:** This raises the question of whether such conserved cancer promoting pathways are identifiable and whether they do indeed transcend primary tissue type. **Hypothesis:** Transcriptomic phenotypes from diverse tumors segregate across tumor primary sites. **Methods:** Transcriptomes derived from both normal and tumor tissues were obtained from The University of California, Santa Cruz (UCSC) Treehouse Project's publicly available dataset. Principle component analysis and hierarchical clustering was performed with and without subgrouping using metadata. **Results:** Analysis of histopathologically-grouped tumors showed that no two groups were significantly similar. Subsequent analyses with agnostic clustering-based groups show incomplete independence of primary site and transcriptomic phenotype. The transcriptomic phenotypes of the clusters included classical cancer pathways and/or metabolomic signatures. These signatures were generally obscured in the absence of correction for primary tissue gene expression through tumor/normal ratios. **Conclusions:** Although there are exceptions, cancer-specific gene expression profiles frequently segregate across primary sites. Subtraction of remnant normal tissue expression appears to greatly improve both functional annotation of each cluster and separation of outgroups.

**Integrated genomic, epigenetic, and expression analyses of ovarian cancer cell lines.** D. Hallberg<sup>1</sup>, E. Papp<sup>1</sup>, G.E. Konecny<sup>2</sup>, D.C. Bruhm<sup>1</sup>, V. Adleff<sup>1</sup>, M. Noë<sup>1</sup>, I. Kagiampakis<sup>1</sup>, D. Palsgrove<sup>1</sup>, D. Conklin<sup>2</sup>, Y. Kinoshita<sup>3</sup>, J.R. White<sup>1</sup>, M.F. Press<sup>4</sup>, R. Drapkin<sup>3</sup>, H. Easwaran<sup>1</sup>, S. Baylín<sup>1</sup>, D. Slamon<sup>2</sup>, V.E. Velculescu<sup>1</sup>, R.B. Scharpf<sup>1</sup>. 1) Johns Hopkins School of Medicine, Baltimore, MD; 2) Jonsson Comprehensive Cancer Center, David Geffen School of Medicine at UCLA, Los Angeles, CA, USA; 3) Penn Ovarian Cancer Research Center, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, USA; 4) Norris Comprehensive Cancer Center, University of Southern California, Los Angeles, CA, USA.

Ovarian cancer is the most common cause of death among gynecological cancers. Despite significant advances in therapies for other solid tumor malignancies, the overall survival of patients with late-stage ovarian cancer has remained dismal with few new options for treatment. The standard therapy involves debulking surgery followed by chemotherapy. Part of the reason for the lack of novel therapies for ovarian cancer has been an inadequate understanding of the underlying molecular characteristics of this disease, especially in the context of cancer cell models that can facilitate the development of various cancer treatments. To improve our understanding of ovarian cancer, we performed genome-wide sequencing analyses of 45 ovarian cancer cell lines of varying subtypes. Given the challenges of genomic analyses of tumors without matched normal samples, we developed a novel approach for detection of somatic sequence and structural changes called Trellis, and integrated these with epigenetic and expression alterations. Alterations not previously implicated in ovarian cancer that are biologically and clinically relevant included amplification or overexpression of *ASXL1* and *H3F3B*, deletion or underexpression of *CDC73* and TGF beta receptor pathway members, and rearrangements of *YAP1-MAML2* and *IKZF2-ERBB4*. Dose-response analyses to targeted therapies revealed novel molecular dependencies, including increased sensitivity of tumors with *PIK3CA* and *PPP2R1A* alterations to PI3K inhibitor GNE-493, *MYC* amplifications to PARP inhibitor BMN673, and *SMAD3/4* alterations to MEK inhibitor MEK162. Furthermore, we found that genome-wide rearrangements provided an improved measure of sensitivity to PARP inhibition rather than the currently used HRD score. This study provides a comprehensive and broadly accessible resource of molecular information for development of new therapeutic avenues in ovarian cancer.

**The genomic landscape and pharmacogenomic interactions of circadian genes in cancer chronotherapy.** L. Han<sup>1</sup>, Y. Xiang<sup>1</sup>, J.S. Takahashi<sup>2</sup>, G.B. Mills<sup>2</sup>, S.H. Yoo<sup>1</sup>, Y. Ye<sup>1</sup>. 1) The University of Texas Health Science Center at Houston, Houston, TX; 2) The University of Texas MD Anderson Cancer Center, Houston, TX; 3) University of Texas Southwestern Medical Center, Dallas, TX.

Cancer chronotherapy, treatment at specific times during circadian rhythms, endeavors to optimize anti-tumor effects and lower toxicity. However, comprehensive characterization of clock genes and their clinical relevance in cancer is lacking. We systematically characterized the alterations of clock genes across 32 cancer types by analyzing data from TCGA, CTRP, and GDSC databases. Expression alterations of clock genes are associated with key oncogenic pathways, patient survival, tumor stage and subtype in multiple cancer types. Correlations between expression of clock genes and of other genes in the genome were altered in cancerous versus normal tissues. We identified interactions between clock genes and clinically actionable genes by analyzing co-expression, protein-protein interaction and ChIP-seq data, and also found that clock gene expression is correlated to anti-cancer drug sensitivity in cancer cell lines. Our study provides a comprehensive analysis of the circadian clock across different cancer types and highlights potential clinical utility of cancer chronotherapy.

**HLI Cancer Search: A scalable, cloud-based search engine for cancer genome analysis.** A. Harley, E. Shinbrot, C. Lau, A. Gylfe, W. Delpont, R. Trivedi, T. Lacey. Human Longevity Inc., San Diego, CA.

**BACKGROUND:** In the era of precision medicine with thousands of cancer genomes sequenced worldwide, information required to perform comprehensive genome analysis is scattered through publications, professional guidelines, and web-based sources. There is a growing need for informatics tools to efficiently centralize and present genomic and associated phenotypic data in a user-friendly fashion. Here, we described the development of HLI Cancer Search -- a multi-omics search engine that integrates various sources of genomic data and ranks cancer alterations based on a set of criteria. This tool allows the user to create their own inquiries with dynamically created results, in contrast similar tools only allow the user to query static data sets for specific questions. **METHODS:** Cancer Search consists of a proxy, query user interface (UI) and the index. The data indexed can come from either HLI somatic sequencing pipeline or from an external partner in the form of a VCF or other tabular formats. Cancer Search utilizes responsive web-based interface with two factor authentication to ensure data protection. **RESULTS AND CONCLUSIONS:** Cancer Search provides millisecond access to data for both individuals and cohorts of samples. Currently we have indexed 400 million distinct variants (out of which 361,000 have annotations related to clinical significant genes and pathways). Patient-level analyses include: 1) comprehensive assessment of single nucleotide variants, copy number alterations, RNA sequencing data, structural rearrangements in both tumor and normal genomes; 2) integrated annotations of 17 data sources including drug labels and guidelines; and 3) advanced genomic analytics and machine learning model predictions. Cohort-level analytics include 1) stratification based on integrative analysis of genomic and phenotypic data; 2) data quality assessment; and 3) advanced genomic analytics including cancer driver analysis, and comparison to other large cancer cohorts. HLI Cancer Search allows analysis to extend beyond both static clinical reports and pre-computed cancer portal analyses to offer versatile and flexible analyses. The system facilitates in depth cancer genome analysis, as well as provides a framework for clinical biomarker discovery by enabling interactive, integrated, large-scale analysis of cancer genomic data at the point-of-care.

**846W**

**Inferring the evolutionary order of somatic mutations with RankNet.** W. Hsieh, W. Lai. National Tsing Hua University, Hsinchu City, Taiwan.

Tumors are well-known for its massive accumulation of mutations along its development. Computational biologists are especially interested in reconstructing the evolutionary history of the somatic mutations in tumors. The issue differs from the phylogenetic/coallescence tree construction of human population because the data is a mixture of cells and there is no clear trace of the coexistence of variants in the same cells. We propose a procedure to decompose a tumor into well-separated subclones according to the allele frequencies of different sets of mutations. The mutations representing the emergence of the same subclone are arranged in an evolutionary tree with the neighbor-joining method according to the subclone proportions in each tumor. The root of the tree is selected by the orders derived from the RankNet across multiple samples. The strategy helps to identify the recurrent mutations across multiple tumors and to trace the driver mutations that potentially propagate the downstream variations.

**847T**

**Biological and functional impacts of tumor suppressor gene inactivation events: A pan-cancer study.** P. Jia<sup>1</sup>, Z. Zhao<sup>1,2,3</sup>. 1) Center for Precision Health, School of Biomedical Informatics, The University of Texas Health Science Center at Houston, Houston, TX 77030, USA; 2) Human Genetics Center, School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX 77030, USA; 3) Department of Biomedical Informatics, Vanderbilt University Medical Center, Nashville, TN 37203, USA.

In cancer, activation of oncogenes and inactivation of tumor suppressor genes (TSGs) are two major driving forces. While oncogenes have been intensively studied and served as promising candidate drug targets, a systematic investigation of the molecular profiles and functional impacts of TSGs, however, is lacking from large cancer studies such as The Cancer Genome Atlas (TCGA). TSGs are difficult to study because their impacts can be easily confused with or overwhelmed by oncogenes. So far, we have collected more than 1000 human genes that were previously reported as TSGs or playing tumor suppressor roles through our Tumor Suppressor Gene database (<https://bioinfo.uth.edu/TSGene/>). In this study, we proposed a novel mathematical model to detect TSG inactivation events based on the widely recognized Two-Hit model. Our method integrates somatic mutation and copy number variation status, accounts for both per-sample mutation load and per-gene mutation rate, and removes sensitive factors that often lead to TSG inactivation but without major driving impacts (e.g., neighbor gene co-deletion by large CNV segments and genes close to telomere or centromere). In total, we identified 276 high confident TSG×cancer events in 28 cancer types using ~8000 TCGA samples. The majority of these events showed significant downstream impact in the form of reduced expression of the TSG itself (*cis*-effect), disturbance on the transcriptome (*trans*-effect), or combinatory effects. Surprisingly, we found many TSGs were associated with large numbers of differentially expressed genes, implying a global disturbance to the transcriptome. Importantly, we found that the expression patterns associated with TSG inactivation events exceeded the strong restriction from cancer lineage. For example, inactivation of the same TSG in different cancer types often formed their own clusters rather than different TSGs in the same cancer types, indicating that the same TSG drove similar biological processes in different cancers. In addition to the well-known TSGs, such as *TP53*, *RB1*, *PTEN*, and *CDKN2A*, we also found a group of chromatin modeling genes that were frequently and recurrently inactivated in pan-cancer, such as *ARID1A*, *ARID2*, and *KDM6C*, although their functional impact is yet to be revealed. In summary, our work systematically quantified the landscape of TSG inactivation events and revealed their transcriptional and signaling footprints; the findings complemented with the oncogenesis in cancer.

**Molecular drivers of localized prostate cancer.** K. Kasaian<sup>1</sup>, T. Yamaguchi<sup>1</sup>, H. Zhu<sup>1</sup>, J. Livingstone<sup>1</sup>, C. Jung<sup>2</sup>, P. Georgeson<sup>2</sup>, J. Penington<sup>2</sup>, A. Papenfuss<sup>2</sup>, N. Corcoran<sup>2</sup>, J. Reimand<sup>1</sup>, C. Hovens<sup>2</sup>, P. Boutros<sup>1</sup>, Canadian Prostate Cancer Network, Australian Prostate Cancer Network. 1) Ontario Institute for Cancer Research, Toronto, Canada; 2) Peter MacCallum Cancer Centre, Victorian Comprehensive Cancer Centre, Melbourne, Australia.

A comprehensive whole genome sequence analysis of several hundred prostate cancer tumors and their matched normal tissues were performed, the cohort was representative of all stages and grades of localized disease. We systematically identified all possible alterations of the nuclear genome, including single nucleotide variants, small insertions and deletions, large structural variants and regions of copy number alterations. These were supplemented by an analysis of the mitochondrial genome for recurrent somatic mutations. Small driver mutations were elucidated using a novel algorithm that corrects for the local background mutation rate and considering known functional elements of the genome. Previously unknown driver mutations in regulatory regions of known cancer genes were found. Similarly, recurrent regions of copy number alteration and loss of heterozygosity were examined for their potential role in tumorigenesis. Regions of hypermutation, defined as statistical over-representation of small mutations and double-stranded breaks, were flagged as putative drivers. Hypermutated regions demonstrating a skew in composition of base changes towards cytosine to thymine alterations in the context of TpC dinucleotides were indicative of kataegis; strong association of such regions with the presence of double-stranded breaks were observed suggesting that APOBEC-mediated repair of the DNA breaks can lead to an elevated number of mutations with defined signatures. Copy number alterations, loss of heterozygosity and structural variant calls were superimposed to look for regions of oscillating copy number and possibly zygosity states which also correlate with the presence of structural break points, such regions across chromosome arms or whole chromosomes are evidence of chromothripsis. Recurrent events were found in about 1% of localized prostate tumours. Association of mutational features and putative driver events with clinical data such as age at diagnosis, T category, PSA level, Gleason grades, biochemical recurrence and cribriform or IDC pathology were performed and somatic events indicative of more aggressive forms of disease were identified.

**Implementing the latest clinical variant guidelines through evolution of a cancer variant interpretation interface.** K. Krysiak, AM. Danos, AH. Wagner, JF. McMichael, S. Kiwala, AC. Coffman, NC. Spies, L. Kujan, EK. Barnell, KA. Clark, YY. Feng, BJ. Ainscough, ZL. Skidmore, CA. Ramirez, JA. Neidich, M. Griffith, OL. Griffith. Washington University School of Medicine, Saint Louis, MO.

CIViC (Clinical Interpretations of Variants in Cancer) is a crowd-sourced, open-access knowledgebase for curating the diagnostic, prognostic, predisposing, and therapeutic utility of cancer variants in a structured, computationally-accessible manner. Evaluation of clinical utility requires staying abreast of the standards, regulations, and resources available for the use of genomic data in clinical applications as well as the expanding medical literature. While the literature alone has created an interpretation bottleneck, the complexity and pace of changes to clinical guidelines and standards have increased disparities between guidelines and variant interpretation resources. CIViC tackles this bottleneck through a mixed gatekeeper model, allowing significant crowd-sourced contributions from a wide range of trainees, researchers, and clinicians—all moderated by field experts. This model enables knowledge curation at a pace beyond what a single organization could achieve while reducing time and curation burden on domain experts. CIViC has contributions from >120 users around the world on 346 genes, 1852 variants, and 413 drugs across 226 diseases. These structured data provide coordinate representations for variants described in the literature and seamlessly describe both germline and somatic alterations with precise ontological annotations. Newly implemented *Assertions* are summarized interpretations that incorporate new standards (ACMG and AMP variant interpretations, FDA approvals, and NCCN guidelines), maintain evidence source provenance, enable real-time reassessment, and promote submission to ClinVar. Created with the same principles as other CIViC entities, *Assertions* are structured to be both human-readable and programmatically accessible, in contrast to many important constituent resources (e.g., NCCN guidelines). An *Assertion* can be created for highly specific variants that can be submitted to ClinVar (e.g., EGFR T790M) or more generic variants unsupported by many resources (ALK fusions), maximizing flexibility and guideline incorporation. In collaboration with fellows undergoing molecular genomics training at Washington University, we are improving our data model to support complex variant combinations (genotypes) and developing this system for better clinical workflow integration. The integration of clinical guidelines into *Assertions* as well as a revised data model, user interface design, and workflow supporting these updates will be presented.

**Tumor-only microsatellite instability classification.** C.K. Lau, A. Harley, E. Shinbrot, A. Gylfe, R. Trivedi, T. Lacey. Human Longevity Inc., San Diego, CA., USA.

With recent approvals of immunotherapy drugs for the treatment of mismatch repair deficient colorectal cancer, it has become of outmost clinical importance to determine microsatellite instability (MSI) in tumors. Traditional methods to determine MSI status is by mismatch repair protein immunohistochemistry, as well as PCR and fragment analysis at the standard five NCI-recommended loci. Recently, several computational tools for determining MSI utilizing next-generation sequencing data have been introduced, among them are mSINGS (Salipante, Clin Can Res 2014), MSIsensor (Niu, Bioinformatics 2014), MOSAIC (Hause, Nature Medicine 2016), and MANTIS (Kautto, Oncotarget 2017). However, one limitation that these methods shared is the requirement of paired normal data. There are a variety of common scenarios in which matched normal tissue is not available for sequencing. **METHODS:** Here, we present a new MSI status detection method using tumor-only sequences. Our method was trained and tested using data from public resource – the Cancer Genome Atlas (TCGA). First, we examined the distributions of microsatellites, then we built a cross-validated classifier for MSI detection. **RESULTS AND CONCLUSIONS:** Our tumor-only classifier achieves precision of 0.96, recall of 0.84, and the performance was robust with loci panels of varying size. When trained on tumor and normal data, the precision of our new method is 0.99, and recall of 0.98. Future analysis includes testing the classifier on MSI positive and negative patient tumors sequenced at HLI. The tumor only MSI classifier can be used to generate clinically meaningful results by identifying patients that might benefit from immunotherapy treatment.

**Comprehensive analysis of genomic alterations for lymph node metastasis in gastric adenocarcinoma revealed the critical role of PI3K/AKT/mTOR pathway.** S. Lee<sup>1</sup>, Y. Song<sup>2</sup>. 1) Department of Hospital Pathology, Seoul St Mary's Hospital, The Catholic University of Korea, Seoul, Korea; 2) Department of Pathology, Hanyang University College of Medicine, Seoul, Korea.

**BACKGROUND:** Gastric cancer is the second cause of cancer mortality worldwide and one of the most frequent cancers in Far East Asian and Korean populations. Early diagnosis is crucial to the prognosis of stomach adenocarcinoma (STAD) patients, which constitute > 90% of gastric cancer. However, a large proportion of STAD patients are diagnosed at advanced stage, resulting in a poor survival rate. In STAD, > 50% of patients have lymph node metastases (LNM) at diagnosis. The presence or absence of LNM is one of the most important prognostic factors following curative resection. This study aimed to assess the differences of the gene expression, DNA copy number and methylation profiling between presence and absence of LNM in STAD samples. **METHODS:** The clinical data, gene expression, CNV and DNA methylation data of STAD were retrieved from the Genomic Data Commons Data Portal. A total of 443 STAD samples were enrolled. **RESULTS:** A total of 10153 differentially expressed genes were retrieved from 371 STAD cases, including 110 LNM(-) and 261 LNM(+) samples. Gene Ontology enrichment analysis revealed several significantly over-represented terms, including cancer related biological process such as PTEN signaling, PI3K/AKT signaling and G-protein coupled receptor protein signaling pathway. Kyoto Encyclopedia of Genes and Genomes pathway enrichment analysis showed that the gene sets in PIK3-AKT, RAS, MAPK signaling pathway were over-represented in LNM (+) samples. Through the analysis of mutation annotated files, we highlighted 118 highly recurrent mutated genes which are associated with PTEN signaling. *PIK3CA*, *PREX2*, *KRAS* and *MAGI2* were commonly mutated genes related to PTEN signaling. From somatic copy number profiles, the deleted genes were associated with pathways related to several infectious diseases, complement system including C1 complex and TGF-beta signaling cascades. The pathways enriched with amplified gene sets also showed association with pathways related to infectious diseases and immune system. Genome-wide view from the methylation analysis revealed no difference between the two groups. **CONCLUSION:** In summary, the PI3K/AKT/mTOR pathway is activated in STAD, which is consistent with previous reports. Our results showed that they might be also critical for LNM in STAD, which suggests a direction for further studies.

**Gene regulation and cell-cell communication underlying intra-tumoral heterogeneity in HCC liver cancer.** B. Losic<sup>1,2,3,4</sup>, A. Craig<sup>2,6</sup>, J. Villacortes<sup>7</sup>, J. van Felden<sup>6</sup>, A. Villanueva<sup>2,3,5</sup>. 1) Icahn Institute for Genomics and Multiscale Biology; 2) Department of Genetics and Genomics, Icahn School of Medicine at Mount Sinai; 3) Graduate School of Biomedical Sciences, Icahn School of Medicine at Mount Sinai; 4) Tisch Cancer Institute, Immunology; 5) Tisch Cancer Institute, Liver cancer; 6) Division of Liver Diseases, Department of Medicine, Liver Cancer Program, Mount Sinai School of Medicine; 7) Boston University.

Intra-tumoral heterogeneity (ITH) in HCC liver cancer is strongly implicated in its treatment resistance and relatively dismal prognosis. We recently initiated an ITH pilot study which multi-regionally sampled 14 treatment-naive patients and harvested 79 tumor biopsies, along with matched adjacent normal samples. Twelve patients were analyzed using bulk omics to obtain readouts of HLA allele specific expression, neo-antigen burden from somatic mutations, and TCR profiling using VDJ sequencing. Immune editing was observed in the neo-antigen landscape with subclonal mutations recruiting the dominant TIL response, which suggestively correlated with clinically observed clonal de-differentiation. To further investigate these clonal ecosystem signals and deconvolve impurity and cell-type effect confounders, we examined 38,564 cells from the remaining two patients (7 biopsies) with 10X Chromium sc-RNA-seq. As expected the clonal ecosystem consisted of a complex balance of cancer associated fibroblasts, myeloid derived, endothelial, B and NKT cells, with quantifiable differences between the two patients. Notably, HCC cells clustered in multiple well-known HCC molecular classes in one patient, but only in one class in the other patient. To estimate the gene regulation ultimately responsible for this variability, we computed celltype specific co-expression networks enriched in the binding motif of key transcription factors, and binarized the activity of these networks in each cell. We found that HCC cells had remarkably regionally specific network activity and transcription factor activation, with pluripotency signaling orchestrated by the Yamanaka factor OCT4 dominating in a poorly differentiated region of the variable patient. Surprisingly, we also uncovered strong evidence that cancer-associated fibroblasts had regionally specific transcription factor activation patterns as well, suggesting highly dynamical and intertwined co-evolution between HCC clones and their microenvironment. We extensively confirm this via immunofluorescence, leading to improved, clinically important estimates for the sampling bias of a single biopsy in HCC. .

**HPV-related human cancers exhibit human-viral hybrid extrachromosomal circular DNA-like structures.** *N. Nguyen<sup>1</sup>, J. Pang<sup>1</sup>, G. Xu<sup>1</sup>, V. Deshpande<sup>2</sup>, V. Bafna<sup>1</sup>, J. Califano<sup>1</sup>.* 1) University of California San Diego, La Jolla, CA; 2) Illumina, La Jolla, CA.

The integration of viral sequences into the host genome is a key driver of tumorigenesis in Human Papillomavirus (HPV) mediated cancers, such as head and neck squamous cell carcinoma (HNSC) and cervical cancer. Viral integration is reported to cause genomic amplification and structural variations near the integration site on the human chromosome, though mechanisms for these changes are unclear. A recent study found extrachromosomal circular DNA (ecDNA) in 40% of human cancer cells, but not normal cells, and that key driver oncogenes were typically amplified on ecDNA, providing a new model for oncogenesis (Turner et al., 2017). We propose that HPV-mediated cancers can contain hybrid human-viral ecDNA (HV-ecDNA) that not only allow for amplification of the human and viral oncogenes, but can also result in indiscriminate and unregulated transcription in proximal human genomic regions downstream of the viral regulatory elements. Previous work using The Cancer Genome Atlas cervical cancer (TCGA-CESC) dataset revealed that regions proximal to HPV integration had a 4-fold higher mRNA expression compared to the same regions without proximal integration (Nguyen et al., 2018). We applied computational methods developed in our lab on 68 cervical cancer samples from the TCGA-CESC dataset and 47 patient-derived HNSC samples to examine the prevalence of HV-ecDNA in cervical and HNSC samples, and whether HV-ecDNA had higher mRNA expression than expected. Our work reveals that 29% of TCGA-CESC samples with HPV integration displayed cyclic hybrid human-viral genomic structures, reminiscent of ecDNA. Human regions on these hybrid structures had an average 5-fold genomic amplification, but an average 18-fold higher mRNA expression compared to the same regions not on hybrid structures. The results on the patient-derived HNSC samples showed strong concordance with the TCGA-CESC results. Of the 23 HNSC samples with HPV integration, 26% displayed HV-ecDNA, with the structures having an average 7-fold genomic amplification, and average 15-fold higher mRNA expression relative to the same regions not on the structure, and a 7-fold higher mRNA expression than regions with proximal integrations but not on any hybrid structures. These structures can display complex human-viral chimeric transcripts with novel splicing patterns, high expression of ncRNA and intergenic regions, and may provide new insights in HPV-mediated tumor progression.

**854F**

**Identification of profiles of mutation and CNA predictive of survival in patients with lung adenocarcinoma.** *K.Y. Oróstica<sup>1</sup>, A. Olivera-Nappa<sup>1</sup>, G. Navarro<sup>2</sup>, J.A. Azenjo<sup>1</sup>, R. Armisén<sup>3</sup>.* 1) Department of Chemical Engineering and Biotechnology, University of Chile; 2) Department of Sciences of Computer Science, University of Chile; 3) Research Center of Excellence for Precision Medicine Pfizer.

Lung adenocarcinoma (LUAD) is one of the most frequent subtypes of Non-Small-Cell Lung Carcinoma (NSCLC), reaching up to 40% of all NSCLC. In addition, LUAD is one of the most aggressive subtypes, where the five-year survival is the lowest compared to other cancers. With the arrival of Next Generation Sequencing (NGS) new therapeutic strategies have been developed, based on the study of the genomic alterations present in tumour cells, which could have an important predictive value of the clinical response. Thanks to this approach, targeted therapeutic strategies have been implemented, based on specific driver mutations present in oncogenes, with lower levels of toxicity and more effective than traditional chemotherapy. However, cancer continues to progress due to the resistance acquired by the targeted treatment. Although the molecular classification of LUAD is a great advance for the development of new therapies, more systematic studies are needed for determining how genomic and clinical characteristics are related to the clinical response of patients with cancer. In this work, we propose to identify specific profiles of co-occurrence and mutual exclusion that alter the clinical response to treatment based on Mutational information and Copy Number Alteration (CNA) in patients with LUAD.

**Estimation of Microsatellite Instability (MSI) using Ion Torrent Sequencing technology.** A. Pankov<sup>1</sup>, A. Zheng<sup>1</sup>, S. El-Difrawy<sup>1</sup>, J. Au-Young<sup>1</sup>, A. Kraltcheva<sup>2</sup>, A. Kamat<sup>1</sup>. 1) Thermo Fisher Scientific, South San Francisco, CA; 2) Thermo Fisher Scientific, Carlsbad, CA.

**Introduction** Immunotherapies to treat malignancies have shown great promise, however, only a fraction of cancer patients respond to immunotherapy, making it imperative to identify biomarkers that predict response. The only two FDA- approved companion diagnostics for immunotherapy treatment require assessment of PD-L1 expression by immuno-histochemistry and MSI status by CE or NGS. Microsatellites are tandem repeats of short DNA sequences (1-6 bp), abundant throughout the human genome. The MSI phenotype in tumors is observed as modifications of the length of repeats induced by DNA polymerase slippage and the inability to correct this slippage due to disruptions in the cancer's mismatch repair machinery. In particular, mononucleotide repeats of greater than 12 nucleotides in length and dinucleotide repeats greater than 10 repeats in length are shown to be most-highly associated with MSI phenotypes across various solid tumors types. Hence these long repeats are considered as candidate markers to detect MSI-H phenotype. **Methods** In this study, we identified 80 (71 dicucleotide and 9 mononucleotide) candidate MSI markers from the literature and selected additional 152 repeats from Exome and Tumor Mutation Load research panels. Concurrently, we developed a method to correct the signal errors in flow space and not in base space to allow for accurate length estimation of some dinucleotide repeats. Using a set of 40 CRC MSI-H research samples, we leveraged information theory to identify the recurrently aberrant repeat loci, and create a predictive algorithm. **Results** To show that our selected repeats may be informative of MSI status, we used statistical model to predict a set of useful sites and further demonstrated the informativeness of the markers using capillary electrophoresis on a separate data set. With a set of well-performing markers, we corrected the sequencing signal and developed a method of identifying aberrant mononucleotide markers against a control sample and an information theoretic approach for a tumor-only classifier using the dinucleotide markers. **Conclusions** In summary, we are developing a novel approach to identifying MSI loci and classifying tumor research samples based on the MSI status. This allows us to use Ion Torrent sequencing technology to identify changes in complex repeat regions of the genome.

**Linkage mapping and structural variant analyses using whole genome sequencing (WGS) identify a novel germline deletion in *ETV6* as the cause of acute lymphoblastic leukemia in an Australian pedigree.** E.R Rampersaud<sup>1</sup>, D.Z Ziegler<sup>2</sup>, I.I Iacobucci<sup>3</sup>, D.T Payne-Turner<sup>4</sup>, M.C Churchman<sup>3</sup>, I.M Moore<sup>5</sup>, K.A.S Schrader<sup>6</sup>, K.T Tucker<sup>6</sup>, R.S Sutton<sup>6</sup>, M.W Warby<sup>2</sup>, V.Q Qu<sup>3</sup>, V.L Levantaki<sup>3</sup>, H.B Berns<sup>6</sup>, S.P Pelletier<sup>7</sup>, G.W Wu<sup>1</sup>, C.M Mullighan<sup>3</sup>. 1) Department of Computational Biology, St. Jude Children's Research Hospital; 2) Kids Cancer Centre, Sydney Children's Hospital; 3) Department of Pathology, St. Jude Children's Research Hospital; 4) Department of Medical Genetics, University of British Columbia; 5) Children's Cancer Institute Australia; 6) Transgenic/ Gene Knockout Shared Resource, St. Jude Children's Research Hospital; 7) Department of Immunology, St. Jude Children's Research Hospital.

**Purpose:** Recent studies have highlighted the importance of inherited predisposition to acute lymphoblastic leukemia (ALL), with identification of loss-of-function germline variants in *TP53*, *PAX5*, *IKZF1*, and *ETV6* in familial and sporadic ALL. We combined genome-wide linkage and analysis of germline SNV/indels and structural variants (SVs) of whole genome sequencing data to identify the genetic basis of familial pre-B ALL and lymphoma in a family with 6 affected individuals. **Methods:** Multipoint parametric linkage analysis was performed using Merlin, assuming an autosomal dominant low-penetrance model. SV detection was performed with CREST, based on de novo assembly of soft-clipped reads. WGS and RNA-sequencing were performed on tumor of one patient with ALL and one with lymphoma. The computationally discovered germline deletion was validated by RT-PCR of the patients' RNA. **Results:** No putative causal nucleotide or indel variant was identified. Linkage analysis identified a single 19cM peak on chromosome 12 with LOD score of 1.8. SV detection identified a 75 bp deletion at the intron 6-exon 7 junction of *ETV6*. This was supported by soft-clipped sequence reads and was experimentally confirmed to cause skipping of exon 7 of *ETV6* and protein truncation. We screened 4500 ALL patients for similar deletions, but no additional cases were found suggesting the deletion is rare. The ALL tumor exhibited hyperdiploidy, P2RY8-CRLF2 fusion and *CDH6*, *KRAS*, and *BTBD1* mutations, consistent with prior studies finding enrichment of germline *ETV6* mutations in hyperdiploid ALL. **Conclusions:** We identified a germline deletion which causes exon 7 skipping and protein truncation of *ETV6*. This is the first report of a potentially pathogenic germline SV in *ETV6*, and extends the known importance of *ETV6* germline variants in predisposing to ALL. A mouse model has been created and functional analyses are ongoing. Deletions of this size are usually missed by other coverage depth or discordant read-based SV detection algorithms, and retaining soft-clipped reads in the mapping is critical for this type of discovery. These data highlight the importance of WGS for identification of germline variants predisposing to ALL, particularly in kindred lacking putative causal variants from exome sequencing.

**Personalized drug combination prediction in triple-negative breast cancer using single-cell sequencing.** Z. Safikhani<sup>1,2</sup>, B. Haibe-Kains<sup>1,2</sup>, M. Park<sup>2,4</sup>, H. Kuasne<sup>3,4</sup>, C. Martinez Ramirez<sup>3,4</sup>. 1) Princess Margaret Cancer Research Centre, Toronto, Ontario, Canada; 2) University of Toronto, Department of Medical Biophysics; 3) Rosalind and Morris Goodman Cancer Research Centre; 4) Departments of Biochemistry, Medicine and Oncology McGill University.

**Problem:** Triple-negative breast cancer (TNBC), representing 20% of breast cancer, is an aggressive subtype with no targeted therapies available. The cancer cells that compose TNBC tumours tend to display highly variable features, which likely underlies the resistance to monotherapies. Hence, a shift away from the single-drug paradigm for new therapeutic strategies is becoming increasingly necessary. We address this issue by finding efficient drug combinations targeting multiple clones of tumour simultaneously by analysing single-cell RNA-seq data of the TNBC samples from patient derived xenografts (PDX) model. **Models:** We develop new predictive models of drug response trained with large amount of preclinical pharmacogenomic data from high-throughput screening of immortalized cancer cell lines against single-agent therapies. These models are built upon the gene expression features with minimum redundancy and maximum relevance to the drug sensitivity. We use variational autoencoder to cluster the high dimensional scRNA-seq and to impute the unexpected dropouts due to technical effects in this data. Model learnt from training phase is applied on single cells to predict the most effective monotherapy for each cluster. An optimization approach is used to find drug combinations targeting different clusters with maximum synergistic effects and minimum toxicity. To reduce the complexity of the cost function it is limited to the combinations of only two drugs. **Results:** We trained our prediction model on a pharmacogenomic dataset of 90 breast human immortal cell lines which have been treated with 80 chemical compounds. The model has been applied on the scRNA-seq data of a collection of four thousand cells. One the most promising combinations candidates reported by our pipeline is Sorafenib + Bortezomib which we aim to validate it in vivo to treat PDX models. **Discussion:** With successful validation, our novel therapeutic strategies and companion tests could reduce overtreatment and unnecessary toxicity by selecting the best drug combinations for each individual TNBC patient. .

**858W**

**Identification of genetic variants associated with risk of familial endometrial cancer.** N.J. Shamsani<sup>1</sup>, T.A. O' Mara<sup>1</sup>, S.H. Kazakoff<sup>1</sup>, K. Nones<sup>1</sup>, F. Newell<sup>1</sup>, A.M Reed<sup>2</sup>, J. Harraway<sup>2</sup>, J. Pearson<sup>1</sup>, A-M. Patch<sup>1</sup>, N. Waddell<sup>1</sup>, A.B. Spurdle<sup>1</sup>. 1) QIMR Berghofer Medical Research Institute, Brisbane, Queensland, Australia; 2) UQ Centre for Clinical Research; 3) Sullivan Nicolaides Pathology/Mater Pathology.

Endometrial cancer, a neoplasm of the uterine epithelial lining, is the most commonly diagnosed gynecologic malignancy in developed countries. Approximately 3-5% of endometrial cancer at the population level is caused by inherited pathogenic variants in one of the mismatch repair (MMR) genes, *MLH1*, *MSH2*, *PMS2* or *MSH6*, and this proportion is increased in cases reporting a family history of endometrial or other cancers. However, many suspected familial endometrial cancer patients do not exhibit tumour MMR deficiency. Inheritance of rare high-penetrance germline variants in other genes is a possible explanation for the underlying genetic cause of some of these familial cases. Whole exome or whole genome sequencing of 35 familial endometrial cancer cases with an MMR proficient tumor profile was performed to explore the possible genetic cause of disease in these patients. A sophisticated pipeline was developed to implement international-grade variant classification guidelines. This included development and validation of MES-SWA and MES-NCSS, two plugins for The Ensembl Variant Effect Predictor (VEP) that use MaxEntScan scores to assist the prediction of variants that cause aberrant splicing through splice site loss or gain. A combination of frequency and bioinformatic filters were used to identify potentially pathogenic variants in 32 known or suspected endometrial cancer predisposition genes. Candidate variants were validated by Sanger sequencing. Three pathogenic/likely pathogenic variants (*ATM* c.7638\_7646del, *MUTYH* c.494A>G, *PALB2* c.3116del) and two variants of uncertain significance (*BRIP1* c.1207C>T, *NBN* c.511A>G) were identified. One potentially spliceogenic variant in *RINT1* c.2067+6T>A was classified as likely benign based on other evidence in the public domain. We have undertaken whole genome sequencing of tumor DNA from the germline *MUTYH* variant carrier, to support *MUTYH* as a probable endometrial cancer predisposing gene. The sequencing of the tumor sample revealed a high proportion of C>A somatic mutations in a pattern which most resembles the COSMIC mutation signature 18, a signature similar to signature 36 that has been associated with *MUTYH* mutations in colorectal cancer and pancreatic neuroendocrine tumors. In conclusion, we have highlighted three known cancer genes (*ATM*, *MUTYH*, and *PALB2*) as relevant for further research studies of familial endometrial cancer.

**A minigene platform to validate novel immunogenic peptides arising from somatic mutations as therapeutic cancer vaccines.** X. Shi, V. Kode, K. Lee, A. Chaudhuri, P. Chakroborty. MedGenome Inc, Foster City, CA.

Cancer vaccines have shown promise in treating late stage cancers (with failed traditional therapies). Somatic mutations provide a rich source of potential cancer vaccines with minimal T cell tolerance. We have built a robust screening assay to test somatic mutations for CD8<sup>+</sup> T cell activation in a T cell – dendritic cell co-culture assay with synthetic peptides added from outside. We have screened more than 125 peptides by this assay and identified cancer vaccines candidates from a large number of somatic mutations. However, our screening assay also revealed that non-mutated wild-type peptides in many instances induced T cell activation, although their HLA binding affinity was weak. We suspect that addition of high concentration of the peptides from outside may overcome their weak HLA-binding property allowing them to bind HLA and activate T cells. To reduce the bias of artificial HLA presentation, we have built a minigene platform to screen pairs of wild-type and mutant peptides to assess their immunogenicity. Predicted mutant immunogenic peptides and their wild-type counterparts were cloned as minigenes and expressed in HLA-restricted antigen presenting cells (APCs). The minigene expressing APCs were co-cultured with allogenic CD8<sup>+</sup> T cells and activation was monitored by the combined expression of IFN-gamma, TNF-alpha and granzyme-A (CTL phenotype of T cells) by flow cytometry. Our screening assay reveals that a significant number of indels are not presented when they are expressed as a longer peptide may be because of the reduced stability of the transcripts. However, their presentation and immunogenicity are preserved when they are expressed as short 9-mer peptides with engineered proteasomal cleavage sites. Our study also identified a range of HLA-binding affinities that correlate with presentation of the peptide on the surface of antigen presenting cells. In conclusion, our analysis demonstrates that the two approaches for investigating immunogenicity of peptides – minigene approach and external addition of peptide approach - have differential utilities for testing and validating the immunogenicity of indels and SNVs. .

**Allelic imbalance profiling of premalignant lesions of the lung.** S. Sivakumar<sup>1,2</sup>, F.A. San Lucas<sup>1</sup>, T.L. McDowell<sup>3</sup>, Y. Jakubek<sup>1</sup>, W. Lang<sup>3</sup>, L. Xu<sup>3</sup>, J. Fujimoto<sup>3</sup>, J. Fukuoka<sup>4</sup>, Y. Yatabe<sup>5</sup>, J. Fowler<sup>6</sup>, G. Davies<sup>6</sup>, E. Ehli<sup>6</sup>, I.I. Wistuba<sup>3</sup>, H. Kadara<sup>1,7</sup>, P. Scheet<sup>1,2,3</sup>. 1) Epidemiology, MD Anderson Cancer Center, Houston, TX; 2) MD Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences, Houston, TX; 3) Translational Molecular Pathology, MD Anderson Cancer Center, Houston, TX; 4) Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan; 5) Department of Pathology and Molecular Diagnostics, Aichi Cancer Center, Nagoya, Japan; 6) Avera Institute for Human Genetics, Sioux Falls, SD; 7) Department of Biochemistry and Molecular Genetics, The American University of Beirut, Beirut, Lebanon.

Lung adenocarcinoma (LUAD) is the largest histological subtype of lung cancer and continues to increase in prevalence in both smokers and non-smokers. Early detection and better understanding of its multi-step progression will be crucial for developing effective prevention measures to thereby reduce the mortality from lung cancer. This can be addressed by investigating atypical adenomatous hyperplasia (AAH), the only known precursor lesion to LUAD. Yet, premalignant genomic studies are challenging, largely due to difficulties in acquiring and assessing aberrations in samples of low cellular fraction samples, features typical of these lesions. Here, we explore chromosomal instability, by virtue of acquired megabase-scale chromosomal aberrations leading to allelic imbalance (AI), in matched AAH, LUAD and normal lung parenchyma samples from 16 stage-I LUAD patients (n=48). We applied hapLOH, a sensitive haplotype-based AI detector, to identify large copy number alterations (e.g., gain, loss) as well as copy-neutral loss of heterozygosity across the genome. Overall, AAHs exhibited significantly lower AI burden than LUADs, with lifetime smokers carrying a higher AI burden than non-smokers. Loss of 17p was the most recurrent event in AAHs of our cohort (6/16) followed by other recurrent events including 1q, 8p, 13q, 16q, 18q, 19p and 19q in three or more cases. Phylogenetic analysis revealed eight cases that showed evidence for shared AI events between matched AAH and LUADs, of which, four cases showed similar overall AI burdens between the tissues. These shared AI events included loss of 17p, 13q, 19p, 19q and 9q, thus providing evidence for their role as truncal events in the pathogenesis of AAH and subsequent transformation to LUAD. Further, by integrating our findings with somatic single nucleotide variants cataloged in these samples, we identified three cases that exhibited a first shared (AAH and LUAD) AI hit, accompanied by a LUAD-specific mutation hit in known LUAD drivers such as KRAS, TP53, NOTCH1, STK11 and KEAP1. Our novel results suggest an early role for large chromosomal aberrations (e.g., 17p loss) as well as acquired secondary hits (e.g., smaller mutations) in the pathogenesis of these premalignant lesions. Further, the similar burden and presence of large truncal events in matched AAH and LUADs might be suggestive of a field of cancerization effect aiding in the clonal selection or expansion of these premalignant lesions.

**861W****Leveraging unique molecular indices to detect chimeric gene fusions.**

B. Vilhjalmsson<sup>1</sup>, F. Lescai<sup>1</sup>, T. Rask<sup>1</sup>, Z. Etches<sup>1</sup>, V. Gregersen<sup>1</sup>, R. Madsen<sup>1</sup>, S. Tian<sup>2</sup>, D. Kamaev<sup>1</sup>, M. Johansen<sup>1</sup>, L. Husted<sup>1</sup>, J. Caffrey<sup>2</sup>, A.-M. Hein<sup>1</sup>, E. Lader<sup>2</sup>, L. Schausser<sup>1</sup>, M. Simonsen<sup>1</sup>. 1) QIAGEN Aarhus, Aarhus, Denmark; 2) QIAGEN Sciences Inc., Frederick, Md, USA.

Fusion genes are driver mutations in several diseases, particularly cancer. Because they produce chimeric proteins, fusion genes are useful biomarkers for diagnosis, prognosis and treatment of in numerous types of neoplasia. Detection of certain fusion genes in a cancer patient therefore becomes an important task in bioinformatics analyses. For this reason, there are many fusion gene detection methods available. However, most of them are not compatible with reads tagged with Unique Molecular Indices (UMIs), and thus unable to make use of their advantages for estimating expression levels and detecting variants (Xu *et al.*, BMC Genomics 2017). To address this, we developed a novel fusion detection method that leverages UMIs to identify gene fusions. We developed a workflow for analysing datasets obtained with the QIAsSeq Targeted RNAscan panels. The method first identifies fusion candidates by re-mapping unaligned ends of reads that map partially to one gene to all gene models of the genome, taking broken paired-end read information into account. In addition, the method considers exon boundaries, fusion redundancy, and other features when aggregating the evidence for the candidate fusion(s). It then re-maps all of the reads to a transcript reference database that includes the identified candidate fusions using the QIAGEN CLC RNA-seq aligner. The method along with user-friendly analysis workflow is implemented in the QIAsSeq Targeted Panel plugin v. 1.1 or higher, which is available in the CLC Biomedical Genomics Workbench. We benchmarked the workflow by applying it to 7 test datasets, and demonstrate that the method is able to detect gene fusions with high accuracy.

**862T****Analysis of next-generation sequencing data on African American hereditary prostate cancer cases identifies CNVs in multiple genes.**

K. Wood Termine<sup>1</sup>, T. Mamidi<sup>1</sup>, M. Baddoo<sup>2</sup>, M. DeRycke<sup>3</sup>, S. Riska<sup>3</sup>, S. McDonnell<sup>4</sup>, D. Schaid<sup>5</sup>, S. Thibodeau<sup>6</sup>, J. Carpten<sup>4</sup>, C. Cropp<sup>5,6</sup>, D. Mandal<sup>1</sup>. 1) Department of Genetics, LSU Health Sciences Center, New Orleans, LA; 2) Tulane Cancer Center, New Orleans, LA; 3) Mayo Clinic, Rochester, MN; 4) Keck School of Medicine of the University of Southern California, Los Angeles, CA; 5) Integrated Cancer Genomics Division, Translational Genomics Research Institute, Phoenix, AZ; 6) Department of Pharmaceutical, Social and Administrative Sciences, McWhorter School of Pharmacy, Samford University, Birmingham, AL.

Prostate cancer (PCa) is the second leading cause of cancer-specific deaths among American men, and there is a significant racial disparity between African American (AA) and Caucasian (CAU) affected men, with AA men having a 60% higher incidence rate than their CAU counterparts. Due to limited genomic data on AA men with PCa, no ancestry specific genetic variants have been detected to date. Copy number variations (CNVs) have been documented in PCa tumors, but changes in CNV have not been studied in germline DNA from hereditary PCa (HPC) cases, which accounts for approximately 15% of PCa cases. The African American Hereditary Prostate Cancer (AAHPC) Study, established in 1997, enrolled 77 AA families from seven clinical sites across the United States (Ann Epidemiol, 2000). The goal of the present study is to identify germline CNVs in whole exome sequencing (WES) data on cases from the AAHPC cohort (early onset and  $\geq 4$  PCa affected/family). We hypothesize that rare germline CNVs in actionable genes contribute to higher incidence of PCa in HPC families with African ancestry. We have analyzed WES data on 14 AAHPC cases from 11 families included in the International Consortium for Prostate Cancer Genetics sequencing study. The CNV calling algorithms CANOES (Nucleic Acids Research, 2014) and XHMM (AJHG, 2012) were used to detect germline CNVs by modeling read counts using a precise distribution and the Hidden Markov Model, and CNVs were visualized using Integrative Genomics Viewer (IGV). CANOES and XHMM called 313 germline CNVs, 127 of which were IGV-confirmed; 33 CNVs were located within 25 cancer-related genes and 12 were specifically within six PCa-related genes. CANOES called germline CNVs in eight cancer-related genes, including two PCa-related genes *DEC1* and *MTUS1*. XHMM called germline CNVs in 12 cancer-related genes, including four PCa-related genes *CHEK2*, *AGR3*, *UGT2B17* and *FAM115C*. Both programs called CNVs in the five cancer-related genes *BTNL8*, *DMBT1*, *RHD*, *CTSB* and *GSTT1*. WES analysis on additional affected family members and other AAHPC families is ongoing. In conclusion, we identified germline CNVs from AAHPC WES data using CNV calling algorithms. The results from this study are consistent with somatic findings, suggesting that the germlines of AAHPC and other AA patients may hold valuable information necessary for discovering clinical biomarkers for PCa, which will allow us to facilitate early diagnosis and disease prevention in AAHPC families.

**863F**

**Fast deconvolution tool for separating subtype specific signals from mixed tumor genomic data.** L. Yang, H. Zhu, JS. Marron. University of North Carolina at Chapel Hill, Chapel Hill, NC.

With the advance of deep sequencing techniques, the heterogeneity within a tumor tissue, referred as intra-tumor heterogeneity, becomes a prevalent confounding factor to tumor genomic studies. Analysis on genomic profilings from heterogeneous tumor samples can potentially lead to false positive differential expression conclusions, and even influence patients' clinical outcomes and therapeutic responses. To address the intra-tumor heterogeneity issue, we develop a Fast Tumor Deconvolution (FasTD) tool to separate the pure tumor signals from tumor-nontumor mixtures in an efficient way. Assuming a linear combination of the abundance of the mixing components and availability of some reference information for the non-tumor part, our semi-parametric regression-based model can quickly provide estimates for the tumor proportion in a mixture, as well as output the tumor specific genomic profile. We demonstrate FasTD is a competitive tumor deconvolution tool for both simulated data and The Cancer Genome Atlas RNA-seq datasets, with no requirement for pre-selected signature genes.

**864W**

**Comprehensive transcriptomic analysis of cell lines as models of primary tumor samples across 22 tumor types.** K. Yu<sup>1,2</sup>, B. Chen<sup>1,3</sup>, D. Aran<sup>1</sup>, T. Goldstein<sup>1</sup>, M. Sirota<sup>1,2</sup>. 1) Institute for Computational Health Sciences, University of California, San Francisco, CA; 2) Department of Pediatrics, University of California, San Francisco, CA; 3) Department of Pediatrics and Human Development, Department of Pharmacology and Toxicology, Michigan State University, Grand Rapids, MI.

Cancer cell lines are commonly used as models for cancer biology. While they are limited in their ability to capture complex interactions between tumors and their surrounding environment, they are a cornerstone of cancer research and many important findings have been discovered utilizing cell line models. Not all cell lines are appropriate models of primary tumors, however, which may contribute to the difficulty in translating *in vitro* findings to patients. Previous studies have leveraged public datasets to evaluate cell lines as models of primary tumors, but they have been limited in scope to specific tumor types. We present here a comprehensive pan-cancer analysis utilizing nearly 10,000 transcriptomic profiles from The Cancer Genome Atlas and the Cell Line Encyclopedia to evaluate cell lines as models of primary tumors across 22 different tumor types. The correlations between cell lines and primary tumor samples varied widely across the 22 tumor types and we identify tumor types that may benefit from the generation of additional cell line models. Additionally, we found that cell-cycle pathways are consistently upregulated in cell lines, while immune related pathways are consistently upregulated in primary tumor samples across all the tumor types. In a case study, we compared colorectal cancer cell lines with primary tumor samples across the colorectal subtypes and identified two colorectal cell lines that were derived from a different cell type than the primary tumor samples. Lastly, we propose a new set of cell lines panel, the TCGA-110, which contains the most representative cell lines from 22 different tumor types as a more comprehensive and informative alternative to the NCI-60 panel. Our analysis of the other tumor types are available in our web app as a valuable resource to the cancer research community, and we hope it will allow researchers to select more appropriate cell line models and increase the translatability of *in vitro* findings.

**865T**

**Pan-cancer biomarker identification: Survival distinctions based on transcriptome-wide RNAseq expression.** S. Zaman<sup>1</sup>, B.I. Chobrutskiy<sup>1</sup>, D.T. Segarra<sup>1</sup>, G. Blanck<sup>1,2</sup>. 1) University of South Florida Morsani College of Medicine, Tampa, FL; 2) Immunology Program, H. Lee Moffitt Cancer Center and Research Institute, Tampa, Florida.

Biomarkers are disease characteristics that represent an outcome associated with a specific disease. Currently, there are few cancer biomarkers that are used in clinical practice. As such, we aim to identify RNA expression levels as biomarkers for disease-specific cancer outcomes, i.e., overall and disease-free patient survival, using available RNAseq and survival data from The Cancer Genome Atlas (TCGA) databases for 28 different cancers (n = 11,049). We used a bioinformatics approach to assess the association of the expression of every gene in the tumor transcriptomes with survival rates. The original algorithm developed for this study first organized the transcriptomes based on differential RNAseq expression data and then matched significant differences in the RNAseq data to survival data for Kaplan-Meier survival analyses. Results indicated that the expression of several genes associated with greater than 15 years survival difference, when comparing the top and bottom quintile of expressers. As an example, we detected an association of greater than 15 years of survival difference with different expression levels of the following genes, for Lower Grade Glioma: *NFE2L3* (p < 0.0001), *ZDHHC22* (p < 0.0001), and *EIF3L* (p < 0.0001). Moreover, our results indicate several genes with greater than 15 years difference in recurrence rate when comparing the top quintile of expressers of a specific gene and the bottom quintile of expressers for that same gene for several cancers. Again using Lower Grade Glioma as an example, for disease-free survival: *TGIF1* (p < 0.0001), *IGF2BP3* (p < 0.0001), and *CRY2* (p < 0.0001). Together, these results indicate that differential gene expression patterns have drastic effects on patient survival and cancer recurrence. Moreover, these results provide a resource for identifying candidate genes whose expression provides profound survival distinctions that may be worth further investigation as biomarkers for improved patient outcomes.

**866F**

**Comprehensive characterization of alternative polyadenylation in human cancer.** Z. Zhang<sup>1</sup>, Y. Xiang<sup>1</sup>, G.B. Mills<sup>2</sup>, L. Han<sup>1</sup>. 1) Department of Biochemistry and Molecular Biology, McGovern Medical School at The University of Texas Health Science Center at Houston, Houston, TX; 2) Department of Systems Biology, The University of Texas MD Anderson Cancer Center, Houston, TX.

Alternative polyadenylation (APA) is emerging as a major post-transcriptional mechanism for gene regulation, and dysregulation of APA contributes to several human diseases. However, the functional consequences of APA in human cancer are not fully understood. Particularly, there is no large-scale analysis in cancer cell lines. Our study characterized the global APA profiles of 6398 patient samples across 17 cancer types from The Cancer Genome Atlas and 739 cancer cell lines from the Cancer Cell Line Encyclopedia. We built a linear regression model to explore the correlation between APA factors and APA events across different cancer types. We used Spearman correlation to assess the effects of APA events on drug sensitivity and the Wilcoxon rank-sum test or Cox proportional hazards model to identify clinically relevant APA events. We revealed a striking global 3'UTR shortening in cancer cell lines compared with tumor samples. Our analysis further suggested PABPN1 as the master regulator in regulating APA profile across different cancer types. Furthermore, we showed that APA events could affect drug sensitivity, especially of drugs targeting chromatin modifiers. Finally, we identified 1971 clinically relevant APA events, as well as alterations of APA in clinically actionable genes, suggesting that analysis of the complexity of APA profiles could have clinical utility. Our study highlights important roles for APA in human cancer, including reshaping cellular pathways and regulating specific gene expression, exemplifying the complex interplay between APA and other biological processes and yielding new insights into the action mechanism of cancer drugs. .

**867W**

**Model-based analysis of positive selection significantly expands the list of cancer driver genes.** S. Zhao, M. Stephens, X. He. University of Chicago, Chicago, IL.

Identifying driver genes is a central problem in cancer biology and has received great attentions from researchers. However, existing methods for detecting driver genes from somatic mutation data struggle to distinguish positive selection signals from highly heterogeneous background mutational processes. Here, we present a powerful statistical approach, driverMAPS (Model-based Analysis of Positive Selection) for driver gene identification. The key feature of driverMAPS is its modeling of mutation rates at the base-level, reflecting both background mutational processes and positive selection. Its selection model captures elevated mutation rates in functionally important sites using multiple external annotations, as well as spatial clustering of mutations. Its background mutation model accounts for both known covariates and local, gene-specific, variation caused by unknown factors. Applying driverMAPS to TCGA data across 20 tumor types identified 159 new potential driver genes. Cross-referencing this list with data from external sources strongly supports these findings.

**868T**

**Deep learning for extrachromosomal DNA detection in metaphase images.** U.C. Rajkumar<sup>1</sup>, K. Turner<sup>2</sup>, J. Ko<sup>2</sup>, W. Zhang<sup>2</sup>, M. Chandraker<sup>1</sup>, P. Mischel<sup>2</sup>, V. Bafna<sup>1</sup>. 1) Department of Computer Science and Engineering, University of California at San Diego; 2) Ludwig Institute for Cancer Research, University of California at San Diego.

Recent studies have shown that extrachromosomal DNA (ecDNA) - circular DNA molecules - occur in ~40% of all human cancers but rarely in normal samples (Turner, Nature 2017). The ecDNA replicate and segregate independently and explain many complex rearrangements of focal amplifications. Moreover, they are enriched in oncogenes, and show tremendous cell-to-cell heterogeneity, suggesting a proliferative and evolutionary mechanism for the cancer cell via modulation of ecDNA counts, as well as a possible marker for cancer progression. As sequence based methods cannot easily distinguish between extra- and intra-chromosomal events, automated cytogenetic analysis of ecDNA containing cells presents an important challenge. We developed a method, ecDetect2, for the automated segmentation of DAPI stained cell metaphase images into nuclei, chromosomes, and ecDNA elements. ecDetect2 is based on U-nets, a variation of fully convolutional networks for semantic segmentation. Specifically, it contains 4 modules: the first 3 use U-nets for binary segmentation of nuclei, chromosomes, and ecDNA, respectively. The final module uses a supervised learning approach to combine the outputs of the deep learning modules to produce a multi-class segmentation and statistically quantify the results in cytogenetic terms. Post segmentation, ecDetect2 computes statistics on cell to cell ecDNA counts. To train ecDetect2, we started with 483 manually annotated metaphase images (1392x1040 pixels<sup>2</sup>) and cropped them into 256X256 sub-images. This final training and cross-validation data-set consisted of 5949 images with chromosomes, 6063 with nuclei, and 587 with ecDNA. To the best of our knowledge, this dataset, which will be continually augmented, is the first of its kind containing ecDNA elements. ecDetect2 was tested on a separate dataset containing 180 images of dimensions 256X256. It achieved an Intersection over Union (IoU) score of 70.1% for ecDNA. In cytogenetic terms, it predicted 489 ecDNA, containing 462 (94% precision) manually marked ecDNAs, and missing only 14 (96% recall). An earlier version, ecDetect (Turner, 2017), based on classical computer vision methods, achieved 36% recall and 97% precision. A majority of the false positives observed for ecDetect2 were due to spurs from intact nuclei that one could mitigate by fine-tuning the nuclei prediction on additional data.

**Automated classification of *BRCA1* and *BRCA2* variants shows near perfect concordance with ENIGMA expert panel assessments.** J.L. Poitras, D. Richards, H. Su, T. Love, R. Yip. QIAGEN Bioinformatics, Redwood City, CA.

As the compendium of putatively disease causing variants expands, gathering the most current and accurate information is critical to computing variant classifications. Manual curation is laborious, time consuming, and error prone, as information critical to variant interpretation may be missed. The QIAGEN knowledgebase includes the most extensively curated database of variant specific publications, as well as data from third party sources such as ClinVar, HGMD, CentoMD, and OMIM. This knowledgebase functions as the cornerstone of our clinical decision support tool, QIAGEN Clinical Insight (QCI), facilitating rapid variant filtering and prioritization, automated ACMG classification, and reporting. Here, we compare the concordance of QCI's variant classification with the ENIGMA expert panel assessments of *BRCA1* and *BRCA2* variants. As of December 2017, ClinVar contained 6154 expert reviewed *BRCA1* and *BRCA2* variants. These variants were exported, and the resulting VCF was uploaded to QCI. QIAGEN curated content within the tool was used to automatically compute ACMG variant classifications and provide underlying evidence. QCI computed classifications were compared with ENIGMA assessments, and demonstrated an extremely high rate of concordance, with 81.2% of classifications perfectly matching ENIGMA's assessments. Moreover, the majority of differences observed would not affect clinical management, occurring either within Pathogenic/Likely Pathogenic or Benign/Likely Benign (11.1%) or Benign/Likely Benign vs VUS (7.2%), bringing the degree of concordance at the level of clinical actionability to 99.6%. Only 3 variants were significantly discordant (Benign/Likely Benign by ENIGMA vs. Likely Pathogenic by QCI). These included synonymous variants with functional data supporting splicing defects not considered by ENIGMA. In summary, with respect to clinical actionability, QCI automated ACMG classification was 99.6% concordant with ENIGMA expert panel variant assessments. This level of accuracy speaks to the quality of the clinical, functional, and population level data in the knowledgebase, as well as the robustness of the underlying algorithm used to apply the ACMG guidelines.

**Integrating DeepVariant into a clinical bioinformatics pipeline.** L. Hon<sup>1</sup>, J. Van den Akker<sup>1</sup>, Z. Mahkovec<sup>1</sup>, G. Mishne<sup>1</sup>, A. Ondov<sup>1</sup>, L. Dorfman<sup>2</sup>, P.-C. Chang<sup>2</sup>, R. Poplin<sup>2</sup>, M. DePristo<sup>2</sup>, J. Ginsberg<sup>1</sup>. 1) Color Genomics, Inc., Burlingame, CA; 2) Google, Inc., Mountain View, CA.

**BACKGROUND:** Bioinformatics pipelines are an integral component in clinical genetic testing based on next-generation sequencing. To maximize sensitivity, add redundancy, and increase system robustness in a clinical setting, ensemble approaches to variant calling can be utilized. Here, we describe a workflow to evaluate the added value of additional callers of Single Nucleotide Variants (SNVs) and insertion/deletions (indels, <50 bp), which was applied to assess DeepVariant. **METHODOLOGY:** To bolster the performance for difficult-to-call variants and regions, Color has previously incorporated multiple variant callers. Given the strong performance of Google's variant caller DeepVariant [1], we wanted to assess the utility of DeepVariant (v0.6) to strengthen variant detection capabilities. We first evaluated sensitivity and specificity using several well-characterized NIST cell lines. However, NIST datasets for comparison are typically limited to high confidence genomic regions where multiple workflows converged to a single consensus call [2]. The core of our evaluation therefore focused on the ability to detect variants that are considered difficult to call. These variants were selected from publicly available cell lines, synthetic DNA, and clinical specimens for which our current set of callers had trouble identifying the correct variant. Thus, this set was strongly enriched for clinically relevant variants in regions of low/high GC content, variants in the vicinity of homopolymers (e.g. *MSH2*, c.942+3A>T), and long/complex indels (e.g. *ATM*, c.7849\_7857delGTCAGAAGTinsAGGTCTCCTTTGAGTGCCTCA). **RESULTS:** DeepVariant performed well in a number of areas such as GC-rich regions, including calling the pathogenic variant *MEN1* c.206\_207insGCCCC in Coriell cell line NA11630. We detected a small number of novel variant calls over our existing pipeline, which suggests a limited impact on our downstream workload. Based on this positive assessment, DeepVariant has been added to our clinical bioinformatics pipeline. Additional analyses are currently underway to more broadly assess the performance of DeepVariant. **CONCLUSION:** To ensure high sensitivity, it is critical to include callers optimized for different types of variants. Here we show that DeepVariant can be used to provide redundancy in variant detection and potentially increase sensitivity, especially in regions of low/high GC content. [1] Poplin et al. Biorxiv 2018 [2] Krusche et al. Biorxiv 2018.

**A study of the new sentieon and edico genomics sequence data processing methods.** *J.M. Bell<sup>1</sup>, S.M. Grimes<sup>1</sup>, H.P. Ji<sup>2</sup>.* 1) Stanford Genome Technology Center, Palo Alto, CA; 2) Division of Oncology, Department of Medicine, Stanford University School of Medicine, Stanford, CA,.

Since the beginning of high-throughput genomics, there has been an exponential increase in the amount of data produced by sequencing. One of the largest challenges has been to produce bioinformatics tools that can keep pace with this increase while performing accurate analysis. We studied the speed and accuracy of two new tools, the Sentieon suite available from Sentieon, and the DRAGEN system available from Edico, compared to the current standard, GATK and MuTect2. The Sentieon program instantiates the GATK algorithms, while the DRAGEN device uses a field-programmable gate array (FPGA) chip to accelerate processing. In order to test these analysis methods, we compared a variety of metrics from an established control genome (NA12878) as well as a series of archival clinical samples that were preserved with formalin-fixation and paraffin-embedding (FFPE), investigating both the relative speed of the analysis methods and the concordance of results. Because DRAGEN also has a copy number variant (CNV) analysis module, we used the standard program CNVkit to generate comparison CNV calls. Sentieon uses a version of GATK recoded in C; it is generally about 20x faster than GATK itself. We have found that germline fresh-frozen analysis of NA12878 is several times faster with DRAGEN than with Sentieon. The rate of analysis can be higher with larger inputs, perhaps owing to lower overhead. Conversely, there is a non-linear loss of speed as FFPE data inputs grow larger. As sequenced FFPE samples produce noisier data than do fresh-frozen samples, we hypothesize that the DRAGEN system is disproportionately affected by the increase in noise as depth increases and is thus slowed. The DRAGEN system includes an integrated variant caller. Results have a high concordance with MuTect2, and certain edge cases filtered by DRAGEN but not by MuTect2 are likely to be false positive calls in MuTect2. In analyzing FFPE data, however, DRAGEN allows a large number of calls that are characteristic of deamination changes (C/G->T/A) but that are filtered out by MuTect2. Edico's CNV caller shows significant overlap with the CNVkit caller but also a number of significant differences that could affect assessment of a tumor sample. In summary, both Sentieon and Edico's analysis methods show significant speed increases over GATK, while the relative quality of analysis varies depending on the characteristics of the input.

**High-state-count negative binomial hidden Markov model improves detection of copy number variation in cell-free DNA for cancer detection and response prediction.** *E.S. Gafni, A.D. Adam M. Drake, K.N. Niehaus, Y.L. Liu, I.H. Haque, J.J. John.* Freenome, San Francisco, CA.

Many cancers harbor large scale copy number variants (CNVs) which can be detected by changes in genome-wide read coverage in sequencing data. Additionally, some tumors release detectable amounts of DNA into the blood as circulating cell free DNA (cfDNA), in which case sequencing of total cfDNA provides information on a mixture of tumor and normal genome composition. However, plasma tumor fraction (the fraction of cfDNA derived from the tumor) is a critical parameter for the ability to detect these CNVs, as apparent changes in read coverage become smaller and more difficult to distinguish from noise as tumor fraction declines. Current cfDNA CNV detection methods [1] have limited sensitivity to these events particularly when tumor fraction is low (<8%). Improvements in the ability to detect CNVs at low tumor fraction may be valuable to assist in the detection of cancer or to monitor its response to treatment. Here we propose a method which uses a negative binomial regression against a panel of normal samples as well as a Hidden Markov Model (HMM) with an optimized implementation of the Viterbi algorithm with a highly discretized state space (>500 states). The negative binomial regression against a panel of normals allows us to correct for technical batch effects assuming consistency in sample processing. The large HMM state space allows us to avoid the complexities of jointly estimating tumor fraction and CNV tumor clonality, where there may not be a single unique solution. We utilize expectation maximization in order to jointly correct for batch effects as well as infer the negative binomial dispersion parameter of each region of the genome. We validate the performance of the method in both simulation and real-world plasma cfDNA data, demonstrating robustness to CNV region size, CNV amplification/deletion level, tumor fraction, and technical artifacts such as GC bias. At genome-wide coverage of 10-15x, we are able to achieve sensitivity to mean shifts of less than 1%, allowing superior detection of CNVs at low tumor fraction and for small relative copy number change, which have utility for the early detection of cancer and response prediction for immune checkpoint therapy, respectively. [1] Adalsteinsson VA et al., Nature Communications 2017

**DEFOR: Depth and frequency based somatic copy number alternation detector.** *H. Zhang<sup>1</sup>, X. Zhan<sup>1</sup>, J. Brugarolas<sup>2</sup>, Y. Xie<sup>1,2</sup>.* 1) Department of Clinical Sciences, University of Texas Southwestern Medical Center, Dallas, Texas 75390; 2) Department of Internal Medicine and Kidney Cancer Program, Simmons Comprehensive Cancer Center, University of Texas Southwestern Medical Center, Dallas, Texas 75390.

Somatic copy number alteration (SCNA) is the change in copy number that has arisen in somatic cells. SCNAs were observed frequently in tumors and recurrent SCNAs were also identified in several types of tumors. SCNA profiling plays an important role to study the mechanism of tumor and guide the therapeutics. In recent years, SCNA detection using high-throughput sequencing is becoming popular that was because of quickly sequencing technology development. Although several bioinformatics methods have been developed for SCNA detection using exome-sequencing data, these methods rely a strong assumption that the median or mean value of the copy numbers of the genome is two (normal status). That assumption was usually used to give an estimation of the depth or depth ratio that represents the normal status. That assumption usually holds for germline copy number variations, because most parts of the genome don't have copy number changes. However, that assumption may not hold in tumor cells where large scale copy number alterations were observed frequently. In such situation, the mean or median value of copy numbers across the genome may be not two, and so the copy number estimated based on that assumption may be unreliable any more. Therefore, the existing methods may not perform well to call SCNAs for the unstable tumor genomes. Samples from tumor tissue are usually contaminated with normal cells from nearby tissue, and the purity of different tumor samples varies obviously. Because the purity of tumor sample affects the observed copy number, it adds another layer of variations in SCNA detection of tumor samples. We developed a new method DEFOR to detect SCNAs in tumor samples from exome-sequencing data. DEFOR supports the estimation of copy numbers in six different statuses: 1) normal status, 2) loss of both alleles, 3) loss of one allele, 4) loss of one allele and followed by the amplification of the remained allele, 5) gain of one allele and 6) gain of both alleles. Allele frequency, depth and purity of tumor samples were considered in the model. Based on the evaluation using real dataset, DEFOR has a good accuracy to detect SCNAs from tumor samples and outperformed other methods especially for unstable tumor cells in which SCNAs occurred in a large proportion of the genome.

**The transcriptome as a diagnostic aid: a pan cancer method for identifying the site of origin of complex metastases.** *J.K. Grewal<sup>1</sup>, S. Gakkhar<sup>1</sup>, Y. Ma<sup>1</sup>, Y.J. Zhao<sup>1</sup>, A. Mungall<sup>1</sup>, R. Moore<sup>1</sup>, H. Lim<sup>2</sup>, D. Renouf<sup>2</sup>, K. Gelmon<sup>2</sup>, S. Yip<sup>3</sup>, J. Laskin<sup>2</sup>, M. Marra<sup>1</sup>, S.J.M. Jones<sup>1</sup>.* 1) Michael Smith Genome Sciences Centre, Vancouver, British Columbia, Canada; 2) Department of Medical Oncology, BC Cancer, Vancouver, British Columbia, Canada; 3) Pathology and Laboratory Medicine, University of British Columbia, Vancouver, British Columbia, Canada.

Next Generation Sequencing (NGS) data can provide biological insights into cancer biology, and also potentially be used to minimize time costs associated with patient work-up and management. However, there is a lack of demonstration of their utility in traditionally manual analytical tasks, particularly for cancer diagnostics. Traditional diagnostics in cancer require pathologist input, and cancer diagnosis is important for providing biological context to genomic analysis findings. Several pilot precision oncology projects are scaling up and need to be able to process large amounts of NGS data quickly and efficiently. The concomitant scale-up in the throughput for diagnostic assessments is a challenging manual task. An automated diagnostic method that utilizes solely NGS data can serve as a powerful orthogonal diagnostic aid to pathologists in such scenarios, or when traditional pathology is inconclusive. We investigated the utility of high throughput RNA-sequencing as a fast and automated approach for cancer diagnostics. We trained an ensemble of neural networks to distinguish 40 primary cancer types and 26 adjacent normal tissues. By adapting previously published weight analysis approaches for neural networks, we identified cancer-specific features that were important in classification. The classifier has high precision and recall for primary cancers and subtypes with mixed histology. Cross-calling patterns reflect known biological similarities within certain gastrointestinal cancers and within cancers with shared cell type of origin. Furthermore, we demonstrate the utility of this method in resolving diagnoses for treatment resistant metastatic cancers and cancers of unknown origin. A subset of these re-diagnoses have been validated by follow-up immunohistochemistry. Lastly, within this body of work we propose solutions to common computational challenges arising with using categorically imbalanced biological datasets. Our method uses the whole transcriptome as input, and is not confounded by tumour content. Its immediate application is as an orthogonal diagnostic in cases where the site of origin of a cancer is unknown, or when standard pathology assessment is inconclusive.

**Regulatory mechanisms of chronic lymphocytic leukemia (CLL) risk variants in mediating target gene expression.** *H. Yan, S. Tian, G. Kleinstern, S. Slager.* Division of Biomedical Statistics and Informatics, Department of Health Sciences Research, Mayo Clinic, Rochester, MN 55905, USA.

The disease-associated single-nucleotide polymorphisms (SNPs) identified by genome-wide association studies (GWASs) mostly reside in noncoding regions of the genome. It has been established that many of these noncoding variants have regulatory roles in mediating target gene expression, often involving the alterations of local chromatin accessibility, histone modifications, transcription factor (TF) binding affinity, and promoter-enhancer interactions. In CLL, we and others have identified 41 GWAS risk variants for which the mechanism of causality remains largely unknown. Herein, we evaluated whether these SNPs affect transcriptional program in CLL. We focused on the epigenetic data for marks mapping to the gene regulatory regions using B cells and/or lymphoblastoid cell lines. Data included ChIP-seq data for three histone modifications (H3K4me3, H3K4me1, H3K27ac) and 73 TFs, as well as chromatin accessibility data generated by ATAC-seq, DNase-seq, and FAIRE-seq. We also used histone modification ChIP-seq and DNase-seq data generated by the Roadmap Epigenomics Project in primary human tissues and cells. Comparing the 41 index SNPs and over 4,000 SNPs in linkage disequilibrium ( $R^2 \geq 0.5$  in the EUR ethnic group in 1000 Genomes Project) with these index SNP to the above epigenetic data revealed their enrichment in regulatory regions, particularly in the enhancer regions, with strong evidence for the allele imbalance and alteration of TF binding motifs. We identified the potential target genes for the casual SNPs using GTEx eQTL data and public Hi-C, capture Hi-C and ChIA-PET data in lymphoblastoid cell lines and/or primary blood cell types. Many of the target genes, such as *BCL2L11*, *ID3* and *IRF2*, showed expression changes in CLL and are known to be involved in hematologic malignancies including CLL. Together, our analysis highlights the role of epigenetic mechanisms in CLL pathogenesis.

**Ranking on cis-eQTL selected transcription factors produces focused and accurate predictions.** *B.P. Kellman<sup>1</sup>, N.E. Lewis<sup>2,3</sup>.*

1) Bioinformatics and Systems Biology, University of California, San Diego, San Diego, CA; 2) Department of Pediatrics, University of California, San Diego, San Diego, CA; 3) Department of Bioengineering, University of California, San Diego, San Diego, CA.

The bioinformatic toolbox is large and growing yet actionable transcription factor (TF) predictions remain an open challenge. Tools such as oPossum, PASTAA use frequently occurring sequence motifs to deduce active promoter regions. These tools produce essential predictions but can be overwhelmed by the presence of similar DNA in epigenetically masked regions. The lack of context specificity can result in a large number of false positive predictions and ultimately limiting the utility of the prediction overall. Recent work in TF prediction using cis-eQTL analysis in GTEx to identify tissue-specific active regions of the promoter. DNA motifs in those active promoter regions were queried in CIS-BP to obtain TFs associated with tissue-specific active promoter sequences (Sonawane,2017). We developed an approach to rank the predicted TFs based on the frequency with which it appears in a background of random gene lists. The probability that a TF is a valid regulator is calculated along a simple cumulative distribution relative to the random gene lists background. We have found this approach to be successful in recovering known regulators of the lysosomal pathway, cholesterol metabolism, and canonical cancer-related pathways. We hope that our ranking these empirically informed TF predictions can sufficiently mitigate the false positive rate of these methods thereby making these tools more useful to the broader bioinformatic and biological community. An implementation of our TF ranking method is available in R (<https://github.com/bkellman/teQTLparse>).

**A reference database of transcription factor cascades in the human genome (TFCascades.info): Implications in cancer biology.** S. Piyawitwanich<sup>1</sup>, G. Ventyana<sup>1</sup>, M. Sudarshan<sup>1</sup>, O.K. Mathew<sup>2</sup>, S.K. Belman<sup>3</sup>, K.W. Johnson<sup>4</sup>, R. Hodos<sup>4</sup>, B.S. Glicksberg<sup>4</sup>, R. Bhattacharya<sup>5</sup>, J. Helico<sup>3</sup>, P. Mukherjee<sup>6</sup>, J.T. Dudley<sup>4</sup>, L. Subramanian<sup>1</sup>, K. Shameer<sup>6</sup>. 1) Courant Institute of Mathematical Sciences, New York University, New York, NY, USA; 2) B3, JKR, Aluva, Kerala, India; 3) Center for Research Informatics and Innovation, Northwell Health, New Hyde Park, NY, USA; 4) Institute for Next Generation Healthcare, Mount Sinai Health System, New York, NY, USA; 5) University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA; 6) Department of Information Services, Northwell Health, New Hyde Park, NY, USA.

Transcription, a central biochemical control system that optimizes gene expression, is mediated by transcription factors (TFs). TFs perform their gene regulatory function singularly or in a cascade mode. Many transcription factors activate not only a gene but also other transcription factors, creating cascades. TFs are primary drug targets of different anti-cancer therapies. Several TF cascades with two or three transcription factors (for example: IRF8-KLF4) have been reported with functional evidence for implications in human diseases. To date, there is no molecular class-specific reference dataset on TF cascades in humans. We built a reference dataset using a predictive framework that combines human TFs compiled using biocuration coupled with protein-protein interaction (177,016 pairs and 8,627 distinct proteins) and biochemical activity data aggregated from STRING database. We identified a total of 37,879 transcriptional cascades with maximum depth of 16 TFs and compiled the data in a centralized reference resource ([www.tfcascades.info](http://www.tfcascades.info)). We also explored The Cancer Genome Atlas data on ovarian cancer ( $n=316$ ) and pancreatic cancer ( $n=258$ ) to assess the impact of transcription cascade on various oncophenotypes including tumor grade, treatment response, relapse rate, survival, and metastasis using graph analysis with a connected component algorithm. By analyzing TF cascade-target aberrations and correlations with oncophenotypes as a computable graph, we built a TFCascade-Oncophenome map, which can be used as a predictive framework to find novel regulatory modules, drug targets, and molecular interventions that could improve the outcomes for cancer patients. Pan-cancer analyses of cascades would help to understand novel transcriptional regulatory cascade networks driving human cancers. Assessment of the regulatory network properties of such systems across various types of cancers and human disease would help to build computable models of disease severity.

**Contrasting whole genome and whole exome sequencing as competing modalities for obtaining perpetual genomic data.** B.G. Kermani. Crystal Genetics, Inc., Los Altos, CA.

From its inception, next-generation sequencing (NGS) has brought the promise of rendering perpetual genomic data (PGD) –where the sequencing is done once, and is utilized *ad infinitum*, serving different applications. While germline applications are often viewed as the main use of PGD, somatic applications are valid subjects as well. In cancer, somatic mutations can be traced longitudinally for monitoring patients, e.g., to evaluate their response to drugs and other treatments. By definition, whole genome sequencing (WGS) can produce perpetual data. As WGS has not yet become economical, whole exome sequencing (WES) has been a major contender in producing PGD. In this work, we show that while WES has found successful applications in many areas, it lacks certain properties to make it fully suitable for producing PGD, particularly for health-related applications. We will show that beyond the obvious concerns on WES, i.e., limited targeted regions, and despite higher coverage, it could be subject to higher false positive and false negative rates, as compared to WGS. Although some of these concerns are partially addressed by extending the exomes to include some non-exonic bases, the economy of exome sequencing still forces many of the available solutions to cover only a limited set of bases, as compared to all possible bases of interest, for a multi-application scheme. In this study, a set of anonymized tumor-normal patient samples is used to contrast the quality of the variant calls in WGS and WES modalities, for the same patients. The study suggests that the quality difference between these two modalities is non-trivial, for both germline and somatic applications. Also, it is shown that, in many cases, even popular variant callers are not able to recover from the quality degradations associated with WES. It is also shown that a hybrid *de novo* genome analysis pipeline coupled with an *in silico* verification (ISV) tool can provide significant resilience to these data quality challenges. In summary, we propose that only WGS, in tandem with a high-quality genome analysis pipeline and verification, can provide a sustainable model for addressing multiple applications, in both germline and somatic domains. In a PGD scheme using WGS, however, the analysis pipeline and verification module play major roles. Without proper analysis and verification, the outcomes may not be of sufficient quality to cover a wide range of applications, especially those related to health.

**879W**

**High-resolution mapping of cancer cell networks by co-functional gene detection.** *E.A. Boyle<sup>1</sup>, W.J. Greenleaf<sup>1</sup>, J.K. Pritchard<sup>1,2,3</sup>*. 1) Genetics Dept, Stanford University, Stanford, CA; 2) Biology Dept, Stanford University, Stanford, CA; 3) Howard Hughes Medical Institute.

Genome-wide CRISPR screens have rapidly accelerated the unbiased and high-throughput investigation of diverse biological systems. Recently, multiple groups have demonstrated mapping of genetic interactions by screening genetic knockouts across several cell line backgrounds in parallel and detecting correlated gene essentiality profiles. Here, we adapt this approach to a broader set of >300 copy-number corrected whole genome CRISPR screens published by the Project Achilles group. We learn a cell line signature of nonspecific sgRNA toxicity and with it eliminate a source of confounding that foils similar correlation-based methods. Our corrected gene profiles confirm known signaling pathways that include cancer drug targets and suggest that the sensitivity of a cell line to a gene knockout is prognostic for cancer drug activity in a surprisingly large number of cases: on average 500 genes per drug. Amongst these profiles, we report than 1 million correlated genes genome-wide that we deem “functional neighbors”. Functional neighbors broadly reflect shared properties of cell networks such as cellular compartment, biological pathway, and protein complex with a granularity that exceeds traditional gene sets. Beyond protein function, we leverage the diversity of the cell line panel to conclusively show that cell type and mutational status illuminate cell signaling paradigms that would be inaccessible with smaller panels of cell lines. Lastly, we employ a gene community detection approach to implicate core genes for cancer growth and summarize functionally redundant signal in whole-genome CRISPR screens. By integrating information from multiple cancer databases, we observe that genes known to be important for cancer frequently associate closely together in the cell network and that topology and function are inextricably linked. This work establishes new algorithms for probing cancer cell networks and motivates the acquisition of further CRISPR screen data across diverse genotypes and cell types to further resolve the complexity of cell signaling processes.

**Establishment of reference samples for the detection of somatic variants in cancer.** *L.T. Fang<sup>1</sup>, W. Xiao<sup>2</sup>*. 1) Bioinformatics Research & Early Development, Roche Sequencing Solutions, Belmont, CA; 2) FDA/NCTR, Jefferson, AR.

The FDA is well aware of next generation sequencing (NGS)'s crucial role in precision medicine. However, development and evaluation of oncology NGS applications is challenging due to the lack of community-validated cancer reference samples. To address this challenge, over 180+ scientists from 60+ institutions have come together to form the Somatic Mutation Working Group of the SEQC2 consortium. We present here a gold set against which new tools and platforms can be benchmarked. We selected a pair of tumor-normal cell lines as the initial reference samples: a triple-negative breast cancer cell line HCC1395 and its B lymphocyte derived normal HCC1395BL. We have sequenced the genome on multiple short-read and long-read sequencing platforms at multiple institutions, and have established high-confidence call sets of germline variants and somatic mutations. In total, we have performed whole genome sequencing (WGS) for each of the genomes to combined coverage depths of 1700X from 12 replicates on Illumina HiSeq, 700X from 9 replicates on Illumina NovaSeq, 600X from 11 replicates on 10X Genomics, and 50X on PacBio. Germline and somatic SNVs/INDELs were obtained primarily based on the 12 Illumina HiSeq and 9 NovaSeq data sets. We used the SomaticSeq framework with six mutation callers and three aligners on each of the 21 WGS replicates to obtain the first release of somatic mutation gold set. The confidence-level of each somatic mutation call was obtained based on cross-institution and cross-aligner reproducibility of each call. There are about 37,000 somatic SNVs and 1,500 somatic INDELs with variant allele frequencies (VAF) ranging from 2.5% to 100% in the gold set. In addition, we also report likely false positives that have been misclassified by certain algorithm(s) in certain sequencing replicate(s). We used four germline callers to obtain the high-confidence germline variants. High-confidence regions were defined based on the limitation of current technologies. Genomic coordinates in high-confidence regions but not specified in the gold set are assumed to be non-variant. We will continuously accept input from the community to advance accuracy and completeness of our reference samples in order to serve as a community standard well into the future.

\* Joint last authors Prostate Cancer (PrCa) is the fourth most common type of cancer worldwide, and the most commonly diagnosed cancer in men in the UK. Few heritable factors predictive of aggressive prostate cancer have been identified to date. Although common variants identified to date explain over a quarter of the familial relative risk of PrCa, GWAS subset analysis of aggressive disease has failed to find loci specifically associated only with the aggressive phenotype. The aim of this study was to find coding germline variants that associate with clinical outcome of PrCa. We sequenced 226 whole genomes from blood DNA from UK samples at a target depth of 30x. We used a GATK pipeline to identify germline mutations. After sample and variant QC, 188 samples were included in the downstream analysis, and 6,532 likely deleterious coding variants were identified. Pathway analysis was applied to all 50 Hallmark pathways from GSEA MSigDB and an additional three gene sets: a curated DNA Repair Gene panel of 175 genes from our previous work, the BROCA extended panel of 66 genes, and a panel of 115 genes comprising candidate PrCa genes we have curated for a study of treatment of DNA repair gene mutation carriers. We used 2 different methods to assess impact of gene sets on poor prognosis using relapse as outcome: (a) multivariate Cox model, with covariates for Gleason, PSA at tumour collection and pathological T score; (b) and a regularized (Lasso) multivariate Cox model, with the same covariates. Both models showed that alterations in the angiogenesis pathway are significantly associated with poorer prognosis ( $p = 0.015$ , no multiple testing correction applied). For angiogenesis, only 3/36 genes (*CXCL6*, *JAG2* and *POSTN*) had likely deleterious mutations, and the Cox model with Lasso penalisation indicated that *CXCL6* is the gene with highest impact (hazard ratio = 2.73). This study is part of an international effort called the Pan Prostate Cancer Group (PPCG), which aims to analyse whole genome sequences from >2000 PrCas, with matched transcriptome and methylome data. PPCG is the largest worldwide single cancer organisation with such datasets, and builds upon the CRUK-UK International Cancer Genome Consortium (ICGC) Prostate Cancer Project. We will use further samples from other PPCG cohorts to validate our results. .

**Enhanced breast cancer risk prediction from imputed gene expression enhanced breast cancer risk prediction from imputed gene expression.** J. Zhou<sup>1</sup>, G.P. McVicker<sup>2</sup>, H.L. Carter<sup>1</sup>. 1) University of California San Diego, San Diego, CA; 2) Salk Institute for Biological Studies.

Early detection for breast cancer is significantly associated with long-term patient survival. Although most individual variants identified in breast cancer contribute weakly to breast cancer risk, they can be combined into genetic risk scores (GRS) to significantly improve risk prediction for some cancer types. An existing method for calculating GRSs uses germline genome-wide significant single nucleotide variants (SNVs); however, this approach is limited to modeling individual contributions of highly statistically significant risk SNVs, which have small effect sizes and account for only a small fraction of heritable disease risk. Furthermore, it is difficult to determine the underlying biological mechanisms by which these SNVs drive breast cancer susceptibility. In this project, we aim to model how genetic variants contribute to disease risk by determining how an individual's SNVs affect gene expression within relevant cell types and then associating these changes with cancer risk. To do this, we performed a transcriptome-wide association study (TWAS) to identify expression-trait associations from a breast cancer GWAS meta-analysis using FUSION (Gusev et al. 2016). Using this approach, we recovered a set of 47 transcriptome-wide significant genes for further study. In conjunction with this analysis, we are training linear models on reference panels of individuals with genotype and expression data in breast-cancer specific tissues to model the functional weights of genes, which can then be used to predict expression in individuals for which expression data is not available. We will map the TWAS results to biological networks and perform network analyses, such as random walk with restart and Google PageRank, to recover core network modules associated with breast cancer risk. Because SNVs often affect disease susceptibility via perturbed gene expression, these modules will be used to develop functionally-accurate GRS with improved predictive power for breast cancer.

**883T****Gene prioritization using HiChIP and eQTL in prostate cancer. C.**

*Giambartolomei<sup>1</sup>, J. Seo<sup>2</sup>, X. Qui<sup>2</sup>, M.K. Freund<sup>1</sup>, N. Mancuso<sup>1</sup>, A. Gusev<sup>2</sup>, M. Freedman<sup>2</sup>, B. Pasaniuc<sup>1</sup>.* 1) UCLA, Los Angeles, CA; 2) Dana-Farber Cancer Institute, Boston, MA.

Genome-wide association studies (GWAS) have led to the identification of >100 prostate cancer risk loci explaining ~33% of familial risk, which usually reside in intergenic enhancers or other noncoding DNA features. While typically risk SNPs are annotated to the nearest gene, these SNPs are likely to influence expression of target genes located kilobases away, in a cell-type and time specific manner. The integration of expression quantitative trait loci (eQTLs) in normal and tumor tissues with GWAS of prostate cancer has proven to be a useful strategy to prioritize genes beyond the nearest gene in the linear genome, and formal statistical approaches have been developed to integrate GWAS and eQTLs (e.g. coloc, TWAS). However, these approaches are still limited in identifying the correct causal genes, with multiple genes normally identified within a region because of statistical correlations between genetic variants. Recently, HiChIP, an efficient novel protein-mediated chromatin-conformation assay, has been used to generate contact maps of active enhancers-to-target genes. Due to the role of enhancer-promoter interactions in the regulation of gene expression, interaction data can be used together with GWAS and eQTL to prioritize target genes for prostate cancer. Herein, we analyzed H3K27ac and K4me3 HiChIP on prostate carcinoma cell lines LNCaP. Using 81,318 case and 61,074 control individuals genotyped on the Oncoarray, we find 247 enhancer-promoter loops that overlap a GWAS signal (95% credible set). We observe that GWAS from prostate cancer are enriched (~66%) within the HiChIP interactions, and that the heritability increases with number of loops anchored at each peak. We further integrate these results with eQTL data from Cancer Genome Atlas (TCGA) to explore the credible SNP-contact genes. We prioritized genes using HiChIP results together with eQTLs and GWAS, and identify genes supported by physical interactions between regulatory elements and their target genes. We demonstrate the advantage of leveraging HiChIP data to facilitate the identification of target genes at GWAS loci.

**Combining enhancer DNA methylation and RNA-seq to map gene regulatory network changes that drive chemotherapy resistance in recurrent ovarian cancer.** *N. Gull<sup>1</sup>, M. Jones<sup>1</sup>, S. Coetzee<sup>1</sup>, A. Reyes<sup>1</sup>, J. Plummer<sup>1</sup>, B. Davis<sup>1</sup>, S. Chen<sup>1</sup>, J.P. Govindavarri<sup>2</sup>, J. Rutgers<sup>2</sup>, J. Lester<sup>3</sup>, K. Lawrenson<sup>1,3</sup>, D. Hazelett<sup>1</sup>, B. Karlan<sup>3</sup>, S. Gayther<sup>1,4</sup>, B.P. Berman<sup>1,4</sup>.* 1) Center for Bioinformatics and Functional Genomics, Department of Biomedical Science, Cedars-Sinai Medical Center, Los Angeles, CA, 90048; 2) Dept of Pathology and Laboratory Medicine, Cedars-Sinai Medical Center, Los Angeles, CA, 90048; 3) Women's Cancer Program, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA, 90048; 4) Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles, CA.

Epithelial ovarian cancer (EOC) is the most lethal and predominant pathologic subtype of ovarian cancer, usually diagnosed in the late stage of disease, leading to a strong decrease in 5-year survival rate as disease severity worsens. The most common subtype of EOC is high grade serous ovarian cancer (HGSOC). There has been little improvement in patient survival or treatment for HGSOC in recent decades, despite surgical resection and chemotherapy over 70% of patients will experience disease relapse, and eventually chemotherapy resistance will progress to fatal disease. Previous studies of methylation in HGSOC primary tumors using microarrays show variations in methylation patterns that differ between chemo-resistant and chemo-responsive patients, such as *FZD10* and *MKX*. Additionally, *BRCA1* promoter hypermethylation (sometimes reported in germline or tumor from patients who do not carry a germline BRCA mutation) was linked to a reduction in patient survival and was observed in patients with recurrent tumors. Other alterations in methylation patterns of oncogenes (*PIK3CA*), tumor suppressor genes (*WT1*), and driver genes (*TP53*) have also been observed in EOC; these alterations indicate key changes in gene regulatory networks (GRNs) and could affect tumor biology. In order to identify changes in the methylome of chemotherapy resistant HGSOC tumors, we have generated a genomic landscape of the changes that occur as a result of chemoresistance in each available tumor (n=73) with whole genome sequencing, whole genome bisulfite sequencing (WGBS), and RNA-seq. Our WGBS data represents the first whole methylome analysis of HGSOC patients to date. These data will allow us to apply methods that we have pioneered to infer GRN changes by combining WGBS and transcriptome data to identify master regulator transcription factors and their downstream target genes that are disrupted as a result of chemotherapy in HGSOC. We have identified several alterations in methylation in chemo-resistant HGSOC tumors; regions of the genome where hyper and hypo-methylated regulatory regions perturb the expression of genes from cell division and DNA repair pathways. Our combinatorial approach has provided a genome-wide *cis*-regulatory epigenetic landscape in ovarian cancer as it acquires and maintains chemoresistance, and identifies potential novel therapeutic targets.

**Effects of structural variation on proximal lncrnas and mrnas in b-cell leukemia.** C. Nodzak<sup>1</sup>, V. Vasconcelos<sup>2</sup>, J.A. Yunes<sup>2</sup>, X. Shi<sup>1</sup>. 1) Dept. of Bioinformatics and Genomics, University of North Carolina at Charlotte, Charlotte, NC; 2) Laboratorio de Biologia Molecular, Centro Infantil Boldrini, Campinas, Sao Paulo, Brazil.

Throughout cellular development the local three-dimensional structure of the genome facilitates coordinated regulation of gene expression. These conserved and cell-type specific organizational and architectural elements of the genome have been denoted topologically associated domains (TADs), and may encompass noncoding and coding genes relegating them to shared nuclear space allowing for possible interactions to occur. Antisense long noncoding RNA (lncRNA) transcripts have been shown to facilitate some aspects of chromatin remodeling at coding gene loci through R-loop formation and binding of proteins capable of modulating the epigenetic state along gene and promoter regions. In addition, lncRNAs may act as microRNA sponges or form complexes with proteins, or directly bind mRNA molecules, which can contribute to changes in the amount of available mRNA. B-cell acute lymphoblastic leukemia has been characterized by a collection of recurrent genomic rearrangements that disrupt the relationship between proximal lncRNAs and mRNAs, and may create non-cognate enhancer mediated gene expression events that contribute to irregular expression of these genes. In this study, we show that the expression levels of lncRNAs and protein coding genes located within cell type specific intrachromosomal topologically associated domains (TADs) from GM12878 are able to accurately classify B-cell acute lymphoblastic leukemia patients by the major recurrent chromosomal rearrangement using published data from St. Jude's and the TARGET initiative. These findings suggest that we are able to capture some regulatory relationships between gene pairs overlooked by simple differential expression, which is of particular significance for discernment between Ph-chromosome(+) and Ph-like samples that share global transcriptome patterns yet lack common genomic rearrangements. We further interrogate the effects of structural variants located nearby TAD boundaries to establish links between structural variation, chromatin topology, lncRNA and gene expression variation among different subtypes of leukemia based on recurrent rearrangements.

**Analysis of the HSF1 transcription program using clustering frameworks to predict clinical cancer endophenotypes.** L. Bang<sup>1</sup>, T. Prince<sup>2</sup>, D. Kim<sup>1,3</sup>. 1) Biomedical and Translational Informatics Institute, Geisinger Health System, Danville, PA; 2) Department of Urology, Geisinger Health System, Danville, PA; 3) The Huck Institutes of the Life Sciences, The Pennsylvania State University, University Park, PA.

Heat shock factor 1 (*HSF1*) is a master transcription factor that regulates the cellular stress response along with enabling malignant cell growth. The *HSF1* transcription program includes over 2,000 genes as defined by chromatin binding, yet linking patient subgroups based on their expression profiles into clinical outcomes is understudied. A rapid iteration method for clustering gene expression profiles was carried out to predict clinical endophenotypes. In this study, we performed the clustering analysis to identify patient subgroups that are associated with cancer endophenotypes. Over and under-expression profiles of genes within the *HSF1* transcription program were attained from TCGA for 5 tumor types: prostate adenocarcinoma (PRAD), breast invasive carcinoma (BRCA), lung adenocarcinoma (LUAD), lung squamous cell carcinoma (LUSC) and low-grade glioma (LGG). Using k-means and hierarchical clustering techniques, patients with common gene expression patterns within the *HSF1* transcription program were found to also have differential patterns of clinical variables. The k-means algorithm was iterated over multiple hyperparameters, and differential distribution of clinical variables in each cluster measured with a chi-square test and validated by comparing with a permutation test. This method allowed us to identify PRAD patients with likely lower or higher Gleason scores. For BRCA, LUAD and LUSC we were able to predict lower or higher tumor grades, while for LGG we could predict tumor histological type. Using clustering analyses may enable us to gain insight into how *HSF1* and its transcription program drives malignancy and influences cancer endophenotypes.

**Detecting cancer vulnerabilities through gene networks under purifying selection in 4,700 cancer genomes.** A. Gupta<sup>1,2,3</sup>, H. Horn<sup>1,2,3</sup>, P. Razaz<sup>1,2,3</sup>, M. Lawrence<sup>1,2,3</sup>, G. Getz<sup>1,2,3</sup>, K. Lage<sup>1,2,3</sup>. 1) Harvard Medical School, Boston, MA; 2) Broad Institute of Harvard and MIT, Cambridge, MA; 3) Massachusetts General Hospital, Boston, MA.

Large-scale cancer sequencing studies have uncovered dozens of mutations critical to cancer initiation and progression. However, a significant proportion of genes linked to tumor propagation remain hidden, often due to noise in sequencing data confounding low frequency alterations. Further, genes in networks under purifying selection (NPS), or those that have undergone negative selection, may play crucial roles in sustaining cancers but have largely been overlooked. We describe here a statistical framework that identifies genes that have a first order protein interaction network significantly depleted for mutations, to elucidate key genetic contributors to cancers. Not reliant on and thus, unbiased by, the gene of interest's mutation rate, our approach has identified 685 putative genes linked to cancer development. Comparative analysis indicates statistically significant enrichment of NPS genes in previously validated cancer vulnerability gene sets. Specifically, the comparisons yield odds ratios of 5.4 ( $p < 2.9e-5$ ) for copy number alterations (CYCLOPS) and 4.7 ( $p < 2.2e-16$ ) for dependencies as determined by knockdown studies (DEMETER). Ninety-five of the 685 NPS genes are not crucial to cells in the general population (probability of loss-of-function intolerance scores  $< 0.9$  for genes in the Exome Aggregation Consortium), and aggregate knockdown of these genes results in aberrant tumor growth, as determined by the Achilles cancer cell line gene knockout database. We are currently validating the highest priority NPS candidate cancer genes through functional assays. As more tumor genomes are sequenced, integrating systems level mutation data through this network approach should become increasingly useful in pinpointing gene targets for cancer diagnosis and treatment.

**Prognostic model for multiple myeloma progression integrating gene expression and clinical features.** C. Sun<sup>1</sup>, H. Li<sup>1</sup>, R. Mills<sup>1,2</sup>, Y. Guan<sup>1,3</sup>. 1) Department of Computational Medicine and Bioinformatics, University of Michigan, Ann Arbor, MI; 2) Department of Human Genetics, University of Michigan, Ann Arbor, MI; 3) Department of Internal Medicine, University of Michigan, Ann Arbor, MI.

**Multiple Myeloma (MM) is a hematological cancer caused by abnormal accumulation of monoclonal plasma cells in bone marrow. With the increase in treatment options, risk-adapted therapy is becoming more and more important. Survival analysis is commonly applied to study progression or other events of interest and stratify the risk of patients. In this study, we present the current state-of-the-field model for MM prognosis and the molecular biomarker set for stratification: the winning algorithm in prediction accuracy in the 2017 Multiple Myeloma DREAM Challenge. Specifically, we built a non-parametric complete hazard ranking model to convert the right-censored data into a linear space, where commonplace machine learning techniques, such as Gaussian process regression and random forests, can play their roles. The model combined the gene expression profile and clinical features to predict the progression of MM. Compared with conventional models, such as Cox model and Random Survival Forests, our model achieved higher accuracy in 3 within-cohort predictions. In addition, it showed robust predictive power in cross-cohort validations and in the validation cohorts. A set of molecular signatures related to MM progression was extracted from our model, which may function as the core determinants of MM progression and of important guidance value for future research and clinical practice. Functional enrichment analysis and mammalian gene-gene interaction network revealed several key biological processes and pathways involved in MM progression..**

**889T****Characterization of chromosomal allelic imbalances through RNA-seq.**

Z. Ozcan<sup>1,2</sup>, F.A. San Lucas<sup>1</sup>, Y. Liu<sup>1,2</sup>, Z. Weber<sup>2</sup>, E. Ehl<sup>2</sup>, G. Davies<sup>2</sup>, R.G. Fowler<sup>1</sup>, P. Scheet<sup>1,2</sup>. 1) Department of Epidemiology, The University of Texas M.D. Anderson Cancer Center, Houston, TX; 2) The University of Texas M.D. Anderson Cancer Center UTHealth Graduate School of Biomedical Sciences, Houston, TX; 3) Avera Institute for Human Genetics, Sioux Falls, SD.

Transcriptome sequencing (RNA-seq) is becoming a standard aspect of tumor profiling, extending beyond transcript quantification and identification of alternative transcripts and gene fusions. For instance, recent advancements in RNA-seq data analyses, allow for computational assessment of allele-specific gene expression and generate profiles of expressed somatic mutations. Here, we identify chromosomal allelic imbalances (AI) through detection of haplotype-specific patterns in gene transcripts. To do so, we obtained RNA-seq and SNP array or whole-exome sequencing (WES) data for five cancers in the TCGA: uterine carcinosarcoma (UCS), lung (adenocarcinoma and squamous cell carcinoma), prostate and pancreatic. AI calls were made in both the exome and RNA-seq data by: (1) calling 1000 Genome Project variable sites in the sequencing data, (2) phasing haplotypes, and (3) characterizing allelic imbalances in RNA and DNA using hapLOHseq. SNP array-based AI was detected with hapLOH. RNA-seq- and WES-derived AI patterns exhibited equivalent specificity (72%) based on comparisons to AI events inferred from SNP arrays, which we consider here as a gold standard. However, RNA-seq appeared to have lower sensitivity, detecting 43% of the chromosomal AI events identified by WES. Interestingly, we observed AI patterns in RNA that were not evident in paired DNA samples and attempted to relate these features to survival in UCS. We found a suggestive negative association ( $P = 0.076$ ), with higher RNA-specific AI load in UCS patients having a median survival of 771 days compared to 1526 days for those patients with lower loads of RNA-specific AI. Our results suggest that analysis of chromosomal AI in RNA-seq has equal specificity for detecting DNA-level AI when compared to exome sequencing, although at lower sensitivities, and thus may be a useful surrogate for DNA changes in resource-limited settings. Clinically, our analyses suggest that patients with higher RNA-specific AI load may have a worse overall prognosis; we are investigating this further in the data from lung, prostate and pancreatic. The AI we identify in the RNA-seq samples may reflect long-range dysregulation for even copy-neutral, balanced, regions of the genome. One possible cause of RNA-specific AI could be the presence of cis mutations that impact a large-region of the transcription of one of the two haplotypes.

**890F****Alignment and analysis of xenograft transcriptomes.** S. Tapas<sup>1</sup>, S.

Ramachandrupa<sup>2</sup>, H. Kumar Adil<sup>2</sup>, D. Chohan<sup>2</sup>, V. Chakraborty<sup>2</sup>. 1) School of BioHealth Informatics, Indiana University Purdue University, Indianapolis, IN; 2) Strand Life Sciences Private Limited, Kirloskar Business Park, Bengaluru, Karnataka, India.

Studies on Patient-Derived Xenografts (PDX) are of immense value in understanding pharmacological mechanisms. However, one of the major challenges is the involvement of stromal cells along with the tumor cells which are of interest. While the Next-Generation Sequencing (NGS) technology has greatly aided in understanding these mechanisms, normal/stromal contamination remains to be resolved to ensure that the expression profiles truly represent the tumor state. Therefore, aligning read sequences to Human Reference alone may not be accurate. Trimming of read sequences based on host reference genome can lead to the loss of reads that are common to both due to homology. It is now agreed that alignment of read sequences to a master Reference consisting of both Human and host would give the most unbiased expression profile. However, due to the memory requirements of dealing with such a large reference and the associated technical challenges makes this approach unappealing to research biologists. Here, we showcase how this could be accomplished easily in StrandNGS, a desktop software for NGS data analysis. To illustrate this approach, we have used data from GSE102370 submitted by Goyette et al. Expression analysis of GSE58644 (Affymetrix arrays) was performed using GeneSpring GX v14.9 software to understand the gene expression profiles of genes that are known to impact survival. A concatenated reference created using reference genomes of mouse (mm10) and human (hg38) was used to align the RNA-Seq samples from GSE102370 in StrandNGS v3.1.1 software. The respective gene annotations were also concatenated. All the downstream analyses were carried out as discussed by the author. A comparison was made between the expression profiles reported by the authors and those that were derived using the current approach. It was observed that the profiles were different and qualifying gene sets varied.

**SoVaTSiC: Somatic variant tool for single cell.** A. Javed<sup>1,2</sup>, J.H.J. Tan<sup>2</sup>, S.L. Kong<sup>2</sup>, J.A. Tai<sup>2</sup>, H.M. Poh<sup>2</sup>, F. Yao<sup>2</sup>, Y.Y. Sia<sup>2</sup>, E.K.H. Lim<sup>2</sup>, T.W. Tan<sup>3</sup>, A.M.T. Pena<sup>4</sup>, D.S.W. Tan<sup>4</sup>, A.M. Hillmer<sup>1,5</sup>. 1) School of Biomedical Sciences, The University of Hong Kong, Hong Kong, China; 2) Genome Institute of Singapore, A\*STAR, Singapore; 3) Department of Biochemistry, National University of Singapore, Singapore; 4) Department of Medical Oncology, National University of Singapore, Singapore; 5) Institute of Pathology, University Hospital Cologne, Germany.

Single cell omics provides an opportunity to interrogate genetic and phenotypic heterogeneity at an inter-cellular level. A key application is in the cancer domain where this heterogeneity can provide an avenue for the tumor to acquire a path to therapeutic resistance. With growing popularity, there is a demand for computational tools to aid single cell analysis. The focus thus far has primarily been on transcriptomics. In particular there are no tools designed to tease apart somatic mutations in single cell genomics data. We provide SoVaTSiC the first software specifically aimed to address this task. The software bundle includes quality control measures along with practical guidelines to fine tune the tool based on the noise (allelic drop out and false negative rate) observed in the data. Previous results in a lung adenocarcinoma patient, showed high accuracy (86% validation rate, combining true positives and true negatives). They revealed insight into tumor phylogeny by identifying key events in tumor evolution. These inferences are supported by the histological evidence. We have further evaluated the software in a direct comparison with the state of the art single cell variant caller MONOVAR, SoVatSiC outperforms in accuracy versus specificity tradeoff in both in-house as well as public datasets. SoVatSiC somatic mutations are more consistent with the inferred phylogeny of the tumor and include mutations of direct therapeutic relevance missed by MONOVAR (which is primarily intended for germline variants).

**892T**

**Single-cell RNA sequencing analysis of the non-small cell lung cancer cell line after DNA demethylating agent treatment.** J.W. Zeng<sup>1,2</sup>, S.F. Su<sup>1,3</sup>, H. Ho<sup>1</sup>, Y.H. Chen<sup>1</sup>, H.W. Chen<sup>4</sup>, K.C. Li<sup>1,5</sup>. 1) Institute of Statistical Science, Academia Sinica, Taipei, Taiwan, Taipei, Taiwan; 2) Data Science Degree Program, National Taiwan University, Taipei, Taiwan; 3) Graduate Institute of Oncology, National Taiwan University, College of Medicine, Taipei 10051, Taiwan; 4) Graduate Institute of Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan; 5) Department of Statistics, University of California, Los Angeles, USA.

**Motivation:** Lung cancer is the leading cause of cancer death worldwide with non-small cell lung cancer (NSCLC) being its most common form. However, the molecular basis of the substantial response-heterogeneity remains unclear. The CpG island methylator phenotype (CIMP) has been identified in NSCLC. CIMP tumors exhibit distinct genetic features that correlate with clinical outcome, thus highlighting the role of DNA methylation in tumorigenesis. To study the gene expression alteration induced by DNA demethylating agents at the single cell level, we applied the single-cell RNA sequencing (scRNA-Seq) on the treated and mock samples of our previously established NSCLC cell line. **Material and Method:** The NSCLC cell line was prepared for the mock and drug treatment. A DNA demethylating agent was used for consecutive three-day treatment. Both mock and treated samples were trypsinized on day seven, and loaded onto the 10x microfluidics chip for scRNA sequencing. We developed a workflow to analyze the scRNA-Seq data from data preprocessing to cell-cycle analysis. Differential expression (DE) analysis was utilized to find the genes that expressed differently between mock and treated samples. **Result:** 511 mock and 797 treated cells were obtained from 10x Genomics Cell Ranger. We performed cell-cycle analysis to distinguish cells in different phases of the cell cycle: G1/S, S, G2/M, M and M/G1. We found that the number of cell cycle associated genes identified in treated cells was less than cells in the mock sample. Also, for cells in the S phase, we identified a list of significant DE genes associating with tumor suppressors. **Conclusion:** scRNA-Seq is a robust and economically practical tool for studying transcriptome at the single cell level, and it provides a better resolution for the drug's impact on the gene expression. Even though the numbers of cells loaded to scRNA-Seq did not reach the optimal number of cells, our workflow was able to identify the cell-cycle correlated genes exhibiting differential expression between the mock and drug-treated lung cancer cell lines.

**Role of alternative polyadenylation dynamics in acute myeloid leukemia at single-cell resolution.** Q. Zhou<sup>1,2</sup>, C. Ye<sup>1</sup>, Y. Hong<sup>2</sup>, Q.Q. Li<sup>1,2</sup>. 1) Western University of Health Sciences, Pomona, CA; 2) Xiamen University, Xiamen, Fujian 361102, China.

Alternative polyadenylation (APA) has been discovered to play regulatory roles in the development of many cancer cells through preferential addition of a poly(A) tail at specific sites of pre-mRNA. A recent study found that APA was involved in the mediation of acute myeloid leukemia (AML). However, unlike gene expression heterogeneity, little attention has been directed toward variations in single-cell APA for different cell types during AML development. Here, we used single-cell RNA-seq data of a massive population of bone marrow mononuclear cells (BMMCs, ~17k) from healthy and AML patient samples to investigate dynamic APA usage in different cell types. Abnormalities of APA dynamics in the BMMCs from AML samples were uncovered compared to the stable APA dynamics in samples from healthy individuals, as well as lower APA diversity between eight cell types in AML. Genes with APA usage specific to the AML samples were significantly enriched in cellular signal transduction pathways that contribute to AML development. Moreover, many leukemic cell marker genes such as *NF-κB*, *STAT1*, *GATA2* and *P27* exhibited APA dynamics that specifically affected abnormal proliferation and differentiation in BMMCs of AML patients. Additionally, mature erythroid cells displayed greater APA dynamics and global 3' UTR shortening compared with other cell types, and APA diversities along with the erythropoiesis process decreased gradually. Our results revealed extensive involvement of APA regulation in leukemia development and erythropoiesis at the single-cell level, providing a high-resolution atlas to navigate cellular mRNA processing landscapes of differentiated cells in AML.

**894W**

**Genetic heterogeneity profiling by single cell RNA sequencing.** Z. Zhou<sup>1</sup>, N. Zhang<sup>2</sup>. 1) Graduate Group of Genomics and Computational Biology, University of Pennsylvania, Philadelphia, PA; 2) Wharton Statistics Department, University of Pennsylvania, Philadelphia, PA.

Single cell RNA-sequencing (scRNA-seq) technologies have made it possible to study tumor transcriptomes at single-cell resolution, allowing better cell type classification and unprecedented study of intratumor transcriptomic heterogeneity. Yet, the underlining mechanisms for tumor initiation, progression, metastasis and relapse are often driven by genetic heterogeneity, that is, subclonal evolution involving genetically distinct subpopulations of cells. Detection of these genetically distinct subclones and understanding the evolutionary dynamics of the tumor is essential for accurate prognosis and effective treatment. A tumor's genetic heterogeneity underlies its transcriptome heterogeneity, and thus, intra-tumor transcriptomic variation needs to be quantified within the context of intra-tumor clonal variation. There is yet no method that can derive the genetic mutation profile and gene expression level for the *same* cell with acceptable accuracy, high throughput, and low cost. Inference of clonal membership from scRNA-seq data is currently unreliable for all but the most dominant clones. Here we propose a computational framework, DENDRO (DNA based EvolutionNary tree preDiction by scRNA-seq technOlogy), that takes scRNA-seq and matched bulk DNA sequencing data for a tumor and accurately reconstructs its evolutionary phylogeny, assigning each single cell from the scRNA-seq data to a subclone. DENDRO utilizes information from both copy number aberrations and single nucleotide mutations in transcribed region, and is based on a likelihood model that accounts for single-cell level expression stochasticity as well as the technical noise in scRNA-seq. The accuracy of DENDRO is benchmarked on *in silico* mixture and spike-in data sets, and its effectiveness is illustrated through case studies using published scRNA-seq data from multiple cancer types. Finally, we demonstrate an online app, based on DENDRO, to guide researchers in experimental design, e.g. determining the number of cells and coverage per cell, for subclonal inference by scRNA-seq data.

**Next-generation sequencing with comprehensive bioinformatics analysis facilitates somatic mosaic APC gene mutation detection in patients with familial adenomatous polyposis.** *E. Kim<sup>1,2</sup>, B. Kim<sup>2</sup>, S.T. Lee<sup>2</sup>, J.R. Cho<sup>2</sup>.* 1) Brain Korea 21 PLUS Project for Medical Science, Yonsei University; 2) Department of Laboratory Medicine, Yonsei University College of Medicine.

**Background:** It was recently recognized that patients with clinical familial adenomatous polyposis (FAP) but without detectable pathogenic mutations are associated with somatic mosaic APC mutation. **Methods:** We reanalyzed the Next-generation sequencing (NGS) gene panel testing results of such patients and tested several variant calling algorithms to identify low level mosaic variants. Twenty-eight patients with clinical suspicion of FAP but no detectable pathogenic variants of colonic polyposis associated genes were included, and endoscopic biopsy samples of patients were analyzed. Variant calling tools HaplotypeCaller, MuTect2, VarScan2, and Pindel were used. We also used 3'-Modified Oligonucleotides (MEMO)-PCR or conventional PCR for confirmation. **Results:** Among 28 patients, seven somatic mosaic pathogenic variants (five frameshift variants and two nonsense variants) were identified, with variant allele frequency ranging from 0.3 to 7.7%. These variants were mostly detected through MuTect2 and Pindel. The somatic mutations found in leukocytes were enriched in the colonic polyp from 7% to 20% in a patient. The somatic mosaic pathogenic variants were further confirmed using MEMO-PCR or conventional PCR. **Conclusions:** NGS testing with an adequate combination of bioinformatics tools is effective to detect low level somatic variants and deletions in a single assay. Because mosaic APC mutation is more frequent than previously thought, the presence of mosaic mutation must be considered when analyzing genetic tests of patients with FAP.

**Algorithm-driven comparison analysis of liquid biopsy samples.** *X. Xu<sup>1</sup>, D. Stetson<sup>2</sup>, D.L. Gross<sup>1</sup>, J. Hull<sup>1</sup>, M. Kaganovich<sup>1</sup>, J. Johnson<sup>2</sup>, J.C. Barrett<sup>2</sup>, B.A. Dougherty<sup>2</sup>, D.A. Caplan<sup>1</sup>.* 1) SolveBio, New York, NY; 2) Translational Sciences, Oncology, IMED Biotech Unit, AstraZeneca, Boston, MA.

**Background** Liquid biopsy, or the detection of tumor-derived DNA from blood samples, is increasingly used in clinical decision making and translational research. The consistency, accuracy, and detection thresholds of this new technique are not well characterized. Comparison analyses of variant and allele frequency detection from the same patient across sample types, commercially available tests, and patient timepoints are crucial to understanding technical and biological limitations of liquid biopsy and implications for individual patients. Currently, comparison analyses are custom, requiring informatics expertise and error-prone manual analysis. **Methods** We created a set of software modules for liquid biopsy comparison analyses, utilizing the SolveBio platform for indexing, querying, and normalizing genomic data. Twenty four replicate plasma samples were sent to 4 commercial circulating tumor DNA (ctDNA) Next Generation Sequencing (NGS) labs. Matched tumor-normal tissue was sent to one lab. Our novel software enabled programmatic 1) normalization of reported genomic data among multiple commercial test reporting formats and panel sizes, 2) algorithmic removal of confounders such as germline and clonal hematopoiesis variants, 3) merging of the results into an easy-to-query table and 4) visualization of patient-level and study-level results. **Results** Our software and analysis pipeline merged 698 calls from 24 patients with 6 sets of results (4 plasma, 1 tumor, 1 normal) into 465 unique variants, saving dozens of person-hours of manual analysis. Programmatic removal of variants classified as germline or clonal hematopoiesis-related reduced this set to 56 variants. We designed novel plots to visualize this complex data. Beyond the initial use case, these software modules have been used in multiple other tissue-plasma comparison studies. Substantial technical characterization of liquid biopsy techniques, labs, and the genomic output is critical for widespread clinical adoption of this technology. Our software platform allows for the comparison and analysis of ctDNA NGS results. We intend to expand our software to enable the cross-lab comparison of emerging biomarkers of therapeutic response, such as tumor mutational burden and microsatellite instability (MSI) status.

**Strelka2: Fast and accurate germline and somatic variant calling.** S. Kim<sup>1</sup>, K. Scheffler<sup>1</sup>, A.L. Halpern<sup>1</sup>, M.A. Bekritsky<sup>2</sup>, E. Noh<sup>1</sup>, M. Källberg<sup>2</sup>, X. Chen<sup>1</sup>, Y. Kim<sup>1</sup>, D. Beyter<sup>3</sup>, P. Krusche<sup>2</sup>, C.T. Saunders<sup>1</sup>. 1) Illumina, Inc., 5200 Illumina Way, San Diego, CA, USA; 2) Illumina Cambridge Ltd., Chesterford Research Park, Little Chesterford, Essex, UK; 3) Department of Computer Science and Engineering, University of California San Diego, La Jolla, CA, USA.

We present Strelka2 (<https://github.com/Illumina/strelka>), an open-source small variant calling method for clinical germline and somatic sequencing applications. Strelka2 introduces a novel mixture-model based estimation of indel error parameters from each sample, an efficient tiered haplotype modeling strategy and a normal sample contamination model to improve liquid tumor analysis. For both germline and somatic calling, Strelka2 substantially outperforms current leading tools on both variant calling accuracy and compute cost. Strelka2's germline calling performance was measured on data from the recent PrecisionFDA challenges. For the PCR+ and PCR-free data, Strelka2's indel F-score improved upon the best submission by 3.2% and 0.11%, respectively, while giving single nucleotide variant (SNV) results within 0.06% - 0.1% of the best submissions. Strelka2 also greatly outperformed recently released versions of GATK4 and FreeBayes in accuracy while being 7.7 and 3.5 times faster, respectively. We evaluated Strelka2's somatic variant calling accuracy by mixing sequencing data of NA12878 and NA12877 to simulate datasets with varying tumor and normal purities. On these *in silico* mixture data, Strelka2 showed substantially higher precision than MuTect2 and VarDict at all recall thresholds over all test datasets, with an average F-score improvement of 19-25% for SNVs and 16-20% for indels. We note Strelka2's tolerance to normal sample impurity, reflecting updates to better support liquid and late-stage solid tumor analyses. At 80% tumor sample purity, a change in normal sample purity from 100% to 90% generated a drop in F-score for MuTect2 and VarDict, respectively, of 65% and 37% for SNVs and 42% and 33% for indels. For Strelka2, the same change only caused a drop in F-score of 5.6% for SNVs and 18% for indels. As was the case for the germline analysis, Strelka2 somatic analysis was substantially faster than available alternatives, demonstrating an average runtime advantage of 8x over MuTect2 and 3x over VarDict. We reiterate that our results were generated with default method settings appropriate for factory-scale analysis, not requiring human intervention to parameterize or connect complex sequences of tools.

**Measuring the effect of genetic variation at splicing junctions using a cellular fluorescence reporter system.** L. Wan, N. Torres, C. Yeh, C. Maclean. Ranomics, Toronto, Ontario, Canada.

Sequencing technologies have facilitated comprehensive cataloguing of disease-associated single nucleotide polymorphisms (SNPs) at intron-exon junctions. However, determining the impact of these variants on alternative splicing or protein function continues to be a significant bottleneck. Minigene assays are the current gold standard for measuring splicing efficiency, but they are tedious to implement due to RNA isolation steps, and offer a qualitative assessment of splicing. To overcome the shortcomings of the minigene assay, we have developed a simple, fluorescence-based reporter to quantify splicing efficiency of an intron-exon junction of interest in human cells. Splicing efficiency can be measured quantitatively and on a per-cell basis by fluorescence microscopy or through cell sorting. Our splicing reporter includes an intrinsic fluorescence control for reporter intake or integration efficiency, and is designed to be flexible and scalable. We have performed pilot experiments with variants of *BRCA1* intron-exon junctions at which pathogenic mutations have been observed that are known to disrupt splicing to demonstrate the clinical and biological relevance of our reporter system.

**899F****Beyond the exome: Identification of novel mutational signatures and oncogenic dependencies in the non-coding genome of multiple myeloma.**

C. Ashby, M.A. Bauer, R.G. Tytarenko, P. Patel, S. Deshpande, F. van Rhee, M. Zangari, S. Thanendrarajan, C.D. Schinke, F.E. Davies, G.J. Morgan, B.A. Walker. University of Arkansas for Medical Sciences 4301 W. Markham St. Little Rock, AR 72205.

In multiple myeloma (MM), over one thousand samples have undergone whole exome sequencing (WES), showing key oncogenic dependencies within molecular sub-groups. Analysis of WES data has revealed two mutational signatures: a non-specific signature and an AID/APOBEC signature associated with the t(14;16) molecular sub-group. However, most of the genome has remained unstudied as a consequence of an almost exclusive focus on the exonic regions. However, we know from other cancers that non-coding regulatory mutations play a role in disease progression, gene deregulation and prognosis. We have examined 10X Chromium whole-genome sequencing (WGS; mean depth=45x) of 98 MM patients in different progressive states. Matching RNA-seq (n=85 patients) and microarray data (n=98) were used for gene expression analysis, as were additional non-matching microarray datasets for outcome (n=1553). Significantly more mutations ( $P < 0.0001$ ) were found in non-exonic (median 7.04 / Mb) vs. the exonic space (median 3.1 / Mb). Mutational signature analysis shows that samples with an AID/APOBEC COSMIC signature have significantly increased mutation counts (median 19692 vs. 26424,  $P = 0.009$ ) in both the coding and non-coding regions compared to those without. Additional mutational signatures detected were somatic hypermutation (sig. 9), a general cancer (sig. 5), and two signatures of unknown origin, one with C>G and T>A mutations in a ApNpT/GpNpC/TpNpA context and the other with mostly C>A and C>T mutations. Mutational hotspots indicative of somatic hypermutation were detected in key B cell maturation genes, including *BCL6*, *CXCR4*, *LTB*, and *BACH2*. Additional hotspots were seen in long noncoding RNAs including *NEAT1*, which has been implicated in a variety of other cancers. Mutations in the promoter region of *NEAT1* led to higher expression, which is linked to a shorter time to progression to MM ( $P = 0.008$ ) and poorer overall survival ( $P = 0.0007$ ). Finally, we performed a mutational enrichment analysis in MM molecular sub-groups, identifying several non-coding RNA genes such as *DANCR* [t(14;20)], *MIR155HG* [t(14;16)] and *MIR663AHG* [t(11;14)] are more frequently mutated in one subgroup compared to the rest of the dataset. We show that WGS identifies additional mutational signatures affecting the non-coding genome as well as mutational hotspots that result in gene dysregulation. This provides additional avenues of investigation to identify novel therapeutic targets in MM.

**900W****High-content phenotyping of human genetic mutations by functional variomics.**

S. Yi<sup>1</sup>, Y. Li<sup>2</sup>, D.J. McGrail<sup>2</sup>, P.K.S. Ng<sup>2</sup>, K.J. Jeong<sup>2</sup>, G.B. Mills<sup>2</sup>, N. Sahn<sup>2</sup>. 1) Dell medical school, Univ of Texas Austin, Austin, TX; 2) UT MD Anderson Cancer Center, Houston, TX.

Human genomes are highly complex with numerous somatic mutations identified across patient populations. Previous studies on genomic mutations have shed light on new means for cancer therapeutic interventions. With rapid advances in next-generation sequencing, accumulating genotypic information in the absence of efficient and systematic functional analyses of genomic aberrations will create a bottleneck in understanding genotype-phenotype relationships in cancer. To address these challenges, here we report a systems-level functional variomics approach integrating high-throughput phenotyping with robust computational analyses to investigate mutation-specific effects. This systematic functional platform consists of massively parallel mutagenesis, sensitive survival assays using growth factor-dependent cell models, and functional network perturbation profiling of mutations on signaling effects. We profile thousands of genomic aberrations, including point mutations, gene fusions and indels, and significantly expand the repertoire of characterized actionable mutations. This study represents a valuable resource and provides insights in prioritizing disease-causing mutations, and uncovering patient-specific disease mechanisms at a high resolution, a critical step towards personalized precision medicine.

**901T****Magnis, a fully automated NGS sequencing-ready library preparation system.**

S. Bigdeli<sup>1</sup>, B. Buehler<sup>1</sup>, S. Im<sup>1</sup>, H. Hogrefe<sup>1</sup>, K-C. Yeap<sup>2</sup>, C-S. Siow<sup>2</sup>, S-K. Lee<sup>2</sup>, S-W. Yuen<sup>2</sup>, O-C. Lim<sup>2</sup>, A-J. Fang<sup>2</sup>, S-F. Ching<sup>2</sup>, R. Bagga<sup>1</sup>, J. Hal-laday<sup>3</sup>, S. Jandle<sup>4</sup>, K. Poon<sup>3</sup>, P. Maunary<sup>1</sup>, R. Allen<sup>1</sup>. 1) Agilent Technologies, San Diego, CA, USA; 2) Agilent Technologies, Penang, Malaysia; 3) Agilent Technologies, Santa Clara, CA, USA; 4) Agilent Technologies, Cedar Creek, TX, USA.

Agilent's Next Generation Sequencing (NGS) target enrichment kits for preparation of sequencing-ready libraries are in widespread use in laboratories around the world. Automation of these complex protocols eliminates the need for training specialists, improves turnaround time, library quality, and reproducibility for NGS libraries. In a large collaborative effort among several groups within Agilent, we are developing a walk away liquid handler system Magnis capable of preparing up to eight NGS sequencing-ready libraries per run without the need of human intervention during the run using both regular and FFPE samples. We have programmed Magnis and optimized Agilent's HaloPlex HS and SureSelect XT HS chemistries to prepare automated Illumina-ready libraries. The system also comes with pre-aliquoted plated reagents for each chemistry made by Agilent's production facility. Prepared libraries can be kept sealed and refrigerated on the deck for up to 72 hours post-run. In a clinical setting, a decreased turnaround time may aid doctors with patient diagnosis. We have made modifications to the manual target enrichment protocols to optimally generate libraries on Magnis using different baits while utilizing innovative techniques for pipetting to prevent well-to-well contamination. An example we use for testing the Magnis system is one of Agilent's latest baits, the cost-effective SureSelect Human All Exon V7 exome, a hybrid-capture solution focusing on the interpretable part of the human genome. Both chemistries have been fine-tuned and optimized, and libraries have been tested for yield and reproducibility. Sequencing has confirmed reliable coverage, specificity, uniformity, and duplicate reads. We have demonstrated that the integrated germicidal UV bulb installed on the deck removes >99.5% of the amplifiable DNA at all tested deck positions in less than 30 minutes. We have also developed qPCR-based spike-in assays to confirm sample to sample contamination below the limit of detection (less than 0.001%). We have used sequencing to address potential run to run, and index contamination between samples. Protocol run time is currently under 8 hours for HaloPlex HS and under 9 hours for SureSelect XT HS. All yield and sequencing specs are targeted to meet the criteria for manually run protocols.

**902F****Detection of gross rearrangements in BRCA1 by next generation mapping and long read technologies.**

M. Bonin<sup>1</sup>, U. Faust<sup>2</sup>, M. Kehrer<sup>2</sup>, N. Maier<sup>1</sup>, A. Gazou<sup>2</sup>, C. Schroeder<sup>2</sup>, S. Kotschote<sup>1</sup>, HG. Klein<sup>1</sup>. 1) IMG M Laboratories GmbH, Martinsried, Bavaria, Germany; 2) Institute of Medical Genetics and Applied Genomics, University Hospital Tuebingen, Germany.

In monogenetic disorders, the functional investigation of rare, unclassified variants helps to analyze their pathogenic relevance and can improve differential diagnosis and predictive testing. Similarly to other human cancer susceptibility genes, the utility of testing in genes associated with hereditary breast and ovarian cancer, such as *BRCA1* and *BRCA2*, strongly relies on the possibility of establishing a relationship between the nature of the observed genetic alterations and their consequences on the functionality of the corresponding protein products. This can be generally inferred for mutations that introduce exonic duplications/deletions, premature stop codons (i.e. truncation) or affect mRNA integrity and/or stability and splicing, giving rise to functionally compromised proteins. However, apart from common polymorphisms, the assessment of the clinical relevance of other allelic variants may not be equally straightforward. We investigate two independent duplications within *BRCA1* gene of breast cancer patients by different molecular methods like Bionano Genomics and Oxford Nanopore (ONT) Sequencing on DNA and RNA level. In case 1 we are able to analyze a genomic duplication within *BRCA1* gene from exon 1 to 19. Initial diagnostic approaches show 31 MLPA positive markers and no relevant mutations in a 12 gene NGS Panel. With the help of Next Generation Mapping (NGM, BioNano Genomics, DNA) and ONT Long Read Sequencing (DNA & RNA) we were able to define the exact location and the orientation of the duplicated region. For the second case we investigate a smaller unpublished genomic duplication within *BRCA1* gene from exon 17 to 23. Also in this case MLPA shows only some positive markers and the NGS panel of 12 relevant genes for hereditary Breast Cancer results without any relevant variants. We performed NGM and Long Read Nanopore Sequencing for two affected *BRCA1* individuals. Using these two approaches we identified the orientation and the genomic location of the structural variants. In addition, both methods are capable of identifying both single and multiple exon deletions. NGM as well as Long Read Sequencing promises to close the diagnostic gap for exonic deletions and duplications in monogenetic disorders.

**903W**

**Characterizing tumor heterogeneity at single cell level.** C. Catalanotti, S. Maheshwari, K. Belhocine, S. Garcia, V. Kumar, L. Hepler, A. Price, T. Wheeler, M. Schnall-Levin, R. Bharadwaj, D.M. Church. 10x Genomics, Pleasanton, CA.

Cancer genomes are highly unstable with new genetic variations emerging even within a single metastatic site. Such heterogeneity is manifested in the forms of multiple genetically distinct clonal populations and is shaped by the ongoing processes of Darwinian selection and drift. To fully understand the landscape of genetic heterogeneity within a tumor is critical for predicting its evolutionary potential. Single cell (SC) genome sequencing is emerging as a powerful tool to explore it, providing a direct readout of the cellular frequency of somatic mutations and relative ploidy, while avoiding the complexities of deconvolution from bulk WGS. However, current SC DNA approaches suffer from low throughput, cumbersome workflow and remain only accessible to a few select laboratories. We have developed a microfluidic, partitioning-based solution that allows sensitive CNV detection of thousands of SCs concomitantly. In this two-step workflow, isolated cells or nuclei are treated to gain complete accessibility to genomic DNA, then co-partitioned along with functionalized gel beads in nanoliter-sized droplets. Barcoded fragments, representing genomic abundance, are then converted into Illumina-compatible libraries. Analysis of our SC whole-genome sequencing data shows excellent coverage uniformity, comparable to leading plate-based SC amplification techniques. We profiled 10,000 single nuclei from five spatially separated sections of a single primary breast tumor. Histopathology analyses reported a 75% tumor purity. We used SC sparse WGS to quantify tumor purity and ploidy across each section and observed an increment in tumor purity from 6% in the first section (S1) to >80% in the fifth section (S5). By aggregating the single-cell data, we inferred pseudo-bulk ploidy profiles ranging from 1.99 to 3.39 across the five sections. To resolve genetically distinct sub-clones in the different tumor sections, we used Euclidean distance measure to identify a group of more than 4000 non-diploid cells from all five samples as cancer cells whose average ploidies ranged from 2.6 to 5.3. Finally, Discriminant Analyses of Principal Component (DAPC) used CNV events to identify 8 major clusters. Spatial clustering of genetically similar single cells suggested a polyclonal model of tumor evolution for this breast. These data provides evidence for the power of scalable SC DNA analyses of CNV for characterizing tumor heterogeneity.

**Exploring the architecture of organoid genomes with PromethION technology.** S. Goodwin<sup>1</sup>, I. Lee<sup>2</sup>, F. Sedlazeck<sup>3</sup>, R. Sherman<sup>2</sup>, M. Kirche<sup>2</sup>, G. Arun<sup>1</sup>, J. Lihn<sup>1</sup>, D. Spector<sup>1</sup>, M. Schatz<sup>2</sup>, W. Timp<sup>2</sup>, W.R. McCombe<sup>1</sup>. 1) Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; 2) Johns Hopkins University, Baltimore, MA; 3) Baylor University, Waco, TX.

Cancers are frequently characterized by structural rearrangements that can confer novel phenotypes, include drug resistance to the cancerous tissue. There is need to accurately characterize a cancers repertoire of structural events in order to provide the most complete insight into tumor pathology. However, recent advances on long read sequencing have shown that short read approaches can miss a significant number of large structural events. Unfortunately the amount of material derived from biopsies is insufficient for comprehensive, long read sequencing. Organoids, a three dimensional cell culture derived from a primary tumor sample, can be grown in the lab and can provide sufficient material for long read sequencing. Despite growing interest in this technology it is unclear what changes to the genome may occur during the organoid generating process, particularly with respect to Structural events. Long read technology, along with short read data can be used to deeply probe the genomic architecture of organoids. The Oxford Nanopore PromethION offers a unique opportunity to explore genome architecture with long reads. The very high throughput and low cost, up to 100Gb per \$2000 chip, allows for greater depth and sample numbers than have been previously possible. This will allow for a deep understanding of the underlying structure of an organoid genome compared to the donor material while also advancing the use of long read sequencing as clinical tool.

**Seeing beyond the target: Uncovering germline research cohorts within targeted tumor-only sequencing data.** A. Gusev<sup>1</sup>, S. Mangul<sup>2</sup>, J. Carrot-Zhang<sup>1</sup>, M. Ducar<sup>1</sup>, L. MacConaill<sup>1</sup>, E. Stupka<sup>1</sup>, M. Meyerson<sup>2</sup>, N. Zaitlen<sup>3</sup>. 1) Dana-Farber Cancer Institute, Boston, MA; 2) University of California Los Angeles (UCLA), Los Angeles, CA; 3) University of California San Francisco (UCSF), San Francisco, CA.

Tens of thousands of cancer patients have had their tumors sequenced to identify clinically actionable mutations. In addition to saving lives, this activity has produced valuable research data, empowering significant discoveries in translational domains. However, the targeted nature of typical clinical tumor sequencing has a constrained research to pre-defined genes, and the absence of matched normal specimens precludes powerful germline analyses. In this work we develop a platform (SBT: Seeing Beyond the Target) to mine discarded and off-target tumor sequences to uncover rich genome-wide data including common germline genotypes, T and B cell receptor sequences, rDNA and mtDNA copy number, and HLA types. Using data sets with both targeted and whole genome genotypes, we show that our approach can be leveraged for accurate inference of individual-level polygenic risk, genetic ancestry, immune profiles, and can empower cohort-scale germline and germline/somatic GWAS studies. Mapping to non-human genomes further empowered recovery of microbial reads, which occurred in numbers sufficiently large to study the taxonomic composition of microbial communities in the tissue type represented by the sample. Several small-scale studies have demonstrated that these features are potential prognostic indicators, and our methods now make them available in large-scale clinical cohorts. We assess performance across real sequenced tumors from diverse cancer types and sequencing platforms, comparing to gold-standard germline genotyping and whole-genome/RNA-seq. We perform SBT analysis of thousands of tumor panel sequences from the Dana-Farber Cancer Institute *PROFILE* cohort. We examine replication of known variants, germline-somatic interactions, and immune profile associations with cancer outcomes. We believe that SBT will greatly increase the research potential of clinical tumor data sets and provide a bridge between the germline and somatic research communities. The full pipeline is available in an efficient, freely available software platform at <https://github.com/smangul1/seeing.beyond.target/wiki>.

**Single-cell transcriptome analysis reveals the gene exchange of cancer cells with high malignant potential and immune cells.** S. Hashimoto<sup>1</sup>, T. Torigoe<sup>2</sup>, H. Iwabuchi<sup>1</sup>. 1) Graduate School of Medicine, Kanazawa University, Kanazawa, Ishikawa-ken, Japan; 2) School of Medicine, Sapporo Medical University, Sapporo, Japan.

We applied novel strategy (Nx1-seq) of single-cell transcriptome analysis to characterize complex heterogeneous samples in the cancer tissue in the myometrial infiltration side (M-side) and endometrial side (E-side) of a human endometrioid adenocarcinoma tissue. Human endometrioid adenocarcinoma tissues are comprised of varying ratios of different cell populations of infiltrating immune cells and cancer cells. Myometrial invasion is an independent prognostic parameter of endometrioid carcinomas and is correlated with the risk of metastasis to the lymph nodes. In addition, it is believed that cells expressing some malignancy-related genes increase at the myoinvasive front. However, in this study, cancer cells in the E-side were highly malignant compared with those in the M-side. Many cells on the E-side were positive for spheroid-specific markers such as SOX2, CTSV and GNG2, which are related to tumorigenesis. In addition to the increased frequency of cells with a cancer stem cell marker in the E-side, the population of EMT in the E-side was higher than in the M-side. Moreover, the population of infiltrating T cells in the tumor, which is a marker for prognosis, was smaller in the E-side compared with the M-side. These data, produced using Nx1-seq, demonstrated that cells with high malignant potential (HMP) were present in the site of the same cancer tissue. Furthermore, when the gene expressions of cancer cells from the E-side and M-side were compared, several genes were identified at sites where cancer cells had HMP. Interestingly, the differential gene expression profile of macrophages and T cells in the E-side and the M-side were similar to those of cancer cells. To confirm this phenomenon, immunostaining of the cancer tissue was carried out. Immunostaining of UCHL1, a highly expressed gene in cancer in the E-side, showed a similar staining pattern in macrophages and T cells as well as cancer cells. In addition, other differential genes were also observed in macrophages and T cells as well as cancer cells. These data showed that many immune cells have the properties (genes) of cancer cells in cancer tissues with HMP. To elucidate this phenomenon, it is very important to clarify the mechanism of new cancer development. Therefore, to achieve more effective cancer therapies, the diversity of cancer cells at each distinct site of tumor tissues must be considered.

**907T**

**Metabolomic and transcriptomic profiling reveals distinct metabolomic patterns and key signalling pathways in tumour tissue of squamous cell carcinoma of the lung.** *L.T. Hoang<sup>1</sup>, E. Starren<sup>1</sup>, S. Willis-Owen<sup>1</sup>, A. Mandal<sup>1</sup>, C. Domingo<sup>1</sup>, A. Nastase<sup>1</sup>, Y. Zhang<sup>1</sup>, K. Lo<sup>1</sup>, E. Lim<sup>2</sup>, A. Nicholson<sup>3</sup>, M. Moffatt<sup>4,5</sup>, W. Cookson<sup>1,5</sup>.* 1) National Centre for Mesothelioma Research, Imperial College London, UK; 2) Department of Thoracic Surgery, Royal Brompton and Harefield NHS Trust, London, UK; 3) Department of Pathology, Royal Brompton and Harefield NHS Trust, London, UK; 4) The Brunei Cancer Centre, PJSC, Brunei; 5) Corresponding Authors.

An increase in glucose, glutamine and lipid metabolism are hallmarks of cancer cells, including the adenocarcinoma (ADC) subtype of non-small cell lung cancer (NSCLC). However, the metabolomic characteristic of the Squamous Cell Carcinoma (SCC) subtype of NSCLC and the differences between the two subtypes are poorly understood. In this study, we investigated pre-treatment profiles of 395 metabolites (Metabolon) in paired tissue samples (tumour with matched normal lung tissue) for 37 NSCLC patients. Twenty patients had ADC with the remaining seventeen having SCC. Transcriptomes were generated from the same paired samples (extracted RNA of tumour and normal lung tissue pairs) run on Affymetrix Gene 1.1 ST Arrays. The transcriptome data was used for Weighted Gene Co-expression Network Analysis (WGCNA) to identify co-expressed gene modules and to search for correlation with the key metabolites. In general, adenocarcinoma and SCC were found to have a similar metabolomic pattern with the predominance of metabolites involved in glucose, glutamine and lipid metabolism. Interestingly, in contrast to ADC, SCC showed two different metabolomic profiles among the tumours. WGCNA revealed two co-expressed gene modules that were significantly correlated with the production of 5'-CMP (Pyrimidine metabolism and DNA damage repair) and creatine metabolites. Among the canonical pathways that were significantly over-represented in these gene modules, the P53 signalling pathway was significantly up-regulated in SCC compared to ADC. This might contribute to a stronger cellular proliferation processes observed in both metabolomic and transcriptomic data from the SCC patient samples. The distinct metabolomic profiles in the tumour of SCC patients and the interaction between the metabolomic and transcriptomic profiles may contribute to the heterogeneity in clinical and treatment outcomes in NSCLC, with diagnostic and therapeutic potential.

**908F**

**Using drug metabolizing enzymes variations in risk stratification algorithm to guide the dosing decision in Rhabdomyosarcoma pediatric patients.** *R.M Labib<sup>1,2</sup>, E EINadi<sup>1</sup>, Hadeer Adel<sup>1</sup>, N.H El-Shafei<sup>2</sup>, L.M El-Sharkawy<sup>2</sup>, M Morkos<sup>2</sup>, S.A Abdelshafi<sup>1</sup>, D Yassin<sup>1</sup>.* 1) Children's Cancer Hospital-57357-Egypt, Cairo, Egypt; 2) Department of Clinical Pharmacy, Faculty of Pharmacy, October University for Modern Sciences and Arts (MSA), Egypt.

**Background / Objectives:** Rhabdomyosarcoma (RMS) is a small round blue cell tumor; representing 7% of all childhood malignancies, and over 50% of all soft tissue sarcomas. Detection of germline variants that determine interindividual variability in pediatric cancer patients' response to chemotherapy is a pathway to more accurate personalized targeted treatment. This trial aims to assess the feasibility of using an algorithm/signature of single nucleotide polymorphism (SNP) to predict response of RMS to chemotherapy. **Design / Methods:** In a cohort of 73 pediatric RMS patients treated with cyclophosphamide based first line treatment, we genotyped multiple candidate SNPs in drug transporters (e.g ABCC3 "MRP3") and drug metabolizing enzymes using restriction fragment polymorphism (RFLP) and taqman pre-designed assays in this pilot. Clinical data on survival, demographics, pathology, chemotherapy dose and clinical response were collected. We examined the association between these genotypes and overall survival, failure free survival (FFS) and achievement of complete response. In phase 2 of this project, we will genotype an array of other less frequent SNPs in DME to assess its frequency and impact in our population. **Results** Blood samples from 73 RMS pediatric patients were collected and genotyped. Patients were enrolled and treated according to IRS-V protocol based on cyclophosphamide. The allelic frequencies of study SNPs were determined. Those SNPs were correlated with all the clinical demographic variables, overall survival and FFS. Carriers of at least one mutant allele CYP2B6 rs2279343 and ABCC3 had significantly longer event-free survival. **Conclusions:** It is possible to transfer genomic results from laboratory to clinical practice in pediatric oncology to support clinical dosing decision. Our preliminary results demonstrated that CYP2B6 c.516T and ABCC3 genotypes may predict FFS in pediatric RMS patients and be used to better stratify risk prior to treatment.

**909W**

**Selective nanopore sequencing of human BRCA1 by Cas9-assisted targeting of chromosome segments (CATCH).** Y. Michaeli<sup>1</sup>, T. Gabrieli<sup>1</sup>, H. Sharim<sup>1</sup>, D. Fridman<sup>1</sup>, N. Arbib<sup>2</sup>, Y. Ebnstein<sup>1</sup>. 1) Chemistry, Tel Aviv University, Tel Aviv, Israel; 2) Department of Obstetrics and Gynecology, Meir Hospital, Kfar Saba, Israel.

Next-generation sequencing (NGS) is challenged by structural and copy number variations larger than the typical read length of several hundred bases. Third-generation sequencing platforms such as single-molecule real-time (SMRT) and nanopore sequencing provide longer reads and are able to characterize variations that are undetected in NGS data. Nevertheless, these technologies suffer from inherent low throughput which prohibits deep sequencing at a reasonable cost without target enrichment. Here, we optimized Cas9-Assisted Targeting of CHromosome segments (CATCH) for nanopore sequencing of the breast cancer gene *BRCA1*. A 200 kb target containing the 80 kb *BRCA1* gene body and its flanking regions was isolated intact from primary human peripheral blood cells, allowing long-range amplification and long-read nanopore sequencing. The target was enriched 237-fold and sequenced at up to 70× coverage on a single flow-cell. Overall performance and single-nucleotide polymorphism (SNP) calling were directly compared to Illumina sequencing of the same enriched sample, highlighting the benefits of CATCH for targeted sequencing. The CATCH enrichment scheme only requires knowledge of the target flanking sequence for Cas9 cleavage while providing contiguous data across both coding and non-coding sequence and holds promise for characterization of complex disease-related or highly variable genomic regions.

**Broad genomic and transcriptomic profiles of Asian breast cancer.** J.W. Pan<sup>1</sup>, M. Zabidi<sup>1</sup>, P. Ng<sup>1</sup>, M.Y. Meng<sup>1</sup>, S. Sammut<sup>2</sup>, B. Sandey<sup>2</sup>, C.H. Yip<sup>3</sup>, P. Rajadurai<sup>3</sup>, O.M. Rueda<sup>2</sup>, C. Caldas<sup>2</sup>, S.F. Chin<sup>2</sup>, S.H. Teo<sup>1</sup>. 1) Cancer Research Malaysia, Subang Jaya, Malaysia; 2) Cancer Research UK Cambridge Institute, Cambridge, UK; 3) Subang Jaya Medical Centre, Subang Jaya, Malaysia.

**Background:** Breast cancer is the second largest cause of cancer-related deaths among Asian women and incidence is projected to rise. Asian breast cancer patients are younger and have a higher prevalence of ER-negative disease, but few genomic analyses of somatic mutations and gene expression of Asian breast tumours have hitherto been described. **Methods:** To characterise the molecular profiles of Asian breast tumours, we conducted whole-transcriptome sequencing (RNA-Seq) and paired tumor-normal whole-exome sequencing (WES) of 576 breast tumours from a hospital-based cohort in Malaysia. WES was done on an Illumina HiSeq4000 platform to a mean depth of coverage of 80X/40X (tumor/matched normal), and RNASeq to a depth of 40X (tumor RNA). Additionally, tumor copy number variation was determined using shallow whole-genome sequencing (sWGS) at 0.1X depth of coverage. Somatic variants were identified using Mutect2 and Strelka, molecular subtypes were stratified according to PAM50 and ic10 clusters, and immune scores were generated using ESTIMATE. **Results:** We show that there is an increased prevalence of *TP53* somatic mutations, a higher proportion of aggressive molecular subtypes, and a higher immune score in Asian breast tumours compared to the predominantly Caucasian breast tumours reported in TCGA and METABRIC. **Conclusion:** Our results contribute to an improved molecular understanding of Asian breast tumours, and lay the foundations for enhancing precision medicine initiatives in Asia.

**911F**

**Comprehensive detection of germline and somatic structural mutations in cancer genomes.** A. Pang, J. Lee, T. Anantharaman, A. Hastie, H. Cao, M. Borodkin. Bionano Genomics, San Diego, CA.

In cancer genetics, the ability to identify constitutive and low-allelic fraction structural variants (SVs) is crucial. Conventional karyotype and cytogenetics approaches are manually intensive. Microarrays and short-read sequencing cannot detect calls in segmental duplications and repeats, often miss balanced variants, and have trouble finding low-frequency mutations. We describe the use of Bionano Genomics's Saphyr platform to comprehensively identify SVs for studying cancer genomes. DNA larger than 100 kbp are extracted, labelled at specific motifs, and linearized through NanoChannel arrays for visualization. Molecule images are digitized and *de novo* assembled, creating megabases long Bionano genome maps. Somatic mutations can be identified by running the variant annotation pipeline, which compares the cancer sample's assembly calls against > 600,000 SVs in Bionano's control sample SV database, and against a matched control sample's variants. In addition, two new Bionano pipelines leverage these long molecules to identify additional somatic SVs: the copy number variation pipeline and the molecule mapping pipeline. By examining the coverage-depth of molecule alignment to the public human genome reference, the pipeline can identify megabases long amplifications and deletions. Similarly, clusters of split-molecule alignments against a reference can reliably find translocations and other rearrangements. We applied this suite of discovery tools to construct a comprehensive map of SVs in a well-studied melanoma cell line, COLO829. We collected 200X of data from the tumor and the matched blood cell line, constructed contiguous assemblies (N50 > 50 Mbp), and called over 6,000 SVs in each genome. Then, we classified 52 as somatic by comparing the tumor and the blood control. Furthermore, molecule mapping identified extra mutations, bringing the total to 78. We verified a known 12 kbp deletion impacting *PTEN*, and t(1;10) and t(10;18) translocations. Furthermore, the copy number profile captured the duplications of *KIT* on chr6 and *BRAF* on chr7, as well as other chromosomal-arm gains and losses. In conclusion, with one comprehensive platform, Saphyr can discover a broad range of traditionally refractory but functionally-relevant SVs, and further improves our understanding of cancer etiology.

**Senescent tumor cells genes expression profiling in papillary thyroid carcinoma.** T. Park<sup>1</sup>, Y. Kim<sup>1</sup>, S. Kang<sup>2</sup>, H. Kim<sup>2</sup>. 1) Biochemistry, Ajou University School of Medicine, Suwon, Korea, Republic of; 2) Pathology, Ajou University School of Medicine, Suwon, Korea, Republic of; 3) Hemato-oncology, Ajou University School of Medicine, Suwon, Korea, Republic of.

Cellular senescence has been perceived as a barrier against carcinogenesis. However, the senescence-associated secretory phenotype (SASP) of senescent cells can promote tumorigenesis. Here, we show senescent tumour cells are frequently present in the front region of collective invasion of papillary thyroid carcinoma (PTC). Although wide variations in SASP expression existed across PTC cases, the expression of interleukin (IL)-6, IL-8 and matrix metalloproteinases (MMPs) was markedly upregulated in senescent tumor cells as compared with levels observed in non-senescent tumor cells. Furthermore, RNA-sequencing analysis revealed upregulation of several chemokines. RNA expression ratios between the non-senescent tumor cells and the senescent tumor cells and found increased expression of several chemokines including CCL4, CCL19, CCL21, CXCL2 or CXCL12 in the senescent tumor cells. These findings suggest that senescent cells are actively involved in cancer microenvironment.

**913T****Linking gut microbiome function to tumour molecular pathways using metatranscriptomics.** *R. Purcell<sup>1</sup>, A. Sullit<sup>2</sup>, F. Frizelle<sup>1</sup>, J. Pearson<sup>3</sup>, S. Schmeier<sup>2</sup>.*

1) Department of Surgery, University of Otago, Christchurch, New Zealand; 2) Institute of Natural and Mathematical Sciences, Massey University, Auckland, New Zealand; 3) Biostatistics and Computational Biology Unit, University of Otago, Christchurch, New Zealand.

Adverse changes in the gut microbiome have been linked with colorectal cancer. However, the majority of studies to date rely on microbiome analysis techniques that purely catalogue the bacterial taxa within samples. Bacterial function is often inferred without taking account of functional redundancy between species. In order to better understand the potential mechanisms of microbial communities within tumours, we have taken a novel approach of interrogating transcriptomic data from colorectal tumours to investigate links between bacterial function and tumour molecular pathways. We accessed a retrospective cohort of ~300 colorectal cancer tumours from our institutional tissue bank and performed transcriptomics to interrogate the expressed RNA in the tumours. Sequencing reads that mapped to the human genome were used as input to a Consensus Molecular Subtype (CMS) classifier, and tumours classified into different subtypes. Tumour molecular pathway analysis was carried out using a variety of pathway and ontology databases including Reactome, Gene Ontology, PANTHER and KEGG. Non-human sequence reads were classified into microbial taxa using a metatranscriptomics approach. Through this approach, we are able to identify bacterial species enriched or depleted in certain colorectal cancer subtypes and, through mapping translated peptide sequences, we are able to investigate the bacterial functional capacity that is active in different subtypes. Through our analysis we find that particular bacterial species are overrepresented in certain subtypes but also we are able to relate tumour microbiome function to molecular mechanisms active within a given tumour sample or tumour subtype, e.g. bacterial lipoprotein expression and host toll-like receptor signaling.

**914F****Arthritis initiated by immune-checkpoint inhibitor cancer therapy is a distinct entity from seropositive rheumatoid arthritis.** *E.D.O. Roberson<sup>1,2</sup>, D. Parks<sup>1</sup>, A.M. Akk<sup>1</sup>, C.T.N. Pham<sup>1</sup>.*

1) Dept. of Medicine, Division of Rheumatology, Washington University, St. Louis, MO; 2) Dept. of Genetics, Washington University, St. Louis, MO.

Human cancers avoid apoptosis and immune surveillance by accumulating new mutations. The mutational process is random, but selective pressure purifies the most advantageous mutations. Accumulation of mutations may form neoepitopes that can stimulate T cell activation by antigen presentation. Immune-checkpoint molecules, like PD-1 and CTLA-4, and ligands, like PD-L1, inhibit T cell activation. Tumors that overexpress these molecules are therefore protected from immune attack. Monoclonal antibodies to these immune-checkpoint molecules are effective and durable treatments in a variety of cancers, including melanoma, non-small cell lung cancer, renal cell carcinoma, and Merkel-cell carcinoma. However, some patients experience immune-related adverse events (**irAEs**) that can be mild (eczematous rash) or serious (CMV activation colitis, thyroiditis, neuropathy, and arthritis). irAE arthritis resembles rheumatoid arthritis (**RA**), and can be severe. An unanswered question is whether checkpoint therapy unmasks pre-existing RA or is a separate entity. We approached used the 10X Chromium single-cell RNA-Seq system to compare PBMCs from an irAE patient and an RA patient. We obtained usable sequence from 1,172 irAE patient cells and from 1,654 RA patient cells. We converted the unique molecular identifier counts per cell to transcripts per million, and projected the data into lower dimensions using Uniform Manifold Approximation and Projection. We calculated enrichment of genes in a cluster by comparing to all other clusters, and estimated cell type using the ImmGen. Several clusters had different fraction cells in the irAE and RA samples. One cluster represented 27% of RA cells, but only 12% of irAE cells. The most similar cell type was activated T cells. Another cluster was only 0.4% of RA cells, but 2.6% of irAE cells, and was most similar to a sub-population of neutrophils. We are currently optimizing feature selection for clustering and identifying the underlying cell populations, including adding complementary CyToF data for cells stored from the same blood draw. However, the difference in fraction of cells in each cluster, some clusters only being present in one individual, and differences in expression of genes sometimes within clusters between patients, suggest that irAE arthritis is not identical to seropositive RA. Additional data from seronegative arthritis will be needed in the future to help determine if irAE arthritis is also distinct from it as well.

**Characterization of breast cancer samples using integrated genomics and metabolomics data.** *R.M. Rodrigues-Peres<sup>1</sup>, A.M. Porcari<sup>2,6</sup>, J. Zhang<sup>3</sup>, K. Garza<sup>3</sup>, J. Lin<sup>3</sup>, B.S. Carvalho<sup>4</sup>, I. Lopes-Cendes<sup>5</sup>, M.N. Eberlin<sup>6</sup>, L.S. Eberlin<sup>3</sup>, L.O.Z. Sarian<sup>1</sup>.* 1) CAISM – Women's Hospital, State University of Campinas - UNICAMP, SP, Brazil; 2) Laboratory of Multidisciplinary Research, São Francisco University (USF), Bragança Paulista, SP, Brazil; 3) Department of Chemistry, The University of Texas at Austin, TX, USA; 4) Department of Statistics, Institute of Mathematics, Statistics and Scientific Computing, State University of Campinas - UNICAMP, SP, Brazil; 5) Department of Medical Genetics, State University of Campinas - UNICAMP, SP, Brazil; 6) Thomson Mass Spectrometry Laboratory, Department of Chemistry, State University of Campinas - UNICAMP, SP, Brazil.

**Introduction:** Genomic and metabolomic studies may contribute to elucidation of pathological mechanisms related to development and progression of breast cancers, besides improving the tumor diagnosis. The aggressiveness of breast cancer is due to genetic factors, including the behavior of altered genes and post-translational mechanisms which may affect the way products of these genes are expressed. The objective of this study was to characterize breast cancer samples through the identification of Copy Number Variations (CNVs) related to a number of genes potentially linked to mammary carcinogenesis and to determine the lipid profile of these samples, in order to establish a link that could possibly explain how these features may affect tumor biology, its development and disease prognosis. **Methods:** Eight samples of ductal breast tumors and eight samples of normal breast tissue of the same women, for control, were selected by histopathological characterization of biopsy specimens. Chromosome Microarray (CMA) technique was then performed to access CNVs from these tumors and Desorption Electrospray Ionization Mass Spectrometry Imaging (DESI-MSI) technique was applied to verify the abundance of lipids on breast tissue. Relations between the data assessed through these analyses were obtained by Metaboanalyst 3.0 tools for metabolic pathways search. **Results:** After data refinement, CMA identified 780 significant regions containing CNVs, which related to 1199 genes. DESI-MSI identified 4 classes of lipids which were significantly more abundant in tumor tissues when compared to normal tissues: glycerophosphoserine, glycerophosphoinositol, glycerophosphoglycerol and glycerophosphoethanolamine. When these genes and lipids were related, the following metabolic pathways were found to be altered: arachidonic acid metabolism ( $p = 0.000361$ ), ether lipid metabolism ( $p = 0.00223$ ), metabolism of xenobiotics by cytochrome P450 ( $p = 0.00674$ ), biotin metabolism ( $p = 0.0445$ ) and one carbon pool by folate ( $p = 0.0489$ ). **Conclusion:** These findings show that amplifications and deletions of key genes can affect the lipid profile in breast tumors and that the described lipids are sufficient to determine whether a tissue is tumoral or not. These processes should continue to be studied for well understanding of how these interactions are influencing the cellular pathways that may contribute to the onset and progress of the breast tumor, aiming to improve the management of the disease.

## 916T

**Novel targeted long read approaches for uncovering undetected mutations in the BRCA1 and BRCA2 genes.** *J.A. Rosenfeld<sup>1</sup>, F. Sedlazeck<sup>2</sup>, S. Goodwin<sup>3</sup>, M. Delabastide<sup>3</sup>, Y. Chen<sup>1</sup>, S. Iyer<sup>3</sup>, C. Boles<sup>4</sup>, S. Ganesan<sup>1</sup>.* 1) Cancer Institute of New Jersey, Rutgers University, New Brunswick, NJ; 2) Human Genome Sequencing Center, Baylor College of Medicine, Houston, TX; 3) Cold Spring Harbor Laboratory, Cold Spring Harbor, NY; 4) Sage Science, Beverly, MA.

Mutations in the BRCA1 and BRCA2 genes are important drivers of many cancers particularly those of the Breast and the Ovary. Because of this cancer linkage, there are screening programs whereby a woman with familial cancer history has these genes sequenced to determine her cancer risk. Historically, this sequencing was done using Sanger sequencing, but more recently, short read Illumina sequencing has become the standard. While these Illumina reads are cheap and allow for the screening of mutations, their short length of 100bp has limited their efficacy in detecting translocations as well as SNPs and short indels. The reason for the lack of detection of SNPs and short indels is due to the difficulty of mapping short reads in regions of the genome that are even mildly repetitive. In order to address these gaps in our understanding of BRCA1 and BRCA2, we have used innovative approaches for targeted long read sequencing of these loci. Whole genome long-read sequencing is cost-prohibitive and traditional capture techniques are insufficient for long-read sequencing. We have used the Sage Science CATCH+ approach that couples Cas9 genome cutting and pulse-field gel electrophoresis to capture DNA for the BRCA loci, achieving ~30X enrichment of the BRCA1 loci. In addition, we have used custom enrichment methods from Swift Biosciences that target 2kb regions of the BRCA genes, achieving more than 100X enrichment of the loci. As a first test, we have used the highly characterized breast cancer cell lines including SKBR3. Once the techniques are validated, we plan to extend our approach to other cell lines and patient samples. Through these approaches, we have identified a genome translocation between chromosomes 13 and 17 and multiple SNPs that were not detected with the traditional Illumina short read approaches. These variants will lead to greater knowledge and understanding of the BRCA genes and their connection to cancers.

**Deep targeted duplex sequencing for low allele fraction variant detection.** *M. DeFelice, B. Blumenstiel, J. Grimsby, M. Fleharty, C. Cibulskis, V. Adalsteinsson, M. Duran, J. Abreu, T. Desmet, S. Gabriel, N. Lennon.* The Broad Institute, Cambridge, MA.

Low allele fraction variant detection from liquid biopsies and other challenging biological sample types poses a unique set of challenges for a large scale research and clinical sequencing lab. With recent advances in DNA targeting and enrichment methods coupled with reduced sequencing costs, there is an increasing demand for sequencing labs to support a variety of deep targeted panels for both cancer and germline research. Specifically, there is demand for developing distinct, disease-specific custom panels and generating extremely deep coverage for detecting low allele fraction variants with high sensitivity from biological samples such as plasma derived cell-free DNA, urine, cerebrospinal fluid, and bone marrow aspirates. Often these research or clinical cohorts number in the 100's of samples rather than 1,000's requiring low per-sample project initiation costs. Historically, targeted gene panels were costly to develop and often economically feasible only when upfront costs were amortized over many thousands of samples. Today, we are able to provide a low cost, rapidly implemented panel service, compatible with a variety of sample types, targets and project size. To achieve this, we have developed a unified library construction and target capture workflow which incorporates duplex unique molecular indices (UMIs) and built a UMI-aware consensus calling pipeline. By integrating balanced array based probe synthesis, short duplex UMI adapters, and a modified single hybridization workflow, we have been able to obtain deep on-target coverage (>90% Selected) with balanced uniformity (Fold-80 <1.5) and rapid turnaround (~3 weeks) for custom panels ranging from 300kb to 2mb in size. UMI duplex adapters on all libraries allow for robust error correction and high sensitivity for low allele fractions (<1%) as well as a low false positive rate (<1FP/MB). This workflow will allow for comprehensive genomic profiling and will be the basis of research and clinically validated assays over the next years.

**Use of molecular identifiers and targeted NGS to enable variant detection below 1% allele frequencies in circulating cell-free DNA.** *A. Wood, S. Sandhu, J. RoseFigura, L. Kurihara, V. Makarov.* Swift Biosciences Ann Arbor, MI.

The growing use of circulating cell-free (cfDNA) necessitates accurate variant detection at less than 1% allele frequencies due to a low population of DNA of interest within total cfDNA. This level of detection is critical for a variety of cfDNA applications including detection of circulating tumor DNA (ctDNA), detection of graft-derived cfDNA (GcfDNA) within normal plasma as a marker of graft integrity after organ transplantation, and for noninvasive prenatal testing (NIPT) where fetal cfDNA is detected at low frequencies in maternal plasma. However, reliable low-frequency variant detection by next-generation sequencing (NGS) is challenging due to background noise from PCR and sequencing errors. Additionally, while NGS is well suited for high throughput analysis, whole-genome sequencing can be cost prohibitive. To overcome these challenges, we employed a targeted NGS assay that uses molecular identifiers (MIDs) to uniquely label individual DNA molecules prior to amplification. MID families consisting of PCR duplicates can be used to distinguish true variants from PCR and sequencing errors and an error-corrected consensus sequence can be generated. We incorporated MIDs into a 17 amplicon EGFR pathway panel that can be used for ctDNA detection in lung cancer and a 101 amplicon SNP panel that contains 92 amplicons targeting SNPs with high minor allele frequency and 9 amplicons that identify gender ideal for GcfDNA or fetal cfDNA detection. These assays generate an NGS library using a single-tube multiplex PCR that is compatible with cfDNA. To test assay sensitivity, we performed low frequency spike-in experiments with control DNA or patient derived cfDNA. We prepared MID libraries from 10-50ng of input DNA and deep sequencing to >20,000x was done to maximize MID family size and optimize generation of a consensus sequence. This analysis accurately and reproducibly identified known variants as low as 0.1%. Importantly, the use of MIDs drastically reduced the number of false positive variants called at less than 1% increasing confidence in low frequency variant calls. Accurate variant calling at these levels is critical to track biologically relevant levels of ctDNA for early detection and monitoring of cancer, GcfDNA to screen for organ rejection after transplantation, and fetal DNA at early stages of pregnancy. This study highlights the power of MID technology in amplicon NGS library preparation to enable low frequency variant detection for cfDNA analysis.

**Linked read technology enables disambiguation of structural variants to *PMS2* and *PMS2CL*.** J. Van den Akker, J. Lock, A. Ondov, A. Khalif, Y. Xu, L. Servais, Z. Mahkovec, A.Y. Zhou, S. Topper. Color Genomics, Inc., Burlingame, CA.

**BACKGROUND:** Pathogenic variants in *PMS2* account for 5-15% of Lynch syndrome, increasing the risk for colon, endometrial and other cancers. However, variant detection in the 3' region of *PMS2* is complicated by the presence of a pseudogene (*PMS2CL*), which shares high sequence homology with *PMS2* exons 12-15. Moreover, sequence exchange between *PMS2* and *PMS2CL*, which prevents analysis relying on minor sequence differences, has been observed in 33-69% of unselected cohorts (PMID 20186688, 20186689). Traditionally, sequencing the 3' end of *PMS2* has relied on a long-range PCR primed from a binding site outside the homologous region. Successful amplification of this >17kb amplicon requires high molecular weight gDNA, which is challenging for biobanked specimens and common sample types such as buccal or saliva of variable quality. In addition, this approach fails if the breakpoints of a structural variant (SV) are unknown, and for complex rearrangements such as gene conversion or reciprocal crossover. Here, we present how these limitations can be overcome with linked-read technology, which reconstructs long DNA sequences from short barcoded fragments.**METHODS:** Genomic DNA was extracted from saliva or blood, and molecular barcodes were incorporated into individual DNA molecules via isothermal amplification using Gel-Beads in Emulsion technology (10x Genomics). These fragments were used as input into the Kapa HyperPrep protocol, followed by target enrichment using a custom SureSelect XT bait set targeting the *PMS2* and *PMS2CL* regions. After sequencing on the NextSeq 550, FASTQ files were analyzed with Long Ranger v2.2.2, supplemented with CNVkit for detection of deletions/duplications by differential coverage.**RESULTS:** A set of >20 SNVs and indels, as well as >10 SVs contained within exons 12-15, were correctly identified in *PMS2* or *PMS2CL*, congruent with analysis by Ir-PCR. Additionally, breakpoints were resolved for 5 novel SVs overlapping exons 12-15. Furthermore, this platform allowed identification of complex rearrangements such as insertion of an SVA element, an inversion including exon 1, a processed pseudogene, and gene conversion.**CONCLUSION:** The data presented here validates the use of 10x linked-read technology to reliably identify variants in *PMS2*. This approach is superior to the traditional long-range PCR approach because it is effective on DNA of lower quantity (<2ng) and lower quality, and can resolve complex rearrangements impacting the 3' end of *PMS2*.

**920F**

**A multi-enzyme DNA repair mix improves library quality and sequencing accuracy.** M.R. Heider, L. Chen, C. Song, L. Sun, P. Liu, L. Ettwiller, L. Higgins, E.T. Dimalanta, T.B. Davis, T.C. Evans. New England Biolabs, Inc., Ipswich, MA.

High-throughput sequencing is a key tool for clinical diagnostic applications such as mutation profiling in diseased tissues and long read, genome assembly methods for identifying pathogens with high taxonomic specificity. Preparation of high quality next-generation sequencing (NGS) libraries is critical for obtaining accurate patient data, but clinical scientists are often limited by the input DNA quality. In cancer genomics, a common source of DNA is formalin-fixed, paraffin-embedded (FFPE) tissue from patient biopsy. FFPE DNA poses many challenges for preparing NGS libraries, including low input amounts and extensive fixation- and storage-induced DNA damage. Additionally, these damage-induced sequencing artifacts raise the background level of mutations, making it difficult to discern true, low frequency, disease-related variants from noise. Even relatively high-quality DNA inputs contain nicks and gaps limiting library yields and read lengths for long read sequencing platforms including Oxford Nanopore Technologies (ONT) and Pacific Biosciences (PacBio). We developed a second-generation DNA repair enzyme mix (V2) that efficiently repairs the most prevalent damage types found in FFPE DNA and further improves the quality and yield of NGS libraries through efficient nick and gap repair. We tested the application of the V2 repair mix in both Illumina and ONT library preparation. We prepared Illumina libraries with and without FFPE DNA Repair V2 for target enrichment studies. Following this, we performed deep sequencing, variant calling analyses, and validated the mutation frequencies using droplet digital PCR (ddPCR). For ONT libraries, we evaluated the benefit of repairing different DNA types prior to library preparation and sequencing. Illumina library yield and quality were improved when DNA samples were treated with FFPE DNA Repair V2 before library preparation. Target enrichment and whole exome enrichment experiments showed that the V2 repair mix did not alter the overall frequency of variants identified, thus it did not introduce bias, but significantly improved the sequencing accuracy by reducing the number of false variant calls. Repaired ONT libraries also showed improved library quality as well as greater read lengths. Enzymatic DNA repair prior to NGS library preparation is a critical first step both for eliminating damage-induced sequencing artifacts in Illumina sequencing as well as improving library quality and read lengths for ONT and PacBio.

**921W****Identification and correction of sample specific sequencing bias for improved copy number variant detection in fixed-cell pellet samples.**

J.B. Smadbeck<sup>1</sup>, B.A. Piteł<sup>2</sup>, S.A. Smoley<sup>2</sup>, S.H. Johnson<sup>1</sup>, N.L. Hoppman<sup>2</sup>, G. Vasmatzis<sup>1</sup>. 1) BioMarker Discovery Group, Mayo Clinic, Rochester, MN; 2) Department of Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN.

As whole-genome next-generation sequencing (NGS) methods are used more widely in clinical practice, there will be a continued push to improve the analytical methods to account for sample quality. The quality of a sample significantly affects analytical results and is often correlated to DNA degradation resulting from the method of sample preservation. Part of this degradation manifests in sequencing bias, whereby different regions of the genome may be over or under sequenced in comparison to the expected baseline level. This makes even a basic whole-genome calculation like copy number variant (CNV) detection prone to false positives. False positives are particularly pernicious in the use of these tests in the clinical space. For this reason it is important to understand the sources of the sequencing bias and have the ability to correct it. One type of preservation method of interest for use in whole-genome NGS analysis is fixed-cell pellet (FCP) preservation, in which cells are preserved in a solution of methanol and glacial acetic acid after being used to prepare slides for conventional chromosome studies or fluorescent in situ hybridization (FISH). We have found that these samples can be effectively used for the detection of breakpoint junctions using the whole-genome mate pair sequencing (MPseq) technology. However, in copy number variant detection it was found that these samples produced a high false positive detection when compared to fresh and frozen samples. In this study we aimed to identify and correct the sources of sequencing bias in FCP samples. We took 12 normal blood and bone marrow samples preserved as fixed-cell pellets and compared their sequencing bias to a set of 40 fresh or frozen normal blood and bone marrow samples. While a typical fresh or frozen sample will have sequencing bias correlated almost entirely with the GC-content, we found that the FCP samples were influenced by properties independent of GC-content. We demonstrate that this bias may be linked to the presence of short interspersed nuclear elements (SINEs). This source and significance of this bias is unique to the FCP samples. We developed an algorithm to correct this SINE bias and showed how this correction aids in the reduction of false positives for FCP samples. Through a full understanding of a sample's bias, a researcher can predict false positive results and make corrections to more accurately analyze these samples with NGS technologies.

**922T****The NantOmics Pharmacogenomics Test: Multi-omic screening of 2,489 oncology patients.** C. Schwartz<sup>1</sup>, J. Little<sup>1</sup>, C.J. Vaske<sup>1</sup>, C.W Szeto<sup>1</sup>, S.C. Benz<sup>1</sup>, S. Rabizadeh<sup>2</sup>, J.Z. Sanborn<sup>1</sup>. 1) NantOmics, Santa Cruz, CA; 2) NantOmics, Culver City, CA.

Numerous oncology drugs have pharmacogenomics warnings on their FDA labels, yet pharmacogenomics screening is not routinely applied in clinical practice. Pharmacogenomics testing is used to reduce the chance of drug-induced toxicities, improve patient outcomes, and reduce treatment costs by tailoring therapies to the patient's genotype. Here we present the NantOmics Pharmacogenomics test, which screens for pharmacogenomics variants related to 19 gene-drug pairs with CPIC guidelines and FDA label indications. Pharmacogenomics screening was performed on whole genome and whole exome sequencing (WES) data of FFPE tumors and matched normals from 2,489 oncology patients. Patients were screened using a panel of 31 germline markers in 10 genes linked to toxicities from 15 cancer therapies. The test has been validated on 10 cell lines from the CDC GeT-RM, on a set of synthetic data, as well as on a cohort of patients previously genotyped by an independent CLIA-validated PCR-based panel. For variants not detectable by WES (intronic and intergenic variants), we investigate exonic variants in linkage disequilibrium to act as proxies to predict toxicity in these patients. We also investigate gene expression variants implicated in toxicity of oncology drugs in patients with RNA sequencing data available. Of the 2,489 patients screened, 96.3% contained a variant with a pharmacogenomics recommendation. Furthermore, 7.4% of patients had genomic variants associated with severe or life-threatening drug toxicities. For all alleles in our clinical panel, we observed similar allele frequencies to those reported in the ExAC database. In all validation studies, we were able to demonstrate that the test detects each variant in our panel, and correctly determines patient genotype in all studied cases. Given the high percentage of patients with potentially treatment-altering genomic variants, these results underscore the need for more routine pharmacogenomics screening in the oncological setting.

**923F**

**High throughput, reduction transcriptomics, using ultraplex RNA sequencing.** *M. Kreutz, J. Shaffer, Q. Jiang, S. Rulli, E. Lader.* QIAGEN Sciences, 6951 Executive Way, Frederick MD.

Elucidating molecular mechanisms and understanding genetic heterogeneity in cancer biology can be achieved through high throughput gene expression analysis and pathway assignment. Recent advances in RNAseq methodologies have enabled accurate gene expression profiling from single cells, but analyzing hundreds or thousands of cells is an arduous exercise in library prep. Here we describe a high throughput 3' RNAseq library prep methodology termed Ultrplex. With QIAseq Ultrplex, Reverse transcription is performed directly on lysed cells, while simultaneously assigning a unique 'cell index' to all cDNA synthesized from a cell. All subsequent transcriptome or targeted panel library steps that follow occur in a single pooled sample; with up to 384 samples assigned per sequencing index. Each 384-plex library is assigned a standard sample index, such that up to 384 pooled 384X libraries can be sequenced together. With this methodology, thousands of transcriptomes or targeted RNA panels can be prepared and sequenced together. Here, we analyze the heterogeneity of an ostensibly uniform population of cancer cells, identifying unique signatures of genes that drive cellular clustering. With QIAseq UPX, high throughput transcriptomic analysis enables the identification and characterization of gene signatures which divide cells into discrete sub-populations based on vectorial gene expression components.

**924W**

**A comprehensive cross-platform comparison of single-cell RNA sequencing using reference samples.** *C. Wang<sup>1</sup>, W. Xiao<sup>2</sup>, W. Chen<sup>1</sup>, Sequencing Quality Control (SEQC)-2 Consortium Single-cell Project Team.* 1) Center for Genomics, Loma Linda University, Loma Linda, CA; 2) National Center for Toxicological Research, FDA, Jefferson, AR.

Rapidly developing single-cell RNA sequencing (scRNA-seq) technologies allow interrogation of the transcriptome in unprecedented detail, but questions arise as to how accurate and reproducible different platforms are; and there is lack of a benchmarking and validation using the standard reference samples. So far, there is no study that has carried out a systemic cross-platform comparison and evaluation on different scRNA-seq technologies using a standard reference sample, in which a large amount of whole genome, whole exome and whole epigenome data are also available to validate the scRNA-seq data. **Under the umbrella of the 2<sup>nd</sup> phase of the Sequencing Quality Control (SEQC-2) Consortium, we exploited a comprehensive study design** including four scRNA-seq platforms, i.e., 10X Genomics Chromium, Fluidigm C1, Fluidigm C1 HT and WaferGen, across five testing sites, using two well-characterized reference cell lines, i.e., human breast cancer cell line with a matched normal control cell line derived from B lymphocytes of the same patient. In addition to the scRNA-seq transcriptomic studies, we also investigate the epigenome including DNA methylome obtained using Illumina TruSeq Epic DNA-seq and chromatin accessibility by ATAC-seq at population cell level from the reference samples. We further interrogate the whole-genome and whole-exome of the reference samples at population cell level with deep sequencing, which would allow us to evaluate the accuracy of scRNA-seq. **Our objectives are:** **1)** to establish a benchmarking and QC metrics for scRNA-seq; **2)** to evaluate the accuracy and reproducibility of scRNA-seq across different platforms; **3)** to evaluate the inter-lab reproducibility of scRNA-seq; **4)** interrogate the epigenomic regulations on single-cell transcriptome in terms of the consistency and the biological discovery across different scRNA-seq technologies. **Conclusions:** Our analyses indicate that both the technical and biological batch effects exist and the reproducibility of scRNA-seq across platforms and sites is dictated by both genes selected and bioinformatics pipelines used. We optimized a bioinformatics normalization method and pipeline to correct the batch effects to achieve the best practice for scRNA-seq analyses. Furthermore, validated by both DNA methylome and ATAC-seq results, we identified a list of genes for benchmarking scRNA-seq performances across different platforms and testing site.

**925T**

**Enzymatic DNA fragmentation for next generation DNA sequencing sample preparation from FFPE tissue biopsy samples.** *M. Borns<sup>1</sup>, B. Rogers<sup>1</sup>, K. Chen<sup>1</sup>, G. Amparo<sup>2</sup>, C. Pabon<sup>2</sup>, L. Niu<sup>2</sup>, B. Arezi<sup>1</sup>, H. Hogrefe<sup>1</sup>.* 1) Agilent Technologies, Genomics Solutions Division, La Jolla, CA; 2) Agilent Technologies, Genomics Solutions Division, Santa Clara, CA.

Mechanical DNA shearing is the most common method for fragmenting DNA for library construction. Current methods for mechanical shearing are difficult, labor intensive, time consuming, expensive, and therefore unsuitable for clinical customers. Because of these drawbacks, enzymatic shearing methods are becoming more popular. However, the enzymatic shearing methods available so far, require additional optimization for different input amounts or when used with samples of varying quality. Here, we address these challenges by developing an endonuclease-based enzymatic double stranded-DNA fragmentation method which generates random DNA fragments from a variety of fresh frozen tissue, blood, and FFPE samples of varying quality and input (in the range of 10-200ng) with a single protocol (i.e., no optimization other than adjusting the PCR cycles). The DNA fragments generated have 5'-phosphate and 3'-hydroxyl termini and are directly used in end-repair/dA tailing without further purification. It is a simple, rapid, streamlined single-tube process. Unlike transposase shearing/tagmentation, it is suitable for library preparation from any FFPE tissue derived DNA including highly-damaged FFPE samples. As we will demonstrate, fragmentation and library preparation experiments using three bacteria of varying GC content (30%-67%) and human DNA shows high coverage uniformity and minimal bias across all GC content. Furthermore, we observe more complex libraries (~50%) across samples of medium to low quality (TapeStation DIN <3) compared to mechanical shearing. This is likely due to lower loss of DNA during the transfer step (i.e., single tube library prep) and/or the presence of more DNA ends that are repairable (as opposed to mechanical shearing). Higher library complexity increases coverage at higher sequencing depth which helps improve the detection of low allele frequency variants (as low as 1%).

**926F**

**AmpliSeq HD: A rapid, custom NGS library prep method that enables detection of mutations present at 0.1% allelic frequency.** *G. Luo, X. Peng, D. Mazur, S. Chen, K. Park, K. Heinemann, B. Ding, A. Hatch, Y. Fu, C. Chin, A. Kraltcheva, M. Andersen.* Clinical Next-Generation Sequencing Division, ThermoFisher Scientific, Carlsbad, CA.

Analysis of circulating cell-free DNA (cfDNA) in the blood has great potential in many clinical applications such as early cancer detection and peripheral monitoring. However, only a small fraction, as low as 0.1%, of the cfDNA sample will carry mutations from cancer cells of the patient. Very high sequencing depth focused on certain regions in the genome is required to capture such rare mutations. For this purpose, a highly sensitive, customizable targeted-sequencing approach will provide a powerful tool for clinical cancer studies to detect different biomarkers. We've developed a customizable library prep method (AmpliSeq HD) that incorporates molecular tags into multiplex PCR. The molecular tags are critical in removing random sequencing errors that would otherwise increase noise and decrease the ability to identify low frequency mutations. An engineered high fidelity polymerase is used here to ensure faithful copy of the original DNA sequence. We introduced a new cocktail of enzymes to enable an AmpliSeq like clean up step to remove primer-dimers produced in multiplex PCR. This digestion is a crucial step in the workflow to enable custom designed panel. We also optimized amplification condition to minimize false positive from cytosine deamination. With all these improvements, the AmpliSeq HD technique will allow rapid targeted library preparation in less than 3hrs with sensitivity to detect variances at 0.1% level in cfDNA or 0.5% level in FFPE DNA samples.

**Genomic analysis of somatic and germline mutations in malignant**

**pleural mesothelioma.** A. Nastase<sup>1,8</sup>, A. Mandal<sup>1,8</sup>, S.K. Lu<sup>1</sup>, H. Anbunathan<sup>1</sup>, S. Gennatas<sup>1,5</sup>, D. Morris-Rosendahl<sup>1,2</sup>, M. Edwards<sup>1,2</sup>, RC. Rintoul<sup>3</sup>, E. Lim<sup>4</sup>, S. Popat<sup>5</sup>, M. Lathrop<sup>6</sup>, A. Nicholson<sup>7</sup>, AM. Bowcock<sup>1,8</sup>, MF. Moffatt<sup>1,8</sup>, WOC. Cookson<sup>1,8</sup>. 1) National Centre for Mesothelioma Research, Imperial College London, United Kingdom; 2) Clinical Genetics and Genomics Royal Brompton and Harefield NHS Foundation Trust, London, United Kingdom; 3) Department of Thoracic Oncology, Papworth Hospital, Cambridge, United Kingdom; 4) Department of Thoracic Surgery, Royal Brompton and Harefield NHS Trust, London, United Kingdom; 5) Department of Medicine, Royal Marsden Hospital, London, UK; 6) Department of Human Genetics, McGill University-Génome Québec Innovation Centre, Québec, Canada; 7) Department of Pathology, Royal Brompton and Harefield NHS Trust, London, United Kingdom; 8) Contributed equally to the study; 9) Corresponding authors.

The genomic landscape of malignant pleural mesothelioma (MPM) is characterised by low mutational burden. Known driver events are in tumour suppressor genes but not in known oncogenes. A thorough interrogation of somatic mutations and germline risk factors may identify new genetic drivers that lead to onset and progression of the disease. This could lead to new therapeutic options as opposed to the current standard of care, chemotherapy, which is of limited benefit in relation to survival. We characterised the mutational profile of MPM with whole exome sequencing (WES) followed by target capture sequencing of DNA isolated from fresh snap frozen tissues. Samples were obtained from Mesobank UK, the BLF funded Mick Knighton Mesothelioma Tissue Bank, Respiratory BRU Biobank and Diagnostic Archive, Royal Brompton Hospital and from an Imperial College London sponsored, prospective study on thoracic cancers undergoing biopsy at St George's Hospital. Samples used for WES, comprised 21 paired (blood and tumour tissues) and 29 un-paired samples from MPM patients. Follow up sequencing was performed on a panel of 57 genes interrogated in samples from an additional 69 patients and the original cohort used for WES. The mean age of the patients was 72.1 (±8.5) years old and the ratio of male to female patients was 5.4:1. The majority of the patients (64.7%) had the epithelioid sub-type of MPM. The somatic mutation spectrum showed recurrent alterations in well known drivers of MPM: *BAP1* (37.7%), *NF2* (23.4%), *SETD2* (9.9%), *TP53* (9.1%), *SETDB1* (7.8%), *SYNE1* (6.5%), as well as genes with rare mutations in MPM: *NCOR2* (5.2%) and *MSH6* (2.6%). In addition, hotspot *NRAS* somatic mutations were identified in two patients with the sarcomatoid sub-type (G12V and Q61H respectively). We also observe germline risk variants in *BRCA2* (frameshift and stop-gained) and one case of *BAP1*. We report identification of mutations in genes that are candidate therapeutic targets. Observation of *NRAS* hotspot mutations in patients with no other known driver mutations hypothetically indicate RAF-MEK-ERK pathway being targeted in at least a fraction of MPM cases. Similarly the *BRCA2* and *MSH6* loss-of-function mutations could indicate a tumour genome with distinct vulnerabilities in the DNA damage response pathway, with potential for neoantigen formation. The implications of these alterations are being investigated further with cell line model systems queried through high-throughput genomic platforms.

## 928T

**Discovering diverse genetic biomarkers using cancer-specific targeted**

**NGS.** J. RoseFigura<sup>1</sup>, S. Sandhu<sup>1</sup>, K. Nakama<sup>1</sup>, B. Reed<sup>1</sup>, J. Irish<sup>1</sup>, P. Dottino<sup>2</sup>, O. Camacho-Vanegas<sup>2</sup>, L. Kurihara<sup>1</sup>, J. Martignetti<sup>2</sup>, V. Makarov<sup>1</sup>. 1) Swift Biosciences, Ann Arbor, MI; 2) Icahn School of Medicine at Mt Sinai, Departments of Genetics and Genomic Sciences, Pediatrics, Obstetrics/Gynecology & Reproductive Sciences and Oncological Sciences 1425 Madison Avenue New York, NY.

In the rapidly evolving cancer field, focused assays for different biomarkers are increasingly important tools. We have developed targeted NGS panels consisting of disease-specific, predesigned content that allow the flexibility to assess SNVs, small indels, and CNVs in a multiplexed single tube assay. Herein, we demonstrate the use of these panels to assess these variant types in validated standards and combine multiple pre-existing panels to evaluate clinical samples from patients with a known disease. The panels used in this study consist of a Pan-cancer panel, a BRCA1/BRCA2 panel, and panels targeting specific cancers, including Lung, Colorectal (CRC), Lynch, Myeloid, and Breast/Ovarian. These panels are based on a Swift's Accel-Amplicon technology, which generates overlapping amplicons for exon-level coverage of contiguous regions in a single tube assay. CNV standards were acquired for *ERBB2* amplification and for *EGFR* and *MET* amplification. The program CNVkit (Talevich et al., 2014) was used to assess copy number. Cell-free DNA (cfDNA) and peripheral blood DNA was acquired from healthy donors. Clinical samples from known Lynch patients were provided by the Martignetti lab at the Icahn School of Medicine at Mount Sinai for proof of concept experiments. The targeted NGS panels demonstrated consistent performance with a wide variety of DNA types, including cfDNA and FFPE DNA. All panels exhibited >90% on target and >90% coverage uniformity. CNV results agreed with DNA standards at copy numbers ratios (>2.9). Six clinical samples, with two corresponding tumors, were initially evaluated using the Pan-Can panel. These results were indicative of Lynch syndrome, so a combined CRC/Lynch panel was also run on these samples to further probe the disease state of the patient. Targeted NGS panels are a powerful tool for assessing the genetic etiology of multiple disease states. We have demonstrated the ability of this technology to identify important disease biomarkers in clinical samples, and to assess CNVs in pre-validated standards. The ability to assess SNV, indels, and CNV in a single tube from 10 ng of sample represents an important tool for assessing diseases in the clinic, as well as in research and discovery settings.

**Ultra-multiplexed CleanPlex® NGS panel: Comprehensive tumor profiling using a fast, single-tube protocol.** *L.Y. Liu, Z. Liu, L. Lee, G. Liu, J. Liu, L.J. Zhang, L. Lin.* Paragon Genomics, Hayward, CA.

Next-generation sequencing (NGS) has become a key tool for screening large numbers of genes and cancer mutations because of its ability to simultaneously sequence a large number of targets. Tumor profiling requires the sequencing of a large number of genes. To most effectively use the paralleling power of NGS, multiplexed targeted sequencing can provide highly comprehensive diagnostic methods for tumor profiling and patient treatment identification. Unique challenges for tumor profiling call for a highly efficient, accurate and robust method for the unbiased enrichment of tens of thousands of target regions. However, an increase in multiplexity can also increase the risk of non-specific primer-primer interactions, decrease uniformity, and increase GC bias. Here we present a highly-multiplexed comprehensive tumor profiling panel containing 19,700+ regions, covering 364 genes. Using the CleanPlex® PCR-based, one-tube method, and an average read depth of ~1000 reads per amplicon, this highly multiplexed amplicon panel exhibits 92% uniformity at 0.2X mean bias, little GC bias, and mutation calling at as low as 1% allele frequency. This panel is compatible with genomics DNA, FFPE DNA or cfDNA, and can be used for monitoring gene mutations or tumor burden. CleanPlex® technology demonstrates that it is capable of creating high quality amplicon libraries with high uniformity, low GC bias, and sensitive variant calling even in ultra-multiplexed libraries with ~20,000 amplicons with a workflow under 3-hours.

**930W**

**Genetic and epigenetic evidence for clonal tumor growth in sporadic parathyroid adenomas.** *K. Brewer<sup>1</sup>, R. Jenkins<sup>1</sup>, J. Costa-Guda<sup>2</sup>, A. Arnold<sup>1</sup>.*

1) Center for Molecular Oncology, University of Connecticut School of Medicine, Farmington, CT; 2) Center for Regenerative Medicine and Skeletal Development, University of Connecticut School of Dental Medicine, Farmington, CT.

**Introduction:** Parathyroid adenomas (PTAs) are benign lesions responsible for the large majority of non-familial cases of primary hyperparathyroidism, and most have long been understood to be clonal outgrowths of a single tumor progenitor cell. However, some recent studies of PTA clonality using X-chromosome inactivation-based assays concluded that a substantial proportion of PTAs are not clonal and may derive from multiple cells. Because of well-recognized pitfalls in interpreting non-clonal (polyclonal) results in X-inactivation assays, we reexamined the clonality of a cohort of sporadic PTAs emphasizing methods that directly detect clonal DNA alterations. **Methods:** Among an original cohort of 83 sporadic, typical, solitary PTAs, 57 (69%) had previously proved to be unequivocally clonal using methods such as loss of heterozygosity at selected chromosome markers, classic comparative genomic hybridization, single nucleotide polymorphism array, and/or candidate gene sequencing. In the present study, we were able to interrogate 24 of the remaining 26 PTAs with still-undetermined clonal status, seeking (1) direct genetic evidence of clonal copy number variation (CNV) using genome-wide high-resolution CytoScan HD array; and (2) indirect evidence of clonality by assaying the consistency of allelic X-inactivation via human androgen receptor assay (HUMARA) on female samples. **Results:** In all 24 tumor samples of unknown clonal status, we identified tumor-specific CNVs compared with the CytoScan pooled reference sample, demonstrating that each of the tumors assayed is clonal. This result was confirmed in a validation subset of individually matched tumor and germline samples. By HUMARA, 14 of 19 (74%) female tumor samples were informative and exhibited a clonal methylation pattern; the remaining 5 yielded inconclusive results in which there were no clear non-clonal (polyclonal) patterns. **Conclusions:** The use of high-resolution methodology to identify changes in the tumor genome offers compelling evidence of the clonality of solitary sporadic PTAs and is informative in cases where X-inactivation studies are nondefinitive, such as in male or uninformative female cases. All 24 tumors interrogated in this study exhibited genetic and, in most cases, epigenetic patterns consistent with clonal outgrowth. In combination with previous data, we now have evidence that a minimum of 81 tumors of the original 83-tumor cohort (98%) are clonal.

## 931T

**Functional mechanisms underlying the association between novel variants, their target genes and prostate cancer risk.** C. Cieza-Borrella<sup>1</sup>, S. Wakerell<sup>1</sup>, Q. Karlsson<sup>1</sup>, S. Merson<sup>1</sup>, R. Rageevakumar<sup>1</sup>, I. Whitmore<sup>1</sup>, E. Anokian<sup>1</sup>, E. Saunders<sup>1</sup>, R.A. Eeles<sup>1,2</sup>, Z. Kote-Jarai<sup>1</sup>. 1) The Institute of Cancer Research, London, United Kingdom; 2) The Royal Marsden Hospital NHS Trust, London, UK.

Prostate Cancer (PCa) is the most frequently diagnosed cancer among men in developed countries and one of the most heritable solid tumours. The effectiveness of PSA screening remains controversial and new molecular biomarkers are needed to improve screening and clinical management of disease. Genome-Wide Association Studies (GWAS) and consequent fine-mapping analysis have identified over 170 low-penetrance PCa susceptibility variants associated with PCa risk; however the mechanisms through which these affect disease risk are still not fully understood. The aim of this study is to functionally characterise candidate SNPs at three finemapped GWAS loci in the DNA repair genes *RAD51B* and *RAD23B* as well as the novel PCa candidate gene *NGEP-L* (*ANO7*), in order to elucidate the biological mechanisms behind their association with PCa risk. Circular Chromosome Conformation Capture (4C) was used in five prostate human cell lines (LNCaP, DuCaP, PC3, PNT1a and RWPE-1) to investigate whole genome interactions between the candidate functional risk SNPs rs7141529 and rs767127 in *RAD51B*, and four candidate European variants in *RAD23B*; rs1771718, rs1771723, rs1746831 and rs1746828. All barcoded libraries were sequenced on a HiSeq 2500 (Illumina) and bioinformatics analysis was performed using the R program 4C-ker. We observed significant interactions between rs767127 viewpoint and *RAD51B* promoter and rs1771723 with *AR* and *E2F3* genes. Results are being validated using 3C. In our latest fine-mapping study we identified three independent PCa susceptibility signals at chr2q37, within the *NGEP-L* gene. This gene encodes a cell membrane protein involved in cell-cell signalling and despite being predominantly expressed in prostate epithelial cells, the long transcript is not expressed in most of the human prostate cell lines analysed by RNA sequencing. We used CRISPR/Cas9 technology and pCMV6-AC-GFP TrueORF vector to knock out and overexpress the gene in order to investigate its role in three human prostate cell lines: RWPE-1, DU145 and DU145 MN1. Positive clones have been selected for proliferation, viability and apoptosis assays in 3D and results of these will be presented. In conclusion, we present here two different approaches used for the functional characterisation of candidate SNPs and novel genes which provide insights into the understanding of their association with prostate cancer risk.

## 932F

**Germline multi-gene testing in unselected endometrial cancer patients.** M. Janatova<sup>1</sup>, J. Soukupova<sup>1</sup>, K. Lhotova<sup>1</sup>, P. Zemankova<sup>1</sup>, M. Borecka<sup>1</sup>, L. Stolarova<sup>1</sup>, M. Vocka<sup>2</sup>, P. Kleiblova<sup>1,3</sup>, F. Lhotova<sup>4</sup>, M. Koudova<sup>4</sup>, S. Tavandzis<sup>5</sup>, L. Foretova<sup>6</sup>, E. Machackova<sup>6</sup>, Z. Kleibl<sup>1</sup>. 1) Institute of Biochemistry and Experimental Oncology, First Faculty of Medicine, Charles University, U Nemocnice 5, 12000 Prague 2, Czech Republic; 2) Department of Oncology, General Faculty Hospital and First faculty of Medicine, Charles University, U Nemocnice 2, 12000 Prague 2, Czech Republic; 3) Institute of Biology and Medical Genetics, General Faculty Hospital and First faculty of Medicine, Charles University, Albertov 4, 12800 Prague 2, Czech Republic; 4) GENNET laboratories Prague, Kostelní 9, 17000 Prague 7, Czech republic; 5) AGEL laboratories Novy Jicin, Purkynova 2138/16, 74101 Novy Jicin, Czech Republic; 6) Department of Epidemiology and Tumor Genetics, Masaryk Memorial Cancer Institute, Zlutý kopec 7, 65653 Brno, Czech Republic.

Endometrial cancer is the most common gynecological cancer, the incidence in the Czech Republic was 37/100000 in 2015. Compared to ovarian cancer, it was supposed that only 2 – 3% of all endometrial cancers are caused by inherited mutations. The majority of hereditary endometrial cancers is associated with Lynch syndrome. Nevertheless, the role of other cancer predisposition genes remains unclear. The aim of our study was to explore the prevalence of various cancer susceptibility genes mutations as well as identification of new candidate endometrial cancer predisposition genes in our set of unselected patients. We analyzed germline DNA of 107 unselected endometrial cancer patients (aged 27-91). We used a custom-designed CZEKANCA panel for the targeted next-generation sequencing (NGS) analysis of cancer-predisposition and candidate genes. The panel targets 219 selected genes with a known predisposition to hereditary cancer syndromes and other genes that code for proteins involved in the DNA repair and/or DNA damage response with uncertain clinical relevance. In total, we identified 12 clearly pathogenic mutations in hereditary cancer predisposition genes in 11 (10,3%) endometrial cancer patients. We found four mutations in *BRCA1*, four mutations in Lynch genes (2x *MLH1*, 1x *MSH2*, and 1x *MSH6*); one patient harbored both *BRCA1* and *MLH1* mutation. In addition we found 2 mutations in *CHEK2* and one mutation in *ATM* and *NBN* each. Four of the mutations' carriers (2x *BRCA1*, *CHEK2*, and *MSH6*) were diagnosed with endometrial cancer only, seven carriers had personal history of multiple tumors. We also found 27 truncating variants of other genes in 26 patients and 38 missense alterations in 31 patients predicted to be pathogenic, whose impact on protein function and clinical significance needs to be evaluated. Our data indicate that the frequency of germline mutations in unselected endometrial cancer patients might be higher than previously expected. It is also showed that endometrial tumors can develop either within Lynch and HBOC syndromes or as a unique cancer diagnose. The mutation spectrum also confirms that wider range of phenotypes associated with germ-line mutations of cancer-susceptibility genes is becoming increasingly apparent. Acknowledgement: This work was supported by grants AZV MZCR NV15-27695A, NV16-29959A and the grants of Charles University PROGRES Q28/LF1 and SVV2018/260367.

**Using massively parallel reporter assay (MPRA) to simultaneously screen for functional variants at 22 common pancreatic cancer risk loci identified by genome wide association studies (GWAS).** A. Jermusyk<sup>1</sup>, L. Gu<sup>1</sup>, L. Rost<sup>1</sup>, J. Choi<sup>1</sup>, L. Collip<sup>1</sup>, J. Zhong<sup>1</sup>, J. Hoskins<sup>1</sup>, I. Collins<sup>1</sup>, S. Chanock<sup>2</sup>, K. Brown<sup>1</sup>, K. Yu<sup>2</sup>, L. Amundadottir<sup>1</sup>. 1) Laboratory of Translational Genomics, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Gaithersburg, MD; 2) Biostatistics Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Gaithersburg, MD; 3) Laboratory of Genetic Susceptibility, Division of Cancer Epidemiology and Genetics, National Cancer Institute, Gaithersburg, MD.

GWAS have identified over 20 pancreatic cancer risk loci in individuals of European descent. After GWAS, fine-mapping and functional analysis must be carried out to identify functional variants from the large number of highly correlated variants at each locus, a time intensive process. We used a high-throughput sequencing approach, Massively Parallel Reporter Assay (MPRA), to simultaneously test correlated variants from multiple pancreatic cancer risk loci for allele specific enhancer activity. We tested 950 germline variants at 22 established and suggestive risk loci in two pancreatic cancer cell lines (PANC-1 and MiaPaCa-2) and a human embryonic kidney cell line (HEK293T). Significant allelic differences were noted for one or more variants at 21 risk loci, indicating that some risk loci may contain multiple functional variants. We validated several of these functional variants by individual luciferase assay and performed electrophoretic mobility shift assay (EMSA) to identify allele specific transcription factor binding. One of these loci we are validating is 22q12 which includes XBP1, a transcription factor important for pancreatic homeostasis and recovery after inflammation. Three of the top variants at this locus from our MPRA analysis also exhibit expression quantitative trait loci (eQTL) in pancreatic tissue datasets (GTEx set, n=115 samples in histologically normal tissues; TCGA pancreatic cancer tissues, n=115) with XBP1. Since XBP1 is an important component of the unfolded protein response (UPR), this may result in an abrogated response to endoplasmicreticulum (ER) stress. We anticipate that our high throughput MPRA approach will shorten the time from GWAS discovery to biological understanding for multiple pancreatic cancer risk loci. This will help us unravel the underpinnings of the mechanisms that influence pancreatic cancer susceptibility.

**High-density genotyping and whole-genome sequencing-based investigation of malignant pleural mesothelioma primary cells.** A.K. Mandal<sup>1</sup>, A. Nastase<sup>1</sup>, T. Chernova<sup>2</sup>, D. Morris-Rosendahl<sup>1,3</sup>, M. Edwards<sup>1,3</sup>, R.C. Rintoul<sup>4</sup>, E. Lim<sup>5</sup>, S. Popat<sup>6</sup>, M. Lathrop<sup>7</sup>, A.E. Willis<sup>2</sup>, A. Nicholson<sup>8</sup>, W. Cookson<sup>1,9</sup>, M. MacFarlane<sup>2,9</sup>, M.F. Moffatt<sup>1,9</sup>. 1) National Centre for Mesothelioma Research, Imperial College London, United Kingdom; 2) Medical Research Council Toxicology Unit - University of Cambridge, Hodgkin Building, Leicester, United Kingdom; 3) Clinical Genetics and Genomics, Royal Brompton and Harefield NHS Foundation Trust, United Kingdom; 4) Department of Thoracic Oncology, Papworth Hospital, Cambridge, United Kingdom; 5) Department of Thoracic Surgery, Royal Brompton and Harefield NHS Trust, London, United Kingdom; 6) Department of Medicine, Royal Marsden Hospital, London, United Kingdom; 7) Department of Human Genetics, McGill University-Génome Québec Innovation Centre, Québec, Canada; 8) Department of Pathology, Royal Brompton and Harefield NHS Trust, London, United Kingdom; 9) Corresponding author.

Malignant pleural mesothelioma (MPM) is a rare and aggressive disease with poor prognosis on chemotherapy standard of care. Research into genomic aberrations that can help to stratify patients are urgently needed. As a model system, primary cells are more representative of the tumour tissue and in this study, using genotyping and whole-genome sequencing (WGS), we aimed to characterise more than 20 MPM primary cells. Twenty-three primary cells (obtained from the MRC Toxicology Unit, Leicester, n=20 and Mesobank UK, the BLF funded Mick Knighton Mesothelioma Tissue Bank, n=3), all derived from patients' tumours and one normal omental mesothelial primary cell were included in the study. All primary cells were analysed by genotyping and 20 of them further through WGS. Regions of significant focal copy-number aberrations (CNA) were identified using a combination of ASCAT (v.2.4.4), DNACopy (v.1.52.0) and GISTIC (v2.0.23) softwares. For WGS, alignment, quality-checking and variant calling were done using BWA, Picard and GATK softwares respectively. Variants were annotated using Ensembl Variant Effect Predictor (VEP; v92). Twenty-one of the primary cells were derived from male patients, with an average age of 68.2 years. Histologically, epithelioid was the major subtype. ASCAT software called eight of the primary tumour cell and the normal omental as 'non-aberrant'. For the aberrant primary cells, locus 9p21.3 containing *CDKN2A* and *MTAP* genes, was the most common deletion, followed by locus 16p13.3 (containing the *RBFOX1* gene). Loss of whole chromosome 4 was also seen in 4/15 (26.7%) of the analysed samples. Among the ASCAT classified 'aberrant' cell that were whole genome sequenced, analysis showed *BAP1* to be the most frequently mutated with 5/11 cases. Also observed were *NF2* in 4/11 cases, *SYNE1* in 3/11 cases and *TP53* in 2/11 cases. These mutations are primarily either frameshift, stop-gain or splice-site altering which indicates the tumour suppressor role of these genes. On the other hand, among ASCAT classified 'non-aberrant', all but one had no mutations detected in hallmark genes. That one primary cell has a splice-site altering *MSH6* mutation. MPM primary cells show similar mutation and CNA profile as tumour tissue, supporting their use as a pre-clinical model for understanding tumourigenesis and drug resistance. Further investigations using DNA methylation and transcriptome profiling are ongoing to make this model system more comprehensive.

**The identification of rare variants in Tasmanian prostate cancer pedigrees using whole-genome sequencing.** K. Raspin<sup>1</sup>, LM. FitzGerald<sup>1</sup>, JR. Marthick<sup>1</sup>, MA. Field<sup>2,3</sup>, RC. Malley<sup>4,5</sup>, RJ. Thomson<sup>6</sup>, A. Banks<sup>7</sup>, S. Donovan<sup>7</sup>, JL. Dickinson<sup>1</sup>. 1) Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania, Australia; 2) Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Queensland, Australia; 3) Genome Informatics, John Curtin School of Medical Research, Australian National University, Canberra, ACT, Australia; 4) Royal Hobart Hospital, Hobart, Tasmania, Australia; 5) School of Medicine, University of Tasmania, Hobart, Tasmania, Australia; 6) Western Sydney University, Sydney, New South Wales, Australia; 7) Hobart Pathology, Hobart, Tasmania, Australia.

Prostate cancer (PCa) is a highly heterogeneous disease with studies suggesting a degree of heritability greater than other cancers. It has been found that as much as 58% of disease risk can be explained by heritable factors. While more than 150 common genetic risk variants have been identified, these variants still only explain a minor portion of risk, are largely of low to moderate effect size, and are functionally ambiguous. There has recently been significant success in the discovery of rare genetic variants contributing to complex disease, through next-generation sequencing of large families, where rare variants are enriched and there is reduced genetic complexity. Here, we have applied whole-genome sequencing (WGS) to several large Tasmanian PCa pedigrees with the aim of identifying rare genetic variants contributing to the development of PCa. Thirty-seven individuals from six PCa pedigrees were WGS on the Illumina HiSeq X™ Ten platform. Variants were prioritised on a per-family basis by frequency (<1% in 1KGP, UK10K, ExAC and ESP), segregation with disease, mutation type (missense, nonsense or splice) and predicted functional consequence (CADD, PolyPhen and SIFT). Unaffected older male relatives and population controls were also WGS and used to prioritise variants based on non-sharing. After additional genotyping in our larger familial and population datasets, familial-based association testing found two variants to be significantly associated with PCa risk. A rare variant in the non-coding region of the *EZH2* gene was identified in two Tasmanian families, and has the potential to effect splicing. *EZH2* is constitutively overexpressed in many cancer, including PCa, and therefore, functional studies are currently underway to determine the effect of the mutation on gene and protein expression. This study was designed to identify new biological pathways involved in the pathogenesis of familial PCa and may lead to novel diagnostic and therapeutic targets for PCa patients.

**Integrating exome and transcriptome sequencing data revealed genes of TLR-activated MAP-Kinase signaling to be clinically important in oral cancer.** R. Singh<sup>1</sup>, M. Pal<sup>1</sup>, B. Roy<sup>1</sup>. 1) Human Genetics Unit, Indian Statistical Institute, Kolkata, India; 2) Department of Oral Pathology, Guru Nanak Institute of Dental Science & Research, Kolkata, India.

**Background:** Oral cancer constitutes about 95% of head and neck cancers and is one of the most prevalent types of cancers in India. Although whole exome studies in oral cancer have reported somatic mutational driver genes, studies on integrating whole exome and transcriptome sequencing data in the same tumors to identify potential therapeutic targets have been rare. **Objective:** Aim of the study is to integrate mutation and expression data to identify potential therapeutic targets in oral cancer. It further intends to explore the impact of somatic mutations on allelic expression imbalance. **Methods:** Whole exome and transcriptome data was generated from 11 pairs of tumor-normal oral cancer samples to uncover somatic mutations and expression deregulation. Allelic expression imbalance was also calculated by comparing the mutated allele frequency in genes and corresponding transcripts in tumor tissues. **Results:** Majority of mutated genes were found to be involved in TLR-activated MAPK signaling. Upon analyzing expression and mutation data, it was realized that genes altered due to mutation were mostly different from those which showed deregulated expression. Genes of receptor nodes (*TLR1*, *TLR2* and *TLR8* and *IFNAR2*) and downstream effector nodes interleukins (*IL8* and *IL1B*) were upregulated while mutated genes mostly accumulated in intermediate MAPK signaling components. Mutations in MAPK signaling and upregulated expression of *TLR2* (most deregulated receptor) and *IL8* (most deregulated effector) were confirmed from TCGA HNSCC cohort. *IL8* was also upregulated in a set of trios (n=14) with oral tumors, leukoplakia and normal samples from same individuals. Few genes of MAPK signaling pathway such as *TP53*, *KRAS*, *FOS*, *GNG12* and *HSPA2* further showed allelic expression imbalance with a preferential expression of mutated alleles than wild type allele. Apart from mutation in *TP53* and *CASP8*, 5-year disease free survival rate was calculated using TCGA HNSCC cohort data and found to be lower than 50% of the patients with mutations in other MAPK signaling genes, such as *CACNA1D*, *CACNA2D4* and *PRKCG*. **Conclusion:** Overall, the results showed importance of *IL8* in progression of leukoplakia to oral cancer, which is reported to be clinically important in other cancers. It also suggests other mutated components of TLR-activated MAPK pathway, *KRAS* and *HSPA2* (with allelic expression imbalance) and *CACNA1D* (associated with survival rate) as potential drug targets, similar to other cancers. .

Kleibl<sup>5</sup>.

1) Institute of Biochemistry and Experimental Oncology, First Faculty of Medicine, Charles University, Prague, Czech Republic; 2) Institute of Biology and Medical Genetics, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; 3) Laboratory of Cancer Cell Biology, Institute of Molecular Genetics of the ASCR, Prague, Czech Republic; 4) Department of Oncology, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic; 5) Research Unit for Rare Diseases, Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University and General University Hospital, Prague, Czech Republic.

Hereditary mutations in *CHEK2* gene predispose to various types of tumors, including breast cancer. Data from next gene sequencing (NGS) revealed a spectrum of other *CHEK2* mutations with a strong population variability. While truncating variants affecting kinase domain are considered as deleterious, the clinical significance of rare missense variants is unknown. The entire *CHEK2* coding sequence was analyzed in 1928 high-risk breast (BC) and/or ovarian cancer (OC) patients negatively tested for BC/OC-susceptibility genes mutations (by gene-by-gene analysis/ multigene NGS) previously and in 2184 geographically-matched controls. We identified 8 truncations in 39 patients (including two revertant large genomic rearrangements) and 25 non-frame shift variants (in-frame deletion or SNV) in 96 patients. Using CRISPR/Cas9, we developed *CHEK2* knock-out cell line enabling functional classification of VUS revealing 12/25 VUS as deleterious. Deleterious mutations were significantly enriched (over controls) in female BC patients (51/1526; 3.34% vs. 8/2184; 0.37%; OR=3.87; p=5.25E-13), male BC patients (4/48; 8.3%; OR=10.17; p=8.22E-5), OC patients (6/354; 1.69%; OR=2.64; p=0.008). The analysis of histopathological data in female BC patients showed that carriers of deleterious *CHEK2* variants develop more frequently luminal A subtype (19/37; 51% vs. 269/898; 30% in non-carriers; p=0.006) and G2 tumors were detected in 27/40 (67.5%) mutation carriers vs. in 399/898 (44.4%) of non-carriers; p=0.0005). Our results demonstrated that functional analyses of *CHEK2* VUS enable sorting of neutral from deleterious mutations that contribute to the BC/OC risk, thus help to identify clinically significant hereditary *CHEK2* variants. Supported by grants AZV NV15-28830A, NV-16-29959A, SVV2018/260367 and GAUK 762216.

**Detection of somatic L1 insertions in single nuclei from cancer tissues.**

K. Yamaguchi, A.O. Soares, J.A. Choi, H.H. Kazazian Jr. Johns Hopkins University, Baltimore, MD.

Long interspersed element-1s (L1s) are transposable elements that proliferate in human genomes. L1 retrotranspositions are endogenous mutagens that cause insertional mutations in chromosomes and have caused over 150 cases of genetic diseases. Recently, our group found somatic insertions in Barrett's esophagus-, pancreatic-, colon- and gastric cancer. These insertions are present in both pre-cancer and cancer, suggesting that L1 insertion events occur before or very early during cancer development. However, from these findings using bulk gDNA from cancer patients, we could not know how the number and varieties of L1 retrotransposition events vary among individual cells and how the cells which have de novo somatic insertions are distributed in pre-cancerous and cancer tissues. To further understand somatic L1 retrotransposition which contributes to cancer induction, we established a new method to detect L1 insertions from single nuclei based on capturing circularized L1 fragments containing 3' flanking gDNA. Using this method, we investigated L1 insertions in single nuclei from colon cancer, liver metastasis, and normal liver. By PCR and Sanger sequencing, we found nine new L1 insertions that were not observed in bulk gDNA from the same patient. From further investigation in single nuclei, we found five other insertions that had been previously observed in bulk gDNA from the same patient. Of these 14 insertions, 4 were also present in normal liver. Therefore using this new technique we can find new somatic L1 insertions in single nuclei that are not found in bulk gDNA study. In addition, many of these insertions in cancer are already present in normal cells. Based on this and future data, we should be able to determine how the new L1 insertions spread in cancerous cells.

**Concordance of *ERBB2* amplification identification in breast primary tumors and cfDNA.** Y. Zheng<sup>1</sup>, T.F. Yoshimatsu<sup>1</sup>, S. Dentro<sup>2,3</sup>, P. Polak<sup>4</sup>, O.I. Olopade<sup>1</sup>. 1) Department of Medicine, The University of Chicago, Chicago, Illinois, United States of America; 2) Wellcome Trust Sanger Institute, Cambridge, United Kingdom; 3) The Francis Crick Institute, London, United Kingdom; 4) Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai Hospital, New York City, New York, United States of America.

**Background:** Breast cancer subtyping in resource poor setting is challenging due to lack of resources including access to molecular pathology. The amplification of the *ERBB2* gene results in overexpression of HER2 protein (human epidermal growth factor receptor 2), and HER2 targeted therapy has been shown to be effective in patients with HER2+ breast tumors. Recent development of robust cell-free tumor DNA (cfDNA) sequencing could be used to determine the HER2 status of tumor before resection. **Methods:** The cfDNA were extracted from plasma samples collected from eight Nigerian invasive breast cancer patients prior to surgery. Ultra-low-pass whole genome sequencing (ULP-WGS, 0.1X) and ichorCNA analyses were performed to quantify the percentage of tumor DNA in the plasma. In contrast, high-coverage WGS (90X) of untreated primary tumors from the same patients has been done and somatic copy number alterations (SCNAs) were called using the Battenberg algorithm. For each patient, we compared the breast cancer SCNAs identified by ichorCNA and Battenberg and particularly in the *ERBB2* region. **Results:** The mean age of the eight breast cancer patients was 51 (SD±9.7) years old. Tumors included in the study were 1 HR (hormone receptor)+/HER2-, 3 HR-/HER2-, and 4 HR-/HER2+. Among five patients (3 HER2- and 2 HER2+) with tumor fraction >0.05 (average 0.19) in cfDNA, the genome-wide and *ERBB2* region-wide SCNA predictions were comparable between the two methods. In addition, two *ERBB2* amplification events were identified by both NGS-based methods, which was in line with the HER2+ status of the patients. In the remaining three patients (1 HER2- and 2 HER2+), Battenberg detected *ERBB2* amplifications in two HER2+ tumors correctly, whereas ichorCNA was underpowered to detect apparent SCNAs including the *ERBB2* amplification, likely due to low tumor fraction in their cfDNA (0.031, 0.04, and 0.041 respectively). **Conclusion:** Our study show that *ERBB2* amplification can be called confidently at time of diagnosis and before tumor resection using cost-effect ULP-WGS from as low as 0.05 tumor fraction, allowing for earlier detection of gene amplification and strategic planning of targeted treatment. Furthermore, the ichorCNA approach accurately captured the SCNA profile of primary tumors from cfDNA, which suggests it can be useful on other clinically actionable SCNA segments in an effort to provide effective treatments earlier.

**Characterisation of renal cell carcinoma associated constitutional translocations by whole genome sequencing-derived structural variation analysis and literature review.** P.S. Smith<sup>1</sup>, H. West<sup>1</sup>, J. Whitworth<sup>1</sup>, J. Cook<sup>2</sup>, M.D. Tischkowitz<sup>1</sup>, E.R. Maher<sup>1</sup>. 1) Department of Medical Genetics, University of Cambridge, Cambridge, United Kingdom; 2) Department of Clinical Genetics, Northern General Hospital, Sheffield, United Kingdom.

Renal cell carcinoma (RCC) is a group of genetically heterogeneous neoplasms originating in the kidney and though most cases occur sporadically, a proportion of cases are heritable. Constitutional translocations, particularly involving chromosome 3p, have been previously reported as a cause of inherited RCC and to date 17 individual cases/families have been described. We have identified a series of rare individuals with constitutional translocations ascertained following a diagnosis of RCC and cytogenetic analysis. To investigate the potential mechanisms of RCC predisposition, we performed whole genome sequencing in three cases (t(2;17)(q21;q11.2), t(3;6)(p14.1;p12.1), t(3;14)(q13.3;q22)). Sequencing was aligned to the GRCh38 human reference build and structural variants were called by Manta structural variation and indel caller. Sanger sequencing was performed to confirm candidate breakpoint regions. Most breakpoints did not disrupt known coding regions suggesting that chromosomal instability rather than disruption of a specific gene may be the cause of RCC susceptibility. However a t(2;17)(q21;q11.2) breakpoint disrupted a region 12Kb upstream of *NLK*, the protein product of which interacts indirectly with F-box/WD repeat-containing protein 7 (*FBXW7*). Interestingly, a RCC-associated constitutional t(3;4)(q21;q31) was reported previously to disrupt *FBXW7* (Kuiper RP et al. Cancer Genet Cytogenet. 2009;195:105-11).

**Using capture-C to map chromatin architecture of 24 renal cancer susceptibility regions in human cells.** L. Jessop<sup>1</sup>, L.M. Colliri<sup>1</sup>, K. Jones<sup>2</sup>, S.J. Chanock<sup>3</sup>. 1) LGS, DCEG, NCI, Bethesda, MD; 2) CGR, DCEG, NCI, Bethesda, MD; 3) DCEG, NCI, Bethesda, MD.

Cancer susceptibility loci identified by genome-wide association studies (GWAS) are frequently located in intergenic regions and are expected to be involved in regulating gene expression. Because regulatory regions can be located distant from their target promoter, it is not straightforward to identify the gene targets of GWAS hits. The chromosome conformation capture methodologies (such as 3C, HiC) have been used to gain understanding about the 3-dimensional architecture of chromosomes and enhancer-promoter interactions; however, the resolution of Hi-C experiments depends in large part on the depth of sequencing, making it difficult to probe specific promoter-enhancer interactions. Others have addressed this limitation by adding a sequence-capture step (Capture-C) to focus on interactions with regions of interest. Here we apply the Capture-C method to 24 regions identified by GWAS as achieving genome-wide threshold for significance, or approaching it, for association with renal cancer susceptibility. HiC libraries were prepared from HEK293T or ACHN cell lines using the 4-cutter, DpnII. The pool of biotinylated-RNA oligos used for sequence capture was designed to cover all SNPs with an LD of  $r \geq 0.2$  to the lead SNPs from each of the 24 GWAS regions. Resulting Capture-C libraries were paired-end sequenced on Illumina HiSeq4000 or NextSeq. After trimming and filtering there were 595M PE reads for HEK293T, and 681.5M for ACHN. Reads were mapped to GRCh37/hg19 using the HiC-Pro pipeline, and the resulting BAM files were processed using CHiCago (settings minFragLen 25, maxFragLen 2500, binsize 1250, all others default) to detect statistically significant interactions. We found 445,773 interactions in HEK293T, and 809,142 in ACHN with a CHiCago signal cutoff of at least 5. We previously reported that rs7132434 regulates expression of *BHLHE41*, at the 12p21 renal cancer susceptibility locus. Our Capture-C results confirm this by showing a physical interaction between this SNP and gene. This new resource will be used to further explore the chromatin interactions of these 24 regions.

**Comparison of intra-tumor heterogeneity and clonal evolution across lung cancer subtypes by multi-region whole genome sequencing.** T. Zhang<sup>1</sup>, J. Sampson<sup>1</sup>, P. Bertazzi<sup>2</sup>, A. Pesatori<sup>2</sup>, D. Consonni<sup>2</sup>, B. Zhu<sup>1</sup>, B. Hicks<sup>1</sup>, X. Hua<sup>1</sup>, J. Shi<sup>1</sup>, K. Brown<sup>1</sup>, S. Chanock<sup>1</sup>, M. Landi<sup>1</sup>. 1) National Cancer Institute, Bethesda, MD; 2) University of Milan, Milan, Italy.

Both lung squamous cell carcinoma (LUSC) and lung cancer with neuroendocrine features (LUNE; i.e., small cell carcinoma (SCLC), large cell carcinoma (LCNEC) and other subtypes) are associated with tobacco smoking and have a very poor prognosis. We sought to characterize their clonal architecture and illustrate how the evolutionary patterns differ across these lung cancer subtypes. We performed multi-region whole genome sequencing of 83 samples from 36 LUSC and 67 samples from 23 LUNE patients that had been resected before systemic therapy. Among somatic copy number alterations, we observed genome doubling intra-tumor heterogeneity (ITH) and massive genomic instability in both subtypes. For somatic nucleotide variants (SNVs), the total mutation burden was higher in LUSC (16.7 average number of mutations/Mb) than LUNE (12.7/Mb), but for SNVs ITH was higher in LUNE. Among driver genes, *TP53*, *CDKN2A*, *CR1*, and *NRK* in LUSC and *TP53*, *KRAS*, *KMT2D*, and *RB1* in LUNE were frequently mutated and were always clonal. Evidence of positive selection was found for *TP53*, *PTEN*, *KMT2D* and *KEAP1* in LUSC, and for *TP53* and *KRAS* in LUNE. As expected, the dominant mutation signatures in LUSC clones included signatures 4, 1, and 5, while APOBEC signatures (2 and 13) were predominantly found in sub-clones. In contrast, very little evidence of APOBEC signatures were found in LUNE. Among structural variants, LUNE had more events (339.25 average number of events/tumor) than LUSC (206.7/tumor), with considerable ITH in both subtypes, particularly in LUNE. In LUNE, the dominant mechanism responsible for SVs included fork stalling and template switching within the microhomology-mediated break-induced repair (MMBIR). We found recurrent fusion events with hotspots including those previously identified near *TTC28/CHEK2* (42% LUSC and 35% LUNE) and *LRP1B* (42% LUSC). Additional hotspots were found in chromosome bands 20p12.1 (22% LUSC), 1p31.1 (19% LUSC) and 12p11.22 (22% LUNE). We found >10-fold higher transposon insertions (LINE1) in LUSC (71.9 average number of events/tumor) than LUNE (6.3/tumor). Our findings improve our evolutionary understanding of these lung cancer subtypes and warrant further investigations on the mechanisms involved in clonal genomic instability.

### 943T

**Genome-wide analysis of G4 sequences overlapped with SP1/MAZ binding sites in the human genome and their roles in gene regulation of the proto-oncogene Bcl3.** V. Bansal<sup>1</sup>, S. Cho<sup>2</sup>, A. Ahmed<sup>1</sup>, K. Kim<sup>1,2</sup>. 1) Department of Molecular Cell Biology, Sungkyunkwan University School of Medicine, Suwon 440-746, Korea; 2) Department of Health Sciences and Technology, SAIHST, Sungkyunkwan University, Seoul, Republic of Korea.

G-rich sequences in the genome of any organisms can fold into a special type of non-canonical structure known as a G-quadruplex (G4). It is believed that G4 structures not only act as physical barrier for transcription or translational machinery but also work as an adaptor for recruiting associated proteins. MYC-associated Zinc finger Protein (MAZ) and Specificity Protein 1 (SP1), transcription factors recognizing GC rich sequences, are well known G4 associated proteins that binds to G4s present in the promoters regions of several oncogenes such as MET, VEGF, HRAS and KRAS for the regulation of their gene expression. Although extensive genome-wide studies have been performed to identify the location and function of G4s, characterization of G4s that contains the binding site for the G4-associated proteins, name it "G4 with associated protein binding site (G4-APB)" has less investigated. In this study, we studied G4 with MAZ and SP1 binding sites (G4-MS) present in the promoter regions of all human genes including 2000 cancer genes to investigate their roles in gene expression as well as in cancer. Among the cancer-associated G4-MSs, we further characterized G4-MS present in the promoter region of Bcl3, a well-known proto-oncogene, to investigate the role of G4 with SP/MAZ site and its effect on Bcl3 promoter in cancer progression. In-vitro studies like CD spectroscopy, Thioflavin T assay, Polymerase stop assay, NATIVE PAGE etc, was used to identify and characterized a G-quadruplex (named PU24WT) present in proto-oncogenic candidate Bcl3 gene near the transcription start site (TSS). Direct Chip binding analysis confirmed the binding of both SP1 and MAZ to PU24WT Bcl3 promoter region. Experimental studies reveal that TMPyP4 treatment decreases the Bcl3 luciferase promoter expression. Accordingly, treatment of TMPyP4 decreased Bcl3 RNA level in human breast cancer cell line. Subsequently, Chip data analysis in the presence of Tmpy4 shows decrease in binding of SP1 and MAZ at the PU24WT Bcl3 promoter region. This is the first study done on G-quadruplex structure in human Bcl3 promoter. In addition, since it was confirmed that TMPyP4 treatment can effectively suppress the Bcl3 expression by blocking SP1/MAZ binding to G4-MS<sub>BCL3</sub>, it is proposed that targeting G4-MS<sub>BCL3</sub> can be used as a novel strategy for breast cancer treatment. **Keywords: G4, BCL3 Promoter, TMPyP4.**

**Methylation quantitative trait loci analysis of human primary melanocytes informs melanoma susceptibility.** J. Choi<sup>1</sup>, T. Zhang<sup>1</sup>, M. Kovacs<sup>1</sup>, M. Xu<sup>1</sup>, A. Vu<sup>1</sup>, S. Loftus<sup>2</sup>, W. Pavan<sup>2</sup>, G. Jonsson<sup>2</sup>, K. Brown<sup>2</sup>, NISC Comparative Sequencing Program, Melanoma Meta-Analysis Consortium. 1) Division of Cancer Epidemiology and Genetics, NCI, Bethesda, MD; 2) NHGRI, Bethesda, MD; 3) Division of Oncology and Pathology, Department of Clinical Sciences, Faculty of Medicine, Lund University, Sweden.

Genome wide association studies (GWAS) have identified a multitude of loci correlated with melanoma risk. While the number of GWAS loci is continuously increasing due to large meta-analyses and rapidly growing cohort-based datasets, functional annotation of these loci still lags behind. To this end, expression quantitative trait loci (eQTL) analysis has been critical in identifying target susceptibility genes from GWAS loci, with abundantly available tissue-level eQTL datasets accounting for highly tissue-specific nature of eQTL. However, eQTL alone is far from complete in GWAS annotation, and alternative QTLs including DNA methylation QTL (meQTL) have not been explored as well. DNA methylation is an interesting molecular feature, where both genetic and epigenetic control contribute to gene expression regulation leading to cellular differentiation, tissue development, and tumorigenesis. To assess genetic contribution to melanocyte-specific DNA methylation, we established meQTL dataset using cultured primary melanocytes from 106 individuals mainly of European descent. To enable multi-QTL integration in the same samples, we also established RNA-based datasets including eQTL, splice QTL, and microRNA QTL. For meQTL, we measured global DNA methylation using Illumina Human Methylation 450K BeadChip, and also obtained >10 million genotypes by genotyping and imputation. In all, we identified *cis*-meQTL for 13,243 methylation probes at a genome-wide significant level (FDR < 0.05). Significant *cis*-meQTLs were mainly observed in CpG probes displaying high methylation variabilities (> 50%), and clustered in close proximity to the CpG sites (< 500kb). meQTLs were significantly enriched in melanoma GWAS loci (4.98E-11; Wilcoxon rank sum test). While formal colocalization analyses are ongoing, 9 of 20 published melanoma GWAS loci including previously characterized *PARP1* locus displayed immediate overlap with significant meQTL. Subsequent integration of melanocyte meQTL with our RNA multi-QTL data will elucidate the interplay of SNP, methylation, and gene expression, which underlies melanoma susceptibility. Further, we are comparing melanocyte meQTL to those from TCGA melanomas (n = 444) and additional melanoma samples (n = 184) to understand the tumor-normal dynamics of meQTL. Our dataset is one of the first and largest cell-type specific meQTL datasets using primary melanocytes, and will benefit melanoma genetics and pigmentation biology community.

**CD44 and EGFR genes expression and response to Cetuximab and Paclitaxel in oral and laryngeal cancer stem cells.** L.A.M. Ferreira<sup>1</sup>, G.M.M Fernandes<sup>1</sup>, A.L.S. Galbiatti-Dias<sup>1</sup>, M.M.U. Castanhole-Nunes<sup>1</sup>, L.F. Hidalgo<sup>1</sup>, R.S. Kawasaki-Oyama<sup>1</sup>, P.M. Biselli-Chicote<sup>1</sup>, J.V. Maniglia<sup>2</sup>, E.C. Pavarino<sup>1</sup>, E.M. Goloni-Bertollo<sup>1</sup>. 1) Genetics and Molecular Biology Research Unit - UPGEM, Molecular Biology Department FAMERP- São José do Rio Preto Medical School – Brazil; 2) Otorrinolaringology e Surgery of Head and Neck Cancer Department - FAMERP- São José do Rio Preto Medical School – Brazil.

**Introduction:** Head and neck cancer stem cells (HNCSCs) correspond to a small population of cells inside the tumor that exhibit self renewal ability and are responsible for tumor initiation, maintenance, origin of metastases and resistance to treatments. **Objectives:** To identify HNCSCs and non-HNCSCs; to investigate the influence of Cetuximab and Paclitaxel treatments in the cell viability, in both cell subpopulations; to evaluate *CD44* and *EGFR* gene expression in HNCSCs. **Material and Methods:** HNCSCs were isolated from two cell lines (HN13-oral cancer and HEP2-laryngeal cancer) by fluorescence activated cell sorting flow cytometry, which identify cells stained with fluorescence-conjugated CD44, CD117 and CD133. CD44-/CD117-/CD133- cells were characterized as HNCSCs and CD44-/CD117-/CD133+ as non-HNCSCs. The scratch assay was performed to evaluate the potential cell migration. *CD44* and *EGFR* mRNA expression levels in non-treated HNCSCs were determined by quantitative real time PCR (qPCR) using TaqMan® Assay, using non-HNCSCs as relative expression control. After, the cell subpopulations were treated with Cetuximab (0.06mg/ml) and Paclitaxel (0.05mg/ml) for 24h, separately. To assess the response to treatments the MTS assay was performed. Statistical analyses were carried out using Chi-square test and  $p < 0.05$  was considered significant. **Results:** HNCSCs presented increased rate of migration compared to non-HNCSCs. We found that HNCSCs from HN13 cell line demonstrated more resistance to Paclitaxel treatment, when compared with non-HNCSCs ( $p < 0.0001$ ). In laryngeal cancer the results were not statistically significant (Table 1). HNCSCs from HN13 cell line presented upregulation of *CD44* gene and downregulation of *EGFR* gene. In HEP2 cell line, the results were opposite. **Conclusion:** The CD44-/CD117-/CD133- cells have stem cell properties. Paclitaxel treatment is less efficient in HNCSCs from oral cancer cell line. Differential expression of *CD44* and *EGFR* genes observed in HNCSCs contribute to a molecular characterization of the different anatomical sites, which is fundamental for the development of specific therapeutic strategies.

Cell lines	Subpopulations	Cetuximab %Cell viability	p-value	Paclitaxel %Cell viability	p-value
HN13	HNCSCs	97	0.074	88	<0.0001*
	non-HNCSCs	91		44	
HEP2	HNCSCs	87	0.5061	50	0.321
	non-HNCSCs	90		57	

**Funding:** FAPESP 2015/04403-8, CNPq, CAPES.

## 946T

**Analysis of enhancer/promoter chromatin interactions in normal and cancer endometrial cell lines reveals candidate gene targets at endometrial cancer risk loci.** D.M. Glubb<sup>1</sup>, P.F. Kho<sup>1</sup>, D.J. Thompson<sup>2</sup>, A.B. Spurdle<sup>1</sup>, T.A. O'Mara<sup>1</sup>, Endometrial Cancer Association Consortium. 1) QIMR Berghofer Medical Research Institute, Brisbane, Australia; 2) University of Cambridge, Cambridge, United Kingdom.

We have previously used genome-wide association studies and meta-analyses to uncover 16 genetic risk loci for endometrial cancer. However, the regulatory targets at these loci have not been systematically evaluated. To identify candidate gene targets at endometrial cancer risk loci, we have assessed chromatin looping interactions between endometrial cancer risk variants and neighboring genes using the global HiChIP technique in endometrial cell lines. As we have found enrichment of endometrial cancer risk variants in H3K27Ac histone modification regions (characteristic of enhancers and promoters), H3K27Ac-associated chromatin interactions were captured for analysis. To perform HiChIP, normal (E6/E7 hTERT immortalized endometrial glandular cells) and cancer (Ishikawa, JHUEM-14 and ARK-1) endometrial cells were cross-linked and proximity ligation performed. H3K27Ac-associated chromatin was isolated and HiChIP libraries prepared before sequencing using the Illumina HiSeq 4000 system. HiChIP paired-end reads were aligned using the HiC-Pro pipeline and filtered for valid reads. The hicchipper package was used to identify and characterise global chromatin interactions (FDR < 0.05). At endometrial cancer risk loci, we identified chromatin interactions between risk variants and more than 60 candidate target genes. Interaction distances ranged from 4 kb to over 1 Mb. Expression of several candidate genes, including *CYP19A1*, *SKAP1*, *SNX11* and *EIF2AK4* was found to associate with endometrial cancer risk in whole blood transcriptome-wide association studies (TWAS). Ingenuity Pathway Analysis revealed that candidate genes were enriched for relevant functional annotations such as morphology of the reproductive system, immortalization, and tumor cell activation, proliferation, adhesion and migration. Furthermore, analyses identified major networks which were enriched for genes involved with p53, MYC-mediated apoptosis, IL-8, IL-2, prolactin, wnt/b-catenin and endometrial cancer signalling. In summary, we have performed the first global studies of chromatin interactions in normal and cancer endometrial cell lines. This analysis has revealed biologically relevant candidate target genes at endometrial cancer risk loci, some of which were supported by TWAS analyses. Transcriptional regulation of candidate target genes by endometrial cancer risk variants and their cellular effects will be assessed in future studies.

**947F****Identification of novel gene expression regulators using HyCCAPP.** *H.*

*Guillen<sup>1</sup>, S. Leng<sup>2</sup>, D. Perumalla<sup>1</sup>, A. Jadhav<sup>1</sup>, M. Olivier<sup>1</sup>.* 1) Wake Forest School of Medicine, Winston Salem, NC; 2) Lovelace Respiratory Research Institute, Albuquerque, NM.

Hybridization Capture of Chromatin-Associated Proteins for Proteomics (HyCCAPP) is a recently developed methodology aimed at identifying, in an unbiased manner, DNA-bound proteins at a region of interest. In this application, we have adapted the approach to identify proteins regulating gene expression at promoter loci of interest. Crosslinked chromatin fragments are enriched through hybridization capture and bound proteins are identified and quantified by mass spectrometry. The *MGMT* promoter has been shown to regulate gene expression in a haplotype-specific manner in lung cancer cells. In an effort to identify haplotype-driven changes in protein binding correlated to distinct hypermethylation profiles within the *MGMT* promoter, H1299 lung cancer cells carrying different haplotypes were analyzed using the HyCCAPP methodology. Novel regulatory binding proteins, specific for individual haplotypes, are being validated using HyCCAPP, while at the same time, assembling the system to identify potentially targetable proteins mediating these interactions. This methodology can be a useful tool to explore known variants associated to changes in gene expression. This work is supported by NIH/NHGRI grants P50HG004952 and R01GM109099 and the Crump foundation.

**948W****Small noncoding RNAs associating with the outcome of breast cancer patients.** *J.M. Hartikainen<sup>1</sup>, S. Heikkinen<sup>2,3</sup>, E. Kärkkäinen<sup>1</sup>, M. Tengström<sup>4,5</sup>, V.-M. Kosma<sup>1,6</sup>, A. Mannermaa<sup>1,6</sup>.*

1) School of Medicine, Institute of Clinical Medicine, Pathology and Forensic Medicine, and Translational Cancer Research Area, University of Eastern Finland, Kuopio, Finland; 2) School of Medicine, Institute of Clinical Medicine, University of Eastern Finland, Kuopio, Finland; 3) School of Medicine, Institute of Biomedicine, University of Eastern Finland, Kuopio, Finland; 4) School of Medicine, Institute of Clinical Medicine, Oncology, and Cancer Center of Eastern Finland, University of Eastern Finland, Kuopio, Finland; 5) Cancer Center, Kuopio University Hospital, Kuopio, Finland; 6) Department of Clinical Pathology, Kuopio University Hospital, Kuopio, Finland.

We have performed small RNA-sequencing (RNA-Seq) of breast cancer (BC) tumors to identify small non-coding RNA (sncRNA) expression profiles which associate with the outcome of the patients. The underlying sample set is the 195 invasive BC tumor and 20 benign breast tissue samples from the Kuopio Breast Cancer Project (KBCP) study material. KBCP material is collected from a genetically homogeneous population of Eastern Finland, and includes e.g. fresh-frozen breast tissue samples, EDTA blood samples and serum, as well as comprehensive background/lifestyle information, clinical, treatment and follow-up data extending up to 25 years. Total RNA was extracted from fresh-frozen tissues using the Ambion mirVana miRNA Isolation Kit. Small RNA-Seq was performed using the Illumina TruSeq Small RNA Library Prep kit and the Illumina MiSeq sequencing instrument. Bioinformatic analysis of non-miRNA sncRNA expression included read quality assessment (FastQC v10.1), adapter trimming (TRIMMOMATIC v0.33), and removal of e.g. ribosomal RNA reads (Bowtie2 v2.2.3). Preprocessed reads were aligned (Tophat v2.0.13) to human reference sncRNA transcriptome (subset of GENCODE v22). Gene-wise read counts were collected using R function GenomicAlignments::summarizeOverlaps (v1.6.3), and statistically significantly differentially expressed (DE) sncRNAs were identified using R package DESeq2 (v1.14.1). Survival analyses were performed using R function survival::coxph (v2.41-3). Multivariate survival analyses that took into account clinical and treatment data identified several survival-affecting sncRNAs. For example, when sncRNA expression levels were divided into two groups at the median and clinical and treatment data were included in the statistical model, we observed 11 sncRNAs independently associating with BC-specific (BCSS), 11 with overall (OS), and 4 with recurrence-free survival (RFS) ( $P < 0.01$ ). Higher expression of 7, 8, and 2 sncRNAs associated with worse BCSS, OS, and RFS, respectively. Accordingly, lower expression of 4, 3, and 2 sncRNAs associated with worse BCSS, OS, and RFS, respectively. Furthermore, we identified DE sncRNAs ( $P_{adj} < 0.05$ ) between benign breast tissue and invasive BC, and among BC cases with invasive, local disease, between TNBC and luminal BC. The identified survival-associating sncRNA profiles may reveal signatures that aid in the prediction of therapy responsiveness, prognosis or patient outcome, and provide targets for future drug development.

**Methylation alterations in developmental and differentiation genes drive resistance to immunotherapy in a melanoma model.** A. Kashef<sup>1</sup>, S. Börner<sup>2</sup>, S. Sivalingam<sup>3</sup>, M. Renn<sup>4</sup>, J. Hausen<sup>5</sup>, T. Tüting<sup>6</sup>, M. Hölzel<sup>7</sup>, P. Krawitz<sup>2</sup>, J. Landsberg<sup>1</sup>. 1) Department of Dermatology and Allergy, University Hospital Bonn, 53127 Bonn, Germany; 2) Sequencing Core Facility, Max-Planck-Institute for Molecular Genetics, 14195 Berlin, Germany; 3) Institute of Human Genetics, University Hospital Bonn, 53127 Bonn, Germany; 4) Rigontec GmbH, 82152 Planegg, Germany; 5) Institute for Genomic Statistics and Bioinformatics, University of Bonn, Germany; 6) Department of Dermatology, University Hospital Magdeburg, 39120 Magdeburg, Germany; 7) Unit for RNA Biology, Institute for Clinical Chemistry and Clinical Pharmacology, University Hospital Bonn, 53127 Bonn, Germany.

**Background:** Therapy resistance limits the efficacy of immunotherapy in melanoma patients. We have recently reported that phenotypic tumor cell plasticity in a proinflammatory microenvironment can drive therapy resistance to an adoptive T cell therapy (ACT). Therefore, we hypothesize that epigenetic alterations beyond the genomic mutations might be the major driver of therapy resistance to immunotherapy. To study the co-evolution of resistant phenotype with the epigenetic landscape in an inflammatory microenvironment, we perform an integrative analysis of exome, methylome and transcriptome profiles of primary and ACT therapy resistant cell lines in HGF-CDK4(R24C) transgenic mouse model of melanoma. **Methods:** We designed different resistance systems based on the origin of resistant cell lines. To analyze if ACT selects for nonsynonymous mutations, we performed whole-exome enrichment followed by sequencing (WES) in primary and ACT therapy resistant cell lines. Methylated DNA immunoprecipitation coupled with next generation sequencing (MeDIP-Seq) is used to track the distribution of methylation alterations in target genomes. Expression profiling data are generated using poly-A enrichment and RNA sequencing. **Results:** Differential methylation (DM) analysis for all samples shows that non-resistant cell lines clustered separately from therapy resistant cell lines. We did not find high impact somatic mutations in the exome data of resistant cell lines that could drive the tumor to therapy resistance while DM analyses show significant methylation alterations in the same gene promoter regions. Differential expression (DE) analysis results are consistent with profound DM clustering in our cell lines. Gene set enrichment analyses for significant DE and DM genes show the highest enrichment scores for developmental pathways and differentiation proteins. **Outlook:** Our data supports the hypothesis that profound changes in methylation patterns drive melanoma cell plasticity and immunotherapy resistance in our experimental model. Further functional studies would shed light on the correlation of "inflammatory tumor microenvironment" and epigenetically driven "resistant phenotypes" in melanoma. **KEYWORDS:** DNA-methylation analysis, Melanoma cell plasticity, Immunotherapy resistance.

**Regulation of human telomerase reverse transcriptase (hTERT) in human glioblastoma LN18 cells.** C. Lavanya, GK. Chetan, MM. Srinivas Bharath, MK. Sabin. Human genetics, National Institute of Mental Health and Neurosciences, Bangalore, India.

**Introduction:** Increased telomerase activity is a common feature of almost all types of cancers. It can be blocked by targeting the *hTERT* activity at both RNA and catalytic subunits. Synthetic transcription factors, antisense oligonucleotides and inhibitors had been used to regulate *hTERT* activity and had showed varied success rates. The present study hypothesized that the telomerase specific inhibitor BIBR1532 can effectively down-regulate the telomerase activity in LN18 glioblastoma cell line. **Methods:** LN18 glioblastoma cell line was treated with different concentrations of BIBR1532 at different time intervals. MTT assay was performed to determine cell viability after BIBR1532 treatment. *hTERT* mRNA and protein expressions were quantitated using qRT-PCR and western blotting. Flow cytometry assay and TRAP assay was performed to detect the rate of apoptosis and telomerase activity in treated and control groups. One-way ANOVA was used to compare the mean values of each variable in control and BIBR1532 treated groups. **Results:** LN18 cells showed a significant dose dependent cytotoxic effect after treatment with BIBR1532. Treatment with 200  $\mu$ M BIBR1532 caused more than 70% decrease in viability of LN18 cells at 48 and 72 h. The level of *hTERT* mRNA expression in cells treated with 25  $\mu$ M, 100  $\mu$ M and 200  $\mu$ M BIBR1532 treated groups was decreased ~ 21% and ~ 61.2% and ~ 77% respectively with a  $p < 0.05$ . We also observed that, the level of *hTERT* protein was decreased to 44%, 61% and 86% at concentrations of 25  $\mu$ M, 100  $\mu$ M and 200  $\mu$ M respectively. The Flow cytometry data showed that the total percentage of apoptotic cells at 200  $\mu$ M of BIBR1532 with 63.6%, 73.8% and 84.5% total apoptotic cells at 12, 24 and 48 h respectively, compared to control. TRAP assay results showed that 25  $\mu$ M of BIBR1532 resulted in a partial inhibition, whereas treatment with 100 and 200  $\mu$ M BIBR1532 inhibited the telomerase activity up to 42.9% and 74.4% respectively ( $p < 0.05$ ). **Conclusion:** BIBR1532 could induce apoptosis in LN18 glioblastoma cells through the down-regulation of telomerase activity at transcriptional and translational level. BIBR1532 may be used as a therapeutic agent to suppress telomerase activity in glioblastoma cell line. Further *in vivo* studies are necessary in order to explore this as a therapeutic agent.

**951W****Characterizing the chromatin accessibility landscape of glioblastoma tumors at the single cell level.**

Glioma refers to brain tumors that develop from cells of glial origin and classified based on the type of cell that give rise to the tumor. These include astrocytic tumors of which glioblastoma multiforme (GBM) is the most prevalent among adults and also has a poor prognosis for survival. There is currently no treatment for GBM and is also one of the most difficult to cure by surgery as the tumor can spread to several regions of the brain. One of the main reasons for the difficulty in treatment is because of the heterogeneous nature of the tumor. In order to characterize the heterogeneity of GBM, single cell technologies need to be used. Here we aim to also use single nuclei RNA-Seq and single nuclei ATAC-Seq to first identify the cell populations within the tumor based on their transcriptome profile and epigenetic chromatin landscape. Using ATAC-Seq to identify regions of open chromatin can help us better understand the regulatory network driving the expression of tumor-specific genes. Using these single cell technologies, we aim to characterize the intra tumor heterogeneity by using sections of the tumor from each patient as well as inter tumor heterogeneity between different patients. ATAC-Seq can be also be used to identify copy number variations in the genome, which can allow us to characterize the genetic aberrations in each tumor at the single cell level. Together, this characterization of GBM tumors at the single cell can assist in designing better treatment options that can target the heterogeneous aspects of the tumor to prevent recurrence.

A catalogue of mutations that drive tumorigenesis and progression is essential to understanding tumor biology and developing therapies. Protein-coding driver mutations have been well-characterized by large exome-sequencing studies; however many tumors have no mutations in protein-coding drivers and few non-coding drivers besides the *TERT* promoter are known. To fill this gap, we analyzed 150,000 cis-regulatory regions in 1,844 whole cancer genomes from the largest uniformly processed whole genome sequencing dataset compiled by the ICGC-TCGA Pan-cancer Analysis of Whole Genomes (PCAWG) project. We developed a new cancer driver discovery method, ActiveDriverWGS, validated it on protein-coding genome and found 47 genes of which >90% are known drivers. We then applied the model to cis-regulatory regions from ENCODE and found 41 frequently mutated regulatory elements (FMREs) enriched in non-coding SNVs and indels. FMREs were characterized by aging-associated mutation signatures and frequent structural variants, highlighting their importance in cancer. FMREs were enriched in super-enhancers and long-range chromatin interactions, suggesting that mutations in these regions drive cancer by altering transcriptional programs of distally located genes. The chromatin interaction network of FMREs, chromatin loops and target genes revealed a subset of FMREs where mutations associated with differential gene expression of known and novel cancer genes, activation of immune response pathways and altered enhancer marks. Thus distal genomic regions may include additional, infrequently mutated drivers that act on target genes via long-range interactions mediated by chromatin loops. Our study is an important step towards finding such frequently mutated regulatory regions and deciphering the somatic mutation landscape and disease mechanisms of the non-coding genome.

**Transfer learning approaches for robust fine-mapping of putative causal regulatory variants associated with colorectal cancer.** A. Shcherbina<sup>1</sup>, S. Bien<sup>2</sup>, J.R. Huyghe<sup>2</sup>, A. Saiakhova<sup>2</sup>, S. Schmitz<sup>3</sup>, D. Conti<sup>4</sup>, T. Harrison<sup>2</sup>, F. Qu<sup>2</sup>, L. Hsu<sup>2</sup>, M. Wainberg<sup>2</sup>, M. Bassik<sup>5</sup>, G. Casey<sup>6</sup>, S. Gruber<sup>6</sup>, U. Peters<sup>7</sup>, P. Scacheri<sup>3</sup>, A. Kundaje<sup>7,8</sup>, GECCO, CORECT, CCFR Consortia. 1) Biomedical Informatics, Stanford University, Stanford, CA; 2) Fred Hutchinson Cancer Research Center, Seattle, WA; 3) Case Western Reserve University, Cleveland, OH; 4) Moffitt Cancer Center, Tampa, FL; 5) University of Southern California, Los Angeles, CA; 6) University of Virginia, Charlottesville, VA; 7) Computer Science Dept, Stanford University, Stanford, CA; 8) Genetics Dept, Stanford University, Stanford, CA.

We present an integrative approach for context-specific fine mapping and interpretation of non-coding disease-associated variants based on deep learning models of regulatory DNA sequence. We used this approach to analyze over 50 genome-wide loci associated with colorectal cancer (CRC) based on a meta-analysis of 125,218 CRC cases and controls from three consortia: Colon Cancer Family Registry, Colorectal Cancer Transdisciplinary Study, and Genetics and Epidemiology of Colorectal Cancer Consortium. First, we trained novel multi-task, convolutional-recurrent neural networks (NN) to accurately map 1Kb bins of DNA sequence across the genome to corresponding DNase-seq (DHS) profiles across 193 diverse ENCODE+REMC cellular contexts. Next, we fine-tuned the reference NNs on DHS and H3K27ac profiles in 21 primary CRC tumor samples and mucosa from 6 healthy controls. This transfer learning approach resulted in significant accuracy gains relative to training only on the CRC relevant tissues. We used DeepLIFT, a feature attribution method for neural networks, to efficiently infer predictive importance scores of every nucleotide in 1Kb bins centered at 23,727 variants across all associated loci, which include 3910 variants in the 99% credible sets of causal variants. Variants with high, robust DeepLIFT scores across multiple samples, bootstrapped models and heterogeneous genomic background sets, highlighting putative functional regulatory variants, were further interrogated using in-silico mutagenesis (ISM) to estimate the signed influence (effect size) of all alleles on local chromatin state. DeepLIFT profiles of nucleotides surrounding high scoring variants further highlighted sequence features such as transcription factor (TF) motifs harboring these variants. Our approach exhibited high specificity. Within each GWAS locus, across 100s of 99% credible set variants and 1000s of background SNPs, only 1-5 SNPs exhibited high and statistically significant functional scores. Several high scoring SNPs overlapped tissue-specific enhancers in colorectal mucosa. Further, these variants were often found at flanks of DHSs directly disrupting, creating or indirectly influencing motifs of lineage-specific TFs. High confidence candidates are being tested using high-throughput CRISPR screens and reporter assays in CRC lines. Our framework can easily generalize to other disease phenotypes and to score non-coding rare variants and somatic mutations including indels and short SVs.

**Exploring the microRNA expression between HPV positive and negative prostate cancer cell lines.** K. Tokarz, T. Vilboux, J. Deeken, R. Iyer. Inova Translational Medicine Institute, Falls Church, VA.

MicroRNAs (miRNAs), a class of small RNA molecules 18-25 nucleotides in length, maintain cellular function by regulating mRNA transcription. miRNAs play a vital role in cell proliferation and apoptosis, and can be considered useful biomarkers of cancer progression. HPV16 is a high risk strain of the human papillomavirus, and the most common detected in tumors. Prolonged infection of a HPV strain can cause various types of cancer, such as cervical, prostate, and head and neck. It has been shown that HPV16 positive tumors have different miRNA profiles than the same tumor type without HPV16. In this study, we wanted to confirm the impact integration of HPV16 on miRNA in prostate cancer (PCa) as well as characterizing similar modification in other cancer types. In addition we wanted to show if HPV18, another high-risk HPV type, has similar effect on miRNA. For this, we performed miRNA sequencing on different cell lines derived from multiple cancer (with or without HPV16 and HPV18) such as PC-3, CRL-1740, and CRL-2876. In this study, we specifically looked at the miRNA expression effecting target genes or pathways in PCa. Using a nuclease protection probe assay, we sequenced over 2200 miRNA probes of a PCa Gleason Grade 4 HPV18+ (CRL-2220), and PCa metastatic HPV negative (CRL-2876) cell line. To analyze the data, we applied a log2 transformation expression of each probe in counts per million. Then the difference in the values of each miRNA probe of the two cell lines was found to determine differential expressions, with the five most upregulated miRNA being: miR-99a-5p, miR-7106-5p, miR-3687, miR-30b-5p, and miR-20b-5p and the five most downregulated miRNA being: miR-155-5p, miR-205-3p, miR-224-5p, miR-31-5p, and miR-205-5p. Looking at the downregulated miRNA, two of the miR-205 family and one miR-31 are present, which correlated to previous studies. In these studies, miR-99 has also been shown to be down-regulated in advanced PCa, inhibiting the growth of prostate cancer cells and decreasing the expression of prostate-specific antigen (PSA). Interestingly, this miRNA cluster has rarely been shown to be upregulated in PCa. One reason for this may be that miR-99a is located on chromosome 21q21, which has been shown to be an integration site for certain strains of HPV. Understanding the effect of HPV18 on miRNA expression would shine some light on the pathophysiology of these HPV positive cancer as well as identifying potential targets for new treatments. .

**Description of novel human endogenous retrovirus-protooncogen chimeric transcripts in acute lymphoblastic leukemia.** *J.M. Valencia-Reyes<sup>1,2</sup>, S.A. Tellez-Camacho<sup>3</sup>, J.T. Granados-Riveron<sup>1</sup>.* 1) Laboratorio de Investigación en Genómica, Hospital Infantil de México Federico Gómez, Mexico City, Mexico; 2) Escuela Superior de Medicina, IPN; 3) Centro Universitario de Ciencias Biológicas y Agropecuarias, Universidad de Guadalajara.

Human endogenous retroviruses (HERVs) are remnants of past retroviral infections acquired during our evolution as a species. Most of the HERVs have lost the infectious capacity through loss or mutation of the *env* gene. Genome's repair mechanisms have also processed multiples copies of HERVs by removing internal sequences leaving only long terminal repeats (LTRs). In turn, these LTRs can behave as potent promoters and therefore potentiate transcription of proto-oncogenes if a HERV integrates somatically upstream one of them or alternatively if an ancestral HERV loss it inhibition by methylation. Recently, in lymphomas, two instances of HERV-proto-oncogene chimeric genes have been described as severity as well as survival factors for neoplastic cells. We have developed a novel methodology to discover new such chimeric transcripts and we have evaluated it efficacy by a proof of principle assay by amplifying selectively a constitutive gene in both commercial high-quality RNA as well as RNA derived from neoplastic ALL bone marrow. So far, we have been able to identify some examples of potential chimeric transcripts, which are being characterized.

**Integrative genome-wide analysis of long noncoding RNAs in diverse immune cell types of melanoma patients.** *Y. Zhang, L. Wang.* University of Maryland School of Medicine, Baltimore, MD.

Genome-wide identification and characterization of long non-coding RNAs (lncRNAs) in individual immune cell lineages helps us better understand the driving mechanisms behind melanoma and advance personalized patient treatment. To elucidate the transcriptional landscape in diverse immune cell types of peripheral blood cells (PBC) in stage IV melanoma, we used whole transcriptome RNA sequencing to profile lncRNAs in CD4+, CD8+, and CD14+ PBC from 132 patient samples. Our integrative computational approach identified 27,625 expressed lncRNAs, 2,744 of which were novel. Both T cells (i.e., CD4+ and CD8+ PBC) and monocytes (i.e., CD14+ PBC) exhibited differential transcriptional expression profiles between melanoma patients and healthy subjects. *Cis-* and *trans-*level co-expression analysis suggested that lncRNAs are potentially involved in many important immune-related pathways and the programmed cell death receptor 1 (PD-1) checkpoint pathways. We also identified 9 gene co-expression modules significantly associated with melanoma status, all of which were significantly enriched for three mRNA translation processes. Age and melanoma traits closely correlated with each other, implying that melanoma contains age-associated immune changes. Our computational prediction analysis suggests that many *cis-* and *trans-*regulatory lncRNAs could interact with multiple transcriptional and post-transcriptional regulatory elements in CD4+, CD8+, and CD14+ PBC, respectively. These results provide novel insights into the regulatory mechanisms involving lncRNAs in individual immune cell types in melanoma and can help expedite cell type-specific immunotherapy treatments for such diseases.

**Comparison of circulating cell-free DNA isolation methods by yield and downstream Pyrosequencing analysis.** *M. Poulin<sup>1</sup>, A. Meyer<sup>1</sup>, E. Zhou<sup>2</sup>, S. Miller<sup>1</sup>, J. Xu<sup>1</sup>, L. Yan<sup>1</sup>.* 1) EpigenDx Inc., Hopkinton, MA; 2) Harvard University, Cambridge, MA.

The use of circulating cell-free DNA (ccfDNA) as a diagnostic substrate for many types of diseases, conditions and genetic abnormalities, is becoming more and more sought after as a non-invasive way of early genetic detection. The current technological challenge is obtaining optimal efficiency in the isolation and quantitation of the very small quantities of ccfDNA in pre or early disease patients. Pyrosequencing is an efficient technology to take advantage of small amounts of highly fragmented DNA. Specific genomic regions can be PCR amplified with a primer pair, in which one primer is biotinylated, and sequenced to interrogate very specific DNA mutations. DNA can also first be bisulfite treated, amplified and sequenced to obtain DNA methylation information at specific CpG sites throughout the genome. We have compared five ccfDNA isolation kits on 8 to 12 samples of human blood plasma for DNA yield and Pyrosequencing sensitivity for several Pyrosequencing assays, both on genomic and bisulfite treated DNA. The genotyping assays will be within SNV hotspots of human *BRAF*, *KRAS*, *IDH1* and *IDH2*. We will also be looking at the methylation of human *MGMT*, *MLH1* and *BRCA1*. This examination will not only determine which kit will result in the greatest yield, but will also assay the potential downstream application of Pyrosequencing assays.

**A high-resolution chromatin interaction epigenomic map of prostate cancer cells.** *S.K. Rhie, A. Perez, F. Lay, S. Schreiner, P.J. Farnham.* Department of Biochemistry and Molecular Medicine and the Norris Comprehensive Cancer Center, Keck School of Medicine, University of Southern California, Los Angeles 90089, CA, USA.

The human genome is densely compacted in three-dimensional space of the nucleus via the action of chromatin-bound histones, with different compartments being in open vs. closed states. Important cellular processes such as transcription occur in the open compartments of the genome. As cells change states, specific genomic compartments transition between open and closed and vice versa, allowing for cell type-specific gene regulation. These genomic compartments are defined by chromatin loops which bring distant regions of the linear genome together in three-dimensional space. Characterizing the chromatin loops in a given cell type is clearly critical for understanding cell type-specific gene regulation. Prostate cancer is the leading cause of new cancer cases and the second most common cancer in men and the fourth most common tumor type worldwide. To better understand the regulatory networks that contribute to prostate tumorigenesis, we have developed high-resolution chromatin interaction epigenomic maps in normal and tumor prostate cells by using in-situ Hi-C. We have compared the chromatin interaction maps with open chromatin regions defined by NOME-seq, active and repressive histone marks and CTCF binding sites defined by ChIP-seq, and transcriptome profiling to provide a comprehensive characterization of chromatin loops in normal and tumor prostate cells. We identified ~6,500 topologically associating domains (TADs) per cell type and annotated these TADs as being enriched for histone marks representing an open (H3K36me3) or closed (H3K9me3 or H3K27me3) state. By comparing TADs, we identified >100 closed (transcriptionally repressed) TADs that changed epigenomic states and >1,000 TADs that changed in size between normal and prostate tumor cells. Moreover, we identified ~20,000 promoter-enhancer loops and potential transcription factors that are enriched at regulatory elements and loop anchors. Interestingly, most of the differentially expressed genes in normal vs. tumor prostate cells had promoter-enhancer loops with similar interaction frequencies between normal and tumor cells. However, the epigenomic states of the regulatory elements located near the loop anchors changed when normal cells transitioned to tumor cells. Our studies provide a list of characterized TADs and loops in normal and prostate cancer cells as a resource to the research community, to enable a better understanding of prostate cancer biology and epigenomics.

**959F**

**Identifying genomic sites with highly predictable DNA accessibility.** *K. Wnuk<sup>1</sup>, J. Sudol<sup>1</sup>, S. Rabizadeh<sup>1</sup>, C. Szeto<sup>2</sup>, C. Vaske<sup>2</sup>.* 1) NantOmics, Culver City, CA; 2) NantOmics, Santa Cruz, CA.

DNA accessibility, chromatin regulation, and genome methylation are key drivers of transcriptional events promoting tumor growth. However, understanding the impact of DNA sequence data on transcriptional regulation is a challenge, particularly in noncoding regions of the genome. Recently, neural nets have improved the ability to predict DNA accessibility in specific cell types. This result was further advanced by model changes, and extended to apply to novel biotypes without need to re-train by adding a RNA-seq gene expression signature as input. Here we analyzed model performance by genomic site and identified where it can be applied with high confidence. Matched RNA-seq (304 samples) and DNase-seq (220 samples) data from 74 unique biotypes from ENCODE were used for evaluation. When applied at 1.71M potential accessibility sites across the genome our convolutional net achieved ROC AUC = 0.897 and PR AUC = 0.621 on held out biotypes, and ROC AUC = 0.913 and PR AUC = 0.725 on held out samples whose biotypes were allowed to overlap training. Although compelling compared to prior results the PR AUC underscored that, when considering all sites, performance still needed to improve. We broke down performance by site type and showed that at promoter and promoter flank regions (per ENSEMBL) accessibility prediction is considerably more reliable: PR AUC = 0.839 in held out biotypes, PR AUC = 0.911 in held out samples with biotype overlap. Performance was not sensitive to whether the prediction site was in proximity to genes used in the input RNA-seq signature. We applied the model to 6 TCGA cohorts for which somatic mutations were available, focusing only on promoter and promoter flank regions. We predicted 10878 sites as constitutively accessible, 40823 as constitutively not accessible, and 52891 as facultative. We also identified 5 cases with unique accessibility patterns across several hundred sites that were specific to single patients. Exploring the impact of mutations, we showed there was higher variance in the influence of INDELS on predicted accessibility of a site than SNPs. Only 5.46% of the sites with INDELS and 1.6% of those with SNPs led to a flipped decision by the classifier. These results demonstrate a new tool to query DNA accessibility of samples at the sequence level in silico, allowing us to explore cohorts for correlations of promoter accessibility to phenotypes of interest and shed light on new links that may be worth further investigation.

**960W**

**Epigenetic driven metastasis in osteosarcoma is suppressed through CDK12 inhibition.** *I. Bayles<sup>1</sup>, M. Krajewska<sup>2</sup>, A. Saiakhova<sup>1</sup>, J. Morrow<sup>1</sup>, C. Bartels<sup>1</sup>, J. Lu<sup>2</sup>, Z. Faber<sup>1</sup>, Y. Fedorov<sup>1</sup>, B. Rubin<sup>3</sup>, D. Adams<sup>1</sup>, R. George<sup>2</sup>, P. Scacheri<sup>1</sup>.* 1) Genetics and Genome Sciences, Case Western Reserve University, Cleveland, OH; 2) Department of Pediatric Oncology, Dana-Farber Cancer Institute; 3) Pathology and Laboratory Medicine Institute, Cleveland Clinic.

Cancer metastasis is a complex multistep process thought to be driven by the acquisition of new mutations in primary tumor cells. However, recent whole genome sequencing studies comparing primary tumors to distant metastasis have not supported this theory. We hypothesized that the metastatic process is instead driven by epigenetic alterations at enhancer elements that endow tumor cells with metastatic traits. We tested this hypothesis in osteosarcoma (OS [MIM 259500]), an aggressive pediatric cancer that primarily metastasizes to lung. Through epigenomic profiling, we identified substantial differences in enhancer activity between primary and metastatic OS tumors, and between isogenic pairs of highly lung metastatic and nonmetastatic OS cell lines. We term these regions metastatic variant enhancer loci, or Met-VELs. Met-VELs drive coordinated waves of gene expression during metastatic colonization of the lung. Moreover, osteosarcoma lung metastasis in mice can be inhibited by knockdown of AP-1 transcription factors that occupy Met-VELs, by inhibition of individual genes activated by Met-VELs, or through TALEN-mediated genetic deletion of individual Met-VELs. Leveraging these findings, we developed an approach to screen for epigenetically-related compounds that could have therapeutic efficacy against metastatic osteosarcoma. The screening approach is based on a lung explant organ culture model called the Pulmonary Metastasis Assay (PuMA) in which metastatic OS cells are cultured directly within the lung microenvironment, thereby more closely recapitulating the natural metastatic setting in humans. Deploying this strategy to screen a library of 114 epigenetically-related compounds, we found inhibitors of *CDK12* [MIM 615514] to be most effective, reducing OS cell outgrowth in the lung by >90% at submicromolar doses. *CDK12* inhibitors impeded elongating RNA Polymerase II in a gene length- and expression-dependent manner. These effects were accompanied by displacement of *CDK12* from active enhancer elements and global changes in gene expression. Together, our studies demonstrate that the epigenome plays a critical role in equipping OS tumor cells with metastatic competence, and that this property may be targetable for therapy. Our studies further offer a framework for rapid preclinical testing of compounds with anti-metastatic activity, and highlight *CDK12* as a potential therapeutic target in osteosarcoma.

**Microbial metabolite butyrate affects allele-specific expression and disrupts chromatin architecture in a colon cancer cell line.** M.G. Durrant<sup>1</sup>, B. Fremin<sup>1</sup>, S.B. Montgomery<sup>1,2</sup>, A.S. Bhatt<sup>1</sup>. 1) Department of Genetics, Stanford University, Stanford, CA; 2) Department of Pathology, Stanford University, Stanford, CA.

Recent studies suggest that the composition of the microbiome can dramatically influence host gene expression and chromatin accessibility. Butyrate is a metabolite and HDAC inhibitor produced in large quantities by bacterial species found in the human gut microbiome. It can act as a source of energy for colonocytes, as an anti-inflammatory agent, and it has been associated with a reduced risk of colon cancer. The mechanism of this anti-cancer effect is not fully understood. We used longitudinal paired ATAC-seq and RNA-seq on the HCT-116 colon cancer cell line to directly determine how the epigenomic response to physiological concentrations of butyrate mediates gene expression. Allele-specific expression (ASE) analysis identified 10 genes, including known tumor growth and metastasis modulators PSPH and PHLDB2, that shift their ASE in response to butyrate, suggesting that *cis*-regulatory variation modulates the impact of butyrate on gene expression. Distinct temporal clusters of butyrate-induced changes in chromatin accessibility emerged. Clusters of peaks that became less accessible (closed) in response to butyrate were strongly enriched for a wide-range of functional pathways, including regulation of Rap protein signal transduction, regulation of JUN Kinase activity, immune and inflammatory responses, and cellular response to trichostatin A (another HDAC inhibitor). These butyrate-induced closed peaks were also found to selectively reside at distal enhancers (Hypergeometric Test, p-value = 1.7e-9) and were strongly enriched for AP-1 binding motifs (HOMER Motif Enrichment, p-value = 1e-30). Our results strongly indicate that the chromatin that closes in response to butyrate treatment is enriched within regions that are actively maintained by the SWI/SNF chromatin remodeler (Hypergeometric Test, p-value = 2.3e-60) and the AP-1 complex (Hypergeometric Test, p-value = 5.4e-107), indicating that many of the previously identified anti-cancer effects of butyrate may be linked to the disruption of SWI/SNF-dependent chromatin maintenance. In summary, we find that physiological concentrations of the microbial metabolite butyrate 1) influences the ASE of genes previously associated with cancer, 2) dramatically affects chromatin accessibility genome-wide, and 2) specifically affects chromatin at sites that are maintained by chromatin remodelers, shedding new light on the mechanism of action of this important microbial metabolite.

**TET1-mediated 5-hydroxymethylcytosine alteration in the pathogenesis of medulloblastoma.** H. Kim<sup>1,2</sup>, J. Li<sup>1,3,4</sup>, Y. Kang<sup>1</sup>, L. Chen<sup>1</sup>, X. Yuan<sup>3</sup>, X. Liao<sup>3,4</sup>, J. Zhao<sup>3,4</sup>, Z. Zhang<sup>3,4</sup>, L. Lin<sup>1</sup>, J. Liu<sup>3,4</sup>, P. Jin<sup>1</sup>. 1) Department of Human Genetics, Emory University, Atlanta, GA; 2) Cancer Biology Graduate Program, Emory University School of Medicine, Atlanta, GA; 3) Department of Neurosurgery, Xiangya Hospital, Central South University, Changsha, Hunan, China; 4) Hydrocephalus Center, Xiangya Hospital, Central South University, Changsha, Hunan, China.

Medulloblastoma (MB) is an embryonal tumor that originates from cerebellum and adjacent brain stem. Standard treatment based on surgery, radiation, and chemotherapy improved survival rate; however, it still remains the most common brain tumor in children, and survivors suffer from several side effects of the treatment. Therefore, the development of targeted therapy through a better understanding of molecular characteristics in MB is needed. Recent studies revealed substantial increase in the level of 5-hydroxymethylation (5hmC) and its significant enrichment at cerebellar enhancers during postnatal development, suggesting a critical role of 5hmC in proper cerebellar development. In this study we examined the abundance of 5hmC in MB and observed a significant depletion of 5hmC compared to age-matched normal cerebellum. Genome-wide 5hmC profiling revealed the differentially hydroxymethylated regions (DhMRs) across the genome and the DhMRs could clearly distinguish MB from age-matched normal cerebellum. Interestingly we observed the acquisition of 5hmC near the genes involved in the Notch signaling pathway. Furthermore 5hmC signature identified in patient samples displayed a substantial overlap with 5hmC signature identified in mouse tumors of SmoA1 mouse model that recapitulates human SHH MB. To determine whether the modulation of tumor-specific 5hmC marks could influence MB tumorigenesis, we manipulated the expression of *TET1*, a key enzyme involved in 5hmC production, in vitro and in vivo. We found that a known *TET1* inhibitor could inhibit the growth of primary tumors derived from SmoA1 mouse in vitro. More importantly, when we crossed SmoA1 mice with *TET1* knockout mice, we observed that the loss of *TET1* could significantly delay the onset of tumor-related symptoms. These results together suggest a potentially important role of 5hmC in MB tumorigenesis and indicate an oncogenic nature of *TET1* in this process. Thus *TET1* could serve as a therapeutic target for MB.

**Detection of epigenetic interactions using a weighted epigenetic distance-based method.** *Y. Wang, S. Wang.* Department of Biostatistics, Columbia University, New York, NY.

DNA methylation plays an important role in cancer progression. Most EWAS (epigenome-wide association studies) performs CpG site-level analysis and discard CpGs without differential methylation when some of these CpGs might be interacting with others on disease outcomes. Exhaustive search for all pairwise interactions on CpG levels are computationally prohibited. Thus, not many studies consider epigenetic interactions, either on CpG levels or on gene levels. Here we propose a weighted epigenetic distance-based method that is able to characterize similarity between any pairs of individuals on methylation measures at multiple CpGs in a gene or a genetic region as well as all pairwise CpG-level interactions. Weights are assigned to both methylation measures and CpG level interactions to up-weight signal CpGs/interactions and down-weight noise CpGs/interactions. We demonstrated the feasibility of the proposed epigenetic distance-based method incorporating interactions in simulation studies as well as the superior performance with weights which is effective in up-weighting signal CpGs and signal interactions than the non-weighted version. Applications to DNA methylation data of The Cancer Genome Atlas (TCGA) breast cancer subtypes identified genes that are differentially methylated between breast cancer subtypes that are due to epigenetic interactions but are missed by comparing methods that ignore epigenetic interactions.

**Integrated genomic profiling reveals cellular epigenetic normalization of salivary dysfunction following AAV2-AQP1 treatment.** *D.G. Michael, T.J. Pranzatelli, C. Zheng, C. Goldsmith, J.A. Chiorini.* Adeno-associated Virus Biology Section, National Institutes of Health, Bethesda, MD, USA.

Each year, approximately 40,000 patients develop head and neck cancers in the United States, with over 500,000 cases worldwide. Of these cases, 50% of patients experience irreversible damage to the salivary glands exposed to the irradiation field. This damage represents a complex epigenetic state in which hundreds of genes are differentially dysregulated as a response to irradiation. This dysregulation results in salivary dysfunction and cell death of acini, resulting in a loss of salivary function. Current treatments are primarily palliative in nature and focus on the replacement of lost oral fluids without significant improvement in quality of life. The use of Adeno-associated viruses for gene therapy is a promising modality for the correction of Mendelian genetic disorders, but little research has been performed on the use of gene therapy to correct complex disorders that arise from the dysfunction of multiple genes. Previous work at the NIDCR has previously demonstrated in humans that administration of the aquaporin-1 water channel to human patients using adenovirus vectors resulted in subjective improvement of xerostomia in patients. A gene therapy trial for salivary AAV2-AQP1 treatment is currently underway at the NIH for the correction of irradiation induced xerostomia. We evaluated the impact of AAV2-AQP1 treatment on mice treated with 16 Gy of gamma irradiation delivered to the salivary glands. 71 days following irradiation,  $1 \times 10^{11}$  AAV2-AQP1 particles was delivered to the submandibular gland of each mouse. By day 200 post-AAV, the treated group exhibited a mean recovery of 68% of salivary function compared to age and gender matched controls. RNA-seq detected 1,985 genes as differentially expressed in the irradiated control group when compared to healthy controls. AAV2-AQP1 treatment reduced differential expression, with only 99 genes detected as differentially expressed ( $>2$  FC,  $p\text{-val} < 0.05$ ). AAV2-AQP1 treatment reduced the Euclidean distance between the healthy and post-irradiation mice by 64%, indicating a substantial recovery of the epigenetic state following AAV treatment. Finally, AAV2-AQP1 treatment normalized the gene regulatory network connectivity of the irradiated salivary gland when measured by ATAC-seq footprinting at a depth of  $> 200$  million reads. Collectively, our results indicate that AAV2-AQP1 treatment resolves the salivary functional defects associated with irradiation via correction of the cellular epigenetic state.

**Non-coding RNAs underlie genetic predisposition to breast cancer.** *J.D. French<sup>1</sup>, M. Moradi Marjaneh<sup>1</sup>, J. Beesley<sup>1</sup>, T. O'Mara<sup>1</sup>, P. Mukhopadhyay<sup>1</sup>, S. Kazakoff<sup>1</sup>, L. Fachal<sup>2</sup>, N. Waddell<sup>1</sup>, D.F. Easton<sup>2,3</sup>, A.M. Dunning<sup>2</sup>, G. Chenevix-Trench<sup>1</sup>, S.L. Edwards<sup>1</sup>.* 1) Department of Genetics and Computational Biology, QIMR Berghofer Medical Research Institute, Brisbane, 4029, Australia; 2) Department of Oncology, Centre for Cancer Genetic Epidemiology, University of Cambridge, Cambridge CB1 8RN, UK; 3) Centre for Cancer Genetic Epidemiology, Department of Public Health and Primary Care, University of Cambridge CB1 8RN, UK.

To date, the focus of Genome Wide Association Studies (GWAS) follow-up studies has been the impact of regulatory variants on the expression of protein-coding genes. However, in many cases, genetic variants with stronger associations with the trait of interest are dismissed as causal because they do not fall in regions marked for enhancer or promoter activity. GWAS combined with fine-mapping have identified 196 strong signals (conditional  $p$ -value  $< 10^{-6}$ ) associated with breast cancer. The majority of candidate causal variants (CCVs) at each signal fall outside protein-coding regions. Breast cancer CCVs are enriched in regulatory elements, but the contribution of long non-coding RNAs (lncRNAs) is still currently unknown. Using targeted RNA sequencing combined with *de novo* transcript assembly, we systematically annotated multi-exonic lncRNAs transcribed from 1.5Mb intervals surrounding breast cancer GWAS signals and assess their contribution to risk. We captured >4000 lncRNA genes (FPKM > 0.5; nearly two-thirds of which are not in GENCODE, FANTOM-CAT or NONCODE databases) and show that breast cancer CCVs are significantly enriched in the exons of the captured lncRNAs but not the promoters or introns ( $P_{\text{perm}} < 10^{-3}$ ). Approximately 75% of the captured lncRNAs are detectable (FPKM > 1) in normal breast or breast tumour RNAseq from The Cancer Genome Atlas (TCGA). Notably, principal component analyses indicate that the expression of these lncRNAs discriminate normal breast from tumour samples and breast cancer subtypes suggesting that these transcripts may play an important role in breast cancer development. Using eQTL analyses we identify 16 lncRNAs whose expression is associated with CCVs in breast tumours (FDR < 0.05). Approximately half of the lncRNA contain the eSNP within the lncRNA exon suggesting that the variants may alter the stability of transcripts, the remainder are located more distally. We performed Capture Hi-C in 6 breast cell lines and provide evidence that these CCVs fall in distal enhancers that regulate lncRNA genes through long-range chromatin interactions. In summary, we identify 874 lncRNAs as candidate breast cancer risk genes based on CCVs that fall in either 1) lncRNA exons, 2) lncRNA promoters or 3) regions that interact with the lncRNA promoters through long-range chromatin interactions. These data indicate that modulation of lncRNAs by risk-associated variants is a predominant mechanism underlying breast cancer development.

**966W**

**Characterizing DNA methylation patterns in pancreatic cancer patients.** *R.J. Jansen<sup>1</sup>, W.R. Bamlet<sup>2</sup>, G.M. Petersen<sup>2</sup>.* 1) North Dakota State University, Fargo, ND; 2) Mayo Clinic, Rochester, MN.

Understanding how methylation changes with cancer development and identifying which methylation markers (CpGs) are important in related conditions (e.g., recent onset type 2 diabetes) has extreme importance when using CpGs as biomarkers for specific diseases or health outcomes. Therefore in this pilot study, we wanted to characterize the effect pancreatic adenocarcinoma (PCa) and recent onset DM has on DNA methylation and determine if these effects vary by genomic context. We sampled 30 non-smoking patients (15 PCa and 15 recent DM) from the Mayo Clinic pancreatic cancer resource of about 3K cases/2K controls and used the Illumina EPIC methylation array to measure methylation of about 850,000 CpGs in DNA extracted from their stored whole blood. We identify disease-associated CpGs adjusted for blood cell type and characterized location in CpG islands (vs. shelf, shore, open sea), and gene regions (vs. intergenic). Overall, we classified about 30 CpGs significantly ( $p < 5 \times 10^{-5}$ ) associated with PCa and DM each, but only 1 CpG that overlap in both the sets of top 100 (those with the smallest  $p$ -values). However, we did observe a similar hypermethylation pattern with respect to genomic region among both sets of significant CpGs. When comparing all CpGs to disease associated CpGs, open sea is enriched among PCa and there is slight under-enrichment among the shore regions. This is in contrast with the few previous genome-wide studies on pancreas tissue-based DNA methylation and PCa with respect to genomic region, where it has been observed that average PCa-associated CpGs in islands tend to be hypermethylated while open seas, shores, and shelves hypomethylated. Using a methylation age prediction model, our sample tended to have younger predicted ages compared to chronological ages with the Spearman correlations as follows: 0.90 for the PCa, no DM group, 0.86 for the PCa, with DM group, 0.81 for the no PCa, with DM group, and 0.93 for the no PCa, no DM group. The lone CpG marker observed in DM and PCa models, shows promise for discriminating Control, DM and PCa, DM patients from one another. Sample size is a major limitation and this analysis is exploratory, even so, the potential modification of LAMA5 methylation and its associated functions including roles in cell adhesion, differentiation, migration, signaling, and metastasis along with a gene mutation affecting sonic hedgehog and GLI1 expression supports a potential important role for LAMA5 in PCa development.

**967T****Tumor-specific DNA methylation signatures in solid and liquid biopsies.**

A.C. Lau, R.L. Goldfeder, C.L. Wei. Genome Technologies, The Jackson Laboratory for Genomic Medicine, Farmington, CT.

Liquid biopsies have the potential to revolutionize cancer diagnosis, therapy selection, and treatment response. Currently, most clinical decisions are based off of tumor extraction and genotyping, however tumor biopsies are often difficult to obtain in that it is slow and painful for the patient. Therefore, as a proxy for tumor tissue profiling, analyzing cell-free circulating tumor DNA (ctDNA) in blood samples offers a fast non-invasive way to access the genetic and epigenetic information of patients' tumor status. Epigenetic regulation is thought to contribute to tumorigenesis across all cancer types. Unlike cancer mutation profiles, which can vary within a single tumor type and are sparse in cell-free DNA (cfDNA), DNA methylation tends to be more consistent and occurs in specific DNA regions. Additionally, 5-hydroxymethylcytosine (5hmC) has a conserved tissue type/cell specific genome-wide distribution, making it an excellent mark to determine tumor origin from a liquid biopsy. Our goal is to characterize the diagnostic and prognostic potential of the cell-free DNA epigenetic modifications 5-methylcytosine (5mC) and 5hmC. In the past, the low amounts of ctDNA in blood samples have presented a challenge in sequencing and identifying different epigenetic modification. We adapted and optimized nano-scale oxidative-bisulfite sequencing and analysis to achieve single-base resolution of 5mC and 5hmC in genomic DNA and ctDNA. We used these technical and analytical methods to sequence the tumor DNA, matching normal DNA, and ctDNA of pancreatic and bladder cancer patients. When comparing tumor DNA to matching normal DNA we found distinct methylation profiles, different levels of enrichment at genomic regions, and a unique set of methylated and hydroxymethylated genes. Additionally, when comparing 5mC and 5hmC patterns found in a solid tumor biopsy to the matching ctDNA, we uncover a high correlation in methylation levels as well as intact cancer-specific methylated and hydroxymethylated genes. The cancer-specific genes with enriched 5hmC patterns were unique to the gene expression pathways altered in the ctDNA tumor cell origin. Therefore, the methylated genes and regions we identified can be used to assay ctDNA alone and act as a faithful surrogate for tumor biopsies. Overall, this method offers potential new avenues to non-invasive diagnosis, monitoring and stratification of cancer progression through the analysis of the ctDNA methylome.

**968F****A pilot study of DNA methylation, epigenetic age, and breast cancer risk status.**

R.M. Lucia<sup>1</sup>, A. Alvarez<sup>1</sup>, I. Masunaka<sup>1</sup>, A. Ziogas<sup>1</sup>, D. Goodman<sup>1</sup>, A. Odegaard<sup>1</sup>, V. Lee<sup>2</sup>, S. Brain<sup>2</sup>, D. Heditsian<sup>2</sup>, T.M. Norden-Krichmar<sup>1</sup>, H.L. Park<sup>1</sup>. 1) Epidemiology, University of California, Irvine, CA; 2) Patient Advocate, Markers for Environmental Exposures Study, Irvine, CA.

**Background:** DNA methylation is a key mechanism of epigenetic regulation, and peripheral blood DNA methylation has been studied for potential markers for breast cancer (BC) risk. DNA methylation markers for some BC risk factors, including smoking and body mass index, have been identified. However, many factors contribute to BC susceptibility, and markers for risk status according to clinical risk models that incorporate multiple risk factors have not been described. In addition, while accelerated epigenetic age has been shown to be predictive of BC risk, the relationship between epigenetic age and BC risk status according to multifactorial risk models is unknown. We conducted a pilot study to test the methods and feasibility of identifying DNA methylation markers for BC risk status and examining its relationship with epigenetic age.

**Methods:** While recruitment of our full study cohort (n=400) is underway, this pilot study included 16 women. Blood samples and questionnaire data were obtained from postmenopausal women ages 45-65 without a history of BC. Lifetime BC risk was estimated for each woman using the Tyrer-Cuzick model. Participants were categorized as high-risk (lifetime risk  $\geq 20\%$ ) or average-risk (lifetime risk  $< 20\%$ ). DNA methylation was measured using the Illumina Infinium MethylationEPIC BeadChip. Following normalization of raw data, differentially methylated positions (DMPs) were identified using an F-test. Epigenetic age was computed according to Horvath's method. Participants were categorized as having accelerated epigenetic age if epigenetic age was greater than chronological age. **Results:** This study identified 6440 DMPs associated with high-risk status, but none remained significant after false discovery rate correction. Among the top 20 DMPs, 40% were near DNA repair genes, potential oncogenes, or potential tumor suppressors. While epigenetic age correlated closely with chronological age in this sample (Pearson's  $r = 0.926$ ), there appeared to be a trend of accelerated epigenetic age among high-risk women, with 67% of high-risk women exhibiting accelerated epigenetic age compared to 50% of average-risk women. The median difference was 1.55 years for high-risk and -0.13 for average-risk women (Wilcoxon p-value = 0.475). **Conclusion:** These results demonstrate the feasibility of the methods involved in the study. Further analysis of our larger cohort will elucidate the relationships between DNA methylation, epigenetic age, and BC risk status.

## 969W

**Allele-specific effects of rs12416605:C/T in miR-938 on the regulation of gastric cancer genes.** Y. Espinosa-Parrilla<sup>1,2</sup>, I. Torruella-Loran<sup>2</sup>, MK. Ramirez Viña<sup>1</sup>, D. Zapata-Contreras<sup>1</sup>, N. Sala<sup>3,4</sup>. 1) Universidad de Magallanes, Punta Arenas, Magallanes y de la Antártica C, Chile; 2) IBE, Institute of Evolutionary Biology (Universitat Pompeu Fabra □CSIC), Experimental and Health Sciences, Barcelona, Catalonia, Spain; 3) Molecular Epidemiology Group, Translational Research Laboratory, Catalan Institute of Oncology-IDIBELL, Barcelona, Spain; 4) Human Molecular Genetics Group, Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Spain.

MicroRNAs are small endogenous regulatory RNAs that are involved in the control of multiple biological pathways. Allele variants in microRNAs are known to contribute to disease by affecting either microRNA expression or function. We have previously identified an association of rs12416605:C/T, in the seed region of miR-938, with the diffuse subtype of gastric cancer and aimed to investigate the functional effect of this SNP. To test the influence of rs12416605:C>T in miR-938 expression, either the C or T miR-938 alleles were transfected in HeLa cells and miR-938 expression was measured by RT-qPCR. The rs12416605 C allele was 1.5 times more abundant than the T allele (Student t-test, p-value < 0.05) indicating that rs12416605 may affect the expression of miR-938. Furthermore, to investigate the effect of rs12416605:C/T on the spectrum of miR-938 target genes, transcriptome analyses on HeLa cells over-expressed with either the C or T rs12416605 alleles were performed. From approximately 500 deregulated transcripts, around 50% were exclusively regulated by one or the other rs12416605:C>T alleles. Additionally, even though both variants presented cancer as the top disease associated with their deregulated genes (Ingenuity Pathway Analysis), several genes implicated in the aetiology of gastric cancer, such as the Fibroblast Growth Factor Receptor 1 (*FGFR1*), the NK2 Homeobox 8 gene (*NKX2-8*) and the chemokine *CXCL12* genes, were specifically deregulated by only one of the rs12416605:C>T alleles and were predicted as miR-938 allele specific targets. All together suggests that rs12416605 may be involved in gastric cancer susceptibility by affecting the regulatory function of miR-938. Grant FONDECYT Regular- N°1170446.

## 970T

**Patterns of X chromosome inactivation differ between tumor and normal ovarian tissue.** S.J. Winham<sup>1</sup>, N.B. Larson<sup>1</sup>, M.C. Larson<sup>1</sup>, S.M. Armasu<sup>1</sup>, J.M. Cunningham<sup>2</sup>, S. Gayther<sup>3</sup>, K. Lawrenson<sup>3</sup>, E.L. Goode<sup>1</sup>. 1) Health Sciences Research, Mayo Clinic, Rochester, MN; 2) Laboratory Medicine and Pathology, Mayo Clinic, Rochester, MN; 3) Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles.

X chromosome inactivation (XCI) is a key epigenetic gene expression regulatory process to silence transcription of one of the two copies in females. However, some genes are known to escape this process and are expressed from both copies, and these escape patterns vary across tissues. Although XCI is specific to females, XCI patterns have not previously been studied in normal ovarian tissue. Furthermore, we have previously shown that XCI patterns may play a role in ovarian cancer (OC), particularly if tumor suppressors or oncogenes are inactivated or escaping in a dysregulated manner. In this study, we assess XCI patterns in normal tissue derived from ovarian and fallopian tube surface epithelial cells from 70 patients, and compared these patterns to those previously described for other tissue types, as well as those observed in tumor tissue samples derived from N=45 OC patients. Using allele-specific expression data, we used a two-stage method to estimate the probability of escape from XCI for over 300 genes. The XCI patterns in the normal ovarian samples were similar to previously published patterns of other tissue types. However, approximately 13% of genes showed patterns across individuals that were different from other tissue types, with these genes being inactivated in ovarian tissue. Many have been previously reported as tumor suppressors in ovarian or other cancers (e.g. *KAL1*, *USP9X*, *DDX3X*, *TRAPPC2*, *TCEANC*, and *KDM6A*). Notably, 63% of these discrepant genes also showed patterns of inactivation in the ovarian tumor samples. While XCI ovarian tumor patterns were concordant for most genes compared to normal ovarian tissue, 9% of genes that were inactivated in the normal samples were escaping XCI in the tumor samples. Furthermore, across 276 genes, 72 genes had significantly different probabilities of escape between tumor and normal samples ( $P < 0.00018$ ), with most showing complete inactivation across normal samples but higher probability of escape in the tumor samples (including *DDX3X*, *TRAPPC2*, *KDM6A*, and *RPS4X*). Notably, *RPS4X* was previously associated with poor prognosis in OC, and *DDX3X* and *TRAPPC2* have also been identified as possible drug targets. We found evidence of a unique ovarian tumor XCI profile, suggesting that XCI may play an important role in OC biology. Additional studies to validate in large samples and to examine somatic changes with paired tumor-normal tissue are needed.

## 971F

**Association of Androgen Receptor (AR) gene CAG repeat polymorphism in prostate cancer and benign prostate hyperplasia in men from India.**

S. Daram<sup>1</sup>, S. Zubeda<sup>1</sup>, S. Poornima<sup>2</sup>, VL. Ayyala<sup>1</sup>, B. Srinadh<sup>1</sup>, P. Shailaja<sup>1</sup>, Q. Hasan<sup>1</sup>. 1) Kamineni Hospitals, Hyderabad, Telangana, India; 2) Kamineni Life Sciences, Hyderabad, Telangana, India.

Prostate cancer (PCA) is the second most common malignancy in men worldwide with incidence and mortality are 3.7 and 2.5 per 1, 00,000 men annually. In PCA, 70% of cases are reported from developed countries because of aggressive screening with the PSA test, Digital Rectal Examination (DRE) and subsequent biopsy. PCA incidence and mortality in major cities of India is 3 to 10 per 1, 00,000 men. Prostate disease is a heterogeneous, which ranges from benign to pathogenic. Androgens acting through Androgen Receptor (AR) play an important role in physiology and etiology of PCA. CAG repeat polymorphism has been associated with PCA in different populations. Aim of the present study was to assess the Androgen Receptor gene CAG repeat polymorphism in Prostate Cancer, Benign Prostate Hyperplasia (BPH) and in comparison with age matched healthy males. Peripheral blood from 315 males was collected after obtaining ethical committee approval. Genomic DNA was isolated using salting out method followed by polymerase chain reaction (PCR) and polyacrylamide gel electrophoresis (PAGE) for CAG repeat analysis. Odds ratios (OR) and 95% Confidence Intervals (CI) were calculated using logistic regression analysis. The CAG repeat in controls range from 20 to 32 with a Mean of 23±3 which is significantly longer when compared with PCA, which showed a range from 9 to 24 with Mean 15±4 and in BPH CAG repeat range from 16 to 25 with Mean 22±2. The odds ratio of BPH and Controls (OR=3.0978 95%CI=1.7611 to 5.4493) showed a significance of P=0.0001, PCA and BPH (OR=9.6000 95%CI=3.2570 to 28.2962) with a significance of P<0.0001, PCA and Controls (OR=29.7391 95%CI=10.1702 to 86.9612) with a significance of P<0.0001. Shorter CAG repeats in AR gene polymorphism were significantly associated with PCA than controls and BPH.

## 972W

**A novel germline *DICER1* mutation in association with thyroid and ovarian Sertoli-Leydig cell tumors.** N. Settas<sup>1</sup>, L. Michala<sup>2</sup>, A. Berthon<sup>1</sup>, F.R. Fau-  
cz<sup>1</sup>, A. Iliadi<sup>3</sup>, A. Gkika<sup>3</sup>, C. Dacou-Voutetakis<sup>4</sup>, A. Voutetakis<sup>4</sup>, C.A. Stratakis<sup>1</sup>.

1) Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH), Bethesda, MD 20892, USA; 2) Department of Reproductive Endocrinology, Alexandra Hospital, University of Athens, Athens, Greece; 3) Department of Biochemistry, Institute of Child Health, Athens, Greece; 4) Endocrine Unit, 1st Department of Pediatrics, Medical School, University of Athens, Athens, Greece.

*DICER1* is an endoribonuclease that acts post-transcriptionally by processing mRNA into siRNA and microRNA, thus leading to mRNA downregulation. *DICER1* syndrome is usually caused by germline variants and is characterized by a variety of benign or malignant tumors: pleuropulmonary blastoma, ovarian Sertoli-Leydig cell tumor, cystic nephroma, pituitary blastoma and thyroid tumors including multinodular goiter. Patients with germline aberrations in the *DICER1* gene may carry additional somatic missense *DICER1* mutations within the associated tumors, located in the metal ion-binding residues of the RNase IIIb domain. Our patient, a 10 yo girl was evaluated for thyroid enlargement. While her thyroid function tests were normal, thyroid sonography revealed three nodules in the right lobe (diameter: 1.9, 2.3, and 3 cm, respectively) that proved hyperplastic nonmalignant after thyroidectomy. She entered puberty at age 11 years and at age 12 years, both breast and pubic hair were Tanner stage IV. Ten months later, during follow-up, breast had regressed to Tanner stage I, hirsutism was present and her voice had notably deepened. Hormonal evaluation showed elevated levels of Testosterone, DHEAS, 17OH-progesterone, Δ4 androstenedione, while Cortisol was within normal range. Ovarian sonography revealed an enlarged right ovary (12cc) while the left ovary was normal (3cc). Right salpingo-oophorectomy was carried out and biopsy revealed an ovarian Sertoli-Leydig cell tumor. Androgens returned to normal levels postoperatively. Genetic analysis revealed a novel germline nonsense *DICER1* mutation (p.W1481\*, c.4443G>A), inherited from her father (in whom sonography revealed multinodular goiter). Further studies in the ovarian and thyroid tissues showed two different somatic missense mutations of the same codon. The ovarian tissue carried the missense mutation p.E1813D (c.5439G>T) in heterozygosity whereas, the thyroid tissue carried the heterozygous missense variant p.E1813Q (c. 5437G>C). Immunohistochemistry revealed that within these tumors, the *DICER1* protein expression was significantly decreased compared to normal tissue. In conclusion we report a novel *DICER1* mutation (p.W1481\*, c.4443G>A) and confirm that patients with germline *DICER1* mutations can develop somatic mutations within the RNase IIIb domain. Our findings show that impaired *DICER1* function affects the thyroid and ovarian tissue homeostasis and offer further proof that *DICER1* is a tumorigenic driver during childhood.

## 973T

***TNS1* gene mutations are present in sporadic pheochromocytomas and paragangliomas.** F.R. Faucz<sup>1</sup>, N. Settas<sup>1</sup>, A. Berthon<sup>1</sup>, S.K. Flores<sup>2</sup>, P.L. Dahia<sup>2</sup>, C.A. Stratakis<sup>1</sup>. 1) Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD; 2) Dept. Medicine and Mays Cancer Center, University of Texas Health Science Center at San Antonio, TX.

Tensin1 is an adaptor phosphoprotein linking integrin to the actin cytoskeleton; it is also involved in fibrillar adhesion formation. Tensin1 is encoded by the actin-binding protein Tensin1 (*TNS1*). *Tns1* knockout (KO) mice develop kidney abnormalities; female mice have also reduced fertility. A *Drosophila* Melanogaster *Tns1*KO model is known as blistery due to defective wing unfolding and consequent blister formation. *PTEN*(phosphatase and tensin homolog), the known tumor suppressor gene, is a paralog of *TNS1*. Genome-wide association studies have linked *TNS1* to asthma, lung disease and colorectal cancer, and *TNS1* expression is reduced or absent in several prostate and breast cancer cell lines. Pheochromocytomas (PH) and paragangliomas (PGL) are neural-crest-derived tumours that are genetically heterogeneous. More and more of these tumors are caused by inherited mutations. In the present study we screened 43 unrelated patients with PGL and/or PH through whole exome sequencing. Among the 27 patients where a known causative mutation was not found (including genes such as *SDHx*, *NF1*, *RET*, *HRAS*, *EPAS1*, *VHL*, and *FH*) we identified a total of 7 different *TNS1* coding sequence alterations, which were predicted to be damaging through in silico analysis. The frequency of patients with a predicted as damaging variation was 33.33% (9/27); a total of 7 variants were non-synonymous substitutions leading to a missense variation. One of these variants was novel (c.5174C>G, p.S1725P). The remaining 6 variants (p.R5W, p.V25I, p.I311M, p.G320R, p.R859W, and p.E869K) were rare or absent in the general population showing a statistical difference when compared with the frequencies found in our sample ( $p < 0.001$  using "ALL" in the gnomAD database (<http://gnomad.broadinstitute.org>)). Immunostaining and additional genetic studies are ongoing to further clarify the role of these genetic changes in PGL and/or PH. We conclude that inactivating *TNS1* sequencing variants may be yet another cause of PH and PGL, adding to the long list of genes involved in these tumors. Our ongoing studies aim at further characterizing the role of *TNS1* in neuroendocrine tumor development.

**CRISPR/Cpf1 as a tool for locus specific delivery of suicide gene in chronic lymphocytic leukemia.** F.C. Lorenzetti<sup>1</sup>, F.T. Papa<sup>1</sup>, S. Daga<sup>1</sup>, S. Croci<sup>1</sup>, F. Niccheri<sup>2</sup>, F. Donati<sup>2</sup>, D. Lopergolo<sup>1</sup>, M.A. Mencarelli<sup>1,3</sup>, A. Gozzetti<sup>1</sup>, M. Bocchia<sup>4</sup>, S. Conticello<sup>2</sup>, A. Renieri<sup>1,3</sup>, F. Mari<sup>1,3</sup>. 1) Medical Genetic, University of Siena, Siena, Italy, Siena, Italy; 2) Core Research Laboratory - ISPRO, Florence, Italy; 3) Genetica Medica, Azienda Ospedaliera Universitaria Senese, Italy; 4) Department of Medicine and Immunological Sciences, Hematology Unit, Azienda Ospedaliera Universitaria Senese and University of Siena, Italy.

Patients with Chronic Lymphocytic Leukemia (CLL) harbouring *TP53* mutations, despite being subjected to burdensome cycles of therapy, do not have many possibilities of healing due to the acquired abilities of *TP53*-mutated clones to escape the control systems. We have recently provided evidence that fully supports the critical role of *TP53*-mutated clones in driving the neoplastic process and that these cells are present several months before disease manifestation and they are enhanced by chemotherapy (Pinto AM et al. Br J Haematol 2018). We present here a suitable example of transformative gene-based medicine using CRISPR/Cpf1 for locus specific delivery of suicide gene in lymphocytes successfully isolated from *TP53* mutated CLL patients. We are able to introduce the gene for the pro-drug converting enzyme herpes simplex virus type 1 thymidine kinase (HSV1-TK) into the genome of cancer cells carrying specific *TP53* mutations. Very promising results are obtained using our system in HEK293 cells line. Implementation of this toolkit and in vivo experiment on mouse are ongoing. The precision specificity and the integration rate of our approach for the genome therapy might make it possible to apply this protocol to clinical setting. Patenting process of this toolkit is ongoing at University of Siena.

**The Fanconi anemia proteins FANCM and FAAP24 limit BLM/Pol $\delta$  dependent telomere instability in the alternative lengthening of telomeres (ALT) pathway.** *M.S. Meyn<sup>1,2,3,4,5,6</sup>, J. Te<sup>2</sup>, M. Komosa<sup>3</sup>, F. Alazrj<sup>3,5</sup>.* 1) Center for Human Genomics and Precision Medicine, University of Wisconsin, Madison, WI; 2) Department of Molecular Genetics, University of Toronto, Toronto, ON, Canada; 3) Program in Genetics and Genome Biology, Hospital for Sick Children, Toronto, ON, Canada; 4) Division of Clinical and Metabolic Genetics, Hospital for Sick Children, Toronto, ON, Canada; 5) Institute of Medical Science, University of Toronto, Toronto, ON, Canada; 6) Department of Paediatrics, University of Toronto, Toronto, ON, Canada.

~15% of human tumours lack telomerase and use the Alternative Lengthening of Telomere (ALT) mechanism to maintain telomeres. ALT is characterized by variable telomere lengths, frequent telomere sister chromatid exchanges, and increases in extrachromosomal telomeric repeat (ECTR) DNA. We previously demonstrated that depletion of FANCD2, a member of the BRCA/Fanconi anemia DNA repair pathway, causes a hyper-ALT phenotype. Using ALT and telomerase-positive human cells, we extend our analysis to the DNA translocase FANCM and its partner FAAP24; proteins which stabilize stalled replication forks, target other Fanconi anemia proteins to damaged DNA, and promote DNA repair. We find siRNA depletion of FANCM or FAAP24 increases telomeric replicative stress in ALT cells as indicated by increased telomeric fragile sites. Depletion results in rapid increases in telomeric DNA content in ALT but not telomerase-positive cells as measured by Flow-FISH and Halo-FISH. Further, these increases in telomeric DNA are primarily due to 4-5 fold increases in ECTR DNA molecules, but not their length. Interestingly, FANCD2 protein localizes to telomeric foci in FANCM or FAAP24 depleted ALT cells, suggesting that FANCM and FAAP24 protect against telomeric replicative stress by directly interacting with replication forks, rather than by recruiting FANCD2 to stressed forks. siRNA depletion of either the BLM DNA helicase or the pol $\delta$  DNA polymerase in ALT cells resulted in telomere shortening and markedly fewer ECTR DNA molecules. Depletion of BLM or pol $\delta$  also suppressed the excessive ECTR production and increased telomere length seen in FANCM and FAAP24-depleted ALT cells, suggesting that these telomere abnormalities are an exaggeration of the ALT phenotype rather than due to a separate mechanism. Our results support a ALT model in which failed telomeric replication forks give rise to DNA breaks and gaps used by BLM/pol $\delta$ -dependent recombination-driven replication processes to drive ALT, which produces high levels of ECTR DNA. In this model, FANCM and FAAP24 restrain the ALT phenotype by promoting recovery of stalled telomeric replication forks. Loss of FANCM or FAAP24 increases the natural substrate for ALT, failed telomeric replication forks, hence the hyper-ALT phenotype observed in FANCM or FAAP24-depleted ALT cells. As the hyper-ALT phenotype is associated with increased cell death, disruption of the BRCA/Fanconi anemia pathway may be a viable treatment strategy for ALT tumours.
